To investigate this pattern of restricted images of mathematics further, we considered participants' responses to other questions about their earliest mathematics experiences. These recollections also tended to focus on learning about number operations, and in school settings. The majority of students described their earliest memory of learning mathematics in number contexts, such as: "Two plus two. It was one of the first things I was asked in math" and "I remember doing the math worksheets in I think it was Grade 1 about the simple addition." A Grade 8 student recollected his earliest mathematics learning as "we were doing adding like one plus one equals two and stuff." Other students commonly described reciting a multiplication table by repeatedly practicing the table or singing a song. Overall, for the majority of students, their first encounter with mathematics learning was described in relation to basic operations.

Discussion

We are concerned that students are developing, through their engagement in the culture of school mathematics, a very narrow vision of the nature of mathematics, one that does not include the full territory of mathematical ideas and topics that are described by mathematicians (and others, such as mathematics educators). While we acknowledge the ongoing scholarly debate about the relationship between school mathematics and the mathematics practiced by mathematicians (e.g., Watson, 2008) and agree that the aim of school mathematics teaching ought not to be entirely commensurate with generating the kind of images of mathematics that mathematicians hold, we do think that the artificially narrow view of mathematics being generated in schools is problematic. Recent research (Rapke, 2012) has shown the synergies that exist among creating and learning, mathematics, suggesting that the nature of school mathematics can (and should) be more like that of research mathematics, including creative exploration in the full scope of mathematical topics.

In the Alberta Program of Studies (curriculum) document for mathematics, from Kindergarten to Grade 5, between 40% and 50% of the expectations align with the Number strand (Alberta Education, 2014). We believe that teachers are guided strongly by the mandated curriculum documents for their jurisdiction and consequently (over)emphasize number concepts in their teaching of mathematics, particularly in the early years. This (over)emphasis on number and operations may be contributing to students' skewed images of mathematics. The mathematics education community has proposed alternative views of mathematics compared to the widespread notion of mathematics as number and computation. For example, Boaler (2008) suggests that, "mathematics is all about illuminating relationships such as those found in shapes and in nature" (p. 18). Such enhanced conceptualizations of mathematics have significant implications for mathematics pedagogy, implying consideration of a wider breadth of mathematical topics as being "basic" to mathematics education. The findings of our study demonstrate the significance of attending to the nature of students' images of mathematics in relation to the culture of school mathematics in Canada.

MATHEMATICS LEARNING AMONG UNDERGRADUATES ON THE AUTISM SPECTRUM

Jeffrey Truman
Simon Fraser University
jtruman@sfu.ca

This study examines the mathematical learning of an undergraduate student on the autism spectrum. I aim to expand on previous research, which often focuses on younger students in the K-12 school system. I have conducted a series of interviews with one student, recording hour-long sessions each week. The interviews involved a combination of asking for the interviewee's views on learning mathematics, self-reports of experiences (both directly related to courses and not), and some particular mathematical tasks. I present some preliminary findings from these interviews and ideas for further research.

Keywords: Equity and Diversity; Geometry, Post-Secondary Education

Background on Autism-Related Research

The Autistic Self Advocacy Network (2014) states that autism is a neurological difference with certain characteristics (which are not necessarily present in any given individual on the autism spectrum), among them differences in sensory sensitivity and experience, different ways of learning, particular focused interests (often referred to as 'special interests'), atypical movement, a need for particular routines, and difficulties in typical language use and social interaction. Over the past few decades, there have been many research studies about learning in students on the autism spectrum, such as those reviewed by Chiang and Lin (2007). A large portion of these studies focus on K-12 students, and particularly elementary students, but some of the ideas and procedures in those studies lend themselves to use in a post-secondary context.

While most mathematics-related research on people on the autism spectrum also takes place among younger children, there have been multiple reports, such as those from James (2010) and Iuculano et al. (2014) which indicate an association between autism and heightened mathematical interest and ability. Due to the young age of the students, however, it remains to be seen whether those tendencies extend to university-level mathematics content.

Interview Procedures

I started out with the intent to find students who were on the autism spectrum and currently taking one or more mathematics courses at SFU. I found help from a center for students with disabilities to recruit for students who would be qualified for the study, and was put in touch with one student who was willing and able to do the interviews. It should be noted that this method will only identify those students who are both able to seek assistance from such a center and see the need to do so, and this constitutes only a portion of the fairly wide autism spectrum.

The student I interviewed, Joshua (a pseudonym) was studying integral calculus and linear algebra. I conducted interviews every week for this term. These were scheduled for one hour, but were sometimes continued for a short time past the scheduled hour. I typically started by asking the student to share any particular thoughts on the week's course materials. I also asked various questions and assigned tasks related to the covered course material. Some of these were tasks that have been used with typical student populations in the literature, such as the example-generation tasks used by Bogomolny (2006) and the Magic Carpet Ride sequence used by Wawro et al. (2012). I have also given other mathematical tasks not directly related to the material covered in the courses being taken, such as the paradoxes examined by Mamolo and Zazkis (2008); one reason for this was the interplay between visual and algebraic explanations seen in some student responses to these paradoxes.

Theoretical Framework

There were several reported characteristics of people on the autism spectrum which I thought could be promising for mathematics education research. In particular, I was interested in details of prototype formation, special interests, and geometric approaches. I will detail each of these with a comparison to the particular findings relevant to them in Joshua's case.

Prototype Formation

I started looking into prototype formation after reading a study by Klinger and Dawson (2001). It suggested that people on the autism spectrum did not form prototypes of objects when given tasks asking about group membership, instead taking an approach based on lists of rules. Although this is presented as a problem, like many other autism-related studies, I suspected that this approach could be helpful for more abstract or proof-based mathematics. I have found many other students having trouble with mathematical questions that appear to result from a prototype-based approach, and this is particularly true when the course focuses on mathematical proof. In fact, I found a very similar division reported in mathematics education research by Edwards and Ward (2004), phrased as lexical or extracted definitions versus stipulative definitions. This did not appear to be the case for Joshua; he reported having this kind of thinking in the past, but was quite focused on “big picture” ideas today (this was, in fact, a recurring phrase in the interviews).

Special Interests and Learning

I found the idea of 'special interests' (variously known as circumscribed interests, splinter skills, savant skills, and a variety of other names with varying connotations within the autistic and research communities) to be applicable to some of my findings. These are intense, focused interests occurring in people on the autism spectrum (often studied in children, like much autism-related research). Some of these are mathematically related, such as a focus on particular facets of arithmetic, prime numbers, or aspects of geometric shapes, as explored by Klin et al. (2007). The development of these interests in later life is something that does not appear to have been studied much in previous research, however. Unfortunately, research in this area (particularly from an Applied Behavioral Analysis framework) can discount these skills or even view them as detrimental to learning, as seen in Dawson, Mottron, and Gernsbacher (2008), and may even attempt to eliminate these skills. From what I have seen, however, such interests can be very helpful in imparting motivation when viewed from the right perspective. Joshua has reported a strong interest in chemistry, which he often used in analogies for mathematical concepts in our interviews. There have been several instances where he has reported more enthusiasm, better understanding, and better performance when able to see chemical applications to the topics in the courses, and has sought out additional information outside the course materials in order to make these connections.

Geometric Focus and Visualization

Particularly due to the work of Temple Grandin, one of the most famous people on the autism spectrum, there is often an association between the spectrum and visualization or spatial reasoning (Grandin, Peterson, and Shaw, 1998). While I would caution against being too broad with an association like that, I did find a strong preference for visual, spatial, or geometric reasoning in the interviews I conducted. This was particularly successful with integral calculus, where the student independently thought about what three-dimensional integrals might be like. The correct conclusion was reported for a 'flat' extension (of multiplying by a constant length), and the student did realize that this would not work for more complex three-dimensional shapes (although not to the point of developing multiple integrals). Reports of classroom progress continually reflected higher performance in areas that could be viewed in a geometric or otherwise physical way. Comparing topics across the two courses, this leads to some surprising results, such as reported satisfaction with washer and shell rotations, but issues with algebraic formulas like dot products.

I found the solution Joshua gave in one interview for the first Magic Carpet Ride task to be particularly notable. I showed the problem setup from the paper by Wawro et al. (2012), giving the two modes of travel with vectors (3,1) and (1,2), and asking for a way to get to the house at (107,64). Since I asked this relatively late, Joshua had already seen the vector material that shows the 'standard' way to do this. However, the solution he gave was instead done by drawing the vectors out on paper. He measured (30,10) and (10,20), plotted (107,64), shifted one of the vectors so that it would end at (107,64), and extended the vectors in order to find via measurement their point of intersection. (I checked this, and it was accurate enough to provide the correct solution.) When asked for an algebraic solution, he calculated the equations of the lines corresponding to those vectors and found their point of intersection, still clearly based on the same visualization.

Paradoxes

I have also presented several paradox tasks during my interviews. I gave the Hilbert Hotel and Ping-Pong ball paradoxes from the paper by Mamolo and Zazkis (2008), as well as the Painter's Paradox (involving the volume and area of Gabriel's Horn obtained by rotating 1/x) and an 'infinitesimal staircase' paradox. The Ping-Pong ball paradox involves an infinite set of Ping-Pong balls (numbered 1, 2, 3, …) being inserted into and removed from a barrel over one minute. In the first 30 seconds, the first 10 balls are inserted, and the '1' ball is removed. In the next 15 seconds, 11 through 20 are inserted and the '2' ball is removed, and so on. The respondents are then asked how many Ping-Pong balls remain in the barrel at the end of the minute. The last one involves a staircase being divided up into finer and finer steps (at each stage having perimeter 2) to approach an incline (of length $\sqrt{2}$). Like many of the students in previous studies, the student I interviewed found these to be strange and paradoxical. However, they also appeared to inspire a great deal of enthusiasm; through having a series of interviews, I was able to see that these paradoxes had inspired independent thinking outside of the interview sessions. The response provided to the Ping-Pong ball paradox was something I also found particularly notable. Joshua first said that there should be infinitely many, then decided that there should be none after being asked what the numbers of the remaining balls were. However, the analogy he provided here was of slowing down molecules at extremely low temperatures in order to study them; it appeared as if this mental image was being used to accommodate the presence of the balls at times prior to the conclusion of the experiment. I also found it notable that I did not see any tendency toward rejecting the mathematical facts after they had been presented, unlike in many of the students in the prior studies.

Limitations and Suggestions

So far, I have only been able to conduct interviews with one research subject, and thus it is important to be careful not to overly generalize the results seen in the interviews. There are also considerations about the content that would apply to the courses that Joshua took, although I think that linear algebra is a fortunate course to have an interviewee from. Some questions that have occurred to me: Would people on the spectrum with less clearly related special interests still use them for mathematical analogies? Is there a tendency for either (more specifically) a bias toward geometric processing or (more generally) a tendency to strongly prefer one type of processing? Are people on the spectrum generally more inclined to accept conclusions that are viewed as paradoxical?

THE MICRO-POLITICS OF STUDENTS' LANGUAGE REPERTOIRES IN COUNTING CONTEXTS

David Wagner
University of New Brunswick
dwagner@unb.ca

Annica Andersson
Stockholm University
annica.andersson@mnd.su.se

Counting is mediated by language – the language used for counting reflects people's meaning and experience of the process, and their experience is impacted by the way language is used. We investigate children's language repertoires for counting in English. With this, we aim to understand better the political nature of counting at the most basic levels. This is to extend the literature, which already identifies political aspects of counting on the macro scale. We theorize the politics of language in mathematics learning as applied to this situation and, as a way of setting up our investigation, we illustrate how counting at the micro-level can be political.

Keywords: Classroom Discourse; Equity and Diversity; Number Concepts and Operations

Introduction

The understanding and experience of counting, like the understanding and experience of any mathematical idea, is mediated by language. Certain language repertoires are necessary to convey the ideas and perhaps even to perform counting action. At the same time, the language used to describe these ideas and enact the processes shapes the way people conceptualize them.

This recursive nature of language compelled us to develop a research project to investigate children's language repertoires in relation to conjecture. We began with contexts involving risk and prediction because we had noticed similarity in language repertoires between prediction and conjecture. We found political implications of the ambiguity in meaning of words that are used for conjecture, prediction, assessment of risk, and establishing authority (Wagner, Dicks, Kristmanson, 2015). Now we extend this work to explore students' language repertoires in contexts involving counting. Data collection will be complete in June 2015, and so we present here our theoretical and conceptual approaches along with some hypotheses that come from our experiences as mathematics teachers and mathematics education researchers. In the conference presentation, we will also present from our empirical results.

The Politics of (Mathematical) Language

Our interest in the experience of counting includes the way counting positions people in relation to each other. Positioning theory (Harré et al, 2009) points us to the distribution of rights and duties, or, in other words, the politics of counting, just as it did in our work that revealed the politics of prediction language (Wagner, Dicks, Kristmanson, 2015). Careful language analysis helps us produce warranted claims about the politics within our research contexts.

> [Politics] is about how to distribute social goods in a society: who gets what in terms of money, status, power and acceptance on a variety of different terms, all social goods. Since, when we use language, social goods and their distribution are always at stake, language is always "political" in a deep sense (Gee, 2011, p. 7).

In this project we understand mathematical education as a number of created and re-created practices within social and cultural contexts. These practices are networked with other practices outside the mathematics classrooms (Valero, 2007). Thus they are political, indicating that power is distributed between the different networking practices. In line with Valero (2004), we understand power as situational, relational, and in constant transformation. Power works between these practices in the network as macro-level processes. However, power also works at the micro-level in the immediate situational contexts between participants and (un)available materials. These micro-level actions are the focus in this project.

The relations between the macro-level practices and participants' micro-level actions are dialectical. Macro-level practices give meaning to micro-level actions, offering participants subject positions. However, the participants' actions also give meaning to the mathematics practices and position themselves in ways that are reflexive, relational and contextual in relation to the discipline and to other individuals in their learning contexts (Wagner & Herbel-Eisenmann, 2009). Thus, participants are implicated in the construction and circulation of power within mathematical practices (Gutiérrez, 2013). We emphasize the importance of power relations between the macro- and micro-levels, through positionings and discourses – in other words how we fluently relate to each other (Gutiérrez, 2013; Wagner & Herbel-Eisenmann, 2009). In this project, the negotiation and distribution of power on the micro-level are foregrounded, while we acknowledge and connect to the related macro-level power distributions, discourses and negotiations (Morgan, 2006). Discourses are about "negotiating and maintaining relationships among its participants" (Morgan, 2012, p. 181) and hence establishing relations and positionings. These relationships also imply a need for us researchers to critically reflect on ethical questions about how we position ourselves and write about the Other, as suggested by Andersson and Le Roux (2015).

We use a systemic functional linguistics framework (SFL) to help us identify the qualities of interpersonal interaction as they appear in the distinctions made through grammar and lexicon. SFL is built on the recognition that language involves the interconnectedness among construction of experience (*ideational* metafunction), relationships with others (*interpersonal* metafunction), and connection with other circulating text (*textual* metafunction) (Halliday, 1973).

Number and Power

At the macro-level, number is often associated with power. School curriculum is positioned as equipping children to be powerful in and outside of school, and number skills are generally taken as central to such numeracy. Bishop (1990) has gone so far as to show how advanced counting systems – exponential based number systems, in particular – made colonialism possible. With rudimentary counting it is hard to organize and hold control over vast resources. Historically, technologies of counting (quantification) are associated with certain political structures (Porter, 1995).

We have not found research that focuses on the micro-level politics of number. When children count, who "gets what in terms of […] status, power and acceptance on a variety of different terms" (Gee, 2011, p. 7)? To illustrate the micro-level interactions in counting contexts, we suggest that, before you read further, you choose some friends and decide amongst yourselves who has been in the most countries. You will have to count the countries you visited of course. After engaging in this activity, the next paragraphs will be more meaningful.

Counting countries seems quite straightforward at first, but it doesn't take long to find controversy. For example, both of us have visited Yugoslavia before it was divided into smaller countries. Shall we count one for Yugoslavia because it was one country when each of us was there? Or can we count three or four (different for the two authors) for the current countries represented by parts we visited? We may decide it counts as one, because it was only one country when each of us was there; a clearer question would be how many national political entities we have visited. However, Germany complicates such reasoning. We have both spent time in East Germany, West Germany and modern, unified Germany. Shall we count all three of these entities that we have visited? Furthermore, one of us travelled through some countries by train. Does it count to travel through a country on a train if one doesn't get off the train? What about flying over a country? Or landing in a country to refuel but staying on the plane? What about a one-hour stop that includes a passport stamp? Or crossing the border and being escorted out by police? And then there are disputed territories, like the West Bank (of the Jordan River), or First Nations (Aboriginal lands never conceded to colonialist governments). These are just some of our political controversies when counting countries. You probably have your own.

When we count, we have to decide what counts and what does not count. For example, what counts as being "in a country", and what counts as "a country"? This is political because different people will have unique reasons for wanting the counting to be done in certain ways. Furthermore, it is possible that you have not travelled outside your country, which highlights yet another political aspect. The question of how many countries privileges people for whom travel has been possible, and thus excludes others. Someone has to decide what to count and that decision sets up certain people's experiences as normative. For example, who decided that counting countries is a worthwhile endeavor (it was us, but you may have made the question your own as you started dialoguing about it with your friends)? Maybe it would be better to count our meaningful interactions with diverse people, or it may be even more appropriate to reflect on the qualities of those interactions instead of quantifying them. Indeed it is possible to travel to many countries and remain insular.

Methodology

As with our earlier work in this project, focusing on the language of prediction, we have students work in groups in class and subsequently interview them to extend the group work. We work with students with relatively limited repertoires and present them with situations that we expect to push them to the limits of their language resources. Thus we begin this work with 4- to 7-year olds, and engage them in counting in increasingly challenging ways. For these tasks, we draw on the tasks suggested by Wagner and Davis (2010), in their article distinguishing between quantity and number sense. We consider the micro-politics of quantification. We consider how participants construct and negotiate roles and responsibilities as they decide what counts (For example, how big does a tree have to be to be a tree? What kind of plant counts as a tree?), how to talk about a quantity when the numbers exceed individuals' quantity sense, and what benchmarks they use for communicating their sense of quantity. Selecting benchmarks requires identifying something that has a taken-as-shared meaning by one's interlocutors. We identify how these micro-political moves are manifested in language. At the end of the complementary interviews with the children we draw attention to things the participants have said and ask them to describe what they mean by these things.

In the interactions with participants, we avoid using specialized mathematical language ourselves and refrain from suggesting to participant students how they might perform the tasks and/or communicate their ideas. We want to identify their strategies for communicating their counting, and consider what these language strategies say about the process of counting and the related politics. Thus, we avoid a deficit perspective that would rate the students on the basis of which skills and language they know. We have already noticed the problems with such deficit approaches – for example, we have evidence that a participant not using a language skill does not indicate inability (Wagner, Dicks and Kristmanson, 2015).

Language is used to make distinctions that are relevant to the people in an interaction. For example, the prevalence of gender distinctions in personal pronouns in many languages signifies that people in those cultures consider it important to make such distinctions. An individual may find a way to avoid making such a distinction and find this a challenge because our language does not have some gender-inclusive personal pronouns – e.g. using 'they' instead of 'he' or 'she'. Such practices may become acceptable to others and enter into a culture's language repertoire. Just as we invent ways to avoid a distinction, we can invent ways to make distinction when no language strategy is established for that distinction. This is a phenomenon at work in mathematical problem solving contexts (Wagner, 2009), and also in scholarship. Thus, in our research, we look for language strategies that enable the process of deciding what to count and what not to count (the process of establishing boundaries or categories). And we consider how these processes are political acts.

Acknowledgment

This research was supported by the Social Sciences and Humanities Research Council of Canada, as part of a grant entitled "Students' language repertoires for investigating mathematics." Opinions, findings, and conclusions or recommendations expressed here are the authors' and do not necessarily reflect the views of the granting body.

ESTABLISHING MATHEMATICAL CARING RELATIONSHIPS WITH UNDERREPRESENTED STUDENTS IN A COLLEGIATE STUDENT SUPPORT SERVICES PROGRAM

Diana Bowen
University of Maryland

Andrew Webster
University of Maryland
awebs@umd.edu

Keywords: Post-Secondary Education; Equity and Diversity; Affect and Beliefs; Teacher Beliefs

While access to higher education in the United States continues to improve, the success of historically underserved students in college, as measured by persistent degree completion, has not progressed in recent decades (Brock, 2010). Moreover, these students remain underrepresented in fields that depend on mathematics (Treisman, 1992; Engle & Tinto, 2008). As such, many universities offer federally funded Student Support Services (SSS) programs to address student success for historically underserved students including minority students, first-generation students, and low-income students. At the University of Maryland, the Academic Achievement Program (AAP) provides administrative and academic support including mathematics instruction and tutoring for historically underserved students. While quantitative research on these programs is common, our study uses qualitative methods including ethnographic interviews and in-depth classroom observation to explore affective responses of both students and teachers during mathematical learning in a SSS program.

Interview participants included eight students and three AAP staff members. Each of the field notes from the interviews and observations were analyzed and coded using grounded theory techniques. Following this work, we considered Hackenberg's (2005) definition for developing mathematical caring relations (MCRs): " Establishing a MCR entails aiming for mathematical learning while attending to affective responses of both student and teacher" (p. 1). This conceptual framework provides a potential lens for examining if and how SSS programs develop mathematical caring relationships and whether or not they play a role in student success. Our study approaches this problem from both the student perspective and the perspective of mathematics instructors and staff in the SSS program to provide a more holistic picture.

Our initial findings indicate students found positive relationships with their mathematics professor or AAP instructor as influential to their success. Students also bring in strong beliefs and attitudes about mathematics from past schooling experiences including experiences with former teachers. Finally, SSS programs may provide additional opportunities for students to form MCRs because of individualized and small-group instruction, but this is only the case if the instructors and students are invested in creating mathematical caring relationships.

INVESTIGATING THE EFFECTS OF CLASSROOM CLIMATE ON MATH SELF-EFFICACY

Robert Chamblin
Central Michigan University
robert.chamblin@cmich.edu

Christine Phelps
Central Michigan University
phelp1cm@cmich.edu

Keywords: Affect and Beliefs (and Emotion and Attitudes); Post-Secondary Education

Students' self-efficacy influences the kinds of activities they are likely to engage in, how much effort they are willing to invest in a task, as well as how much they will persevere in the face of challenges and disappointments (Bandura, 1977). This means that even if a student has the appropriate skills and incentive, they may still not be academically successful due to low self-efficacy. This makes self-efficacy an important research construct. The focus of this study is to examine how the classroom environment that the teacher creates and the strategies the teacher uses can influence a student's mathematics self-efficacy.

Previous research suggests that there is a relationship between classroom environment and self-efficacy. For example, Ebert-May, Brewer and Allred (1997) and Fencl and Scheel (2005) found that college students' beliefs in their own ability to be successful in a college science class could be improved by the use of a variety of cooperative learning techniques. However, the relationship between classroom climate and improvements in student self-efficacy is not well understood and little work has been done on this in the area of mathematics.

In order to better understand the relationship between classroom climate and mathematics self-efficacy, we conducted a qualitative study where we interviewed seven college students twice. These college students came from education, pure mathematics, and a Calculus course in order to examine the development of self-efficacy in different populations. Our aim was to look for factors within the classroom which may have influenced the development of a student's math self-efficacy.

Initial results suggest that students with a high self-efficacy in mathematics in all three categories describe their mathematics confidence being influenced by the perceived support and encouragement from their teacher. Some characteristics that were mentioned as a way to create a supportive environment in the classroom included vocal support of the student, flexibility from the teacher, and opportunities for group work. Results have implications for how we design mathematics classrooms that support and encourage productive mathematics self-efficacy.

THE PROFILE OF STUDENTS' BELIEFS: THE COLOMBIAN CASE

Francisco J. Córdoba-Gómez
Instituto Tecnológico Metropolitano
fjcordob@yahoo.es

Keywords: Attitudes and Beliefs; Gender; High School Education

Theoretical Background

Beliefs are a powerful force in the behavior of people. If a person believed firmly that can do something, he or she will do it, and if instead believes it is impossible to do, nothing will change his mind and convince that it is possible. The beliefs that people have about themselves and what is or is not possible in the world around them have a great effect on the daily efficiency. All people have in turn beliefs that serve as resources and beliefs that limit them considerably in different areas of their lives (Dilts, 2004). As stated Kober (2015), students of all ages have understandings, skills and beliefs that significantly influence the way in what they remember, reason, solve problems and acquire new knowledge. Only the factor related to personal competence in mathematics is shown.

Methodology and Results

In the data gathering it was used as an expanded and contextualized version of the questionnaire on beliefs about mathematics (*Mathematics-Related Belief Questionnaire, MRBQ*) developed at the University of Leuven (Op 't Eynde & De Corte, 2003) and originally implemented in Belgium (Op't Eynde & De Corte, 2003, 2004). An additional element in this work was that some qualitative questions were asked, which allowed to obtain additional information about the beliefs in a more natural and spontaneous way from students. The sample consisted of 950 students (509 males and 439 females, 2 unanswered) between 14 and 17 years of age of six public institutions. For all final responses (950 students) a reliability analysis using Cronbach's alpha was computed, obtaining an appropriate value of $\alpha = 0.933$.Some of the responses to the qualitative and quantitative questions are shown in table 1.

Table 1: Some responses to qualitative questions by gender

Qualitative questions				Quantitative items	
	M	W	Total (%)		**Total mean**
Math is my favorite subject	85	45	13.7	Mathematics requires more memory than imagination and creativity	2.45
Career choice (engineering or related)	97	20	12.3	If I have had any difficulty with math in school, I will surely have in college	2.29
Do you think your math skills could improve at some point? Yes	250	183	45.6

AN EQUITABLE APPROACH TO THE STUDY OF UTILITY IN MATHEMATICS EDUCATION

Tracy Dobie
Northwestern University
tdobie@u.northwestern.edu

Keywords: Middle School Education; Equity and Diversity; Affect and Beliefs

As students continue to question teachers about the usefulness of mathematics, and the Common Core State Standards urges teachers to help students view math as useful, it becomes increasingly important to interrogate our conceptualization of usefulness. Currently, utility research primarily focuses on the usefulness of mathematics for everyday life now or in the future and for one's future career, with emphasis on usefulness for the individual. However, I propose a more equitable approach that incorporates students' developmental needs and values, as well as sociocultural context. This might be particularly important for groups of students that have been historically underserved in math education. For example, U.S. working-class contexts often promote interdependence, or connectedness and the needs of others (Grossmann & Varnum, 2011), rather than independence. Thus, students from working-class backgrounds might be more motivated by uses of mathematics for interdependent purposes, as some social justice research promotes (Gutstein, 2006). Similarly, considering adolescents' developmental needs also suggests the importance of one's relation to others: Social responsibility is a main goal for early adolescents in the school setting (Wentzel, 1993). Since negative consequences can result from a mismatch between an adolescent's developmental needs and features of her environment (Eccles et al., 1993), such values are especially important to consider.

Preliminary findings presented are part of a larger project with four 7th grade math classes in a predominately Latino/a working-class suburb of a large Midwestern city. Survey results reveal that students have strong interdependent reasons for wanting to do well in school. Of twelve items, "make my family proud," "help my family out after I graduate," and "provide a better life for my own children" received the highest mean ratings of importance. Qualitative data from student interviews also corroborates this finding. However, students reported perceiving mathematics as more useful for accomplishing individual goals than for helping their families. This highlights a potential mismatch and suggests one way we might attack the broader enduring challenges of a) finding ways to make mathematics instruction more equitable and b) improving student motivation in mathematics. By broadening our conception of usefulness and leveraging students' values and experiences, we can highlight uses of mathematics for valued domains and help underserved students feel more connected to the mathematics they are learning.

RACIAL IDENTITY AND MATHEMATICS LEARNING AND PARTICIPATION WITH MIDDLE GRADES STUDENTS

Andrew Gatza
Indiana University, IUPUI
agatza@iupui.edu

Erik Tillema
Indiana University, IUPUI
etillema@iupui.edu

Keywords: Cognition; Equity and Diversity; Learning Theory; Middle School Education

Despite calls for equity in school mathematics, major inequities along racial lines persist (e.g., Gutierrez, 2008). Although these inequities are well documented, race and racial identity have been under theorized in relation to mathematics learning and participation (Martin, 2009), and consequently mathematics is often framed as a neutral curricular domain (Battey, 2013). This is problematic because of the potential impact racial-mathematical socialization, mathematical identity, and racial identity have on mathematical learning and participation (English-Clark, Slaughter-Defoe, & Martin, 2012). While numerous studies have investigated mathematical learning, there is a dearth of research that investigates the intersection between racial identity development and mathematical learning. Addressing this issue is particularly important for middle grades students because identity formation is actively occurring then (Way, Hernández, Rogers, & Hughes, 2013).

This poster outlines one way the intersection of racial identity and mathematical learning and participation can be studied with middle grades students. We use a radical constructivist framework to study mathematical learning (Von Glasersfeld, 1995) and draw upon racial identity development (e.g., Helms, 1994) and colorblindness (Bonilla-Silva, 2010) literature. The study included 18 racially and mathematically diverse 7th and 8th graders from an urban public school and, consisted of four interviews—three on mathematical generalizations, and one on racial identity and student experiences in mathematics classes. These interviews will be analyzed for mathematical generalizations (Ellis, 2007) and the ways in which students' and teachers' racial identities impact these interactions. The following research questions guide this study: 1) what are themes regarding race and racial identity among middle grades students, particularly related to mathematics? 2) how might the racial identities of students and their teachers impact interactions aimed at supporting students to make mathematical generalizations? 3) what connections might be drawn between students' racial mathematics identities and their willingness to participate in challenging mathematical problem solving situations?

JUSTIFICATION IN THE CONTEXT OF LINEAR FUNCTIONS: GESTURING AS SUPPORT FOR STUDENTS WITH LEARNING DISABILITIES

Keywords: Equity and Diversity; Algebra and Algebraic Thinking

Educational policy mandates access to challenging mathematics for students with learning disabilities (LD) (Confrey et al., 2012; No Child Left Behind, 2002). Rather than spending a disproportionate amount of time receiving procedural instruction, mathematics and special education researchers have recommended providing students with LD more opportunities to engage in solving challenging, conceptual mathematics tasks and justify their problem solving processes (National Council of Teachers of Mathematics, 2000; Woodward & Montague, 2002).

To meet these expectations, students with LD will likely need key supports and strategies to minimize difficulties with memory and processing (e.g., working memory) while engaging with challenging mathematics (Keeler & Swanson, 2001). During the challenging task of justifying problem solving processes, gesturing can be a key support for students with LD as they manage the difficulty of this process (Goldin-Meadow, Nusbaum, Kelly, & Wagner, 2001).

The researchers in this study conducted a qualitative case study to analyze the justification processes of ten students with LD enrolled in an Algebra I course working in the context of linear functions. We transcribed approximately eight teaching sessions for each participant, coded the data, and organized the data into emerging themes (Brantlinger et al., 2005). An independent rater monitored interpretive validity during data analysis (Maxwell, 1992).

The findings indicated that gesturing often served as a support for memory and processing as the students with LD developed their justification skills. The students often used gestures to point to equations and coordinate planes during mathematical conversations. They also often used their forearms to demonstrate the slope of a line while describing their thinking processes. As the learners became more sophisticated at justifying their problem solving processes (as well as more knowledgeable of linear functions concepts), they relied less on gesturing and informal language and become more frequent users of formal mathematical language. More research is needed to describe how gesturing may provide support for students with LD as they engage in discussions about challenging mathematical topics.

Keywords: Affect and Beliefs; Post-Secondary Education

Remediation is a long standing and growing phenomena in mathematics education and in the transition to higher education, but there has been limited attention to remedial classrooms and students' learning experiences in these settings. Remedial mathematics courses offered in four-year universities "provide beginning college students with another chance to learn or (relearn) the mathematics supposedly taught to them in high school." According to the National Center for Education Statistics (NCES), remedial mathematics courses are listed in 80% of four-year university course catalogs. Nearly 40% of all "traditional undergraduates" take at least one remedial course in reading, writing, mathematics or some other content area; this figure has risen considerably since the NCES report of 1989 (Lesik, 2006).

The goal of this research project is to explore the effects of remedial mathematics courses on students. More specifically, we expect to uncover how students in mathematics remediation courses experience persistence in STEM related fields.

The sampling procedures will ensure that the participant pool includes African American students pursuing a diverse array of potential major concentrations. The selected participants will be African American students enrolled in remedial courses offered at a Midwestern university.

Using a phenomenological approach, this study employs classroom observations, student surveys and semi structured interviews of selected students enrolled in remedial courses. This research centers on theoretical frameworks developed to study mathematics learning as a narrative construct (Martin, 2000; Sfard & Prusak, 2005). Data analysis of interview transcripts will consist of coding and categorizing emergent themes to be used to recommend interventions and suggestions for the improvement of course administration.

We expect to uncover students' attitudes and beliefs concerning the effects of these courses on their persistence in their academic programs and offer suggestions for program improvement policies.

PARENTAL EXPECTATIONS FOR HIGH SCHOOL STUDENTS IN MATHEMATICS

Forster D Ntow
University of Minnesota
ntowx001@umn.edu

Nii Ansah Tackie
University of Minnesota
tacki001@umn.edu

Keywords: Instructional Activities and Practices; Teacher Beliefs; Equity and Diversity; Affect and Beliefs

This study builds on both expectancy-value theory and Martin's (2000) concept of sociohistorical contexts. Expectancy-value model suggests that parents' expectations for their children serve as strong predictors of children's expectations to succeed in their studies (Froiland, Peterson, & Davison, 2012). Froiland et al (2012) indicate that early parental expectations for children's post-secondary educational goals has a stronger effect on 8^{th} grade achievement than assisting in doing homework. Also, Martin (2000) indicates that African American parents draw on sociohistorical accounts such as their own mathematics learning experiences in socializing their children into the subject and setting expectations for them.

African American students suffer from the effects of having 'spoiled identities' namely; low quality instruction and overrepresentation in mathematics courses which lead to nowhere academically (Inzlicht & Good, 2006). This is due to a general belief, promoted by dominant narratives about African American students, that their parents do not value education. While some of these narratives may be true, Martin cautions that the school experiences of African American parents is much more nuanced than often reported. In order to account for the influence of African American parents on their children's mathematics achievement, this study focused on parents' mathematics learning experiences and their expectations for their children regarding the study of mathematics. The following research question guided the study; what is the nature of African American parents' mathematics learning experiences and how do they draw on their learning experiences to set mathematics goals for their children? Using a case study design study, we report on two African Americans parents whose children were enrolled in mathematics tutoring and mentoring program based in a large Midwestern University. Both parents were interviewed lasting about 30 minutes. The interviews were transcribed by both authors and coded for themes using a grounded theory approach. Results indicate that both parents did not identify themselves as 'math persons' in school. A typical comment is: "I am not good at Math, I am English major (Grace: parent)." However, these parents expressed regret at not taking mathematics serious in school because they are unable to assist their children in doing homework. Contrary popular narratives that African American parents have low value for education, we found that these parents had high levels of expectations for their children. Both of them did not expect their children to obtain grades lower than B in mathematics. Grace, whose daughter is in an Advanced Placement class comments:" I expect her to be challenged so if her math becomes too easy I expect her to take math courses to challenge her." Implications from this study regarding parent-teacher relationship will be shared during presentation.

STUDENTS' IMAGES OF MATHEMATICS EXPLORED THROUGH DRAWINGS

Jennifer Plosz
University of Calgary
jennifer.plosz@ucalgary.ca

Jo Towers
University of Calgary
towers@ucalgary.ca

Miwa Takeuchi
University of Calgary
miwa.takeuchi@ucalgary

Keywords: Affect and Beliefs

In this poster, we explore images of mathematics held by Kindergarten to Grade 9 students. We draw on data collected within our project, which investigates students' experiences learning mathematics in Canadian K-12 schools and post-secondary institutions, and the ways that these experiences contribute to students' images of mathematics and their mathematical identities. To date, 94 interviews have been conducted. In this poster we present examples of students' images of what mathematics is, as explored through the drawings they created in response to prompts about what mathematics means to them. The theoretical frame underlying this research is enactivism—a theory of embodied cognition that views learning as reciprocal activity in which the teacher brings forth a world of significance with the learners within a cultural milieu (Maturana & Varela, 1992). Our frame, then, prompts us to seek to understand *how* students come to have particular relationships with mathematics and *what* mathematics means to them.

Few studies have explored students' drawings as a means to understand their perspectives on mathematics, however, in this genre, Perkkilä & Aarnos (2009) suggest that students view mathematics as a solitary pursuit involving only certain types of mathematics. These findings are also reflected in research involving the general public, which tends to show narrow, stereotyped views of mathematics as a subject area, a perspective also reflected in the popular media, which tends to portray mathematics narrowly as numbers and arithmetic or as financial mathematics (Hall, 2013). This narrow view of mathematics contrasts with the breadth of perspective on mathematics discussed by mathematicians and mathematics educators. For example, French mathematician, Claire Voisin, who specializes in algebraic geometry, has described mathematics as "movement trying to express itself" while Peter Taylor (2014), a mathematician at Queen's University in Ontario, Canada, notes that mathematics is that which is "eternal and has beauty and structure to die for" (p. 34).

Our findings, developed through thematic analysis of the drawings, overwhelmingly show that participants' images of mathematics are narrowly focused on number and basic operations. We are concerned that students are developing, through their engagement in the culture of school mathematics, a very narrow vision of the nature of mathematics—one that does not include the full territory of mathematical ideas and topics. Our poster presents examples of drawings contributed by K-9 students, examines schooling structures that contribute to these images (e.g., narrow, number-focused curricula in the early years), and discusses implications for teaching.

THE INVISIBLE HAND OF WHITENESS AND THE COMMON SENSE OF MATHEMATICS EDUCATION REFORM

Alyse Schneider
University of California, Berkeley
alyseschneider@berkeley.edu

Keywords: Equity and Diversity

Background and Theoretical Perspective: This poster presents the components of a critical analytic essay on the state of mathematics education research and reform. Agreeing with Martin (2013) that mathematics education research "increasingly purports to be committed to equity for all children" (p. 323), despite the absence of clear evidence of progress made toward this goal within the past 30 years of reform (Martin, 2003), I consider what and whose other goals this rhetoric has served. As the mathematics education research community has been impressively successful in realizing what Wolfmeyer (2014) refers to as "national mathematics"—culminating in the Common Core State Standards—I take a critical look at this historical moment.

This paper argues that equity rhetoric and increased curricular centralization are linked through the "common sense" (Gramsci, 1971) of mathematics education research and reform. Gramsci has used the concept of "common sense" to describe how *ideas* support an "elite" in winning and rewinning consent to rule. With this as a framework, I provide an analysis of processes by which the prevailing common sense of mathematics education research is informed by the set of racial (and racist) representations oft referred to as whiteness (Mills, 1997), as well as geared toward profitable, top-down measures of social control in corporate capitalism.

Conclusions: I present and interrogate three ideas that are common sense to mathematics education research and reform. The first is the raced, classed, and spatially-located imaginary of the "urban child" apart from the imagined "white social body" and deemed in need of reform by way of school mathematics (Martin, 2013; Popkewitz, 2006; Leonardo & Hunter, 2007). Second is the scientific and moral authority of mathematics education researchers to decide what types of pedagogy benefit the "urban child". This authority is constructed through theoretical paradigm shifts that appear to afford a more favorable view of "the child" through the gradual inclusion of additional dimensions of "context." It is also constructed in juxtaposition to stereotyped representations of opponents to reform, which have included mathematicians and cultural conservatives but erased teachers and academics of color making critiques of process-oriented pedagogy (Delpit, 2006). The third common sense idea is that mathematics education reform should be linked to broader and profitable structures for top-down administration. Curricular standards are stamped with the values of reform pedagogy (e.g. problem-solving and mathematical practices), and thus enjoy a common sense association with equity. In turn, centralized standards to train teachers in, develop curriculum for, and assess understanding of expand both markets for these services and possibilities for "urban" school surveillance.

Keywords: Equity and Diversity; Elementary School Education; Middle School Education

Because of global mobility of populations, mathematics classrooms in many parts of the world are becoming linguistically and ethnically diverse. In the school district in which we conducted the research reported here, more than 25% of students are considered to be English language learners. Previous studies have found that teachers tend to assume that mathematics learning is universal, while immigrant students and parents can bring different expectations and norms (e.g., Gorgorió & Abreu, 2009). In order to better understand immigrant students' trajectories of mathematics learning, we examine their lived experiences of learning mathematics as revealed through autobiographical interviews and artistic renderings.

The broader study of which this is a part investigates students' experiences of learning mathematics in Canadian schools, and the ways that these experiences contribute to students' images of mathematics and their mathematical identities. To date, 94 autobiographical interviews have been conducted with Kindergarten to Grade 9 students. This project also utilized drawings in order to reveal students' experiences that cannot necessarily be verbalized. In this poster, we focus only on students who had prior schooling in countries other than Canada. To interpret this element of our data, we draw from sociocultural theory, which seeks to understand how cultural practices and artifacts mediate human learning (Cole, 1996).

Our results indicate that the majority of immigrant students in our study described differences in mathematics learning experiences between Canadian schools and schools in other countries. Differences were commonly identified in the following areas: practices of homework, individual learning and group work, the way teachers reward "good mathematics students," and support and help from teachers. These differences tended to contribute to some immigrant students' confusions, struggles, and frustrations in school mathematics learning in Canada. For example, some students reported how they were negotiating multiple norms regarding group work. Another significant common thread was pressure from parents to succeed in mathematics. Many immigrant students in our study were learning additional mathematics at home with their parents or supplementing school learning by afterschool mathematics learning programs. Some of the student drawings and narratives revealed how students conceptualized mathematics as a competitive, performance-oriented discipline, an orientation that seemed to be at odds with the educational cultures of the Canadian schools in which they found themselves.

Despite the common teacher belief that mathematics learning is universal, our study unveils ways in which immigrant students are navigating different norms and practices of mathematics learning. Our research implies that language learning is not the only support needed, but negotiation of meaning attached to school mathematics practices is also necessary to better support immigrant students.

Keywords: Affect and Beliefs; Elementary School Education

Purpose. It is well documented that relationships have profound effects on our well-being and quality of life (Landsford et al., 2005). The teacher-student relationship is no exception. While there is no consensus on effective teaching, it is clear that effective teachers focus both on content and caring (McEwan, 2002). However, in the field of mathematics education, we have little empirical evidence to show exactly how teacher-student rapport and students' mathematics achievement are related. The purpose of this study is to use a large sample size to examine the relatedness of teacher-student rapport and students' mathematics achievement. The central research questions to be addressed in this study are: Are teacher-student rapport and students' mathematics achievement related? If so, what is the magnitude?

Method. A total of 6,916 third graders from Central China participated in the study. This study is part of a large research project at Beijing Normal University. Each of the third graders was asked to complete an affect questionnaire and a mathematics assessment. Four of the questions in the affect questionnaire involve teacher-student rapport: (1) When I have different views from my teacher or textbooks, I have an opportunity to explain my thinking; (2) When I face challenges, I am not willing to ask my teacher for help because I am worried about any criticism from the teacher; (3) When I make mistakes, the teacher encourages me to find the mistakes by myself and correct them; and (4) When I improve my mathematics achievement, the teacher gives me praise. The mathematics assessment involves items on number and algebra, geometry and spatial reasoning, and probability and statistics. These are three of the content strands in the Chinese curriculum standards. The data was analyzed by correlation analysis and regression analysis.

Results. The results of the study showed that there are moderate correlations between teacher-student rapport and mathematics achievement in each of the content strands. In particular, the correlation coefficient between teacher-student rapport and student achievement on number and algebra is .221, .159 between teacher-student rapport and student achievement on geometry and spatial reasoning, and .097 between teacher-student rapport and student achievement on probability and statistics. Regression analyses showed that, although the four items on teacher-student rapport can significantly predict students' achievement in number and algebra, geometry and spatial reasoning, and probability and statistics, only less than 5% of the variance can be explained.

Conclusions. This study shows that a good teacher-student rapport plays an important role in improving students' academic ability in terms of number and algebra. We will explore the reasons why a good teacher-student rapport can promote students' academic ability in the future.

iweiland@msudenver.edu

The purpose of this research was to understand how lesson study participants in a teacher education program professionally noticed as they engaged in meetings as a component of the professional development cycle. Specifically, the focus was on how the context of lesson study provided opportunity for professional noticing, defined as attending to students' mathematical thinking, analysing students' mathematical thinking, and deciding how to respond when teaching on the basis of students' thinking. Results indicated that the structured format of lesson study in the teacher education program both afforded and constrained the incidences of verbalizing professional noticing in a group setting. Findings provide perspective for structuring lesson study for use in teacher education programs to support professional noticing.

Keywords: Elementary School Education; Teacher Education-Preservice

Statement of Purpose

Recent findings in mathematics education highlight the importance of focusing on students' mathematical constructions for knowing how to support future learning and development (Norton & McCloskey, 2008). Professional noticing is a specialized practice that encompasses: a) attending to students' thinking, b) analyzing students' thinking, and c) deciding how to respond on the basis of thinking (Jacobs, Lamb, & Philipp, 2010; van Es & Sherin, 2008). From this point forward we refer to this type of professional noticing as *noticing*. Lesson study is a professional development process that provides context for noticing, but has most commonly been used with inservice teachers. While the use of lesson study with preservice teachers is limited, teacher education programs implementing this practice can provide opportunities for preservice teachers to notice through reflection (Murata, 2011). Knowing more about supporting preservice teachers' noticing through lesson study is important for structuring teacher education programs to focus attention on students' mathematical understandings. This study seeks to answer the following research question: How do preservice teachers (teacher candidates who are presently in a teacher education program) professionally notice as they engage in the lesson study process?

Theoretical framework

In recent years, research studies have examined methods for teacher preparation related to teacher knowledge, effective teaching, and the relationship between knowledge and teaching (Cochran-Smith & Zeichner, 2005). Providing preservice teachers with opportunities to understand student-centered teaching and develop the pedagogical content knowledge necessary for effective instruction is essential for promoting high leverage teaching practices (Hill, Ball, & Schilling, 2008;). One method for developing this type of knowledge is through cultivating the ability to notice (Jacobs, et al., 2010). The notion requires attention to student thinking through "both observation and the medium through which observation takes place" (Mason, 2011, p. 45). During the process of noticing, effective teachers become aware of students' thinking and are able to construct tasks that direct attention to relevant learning opportunities (Mason, 2011).

The meaning of noticing has developed through literature on professional vision, which has explored nuances between varying stakeholder perspectives on classroom events and influencing factors that shape those viewpoints (Goodwin, 1994). Studies on professional vision commonly focus on teachers recording and studying their practice and researchers analyzing the noticing and reasoning of the teachers involved. Seidel et al. (2011) describe professional vision as the intersection between noticing and knowledge-based reasoning with the assertion that this type of reasoning involves the ability to describe what was noticed, link observations to prior knowledge about teaching and learning, and connect to theory to predict future classroom events. A distinguishing factor between noticing (Jacobs et al., 2010) and professional vision is the difference with foreseeing future practices (Seidel et al., 2011). Considering the roots in professional vision, we focus on noticing as the guiding framework in our study because of the preservice teacher context and importance of basing teaching decisions on evidence.

Related Literature

The following describes lesson study as traditionally practiced with inservice teachers, followed by a review of the literature on lesson study with preservice teachers.

Lesson Study Overview

Teacher knowledge can be fostered through the process of lesson study, leading to improvement in instructional practice (Murata, 2011). Lesson study, originally termed *Jugyokenkyu* in Japan, means lesson and study or research (Fernandez, 2010). During the lesson study process, participants, usually a small group of 5-7, begin by setting a goal for the lesson study process and then working collaboratively to plan a lesson to teach in one of their classrooms. To plan the lesson, participants study research materials, curriculum guides, and other artifacts to decide on appropriate instructional methods and content for a mathematics lesson. Next, a teacher in the group teaches the lesson to his or her students while the other participants observe the lesson. Following the lesson, the participants meet together to reflect on the lesson and to revise the lesson for teaching in another classroom. Once the lesson is revised, the modified version is taught in another teacher's classroom. This student-focused process affords participants the opportunity to notice different aspects of the lesson (Murata, 2011).

Lesson Study with Preservice Teachers

As lesson study has expanded beyond Japan to other countries and contexts, the process has begun to infiltrate teacher education programs (Fernandez, 2010). Recent research findings indicate that lesson study provides a context for preservice teachers to make connections between theory and practice as they take part in multiple components of the teaching cycle, including designing lessons and teaching (Murata, 2011). As a result, there is increased interest in knowing more about supporting preservice teachers' professional practices in lesson study.

Methodology

This research focuses on the use of lesson study with preservice teachers as a component of a teacher education program at a public university in the Midwestern portion of the United States. Case study methodology was employed to analyze how these participants noticed during seven iterations of the mathematics lesson study process (Yin, 2009).

Participants and Context

Participants in the case study included one team, comprised of six preservice teachers, one classroom teacher, and a university facilitator who taught the university course. Consistent with case study research, we focus on this one team of participants, as opposed to a larger number of participants, to provide opportunity for an in-depth examination of the practices and understandings of these individuals (Yin, 2009).

The format for the lesson study cycle was predetermined based on a university protocol. To begin the first cycle, the team met together to plan a mathematics lesson that would be taught by preservice teachers in the classroom teacher's first grade classroom. Weekly, two of the preservice teachers taught a whole-class mathematics lesson while the other participants (four other preservice teachers, one classroom teacher, and the university facilitator) observed the lesson and took detailed field notes. Following the teaching, the group met to reflect on the teaching with an aim toward discussing students' mathematical thinking. The university facilitator led these meetings and followed a protocol that provided opportunities for all participants to share their ideas. Following these reflective discussions, the team made plans for the next lesson that would be taught and the iterative cycle repeated. For the purposes of this research, we focus on the reflective meetings that occurred in this cycle following the teaching. We refer to these meetings as the *lesson study analysis meetings*; each of the seven iterations of the process included one of these meetings. Therefore, data for this study are video recordings of these seven meetings and the accompanying transcripts.

Data Analysis

The purpose of data analysis was to: 1) Identify instances of noticing during the lesson study analysis meetings, and 2) Understand how preservice teachers were noticing based on conversational interactions with the other team members. Data were analyzed in two phases: Phase One and Phase Two.

In Phase One, all data were coded by talk turn, signified by a change in speaker. Data were analyzed based on the degree of noticing as defined by Jacobs et al. (2010): attending (describing students' actions or words), analyzing (interpreting student actions or words), or responding (describing pedagogical suggestions for future teaching). Across the seven transcripts, 809 talk turns were coded by each of two researchers. The researchers met to reconcile differences in codes.

In Phase Two, data identified as noticing from Phase One were coded a second time to understand how preservice teachers were noticing based on conversational interactions. These instances were open coded (Corbin & Strauss, 2008). Identified themes included talk turns that were: based on a previous comment, initiated response, narrowed conversation, provided generalization, negotiated, asserting expertise, making a connection, addressed another issue, prompting participants, or provided context. These themes provided an explanation for how and why the noticing occurred within the context of the lesson study analysis meetings.

Statement of Results

Findings from this study indicate: 1) Noticing from the preservice teachers occurred in response to a prompt by the university facilitator, 2) When responding to this prompt, the preservice teachers commonly answered independently, meaning their conversation did not build on what others said, instead they reported one by one without continuity in the conversation topic, and 3) Preservice teachers noticed by attending and analyzing student thinking, but they rarely attended, analyzed, and decided how to respond on the basis of students' thinking about the same subject. The following provides short excerpts of data to provide evidence for these themes. Further data will be presented if accepted for presentation.

Response to Prompt

The preservice teachers noticed in the lesson study analysis meetings when the facilitator gave a prompt eliciting a discussion on students' mathematical thinking. The prompts encouraged the preservice teachers to respond about how students were thinking about mathematics, which resulted in noticing. Prompts included, "Let's focus on evidence of students' thinking," and, "What were specific ways students were thinking?" Following these prompts, it was common for the preservice teachers to engage in conversation to answer the facilitator's questions, during which they attended to students' thinking or analyzed evidence of student understanding. As this occurred, patterns of initiating and responding took place, meaning the facilitator would initiate a conversation, and the preservice teachers would respond. The following provides an example of a prompt, followed by noticing:

Facilitator: Alright, what are some specific ways that student work, students were thinking that you saw, observed as you were walking around?

Preservice 3: One thing I saw, Meagan, it was on the worksheet, and she constantly referred to the number line and I thought that was pretty neat because she's using her tools, the tools around. And like I said, I saw major improvement with Meagan, so I can tell that she's able to, able to, now being able to use tools around her without saying hey, look at the number line if you get lost!

Preservice 2: And I saw that with a lot of kids, actually while they were doing their worksheet, I know this is six oranges but how do I write six? Have them look at their number line and then would count up to six, they're like oh! And then they would write the six down, like they knew the objects.

In this instance, the facilitator asked a specific question, and even encouraged the preservice teachers to discuss students' thinking in the prompt. Following the prompt, preservice teachers responded by specifically discussing how students were making connections between figures of pieces of fruit and writing the corresponding numeral. Thus, the preservice teachers responded to the prompt by providing evidence about how students were thinking as they were learning to count and abstractly represent quantity with numerals.

Individual Response

As the facilitator gave a prompt and the preservice teachers responded, it was rare for the preservice teachers to relate their responses to other responses (as was done in the aforementioned example when Preservice Teacher 2 continued discussing the same topic Preservice Teacher 3 had initiated). Instead, it was typical that the preservice teachers would independently report on what they had noticed instead of trying to make connections across the different types of students' thinking that were noticed. Essentially, each preservice teacher responded to the prompt as if the other preservice teachers had not already responded, which resulted in a defragmented conversation in which the conversation did not build, but rather preservice teachers operated as individuals all responding on their own to the same prompt. The following provides a small excerpt to demonstrate this pattern:

Facilitator: Right we're just going around and saying what went well.

Preservice 4: I thought the book was a really good way to launch off your lesson. I think since they were familiar with the book that also helped. You know they knew what the book was about and were excited about it.

Preservice 5: Um, I think… I liked that they were able to take something home. The kids were really excited that they could keep this so you know, they were proud of what they did, which I thought was nice.

Preservice 6: I liked how you guys did the counting from like all the way up to twenty because they were doing five, ten and twenty. There were some kids having trouble with the higher numbers so it was like as a group they got to explore the numbers.

Preservice 2: Um, I liked the little wrap up at the end and kind of liked the flashcard thing where you held up the numbers and they tell you.

The preservice teachers each responded on their own to the facilitator's prompt; their comments did not clearly connect to each other to create a cohesive conversation. Instead, each preservice teacher highlighted something she noticed and contributed to the discussion by responding to the prompt, but not necessarily responding to the other preservice teachers' responses.

Attended and Analyzed

Across the seven transcripts, the preservice teachers engaged in noticing by attending to students' thinking, analyzing their mathematical thinking, and deciding how to respond on this basis; however, these three types of noticing did not commonly occur together. Instead, the preservice teachers engaged in dialogue that included attending to students' thinking and analyzing students' thinking, but did not make clear connections based on this evidence to verbalize noticing about how to respond. This does not necessarily indicate that they did not consider this connection mentally, however verbal evidence was rarely present in the lesson study analysis meetings. When the preservice teachers did make comments about how they would respond, they were often disconnected from conversation that attended to or analyzed student thinking. In other words, attending and analyzing occurred at points in the meetings and deciding how to respond occurred at separate times in the conversations. Therefore, incidences when all three identified types of noticing took place based on the same idea were rare. Within each meeting, it was common for attending and analysis to occur at the beginning of the meeting and for noticing that focused on responding to occur at the end; there was essentially a shift mid-way through the lesson study analysis meetings. Possible explanations for this are included in the discussion section.

Discussion of Results

The intent of this research was to describe how preservice teachers noticed as they engaged in the lesson study process. This information is critical for teacher educators to consider as it provides insight for knowing how to better support preservice teachers' focus on students' mathematical thinking through the act of noticing.

Importance of Prompts

As the preservice teachers engaged in the lesson study process, the prompts the facilitator asked were paramount in eliciting responses in which the preservice teachers noticed. The facilitator asked very pointed questions about students' thinking, to which the preservice teachers responded. In this way, the facilitator encouraged routine noticing by providing a context that required preservice teachers to be reflective in their responses and consider students' thinking (Miller, 2011). In doing this, the facilitator provided scaffolded support that is necessary for teaching others to notice (Star, Lynch, & Perova, 2011). Thus, the facilitator's prompts supported noticing by scaffolding preservice teachers' thoughts and directing them toward students' thinking. This is an important finding for teacher education programs looking to provide a similar context for the development of professional practices. In this instance, it was the facilitator's questions and prompts that often elicited noticing from the preservice teachers.

Attending and Analyzing

When noticing occurred, the preservice teachers commonly attended to students' thinking and analyzed their thinking (Jacobs et al., 2010). This required the preservice teachers to observe classroom events and make interpretations based on these events (van Es & Sherin, 2008). Hence, the lesson study analysis meetings provided a focused and specific context in which this type of analysis could occur, indicating the plausible benefits of using lesson study in a teacher education program. Within the context of lesson study, the preservice teachers engaged in a structure that was focused on students' thinking: as they taught or observed lessons, they were cognizant that they were going to be asked to report back on the basis of students' understanding. Likewise, as they planned lessons, they were mindful that they would be held responsible for teaching and or observing the lesson and then reflecting on the lesson—this process provided them the opportunity to complete a cycle of formative teaching by engaging in the three components of noticing. These findings indicate that teacher education programs should consider the possible benefits of lesson study for promoting the noticing practices of preservice teachers.

Lesson Study Structure

Despite the positive outcomes based on the noticing that occurred in the lesson study analysis meetings, findings identified segmented noticing responses in the meetings. Specifically, attending and analyzing student thinking was often separated from discussions about deciding how to respond on the basis of students' thinking (Jacobs et al., 2010) One possible explanation for this findings is the structure of the lesson study analysis meetings, as designed by the teacher education course. With the course, the facilitator followed a protocol in which the group reflected on the previously taught lesson, then discussed changes they could have made to the lesson to improve student thinking, and concluded by planning the next lesson. Perhaps the structure constrained the inclusion of further discussion of implications of analysis of students' thinking because preservice teachers and the facilitator understood the structure of the lesson study analysis meeting to progress along those three steps. This also could be related to the finding that the preservice teachers did not necessarily build their comments based on the aforementioned comments. These results indicate that a more fluid structure to the lesson study analysis meetings may provide for increased incidence of all three types of noticing occurring at the same time. For teacher education programs, this structure within lesson study may initially be helpful for encouraging noticing; however, facilitators or programs should be aware of this disconnect among the three types of noticing and perhaps reduce the stringency of a similar protocol for the meetings over time. Nevertheless, findings show promise for the use of lesson study in supporting preservice teachers to professionally notice.

PRE-SERVICE SECONDARY TEACHERS LEARNING TO ENGAGE IN MATHEMATICAL PRACTICES

Erin E. Baldinger
Arizona State University
eebaldinger@asu.edu

The Common Core Standards require students to learn content and mathematical practices, and so teachers must have content knowledge and be able to engage in practices themselves. This raises the question of how novice teachers learn to engage in mathematical practices. I investigate pre-service secondary teacher learning of mathematical practices following participation in a mathematics content course for teachers using a pre/post design. Four participants completed think-aloud interviews solving algebra tasks. All participants increased their engagement in mathematical practices and began to engage in them in more nuanced ways. Many changes in participants' practice engagement were related to opportunities to learn in the content course around making sense of problems, justification, and attention to precision. These results have important implications for teacher preparation and research on teacher learning.

Keywords: Teacher Education-Preservice; Mathematical Knowledge for Teaching; Teacher Knowledge; Problem Solving

What mathematical understanding is necessary for high school teaching, and when and how do teachers develop it? Recent research answers this question by considering mathematical knowledge for teaching (MKT) –mathematical knowledge entailed by the profession of teaching (Ball, Thames, & Phelps, 2008). This view of professional knowledge requires considering knowledge of school mathematics, knowledge of mathematics beyond the school curriculum, knowledge of how to unpack the mathematics of the school curriculum, and pedagogical content knowledge. Implicit in the definition of MKT is the relationship between knowledge *of* mathematics and engagement *in* mathematics. One way to describe the act of engaging in mathematics is through the lens of the mathematical practices. Thus, practices and mathematical knowledge for teaching must be considered jointly when investigating teachers' mathematical preparation. In this paper, I explore pre-service teacher learning of mathematical practices.

Teacher Engagement in Mathematical Practices

Mathematical practices describe the tools needed to *do* mathematics. They include making a conjecture, justification, and attention to precision(Common Core State Standards, 2010). Because mathematical practices are a key part of the Common Core, a focus on teacher engagement in them has become a particularly salient issue for current research. Despite robust literature on teacher knowledge, teacher engagement in mathematical practices has not been explicitly incorporated into commonly used definitions of MKT. "Conceptions of teacher knowledge have seldom considered the kinds of mathematical practices that are central to teaching. For example, rarely do teachers have opportunities to learn about notions of definitions, generalization, or mathematical reasoning" (RAND, 2003, p.21). Attention to teachers' engagement in mathematical practices matters for two reasons. First, teacher engagement in practices helps demonstrate what teachers *do* with the mathematical content that they *know*. Second, the ways in which teachers engage in practices themselves may affect how they teach students to engage in practices.

I draw on the mathematical practices identified in the Common Core Standards to describe ways in which secondary novice teachers *do* mathematics. I conceptualize teacher engagement in mathematical practices as being intertwined with MKT, just as the standards of mathematical practice are necessarily embedded within mathematical content (McCallum, 2014). Teacher engagement in practices as mathematical problem solvers themselves is connected with subject-matter knowledge. Similarly, understanding how to teach students to engage in practices is connected to pedagogical content knowledge.

Much of the existing literature on teacher engagement in mathematical practices emphasizes proof. Overall, research on teachers and proof has endeavored to (1) understand teacher beliefs about proof and its role in the classroom (e.g., Knuth, 2002; Staples, Bartlo, & Thanheiser, 2012) and (2) investigate teacher knowledge related to the analysis of specific types of proof (e.g., G. Stylianides, A. Stylianides, & Philippou, 2007). However, there remains a gap in the literature about how teachers actually engage in proof themselves. Given the emphasis on mathematical practices in the Common Core Standards(2010), it is critical to investigate teachers' engagement in proof, in addition to their knowledge about it.

Equally important is research that investigates practices more broadly, looking beyond formal proof alone. Mathematical practices rarely occur independently of one another, making it critical to look at them in concert with each other and within a variety of mathematical content domains. Investigating teacher engagement in mathematical practices more broadly will contribute a great deal to understanding teachers' MKT and its link to mathematical practices. Just as pedagogies of enactment support novice teachers in learning to teach (Grossman et al., 2009), teacher engagement in mathematics can support student engagement in mathematics. This makes it essential to conduct research that focuses on teacher engagement in mathematical practices connected with teacher content knowledge. If we argue that teachers need to develop MKT and need to engage in mathematical practices, what then does it look like for teachers to be learning to engage in mathematical practices?

Teacher Learning

Following (Lave & Wenger, 1991),I take a situative perspective on teacher learning; that is, learning is described as a change in the way a teacher participates in a community of practice. In the context of teachers learning math content and practices, evidence of learning can come from changes in the way teachers interact with one another in the context of solving a math problem, but it can also come from changes in the way they individually reason about a math task (Cobb & Bowers, 1999). Focusing on mathematical practices in particular, learning means looking at the way teachers take on, or appropriate (Moschkovich, 2013; Rogoff, 1990), the mathematical practices and how they transform their engagement in those practices within a community of mathematics teachers. For example, a pre-service teacher might appropriate the practice of justification by utilizing more mathematically appropriate proofs or explanations (such as using examples to motivate a generalized proof, rather than using examples as proof).

In this study, I consider the following question: What did participants in an abstract algebra course for future secondary teachers learn about mathematical practices? In particular, I examine the extent to which their engagement in mathematical practices changed from the beginning of the course to the end of the course.

Methods

To answer this question, I conducted a case study of an abstract algebra course designed for future secondary teachers. The course took place at the beginning of a yearlong preparation program. I selected this site for my case study largely because of the program's commitment to the deep mathematical preparation of future teachers. A mathematician taught the course; he tailored the course to attend to the needs of the teachers he was preparing. I observed all sessions of the abstract algebra course. The course met for ten weeks for three hours each session.

Participants and Data Sources

Four pre-service teachers participated in the study. Though these participants are not a representative sample of all future secondary math teachers, their mathematical preparation is consistent with that of typical pre-service secondary math teachers. The participants each had different trajectories into teaching and as such represent different specific features of novice teachers. It is valuable to treat each participant as an individual case study. Daniel entered the teacher preparation program after a long career in engineering and business. He had an undergraduate degree in engineering. Laura was a paraprofessional for several years before pursuing her math credential. She had a math major, but expressed a lack of confidence in her math ability. Sam served in the military after high school and then got an associate's degree in engineering. He later returned to school to finish his undergraduate degree in math and then complete his credential. Tim entered the teacher preparation program immediately after completing his undergraduate degree in math and physics.

At the beginning and end of the abstract algebra course, participants completed in-depth task-based interviews. Participants were asked to think aloud as they solved (Ericsson & Simon, 1980), and they engaged in "free problem solving" (Goldin, 1997). Though the interview tasks addressed high school content, the problems were non-familiar, that is, participants were unlikely to have seen any of the particular problems before. I investigate participant learning by comparing participant engagement in mathematical practices at both time points. Because of the think aloud structure, participants' solutions were both oral and written.

Data Analysis

I coded each interview for engagement in mathematical practices, using the Common Core practice standards as a framework and dividing each standard into sub-codes. For example, during the pre-interview algebra task, Laura decided to test some specific values to make sense of a more general algebraic statement. She said, "I'm just going to put real numbers in this for a minute". I coded this as trying a special case (MP1), because it was evidence trying a particular example while solving a general problem. Table 1 shows additional mathematical practice codes.

Table 1: Sample mathematical practice codes

Code name	Code description	Example
Connect representations (MP1)	Explain correspondences between equations, verbal descriptions, tables, and graphs	Sam (pre): Your slope is going to be somewhere in the middle, and then when you add these together [*(b + d) in the equation* $(f + g)(x) = (a + c)x + (b + d)$] the intersect is going to be somewhere in the middle [*indicates origin of the graph*].
Test conjectures (MP3)	Make conjectures and build a logical progression of statements to explore the truth of their conjectures.	Daniel (post), after conjecturing that the slope must always be -1: So I will pick a point that's at (1, 2) [*plots (1, 2)*]. That's one of the points. The other point should be at (2, 1) [*plots (2, 1)*]. Nicely, we see this slope is now going to be negative [*connects points (1, 2) and (2, 1)*].

Using a multiple case approach (Miles & Huberman, 1994), I describe participants' individual learning as well as investigate trends across participants. I used analytic memos to create problem-solving cases for each task. I looked across the four participants at each time point to identify similarities and differences in their content knowledge and practice engagement. Finally, I looked for change over time by comparing the pre and post interviews.

Interview Tasks

The algebra tasks used during both think aloud interviews required participants to prove a statement about linear functions. This makes them excellent sites to consider participant learning around proof and justification along with other mathematical practices. Both tasks focused on high school level content, though the particular tasks themselves were unfamiliar to participants. Both dealt with linear functions, a standard part of school algebra. Both tasks also required participants to prove a general statement about linear functions was true. The focus on the pre-task was on the sum of two functions at a particular point. The focus on the post-task was on the *x*- and *y*-intercepts of a particular line. Table 2 shows the pre and post algebra tasks.

Table 2: Interview algebra tasks and key features

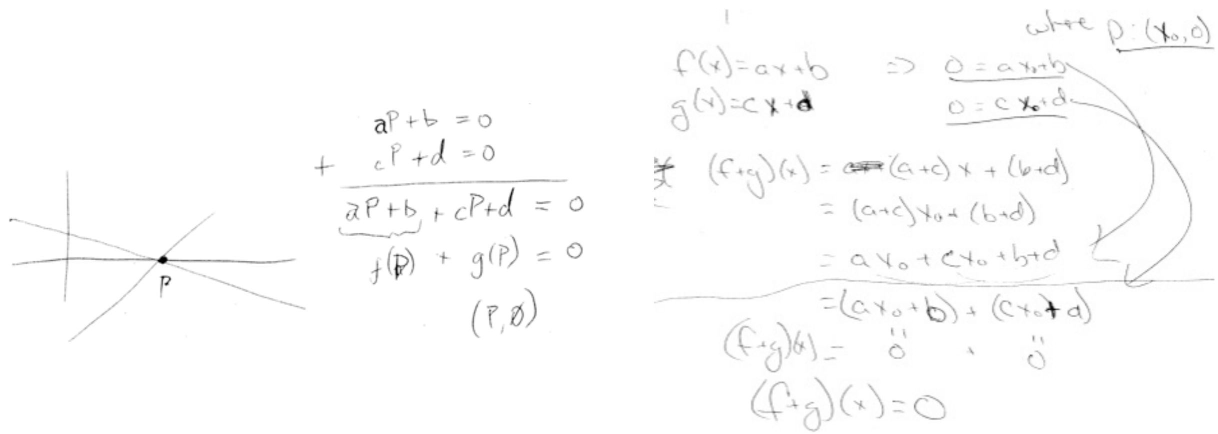
	Pre-Interview Algebra Task	**Post-Interview Algebra Task**
Key features	High school level content Linear functions Prove a general statement is true Focus on the sum of two functions at a particular point	High school level content Linear functions Prove a general statement is true Focus on the *x* and *y*-intercepts of a particular line
Tasks	Prove the following statement: If the graphs of linear functions $f(x) = ax + b$ and $g(x) = cx + d$ intersect at a point P on the x-axis, the graph of their sum function $(f+g)(x)$ must also go through P. (TEDS-M International Study Center, 2010)	Take a point (p, q) on the Cartesian plane. Reverse the coordinates to obtain a second point (q, p). Prove that on the line between these two points, the x-intercept and the y-intercept are the sum of the coordinates.

Findings

As a group, participants engaged in many of the mathematical practices, and the practices they engaged in were directly related to the nature of the tasks. All participants worked to make sense of the problems (MP1), create representations (MP2), construct arguments (MP3), and attend to precision (MP6); three participants engaged in making use of structure (MP7). Nobody engaged in modeling with mathematics (MP4), for instance, because the tasks did not entail mathematical modeling. All four participants showed changes in their engagement in mathematical practices, but the nature of the changes varied across participants. In this section, I explore these changes in detail. Additionally, I connect some of the observed changes in math practice engagement back to the opportunities to learn present in the abstract algebra class.

Learning to Justify and Attend to Precision: Daniel and Tim

Daniel and Tim both did very well on the pre-tasks. Daniel produced a complete and correct algebraic argument, providing his rationale aloud as he talked through his solution. He supported his argument with graphical examples (see Figure 1a). Tim produced a complete algebraic argument that was nearly correct except for an imprecise use of mathematical notation (see Figure 1b). Tim did not show substituting a point P into the equation, though that seemed to be his intention based on what he said. So his final line reads as though the result were true for any x value, rather than for a particular value of P (he wrote $(f+g)(x) = 0$, rather than $(f+g)(x_0) = 0$). Based on their performance, it seemed as though there would be little opportunity to see growth on the post task. However, both showed growth across several mathematical practices.



(1a) Daniel's work (1b) Tim's work

Figure 1: Daniel and Tim's written pre-task work

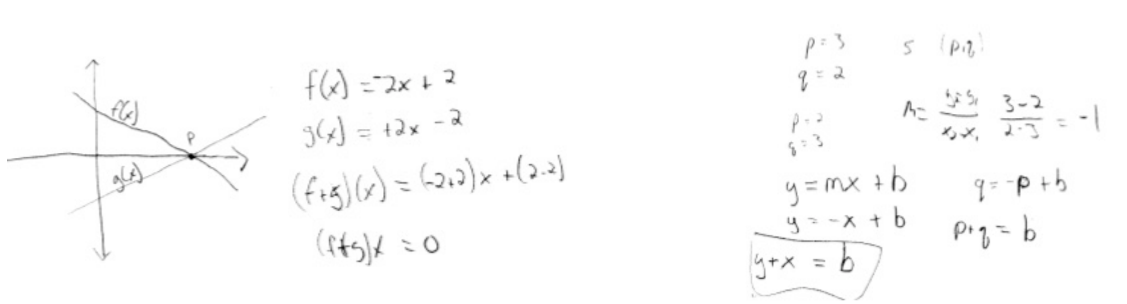
Daniel showed growth through more substantial and meaningful connections between his algebraic and graphical representations, and through his attention to precision. He took the same basic approach to the two problems, using a mostly algebraic approach with graphical examples on both. On the post-task, Daniel made stronger connections between the two representations (MP1) than he had on the pre-task in order to overcome an initial error. On the post-task, Daniel also carefully noted which variables were free and which were fixed. This attention to precision (MP6) enhanced the rigor of his final proof, giving him a more complete and detailed argument (MP3) than his work on the pre-task had been, even though both were correct results.

Tim also showed growth in his attention to precision (MP6), along with attending to the domain of his argument (MP3) and the way in which he communicated his conclusions. In particular, he distinguished between his preliminary scratch work and how he would develop a more formal proof. These changes allowed Tim, like Daniel, to produce a rigorous and detailed proof on the post-task that showed growth over his performance in the pre-task.

Learning to Make Sense, Persevere, and Justify: Sam and Laura

Sam and Laura struggled with the pre-tasks, though in different ways. Sam attempted to use an algebraic representation, but misinterpreted the problem and was unable to construct a complete argument. Laura tried using a special case, but due to not attending to all the conditions of the problem, chose an example that led her to believe the statement she had to prove was false, even though participants were told to prove the statement was true. After conjecturing that the statement was false, Laura did not attempt to justify her conjecture in any way.

In the post-task, Sam showed tremendous growth. He was able to accurately analyze the given information, monitor his progress and develop a solution plan, and choose a generative special case (MP1). One difficulty he had with the pre-task was choosing a special case that was too specific, and obscured some of the generality of the problem. In the post-task he chose a more appropriate special case (see Figure 2). Then he was able to generalize from the special case, something he had been unable to do in the pre-task. He also compared his special case argument to his more general argument and was able to evaluate them (MP3). Sam went from being unable to complete an argument to having a full, nearly complete proof. His work on the post-interview task was limited only by not attending to the meaning of his variables.



(2a) Sam’s pre-task special case (2b) Sam’s post-task special case

Figure 2: Sam’s pre and post-task special cases

Laura too demonstrated substantial change through her work on the post- task (see Figure 3). In this case, she correctly selected a special case (MP1) and was able to construct a complete and correct argument for that special case (MP3). She did so through increased work connecting representations (MP1). She also engaged in communicating her conclusions and evaluating her arguments (MP3), two practices not visible in her pre-task interview due to her early incorrect conjecture. Though she did not attempt to generalize her special case result, Laura commented that she knew that was the next step. She showed important changes in the way in which she engaged in the practice of justification (MP3).

Figure 3: Laura’s pre and post-task written work

Discussion: Connections to Opportunities to Learn

Overall, participants changed their engagement in mathematical practices, particularly making sense of problems (MP1), constructing arguments (MP3), and attending to precision (MP6). The results hint at the possibility of a learning trajectory around practice engagement. Laura and Sam improved in how they made sense of the problems, and this supported them to better construct reasonable arguments. Tim and Daniel demonstrated proficiency in making sense of the problems in the pre-task, but showed growth in communicating their conclusions and through their attention to precision.These particular practices were also a major focus of the abstract algebra class participants were taking(Baldinger, 2014).

Participants regularly had opportunities to make sense of problems during the abstract algebra course. For example, the professor emphasized how participants could use a special case to help them discover a more general solution. This is the approach Sam took on the post-task, and the approach Laura knew she should take.Participants also had opportunities to construct arguments and justifications. One such opportunity to learn occurred when the professor talked about communicating conclusions and the differences between scratch work and formal proof. This echoes the distinction Tim described in his work on the post-task.A third focus of the class was attention to precision. For example, the professor explicitly discussed the importance of defining the meaning of variables in a problem. Daniel and Tim both built on that in their work on the post-task. Participants' performance on the post-task reveals some important connections to the opportunities to learn in the abstract algebra course. This suggests the potential value of the content course as a site for learning about mathematical practices. Participants also reflected that they had learned how to engage in mathematical practices in the course (Baldinger, 2014), providing further evidence to support the idea that the improvements in performance on the post-task might be related to the learning opportunities in the abstract algebra course.

Implications and Future Directions

This case study illustrates what four pre-service secondary teachers learned around engagement in mathematical practices at the beginning of their teacher preparation. Though their learning was related to their experiences in the abstract algebra course, this is not necessarily a causal relationship; participants had numerous other learning experiences during this time. Additionally, these four participants are not representative of all pre-service teachers, and their learning trajectories are not necessarily "typical". However, each unique case provides insight into the variety of learning trajectories experienced by pre-service teachers.

There are several implications based on the results of this study. First, not surprisingly, these pre-service teachers exhibited distinctive learning trajectories for mathematical practices. In this case, despite differences in their starting places, all four participants showed changes in their engagement in mathematical practices. This suggests that teacher preparation programs can be sites for learning to engage in mathematical practices, just as the programs can be sites for developing other knowledge necessary for teaching. Additionally, such diverse learning trajectories need to be accounted for in the design of teacher preparation programs.

The abstract algebra course was clearly an important site for participants to learn to engage in mathematical practices. Incorporating more opportunities of this nature might support teacher engagement in a wider range of practices. Building on that, the practices proved portable across content levels. The participants learned to engage in these practices addressing college-level mathematics, but demonstrated their engagement on secondary-level tasks. This emphasizes the value of mathematics content courses beyond developing content knowledge.

Through engaging with multiple practices in an interconnected way, participants were more mathematically productive on the post-task than on the pre-task. Laura's post-task highlights the way engagement in communicating her conclusions (MP3) depended on her ability to connect her algebraic and graphical representations (MP1). Daniel and Tim's solutions show how attention to precision (MP6) can improve the quality of an argument. The interconnectedness suggests the value of learning about practices in conjunction with one another. The implication for teacher preparation is to provide multiple opportunities for pre-service teachers to engage in a variety of practices, rather than focusing on a single practice. Furthermore, this suggests the value of looking more holistically at practice engagement in research.

This study raises a question about how to measure engagement in mathematical practices in a way that accounts for varied learning trajectories.The interview tasks used in this study did this by focusing on accessible high school level content. However, the choice of tasks also limited the practices that might have been assessed. Additionally, the in-depth interviews conducted for this study were exceptionally illuminating but would be inefficient to implement across large teacher preparation programs.Given the importance of understanding teachers' engagement in mathematical practices, it is important to identify alternative measurement strategies.

The standards of mathematical practice in the Common Core (2010) provide a practical motivation for understanding how practices are learned and how they can be taught. It is reasonable to imagine that if teachers have not had opportunities to engage in mathematical practices themselves, it will be difficult for them to create opportunities for their students to engage in mathematical practices. Learning to engage in mathematical practices can be seen as a first step toward learning to teach others to do so, creating an imperative to more fully understand teacher learning around mathematical practices.Future research must consider other contexts for learning along with other content areas. That will help develop a more complete picture of teacher learning around practices and provide greater insight into how to structure relevant learning opportunities. Additionally, it will be valuable to consider the relationship between a teacher's ability to engage in mathematical practices and the strategies that teacher uses to support student engagement in mathematical practices. Teachers must be able to support students in all aspects of their mathematical learning, and should have opportunities to learn to do this as part of their preparation. Understanding teacher learning around mathematical practices is a crucial part of supporting teachers in their work with students.

Supporting students to build robust fraction schemes and operations is an enduring challenge in mathematics education. Recent research has explored a developmental trajectory of fractions schemes and operations constructed by upper-elementary and middle school students in an effort to support student learning. This study broadened the existing research by investigating PreK–8 preservice teachers' construction of fractions schemes and operations. This paper specifically explores data from PreK–8 preservice teachers regarding one scheme (Iterative Fraction Scheme) and way of operating (Three Level Units Coordination). Results focus on 13 special cases that disagreed with current conceptions of the developmental trajectory.

Keywords: Learning Trajectories (or Progressions); Mathematical Knowledge for Teaching; Rational Numbers; Teacher Education-Preservice

Introduction and Objectives

In light of the enduring challenge that understanding fractions concepts places on PreK–8 preservice teachers (PSTs), our research project sought to validate a developmental trajectory of fractions schemes and operations specifically for PSTs. In particular, this study extends current research that has worked to establish this trajectory for elementary and middle school students (Hackenberg, 2007; Norton & Wilkins, 2012; Steffe & Olive, 2010). For this study PSTs responded to tasks designed to determine the fractions schemes and operations with which each participating PST seemed to operate.

The initial goal was to validate the established trajectory with a new population. Upon analysis of the data, the trajectory seemed consistent with previous research; that is, each lower level of fractional understanding appeared to be a prerequisite to higher levels of understanding. However, upon further analysis, 13 special cases emerged that deviated from this trend. In these 13 cases, PSTs demonstrated ways of operating that aligned with an Iterative Fraction Scheme (IFS) while simultaneously lacking the prerequisite operation of Three Level Units Coordination (3UC). This paper focuses on our work examining these special cases. We worked to answer the research question "Must PSTs interiorize 3UC before constructing an IFS?" Although studies have shown that, without 3UC, elementary and middle school-aged students cannot develop an IFS (e.g. Hackenberg, 2007; 2010), it appeared possible for PSTs to do so.

Background and Theoretical Framework

PSTs and Fractions

Many studies document PSTs' difficulties with making sense of fraction concepts and fraction computation, particularly related to fraction division (e.g., Ball, 1990; Borko, Eisenhart, Brown, Underhill, Jones, & Agard, 1992; Newton, 2008; Tirosh, 2000; Van Steenbrugge, Lesage, Valcke, &

Desoete, 2014). One possible cause for this enduring challenge is the prevalence of part-whole thinking in U.S. mathematics curriculum (Newton, 2008; Watanabe, 2007; Yang, Reys, & Wu, 2010). Part-whole thinking is a common way to define fractions: The fraction m/n is defined as m equal-sized parts out of n, where a total of n parts make up the whole (where m and n are positive integers). Using this fraction scheme, 3/4 would be thought of as 3 equal-sized parts out of 4.

Previous studies have established that PSTs rely primarily on part-whole thinking (Newton, 2008; Sowder, Bedzuk, & Sowder, 1993; Tirosh et al., 1998; Zhou, Peverly, & Xin, 2006). Although part-whole reasoning can provide an initial understanding of fractions, research has documented the limitations of part-whole reasoning (Mack 2001; Olive & Vomvoridi, 2006; Saenz-Ludlow 1994). One of the major limitations of part-whole reasoning relates to understanding improper fractions. Students typically struggle to reason with fractions greater than 1 when the only way they know to think about fractions is part-of-a-whole (Thompson & Saldanha, 2003). When 3/5 only makes sense as three parts out of five, it is difficult to make sense of 7/5, or seven parts out of five.

Besides the reliance on part-whole thinking, another possible cause for PSTs' issues with thinking about improper fractions as numbers is difficulty with coordinating multiple levels of units (Hackenberg, 2007). Construction of improper fractions as numbers requires the *interiorization* of coordinating of three levels of units (Hackenberg, 2007, 2010; Norton & Wilkins, 2012). *Interiorization* is the reorganization of internalized actions as an assimilatory structure; students who have interiorized actions (as operations) do not need to carry them out in activity (i.e., they can be taken as given prior to activity) (Olive, 2001).

Table 1: Fraction Schemes

Schemes	Associated Mental Actions
Part-Whole Fraction Scheme (PWS)	Producing m/n by partitioning a whole into n pieces and disembedding m of those pieces.
Partitive Unit Fraction Scheme (PUFS)	Determining the size of a unit fraction relative to a given unpartitioned whole by *iterating* the unit fraction to produce a continuous partitioned whole.
Partitive Fraction Scheme (PFS)	Determining the size of a proper fraction relative to a given unpartitioned whole by *partitioning* the proper fraction to produce a unit fraction and *iterating* the unit fraction to reproduce the proper fraction and the whole.
Reversible Partitive Fraction (RPFS)	Reproducing the whole from a proper fraction of it by *partitioning* the fraction to produce a unit fraction and *iterating* that unit fraction the appropriate number of times. Note that the action of partitioning implicitly involves splitting because partitioning is used to reverse the iterations of a unit fraction (e.g., 3/5 as three iterations of 1/5).
Iterative Fraction Scheme (IFS)	Reproducing the whole from an improper fraction of it by partitioning the fraction to produce a unit fraction and iterating that fraction unit fraction the appropriate number of times. Note that, in addition to splitting, this way of operating implicitly involves coordinating three levels of units: the unit fraction, the improper fraction, and the proper fraction contained within it.

Fractions Schemes and Operations

Steffe and Olive (2010) suggest a learning trajectory for students' development of fractions knowledge in terms of schemes and operations. The hierarchy of schemes is found in Table 1. In addition, two ways of operating also essential to this framework: 1) Splitting, which is the mental action of simultaneous *partitioning* and *iterating*, and 2) mental actions associated with Three Level Units Coordination (3UC).

Methods

Context and Participants

The participants were 109 undergraduates enrolled in the first of three required mathematics courses for PreK–8 PSTs. The focus of this first course was number concepts and operations, including fractions. The 109 students include only those taking the course for the first time. Of the 109 participants, about one-half were freshman (52%), about one-third were sophomores (31%), and the rest were upperclassmen (17%).

Data Collection

The participants were given a fractions schemes and operations assessment at the beginning of the semester, specifically before any instruction related to fractions or fraction computations. The assessment contained four items associated with each of the seven fractions schemes and operations (see Table 1), resulting in a total of 28 items. Each item was designed to provoke a response that would indicate whether or not the student had constructed that particular scheme or operation. These items were developed for and previously used with upper elementary and middle school students (Norton & Wilkins, 2012; Wilkins & Norton, 2011). However, PSTs have and tend to use knowledge that upper elementary and middle school students do not necessarily automatically use (e.g., fraction division algorithms). Therefore, to obtain a better understanding of the PSTs' ways of operating, the participants were also asked to provide a brief written explanation for their responses.

Two coders independently rated the responses using both the written work on the assessment and the brief explanations provided, according to Norton and Wilkins (2009, p. 156). Each item was given a score of 0, 0.4, 0.6, or 1 based on the amount of evidence observed for a given scheme or operation (see Table 2).

Table 2: Scoring Rubric

Score	Evidence Shown
0	Strong counterindication that the PST could operate in a manner compatible with that particular scheme or operation
0.4	Weak counterindication that the PST could operate in a manner compatible with that particular scheme or operation
0.6	Weak indication that the PST could operate in a manner compatible with that particular scheme or operation
1	Strong indication that the PST could operate in a manner compatible with that particular scheme or operation

Each coder summed the four individual item scores, resulting in an overall raw score between 0 and 4for each scheme or operation. The overall raw scores were then used to infer whether or not the PST had constructed that particular scheme or operation. Overall raw scores greater than or equal to 3 indicated that the PST had constructed that particular scheme or operation. Overall raw scores less than or equal to 2 indicated that the PST had not constructed that particular scheme or operation.

Overall raw scores between 2 and 3 required each coder to infer from all the given information whether or not the PST had constructed that particular scheme or operation. If a disagreement occurred between the two raters, the raters reexamined all the relevant information together to reach a consensus. (The average kappa statistic for measuring inter-rater reliability for 3UC was .81 and for IFS was .93.)

Data Analysis

First, descriptive statistics were calculated in order to compare the percentages of PSTs that had constructed each of the different schemes and operations. For this paper, we focus in particular on Three Level Units Coordination (3UC) and the Iterative Fraction Scheme (IFS).

Second, data were entered into 2 × 2 contingency table to examine the hypothesized association between 3UC and IFS. The gamma statistic, G, was used to test the magnitude of the association (Siegel & Castellan, 1988). We were specifically interested in testing whether the interiorization of 3UC preceded the construction of an IFS. Based on prior research (Hackenberg, 2007; 2010), we predicted a direct or positive association between the interiorization of 3UC and the construction of an IFS, specifically that the interiorization of 3UC occurs prior to the construction of an IFS. If the data associated with 3UC and IFS are consistent with this hypothesis, then we would find a positive direct association (i.e., $G > 0$) and a *weak monotonic relationship*. A weak monotonic relationship is characterized by a staircase pattern in the contingency table, with data falling predominantly in the diagonal and lower left cell. Because the G statistic is a symmetrical measure of association it does not by itself provide evidence of developmental order among the schemes and operations.

Following procedures outlined by Wilkins and Norton (2011) we tested for developmental order among the schemes and operations by first visually examining the table for evidence of a staircase pattern. Empirically, using a binomial test, we tested whether the difference in the number of cases in the off-diagonal cells was in the hypothesized direction and different from what would be expected by chance. We hypothesized a direct (positive) association between 3UC and IFS and also hypothesized a developmental order. For this hypothesis we used a one-tailed gamma and binomial test.

Results

In Table 3, descriptive statistics for 3UC and IFS are presented. Less than half of the PSTs had interiorized the coordination of three levels of units (47%). About a quarter of the PSTs had constructed an IFS (27%).

Table 3: Descriptive Statistics

Scheme/Operation	Percentage	*SD*
3UC	47%	0.50
IFS	27%	0.44

Based on our hypothesis, PreK–8 PSTs should interiorize 3UC prior to constructing an IFS. Table 4 presents the frequencies of PSTs' construction of an IFS and coordination of three levels of units. Overall, no association between the coordination of three levels of units and the construction of an IFS was found ($G = .23$, $p = .15$, one-tailed). An examination of the off-diagonal cases ($n = 48$) found 13 PSTs who had constructed an IFS prior to interiorizing the coordination of three levels of units. This is a relatively large number of cases that counter the hypothesis. However, the distribution of the off-diagonal cases was statistically beyond chance; exact binomial, $p = .001$ (one-tailed).

Table 4: Frequency of 3UC and IFS Scores

	IFS		
3UC	0	1	Total
0	45	13	58
1	35	16	51
Total	80	29	109

Note. $G = .23$, $p = .15$, one-tailed; Exact Binomial $p = .001$ (one-tailed).

Because the result from the gamma statistic is inconsistent with the theory relating 3UC and an IFS (Hackenberg, 2007; 2010), it is important to further examine the 13 students found to have constructed an iterative fraction scheme prior to interiorizing the coordination of three levels of units. One point of concern is that the fractions tasks used in the assessment were designed for upper elementary and middle school students. As previously discussed, PSTs have and use knowledge that upper elementary and middle school students do not automatically employ. For example, by using algorithms for dividing fractions or finding equivalent fractions, PSTs' procedural responses to the 3UC and IFS tasks, as well as their written explanations, may actually mask evidence providing an indication for (or evidence providing a counterindication against) interiorizing 3UC or constructing an IFS. For both the 3UC and IFS tasks, the 13 PSTs responses were re-examined to find patterns in their thinking and representations.

One observation found was that many of the 13 PSTs used either fraction division or equivalent fractions to answer the 3UC tasks. For example, Figure 1 shows how one PST used fraction division to answer a 3UC task. In her explanation, the PST described her thinking: "The pizza shows 3/4 of a pizza and each person wants 1/8 so I divided 3/4 by 1/8. I found the reciprocal making it 3/4 ÷ [sic] 8/1 and found that 6 people could get 1/8 of the pizza." Although her answer is correct, her procedural work and written description do not provide clear evidence that this PST is actually coordinating three levels of units.

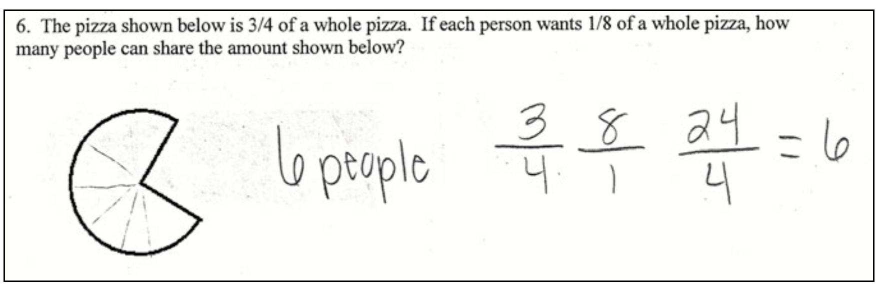

Figure 1. PST used fraction division to answer a 3UC task.

Figure 2 exhibits how another PST solved a 3UC task, this time using equivalent fractions. In her written work, she explained that she wanted to find out "how many eighths are in 3/4 so I multiplied top and bottom by 2 to reach eighths and I got 6/8. Therefore 6 people can have 1/8 of the 3/4 pizza." Again, the procedural work and written explanation do not provide evidence for or against this PST having interiorized 3UC.

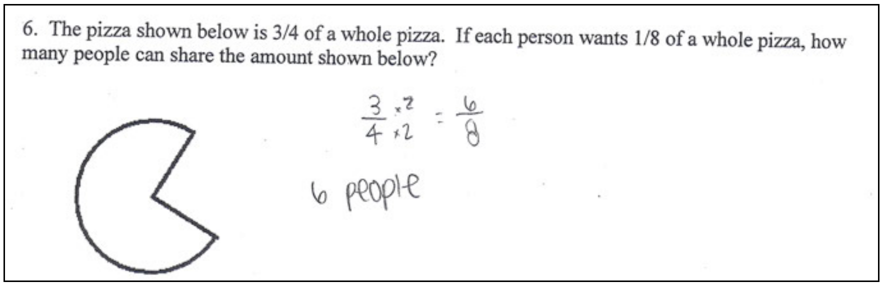

Figure 2. PST used equivalent fractions to answer a 3UC task.

Another observation found in the responses to IFS items was that over half of the 13 PSTs changed the given improper fraction to a mixed number to find an answer. Although these PSTs were able to determine the correct answer, it seemed that they would have been unable to do so without converting to a mixed number based on their written explanations. As an example, one PST (see Figure 3) wrote in her explanation, "I changed 7/3 to a mixed fraction and saw it was roughly twice the size as the candy bar so I split it into thirds and counted 3/3 to make one." If this PST had constructed an IFS, she would likely respond by partitioning the given stick into seven equal pieces and taking three of those pieces to represent the whole candy bar—a more efficient way of operating. In this illustrative work, it seems as though the PST relied on the mixed number of 2 1/3 to solve the task instead of considering the improper fraction of 7/3 as a number in its own right.

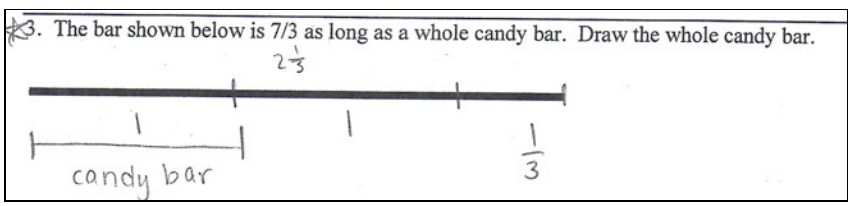

Figure 3. PST used a mixed number to answer an IFS task.

Also, almost half of the 13 PSTs examined demonstrated some level of confusion in their responses to IFS items. Even when they provided correct representations and answers, these PSTs exhibited a lack of confidence in their work. For example, one PST explained, "I'm having trouble understanding the amounts when the given amount is over 1." Another PST expressed confusion when the given diagram (which represented an improper fraction) was a half circle: "I got confused looking at the diagram because the picture doesn't look bigger than a whole." The confusion unveiled in responses like these raise further questions about these PSTs' construction of an IFS.

The analysis of the 13 PSTs' responses suggests that some PSTs may have actually interiorized 3UC, but their use of procedures and algorithms potentially mask the coordination of the three levels of units. In addition, some issues related to the IFS tasks, such as relying on mixed numbers, may have been overlooked and resulted in a false identification of that PST constructing IFS. As such, our results call for further investigation.

Discussion

We found that assessing the interiorization of Three Level Units Coordination (3UC) in PreK–8 preservice teachers is challenging. Primarily this challenge arose from the PSTs' automatized mathematical procedures that upper elementary and middle school students may still be in the process of learning. Instead of having to coordinate three levels of units on these tasks, PSTs may just be using their procedural knowledge for dividing fractions or finding equivalent fractions. These computational procedures mask evidence for or against the interiorization of 3UC. While PSTs may be able to use a procedure (see Figures 1 and 2) to find a correct answer, they often do not demonstrate evidence for or against their ability to view 3/4 of a whole pizza as three 1/4 pieces, where four such pieces would make up a whole pizza, and that each 1/4 piece contains two 1/8 pieces.

Likewise, we found assessing whether or not PreK–8 preservice teachers have constructed an iterative fraction scheme (IFS) to also be challenging. Two reasons for this challenge are the PSTs' use of mixed numbers and lack of confidence. Hackenberg (2007) claims that when students cannot consider an improper fraction as a number in its own right, and rather must change the number to a mixed number, then the student has not constructed an IFS. Some of the 13 students found to have constructed an IFS prior to interiorizing 3UC may have "fooled" us into believing they had constructed an IFS even though they relied on mixed numbers to reach (and represent) their solution. In addition, the PSTs were often confused about the problem statement as well as their solutions to IFS items. In retrospect, we wonder whether we should have inferred that a PST has constructed an IFS when they exhibit confusion and lack confidence in their solutions.

From part of the analysis of our data, it seems that some PreK–8 preservice teachers may have constructed IFS without the interiorization of 3UC. However, because of the problematic assessment of these items, as noted above, it is difficult to make a definitive conclusion. Because PSTs' difficulties with fraction concepts and fraction computations is an enduring challenge for researchers and teacher educators alike, this current research should be expanded. One starting point is to redesign the items used in our current assessment (which were originally designed for upper elementary and middle school students) so that PSTs cannot use procedures and algorithms to solve; instead, they must rely on their constructed schemes and interiorized operations. Another expansion of our research is to conduct clinical interviews with the PreK-8 preservice teachers to better understand whether or not they had truly interiorized 3UC or constructed an IFS.

In addition to the advancement of research, changes should also be considered in required mathematics courses for PreK–8 preservice teachers. For example, instead of using language that reinforces part-whole thinking (i.e., describing the fraction 4/5 as four equal-sized parts out of five), instructors can emphasize language that encourages a more iterative way of thinking (i.e., describing the fraction 4/5 as 4 equal-sized parts, each of which is 1/5 of the whole). In addition, instructors can incorporate more instructional tasks and activities that involve improper fractions, such as asking PSTs to model and describe improper fractions using representations or manipulative materials such as Pattern Blocks. These practices may help PSTs move towards interiorizing the coordination of three levels of units and constructing an IFS.

With the call for students as young as fourth and fifth grade to operate with higher-level schemes and operations (CCSSO, 2010), it is imperative that future PreK–8 teachers also be able to operate with higher-level schemes and operations. Both research and practice can help to accomplish this goal.

In this paper, we analyze efforts to encourage teachers' attention to student thinking through a professional development (PD) program. We describe three groups of teachers within the same program who completed different types of assignments, either conducting interviews, planning classroom activities, or both. In both types of assignments, teachers were prompted to explicitly address student thinking. Teachers attended to specifics of student thinking when conducting and analyzing interviews, but struggled to do so when planning activities. While acknowledging the value of sustained attention to revision of lessons, reviewing classroom videos, and utilizing different forms of classroom discourse, we argue that conducting and analyzing interviews is an underused activity that can and should be an important part of teachers' professional development if we seek to encourage attention to student thinking.

Keywords: Teacher Education-Inservice (Professional Development); Classroom Discourse

Introduction and Theoretical Perspective

Student-centered teaching in mathematics classrooms has been at the heart of reform movements and curricula in recent years. We take the perspective that attention to student thinking is important, but that learning to notice and understand what students are doing is a difficult process. Recently, Schoenfeld (2011) has called us to consider how the practice of attending to student thinking may be developed. In the present paper, we respond to this call and argue that engaging teachers in conducting and analyzing mathematical interviews with students is extremely productive. To support this claim, we describe the work of teachers in an extended PD program that had the dual goals of enhancing teachers' mathematical content knowledge of functions and a functional approach to mathematics and enhancing teachers' understanding of students' mathematical thinking.

Attempts to enhance mathematics instruction in the United States (US) have embraced the ideas of student-centered or responsive teaching in varying ways. For example, Chapin, O'Connor, and Anderson (2009) describe types of classroom talk designed to elevate and utilize student contributions, such as restating student ideas in other terms and asking other students to address a proffered student idea. These strategies, and others designed to encourage rich student discussion in the mathematics classroom, are valuable, as is helping teachers to develop them. However, teachers cannot utilize these productively unless they are able to quickly understand what a student is saying or determine what questions to ask to clarify the student's thought. Thus, attention to and understanding of student thinking must underpin and accompany any strategies for encouraging classroom discussion.

Similarly, PD often includes activities in which teachers create, review, and revise lesson materials and implemented lessons. The Japanese "lesson study" model (e.g., Lewis, 2000) includes these kinds of activities, and they are the focus of the recent call from Hiebert and Morris (2012) to shift attention away from teachers and towards the artifacts of teaching, including constantly revised lesson plans. Hiebert and Morris state that a key feature in the plans would be that "students' likely responses to instructional tasks and questions are predicted to allow teachers to plan how to use students' thinking during the lesson" (p. 95). Here, they, too, lend their support to the importance of attending to student thinking. In both of these models, being able to understand the students is essential to the work that the teachers are being asked to do, and again must either precede or develop along with the focus activity of revising materials. There is also a logistical challenge to the idea of using lesson creation and revision as part of PD in the US. As seen both in lesson study and in Hiebert and Morris' vision, these are practices to be taken on and sustained by groups of teachers. This is at odds with most PD for in-service teachers. Teachers may be from different schools using different curricula; they may also have time allocated for PD only sporadically. As a result, any attempt to focus sustained attention on lesson plans is interrupted, as teachers are not able to repeatedly implement and revise these "artifacts." While some schools have recognized that teachers may benefit from shared planning time and collaboration with their peers, it remains to be seen how widely this will be sustained and whether or not researchers will be able to access these practices and determine whether and how they enhance teachers' attention to student thinking.

However, research has shown that teachers can change how they attend to student thinking after PD that encourages this attention directly. For example, the video clubs described by van Es and Sherin (2008) show that teachers engaged in discussing videos of their teaching shift what they attend to, or "notice." Past work from Carpenter, Fennema, Peterson, Chiang, and Loef (1989) showed the results of a PD course in which teachers learned about student thinking in mathematics. Their approach, Cognitively Guided Instruction (CGI), included examination of student explanations. The teachers who took the course had significantly higher scores in knowledge of student strategies for their students, as compared to a control group of teachers. In addition, the students of the teachers who had participated in the CGI PD spent significantly less classroom time on number fact problems, yet they did significantly better than the students of control group teachers on questions of this type on a standardized test.

This work has been continued by Jacobs, Lamb, Philipp, and Schappelle (2011), using resources from CGI to provide sustained PD that included examining written work and video from classrooms. They showed that teachers improved in the extent to which they could attend to student thinking after extended participation in the PD. They assessed this by evaluating each teacher's responses as the teacher watched a videotaped interview with a student. Since Jacobs et al. consider teachers' viewing of a video of an interview to be suitable ground to elicit and measure teachers' attention to student thinking, this implicitly supports our suggestion that teachers have much to gain from analyzing interviews. We suggest that this becomes an even more powerful activity when the teachers conduct the interviews themselves and when the interviews are used to develop, and not just assess, the practice of attending to student thinking. By carrying out the interviews themselves, teachers have the benefits of evaluating the resulting video, but also the experience of attending to and responding to the student thinking in the moment.

Interviewing has been a powerful tool for researchers to gain rich insight into student thinking and capabilities. However, we argue that we have not sufficiently tapped this resource for teachers. We take the position that interviewing, as outlined by Ginsburg (1997), is not so very different from the forms of classroom talk endorsed by Chapin et al. (2009). In order to use "productive talk moves" in the classroom, a teacher has to be in the position of attending to students' thinking. We argue that through interviewing, teachers can take advantage of concentrating on student's responses without the responsibilities of managing a classroom in order to (1) begin to build a knowledge base of student ideas around particular mathematical topics, and (2) develop skills in attending to student thinking that they can then extend into the classroom.

In this paper, we report on our work with middle school mathematics teachers from multiple districts and schools engaged in a single PD program. The program focused on deep mathematical content knowledge of functions and a functional approach to mathematics as well as attention to student thinking. To encourage teachers to attend to student thinking, assignments included watching and responding to classroom videos, examining pieces of student work and classroom transcripts, and responding to questions asking teachers to predict what they thought students would do with different mathematical scenarios. In addition, we provided teachers with assignments in which they could choose to plan a lesson or to conduct an interview with a student. By comparing cases of three groups who completed different kinds of activities, we illuminate some of the benefits of having teachers conduct interviews as a way to consider student thinking, as well as describe challenges inherent in using lesson planning with the same intent. We argue that conducting and analyzing interviews with students can allow teachers to examine student thought in depth and that this should be put to use in PD.

Method

The data for this paper come from a PD program that offers three graduate-level semester-long courses, conducted partially online. To date, the program has had three cohorts of approximately 60 teachers each, from nine school districts. Here, we analyze the work of some of the teachers in the third course of the first cohort.

In this course, we had four three-week units, each unit concluding with an assignment that was framed as "Engaging Students." For each of these four assignments, teachers worked in groups of two to four; each group could choose to conduct and analyze interviews with students, or they could create a learning activity. We did not require teachers to develop a full-class activity that would extend for an entire class period, nor did we require them to use any particular lesson plan format.

Table 1: Assignment details

First option: Interview	Second option: Activity plan
With your group, discuss and compare what you each found in your interview. Together, write a brief report on what you found in your set of interviews. Make sure you include the following in your group report: What did the set of your group's interviews show about students' ways of thinking about inequalities? What did students say or do that surprised you? Use evidence from the transcripts of the interviews to support your ideas. How might the students' ways of approaching this problem help or hinder their understanding of equations and inequalities in future mathematics? What more would you like to be able to ask your students in order to better understand their thinking?	What is one mathematical idea, preferably relating to this unit's content, that your students have difficulty with and that you hope to address with an activity? What understandings do you think your students already have that can form a foundation for improved understanding of that idea? What misunderstandings do you think your students have that may hinder their understanding of that idea? What would you like to know about your students' understanding of that idea? Focus on students' understanding of the mathematical idea, rather than (or in addition to) their performance of specific tasks or algorithms. Work together to design a single activity (not necessarily a complete lesson) appropriate to your grade levels that addresses the idea you identified, builds on their understandings, and/or

	addresses their misunderstandings. Design the activity so that you will learn something new about your students' reasoning.

The option to create an activity was intended as a way to allow teachers to apply their knowledge of student thinking to teaching practice. The text of the assignments is shown in Table 1.

In both cases, teachers were asked about student thinking and asked to describe their students' thinking about the content included in the interview or activity. PD facilitators gave feedback to assignments in writing via an online forum.

Table 2: Assignment choices

	Number of teachers	Grades taught	Unit 1	Unit 2	Unit 3	Unit 4
Group 1	4 teachers	5, 9	learning activity	learning activity	learning activity	learning activity
Group 2	2 teachers	7, 8	interview	interview	interview	learning activity
Group 3	3 teachers	6, 8	interview	interview	interview	interview

We chose three groups of teachers to analyze here. Group 1 chose to do learning activities for all four units. We selected this group because they were the only ones in the entire cohort who made this choice, not completing any interviews. Group 2 chose to do three interview assignments, followed by a learning activity for the fourth unit of the course. We selected this group, the only one to follow this specific pattern of choices, because we theorized that the interview assignments might better prepare them for the learning activity assignment. Group 3 chose to do four interview assignments. We selected this group because it represented the opposite end of the spectrum from Group 1. There were multiple groups (nine groups, out of nineteen in the cohort) selecting only interviews; from those, we chose Group 3 because they shared similar characteristics with Groups 1 and 2 as indicated through classroom observations carried out at the outset of the PD program using the Reformed Teaching Observation Protocol (RTOP) (Sawada et al., 2002). Together, these three groups illustrate a variety of paths followed by teachers.

For each group, one researcher reviewed the teachers' written analysis, the interview transcripts and/or activity plans, the online forum discussions, and the PD facilitators' feedback and produced a "thick description" (Geertz, 1973) of each group's work. Next, a second researcher reviewed each of the artifacts again and revised and added to the description.

The results we present below allow us to provide insights into the utility of these assignments and offer points of consideration for PD design.

Results and Implications

Analysis of the teachers' work showed that when teachers created learning activities, their attention to student thinking was not as detailed, not as specific, and did not form as substantial a portion of their work. They did address student thinking in some cases, but it was because the assignment required it. That is, they were responding to our questions in order to complete the assignment, not because attention sprang organically from planning an activity.

Group 1: Four learning activities – beginning to address generalities of understanding

In their learning activity for Unit 1, the group members planned an activity in which different types of candy represented positive and negative numbers and unknowns. However, it was unclear how the structure of the activity itself took into account their students' thinking. In response to the question, "*What understandings do you think your students already have that can form a foundation for improved understanding of that idea?*", they wrote only, "*Our students have the foundation of how solve an equation with the goal of isolating the variable.*" Here they made a general statement about what their students might be able to do, but did not provide evidence or specifics to support their claim. In response to the question, "*What misunderstandings do you think your students have that may hinder their understanding of that idea?*", they listed four related items: "*Vocabulary word - inverse // Inverse means the opposite in effect. The reverse of. // Some students lack the understanding of what an inverse operation is // Solve for an unknown within the equation.*" Here, they pinpointed the absence of a skill, but did not address what it is that their students *do* think or give any information other than the summary assessment. The Unit 2 work was similar.

By the Unit 3 learning activity, there is some evidence that Group 1 did try to respond to the instructors' requests that they provide more evidence and specifics about student understanding. They stated that, "*some of our students tend to be stronger graphing information than verbally interpreting it.*"In this statement, the group made some progress in attending to student thinking: they avoided listing mathematical competencies as "student understandings," as they did in Units 1 and 2, and instead addressed differences among students. The statement suggests that the group felt that their students had different competencies to build upon. However, note that the statement is still general and lacks supporting evidence. This continued in Unit 4, with general comments forecasting difficulties their students would have with the activity such as, "*Finding the connection between the word problem and the graph will be difficult for [the students].*"

Group 2: Three interviews and a learning activity – progress and regression

In conducting their interviews for Unit 1, Group 2 focused on correct and incorrect answers from students, following up more on incorrect responses and pushing for correct notation. While the correct/incorrect answers were also a focus of their written analysis, they did state that they understood why their student gave a particular incorrect answer: "*I feel that this was an overgeneralization of solving for the variable… As a side note, this makes sense to me. In the process of practicing the solving of inequalities, students made the observation that it 'was like solving an equation.'*" They also suggested a way to investigate the student's understanding: "*we would be interested in how this student would graph the inequality on a number line that has no values listed.*" Taken together, these two quotes demonstrate that Group 2was beginning to consider why students might give particular answers and how they might follow up on their perceptions of student thinking.

In Units 2 and 3, Group 2 continued to try to meet the assignment and instructors' requests for specific evidence and for details about student thinking. The group's primary focus was still on what students didn't understand in comparison to what they did; for example, they wrote, "*the 8th grade student didn't really to seem to understand the problem clearly.*" While they did not articulate details about students' thinking, they did identify specific issues and consider how to address them. In Unit 2, the group noted that a student seemed to have "*difficulty with the coordinate grid*," so their suggestion was to remove the grid and see how the student would approach the problem. In Unit 3, they directly addressed both their attempts to understand student thinking and their challenges: "*His misunderstanding of the line being diagonal confuses us. He seems to think the line on the apples graph is diagonal but the line on the oranges graph is not. (Refer to [line in interview transcript].) It was interesting watching him gesture with his hands to determine that both lines were indeed diagonal.*"

In Unit 4, with each teacher having previously completed three interviews, Group 2 decided to create a learning activity, asking students to find the length of the diagonal of a rectangle with an area of 90 cm^2 and length and width that were consecutive integers. While they included mention of having students explain their strategies, the background they gave on student thinking to justify the activity was quite general: "*Students are able to use formulas to solve problems as long as the problem is straightforward and there is only one step involved.*" The course assignment did not require Group 2 to implement and analyze the activity, but this group chose to do so. In the process, they tried to return to addressing specifics of student thinking: "*many of the students totally fell apart and started trying to do some different things instead of using the Pythagorean Theorem. One student in particular added 44 and 46 to get 90. A few other students tried to add some other numbers together. One student divided 90 by 2 to get 45 and then divided 45 by 2 again to get 22.5.*" They listed the student strategies, but did not try to determine why the students had used these, nor did they offer suggestions for what they might do when confronted with these student ideas, as they had done in Units 2 and 3.

Group 3: Four interviews – developing focus on individual students

As with Group 2, the Unit 1 interviews from Group 3 focused on students' correct and incorrect solutions. They had asked students to shade a number line to show a<12, and their analysis of the interviews included evaluative comments like, "*One student did not seem to understand what "less than" meant, he actually included 12 as a possible solution.*" While the students' accuracy was at the forefront, the group did demonstrate that they were considering specifics of what students were doing: "*Zero was a point of confusion for the inequalities. For example, when a student answered verbally he believed that all the solutions had to stop at zero, but when asked to place the "a's" on the number line he realized the solutions could include values less than zero.*" The Unit 2 work was similar.

In Unit 3, the group designed their own interview tasks. They stated that they designed this activity, which used drawings to depict a scenario that they then asked the students to graph, because the students struggled with graphing in the Unit 2 interviews and they wanted to think of ways to scaffold a graphing activity: "*we hypothesized that the images would aid the students in both activities if the student began with the image problem.*" They refer to specifics from their Unit 2 interviews as they're justifying their choice of topics here; however, when they shift to discussing the actual items, they revert to generalities. For example, to address the question, "*What understandings do you think your students already have that can form a foundation for improved understanding of that idea?*" they write, "*variables, linear relationships, coordinate plane*". The use of a list of topics, rather than what students understand about the topics, is similar to the work of Group 1, as described above. While the teachers in the group did go on to conduct the interviews, their analysis of the interviews was only a few sentences long, and mainly addressed whether or not the students thought the pictures were helpful.

In Unit 4, Group 3 again used the interview tasks supplied by the PD program. The group shifted away from their prior emphasis on correct answers, and mentioned wanting students to understand the full scenario in the problem. However, their statements often did not include specific supporting evidence; for example, "*Student 2 was able to independently arrive at two solutions and eventually was able to explain a deeper understanding of the scenario than student 1.*" After the departure in Unit 3, they again considered what individual students were doing, but they did not progress in providing evidence as much as Group 2 had.

Implications

As seen in the examples above, when teachers creating a learning activity did address student thinking, it was often generalized because they didn't have a case to examine. However, when teachers conducted interviews, we can see more instances where their analyses maintained a focus on the specifics of student thinking. For example, Group 2 wrote descriptions of the students' progression through the problems, pointing to specific moments in the transcript to justify times when they claimed the students were confused. In addition, while Group 2 exhibited attention to student thinking during the three interview assignments they completed, the activity plan that they devised for the fourth assignment, after the interviews, showed the same type of generalizations as seen in the work of Group 1. This shift away from attending to student thinking was also seen in the Unit 3 work of Group 3, in which they focused on designing interview tasks, rather than on conducting and analyzing their interviews. While Group 3 had not demonstrated the depth of attention to student thinking that we saw from Group 2, the Unit 3 work of designing the interviews seemed to detract from the attempts they had made in Unit 1 and Unit 2 to focus on specifics about what students were doing. While all groups show some evidence of shifts in their work, and all groups show room to continue to develop their attention to student thinking, these cases begin to illuminate the advantages of interviews.

In planning activities, we were asking teachers to recall student thinking from the past. Conversely, when the teachers conducted interviews, they had the video and written work, as well as recent memories. The specificity of what they had available to them allowed them to remain focused on students' thinking. While this specificity would also be a benefit of having teachers watch classroom videos, as in Van Es and Sherin (2008), the interviews afforded teachers the opportunity to focus on one student at a time without having to manage as many other tasks. This was the case both while conducting the interviews and while reflecting upon them. This advantage emerged in the example above from the Unit 4 activity plan by Group 2. When they reflected on their activity after implementation, they reverted to listing many student answers, rather than taking a deeper look at particular instances of student thinking.

Certainly, this analysis uses only a few cases of groups of teachers. Thus, it shows us what is possible when teachers conduct and analyze interviews, but of course it cannot conclusively say what the results would look like in a large-scale comparison of groups of teachers doing different series of assignments. It is also important to note that here we are analyzing teachers' work in groups, but each group has multiple teachers working together on joint final products. These joint analyses reflect the work of the group, but it's not possible to know how each individual contributed or what they might have done differently if they were working on the same task alone (see Bautista, Brizuela, Glennie, and Caddle (2014) for an examination of this issue). An additional complication is that when teachers chose to do interviews, the feedback from facilitators after each assignment was more consistently focused on the teachers' attention and interpretation of student thinking. When teachers planned activities, the facilitators tried to address student thinking, but also commented on the structure of the activity. This may be valuable feedback on an important task of teaching, but it means that facilitators devoted less time and space to supporting teachers' understanding of student thinking. As with the teachers, facilitators lacked a case to examine, and it adversely affected the support they were able to offer.

Researchers have much to learn about how to promote teachers' attention to student thinking, including how it may grow and evolve while teachers conduct and analyze interviews with students. While future work should include more rigorous examination of a larger number of groups of teachers, this analysis highlights some lessons for teacher educators and PD providers. Certainly, activity planning could be undertaken in a thorough and specific way, with constant revision, as well as videos of implementations, as suggested by Hiebert and Morris (2012). Equally, analyzing classroom video (e.g. Van Es & Sherin, 2008) can enrich teachers' understandings as well. Our analysis does not detract from these other approaches; rather, it shows the rich opportunities that arise when teachers conduct and analyze interviews with students. As mentioned, many PD opportunities involve teachers from different grades, different schools, or who are using different curricula. Interviews can be conducted and analyzed even within these constraints, and teachers' attention to student thinking can be enriched as a result.

Formal lesson plans have long been touted as a best practice in mathematics teacher preparation. Experienced teachers frequently view formal lesson plans as nonessential to the planning, implementation, and evaluation of instruction. We discuss results from an online survey designed to make the perspectives of 60 prospective and practicing mathematics and special education teachers regarding lesson plans explicit. Practicing teachers identified their use of formal lesson plans as a reflective tool and for organization purposes, whereas for prospective teachers lesson plans served as a guide and for accountability reasons. Finally, we describe future mathematics teacher education engagements designed to promote productive yet practical perspectives of formal lesson plans.

Keywords: Teacher Beliefs; Teacher Education-Inservice; Teacher Education-Preservice

Introduction

Planning for a lesson has long been recognized as a primary factor impacting the efficacy of classroom instruction. According to Brahier (2013), "The effectiveness of a lesson depends significantly on the care with which the lesson is prepared" (p. 141). Focused lesson planning has been shown to support teachers' implementations of cognitively demanding tasks, help teachers anticipate students' cognitive challenges, and support the generation of questions teachers can ask that promote and elicit student thinking (Boaler & Staples, 2008; Franke & Kazemi, 2001; Henningsen & Stein, 1997). Smith, Bill, and Hughes (2008) assert, "One way to both control teaching with high-level tasks and promote success is through detailed planning prior to the lesson" (p. 133).

As introduced by Morine-Dershimer (1977) and described by Schoenfeld (1998), a teacher's lesson image is "the teacher's envisioning of the possibilities and contingencies related to a lesson" (p. 17). Furthermore, a teacher's lesson image includes the teachers' expectations for how students will engage with certain tasks or activities, what students might find straightforward or challenging, and potential student responses to the lesson's tasks and activities and how the teacher expects to deal with them (Schoenfeld, 2010, p. 233). As such, a teacher's lesson image incorporates everything related to how the teacher imagines the lesson will unfold (Schoenfeld, 1998, p. 18). Although the idea of a lesson image is more preponderant in literature with reference to experienced teachers, one need not have taught a lesson in order to have some image for how instruction might play out. Therefore, prospective and early career teachers should be motivated to imagine and anticipate how students might engage with instruction, envision the understandings and ways of thinking students might learn from alternative instructional approaches, and the ways in which discourse invites mathematical thinking and reasoning (Grouws & Shultz, 1996; Thompson, 2002).

One tool that encourages teachers to make their lesson images explicit, and potentially objects of thought and reflection, is the formal lesson plan. According to Brahier (2013), "A lesson plan…is a road map that can be used by the teacher to provide structure to the lesson" (p. 165). Furthermore, written lesson plans help motivate teachers to think deeply about their classroom tasks and activities and attempt to anticipate how students might interpret a task, the methods or strategies (correct and incorrect) students might use to make sense of the task and work toward a solution, and how those "strategies and interpretations might relate to the mathematical concepts, representations, procedures, and practices that the teacher would like his or her students to learn" (Smith & Stein, 2011, p. 8). As such, formal lesson plans permeate teacher preparation programs in general and mathematics methods classes in particular. As described by Kagan and Tippins (1992), "In virtually every teacher education program, considerable time is spent teaching novices how to write detailed, linear lesson plans" (p. 477).Although much less pervasive, research in professional development in mathematics education has included formal lesson plans as a data generating and analysis component (e.g., Burns & Lash, 1988; Morine-Dershimer, 1977; Smith, Bill, & Hughes, 2008). In addition, the creation and implementation of formal lesson plans and reflecting on how students engaged with instruction has been used with practicing teachers as a means to support teachers' development of instructional practices that promote "framing and solving problems, looking for patterns, making conjectures, examining constraints, making inferences from data, abstracting, inventing, explaining, justifying, challenging, and so on" (Stein, Grover, & Henningsen, 1996, p. 456).

Unfortunately, lesson plans have typically been viewed by teachers as a script or directions for executing a lesson that emphasizes procedures and structures, with "limited attention to how the lesson will help students develop understanding of key disciplinary ideas" (Smith & Stein, 2011, p. 76). According to Kagan and Tippins (1992), "Traditional university coursework may exaggerate the importance of daily lesson plans…[and] an emphasis on detailed written lesson plans may even be somewhat detrimental in that it masks the importance of improvisation" (p. 478). Moreover, research has consistently shown that "experienced teachers do not use written lesson plans…[and] at most…jot down an outline or list of topics to be covered during the lesson, using a cryptic shorthand" (Kagan & Tippins, 1992, pp. 477-478). Practicing teachers tend to regard formal lesson plans as useful only for student teachers or when they need to plan a new unit, perhaps with new standards, or as a required component of a formal administrative observation of their instruction (Kagan & Tippins, 1992).

Purpose of the Study

Disparity between prospective and practicing teachers, regarding the expectations of and value to developing, discussing, and revising formal lesson plans, highlights a need to better understand these distinctions from a situational perspective (Peressini et al., 2004), where teacher learning is "understood as a process of increasing participation in the practice of teaching, and through this participation, a process of becoming knowledgeable in and about teaching" (Adler, 2000, p. 37).In this article we present results from a study designed to better understand teachers' perspectives on the role formal lesson plans can and do play in the teaching and learning of mathematics. Specifically, the study was designed to address the following research questions:

- What are practicing (or in-service) teachers' perspectives on the role lesson plans play in their instructional practices?
- What are prospective (or pre-service) teachers' perspectives on the role lesson plans play in their instructional practices?
- How do practicing and prospective teachers' perspectives regarding lesson plans compare and contrast?

Methods

Study participants consisted of two samples: (a) 28 practicing teachers comprised of middle (grades 5-8) and secondary (grades 9-12) school mathematics teachers and intervention specialists (special education teachers); and, (b) 32 prospective teachers comprised of early childhood (grades K-3), middle childhood (grades 4-9), secondary (grades 7-12), and special education (grades K-12) license seeking teacher candidates. Potential participating teachers were emailed a link to an online survey designed to make explicit their perspectives on the role formal lesson plans play in their practice (see http://kentstate.az1.qualtrics.com/SE/?SID=SV_cCou1lOt7M930zj)

Survey Respondents (Study Participants)

The survey response rate for practicing and prospective teachers was 31.1% (28 of 90) and 20.1% (32 of 159), respectively. Practicing teachers ranged from first year math teachers to those with 30 years of experience. A comparison of the number of respondents by grade band, specialization, and teacher education program is displayed in Table1 below.

Table 1: Teacher Survey Participants by Grade Band, Specialization, or Program

Practicing Teachers	Number of Respondents	Prospective Teachers	Number of Respondents
Intervention Specialist	13	Special Education Licensure Program	21
Math Content, Grades K-2	0	Grades K-3 Licensure Program	3
Math Content, Grades 3-5	1	Math Content, Grades 4-9 Licensure Program	3
Math Content, Grades 6-8	5	Math Content, Grades 7-12 Licensure Program	5
Math Content, Grades 9-12	11		

Analysis

A situative perspective suggests that knowledge, beliefs, and practices are indissoluble from the situations in which they occur (Putnam & Borko, 2000). As such, learning to teach mathematics "occurs in many different situations—mathematics and teacher preparation courses, pre-service field experiences, and schools of employment" (Peressini et al., 2004, p. 67). The samples of teachers examined here represent individuals at different ends of a teacher-learning trajectory: teachers at the mathematics methods stage (prior to student teaching) and teachers at various levels of experience as practicing teachers.

In the following section, we examine and compare practicing and prospective teachers' perspectives on the role formal lesson plans play in their practices. We focus on two specific comparisons: (a) the role of lesson plans for prospective teachers, and (b) the role of lesson plans for practicing teachers. Analysis involved both qualitative and quantitative methods.

The role of lesson plans for prospective teachers. Survey respondents were asked their perspectives on the role lesson plans serve prospective teachers. Practicing teachers indicated a wide spectrum of perspectives. Sample responses included, "Prepares you to think about all of the things that can occur in a period…makes you start thinking about how to organize the time in class" and, "They help a pre-service teacher realize and get used to every aspect that is involved in teaching on a daily basis. It helps with time management and relating teaching to things that are meaningful in students' lives."

Individual members of the research team, which consisted of the course instructor and three graduate students enrolled in a graduate level course on mathematics education research, examined practicing teachers' responses and developed themes with which to categorize these responses (Strauss & Corbin, 1998). The entire research team then reviewed and discussed each category, category (theme) descriptors were made consistent, and teacher's responses were re-classified to support coding reliability. The final categories arrived at through examination and discussions align, to a degree, with Clark and Peterson (1986) "types" and "functions" of planning. In order to provide a better understanding of the categories (or themes) the research team settled on, it will be beneficial to exemplify what we considered a representation of each (Table 2).

Table 2: Sample Practicing Teachers' Responses in Regards to Corresponding Categories

Category (Theme)	Sample Practicing Teacher Response
Confidence	"The lesson plan can add to their confidence…"
Guide	"[Lesson plans give] you have a general idea of what you want to accomplish and how you are going to do it." "[Lesson plans] help them understand what they have to know."
Instructional Flow	"[Lesson plans] do help a new teacher understand the flow of the lesson..."
Keep on Track-Accountability	"[Lesson plans]…make sure standards are taught."
Keep on Track-Locally	"[Lesson plans] forced me to put things on paper, such as time spent on an activity…" "It helped me to have typed lesson plans early on because included everything I was to cover in the lesson."
Keep on Track-Globally	"[Lesson plans] help a new teacher understand the flow…of the week/month…[and] can help a new teacher…transition from one unit to the next."
Organization	"[Lesson plans] helped [me] to learn what goes where and how to find the resources." "[Lesson plans] help structure their day when feeling overwhelmed."
Reflective Tool	"[Lesson plans] prepare you to think about all of the things that can occur in a period." "Thinking about how to tie lessons to each other as well as the standards looking for connections."
No Productive Purpose	"None."

Prospective teachers also indicated a wide variety of perspectives regarding the role formal lesson plans serve a prospective teacher. Responses ranged from, "They make you thoughtfully decide what to teach and how to teach it so that it would be effective," to "They serve as a guide to the teacher so they can accomplish what they want, and do it in an organized fashion."

The process by which the research team categorized prospective teachers' responses followed the same stages as described above for practicing teachers to support coding reliability. After individually examining and categorizing teachers' responses, the entire research team reviewed and discussed each response and its categorization, re-classifying responses as needed. The percentage each category (i.e., theme) was indicated by prospective and practicing teachers is displayed in Figure 1.

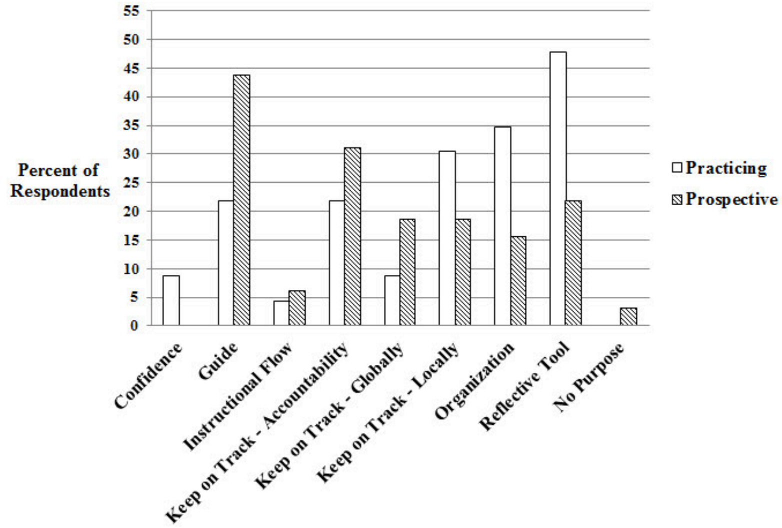

Figure 1: Practicing and Prospective Teachers' Responses to the Role that Formal Lesson Plans Serve Prospective Teachers

There were substantial differences between the percentages of practicing and prospective teachers' responses for "Reflective Tool," "Guide," and "Organization." Practicing teachers indicated formal lesson plans serve prospective teachers as a "Reflective Tool" 26% more and "Organization" 19.2% more than did prospective teachers. Taking into account that our sample of prospective teachers had been limited, in general, to observing K-12 instruction and tutoring individual students as part of their respective prior and current mathematics methods course field experiences, it is not surprising they would identify formal lesson plans as a "Reflective Tool" to a much smaller degree than practicing teachers. Regarding "Organization," practicing teachers used the term in the sense of helping a prospective teacher "prepare" or be "well planned" for a lesson. As observers or class tutors, our sample of prospective teachers would have limited understandings of how and what to prepare for pragmatically. Therefore, it seems reasonable that prospective teachers would indicate "Organization" to a much smaller degree than practicing teachers.

Prospective teachers identified "Guide" as a role formal lesson plans serve prospective teachers (i.e., themselves) 22% more than did practicing teachers. Prospective teachers used the term "Guide" in ways similar to how practicing teachers employed the term; that is, in very general ways. For example prospective teachers' responses included, "[It] will be a guide to help with my instruction"; whereas sample practicing teachers' responses, included, "[A] basic outline." Both groups of teachers used the term "Guide" in the sense described by Kagan and Tippins (1992), where a teacher simply "jot[s] down an outline or list of topics to be covered during the lesson, using a cryptic shorthand" (p. 478). Although our sample of practicing teachers may plan their lessons mentally, without committing much to paper as described by Kagan and Tippins (1992, p. 478) and suggested by their identification of a lessons plan as a "Reflective Tool," prospective teachers (especially at the mathematics methods stage) lack the experiences to think of lessons in terms of students developing understandings and skills, rather than in terms of topics.

The role of lesson plans for practicing teachers. Survey respondents were asked their perspectives on the role lesson plans serve practicing teachers. Practicing teachers indicated a wide range of perspectives regarding the role that formal lesson plans serve a practicing teacher (i.e., themselves). Sample responses included that lesson plans "help better organize the teacher and to keep track of what they taught or modified, and what is working and not working" to "I feel it is burdensome." Prospective teachers also indicated a wide array of perspectives regarding the role they envisioned formal lesson plans serving in their future as a practicing teacher. Responses ranged from, "They will help me improve my teaching by allowing me to look back at what I taught and fix my mistakes. It is a way to better my teaching," to "Formal lesson plans will be a requirement that I will do because it is required but not because it is valuable to me or my time."

Individual members of the research team examined and categorized teachers' responses using those categories (or themes), if possible, described earlier in Table 2. Next, the entire research team reviewed and discussed each response and its categorization, re-classifying responses as needed. These discussions again supported coding reliability. The percentage each category (i.e., theme) was indicated by prospective and practicing teachers is displayed in Figure 2.

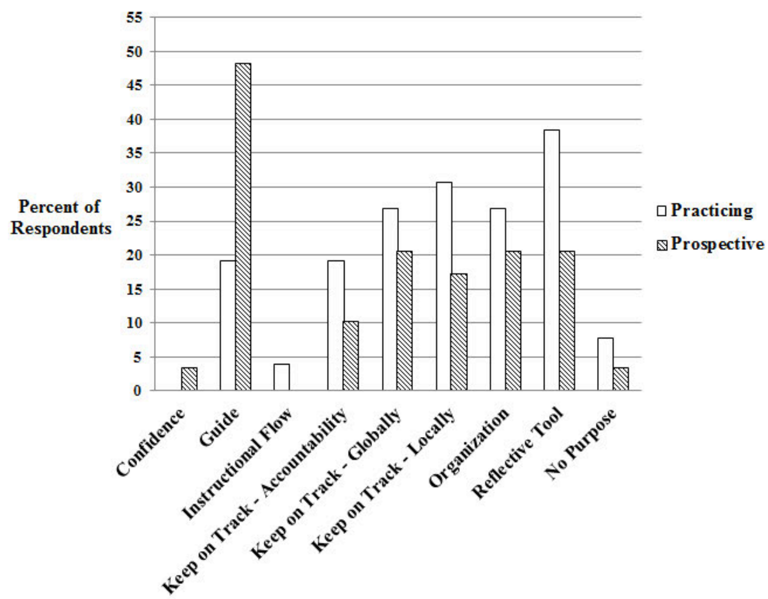

Figure 2: Practicing and Prospective Teachers' Responses to the Role that Formal Lesson Plans Serve Practicing Teachers

There were substantial differences between the percentages of practicing and prospective teachers' responses for "Guide" and "Reflective Tool." Prospective teachers indicated formal lesson plans serve practicing teachers as a "Guide" 29% more than did practicing teachers. As with teachers' responses to the role lesson plans serve prospective teachers discussed in the previous section, both groups of teachers used the term in very general ways, as an outline or list of topics to be covered during the lesson (Kagan & Tippins, 1992). Practicing teachers identified "Reflective Tool" as a role formal lesson plans serve practicing teachers (i.e., themselves) 17.8% more than did prospective teachers. As indicated in the previous section, such differences could be accounted for by prospective teachers' lack of experiences at designing and enacting instruction.

Discussion

In this report we described and compared prospective teachers' (at the mathematics methods stage of their respective licensure programs) perspectives of the role formal lesson plans can and do serve in mathematics teaching and learning with practicing teachers' perspectives. Analyses of teachers' responses to survey questions designed to make teachers' perspectives explicit indicated that our sample of prospective teachers had reasonable perceptions of district and school expectations they will encounter, regarding lesson plan requirements, as early career teachers—at least compared to our practicing teacher sample. In addition, we described how analyses suggest that lesson plan activities for prospective teachers at the mathematics methods stage should: (a) promote and reinforce a focus on student thinking and learning, rather than a focus on covering topics; (b) minimize the potential for interpretations that convey formal lesson plans as something done simply by mandate; and (c) model and engage teachers in authentic planning, enactment, and reflection sessions. Furthermore, analyses suggest that universities and licensure programs should seek consistency in their mathematics methods courses regarding: (a) resources faculty promote to their students (i.e., prospective teachers) and (b) the amount of time prospective teachers should anticipate spending developing and revising their lesson plans once they have entered the field.

Prospective teachers' inclination to view formal lesson plans as a "Guide" aligns with Kagan and Tippins (1992) suggestion that lesson plans be defined as a brief outline of instructional procedures to be used to supplement teachers' guides and other curricular materials and resources (p. 477, 488).Rather than pushing for lesson plans to be viewed as a "Reflective Tool" or a means to keep instruction "On Track," as identified by our sample of practicing teachers, mathematics methods instructors should allow for students (i.e., prospective teachers) to initially view lesson plans an outline or guideline. According to Kagan and Tippins (1992), once enacted, these lesson plans should be revised to reflect the "spontaneous modifications that occurred during class (p. 488)," thus becoming a record of interactions. Such a process has the potential to promote a more natural transformation of prospective teachers' perspectives of the utility of formal lesson plans toward student learning; thus, supporting prospective teachers' development of productive lesson images. It seems reasonable to expect prospective teachers' experiences at developing lesson plans, attempting to enact lesson plans, and reflecting on these attempts to vary somewhat across licensure programs and universities. The number and content of mathematics methods courses prospective teachers take, the amount and context of field experiences, and the faculty assigned to teach mathematics methods courses all have significant impact on these experiences. Results presented here do not address these distinctive experiences. Future research should explore how such potentially disparate experiences impact prospective teachers' expectations of the realities of mathematics teaching.

With a situative lens, a focus on teachers' perspectives regarding formal lesson plans supports the development of models of teachers' understandings and ways of thinking at two distinct points (i.e., contexts) along a teacher-learning trajectory: the mathematics methods stage, prior to student teaching, and the practicing teacher stage. Although each of these "stages" is idiosyncratic, with the practicing teacher stage itself encompassing a continuum of experiences and contexts, such a focus supports the development of productive learning-to-teach situations for prospective teachers. Such situations have the potential to be successfully re-contextualized in prospective teachers' future K-12 classrooms (Peressini et al., 2004, p. 70).

Finally, this study did not include one important set of data points, those of prospective teachers' perspectives during student teaching. As such, future research should explore teachers' perspectives on the role formal lesson plans serve at three distinct stages of a teacher-learning trajectory: prospective teachers enrolled in program-specific mathematics methods courses, prospective teachers during student teaching, and practicing teachers—including those teachers serving as cooperating or mentor teachers during student teaching.

FINDING VOICE: TEACHER AGENCY AND MATHEMATICS LEADERSHIP DEVELOPMENT

Dana C. Cox
Miami University
dana.cox@miamioh.edu

Beatriz S. D'Ambrosio
Miami University
dambrobs@miamioh.edu

In the course of engaging with a Mathematics and Science Partnership (MSP) project, we planned a yearlong Leadership Academy that fit under the "train the trainers" model for professional development. Midway through, teacher leaders rejected a traditional conception of leadership based on expertise, individualism, and the transmission of knowledge. This proved to be a moment of critical mass wherein the project was democratically reinvented around a model of shared leadership where teacher leaders were positioned as ambassadors of a culture of inquiry. We were able to document three catalysts for this shift as well as the conditions that existed such that these catalysts could prove effective at producing change. We present here our findings on what happens when we allow teachers to take power and experience agency in a teacher leadership development program.

Keywords: Teacher Education-Inservice; Teacher Knowledge; Elementary School Education

Introduction

Answering the RFP for a state MSP grant, we planned a yearlong Leadership Academy that fit under the "train the trainers" model for professional development. We proposed to engage nine teacher leaders in an intensive study of their own practice and the Measurement and Data strand of the Common Core State Standards for Mathematics (CCSSO, 2010). At the conclusion of their study, the Teacher Leaders (TL) would plan and enact a two-week-long institute for their colleagues in the district. Our proposal adopted a leadership development stance akin to a game of telephone. As Mathematics Teacher Educators, we understood teacher leadership as an automatic byproduct of providing long-term, high-quality professional development to teachers and giving them a platform to share what they'd gained with others.

We were shocked mid-way through when teachers who had been happy to participate in our curricular activity balked at the thought of identifying as teacher leaders. One wrote, "I am not sure that I really want to become a teacher leader…just because you try something doesn't make you an expert and teachers may be afraid of being perceived as representing themselves in that way."

In this moment, we confronted a living contradiction (Whitehead, 1989) in our assumptions and stance. At all times, we believed that teachers deserved agency and voice and intended to empower them as instructional leaders. However, the game of telephone positioned teachers as message receivers and ourselves as the adjudicators of expertise (a title that the teachers rejected) and denied teachers the very things we had intended the program to develop.

We were able to recognize the contradiction in the midst of our project having previous experience with such work (Cox et al., 2014). Our story focuses on the impact of that dissonance and its role in our process of reconstructing our leadership development program midstream. We will present here our findings on what happens when we allow teachers to take power and agency in a Teacher Leadership Development (TLD) program.

Leadership Development

Current reform initiatives have led the mathematics education community to consider the professional development of teachers as leaders. There are multiple models of leadership development and relatively little research on the effectiveness of these models. As such, we have made decisions to situate our work at the intersection of best practices for professional development of teachers of mathematics and their development as teacher leaders. With current demands for professional development programs that will reach large numbers of teachers, the idea of teachers themselves participating in the professional development of their colleagues is appealing to the mathematics education community. Koellner, Jacobs, and Borko (2011) call for the purposeful preparation of a cadre of leaders who can implement effective high-quality PD. They identify three features that are critical for the effective preparation of these leaders, that coincide with the features of quality PD for teachers: "(1) fostering a professional learning community, (2) developing teachers' mathematical knowledge for teaching, and (3) adapting PD to support local goals and interests" (pg. 116).

Like so many professional development providers Koellner, Jacobs and Borko (2011) frame their PD around three design principles: "fostering active teacher participation in the learning process, using teachers' own classrooms as a powerful context for their learning, and enhancing teacher learning by creating a supportive professional community" (p.117). Engaging teachers in worthwhile mathematical tasks, creating opportunities for reflection on their learning, supporting teachers to critically analyze their practice, analyzing student work, considering a multiplicity of teacher moves as possible for a given teaching episode, are all examples of the types of engagements used by mathematics teacher educators to create a high quality PD experience for teachers that attend to these three principles.

Underlying a large number of leadership development projects we find a predominance of a design principle where teacher leaders experience, as learners, the PD that they will provide to others. In general, a collaborative and problem-based approach that is situated in problems of practice are used. These approaches are identified by Davis, Darling-Hammond, LaPointe, & Meyerson (2005) as features of high quality leadership development programs as they discuss the preparation of highly effective school principals.

This theory about the development of leaders produces leaders who exemplify expertise, who stand apart from other teachers whom they call colleagues, and who take on a separate role as "leader" that may include duties such as facilitating district professional development, coaching, classroom observation and peer review of teaching. In contrast, the shared leadership model suggests that teacher leadership is less about standing apart and more about standing beside. Schlechty (2001) describes shared leadership as, "less like an orchestra, where the conductor is always in charge, and more like a jazz band, where leadership is passed around among the players depending on what the music demands at the moment and who feels most moved by the spirit to express the music," (p. 178).

In our experiences, shared here, we describe the dissonance that is created when a leadership group favors a shared leadership model, but engages in a professional development experience aimed at establishing expertise and elevated status.

Project Background

Our MSP was designed to meet the recommendations of best practices in the development of teacher leaders as described by the federal MSP program. We began with the selection of a small cadre of teacher leaders who would remain classroom instructors throughout and after the project. From there, we developed a three-strand curriculum (content, pedagogy, leadership) to be delivered in a Leadership Academy conducted over the course of a school year. We adhered to three principles when designing the curriculum:

- Teachers should encounter a variety of engaging and interactive activities (c.f. Even, 1999; Nesbit et al., 2001) conducted in a constructivist environment (Khourey-Bowers et al., 2005).

- Learning should be individualized and grounded in professional inquiry and specific classroom practice (Khourey-Bowers et al., 2005).
- A learning relationship should be at the heart of the academy and focus should be placed on establishing and supporting partnerships between individual teachers and university partners.

Our Academy met six times in cycles, each cycle having the same basic structure. We'd start each cycle with a seminar where we met as a whole group including nine teacher leaders, six university partners, and one evaluator. In the weeks following a seminar, we'd spend time on individual reflection and meet in partnerships. The Academy would culminate in a 60-hour Summer Institute for math/science teachers in their district. At this institute, teacher leaders would engage their colleagues in conversations about their mathematical and pedagogical work in the Academy as well as in questions of future practice.

University partners were thoughtfully matched (prior to our first seminar) to teacher leaders based on pedagogical interests or expertise and the personal preferences of faculty members about school or geographical location. Thus, one-on-one relationships were established early in the project and remained consistent throughout, documented as a best practice (Howe & Stubbs, 2003). We designed a series of partnership activities. From mathematical problem solving to curriculum alignment activity, to conducting mini action research projects into student reasoning (Even, 1999), to the activity of facilitating public discussion (Harris and Townsend, 2007; Howe and Stubbs, 2003; and Nesbit et al., 2001), our teacher leaders would be immersed in inquiry and intellectual exploration.

Measurement and data and the eight mathematical practices within the CCSSM (CCSSO, 2010) were selected by district administrators as target areas for district improvement. Thus, those two areas formed the mathematical basis for our seminar curriculum. We had intended there to be a two-way flow of influence between the seminars and the partnership activity. The interplay of ideas between large and small groups, 1.would keep our curriculum and professional learning grounded in real practice; 2. help the group note contextual similarities and differences; and 3. scaffold learning for all participants. We had intended to establish a professional community of practice (Lave & Wenger, 1991) for the teachers. Teacher leaders would gain authority, capable of establishing a line of inquiry (mathematical or pedagogical), pursuing that inquiry alongside partners, and presenting their findings to a larger group. In this way, teacher leaders would be empowered to be reflective practitioners and to engage in a rigorous examination of their own practice and the mathematical culture of their buildings and district.

We intended the summer institute to be a replication of the activity of the Academy on a smaller scale. There would not be enough time for individual teachers to conduct their own inquiries into classroom practice, but they could benefit from the experiences and data collected by the teacher leaders in the Academy. Like the transitive property or a *game of telephone*, we expected the lessons of the Academy would translate to good district-wide professional development, an expectation supported by Wallace et al. (1999) and Miller et al. (1999).

Methodology

Presented here is one slice of a two-year project aimed at uncovering what happens when we allow teachers to take power and agency in a Teacher Leadership Development (TLD) program. Data relevant to this study were taken from transcripts of LA Seminars, partnership meetings, and also teacher blogs and journaling responses. Data spans the first year of our MSP project.

Data were transcribed and analyzed by the researchers. Each researcher conducted multiple readings and interpretations using a hermeneutic process (Kinsella, 2006). Interpretations were substantiated and validated as we contrasted our interpretations and sought common ground, thus enriching our understanding of our teacher and the development of their identity as leaders.

Findings

Data shared here come from three key episodes in our project. We refer to these episodes as *catalysts* because of their potential to leverage change. The three episodes, *Mentoring Peers?, Angela's Rejection of Leadership*, and *Leading Through Practice* stand in concert with other events, however stand apart in the sense that they had a profound impact on the planning and enactment of our Leadership Development Program.

Mentoring Peers?

In our third seminar, we asked TLs to consider leaders within their communities, district, and lives. We invited them to describe their mentors and asked, " To whom do you listen?" Each of us shared anecdotes about those in our lives who had been our teachers and when we felt we had strong relationships with mentors.

In the ensuing conversation, TLs shared their previous experiences with leadership models (such as state mentorship programs) that had indicated to them that assigned partnerships rarely produced chemistry and that the mere act of assignment destroyed a part of the intended relationship.

When TLs imagined leaders or described individuals who had an impact on their own practice, the relationships seemed more serendipitous and unplanned. Leadership happened in the small conversations outside classroom doors (Terry), in the examples witnessed by accident (Marissa), or in the lessons that were co-planned, co-constructed, and co-enacted by two eager colleagues who were not organized into a false or assigned hierarchy (Molly and Shannon).

Furthermore, teachers challenged the notion of models of leadership that implied a mentoring experience with peers. Angela described her experiences as a mentor when she was asked to help her team implement what she had learned in a professional development experience about Professional Learning Communities (PLC).

> "We have weekly PLCs and at my grade level they don't work. I attended the training in Saint Louis about 5 years ago but no one else in my grade level did. It didn't work well when we tried to come back and tell the other teachers what we had experienced. We basically pretend each week to collaborate in a meaningful way but teachers are not invested in the process." (Angela)

Angela's Rejection of Leadership

Reflecting on the conversations about mentoring in her blog post, Angela provided an abrupt catalyst for change. Angela called into question the model of leadership that had been here-to-fore assumed (emphasis hers).

> "I am not sure that I really want to become a teacher leader," wrote Angela, "I think that people choose the "mentors" that they have in their lives and I am very leery of being in a position of "leadership" when it has been forced upon ANY one."

She had begun to question her position within the district and as a "MSP Leader". Angela equated leadership with expertise. She was adamant that she did not want to be perceived as someone with expertise--or more specifically, as someone who *considered herself an expert.* Angela was worried that, by association with the MSP, others would assume that she was an expert, or even worse, assume that she thought that she was an expert.

> "As I watched the presentation given by two teachers today, I thought of all the teachers in the district who have done similar things for much longer than twice and somehow putting people and ideas in front of others is in some way suggesting that they are experts. Could this be why

no one wants to be watched teaching? Just because you try something doesn't make you an expert and teachers may be afraid of being perceived as representing themselves in that way. We are always trying new things and how many of our new ideas really stand the test of time."

In this same time period, in a small group meeting, Angela expressed a new vision of what leadership might entail. She later wrote, "I don't want to be a part of a group of leaders. I want to be a part of a leadership group." To unpack this statement as a unified group and eventually negotiate what leadership would mean to us would mean redefining leadership and constructing a new purpose for our MSP project.

Leading Through Practice

In seminar one, we were still playing the role of the PD providers, wanting to plan and account for every minute of the four hour block of time we had set aside. Our rationale -- teachers' time is valuable, we need to make sure they take away something worthwhile from a Saturday morning spent with us. We decided on an activity that seemed important for the roles of leaders. We decided to collaboratively create a timeline of children's experiences with measurement (the mathematical content focus of our funded PD project) when going through their school district. Following this activity, time was allotted for teacher leaders and university partners to begin to articulate inquiry projects as they considered the teaching of measurement.

The rich conversations that ensued, the difficult questions that were asked, the thoughtfulness with which the group considered the timeline of experiences were beyond our expectations. While staying within the predetermined activity, teachers used their voices to provoke shifts in the agenda. Advocating for herself, one teacher (Ellen) remarked that it made no sense for her to engage in a cycle of inquiry about student reasoning and thinking about measurement and data since she wasn't slated to teach the topics. Another group of teachers (Molly, Shannon, Christine, Anne) noticed within the timeline the activity of measuring one's foot in Kindergarten, 2nd grade, 3rd grade and again at fifth grade. The group, rather than jumping to conclusions, wondered whether that was needless repetition or if there was something useful to gain. They proposed it as a question for the larger group.

It was clear to us that the teachers knew their curriculum well, they had given much thought as to the placement of topics in their own grade level, but had never had the opportunity to hear from their colleagues and create a mental picture of the vertical alignment of a child's experience. We were fortunate to have the voices of a few participants who had experiences in different grade levels -- either because they had taught at different levels and recently been reassigned (Ellen, Molly, Shannon), or because they were intervention specialists (Marissa) and lived in multiple classrooms of different grade levels. This activity generated an opportunity to share their expertise across grade levels and across buildings.

In addition to advocating for an individualized approach to our planned cycles of inquiry, teachers used a collective voice to exert pressure on our planning of future agendas for the Academy. During seminar two, Marissa and Terry offered to share a brief "fifteen-minute" story about an episode that occurred in Terry's classroom in the time between our meetings. Their short story evolved into a two-hour discussion with audience participation. Their peers' interest in their work was a great surprise to them. The many questions and the request for ideas as to how they would recommend modifications for the task for other age groups generated a rich discussion and positioned Marissa and Terry as having pieces of practice that were worth sharing and discussing. What began with excitement about what had transpired in their classrooms turned into a curricular experience for others where we continued to interpret and analyze the event. The result was empowering, not only to them, but also to others who then followed their lead. The remaining seminars were filled with such presentations and examinations of practice.

Discussion

Allowing these catalysts to have an impact on the structure of our MSP required three conditions: 1. a culture of non-evaluative listening; 2. the willingness of all participants to unpack our expectations and experiences with leadership; and 3. a conscious choice on the part of university partners to equalize the power relationships within the partnership. We will establish each of these conditions below along with how they facilitated change.

First, we were predisposed to listen to participants and hear their comments without judgment. We made the conscious choice to step back from our planned curriculum and forward into a space that allowed for multiple funds of knowledge (Moll, 1992). In stepping back, we gave teachers agency to construct alternative paths based on professional motivations and interests.

Each participant in the Academy began to shape a vision of what it would mean to take part in the MSP and what we would be doing during the Academy. The original plans for the Academy quickly disintegrated giving way to a new concept and a new reason for being. We are not naive to think that all of us shared a common vision, but our visions were converging to at least a few common aspects, these being that the teachers would be presenting for a good part of the Academy seminars, and also that issues were arising in the smaller partnerships that were valuable to bring to the large group for their deliberation.

Second, we committed to the work of consciously unpacking our expectations and experiences with leadership. This required the participation of every person involved. It allowed for a shift from thinking about leadership as belonging to or living within the individual toward thinking about the power of the collective. As a group, we have more power than as individuals to change perception, to lift our voices and have our ideas heard by others in our community. This requires that we shift our perception of leaders as those with expertise toward where leaders are willing to seek a deeper understanding and share that inquiry process publically with others.

Marissa and Terry were moved by the spirit that Schlechty (2001) describes and we, the participants, were inspired by their music to ask our own questions, to examine our own lived classroom experiences, and to modulate their melody in our own style and timbre. Their experience, because it was shared, reverberated throughout our group.

Third, as members of this partnership who had the power to determine the curriculum and structure of the project, we, the university partners, consciously chose to equalize the power structure and to give teacher leaders agency in their own professional development. At the outset, we did not view teachers as agents of and for change, but as agents that needed to be changed (Roesken, 2011).

As a result, in the course of the Academy, participant (university partners and teacher leaders) roles in PD began to blur and shift. From recipients or attendees of PD, teacher leader roles would morph to planning and delivering PD themselves. Our roles as university partners morphed from the planners and deliverers of PD to a place where we were active participants reflecting on our personal practices as teachers of teachers as well as grounding our practice in the real lived experiences of local classrooms. In this way, we were able to define expertise to include multiple funds of knowledge and in blurring the lines between the providers and the receivers, the teacher leaders have autonomy in crafting, (re)shaping, and enhancing their practice (Diaz-Maggioli, 2004). In as much as the teacher leaders perpetuating this model in the summer institute, they passed that autonomy on to their colleagues within the district as well.

Conclusion

In the course of this project, teacher leaders found professional voice, not only defining for themselves what needed to be accomplished beyond classroom doors, but also envisioning their role in accomplishing it. This has direct implications for personalizing local and state reform policies and implementing the Common Core State Standards. Ultimately, what we have learned is that it is not a matter of trusting that teachers will be productive with neither assigned direction nor oversight. It is the act of not even questioning them that ensures both agency and voice.

As a group, we also reformulated what it means to lead. What began as a game of telephone morphed into a model of shared leadership. Teacher Leaders became ambassadors of our culture of inquiry, but also remained a part of the community within their buildings and district. This was an integral facet of the experience for the teachers like Angela who did not want to be perceived as held aloft as experts in their field, entirely distinct from their colleagues. By establishing an environment where teachers had agency, we had opportunities to come to know ourselves in relation to one another. We realized that we are not only individuals, but are also framed by our participation within the community. Leadership identities were shaped by our shared experiences, but also by coming to grips with our histories in the district, in our schools, and by coming to understand how we are viewed by others because of how we use and have used our professional voice(s).

Lastly, by challenging conceptions of expertise and including multiple funds of knowledge, Academy learning opportunities were based on the realities of the classroom and occurred naturally in the course of investigating classroom practice in small supportive partnerships. This learning was rigorous, supported discussion of content and pedagogy, and had an immediate effect on classroom activity.

Although English language learners (ELLs) are one of the fastest growing groups of students in the United States, many teacher preparation programs have yet to require preservice teachers (PSTs) to receive training in effective practices for teaching ELLs. We examined a four-week field experience pairing an elementary PST with an ELL. We examined the strategies PSTs used to support ELLs as they implemented cognitively demanding mathematics tasks. Through interviews, observations, and written reflections, we found that the PSTs tried to support students, with varying degrees of success, by allowing for multiple modes of communication, including visual supports, pressing for explaining, and checking for understanding. Implications for teacher preparation are discussed.

Keywords: Equity and Diversity; Elementary School Education; Teacher Education-Preservice

Recent curricular reforms have emphasized the importance of engaging all students in rich mathematical activity (e.g., National Council of Teachers of Mathematics, 2000; National Governors Association Center for Best Practices (NGA Center) and the Council of Chief State School Officers (CCSSO), 2010). Rather than passively participating in mathematics classrooms, children are expected to actively engage in the mathematical practices. The shift toward engagement in the mathematical practices has come with an increase in the linguistic demands of the mathematics classroom. For example, students are expected to justify their solutions and to critique the reasoning of others. To engage in these practices requires extensive communication skills in not only everyday English, but also the academic language of mathematics.

In conjunction with curricular reforms, the demographics of U.S. public schools are undergoing significant changes. English language learners (ELLs) are one of the most rapidly increasing groups of students (Wolf, Herman, & Dietel, 2010). In states such as Texas, California, and Florida where ELLs have made up a sizeable portion of the school population for a number of years, teacher education programs are required to prepare preservice teachers (PSTs) to teach ELLs. Many states with historically low numbers of ELLs are now experiencing dramatic increases in their ELL population. This has driven the need for these states to consider ways to prepare teachers to work with the realities of today's classrooms.

Despite estimates that nearly every teacher in the U.S. now has at least one ELL student, teachers are still underprepared to teach ELLs. In 2008, Ballantyne and colleagues found that only about a third of teachers had received training in strategies to support ELLs. The need for greater attention to strategies for teaching ELLs is further evidenced by the persistent achievement gap among ELLs and their native English-speaking peers (Fry, 2008). There is widespread agreement that teacher education programs must prepare PSTs to work with ELLs. Increasingly, researchers in mathematics education have examined PSTs' work with diverse groups of students (e.g., Aguirre et al., 2012; Foote et al., 2013; Turner et al., 2012; Wager, 2012), though these studies did not focus on ELLs in particular, but on the broader group of students characterized as culturally and linguistically diverse. Because ELLs are simultaneously learning language and mathematics, meeting the needs of ELLs in the mathematics classroom may require teachers to learn skills and knowledge specific to supporting

ELLs. In this study we examined a four-week field experience for PSTs to engage in mathematics with ELLs. The following question guided our work, *What instructional supports do PSTs enact when implementing cognitively demanding mathematics tasks with ELLs*? The answer to this question was important in helping to provide a foundation from which to build further work in determining effective means of preparing PSTs to teach ELLs.

The present study will provide greater insight into PSTs' work with ELLs in particular; a topic few researchers have examined. Downey and Cobbs (2007) and Pappamihiel (2007) conducted empirical studies that offered fieldwork opportunities for PSTs to teach mathematics to ELLs. Downey and Cobbs' study was situated in a university-based teacher preparation program that required elementary PSTs to complete one-on-one tutoring fieldwork with a culturally diverse student. As a result, the PSTs deepened understanding of the relationship between cultural diversity and mathematical learning. In the Pappamihiel study, content-area PSTs who spent 10 hours with an ELL changed their views and recognized that more acceptance and adaptation are essential of multicultural perspectives. Fernandes (2012) observed how middle school mathematics PSTs noticed ELLs' understanding in mathematics through task-based interviews. He found that the PSTs started adopting ELL strategies from an intervention course and became aware of ELLs' needs and challenges. McLeman and colleagus (2012) found that field experiences with ELLs in conjunction with reading ELL literature were valuable in helping PSTs learn instructional strategies for ELLs and helping them understand linguistic complexity such as academic language. These studies suggest that field experiences with ELLs have promise, therefore we wanted to understand how one such experience might help PSTs develop strategies for supporting ELLs in enacting cognitively demanding tasks.

Perspectives

We frame this study in a situated-sociocultural perspective (Moschkovich, 2002) of learning. Because we are interested in the supports the PSTs provided, we focus this study on the learning and experiences of the PSTs. We view learning as discursive activity and that PSTs participate in a community of practice as they draw on a variety of resources in developing sociomathematical norms with their students (Moschkovich, 2002; Yackel & Cobb, 1996). That is to say, we focus on what the PSTs are capable of and the ways they draw on these capabilities to extend their own learning that will, in turn, support ELLs.

In considering the strategies the PSTs might employ, we draw on the work of Chval & Chavez (2011). Chval and Chavez described seven, research-based strategies they characterized as key to supporting ELLs' mathematical proficiency. These strategies included: (1) connecting mathematics with students' prior knowledge, (2) fostering a classroom environment that is rife with language and mathematics, (3) allowing for the use of multiple modes of communication, (4) including visual supports, (5) connecting mathematical representations to language, (6) recording key ideas and representations, and (7) discussing students' writing (Chval & Chavez, 2011). These strategies support students' use and development of academic language (Cummins, 1980) in conjunction with their development of mathematics and served as a framework to guide our examination of the PSTs' work with the ELLs.

Methods

The purpose of this study was to examine the supports elementary PSTs employed when enacting cognitively demanding tasks with ELLs. Four PSTs—Kimberly, Hannah, Morgan, and Fiona—participated in the study, all of whom were juniors in a four-year undergraduate elementary education program at a large research university. Each PST was white and spoke English as her native language. One PST, Kimberly, stated that while not fluent in Spanish she was able to communicate in that language. All four PSTs had limited prior experiences working and learning about ELLs and were eager to put their limited knowledge into practice.

The four ELLs were native Korean speakers. Kyong-Tae, Jin, and Ho-Min had each been in the United States for about six months, Hwa-Young had been in the United States for a little over a year and was also a fluent Japanese speaker. We purposefully (Patton, 2002) selected students enrolled in classes specifically for ELLs but were at or above grade level in mathematics. This allowed the PSTs to gain experience with students who were not yet fully fluent in English without having to also support students who struggled greatly in mathematics.

The field experience centered on the PSTs' weekly, one-on-one meetings with their assigned ELL. The field experience spanned four weeks and each meeting lasted approximately 30 minutes. Prior to each meeting, the PSTs were given a cognitively demanding task that they were to enact with the student. The PSTs were asked to complete a lesson plan detailing their plan for the meeting and given free reign to modify the task and make use of any resources they wished. During the meeting, the PSTs enacted their plan with their ELL.

Data Sources & Analysis

We used qualitative methods in order to gain rich descriptions of the PSTs' interactions with their ELLs (Patton, 2002). Each PST completed a survey before and after the field experience. These surveys contained both open-ended and Likert scale items and provided insights into the PSTs' teaching experiences, prior experiences with ELLs and thoughts about issues of equity and diversity in the classroom and their teacher preparation program. We collected the PSTs' written lesson plans that detailed the learning objectives, their procedures, planned modifications, and assessments. After each meeting, the PSTs crafted a written reflection.

For each weekly meeting, the PSTs would arrive half an hour before their ELL student to participate in a pre-meeting interview. In these video recorded interviews we asked the PSTs to discuss their lesson plans and planned supports in depth. We also observed and video recorded the meetings with the ELLs during which the observer took field notes on moments on which to follow up with the PST. Immediately following each meeting, we conducted a video recorded post interview with the PSTs. The post interview investigated the PSTs' immediate reactions to the meeting, things she would do differently if she could do the meeting again, and thoughts for the subsequent meeting. All video data was fully transcribed.

Using themes previously described from Chval and Chavez (2011) and additional themes that emerged from initial rounds of analysis, we generated a list of codes to use in our subsequent analysis of the interview and meeting data. To establish inter-rater reliability (Patton, 2002), two coders worked to code each data source. From this initial analysis, we further refined our codes and recoded the data. Then, we collapsed the codes into larger categories. For the present study, we examined the most commonly occurring categories that were present in all four of the PSTs' data sets to better understand what strategies the PSTs used and how they supported the ELLs in enacting the tasks.

Findings

Each of the PSTs employed a number of strategies to support their ELLs during the weekly meetings. These supports were both intentional and unintentional. The following sections describe those supports that were most frequently employed across all four PSTs. These supports included using multiple modes of communication, using visual supports, pressing for explanations and meanings, and checking for understanding.

Allowing Multiple Modes of Communication

All four PSTs encouraged their ELL to make use of multiple modes of communication during the weekly meetings. We defined multiple modes of communication as teacher actions that encouraged/allowed students to communicate meaning and thinking through the use of speaking, writing, gesturing, drawing, manipulating, and/or using a first language as they grow in language and mathematical proficiency (Chval & Chavez, 2007).

Across the data set, when PSTs referred to speaking as a mode of communication, they did so in one of two ways: as an alternative to writing (when unable to) or as a means to explain or communicate one's process (i.e. reaching a solution), thinking, or ideas. When Morgan employed this strategy during week two, she asked her student "And this, this time can you try, maybe, telling me what you're doing? Talking about it?" With this question, Morgan was asking her student to verbally explain his process and thinking while problem solving.

During the pre-interview sessions, all four PSTs described drawing as another way to explaining one's thinking in lieu of writing or speaking. The PSTs readily identified that their ELLs may have difficulty communicating in English and discussed the need for other methods of communication to relay their mathematical thinking. There was one occurrence when Hannah verbalized this to her student during a session. During week 2, she said, "Can you draw some over here? Let me help you out (began to draw 24 circles on the paper by 6 x 4)." In this instance, Hannah offered an alternative method of communication to her student; however, she also took over this communication by drawing the representation, removing some challenging aspects of the problem and reducing the cognitive demand.

When PSTs used this strategy with regards to writing, they did so in several ways. During pre-interviews, the PSTs identified that writing would be used to communicate explanations, equations, processes, and thinking and to improve language development. While working with students, three of the four PSTs made use of this strategy to provide an additional method of communicating, specifically for explanation. In all instances, with two exceptions, requesting students to write their explanations did not impact the cognitive demand of the task. In the two instances where the cognitive demand was impacted, the PSTs stated a pathway for solving the problem after stating. For Fiona, in week 2, she stated, "So, how can you write a sentence to explain how each stadium is compared to each other? So are they all the same number? Is one stadium bigger than the other stadium?" For Morgan, in week 2, she stated, "If you need, you can write it out. And you can start subtracting numbers." In both statements, in addition to suggesting the student write their thinking they also suggested a pathway for reaching a solution, which thereby reduced the overall cognitive demand of the task.

Providing Visual Supports

Throughout the four weeks, each of the PSTs included visual supports in her lesson planning and implementation. We defined visual supports as concrete objects, videos, illustrations, or added emphases (bolding, color-coding, etc.) on written tasks. These supports were used in various ways by the PSTs but generally involved the use of manipulatives or images.

Hannah, Fiona, and Kimberly used manipulatives in the meetings with their ELLs. These manipulatives included alien cutouts, connecting cubes, and small vehicles intended for the students to use in their exploration. In some cases the PSTs used the manipulatives to demonstrate a certain solution strategy as in the following excerpt from Fiona's second meeting.

Fiona: It's impossible? Let's work through this, ok, because it's possible. It's kind of confusing, I know. So, if I have [moves one of each 2, 3, and 4 eyed cutouts of creatures into center of table]—how many eyes do I have?

Jin: 9 eyes
Fiona: How many more do I need to get to 24 eyes?
Jin: 15
Fiona: 15. So is there a way I can use the rest of these [cutouts] to make 15 eyes?

Throughout the lesson, it was Fiona, and not her student, that used these manipulatives, leading to an imposed solution strategy. This lowered the cognitive demand on the student by removing the challenging aspect of developing a solution. In the majority of instances involving manipulatives, the PSTs elected to implement them in a similar manner to Fiona.

Finally, all four PSTs used imagery in their lessons. For example, Kimberly drew a picture of a group of coconuts to help define "pile." Although many images were used as linguistic supports, some were utilized as scaffolds for mathematical learning. In the fourth task, in response to Morgan's student's ineffective attempts to find the perimeter of a complicated shape, she drew a simpler example for him to examine. This figure was intended for him to explore his own strategy in an easier setting before returning to the larger figure, applying his exploration, and correcting his mistake. However, as the following excerpt shows, this did not occur.

Morgan: Ok. Alright, so you just added- so can you tell me what you did? What did you add together? All of the what? What did you add all of? You added all- all the sides?
Ho-Min: Yes,
Morgan: Sides, together?
Ho-Min: Yes.
Morgan: Yeah, all sides. Ok. So on [the first problem], when you did this for perimeter, you added all the sides, but you made- you made new sides. With these lines. See, you added these also. But with this shape, see here-

Morgan stopped requiring the student's reflection and instead used her drawing to show him his mistake and how to solve the problem. When the PSTs used such scaffolds, they often relied on them as a crutch themselves, prompting the use of strategies that lowered the cognitive demand.

Most visual supports were implemented to allow students to organize their mathematical thinking. However, there was often conflict between the planned intention and their actual use. When the PSTs relied on the visual supports too heavily, they tended to think for the students and provide a solution method or an idea instead of encouraging the student to use the supports in his or her own way. Thus, the visual supports more often led to lowered cognitive demand, even though the PSTs may not have been intended to do so.

Pressing for Explanation and Meaning.

PST actions that pressed a student to explain his/her solution or meaning of task statement were one of the prevalent strategies that all of the PSTs frequently used throughout the four weeks. The most popular format they used to press students to explain about their solution was questioning and they usually asked students to explain more details and rationale about their work. However, they sometimes took on command forms such as "Explain what you mean by that" or "Tell me about how you figured that one out."

The PSTs most frequently prompted students to justify their solution and/or provide more details about their solution strategies. Hence, the PSTs' press for student explanation usually came after students finished or stopped their solving process. They used various types of questions ranging from general inquiries such as "Why do you think so?" or "How did you find out?" to more specific ones such as "Why did you decide to add these and not something else?" or "Where does the 12 come from?" Other ways the PSTs employed this strategy included asking students about the meaning of the task statement, asking clarifying questions, asking for students' current thinking, asking for students' plans to solve the task, and pressing students to think further.

Each PST favored one particular approach in pressing for meaning. For example, Kimberly's use of this strategy involved asking her student for justification and more details. Hannah used instances of her student's work to ask questions such as "I saw you looked over your piece of paper over here. What were you just thinking?" This type of question evidenced her careful observation of her student's activity and was particularly effective in eliciting her student's explanation of her mathematical thinking.

When the PSTs used this strategy, in general it seemed to provide students an opportunity to speak with longer expressions and to think more deeply about their solutions. However, this was not always the case. Consider the following excerpt.

Kimberly: Ok. (he writes) Ok, how did you find that?
Kyong-Tae: Mm, (long pause) I don't know. I just found.
Kimberly: Yeah, well I saw you do it and I was thinking about how I would have done that in my head, so I saw what you did, first was you found the two- eyed creatures right? And you found five of those and that gives you how many eyes?

In the first line, Kimberly asked her student to explain about his solution pathway. However, the student could not come up with an explanation after a long pause. Kimberly did not provide him with support to find appropriate words or use guiding questions; instead, she provided her interpretation on his work. In this case Kimberly took on much of the thinking for the task.

Most of the instances in which the PSTs pressed for explanation sought to maintain the cognitive demands of the given task. By asking students to explain their thinking after arriving at a solution, the PSTs maintained the initial intent of the tasks. There were several instances, as in Kimberly's excerpt above, in which the PSTs pressed for explanation but did not support students or hold students accountable for responding to the questions. This led to the PSTs suggesting specific solutions, or moving to another task without further discussion.

Checking for Understanding

Each of the PSTs frequently checked for their ELL's understanding during task implementation. Checking for understanding usually occurred after the PSTs presented the student with the task and allowed them time to read it. For example, in week two Kimberly gave Kyong-Tae a task about space-creatures and said, "Ok, well this is the first one that I put together for you. And I want you to read it before anything else. [Very Short Pause] Okay, are there any words on there that you don't know?" Asking if there were any words the ELLs were unfamiliar with was a common strategy to check for understanding among the PSTs.

Once the student identified unfamiliar words, the PSTs similarly responded by defining the words for the child by attempting to connect to the child's prior knowledge. For example, Hwa-Young did not know what *creature* meant and Hannah tried to explain by connecting to other words Hwa-Young might know.

Hwa-Young: Creature.
Hannah: You know what that is.
Hwa-Young: Nope
Hannah: Okay. So, a creature is a broad term that covers multiple animals, so it could be, do you know what a monster is,
Hwa-Young: Yes.

Hannah: Do you know what an alien is
Hwa-Young: Alien?
Hannah: Like, UFO, like Ti-Yoong Ti-Yoong (make a sound of UFO).
Hwa-Young: Oh, oh, I know.
Hannah: Okay, so monsters, aliens, bugs, animals, they are all considered creatures,
Hwa-Young: Oh.
Hannah: So, today, it's going to be the space creatures, so it's going to be aliens. That would say.
Hwa-Young: Okay. Aliens.

In this excerpt, Hannah attempted to define the term *creature* for Hwa-Young by comparing it to other terms such as alien or monster. She also pantomimed a UFO in an attempt to support Hwa-Young in understanding the concept.

This support for language was common among the PSTs when finding the student was unfamiliar with a term after checking for understanding. Checking for understanding was most often used to check for *linguistic* understanding, not mathematical understanding. As such, there were several missed opportunities to support their students' mathematics misconceptions because they assumed the students' misunderstandings stemmed from language, not mathematics.

Discussion & Conclusion

During the four-week field experience, we found that the PSTs employed a number of strategies in attempting to support their ELLs. These strategies were not prompted by the research team, but rather by their own experiences working with the students. Each of the PSTs reported no prior experiences specifically focused on the mathematics education of ELLs in their teacher preparation program. As such, this study provides some insight into the strategies teachers might draw on without further formal preparation.

The PSTs drew on a limited number of strategies in supporting their ELLs. Over time the number of strategies did not increase but the ways in which they used the strategies changed, as did the frequency in which they employed the strategies. For example, Morgan, whose student was hesitant to speak, drew more on multiple modes of communication for her student throughout the weeks. In addition, she broadened her range of acceptable communication from spoken and written to include drawing and gestures throughout the experience. However, Morgan was unable to employ strategies that allowed her to elicit detailed descriptions of Ho-Min's mathematical thinking. His thinking was often shown by a calculation on a page or gesture to a solution, leaving Morgan to assume the process behind these artifacts. Morgan and her peers' experiences suggest that while the PSTs did learn from prior experiences with their ELLs, this experience was not sufficient to fully meet their students' needs.

We also found that the PSTs had difficulty determining whether students' struggles stemmed from linguistic or mathematical misunderstandings. As such, the PSTs typically supported the linguistic aspects of the task without considering possible mathematical misunderstandings. Further, they typically attempted to take on the mathematical thinking in an effort to support the students. This implies that PSTs should be provided with guided experiences that help them begin to support both the mathematics and linguistic needs of their ELLs while also maintaining the cognitive demand of mathematics tasks.

In analyzing the PSTs' final reflections and surveys, we found that completing the field experience left the PSTs with the view that ELLs are capable of any task. This is in contrast to earlier thinking present in their pre-surveys that particular tasks are more appropriate for ELLs. Further, the PSTs were also more aware of their lack of preparation to teach ELLs following the experience. This implies that the field experience allowed the PSTs to better understand the need for further learning in this area. Though further research is needed to understand how teacher preparation programs might better prepare PSTs for the increasing number of ELLs, this study suggests that PSTs' natural inclinations to support ELLs is not sufficient to support both the linguistic and mathematical needs of ELLs. Teacher educators should build on PSTs' natural inclinations and provide further support to help them learn to better accommodate ELLs. PSTs need explicit instruction and experiences enacting both mathematical and linguistic supports with ELLs to help build on ELLs' cultural, mathematical, and linguistic resources as they help them develop linguistic and mathematical proficiency.

The effective use of digital technologies in school settings calls for appropriate professional development opportunities for inservice teachers. How has professional development shifted in support of mathematics teachers integrating these technologies in their teaching? This study explored the impact of digital technologies in mathematics inservice professional development over the past four decades and examined how various technologies, content strands, grade-level bands, teacher outcomes, and student outcomes were being used to design mathematics professional development on integrating technology. This study provides recommendations to mathematics teacher educators as they transform professional development to meet the challenges faced in integrating new and emerging technologies in their instruction.

Keywords: Teacher Education-Inservice; Teacher Knowledge; Technology

What it means to teach mathematics has changed over the past four decades. The development and availability of mathematics educational technology is a key factor in how the mathematics classroom looks different than 10, 20, 30, or 40 years ago. Professional development provides opportunities for inservice teachers to experience new methods of both teaching and learning mathematics with technology and to collaborate with colleagues about pedagogical strategies they use when implementing these technologies.

Guskey (2000) defined professional development as, "those processes and activities designed to enhance the professional knowledge, skills, and attitudes of educators so that they might, in turn, improve the learning of students" (p. 16), which is the definition used in this study. Professional development can be short-term or ongoing and may take many forms such as workshops, sessions during teacher inservice training, institutes and sessions in the summer, individual classroom interactions, lesson study, professional learning community models, online sessions, or video-series. When professional development is effective, teachers may take new ideas back to their classrooms and implement new strategies and use technology in different and/or new ways.

To address ongoing challenges in mathematics educational professional development, we sought to examine extant literature in the field, analyze trends therein, and facilitate present and future improvements to both teaching and learning. The research questions that guided the present study were: (1) What types of technology and content areas have been the focus of professional development research over time? (2) What types of technology and grade bands have been the focus of professional development research over time? (3) What types of outcomes are used to measure effectiveness of mathematics educational technology professional development; have they changed over time, and how do they vary across grade levels?

Conceptual Framework

Two frameworks were applied to the analysis of a database of mathematics educational technology studies identified by a systematic review: Technological Pedagogical Content Knowledge (TPACK) and Comprehensive Framework of Teacher Knowledge (CFTK). The TPACK framework (Mishra & Koehler, 2006; Niess, 2005) describes the unique set of knowledge needed to effectively integrate technology into the classroom in conjunction with appropriate pedagogical content knowledge (as in Ball, Thames, & Phelps, 2008; Shulman, 1986). TPACK extends beyond knowledge of how to use the technology proficiently and encompasses a deeper and transformed knowledge for understanding how subject matter, pedagogy, and technology are integrated to provide richer learning experiences. Subsets of the TPACK framework include Technological Knowledge (TK), Pedagogical Knowledge (PK), Content Knowledge (CK), Technological Pedagogical Knowledge (TPK), Technological Content Knowledge (TCK), and Pedagogical Content Knowledge (PCK). TCK was used to support research question one while TK was used to support research question two.

CFTK (Ronau & Rakes, 2011) describes an all-encompassing structure for studying and understanding the complex nature of knowledge required for teaching as a highly complex interaction of multiple aspects of teacher knowledge across three dimensions: Subject Matter and Pedagogy (Field dimension), Discernment and Orientation (Mode dimension), and Individual and Environment (Context dimension). These teacher knowledge outcomes and an extension of these outcomes to student outcomes were applied in the analysis of research question three.

Method

The present study is part of a larger, more comprehensive study that analyzed mathematics educational technology papers published between 1968 and 2009. For the literature search of the comprehensive study, we followed a systematic process based on the techniques outlined by Cooper, Hedges, and Valentine (2009) and Lipsey and Wilson (2001); for example, we defined constructs before coding, defined keywords before conducting the literature search, defined a coding process, trained coders, and cross-checked results. To obtain the overall sample, a wide array of databases were searched using terms to restrict the sample, based on two criteria for inclusion: (1) The paper must examine a technology-based intervention (e.g., technology, calculators, computers), and (2) The paper must be focused on the learning of a mathematics concept or procedure (e.g., mathematics, algebra, geometry, visualization, representation). We searched the following database platforms (and the databases within those platforms): EBSCOWeb (ERIC, Academic Search Premier, PsycINFO, Primary Search Plus, Middle Search Plus, Education Administration Abstracts), JSTOR (restricted to the disciplines of Education, Mathematics, Psychology, and Statistics), OVID, ProQuest (Research Library, Dissertations & Theses, Career & Technical Education), and H. W. Wilson Web (Education Full Text). We also examined the bibliographies of the papers we identified through this search in order to identify potentially relevant papers that were missed in our searches. For further details about this process, see Ronau, Rakes, Bush, Driskell, Niess, & Pugalee (2014). Altogether, our literature search of the comprehensive study resulted in 1,210 papers.

In order to code the 1,210 papers, we created a Microsoft Access database with over 200 variables, with each coder paired with each of the other coders (i.e., six coders = 15 coding teams) so that each paper was both coded and cross-checked. The new coding format created a counter-balanced design with all six coders, providing a way to maximize construct validity and inter-rater reliability of the coding. Our overall inter-rater agreement was 91.5% (Number of Agreements out of the Total Number of Possible Agreements), from which we concluded that the inter-rater reliability for the comprehensive study was high. Upon completion of coding for the comprehensive study, a filter was applied to the database to extract the papers that were coded as teacher development. Next, each paper was read to make certain it aligned with Guskey's (2000) definition of professional development and to verify that the professional development was non-credit bearing (not part of a degree program) and took place after initial teacher certification (preservice education was not included). Using this criterion, 21 of the 1,210 papers were retained for the present study.

Results

None of the papers in our subsample of 21 professional development papers were found in the 1960's or 1970's. For each subsequent decade, the ratio of professional development papers per total number of technology papers in mathematics education was 2/48 in the 1980's (4.14%), 3/320 in the 1990's (.94%), and 16/818 in the 2000's (1.96%). To answer research question one, the number of times each technology type was used as compared to content strand per decade was analyzed (see Table 1).

Table 1: Technology Type Compared to Content Strand by Decade

Decade and Content Strand	Calculator	Computer Software	Interactive Whiteboards	Internet	Probeware & Motion Detectors	Other Technology
Total for 1980	**2**	**0**	**0**	**0**	**0**	**1**
Number	1	-	-	-	-	-
Not Specified	1	-	-	-	-	1
Total for 1990	**0**	**3**	**0**	**1**	**1**	**0**
Algebra	-	3	-	1	1	-
Total for 2000	**7**	**13**	**1**	**3**	**5**	**2**
Algebra	2	3	-	-	2	-
Algebra, Geometry, Data Analysis	1	-	-	-	1	-
Algebra, Probability & Statistics	1	2	-	1	-	-
Algebra, Geometry, Calculus	-	1	-	-	-	-
Number	-	-	-	-	-	1
Probability & Statistics	-	2	-	-	-	-
Not Specified	3	5	1	2	2	1
Technology Type Total	**9**	**16**	**1**	**4**	**6**	**3**

Note. $N = 21$ papers. The number of papers per decade is not always the sum of the row because some papers addressed more than one technology type and/or content strand area. The Other Technology consisted of computer programming, personal digital assistants, and video clips.

The content strands addressed within the professional development papers in the 1980's were limited to number content or was not specified, with calculators used in both studies. Algebra content was the only content strand addressed in the 1990's, and the technology for all three papers was computer software, specifically graphing software in two papers and presentation software in the third paper. In the 2000s, there were six different reported content strands. The algebra content strand was addressed most often (six of 13 papers). In the three papers that solely included algebra content, one paper discussed using graphing software and two papers discussed using spreadsheet software. One of the two papers coded as algebra and probability and statistics content discussed using geometry software while the other paper used spreadsheet software. The paper coded as algebra, geometry, and calculus content discussed using geometry software. The computer software used in the two probability and statistics content papers was statistics software. Professional development papers written in the 2000's displayed the greatest variety in technology use, with a growing use of the Internet. Many papers (n = 6; 37.5%) however, did not specify the content addressed in the professional development.

To answer research question two, the technology used and teacher participants' grade-level band reported in the papers was analyzed (see Table 2). Across all three decades, two papers included K-5 teachers; one included a combination of K-5, 6-9, and 10-12 teachers; seven included 6-8 teachers only; five included both 6-8 and 9-12 teachers; five included 9-12 teachers only; and one did not specify the grade-level band.

Table 2: Technology Type Compared to Grade Band by Decade

Decade and Grade Band	Calculator	Computer Software	Interactive Whiteboards	Internet	Probeware & Motion Detectors	Other Technology
Total for 1980	**2**	**0**	**0**	**0**	**0**	**1**
K-5	1	-	-	-	-	-
K-5, 6-8, 9-12	1	-	-	-	-	1
Total for 1990	**0**	**3**	**0**	**1**	**1**	**0**
Unspecified Grade	-	1	-	-	-	-
6-8, 9-12	-	1	-	1	1	-
9-12	-	1	-	-	-	-
Total for 2000	**7**	**13**	**1**	**3**	**5**	**2**
K-5	-	-	1	-	-	-
6-8	2	7	-	2	1	2
6-8, 9-12	2	4	-	-	2	-
9-12	3	2	-	1	2	-
Technology Type Total	**9**	**16**	**1**	**4**	**6**	**3**

Note. N = 21 papers. The number of papers per decade is not always the sum of the row because some papers addressed more than one technology type and/or grade band. The Other Technology consisted of computer programming, personal digital assistants, and video clips.

The most common technology used was computer software, followed by graphing calculators, probeware, Internet, other technology, and interactive whiteboards. Technology for grades 6-8 and 9-12 teachers varied more widely compared to grades K-5. Professional development for grades K-5 in the papers was limited to either calculators or interactive whiteboards. Professional development for grades 6-8 or 9-12 teachers, on the other hand, included calculators, computer software, the Internet, probeware and motion detectors, and other technology, including computer programming, personal digital assistants, and video clips.

To answer research question three, we analyzed outcomes (student and teacher) being addressed in the professional development papers, organized by grade band and decade (see Table 3). While the total number of professional development studies was21, the total count of outcomes as shown in Table 3 was51, as many studies had more than one outcome. Teacher outcomes were measured more often than student outcomes. Teacher orientation was the most common outcome measured, which was measured in 15 studies (2, 3, and 10 from the 1980's, 1990's, and 2000's respectively), followed by 10 studies (0, 2, and 8 across the three decades) which measured teacher knowledge of pedagogy, and 9 studies (1, 2, and 6 across the three decades) that measured teacher knowledge of subject matter.

Table 3: Outcomes Compared to Grade Band by Decade

Decade and Grade Band	Student Achievement	Student Orientation	Student Behavior	Teacher Knowledge Subject Matter	Teacher Knowledge Pedagogy	Teacher Knowledge Discernment	Teacher Knowledge Orientation	Teacher Knowledge Individual	Teacher Knowledge Environment	Teacher Orientation
Total for 1980	**1**	**0**	**0**	**1**	**0**	**0**	**0**	**0**	**0**	**2**
K-5	1	-	-	-	-	-	-	-	-	1
K-5, 6-8, 9-12	-	-	-	1	-	-	-	-	-	1
Total for 1990	**1**	**1**	**0**	**2**	**2**	**0**	**1**	**0**	**2**	**3**
Unspecified Grade	-	-	-	1	1	-	1	-	1	1
6-8, 9-12	-	-	-	1	1	-	-	-	1	1
9-12	1	1	-	-	-	-	-	-	-	1
Total for 2000	**1**	**2**	**1**	**6**	**8**	**3**	**1**	**2**	**1**	**10**
K-5	1	-	-	1	1	1	-	-	1	1
6-8	-	-	-	2	3	1	-	-	-	4
6-8, 9-12	-	1	-	-	1	1	-	1	-	2
9-12	-	1	1	3	3	-	1	1	-	3
Outcome Total	**3**	**3**	**1**	**9**	**10**	**3**	**2**	**2**	**3**	**15**

Note. N = 21 papers. The number of papers per decade is not always the sum of the row because some papers addressed more than one outcome and/or grade band.

Teacher knowledge of Discernment or Individual Context in relation to technology was not addressed in professional development research until the 2000's.Both of these knowledge constructs tend to be student-centered and are not as easily observed or measured. Since only three studies included K-5 teachers, there were no trends to describe how the outcomes varied across grade level. With regard to student-related outcomes, student achievement (n = 3 out of 21 papers, 14%) and student orientation (n = 3 out of 21 papers, 14%) were studied most often. As the numbers for student outcomes were so small, there were not clear patterns or trends through the decades.

Discussion

This study found very little published research on professional development focused on technology in teaching and learning mathematics, which was surprising given the long-standing calls from professional organizations such as the National Council of Teachers of Mathematics (1989, 2000) for mathematics teachers to incorporate new technologies in the classroom. Only 21 studies of 1,210 total studies in our sample of mathematics educational technology papers addressed professional development. Limited published professional development research impairs the ability to advance the field of mathematics educational technology professional development. Shavelson and Towne (2002) stated, "Scientific studies do not contribute to a larger body of knowledge until they are widely disseminated and subjected to professional scrutiny by peers" (p. 22). Therefore, a reasonable direction for researchers who conduct mathematics educational technology professional development is to measure the outcomes of their efforts and publish the results of their work. Also, researchers might focus on conducting and publishing further research on professional development with K-5 teachers as only three of the 21 studies included these teachers. Since many students are currently required or will be required to take a computer-based state standardized assessment, some K-5 classrooms now have some sort of 1:1 structure in place (e.g., laptop carts, chromebooks, iPads). Research is needed on how to use these resources to enhance mathematics learning effectively, and professional development research is needed to help providers improve teachers' ability to integrate technology in their classrooms effectively. Furthermore, how technology can enhance learning is content-specific, and too few of the published studies reported the content area that was addressed during the professional development. Future studies need to explicitly identify the content area being studied so that teachers and researchers can build on the work appropriately. Also, the effectiveness of the professional development with any explicit measure related to student knowledge, orientation, or behavior was often omitted. These results align with Sztajn's (2011) concerns, who argued that norms and standards for reporting on professional development studies are needed. Still, consistent with Supovitz and Turner (2000), such standards must include the specific content area(s), grade band(s), and technology type addressed in the professional development. The constructs of the study must be clearly and explicitly stated, threats to validity discussed, and research methodologies clearly articulated as purported in the scientific principles 3 and 4 (Shavelson & Towne, 2002).

Future Directions

The historical data we analyzed in mathematics educational technology literature denotes a clear need for future research measuring the effectiveness of professional development focused on technology in teaching and learning mathematics. Professional development efficacy can be measured by using observational tools, teacher knowledge assessments, and teacher surveys to assess teachers' change in practice. These changes should evaluate instructional activities and practices, classroom discourse, the fidelity in which the curriculum is implemented, teacher knowledge, and teachers' beliefs. Another reasonable direction is to measure changes in student learning/achievement, although we recognize the challenge in collecting such data and the necessity of an extensive length of professional development to gather the data to evaluate this change.

Research analyzing technology-focused professional development in mathematics education could make great strides in mitigating the field's traditional challenges by pointing to specific research-supported methods for improving future professional development.

SOCIAL CAPITOL, SOCIAL NETWORKS, AND LESSON STUDY: SUSTAINING MATHEMATICS LESSON STUDY PRACTICES

Bridget K. Druken
San Diego State University
druken@rohan.sdsu.edu

I investigate the sustainability of lesson study as mathematics teachers who participated in a 3-year professional development partnership engage in a district scale-up lesson study professional experience. This study answers three questions: (1) what are K-12 teachers' conceptions of sustaining mathematics lesson study, (2) what practices of lesson study continued after the grant as reported by participants, and (3) what are supportive and constraining factors in continuing lesson study after external funding ends when there is both reported desire from teachers as well as some district support? Survey and interview data are analyzed using grounded theory and social network analysis for patterns in and structure to activities. Findings suggest rich conceptions of lesson study, the continuation of particular lesson study practices, and the importance of integration and linkage as factors that supported or hindered lesson study.

Keywords: Policy Matters; Teacher Education-Inservice (Professional Development); Instructional Activities and Practices

Introduction

Though lesson study shows promise as a vehicle for professional development (Stigler & Hiebert, 1999; Yoshida, 2012) and has been described as a sustainable form of professional development, little research exists on what would help to support teachers in continuing lesson study past the life of a grant. Why do some mathematics teachers of lesson study continue while others do not, particularly when teachers express interest and have some district support? Therefore, to develop a better understanding of sustainability with respect to lesson study, the field is in need of a deeper understanding of how to support the continuation of lesson study.

The purpose of this report is to examine teachers' conceptions and practices of lesson study, and factors that supported and constrained teachers' ability to continue to engage in lesson study. The setting for this study is unique in that participants surveyed and interviewed come from one network of U.S. mathematics teachers of grades 3 through Algebra 1 (students 8–14 years old) who participated in a three-year professional development partnership that used lesson study and who expressed interest in and had some district support for continuing lesson study after grant funding ended. In this report, I answer the following research questions:(1) what are K-12 teachers' conceptions of sustaining mathematics lesson study, (2) what practices of lesson study continued after the grant as reported by participants, and (3) what are supportive and constraining factors in continuing lesson study after external funding ends when there is both reported desire from teachers as well as some district support?

Background

Lesson study has been described as a vehicle for developing and sustaining professional learning communities whose goal is to improve instruction (Yoshida, 2012). Research on mathematics lesson demonstrates the potential to enhance teachers' knowledge about mathematics content (Alston, Pedrick, Morris, & Basu, 2011; Fernandez, 2005; Lewis, Perry, & Hurd, 2009; Meyer & Wilkerson, 2011; Robinson & Leikin, 2012; Yoshida 2012), change teaching practice (Hart & Carriere, 2011; Murata, Bofferding, Pothen, Taylor & Wischnia, 2012; Olson, White & Sparrow, 2011), nurture professional communities of teachers (Lieberman, 2009; Lewis, Perry & Hurd, 2009; Saito, Khong,

& Tsukui, 2012), and help teachers understand how to teach mathematics aligned to reform efforts (Lee & Ling, 2013; Lewis & Takahashi, 2013; Takahashi, Lewis & Perry, 2013). These foci – enhancing mathematical content knowledge, changing teachers' practice, nurturing professional communities, and helping teachers teach in ways aligned to reform efforts – are ways in which lesson study has contributed to the improvement of learning and teaching mathematics, benefiting both teachers and students. Yet researchers call for more research in lesson study (Fernandez, 2005; Lewis, Perry & Murata, 2006). Future research pathways would be impossible without teachers continuing to implement and engage in lesson study.

Although many educators involved in lesson study research and work describe it as a sustainable form of professional development, little research exists that seeks to understand aspects of engaging in lesson study that ensure its continued success (cf. Gero, 2015; Lewis & Perry, 2014; Saito, Khong & Tsukui, 2012). Factors that hinder lesson study include engaging in collaboration, observating a lesson, the potential critique of a teacher's lesson and teaching, and the collision with the existing culture in districts with the tenants of lesson study (Gero, 2015). Saito, Khong & Tsukui (2012) found that faith in meetings, support and enthusiasm from principals and other senior teachers, and the desire to retain respect from external parties supported teachers in continuing to organize PLCs with lesson study. This study furthers research on these factors to add to a deeper research base on continuing lesson study.

Theoretical Perspective

The theoretical model of lesson study used in this study is based on Japanese Lesson Study (Fernandez, 2005), which consists of teachers collaboratively (a) *investigating* content and setting goals for the research lesson, both content-focused and broader site based goals; (b) *planning* a research lesson that seeks to inquire into how students learn a particular topic or sets of topics; (c) *teaching* and *observing* a live research lesson while gathering student data; and (d) finally, *debriefing* on specifics of what was learned from the lesson as well as more generally about teaching and learning mathematics (Lewis, Perry, & Hurd, 2009). Optionally, teachers may modify their research lesson and opt to teach it a second time, collecting data on student thinking and debriefing again.

Yet to understand how mathematics teachers engage in professional activities like lesson study requires understanding how they are situated within their site and district. Consequently, this study is shaped by the perspective that teaching is embedded within institutional settings like classrooms, school sites, and districts with teachers members of communities (Cobb, McClain, Lamberg, & Dean, 2003). Additionally, understanding how mathematics teachers engage in professional activities requires understanding the nature of collaborative activities that the teachers engage in both in informally arranged groups and formally arranged groups by the school or district.

Supporting the work of teachers in complex institutional settings also requires attention to different types of resources supporting teacher work (Gamoran et. al, 2003). These include *material resources* (physical objects or information like curriculum or activities), *human resources* (qualities of people that can be changed like training someone to be a math coach), and *social resources* (attributes of relationships, roles or modes of communication like connections to math coaches and other people). I examine social resources for this study, which is one way to understand conditions for sustainability (Gamoran et al., 2003).

Sustainability is defined as maintaining generative practice, or to keep growing and learning (Franke et al., 2001; Gamoran et al., 2003). I use Gamoran and colleagues' (2003) framework for conditions for sustainability to inform data collection and analyses, which was derived from an economic growth model (Woolcock, 1998). To understand how social capitol is embedded in groups among complex institutional settings, Gamoran and colleagues describe the four conditions for sustainability as integration, linkage, organizational integrity, and synergy. *Integration* refers to shared values, mutual expectations, levels of trust, and norms. *Linkage* refers to the social relations that attract resources. *Organizational integrity* refers to the effectiveness of the organization in distributing human and material resources. Finally, *synergy* refers to whether the efforts of the teacher community is aligned with the efforts of the school and district. For this study, I restrict my analyses to integration and linkage.

To conceptualize and document social resources like integration and linkage, I use the perspective of social network wherein the goal is to understand how individual actors are embedded in social structures by examining relationships among actors in addition to attributes of individuals (Carolan, 2014; Daly, 2010).

Methods

Participants

A subgroup of six primary teachers, one principal, and one district administrator is selected from a larger data set to examine in detail due to the high concentration of former grant teachers at one site and reported support by their principal.

Context

The study began with a survey administered on the last day of the former partnership where approximately 75% of 80 teachers described an interest in continuing lesson study. Thus, all participants in the current study recently participated in this three-year university partnership that sought to improve teachers' instruction on algebraic thinking. The three-year partnership was structured to include a 40-hour week long summer institute for teachers focused on mathematics content, student thinking, and pedagogy; four rounds of lesson study during each school year that utilized Japanese Lesson Study; and mathematics coaching. For the lesson study component, eighteen groups of 3-6 teachers each engaged in two lesson study cycles per year and observed two lesson study cycles per year. Groups were arranged to consist of cross-site and cross-district participants but are now reconstituted groups as relations among teachers shifted with the conclusion of the grant.

Data Collection and Analysis

Data were collected after external support from the university ended, or the first school year, 2013-2014, following the conclusion of the grant. A survey and interview instrument were constructed and administered. The survey results were collected in October 2013 and asked for lesson study cycles and components completed, resources needed for lesson study, support given by principal and fellow teachers, and any additional comments. From these surveys, I gathered participants to engage in individual, semi-structured interviews and asked about who teachers worked with, the nature of their activities, their work with lesson study, resources that support their work, resources that support lesson study, and changes they would make if they were to do another cycle of lesson study. I used a snowball technique for collecting interviews, which involved interviewing those participants named by interviewees (Carolan, 2014; Cobb, McClain, Lamberg & Dean, 2003; Cobb, Zhao & Dean, 2009). I then interviewed principals of participants to learn more about the work of teachers at their school site.

Data were analyzed using grounded theory methods (Corbin & Strauss, 1990), with the methods of open coding and constant comparison methods used to derive themes in the data. Analyses were also informed by Woolcock's (1998) conditions of sustainability on integration and linkage and analyzed using social network analysis (Carolan, 2014). Specifically, egocentric networks were inferred from interview data and analyzed for qualities such as like density and structure.

Results

I first characterize participants' conceptions of what it means to engage in lesson study using data from interviews. I then report on which aspects of lesson study have continued as reported by participants on surveys and during interviews. Finally, I describe factors that support and hinder teachers' potential to continue engaging in lesson study using analyses on survey and interview data.

Teacher' Conceptions of Lesson Study

To address the first research question on teachers' conceptions of lesson study, I analyzed teacher responses to characterizations of lesson study. Their responses targeted three general areas to varying degrees – (a) the structure or protocol associated to engaging in lesson study, (2) the nature of the activities that comprise lesson study, and (3) the focus or purpose of the described structure or nature of activities.

Structure. Most all participants described the structure of lesson study to include planning, teaching, observing the research lesson, collecting data during the research lesson, and then debriefing on the research lesson. Five participants included the goal setting stage in addition to the planning. There was a strong emphasis on student thinking for all participants, and often for all components. Ways in which the conceptions of structure varied included whether or not the participant described a second enactment of teaching, observing, and debriefing on the research lesson.

Nature of Activities. As mentioned before, most all teachers described activities as including goal setting, planning the research lesson with attention to questioning techniques and student misconceptions and responses, observing the lesson while one teacher taught the lesson and others collected student data, and finally debriefing the lesson where the teacher of the lesson would comment first on what went well and changes they would make to improve the lesson based on their goals.

Focus. Two teachers described the focus or purpose of lesson study as a way to unpack the teaching practices (e.g. understanding assessment, standards, or student thinking). Primary teacher Gillian[1] reported that, "It's more of a philosophy of how to approach what you're doing professionally in the classroom. It's the philosophy of teaching, if you will." Four participants described it as an activity to better understand student thinking. Jimmy described lesson study as useful for observing student thinking and "to be the one standing back and listening. And, you know, asking the kids to explain themselves." One participant described the focus of lesson study as improving mathematics content knowledge as well as pedagogy. One participant described lesson study as a way to create polished lessons, in addition to a way of understanding student thinking.

In summary, teachers conceptions of lesson study aligned with how experts in the lesson study literature describe lesson study. This finding is significant with the strong presence and focus of student thinking in conversations.

Practices of Lesson Study That Have Continued

Most teachers (N=4) reported engaging in one cycle of lesson study in the beginning of their school year (See Table 1). During this cycle of lesson study, teachers reported to engage in goal setting, planning the research lesson, observing the research lesson and collecting student data while one teacher taught, debriefing on the research lesson with final reflections. This effort was initiated and supported by the district. It differed from former grant efforts in that there was less time for planning (three hours on average versus six hours), shorter time between the planning and enactment of the lesson, and only one cycle of lesson study planned for the year. Those study participants that participated in this effort served as facilitators of lesson study for teachers who had never participated in lesson study.

Though not all participants completed a round of lesson study, participants reported continuing practices of lesson study. Most significantly, all participants reported engaging in the practice of analyzing student thinking. For example, one primary school teacher participant named Bertha

Table 1: Practices of Lesson Study Reported to Continue

Table 1

Practices of Lesson Study Reported To Continue

	Teachers						Administrators	
Practice	Bertha	Carmen	Jimmy	Ben	Mia	Gillian	Ron	Kono
Complete Cycle of Lesson Study		X	X	X	X			X
Unofficial Cycle			X		X	X		
Goal Setting	X	X	X	X	X	X		X
Planning	X	X	X		X	X		
Observing							X	X
Analyze Student Thinking	X	X	X	X	X	X	X	X
Debriefing	X	X	X		X	X	X	

highlighted one of her conversations with her colleague by recalling her notes from a lesson study:

> The kids were just kind of brain storming what is multiplication. And one of the notes that the kids came up with that Carmen and I had on our notes was, multiplication is, you know, a bunch of things. But one of the things that stood out was when you multiply, the value always increases. I think that's what it was. And then somebody was having a conversation, where they said, 'Yeah.' And I always though that, too. But then they're talking about, 'Yeah, but what about when it's multiplied by 1 or 0, it does not increase.'

Mia, a primary school teacher participant, described an example of the role that student thinking played in her work with colleagues. She gave the example on how to modify a multiplication task with fractions to a multiplication task with whole numbers to help scaffold a problem for a student. "If they're not understanding that it is 3/4 of one half, and it is getting smaller. Why? Because they're not understanding that it's groups of. Oh, so that's multiplication. So we have to come back with, if you have 3 times 5, bring it to an array." These two examples highlight the role that student thinking played in the reported activities of participants.

None of the teacher participants reported observing their colleagues' lessons, though administrators like the principal and Teacher on Special Assignment (TOSA) reported observing teachers. Most teacher participants reported planning and debriefing together, oftentimes during formally arranged time like Professional Learning Community (PLC) time and during informally arranged times like lunch or sporadically throughout the day. Gillian reported meeting at a coffee shop after school to debrief with fellow teachers on what students did during the lesson.

> And it was not, umm, full scale lesson study, I would say. It was more, why don't we try this lesson. And then after the lesson we collaborated. We met at Starbucks to talk about, you know, how everything went. And, and share information on what the kids were doing. So I would, I would call it kind of like a mini lesson study. Cause we didn't, umm, we didn't do the observing of each person doing the lesson. So it was more that we, we had common planning and debriefing. Which I think is a good option when you can't get release time.

Factors that Supported and Hindered Lesson Study

Two factors that have the potential to support the continuing of lesson study as a form of professional development include integration and linkage. Integration levels, referring to the shared values, mutual expectations, levels of trust, and norms, were reported low for those teachers who described it as unlikely to engage in lesson study with their colleagues. For instance, both Bertha and Carmen reported shared values of what constitutes effective teaching and mutual expectations in terms of wanting professional collaboration time to focus on students' mathematical thinking and designing lessons that elicit their thinking. Yet their two colleagues in their formally arranged grade-level PLC did not share similar goals (See Figure 1). Bertha exemplifies this theme in the following data:

> And then on my team, not everybody values math the same way, not that I love math. I really don't really like math, but it intrigues me because I don't know about it and I want to know more about it. But I think that. I'll say some teachers on our team don't really see the value behind the lesson study because they haven't been through it. They don't know what it is, and they just know that it's, oh it sounds like a lot of work. It sounds like a lot of time. It sounds like a lot of planning. I don't have time for that. I'm just going to do the lesson that I've always done.

Thus, Bertha reported a difference in the way her PLC members valued mathematics. Carmen, her fellow PLC member also interviewed for this study, explains that one reason for the difference in values on mathematics could be explained by the engagement in union policy by the other two members.

> There's a clause in there that says in PLC that it has to be teacher driven, and teacher, like, decided upon. So, if two of the four people on the grade level want to do lesson study, but two other people, or one other person who doesn't want to do lesson study, we can't make those people do lesson study.

These data exemplify instances of low levels of integration and signify a challenge of continuing lesson study with these colleagues.

To exemplify linkage, I present egocentric network data in Figure 1. In this figure, vertices indicate participants and undirected edges between a pair of vertices indicate a reported significant professional relationship in the form of work related activities between the two participants. For instance, the single edge *BC* between vertices *B* and *C* represent activities such as engaging in planning conversations, focusing on students' mathematical thinking, and also conversations about mathematics content.

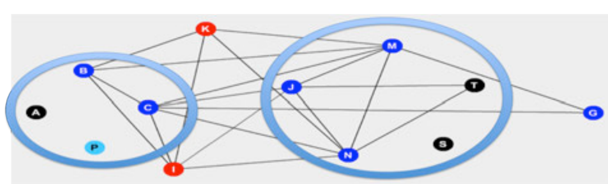

Figure 1. Network of participants derived from interview data. Formally arranged grade level groups are indicated by a circle. Red vertices represent administrators, blue vertices represent participants interviewed for the current study, light blue vertices represent former grant teachers not interviewed for the study, and black vertices represent teachers not interviewed for the study and not a former grant teacher. The circles each represent a formally arranged grade-level PLC group.

The *size* of each participant's neighborhood, or the other vertices that each vertex is connected to, range from two to six. In other words, teachers reported to exchange information while engaging in activities ranging with two to six specific colleagues, with an average number of connections to others out of participants for this study being 4.75 (vertices A, P, T, and S were not participants for this study and consequently are not calculated for size). The *density*, or the extent to which a participant's connections are connected to one another, is found by dividing the number of ties for one participant by the total number of potential ties to other participants. For instance, the total number of ties in this network can be calculated as 8!/2!(8-2)! This number, which counts the total number of ways 8 participants could be connected to one another exactly once, is 28, making the density of this network a total of 19/28, or approximately 67%. The *distance*, or the mean of the shortest path lengths among all connected pairs of participants, for each participant ranges from 1.14 (for instance, vertex C is connected to all but one by 1 path, and connected to K by a path of length 2, making the mean of 1+1+1+1+1+1+2 equal to 1.14) to 1.5 (for instance, vertex G is connected to all but two by a path of two, and connected to M and C by a path of length one, making the mean of 1+1+2+2+2+2+2 equal to 1.5).

These three measures – size, density, and distance – suggest a way to quantify the measure of linkage. These moderate levels of linkage suggest some potential in continuing lesson study.

Conclusion

Little research exists on issues surrounding the sustainability of lesson study for mathematics teachers. This research examined practices of teacher communities that get reorganized when relationships among teachers shift; in particular, when relationships and funding between teachers and university faculty who engaged in mathematics lesson studies end.

Findings from this study highlight teachers' conceptions of what it means to engage in lesson study and reported practices of lesson study that continued past the end of the grant. Findings also highlight the need to attend to social relations among teachers and administrators in one district to better understand issues of sustainability. It was evident that many teachers from the former grant wanted to continue to engage in lesson study. Additionally, districts attempted to put in place supports for these teachers to continue to engage in lesson study. Integration and linkage were shown to be important factors in continuing lesson study; low levels of integration or linkage suggested low potential for continuing while high levels of integration or linkage suggested high potential for continuing.

We traced the impact of a sequence of five research-based professional development sessions on a cohort of mathematics teachers' Mathematical Knowledge for Teaching. The sessions focused on task design and implementation as a means of building teachers' pedagogical capacity. Findings revealed that teachers' pedagogical knowledge pertaining to student thinking, if not their practice, was influenced by the activities they experienced.

Introduction

Improving the quality of Mathematical Knowledge for Teaching (MKT) among teachers has been at the forefront of mathematics education reform agenda for quite some time. Within the last three decades, advances have taken place in defining accurately and precisely what mathematical knowledge for teaching might mean and the various dimensions that are embedded in the construct (Ball, Thames, & Phelps, 2008), developing theoretical models that inform how teacher learning of this body of knowledge might be best grounded (Borko, 2004), and identifying features of effective professional development programs that facilitate such learning for teachers (Garet, Porter, Desimone, Birman, & Yoon, 2001).

Less clear however, are the specific domains of MKT of teachers that are enhanced by their participation in research-based professional development programs or empirical data that support changes as the result of their newly acquired knowledge (Sztajn, 2011). In this paper, we will describe the findings of an exploratory research project in which we traced the impact of a series of professional development sessions focused on task design and implementation on teachers' pedagogical content knowledge.

Background

Building on two of Shulman's categories of teacher knowledge (content knowledge and pedagogical knowledge), Ball, Thames, and Phelps (2008) defined six domains of Mathematical Knowledge for Teaching (MKT), which they defined as the "mathematical knowledge needed to carry out the work of teaching mathematics" (p. 395). While Ball and colleagues distinguished between content knowledge (Subject Matter Knowledge) and pedagogical knowledge (Pedagogical Content Knowledge) as Shulman did, they more specifically designated three domains within each. Within Subject Matter Knowledge, they defined Common Content Knowledge (CCK), Specialized Content Knowledge (SCK), and Horizon Content Knowledge (HCK). The CCK domain includes knowledge of mathematics that students must learn, while the SCK domain includes knowledge of mathematics that is specific to the classroom environment (e.g. analyze student errors). HCK is described as "a view of the larger mathematical landscape that teaching requires" (Hill & Ball, 2009, p. 70).

Within Pedagogical Content Knowledge, Ball and colleagues (2008) distinguished between Knowledge of Content and Students (KCS), Knowledge of Content and Teaching (KCT), and Knowledge of Content and Curriculum (KCC). In the KCS domain, teachers must understand how students may come to understand a concept, while in the KCT domain teachers must make instructional decisions that best facilitate student learning. KCC requires that teachers know the standards and curriculum not only for a specific mathematics course, but also across grade levels, courses, and subject areas.

Guskey (2003) argued that the primary goal of professional development (PD) programs is to "bring about change in the classroom practices of teachers" (Guskey, 2002, p. 381). In order to achieve this goal, researchers have identified characteristics of teacher PD programs that tend to advance teacher learning and shifts in practice. Among them include opportunities for sustained interactions over time, collective participation by participants, and activities that are content-focused and grounded in the teachers' everyday practice (Garet et al., 2001).

The use of mathematics tasks in PD sessions has been found to influence teachers' teaching knowledge and their instructional practices. Through activities with mathematics tasks, teachers can increase their capacity to implement the curriculum with coherence across multiple grade levels (Ferrini-Mundy, Burrill, & Schmidt, 2007), improve their problem solving skills (Guberman & Leikin, 2013), and increase their content knowledge of mathematics (Silver, Clark, Ghousseini, Charalambous, & Sealy, 2007).Boston (2013) found that teachers' capacity to identify cognitive demands of tasks, as well as identify the opportunities particular tasks provided to elicit student thinking, was increased by participation in a PD program that focused on the cognitive demand of tasks. What remains to be learned about the use of tasks in PD programs is how the modification of traditional tasks and their implementation in the classroom builds teachers' pedagogical capacity.

Drawing from this body of scholarly ideas, a series of 5 PD sessions for mathematics teachers who were expected to serve as instructional leaders in their respective schools was designed. Prominently, relying on Cognitively Guided Instruction (Carpenter, Fennema, & Franke, 1996), we intended to engage teachers in building their own knowledge of mathematics through investigating children's understanding of mathematics content and using that knowledge to guide instruction. In implementing the sessions, we capitalized on five practices recognized to be pivotal to orchestrate productive mathematics discussions (Smith & Stein, 2011). The primary focus of our work was facilitating knowledge development of the teachers through the creation and implementation of rich mathematical tasks, and then considering different solution strategies (appropriate or inappropriate) students might use on the tasks as a way of anticipating what may need to be addressed in instruction.

The Five Practices for Orchestrating Productive Mathematics Discussions includes the planning and selecting of appropriate tasks for classroom activity (Smith & Stein, 2011) since this venue has been recognized to have an impact on the mathematics students engage with (or not) in the classroom (Hiebert & Wearne, 1993). Coupled with the understanding that textbooks and teacher resources are often limited in their offering of tasks that require reasoning of children (Thompson, Senk, & Johnson, 2012), two of the PD sessions were focused on task selection and design in motivating mathematical thinking among school learners. Brown and Walter's (1983) problem posing framework served as the primary guide for organizing teachers' activities during these sessions. The teachers were first presented with a task, and asked to list its attributes. They then removed constraints from the task and rephrased it in a way that could substantially extend learners' thinking. The goal was for the modified tasks to reflect characteristics of rich mathematical questions: tasks that provide multiple entry points, multiple solution strategies, and opportunities for students and teachers to develop deeper mathematical connections (Stein, Grover, & Henningsen, 1996). Our research goal was to determine the knowledge teachers may have gained from such experiences based on their classroom implementation.

Methodology

Setting & Participants

The participants in this study consisted of 12 mathematics teachers expected to serve as instructional leaders in their own respective schools using a coaching model. The participants' prior mathematics teaching experience ranged from 1-31 years, with a mean of 13.9 years. All teachers engaged in a year-long PD program that was grounded in principles of Cognitively Guided Instruction (Carpenter et al., 1996). This approach was used to help teachers develop capacity towards shifting classrooms from teacher-centered orientation to a more student-centered environment. The PD sessions that served as the basis for our exploratory inquiry consisted of series of five sessions that lasted approximately 3 hours each (a total of 15 hours). The fourth session in this series used the problem posing framework of Brown and Walter (1983) to assist teachers in learning about how to modify mathematics tasks to advance students' mathematical thinking. The teachers were asked to revise a task that already existed in their practice or curriculum materials, implement it the classroom, and then reflect on what they learned from doing so.

Data Collection

Upon the creation of the new tasks to be implemented in the classrooms, the teachers were asked to identify mathematical and pedagogical goals they intended to meet using the new tasks. They were also asked to collect samples of student work (correct or incorrect) and to comment on what they may have gained from the experience. The participants submitted their reflections/assessments electronically. For this particular study, the teachers' original and revised tasks, as well as their responses to four questions served as the primary sources for data analysis: (1) How is your revised task different from the original task? Describe the process you used to adapt the task from the original task.; (2) What additional questions did (or would) you or your teacher ask to elicit, scaffold, or extend student thinking?; (3) What insights into your students' mathematical thinking and understanding did the revised task provide that the original task may not have been able to provide?; and (4) How would you adapt or implement this task differently in the future and why?

Data Analyses

The original and revised tasks submitted by the teachers were coded using Stein, Smith, Henningsen, and Silver's (2000) categories of level and kind of cognitive demands and/or thinking processes in mathematics classrooms: high-doing mathematics; high-use of procedures with connections to concepts, meaning, and/or understanding; low-use of procedures without connections to concepts, meaning, and/or understanding; and low-memorization. An example of our coding procedure is show below, illustrating the original and the revised tasks submitted by one teacher:

> *Original*: There are twenty-one shells. The shells are evenly divided among three students. How many shells will each student get? A. 6 B. 7 C. 8 D. 9

> *Revised*: Susie has 24 gumballs. She wants to share them with some friends. She wants to make sure each friend gets the same amount of gumballs. How many different ways can you come up with for Susie to share her gumballs with friends? Show all the ways below.

The original task was coded as low-use of procedures without connections to concepts, meaning, and/or understanding, and the revised task was coded as high-use of procedures with connections to concepts, meaning, and/or understanding. Once the codes were generated, further analysis determined strategies the teachers used to revise the original task.

The teachers' responses to the four reflection questions were coded first using the Mathematical Knowledge for Teaching framework (Ball et al., 2008). The unit of analysis was one sentence. If two or more sentences referred to the same idea, the two sentences were coded once, and if a sentence contained two or more phrases that fell into different codes or ideas, the phrases were coded separately. Three independent researchers coded the teachers' responses. Coding results were compared among the researchers; if disagreement occurred, discussions were held to reach agreement on the coding for each response. Disagreement on the coding occurred and was remedied five times.

The following excerpt from one of the teachers' responses to question (1) serves as an example of our coding procedure:

> The original task was simple math. There was not a lot of higher level thinking involved. The students had worked on this type of equivalent fractions for some time. It came pretty easy to them. We needed to create a task that would challenge the students and take the math they learned and apply it to a real life situation.

The first two sentences were coded once as Specialized Content Knowledge, the second two sentences were coded once as Knowledge of Content and Students. The last sentence was coded twice as Knowledge of Content and Teaching (one code for "challenge the students" and one code for "take the math they learned and apply it to a real life situation").

The codes that were identified for the responses to each question were tallied corresponding to each participant. Since question (2) primarily elicited responses in the MKT domain of Knowledge of Content and Teaching, the question-type framework as described by Boaler and Brodie (1994) served as a second level of analysis for the teachers' responses for question (2). The responses to question (4) also overwhelmingly fell into the KCT domain, so they were coded on a second level as either related to content or pedagogy.

Results

Original and Revised Tasks

The coding results for cognitive demand level and type of the original and revised tasks are summarized in Table 1.

Table 1: Cognitive demand level and type for original and revised tasks (n=12)

	High-doing mathematics	High-procedures with connections	Low-procedures without connections	Low-memorization
Original task	0	0	10	1
Revised task	0	7	5	0

Note that all of the original tasks were low level cognitive demand (one of the tasks did not provide enough information to be coded), and that 7 of the 12 revised tasks increased the cognitive demand level to high. The teachers who increased the cognitive demand from low to high did so by removing constraints in the task to allow for multiple solutions, asking students to provide explanations and visual representations, introducing new mathematics content, and requiring students to give non-examples.

Five teachers submitted original and revised tasks that were both categorized as low-procedures without connections. While they did not increase the cognitive demand of the task, these teachers added a context or changed the language of the original problem to revise their task. For example, one teacher's original task, a worksheet of 3-digit subtraction problems, was revised to include three 3-digit subtraction problems placed in a context, one of which included "There are 300 dogwood trees currently in the park. Park workers cut down 115 dogwood trees today. How many dogwood trees are left in the park?".

Reflection on the Task and its Implementation

Six teachers responded to all four questions, and six teachers responded to questions (1) and (2) only. Table 2 is a summary of the MKT codes, specifically in the domains of SCK, KCT, KCS, and KCC that were generated from the teachers' responses to each question, illustrating the knowledge domains that may have been influenced as a result of the activity.

Table 2: Domains of teacher knowledge elicited by four reflection questions

	Specialized Content Knowledge (SCK)	Knowledge of Content and Teaching (KCT)	Knowledge of Content and Students (KCS)	Knowledge of Content and Curriculum (KCC)	Total
Question (1)	11	32	7	4	54
Question (2)	0	57	0	0	57
Question (3)	11	14	5	0	30
Question (4)	0	13	0	0	13
Total	22	116	12	4	154

For question (1), in which the teachers were asked to compare their original and revised tasks, 11 of the 12 teachers made statements that compared the tasks in terms of the different levels or types of thinking the tasks may (or may not) elicit from children. For example, teachers stated that the revised task was more open-ended than the original and would thus require students to use their own thinking to solve the problem, or that the new task would require a higher level of thinking than the original task. Six teachers explicitly stated that they removed a constraint or piece of information in the original task to make the revised task more open-ended. Five teachers responded that the revised task would require different mathematics content than the original task.

For question (2), the teachers stated questions they asked or would ask to elicit, scaffold, or extend student thinking. In total, the teachers stated 57 questions, all coded as KCT. 66.7% of the questions asked students to go deeper than the revised task, categorized in the Boaler and Brodie (2004) question-type framework as extending thinking (n=18); probing, getting students to explain their thinking (n=14); exploring mathematical meanings (n=4); and linking and applying (n=2). Questions posed by the teachers in these categories included "How might your ideas change if Susie includes herself in the equal sharing?" (extending thinking) or "Do you think those represent the same solution or different solutions?" (exploring mathematical meanings). The remaining 33.3% of the questions geared students toward finding the answer to the posed task. These questions fell into the categories of orienting and focusing (n=12), gathering information (n=5), inserting terminology (n=1) and establishing context (n=1). Questions posed by the teachers in these categories included

“What is this problem asking you to do?” (orienting and focusing) and “How did you know this was a subtraction problem?” (gathering information).

For question (3), the 6 teachers who implemented the task reported what they learned about student thinking as a result of implementing the revised task. All six of the teachers claimed to gain insight into their students’ thinking, their misconceptions, and where they may struggle with the content. For example, one teacher stated “it was apparent which students recognized that there was a missing addend and that an efficient way to find the missing addend is to subtract.” Four of the six teachers reported improving their SCK as a result of implementing the task, stating that the task provided opportunities for students to use multiple representations and solution strategies, and for the teacher to interpret student work and student thinking on their particular topic.

For question (4), the 6 teachers who implemented the task reflected on how they would implement the task differently in the future. The teachers’ responses to this question generated 13 KCT codes, 5 related to content, and 8 related to pedagogy. For an example of a pedagogy modification, one teacher stated that she might “have different students solving the same problem but with different numbers of gumballs. This may allow for more connectedness about numbers being divided up in different ways.” Pedagogically, a different teacher thought he would “give students more time to work through the task, provide manipulatives, encourage collaboration and communication, and strategically have students share ideas.”

Summary

All of the teachers revised a traditional task to be implemented in the classroom with the intent to offer more open-ended venues for student explorations. Of the 6 teachers who revised a low cognitive demand task to a high cognitive demand task, 3 implemented the revised task in their respective classrooms. The reflections of these 3 teachers revealed that their revised task gave them more insight into student thinking, the reflection comments offered by these individuals indicated that they felt the new questions allowed their students to learn more mathematics and make deeper connections as a result. These 3 individuals also reported that they felt more efficacious in guiding the classroom discussions in a manner that deviated from additional tell, show, and correct pattern.

In their reflections, all 12 teachers reported ways in which their Mathematical Knowledge for Teaching may have been influenced by their participation in the PD sessions and related activities. Overwhelmingly, the knowledge the teachers claimed to gain could be described as pedagogical, as 75.3% (n=116) of the teachers’ responses described ways their Knowledge of Content and Teaching was impacted as a result of the activity. The teachers claimed to have gained knowledge of strategies they could utilize to modify a traditional task to create a task that is more open-ended, allows for multiple solution strategies, and requires students to use their own thinking. The 6 teachers who implemented the task cited ways the new task enabled them to better facilitate mathematical discussions that focused on student thinking and making mathematical connections.

Six teachers who implemented their revised task in the classroom cited ways that this process influenced their Knowledge of Content and Students. One articulated her heightened awareness of student thinking as she stated “it was clear that the students did understand the relationship between multiplication and division. This is something that the original task would not have brought out about student understanding.” Two of the teachers noted that students had difficulty finding new strategies that were different than the strategies their teacher had taught them. This leads us to conclude that the enactment of the revised task in the classroom, not just its revision as an isolated activity, is critical in impacting teachers’ pedagogical knowledge.

Conclusion

The main goal of our exploratory research was to determine what aspects of teachers' Mathematical Knowledge for Teaching could be influenced by PD sessions guided by the principles of CGI and with a focus on designing rich, open-ended tasks. The reports of these participants indicated that their pedagogical knowledge pertaining to their understanding of student thinking, if not their practice, was influenced by what they had learned as a result of implementing the revised tasks in their respective classrooms. Additionally, the teachers who revised the traditional task from low to high cognitive demand claimed their students learned different mathematics content and made richer connections as a result of engaging with the revised task.

The National Council of Teachers of Mathematics (2000) and the Common Core State Standards for Mathematics (National Governors Association Center for Best Practices and Council of Chief State School Officers, 2010) require that children have the opportunity to engage with mathematics in ways that foster understanding, sense making, and reasoning. No longer is the traditional drill and practice classroom environment acceptable to meet these standards. But teachers must be given learning opportunities that may foster the pedagogical and content knowledge necessary to facilitate such a classroom environment. The PD program and sessions that informed this research gave teachers valuable tools and increased pedagogical capacity necessary to take their current classroom materials and adapt and implement them in ways that may help children reason more deeply about mathematics to meet these new standards.

RISKY BUSINESS: MATHEMATICS TEACHERS USING CREATIVE INSUBORDINATION

Rochelle Gutiérrez
University of Illinois at Urbana Champaign
rg1@illinois.edu

In an era of high stakes education and the persistence of racism, classism, and the politics of language, there is evidence that teachers may benefit from learning creative insubordination, the bending of rules in order to advocate for all students to learn mathematics. Even so, we know little about how or why teachers decide to take risks when stakes are high. This study examines the experiences of secondary mathematics teachers moving from pre-service to full-time teaching and their choices of whether or not to use creative insubordination in their working contexts. It highlights three rationales that justify taking risks: 1) Changing the minds/practices of others, 2) Projecting an identity one can be proud of, and 3) Modeling advocacy behavior for bystanders. Implications for future research and teacher education are offered.

Keywords: Equity and Diversity; Teacher Knowledge; Teacher Beliefs, Teacher Education-Preservice

In an era of high stakes education and the persistence of racism, classism, and the politics of language in society, professional development for mathematics teachers has started to expand beyond developing forms of pedagogical content knowledge that draws upon deep understanding of mathematics (Ma, 1999; Hill, et al., 2005) and students' funds of knowledge (Civil, 2002; Turner et al., 2012; Aguire & Zavala, 2013) to include an understanding of privilege, oppression, and political knowledge (Willey & Drake, 2013; Bartell, 2011; Gutiérrez, 2012, 2013a, b, in press). The importance of political knowledge and creative insubordination is underscored by the derailing of successful mathematics departments such as Railside High and Union High (Boaler & Staples, 2008; Nasir et al., 2014; Gutiérrez, 2013a; Gutiérrez & Morales, 2002). That is, these mathematics departments had long histories of success with low income Latin@ students who normally do not have positive experiences or reach advanced levels of mathematics while in high school. Yet, the politics of their districts kept teachers from either maintaining the practices they had developed or eventually pushed teachers out who were beaten down by a climate of alienation and deprofessionalism. The stories of these departments indicate that professional development around issues of pedagogical content knowledge and commitment of teachers to all learners may not be enough to sustain success in student learning when larger political debates about public schooling and testing arise. As such, some teacher education programs have adopted a broader lens of equity, including actively providing opportunities for teachers to not only deconstruct the deficit narratives that circulate in schools, but also speak back to those narratives through direct actions. One of those forms of speaking back through actions is creative insubordination, the bending of rules in order to advocate for one's students.

Creative Insubordination in Mathematics Teaching

Our project began using the term "creative insubordination," having heard it first in activist circles in the late 1970s and early 1980s and growing up. Later, we learned that in their ethnographic work conducted in Chicago Public Schools, Crowson & Morris (1985) found "widespread rules and directives violations among site-level administrators" that they labeled partly as "creative insubordination" because these violations were benign and counter-bureaucratic and substituted the

Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

principal's values for those implicit in organizational policies directed from above. Summarizing various studies, Roche noted:

> Creative insubordination has two main purposes: to ensure that the system directives do not impinge unfairly or inappropriately on teachers and students and to avoid the possible backlash that outright defiance might incur. Crowson (1989) and Haynes and Licata (1995) argue that when principals use creative insubordination, the counterbureacratic behaviors they adopt often contain a moral element designed to balance antieducational consequences." (Roche, 1999, 257-8)

Our work (Gutiérrez et al., 2013; Gutiérrez & Gregson, 2013) builds upon and extends the early research on creative insubordination by connecting it with teachers and showing its usefulness within the context of secondary mathematics. With respect to mathematics teaching, creative insubordination includes the following acts: creating a counter-narrative to the achievement gap; questioning the forms of mathematics presented in school; highlighting the humanity and uncertainty of mathematics; positioning students as authors of mathematics; challenging deficit narratives of students of color; renaming a course to reflect the fact that it only covers Western, Euclidian geometry, not all geometries that are practiced in the world; refusing to go along with procedures at a workshop that asked teachers to publicly endorse the Common Core State Standards in mathematics; and convincing a co-teacher that the mathematics being taught needed to reflect a more rigorous curriculum so that students understood why procedures worked.

Elsewhere, I have described the concept of *political conocimiento for teaching mathematics* (Gutiérrez, 2012; 2013a) that connects mathematical content knowledge, pedagogical knowledge, knowledge with communities, and political knowledge within a community of like-minded individuals. This concept of political conocimiento for teaching mathematics takes into consideration the history of mathematics teaching and learning in a global society. In addition, I have articulated both a model of teacher education that supports the development of political knowledge, as well as taxonomy of strategies for creative insubordination and language practices that keep teachers from being dismissed in political situations (Gutiérrez, 2014). This study seeks to extend that knowledge by asking: What compels mathematics teachers to take risks in their working contexts to advocate for historically marginalized students and their learning when the stakes are high and the benefits of taking risks are not always clear?

Risk taking is normally viewed as a process whereby an individual weighs the costs and benefits of an action and finds the benefits outweigh the costs. The majority of the research conducted on individuals taking risks falls within the area of risky sexual behaviors, risky business ventures, or risk taking in health. Within education, there is some evidence that both support from leadership (Blase, 2000) and strong internal feelings of power and a sense of responsibility (Anderson & Galinsky, 2006) can encourage individuals to take more risks. Moreover, some researchers have suggested that risk taking may be a sign of great teachers (Brazeau, 2005). However, outside of the context of innovating their pedagogy to align with reform-based mathematics, we know very little about the risk taking behaviors of mathematics teachers in a context of political situations.

All of the participants in this study acknowledged the utility of creative insubordination (which requires taking risks) in their student teaching and current working contexts as well as expressed a desire to use it. However, not all of them did so. As such, this study sought to understand the phenomenon of risk taking for mathematics teachers, how they interpreted risks and how they decided whether or not to take a stand in a political situation that involved power dynamics.

Methodology

This study is part of an ongoing, NSF-funded, longitudinal investigation of secondary mathematics teachers who have been provided with an alternative teacher education program that foregrounded issues of equity, social justice, creative and rigorous mathematics, and political knowledge. Over a period of 2 years each, four cohorts of teachers (n=19) participated in a 3-hour bi-weekly seminar, a partnership with a Chicago public high school teacher, several professional development sessions including an annual summer boot camp and conference attendances, a weekly after-school mathematics club, and biweekly individual mentoring sessions. These structural aspects of the teacher education model supported several conceptual goals, including broadening and challenging knowledge, noticing multiple interpretations, developing an advocacy stance, and rehearsing creative insubordination (Gutiérrez, 2013a). Rather than offering a set of "effective practices" to follow (Bartolomé, 1994), one guiding principle of this teacher education model was "The Mirror Test:" the ability to look oneself in the mirror everyday and say, "I'm doing what I said I was going to do when I entered the profession of mathematics teaching." This notion of a mirror test underscored the idea that being a great teacher for students who have historically been marginalized (e.g., students who are black, Latin@, low income, English learners, and/or immigrants) means carrying out one's practice in a way that is consistent with one's philosophy and ethical stance.

The data for this study draw from transcripts of 78 seminars and selected mentoring sessions between 2009 and 2014. Transcripts were coded (Lincoln & Guba, 1985) to identify major themes around the interpretation and use of creative insubordination, including types of political situations in which teachers find themselves (e.g., battles over curriculum, use of technology, high stakes testing), types of power dynamics involved (e.g., teacher-student, teacher-parent, student-student, teacher-administrator), underlying issues (stereotypes of who is good at math, deficit views of students of color, watering down of curriculum, lack of low income students in advanced courses or higher tracks), types of creative insubordination strategies teachers used under different contexts (e.g., seek allies, challenge with evidence, turn a rational issue into a moral one). Because I was interested in the phenomenon of risk taking as it related to creative insubordination, I began analyzing data by first sorting participants into categories of high and low use of creative insubordination. I identified five teachers who consistently reported using creative insubordination in their student teaching and full-time teaching, three who never or very rarely used creative insubordination in either context, and the rest who sometimes used creative insubordination. Focusing on the high users of creative insubordination, I turned to their rationales for why they did so in any given situation as well as the questions they raised to others who chose not to use creative insubordination. I was most interested in how these high users justified taking a stand on an issue when others in the group might not have done so if faced with the same scenario. From there, I looked at the infrequent users of creative insubordination to understand better what challenges they saw that seemed insurmountable or that did not seem worth risking their status or relationship with colleagues, students, or administration. I used member checking (Lincoln & Guba, 1985) to corroborate findings. I report on the trends here.

Findings

A review of the transcripts indicated that teachers are often willing to take risks when they immediately benefit from doing so. For example, one teacher in our work group didn't pause before defending herself when a student of hers was leaving her classroom and made a disparaging remark about whites. However, teachers are more cautious when they are risking their status or credibility with colleagues to defend students or a more rigorous form of mathematics.

Changing the Minds of Others

Teachers in this study tended to be most likely to take risks in their teaching practices with students and their interactions with others when they were optimistic that their actions would have some positive effect on the decision-making process of others. In particular, when faced with political situations, ones involving power dynamics, they tended to gauge whether they could diplomatically disagree with someone and get an alternate view onto the table in a way that would not be dismissed. They considered the language they would use and the contexts in which they found themselves so that they were the most effective.

One high user of creative insubordination was faced with a cooperating teacher who had low expectations for students in an Algebra II course populated by older students. He laid out an argument to the cooperating teacher about the internal consistency of mathematics presented in class (how students needed to relate polynomials with integers) because he knew that an argument based solely on what students were capable of was not going to sway him.

> He showed me the curriculum, topics that I needed to cover. There's like synthetic division, but there's nothing else like…And, synthetic division is basically just an algorithm. And, I'm gonna have to just say, "it works." …I don't want to argue against him because I don't want to step on his toes. I need to be wise in what I say so I don't sever that relationship with my coop. I just think about it in my head, then I try to think about how he would take it. From there, I try to compromise my own words. I was going to say this, but I try to come up with a better wording. I try not to say things right away. I know that the issue is very fresh and he may think I am acting on impulse. I try to make sure there is no room for my statement to be misconstrued as I'm just challenging him. Trying to be wise in my timing on things. I know he feels pretty strongly about things and I try to my best of ability, weighing the risk and reward. Is this going to be something worth fighting over? A lot of times, I'll say, "Let's wait a bit and see what happens."

This teacher, a high user, talks about his process for weighing the risks, and sometimes choosing not to fight a particular battle. In doing so, he suggests that he considers who he is talking with and in what context to help him choose his words wisely so that he is not simply dismissed. In this sense, his focus is partly on changing the mind of the person he faces.

Projecting an Identity that One Can be Proud Of

Another rationale that arose for the high users that did not arise for the infrequent or rare users of creative insubordination was the idea that risk taking is worthwhile even if one is not sure of the outcome for others because it reflects who you are. When faced with a school meeting where the school administrator suggested that the achievement gap was due to black student culture, one teacher clarifies that she was not sure how the administrator would respond to her correcting his statement publicly, but she was also projecting a particular identity that she could be proud of. She says,

> Okay, this is also the boss and I've only taught one year. I don't know how I'm going to say what I want to say without sounding like, "I straight out disagree with you" in a respectful way…[I was] Just feeling, a lot of fear…But, I have to let myself be known to people. This is the kind of person I am, this is what I believe in, and if you wanted to talk about something that is important with respect to race, I'm the kind of person to talk to.

Her rationale highlights the fact that she was willing to risk her status with a superior not just because she thought she might change his mind about black students and the achievement gap, but because her actions were signaling something about herself to others. She counsels others in the teacher group who are less inclined to take risks when they feel uncomfortable to consider how they'll feel about themselves in the end.

> It's about changing our behaviors not our ideals. It's about not saying you stand for problem solving and then not doing any problem solving in your class.

This same teacher faced a black student who when she passed him over to help another student when he raised his hand, publicly called her out as racist. She felt the need to stand up to him in a similar way, less because she thought he was serious about thinking she was racist or because she was trying to change his mind, but because she wanted other students in the class to know what kind of a teacher she was, someone who was comfortable talking about race.

Returning to the case of the high user who faced a cooperating teacher with low expectations who did not want to increase the rigor of mathematics in his class, the high user explains that he wanted to change his mind, but that was not his only goal.

> That's just not how I do things. I didn't know if I was going to change his mind. But, I just needed him to let me do what I wanted. I couldn't be him.

This high user of creative insubordination expressed a similar rationale for standing up to a student who made a stereotypical comment about certain people being good at mathematics. He witnessed a student who was struggling with a problem turn to another and exclaim, "Put on your Asian hat and help me do this problem." He explained,

> I don't know if he really thinks that or they're just joking, but I couldn't just stand there and, I don't want to signal that that's okay in my class. Maybe that's okay in other classes, but not for me.

Again, we hear the rationale less about weighing the benefits and risks for impacting the student who made the stereotypical comment and more about what it signals to his class about the kind of teacher he is and what is allowable in his class.

Modeling Advocacy Behavior for Bystanders.

Mentioned less often than changing the minds of others or projecting a particular identity was the idea that even if one's actions didn't convince others to change policy or their beliefs about which students were capable of advanced mathematics, using creative insubordination had the possibility of influencing others who were bystanders to stand up in similar ways to such comments. Again, this rationale was more present among the comments made by high users of creative insubordination than those who were infrequent or rare users.

One teacher (a less frequent user) was faced with a superior in the mailroom and wasn't sure how to respond to his stereotypic comment about Asians being good in math.

> He said it in an offhand way. There was a student who was Asian and was not good in math. He said, "She's Asian and you wouldn't expect that." He said it so quickly and kept moving on with the story… I work there, so I can't have him mad at me. I don't want him to say something to my boss… being the younger person talking to an older person, is it my place to be saying something? What are the consequences of speaking up? I know him well enough to know that had I said something, he wouldn't have any respect for what I said. So, is it even worth mentioning?

Three fellow teachers, high users, counsel her,

> T1: I think so,

T2: I think so too. One thing, it's easy to make assumptions about people that protect us from putting ourselves out there. I'm not saying that you did…It's really easy to assume something about someone to keep me from getting out of my comfort zone. You could say how he would have responded, but to say something, even if you are casual about it, he is probably going to reflect on his comments regardless of how you think of what he is thinking. I think it's important for us to get out of our comfort zones because it is how we are going to grow and how we are going to make a difference…

T1:… the first step is by putting yourself out there; you are making a change within yourself. Then, you can help others make the same change. How can I help others in my classroom take that risk to see others differently if I cannot do that? How can I start to live more like what I believe in? The little things are what matter.

T3: I really like what was just said. I think it is really good that a lot of us are feeling this discomfort. I don't know if I would have acted. I think if I hadn't, I think I would have looked back and said, "Shoot, why didn't I? It's good that we are even feeling that drive and that tension. It's there because you are taking a real risk when you are doing that. Especially as a white person, that risk doesn't benefit us. We can, it benefits us by not taking the risk. Maybe the person you are talking to might not get the message. But, you may become a role model for the observer. That other person will see you taking that risk. Especially as a white person. That is really strong and a way to start making change too.

Another high user gives a similar explanation for standing up for students even when it doesn't benefit her as a white person. A rare user of creative insubordination asked her how she gets the guts to do what she does. She responds that when faced with racist comments about her students of color, she does not naturally know what to say or how to say it, but she takes the risk because of what it says to other white people.

> I'm white and it is really hard to get your privileges pointed out to you, and you know you didn't earn them and you… One privilege is to be able to walk around this discomfort and to be able to walk away from it…I feel really nervous right now, that fear, feeling uncomfortable. Because we are in the majority, we can just choose to leave the conversation. It's extra important for us to get into these uncomfortable situations. We need to commit ourselves to not taking it and not walking away from it because we can signal to others what is possible.

She recognizes that standing up to racist comments by individuals one faces is not always for the benefit of that person changing, but for other bystanders to witness what it looks like for a white person to stand up for the rights of others.

Conclusions

Teachers in this study were provided with professional development that supported their understanding of and inclination to use creative insubordination, to not simply go along with the status quo but to stand up to racist comments, deficit-based perspectives on students, mathematical practices that emphasized procedures and memory over conceptualization, and/or stereotypes of who is good at mathematics. However, some teachers were more likely to stand up for their students, even if it meant risking their status or relationships with others.

There was a greater propensity for high users of creative insubordination to rely on a rationale that extended beyond the likelihood that their actions would be met by a change in belief or action by the person with whom they were facing in a political situation. These individuals tended to consider what kind of identity they were projecting to others, as well as whether their actions might provide an incentive for others to also speak up or advocate for historically marginalized youth and their rights to learn rigorous mathematics. That is, they were often willing to take a stand even if they knew their arguments or suggestions for alternate policies or actions were likely to fall on deaf ears. They did so knowing that their choice not to go along with the status quo was a means by which they could look themselves in the mirror each day.

Understanding the rationales of high users of creative insubordination can help teacher educators and professional developers to emphasize the importance of looking beyond the immediate gain of winning an argument with a colleague or changing a policy. The choice to focus on the projection of one's identity and the possibility of influencing bystanders suggests a longer term approach being used by teachers who seem more willing to take risks to advocate for all students to learn meaningful mathematics.

CONNECTING MULTIPLE MATHEMATICAL KNOWLEDGE BASES: PROSPECTIVE TEACHERS' CONCEPT MAPS OF ASSESSING CHILDREN'S UNDERSTANDING OF FRACTIONS

Lynette D. Guzman
Michigan State University
guzmanly@msu.edu

This study investigates how 20 prospective elementary teachers make connections among children's multiple mathematical knowledge bases in their thinking about assessing children's understanding of fractions. The researcher facilitated concept-mapping tasks to examine the ways the prospective teachers linked concepts related to children's lives and experiences and children's mathematical thinking. This paper focuses on high-level tasks as a potential entry point to build stronger connections between assessing children's understanding of mathematics and children's multiple mathematical knowledge bases in teacher education. Additionally, I discuss implications for teacher educators and considerations for further research.

Keywords: Teacher Education-Preservice; Teacher Knowledge; Equity and Diversity

A role of teacher education programs is to provide support for prospective teachers to develop professional skills that are specific to and required for teaching. Mathematics teacher educators may provide opportunities for prospective teachers to recognize and validate children's many ways of knowing mathematics, which is especially powerful for addressing the needs of students who are traditionally marginalized in the mathematics classroom. Mathematics education researchers emphasize the importance of eliciting and building on children's mathematical thinking in teaching mathematics (e.g. Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Jacobs, Lamb, & Philipp, 2010). Supplementing this focus on children's thinking, more recent research calls for incorporating children's home and community-based mathematical *funds of knowledge* in mathematics teaching to support student learning of mathematics (e.g. Aguirre et al., 2012; Turner et al., 2012). When teachers consider children's funds of knowledge, they ultimately have more resources to draw upon and inform their teaching practice to design meaningful classroom experiences that incorporate their students' knowledge and experiences outside the mathematics classroom. There is limited research, however, on how prospective teachers connect the role of assessing children's understanding of mathematics to incorporating children's funds of knowledge in their mathematics teaching. The purpose of my study is to better understand in what ways prospective teachers make this connection in the context of an elementary mathematics methods course. In this paper, I address the following research question: In what ways do prospective elementary teachers link concepts related to children's multiple mathematical knowledge bases to assessing children's understanding of fractions?

Theoretical Framework

Aguirre and colleagues (2012) defined children's *multiple mathematical knowledge bases* as children's mathematical thinking and children's community, linguistic, and cultural funds of knowledge. By building stronger connections among children's multiple mathematical knowledge bases, teachers may have opportunities to learn from their own practice while making intentional instructional decisions that support their students' learning in meaningful ways by connecting students' funds of knowledge to their mathematics classroom experiences. In this study, I am interested in the connections that prospective teachers make between children's multiple mathematical knowledge bases and their thinking about assessing children's understandings as part of their professional practice.

Given the intricacies of teaching practice, I draw on concept mapping as a tool that provides prospective teachers with a learning opportunity to create a representation of their thinking about relationships between concepts related to teaching practice. The research literature on concept mapping in teacher education provides evidence that its use as a research tool is valid and robust. Scholars have used concept map artifacts to examine teacher knowledge about mathematics content (e.g. Williams, 1998; Hough, O'Rode, Terman, & Weissglass, 2007) and knowledge about teaching skills (e.g. Beyerbach & Smith, 1990; Koc, 2012).Other researchers studied the validity of using concept maps as a research tool in education. For example, Miller et al. (2009) examined the capability of concept maps as a research tool by studying pre- and post- concept maps by 251 prospective and practicing teachers. The authors used a concept map scoring method (Novak & Gowin, 1984) and found that participants' concept map scores distinguished expert to novice levels in conceptual understanding and growth over time. My research question focuses on how prospective teachers make connections among concepts related to children's multiple mathematical knowledge bases, and I am using concept maps to gather evidence of these connections by examining how concepts in their maps are linked together. I based my research design on work by Hough and colleagues (2007) who partially used qualitative content analysis to compare teachers' pre-maps and post-maps from beginning to end of a professional development program.

Method

I conducted this study within the context of a larger research project that produced modules designed to teach prospective elementary teachers to make stronger connections in mathematics lessons between children's mathematical thinking and children's lives and experiences. In my research, I collected data from20 prospective teachers enrolled in a15-week elementary mathematics methods course using activities from these modules. This paper reports data from and analysis of individual concept maps constructed in the last week of the course and individual reflections on the connections within the concept maps. All prospective teachers created these artifacts during their regular class meeting time and location; however, the methods course instructor was not present during these activities. All names in this paper are pseudonyms.

Data Collection

During the last class meeting of the semester, I explained concept maps and the concept map activity to the whole group. In this activity, I prompted prospective teachers to create a concept map to represent their knowledge about *assessing children's understanding of fractions*. I selected "fractions" as a specific mathematics topic to consider because it was a major topic in the mathematics methods course. I explicitly instructed prospective teachers to think about this concept map activity with a network structure, rather than a hierarchical structure with downward flow, to encourage making connections among any and all related concepts on their maps. I emphasized connections among concepts because I wanted prospective teachers to focus on indicating links between concepts to answer my research question.

First, prospective teachers individually created a concept map on a legal-sized sheet of paper with the option to draw the map entirely by hand or to write concepts on provided sticky notes to place on the sheet of paper. I did not provide prospective teachers with any initial concepts to consider, but I did provide black pens for this part of the activity. Next, I asked prospective teachers to have a focused discussion about evidence of connections among children's multiple mathematical knowledge bases in their concept maps. These discussions occurred in groups of four people. After a few minutes, I interrupted small group discussions to direct attention to specific concepts related to children's multiple mathematical knowledge bases that I provided on a sheet of paper: Children's mathematical thinking; Problem solving strategies; Making sense of students' mathematical ideas; Students' personal experiences; Students' interests and activities; Students' home and community knowledge bases (e.g. regular routines, places in community); and Funds of knowledge (e.g. cultural, community, and linguistic resources).

I asked each group to review the list and determine if any of these concepts connected to their concept maps. I also asked each group to discuss how they would change their concept maps to include any of the provided concepts but explicitly instructed them not to change their maps during the discussion. While prospective teachers had discussions in their groups, I collected all black pens and distributed red pens. I designed this activity in two parts with different colored pens to distinguish and collect data for both parts (before and after focused group discussion). After discussion, prospective teachers individually revisited their concept map to make any changes with red pens. Finally, prospective teachers individually wrote a brief reflection about evidence of children's multiple mathematical knowledge bases in their map.

Data Analysis

I used content analysis techniques to examine links and concepts within prospective teachers' concept maps by specifically looking for evidence of children's multiple mathematical knowledge bases in their maps. I first coded all concepts in the maps using three initial categories: Mathematical Concepts, Assessment, and Children's Multiple Mathematical Knowledge Bases. I created these a priori categories based on my research question and concept map prompt. I started analysis by coding five concept maps at a time with the initial coding scheme and identifying any concepts that did not seem to fit well in any of the categories. Through multiple rounds of this iterative process, I refined my coding scheme to include emergent categories based on patterns from my analysis. Table 1 contains my final coding scheme, definitions, and examples from concept maps.

Table 1: Final coding scheme with examples

Category	Definition	Notes	Examples
Mathematical Concepts	Includes all concepts related to fractions (types and parts of fractions, definitions) or number & operations more broadly	Same as a priori category	Numerator; Reciprocal; Common denominator
Representations and Tools	Includes representations such as number lines, manipulatives, and examples of fractions	Emerged from iterative coding process	Number lines; Pie charts; ½
Teaching Practices	Includes examples of and concepts related to assessment (design and types), activities, tasks, and instructional planning	Broader category of a priori *Assessment* category	High level tasks; Formal assessment; Differentiation
Children's Mathematical Thinking	Includes examples of and concepts related to students' prior knowledge, solution strategies, specific common understandings and misconceptions	*Children's Multiple Mathematical Knowledge Bases*	Problem solving strategies; Misconceptions; Seeing students' thinking
Children's Lives and Experiences	Includes examples and concepts related to children's funds of knowledge: linguistic, community, home, and cultural knowledge		Funds of knowledge; Relate to students' interests; Culturally relevant

Mathematical Concepts remained a category, Representations and Tools emerged as a new category, and I broadened the a priori Assessment category to include all concepts related to Teaching Practices. I decided to split the Children's Multiple Mathematical Knowledge Bases category to make a distinction between *Children's Mathematical Thinking* and *Children's Lives and*

Experiences because I wanted to compare how prospective teachers represented both concepts in their maps. Finally, I used the prospective teachers' brief reflections as another source of data to examine how prospective teachers saw evidence of children's multiple mathematical knowledge bases in their concept maps.

Results

Across the group, nearly half (48.89%) of all links in the maps connected concepts related to children's multiple mathematical knowledge bases to concepts I coded as Teaching Practices. In particular, seven prospective teachers made a direct link between children's multiple mathematical knowledge bases and *high-level tasks*. A key finding from my analysis suggests that high-level tasks may be a possible entry point to strengthen connections between children's multiple mathematical knowledge bases and assessing children's understanding of mathematics. In this section, I will highlight three examples of how prospective teachers made these connections with particular attention to high-level tasks in their concept maps and reflections.

As shown in Figure 1, Avery has *high-level task* as a concept directly connected to *assessing children's understanding of fractions* with a cluster of concepts also connected to it. After editing the map, Avery added *problem-solving strategies* to this cluster of concepts, which I coded as a concept related to children's mathematical thinking. Avery also added *connect to students' experiences*, *use students' names*, and *connect appropriate funds of knowledge* to this cluster, which I coded as concepts related to children's lives and experiences.

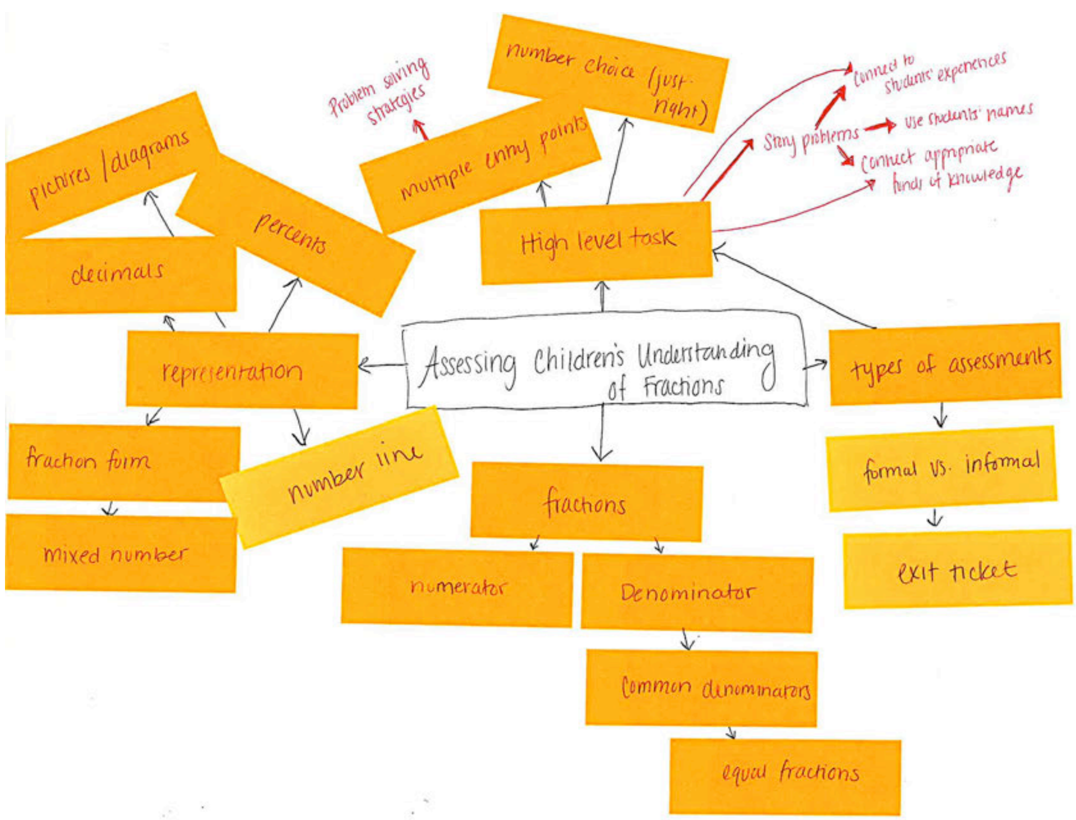

Figure 1. Avery's end of semester concept map.

In the end of semester reflection, Avery explicitly wrote about seeing evidence of connecting children's multiple mathematical knowledge bases to assessing children's mathematical understanding by using high-level tasks:

> *Avery*: I made the biggest connection between developing *high-level tasks*[emphasis added]with relating students' experiences and funds of knowledge. When assessing students and how they think we need to make sure that all students relate to the problem and can understand the context or background of a problem. The material needs to be relevant to every child so that they can one day use their knowledge in the real world. Even something as small as changing the names in a story problem will increase student interest and motivation.

Avery points to a connection between creating high-level tasks to assess students' mathematical understanding and using relevant information about students' funds of knowledge. Avery also notes that it is important to acknowledge students' relationship to mathematical problems, including the problem context and background. Part of this relationship may be related to student motivation, but Avery focuses on the potential utility of mathematics in students' lives outside of the mathematics classroom.

Similarly, other prospective teachers indicated evidence of children's multiple mathematical knowledge bases by connecting these concepts to high-level tasks. Figure 2 shows Morgan's end of semester concept map with these connections. In this map, *utilize students' funds of knowledge* is the lead concept of an added cluster directly connected to *assessing children's understanding of fractions, fraction vocab*, *number talks*, *exit tickets*, *high-level tasks*, and *allow multiple representations*. Additionally, Morgan added a direct link between *high-level tasks* and *allow multiple representations* in the edited map.

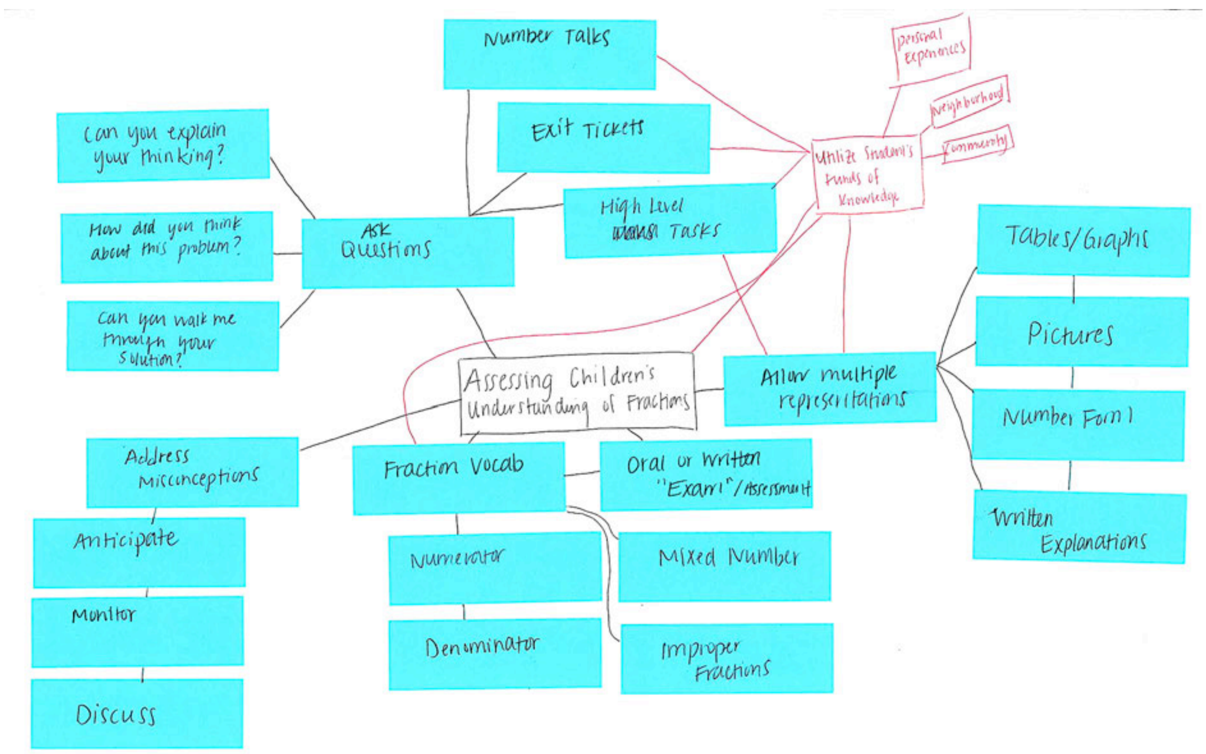

Figure 2. Morgan's end of semester concept map.

In the brief reflection, Morgan explained that *high-level tasks* and *multiple representations* connected to concepts related to children's multiple mathematical knowledge bases:

> *Morgan*: Creating *high-level tasks* [emphasis added] that provide students with multiple entry points into problems allowing them to think and use strategies that makes sense to them will tap into students' prior knowledge of what they already know and what strategies they are comfortable using. Allowing students to use *multiple representations* [emphasis added] also connects to their experiences of what types of strategies they have used in school before and what representations they prefer to use.

Morgan's brief reflection provides evidence of connections between high-level tasks and students' mathematical knowledge and strategies from in-school mathematics experiences. It is not clear, however, in what ways Morgan is making connections between high-level tasks and students' funds of knowledge. Similarly, it is not clear in what ways Morgan is making connections between multiple representations and students' funds of knowledge, even though there are links between these pairs of concepts on Morgan's map.

One prospective teacher, Harper, noted that there was evidence of concepts related to children's mathematical thinking before editing the map, such as *number talks*, *seeing students' thinking*, and *high-level tasks*. After editing the map, Harper added more concepts related to children's lives and experiences:

> *Harper*: At first, the only discussion I had about mathematical thinking was in describing how we can use number talks to see students thinking, and allowing them to explore different strategies with *high-level tasks* [emphasis added]. Once I edited the map, I added things about students' home life, community, personal experiences, etc.

Harper initially highlighted eliciting students' mathematical thinking through number talks, which is an activity in which students participate in 15-minute conversations about computation problems to communicate their mathematical thinking. Harper also describes how high-level tasks provide opportunities for students to explore different problem solving strategies, which is also closely connected to students' mathematical thinking. Harper does mention a shift to focusing on students' funds of knowledge only after the discussion and editing process.

An Interesting Case to Explore

Out of all the prospective teachers' brief reflections, Parker was the only participant who claimed to not see evidence of children's multiple mathematical knowledge bases in the end of semester concept map (see Figure 3). Parker explained that there was no evidence of concepts related to children's multiple mathematical knowledge bases in the map because of Parker's ways of thinking about assessing and about using funds of knowledge in mathematics teaching:

> *Parker*: I think there is no evidence because I thought of assessing in the pedantic sense. I thought that experiences of the children would go more along with the *actual teaching* [emphasis added] of concepts… I could add funds of knowledge to the concepts that I stated as being a part of a formal assessment.

I highlight Parker's reflection as an interesting case because I heard multiple prospective teachers voice similar thoughts during small group discussions about funds of knowledge being more directly related to the process of teaching mathematics rather than assessment, which could follow the act of teaching. From the methods course materials, I have evidence that prospective teachers adapted existing tasks and curriculum materials, but I have little evidence that prospective teachers have designed assessments at this point in their preparation program. One prospective teacher told me during the whole group discussion that they have experience adapting problems to align with students' needs although they have not created assessments in the course. Consequently, this evidence made me wonder about how prospective teachers' made sense of the phrase "*assessing children's understanding*" in the root of this concept map activity, and ultimately, how their understandings influenced the construction of their concept maps.

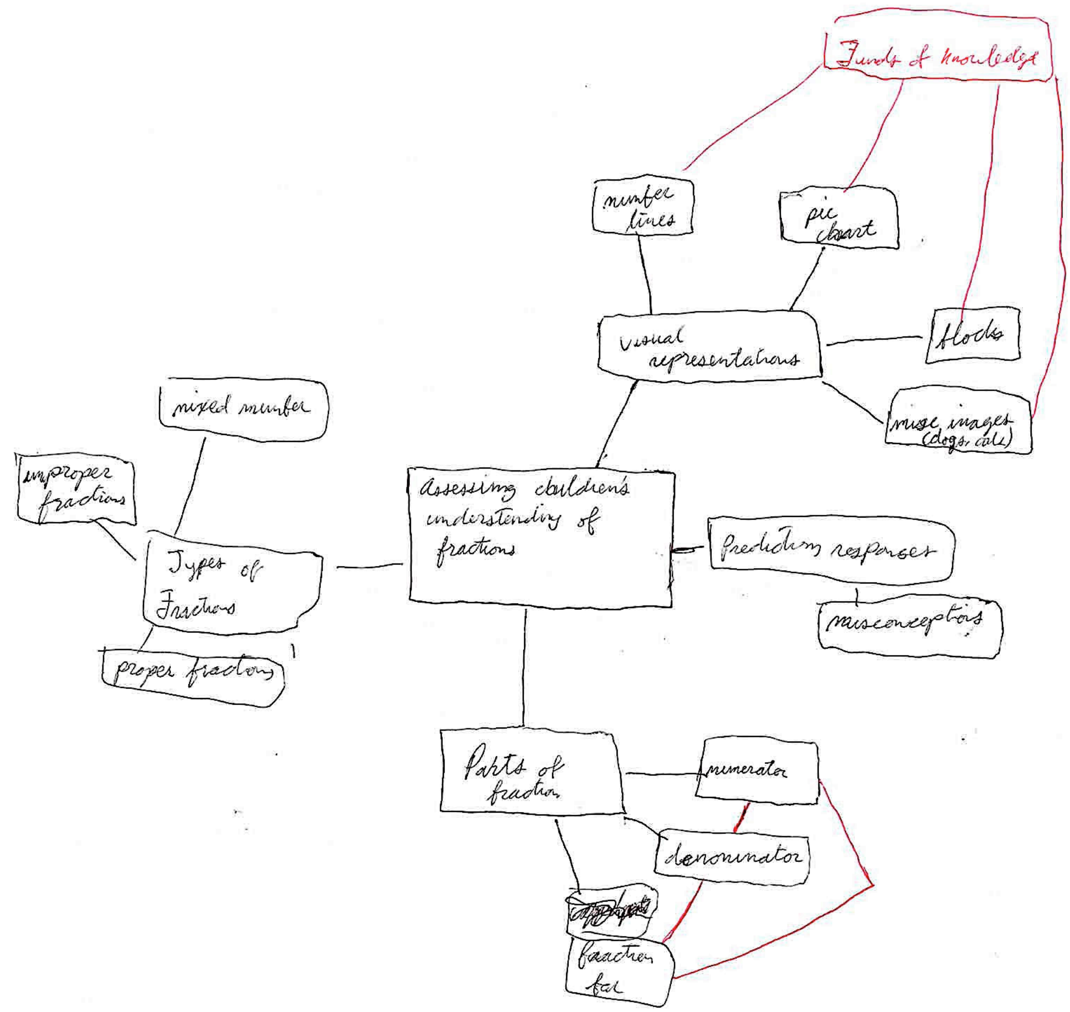

Figure 3. Parker's end of semester concept map.

Discussion

This study investigates in what ways prospective elementary teachers make connections among *children's multiple mathematical knowledge bases* in their thinking about assessing children's understanding of fractions. In the following, I describe implications for teacher educators and considerations for further research.

Teacher educators may support prospective elementary teachers to make explicit and stronger connections among concepts related to children's mathematical thinking, children's lives and experiences, and assessing children's understanding of mathematics. One entry point to better support these connections involves emphasizing *high-level tasks* as a concept related to teaching practices that connects to *both* children's mathematical thinking and children's lives and experiences. From my analysis of concept maps and brief reflections, I found strong evidence that the prospective teachers in my study made connections between high-level tasks and children's mathematical thinking. Based on an interesting case I found in the data, another implication for teacher educators is to be cognizant of a possible perception that funds of knowledge, including children's lives and experiences, are not used or useful in assessing children's understanding of mathematics. I would recommend a stronger focus on assessment as one of many teaching practices and the role of assessment for equitable teaching practices that serve the needs of all students, especially those who are traditionally marginalized in the mathematics classroom.

For further research, I would be interested in gathering more information about how prospective teachers make sense of the concepts related to *children's multiple mathematical knowledge bases*. Although prospective teachers made connections among these concepts, I noted that the concepts used more general language and did not include specific examples of how children's multiple mathematical knowledge bases connected to *children's understanding of fractions*. More specifically, I would like to examine *whose* multiple mathematical knowledge bases are represented in these concept maps. Are particular racial or ethnic groups of students in mind when we use the phrases *funds of knowledge* or *multiple mathematical knowledge bases*? Where do understandings of multiple mathematical knowledge bases come from (e.g. content in course readings/activities, prior experiences with children, etc.)?

This project examines how prospective elementary teachers (PSTs) framed the idea of drawing on multiple mathematical knowledge bases (MMKB)—children's mathematical thinking and funds of knowledge— for diverse learners, in the context of adapting curriculum. We analyzed 47 written reflections of PSTs' analyses of an existing mathematics curriculum. Using inductive analysis, we identified four themes related to how PSTs evaluated the curriculum and identified possible spaces for small adaptations. Findings describe how these four themes related to incorporating MMKB. We discuss implications for mathematics teacher education.

Keywords: Equity and Diversity; Teacher Education-Preservice; Elementary School Education

The field of mathematics teacher education has begun to address how the cultural, linguistic, and socioeconomic positionality of students impacts their learning opportunities (Zevenbergen, 2001). Unfortunately, the focus on children's sociocultural identity in the classroom often appears as a separate subset of study from the more traditional focus on the psychology of mathematics education (Aguirre et al., 2012). Typically, children's home- and community-based knowledge receives much less attention in teacher education than children's mathematical thinking (e.g., problem types, solution strategies, etc.; Carpenter, Fennema, Peterson, Chiang & Loef, 1989) (Aguirre et al., 2012). In mathematics teacher education, the emphases on children's mathematical thinking and on children's home- and community-based knowledge and experiences remain largely disjointed, leaving prospective teachers (PSTs) ill-equipped to meaningfully integrate both important sources of mathematical knowledge and learning.

Research continues to reveal how a majority white, female, middle class teaching force struggles to effectively teach a diverse student population (Sleeter & Milner, 2011). This enduring challenge in education, more broadly, has serious implications for mathematics teacher education at all levels. The purpose of this paper is to examine how elementary PSTs make sense of addressing the needs of historically underrepresented populations in school mathematics during their mathematics methods course. In particular, we examine PSTs' work on a curriculum analysis assignment to better understand how PSTs frame meeting the needs of historically underrepresented populations through mathematics curriculum adaptation.

Theoretical Perspectives

Theoretical perspectives from two strands of research on elementary mathematics teaching and learning guide this project. First, the extensive body of research on mathematics instruction that centers on children's mathematical thinking (e.g., *Cognitively Guided Instruction*, Carpenter, et al., 1989) provides a basis for developing PSTs' knowledge of children's mathematical thinking in ways that change beliefs and shape classroom practices. Second, research that documents the benefits of drawing upon the cultural, linguistic, and community-based knowledge of historically underrepresented groups (Ladson-Billings, 2009; Turner, Celedón-Pattichis & Marshall, 2008) guides PSTs' development of leveraging home- and community-based knowledge in mathematics instruction. In particular, this project draws on the theory of *funds of knowledge*(FoK) for teaching. FoK refer to the "historically accumulated and culturally developed bodies of knowledge and skills essential for household or individual functioning and well-being" (Moll, Amanti, Neff, and

Gonzalez, 1992, p. 133). Using students' FoK for mathematics teaching means that classroom instruction utilizes the cultural, linguistic and cognitive resources from home or community settings to promote students' learning of the standard mathematics curriculum in school settings (Moll et al., 1992).

Although both strands of research are well developed, they remain disconnected in mathematics teacher education, as mentioned above. As a result, the field of mathematics education lacks a deep understanding of how teachers might learn to integrate the focus on children's mathematical thinking with the emphasis on home- and community-based knowledge. This project aims to bridge these two bodies of research by guiding K-8 PSTs to use children's *multiple mathematical knowledge bases* (MMKB) to support student learning. In this paper, we refer to MMKB as the integration of children's mathematical thinking and children's FoK (Aguirre et al., 2012). More specifically, the research question for this project is: How do K-5 PSTs frame the idea of drawing on MMKB, specifically for historically underrepresented student groups, in the context of adapting curriculum?

Methods

The research presented in this paper is part of a larger project, TEACH Math. In this section, we briefly discuss the goals and methods of the larger project and provide details about the specific data collection and analysis that produced the findings presented here.

Research Overview

The TEACH Math project aims to transform elementary mathematics teacher preparation so that new generations of teachers will be equipped with powerful tools and strategies to increase student learning and achievement in mathematics in our nation's increasingly diverse public schools. The project involves iterative refinement of three instructional modules for elementary mathematics methods courses designed to explicitly develop teacher competencies related to mathematics, children's mathematical thinking, and community and cultural FoK. Across these three modules, PSTs develop specific knowledge, beliefs, and dispositions related to MMKB.

Research has occurred at six university sites across the United States, with data on PSTs' work in all three modules collected from elementary mathematics methods courses at each of these sites. We analyzed data collected at one university site, a large university in the Midwest located near a small city with an increasingly diverse population. For this analysis, we used data collected from an activity in two K-5 mathematics methods courses at this university, each with a different co-principal investigator (PI) as course instructor.

In the activity selected for this analysis, Analyzing Curriculum Spaces, PSTs analyzed an existing elementary mathematics curriculum to identify opportunities for accessing, building on, and integrating children's mathematical thinking and children's home and community-based mathematical FoK (i.e. MMKB). We refer to places in the curriculum where teachers can make these types of small adjustments as curriculum *spaces*(Drake et al., 2015). This activity is one of four in the Classroom Practices Module in which PSTs learn to analyze classroom practices through four lenses: teaching, learning, task, and power and participation. In this specific activity, PSTs use a tool, Curriculum Spaces Table, designed by the co-PIs, to guide PSTs' identification and adaptations of curriculum materials that create spaces for eliciting and building on children's MMKB.

The Curriculum Spaces Table has three sections. In the first section, PSTs identified the central mathematical goal or ideas of the lesson. In the second section, they answered questions about the different phases of the lesson (e.g. launch, explore, summarize). The questions included: (1) What makes the task(s) in each phase good and/or problematic?; (2) What are opportunities for activating or connecting to family/cultural/community knowledge in each phase of the lesson?; (3) How does each phase of the lesson open spaces for making real-world connections?; (4) What are opportunities for students to make sense of the mathematics and develop/use their own solution strategies and approaches?; (5) What kinds of spaces exist for children to share and discuss their mathematical thinking with the teacher and the class?; (6) Where does the mathematical authority reside in the lesson? In the final section, PSTs proposed possible adaptations for the lesson phases or the overall lesson.

Data Collection and Analysis

Data for this paper included PSTs' written reflections on their use of the Curriculum Spaces Table to analyze the *Stickers: A Base-Ten Model* lesson from Grade 3 *Investigations in Number, Data, and Space* (TERC, 2008, p. 26-33). We analyzed a total of 47 written reflections. Participating

Primary Theme	Definition	Subthemes & Definitions (if applicable)
Learning Supports	Aspects of the lesson/teaching provide supports to facilitate student learning of mathematical content, including ***scaffolding*** (i.e. gradually decreasing the need for learning aids as students' comfort with language, concepts, etc. increases); ***teacher questioning***(i.e. various forms of questioning recognized to support learning (Boaler & Brodie, 2004)); or ***differentiation*** (i.e. individualized adaptations of lessons/tasks).	**General Learning Supports:** Considerations that will arise in essentially every classroom setting; no reference to FoK.
		Learning Supports for Diverse Learners: *give diverse learners access to the mathematical content*; particularly important when the class included culturally and linguistically diverse students or special education students; may or may not reference FoK.
Prior Knowledge	Aspects of the lesson/teaching are ***relevant to the students' prior knowledge***. The teacher or students can provide this connection to prior knowledge.	**School-Based Knowledge:** Prior knowledge that arose in a school-based setting.
		Funds of Knowledge: Prior knowledge that arose from community/family/cultural knowledge or experiences.
		Not-Specified: Source of prior knowledge is not specified
Motivation	Aspects of the lesson/teaching are ***relevant or familiar to students*** for the purpose of ***engaging or motivating students***.	
Children's Mathematical Thinking	Aspect of the lesson/teaching accessed, built on, or integrated children's mathematical thinking, including references to: (1) students' mathematical ***explanations and justifications***; (2) orchestration of mathematical ***discussion*** (Smith & Stein, 2011); and (3) specific mathematical ***features of the task*** (e.g. manipulatives, multiple representations, multiple strategies).	

Figure 1: Coding Themes & Definitions for Content of Written Reflections

PSTs were reflective of national demographics (i.e. mostly white, middle-class females). In the written reflections, PSTs discussed strengths and limitations of the lesson, spaces they identified for eliciting and building on children's MMKB, and the ways in which using the Curriculum Spaces Table aided in their analysis.

We analyzed the written reflections through an iterative coding process. The first two authors of this paper began the coding process separately, analyzing two of the written reflections and noting themes. We compared our initial impressions and used the themes to develop an initial codebook. We continued coding separately, comparing analyses, and revising the codebook until we produced a final (seventh) version of the codebook (Figure 1). Throughout our development of the codebook, we continually looked for confirming and disconfirming evidence of the identified themes (Erikson, 1986).

Using the final version, we coded the remaining written reflections together, discussing discrepancies and reaching consensus on coding. Written reflections were coded at the paragraph level (as denoted by the participant or roughly 10-15 lines) because surrounding sentences (or turns) provided important context for identifying themes. The codebook provided exhaustive codes (i.e. every paragraph received at least one code), but primary codes were not mutually exclusive.

We used the codebook described above to identify major themes related to the *content* of PSTs' written reflections, and we created a second coding stream to identify themes related to PSTs' *evaluation* of the curriculum. This secondary coding stream represented three major themes in PSTs' analyses: (1) Strength; (2) Weakness; and (3) Curriculum Space (Figure 2). Coding in these two streams allowed us to examine both the specific aspects of the lesson/teaching that PSTs identified in their curriculum analysis and whether PSTs framed those aspects of the lesson as strong/weak or spaces for adaptation. We linked codes in this second stream directly to codes in the first stream. For example, sometimes PSTs discussed ways in which the lesson provided learning supports, and they clearly identified those learning supports as strengths of the lesson. Such a paragraph would receive a "learning supports-strength" code. In some cases, PSTs did not clearly evaluate lesson aspects as a strength/weakness or a space for adaptation, and we did not use the second coding stream. Codes in the second stream were not mutually exclusive because some paragraphs included a discussion of both strengths and weaknesses of the same aspect of the lesson and because curriculum spaces were generally identified alongside weaknesses.

Primary Theme	Definition	Subthemes & Definitions (if applicable)
Strength	PSTs evaluated some aspect of the lesson/teaching as strong.	
Weakness	PSTs evaluated some aspect of the lesson/teaching as weak or limited.	**Too little** – Weakness or limitation resulted from too little of an aspect (e.g., too little support for diverse learners)
		Too much – Weakness or limitation resulted from too much of an aspect (e.g., too much explaining/telling by the teacher)
Curriculum Space	PSTs identified an aspect of the lesson/teaching where the curriculum could be adapted. This code was used both when the PST made a specific adaptation suggestion (e.g., I would let the students try the problem on their own first.) or when the PST talked more generally about spaces in the curriculum (e.g., The lesson needs to be adapted for English Language Leaners (ELL).)	

Figure 2: Coding Themes & Definitions for Evaluation by PSTs

Findings

In this section, we share the major themes that emerged across the written reflections. We found that attending to children’s mathematical thinking represented the most dominant theme (Table 1), and we present these findings first. Attention to the needs of historically underrepresented populations of students, specifically, emerged under several different themes - learning supports, prior knowledge, and motivation. We present findings related to each of these themes separately. Overall, FoK and diverse learners received lesser attention in PSTs’ curriculum analysis.

Table 1: Percent of total codes (n=1086) by specific code/theme

Children’s math thinking	Learning supports		Prior knowledge		Motivation	Other
35.6%	17.7%		11.8%		7.8%	27.1%
	General	15.2%	School	4.2%		
	Diverse	2.5%	FoK	4.7%		
			Unspecified	2.9%		

Attention to Children’s Mathematical Thinking

PSTs paid considerable attention to aspects of the lesson that accessed, built on, or integrated children’s mathematical thinking (Table 1). PSTs identified both strengths and limitations in the ways the lesson attended to children’s mathematical thinking, and they recognized spaces for adapting lessons to integrate, build on, or elicit children’s mathematical thinking beyond opportunities already offered in the lesson. Consider the following excerpt:

> The launch of the lesson is very important in making the lesson effective in promoting students’ learning…Students might only use one method of solving the task if they were not taught multiple ways to see the numbers. The lesson provides opportunities for students to explore but the lesson could summarize more in a group discussion format. In doing a discussion students could share their solutions and allow other students to ask questions, compare, or justify their own thinking…

In this reflection, the PST identified aspects of the launch as strong but also recognized limitations in and suggested adaptations for eliciting student thinking, particularly in the summary discussion.

Learning Supports

Among all relevant themes for our research question, learning supports, both general and specific to diverse learners, represented the second most common theme in written reflections (Table 1). Learning supports for diverse learners represented 2.5% of all codes. This means that fewer than 15% of all reflections on learning supports focused on diverse learners, specifically. In other words, overwhelmingly, PSTs seemed to focus on general learning supports in their analysis of the lesson. The following PST identified general learning support as a strength.

> This lesson…gives [students] a way to visualize the patterns and fully understand what it means to add by ten as opposed to just giving them a problem and hoping they figure out the answer. Giving students ways to remember patterns is more beneficial in my opinion.

When PSTs did discuss learning supports for diverse learners, a greater proportion of the codes occurred alongside codes for weaknesses than alongside codes for strengths in the lesson. The following excerpt is from a rare instance where a PST identified strengths of the lesson in regards to supporting the needs of diverse learners:

> This lesson states, "As frequently as possible, refer to strips as *strips of 10* to reinforce the groupings of 10s and 1s". When teaching I think it is important to pay attention to the vocabulary you are using and try to keep it the same throughout. Especially when thinking about ELL students…using the same words to describe something throughout a lesson can help decrease confusion of word meanings and phrases.

More commonly, PSTs expressed that the lesson inadequately addressed the needs of diverse learners: "This lesson also limits ELLs. At no point in the lesson do I see any talk of ELLs so that's something that could limit their learning." Despite being able to identify learning supports for diverse learners as a weakness in the lesson analysis, however, only approximately 11% of all suggested adaptations related to learning supports focused on the needs of diverse learners, specifically.

Prior Knowledge

Prior Knowledge represented one of the most identified categories relevant to how K-5 PSTs framed the idea of drawing on MMKB, specifically for historically underrepresented student groups, in the context of adapting curriculum (Table 1). PSTs discussed home- and community-based FoK with roughly the same frequency as school-based prior knowledge. Figure 3 provides example excerpts of school-based prior knowledge, funds of knowledge, and prior knowledge with an unspecified source.

Examples of Prior Knowledge Themes	
School Based	"The lesson connects back to Sticker Station done in second grade so it utilizes [students'] background knowledge."
FoK	"Aspects of the lesson plan that stand out as especially important for making the lesson effective in promoting students' learning are…that the lesson opens spaces for making connections to their family/cultural/community knowledge."
Non-Specified	"I do believe that it is possible to be responsive to students' thinking and background knowledge while also using the curriculum materials."

Figure 3: Examples for Each Category of Prior Knowledge

Only a small percentage of PSTs identified prior knowledge (combined) as a limitation in their lesson analysis; however, when PSTs did identify prior knowledge as a weakness, they overwhelmingly focused on FoK, specifically. Consider the following excerpt:

> I thought the lesson was limited at making a connection to cultural, community, and/or family knowledge. It was great that the lesson used stickers which students were familiar with from the sticker station store in 2nd grade. This would hook student's interest and motivate them for the lesson.

As the above quote illustrates, school-based prior knowledge was rarely identified as a weakness in the analysis of this lesson. PSTs who identified FoK as a weakness in this lesson also generally discussed adaptations related to FoK. The focus on adapting the lesson to attend to FoK, however, represented less than 10% of all identified spaces for adaption. For example:

> The teacher could have had students create their own problems using something from their culture, home, or of interest that could be bundled in a set of 10 or used individually; for example, my case study student was very interested in basketball and played it at home with family often. He could create a problem having one team of basketball players represent the 10's place and an individual basketball player representing the 1's place. They could then share these

> problems in partners or with the whole class. I feel if students could connect with the problem better, it would better promote students learning.

Motivation

Attention to engagement and motivation in the lesson plan was common throughout the reflections, receiving about 8% of the codes. PSTs identified aspects of the lesson that attended to motivation in both strong and limited ways. Nonetheless, about 10% of codes related to curriculum adaptations identified motivation as a space for improving upon the lesson, suggesting an overall desire to improve engagement and motivation in the lesson.

> If students are forced to complete tedious, uninteresting tasks, their motivation for learning the material will decrease…However, if a teacher is allowed to use the requirements of the curriculum materials as a guide to the objectives students are expected to learn and revise the material to the interests of the students, both motivation and success in learning the material will increase.

Additionally, as a specific focus of the study, students commonly referred to engagement and motivation when discussing the purpose of integrating students' FoK. The quote in the prior knowledge section above offers one example of this connection, but the following excerpt also illustrates how PSTs linked FoK to motivation.

> [This analysis] helps me to think how I should engage real-life objects with my lesson plans and how it would help [students] to have clearer understandings…[students] not only easily learn how to add and subtract multi-digit numbers, but also learn how to engage their class lessons in their real life.

We interpreted this PST's use of "engage" as evidence of attention to students' motivation or interests.

Discussion and Conclusion

Even though the mathematics methods courses in the TEACH Math project aimed to integrate a focus on children's mathematics thinking and children's FoK, the emphasis given by the PSTs still seems unbalanced. Of all the themes discussed by the PSTs in their curriculum analysis, less than 10% focused on children's FoK specifically (i.e. prior knowledge: FoK or learning supports for diverse learners). PSTs overwhelmingly attended to aspects of the lesson focused on children's mathematical thinking (over 30%). These findings suggest that the two emphases, children's mathematical thinking and children's FoK, remain disjointed. Other teacher educators/researchers have observed similar trends when PSTs use lesson analysis tools that attend to both children's mathematical thinking and FoK (Aguirre, Zavala, & Katanyoutanant, 2012). Even though FoK received less attention than we might have expected given the methods course goals, the fact that some PSTs emphasized FoK and suggested lesson adaptations, while still attending to children's mathematical thinking, offers hope of balancing these two important emphases in mathematics teaching.

The equal attention to school-based prior knowledge and FoK offers some hope of guiding PSTs to consider MMKB in their lesson analysis, but prior knowledge, overall, received only limited attention in PSTs' analyses. These findings suggest a need to understand how PSTs frame FoK. In the rare instances when PSTs attended to children's FoK, they commonly discussed the practice in terms of motivating or engaging students. In science education, teachers' rationale for attending to FoK ranges from motivating students to increasing access to the content to changing the content itself (Barton & Tan, 2009). A deeper understanding of the reasons PSTs focused on FoK in the context of mathematics curriculum analysis could shed light on more effective ways of balancing the emphasis on children's mathematical thinking with FoK. The range in motivations for attending to FoK raises questions about which framings promote consideration of MMKB and challenge deficit views of historically underrepresented students.

Findings from this study also have implications for research on how teachers learn to adapt lessons to attend to the needs of historically underrepresented students, once they have identified the need for such adaptions. Those PSTs who attended to FoK in their reflections overwhelmingly identified a need for incorporating more focus on children's home- and community-based knowledge into the analyzed lesson. The ability of some PSTs to identify spaces for and to recognize the importance of incorporating MMKB suggests that this type of analysis holds promise. Nonetheless, PSTs did not necessarily suggest specific lesson adaptations or specific spaces in the lesson where adaptations might occur. This finding suggests that PSTs might need more support in thinking about how to adapt mathematics lessons to integrate, meaningfully, children's mathematical thinking with children's FoK. Further research is necessary to support PSTs in analyzing lessons and adapting them in order to support the needs of diverse students.

This mixed-methods study examines effects of implementing a mock edTPA task on prospective elementary teachers' perceptions of teaching effectiveness. Results from the Mathematics Teaching Efficacy Beliefs Instrument document a significant change in participants' beliefs that they can effectively teach mathematics. Qualitative results illuminate participants' growing confidence in their understanding of elementary mathematics, their ability to recognize and attend to children's thinking, and their use of pedagogical tools and resources to support children's learning.

Keywords: Teacher Education-Preservice; Teacher Beliefs; Teacher Knowledge

Background and Purpose

Teacher preparation and initial certification are undergoing significant changes as a result of new policy. Teacher performance assessments, including edTPA, are at the center of these policy changes and play a consequential role in some states for prospective teachers' eligibility for initial certification. One teacher preparation program recently implemented edTPA, and data for this study were collected during the first semester that edTPA had consequences for program graduates. This study occurs in the context of a mathematic methods course preparing prospective teachers for the math task in the elementary education edTPA. Current research is suggesting that it is important for mathematics content courses to introduce the academic language needed to be successful with teacher performance assessments (Lim, Moseley, Son, & Seelke, 2014). However, a national survey conducted by Masingila, Olanoff, and Kwaka (2012) shows the majority of elementary mathematics content courses are taught by instructors in mathematics departments. Therefore, by default, teacher preparation programs must take the lead in preparing prospective elementary teachers (PSTs) for teacher performance assessments such as the edTPA.

This study examines how one elementary mathematics methods instructor prepared PSTs for edTPA through a focus on Cognitively Guided Instruction (CGI) as an approach to instruction. In the mathematics methods course, the final course assessment was the implementation of a mock edTPA task. It is hoped the findings of this study will provide insights into ways to prepare PSTs for successfully completing edTPA, while maintaining a focus on effective pedagogy in elementary mathematics. This study seeks to answer the following two research questions:

- What changes occur in elementary prospective teachers' mathematics teaching efficacy beliefs during a mathematics methods course implementing a mock edTPA task?
- What are the perceptions of PSTs about their mathematics teaching effectiveness upon completion of a mathematics methods course implementing a mock edTPA task?

Theoretical Perspective and Related Literature

edTPA is a standardized high-stakes assessment modeled after the Performance Assessment for California Teachers (PACT). PACT was developed by researchers and teacher educators at Stanford

University. The intent of edTPA is to move the measure of PSTs' effectiveness from an individual university responsibility to a state or national level (Sato, 2014). Several prominent organizations, including AACTE, CAEP, NCATE, and CCSSO, have supported the need for teacher performance assessment to predict PSTs' effectiveness. edTPA is composed of four teaching tasks designed to focus on planning, implementing, and assessing instruction based on a central focus selected by the PST. The fourth task concentrates on mathematics instruction, and PSTs are required to consider student's mathematical thinking to plan, implement, and assess instruction. PSTs are then evaluated on their ability to analyze their effectiveness as a mathematics teacher implementing instruction focused on student's mathematical thinking and learning.

In the field of mathematics education, numerous studies have linked teachers' pedagogical beliefs and pedagogical content knowledge to students' learning of mathematics (Peterson, Fennema, Carpenter, & Loef, 1989; Campbell, Nishio, Smith, Clark, Conant, Rust, DePiper, Frank, Griffin, & Choi,2014). PSTs' affect (e.g., emotions, attitudes, and beliefs) and knowledge undoubtedly also play an important role in learning, including successfully completing the edTPA Task 4. Teacher affect has been conceptualized as a continuum (Philippou & Christou, 2002). Feelings and emotions have been found to be short lived, highly charged, and unstable. Feelings and emotions are on one end of the continuum, with beliefs on the other end. Beliefs have been found to be more cognitive in nature and also more stable. One belief construct important to PSTs' learning in mathematics methods and eventual classroom teaching is teaching efficacy beliefs. Mathematics teaching efficacy beliefs have been considered as two-dimensional: involving personal mathematics teaching efficacy and mathematics teaching outcome expectancy. Personal mathematics teaching efficacy is the beliefs a teacher holds about his or her skills and abilities to teach mathematics effectively. Mathematics teaching outcome expectancy is a teacher's belief that effective teaching will yield positive student outcomes regardless of external factors. These beliefs impact PSTs' perspectives and understandings of subject matter, therefore this can impact how PSTs perceive and understand elementary mathematics content and pedagogy (Fives and Buehl, 2014; Philipp, 2007;Swars, 2005; Richardson, 1996; Pajares, 1992).

Cognitively Guided instruction (CGI) (Carpenter, Fennema, Franke, Levi, & Empson, 1999) is an instructional model focused on children's mathematical thinking. It is designed to support teachers' instructional decisions in ways that allow them to connect the informal knowledge of students' mathematical thinking with the formal mathematics. A majority of the instructional time in a CGI classroom should be dedicated to discourse (i.e., dialogic discussion about mathematics). During discourse, teachers make real-time decisions about children's knowledge and orchestrate the mathematical discussion through intentional questioning. Professional development focused on CGI has proven to enhance teacher's pedagogical content knowledge and shift their beliefs (Carpenter et al., 1989; Carpenter et al., 1993; Fennema et al., 1996; Swars, Smith, Smith, & Hart, 2009). Students in classrooms aligned with the pedagogy of CGI have also been shown to perform better on number sense tasks than peers not receiving similar instruction (Higgins & Parsons, 2010).

Methods

Participants and Context

The participants in this study were 33 PSTs enrolled in two sections of a 3 credit-hour mathematics methods course. Their ages ranged from 19-48 (30 females and 3 males). They were in the second semester of their initial teacher certification program at a large, urban university in the southeastern United States. The duration of the teacher preparation program was two years and used a cohort model. This teacher preparation program includes campus-based courses and a field component for the first three semesters. The PSTs attended courses two days a week and were in their field placement for two days per week. The field component followed a developmental model, progressing from prekindergarten through fifth grade during three semesters. The fourth and final semester consists of a full-time student teaching experience.

Course Design

As mentioned, the PSTs were enrolled in a mathematics methods course, which consisted of a 14-week semester and met one day a week for 2 and ½ hours. The instructor taught the course from a social constructivist perspective. The primary goal was to develop beliefs and practices that aligned with the practices described within the NCTM's *Principles to Actions: Ensuring Mathematical Success for All* (NCTM, 2014). The purpose of these practices is to integrate the content outlined in the Common Core State Standards (CCSS-M) with NCTM's curriculum standards and principles (NCTM, 2000). Therefore, the methods course used the practices in *Principles to Actions (PtA)*to frame course assignments and instructor feedback on those course assignments, classroom discourse, and learning activities during course sessions.

Learning activities in the course were focused on experiences that supported the PtA. For example, one principle states to "elicit and use evidence of student thinking" (NCTM, 2014). Therefore, PSTs were asked to conduct interviews with students in one-on-one settings during their field experiences. Once they completed the interview they would submit their final analysis for feedback and an assignment grade. As they continued to grow and have experiences with eliciting students' thinking, they were introduced to materials that would assist them in facilitating whole group lesson implementation. The students were then asked to select a central focus and anticipate students' potential strategies with a story problem they designed.

The final assessment component of this course was a teacher performance assessment (edTPA) mock task. This task focuses on how PSTs are able to plan, implement, and analyze elementary students' mathematical thinking. A central focus must be selected that allows students opportunities to develop conceptual understanding, procedural fluency, and problem solving knowledge. The PST must speak to these types of knowledge when they are analyzing the elementary students' mathematical thinking. The purpose of the mock assessment task was not only to familiarize PSTs with the evaluation process, but to introduce the academic language of the edTPA assessment, alongside the academic language of the mathematics content standards and principles for teaching.

The primary course goal was for PSTs to align their pedagogical beliefs and practices with the PtA teaching practices, and a secondary goal was for the PSTs to have a successful experience with the mock edTPA task. In order to meet these goals it is important to have a pedagogical model that integrates these theoretical ideas, so the primary text for the course was *Children's Mathematics: Cognitively Guided Instruction* (Carpenter et al. 1999). Cognitively Guided Instruction (CGI) was the approach to instruction selected to allow PSTs to construct ideas about student's mathematical thinking and problem solving capabilities, strengthen their own mathematical content knowledge, and to build their confidence teaching mathematics through implementation of CGI in their field placements.

As shown in Figure 1, this course began with introducing the Common Core State Standards for Mathematics (CCSS-M) to situate the relevance of CGI within PST's current field placements and future classrooms. Then, language and ideas in course learning activities and assignments immersed students in CGI. Students began with early number concepts and progressed through number and operations leading into algebraic thinking. As students became more familiar with the CGI framework and implementation materials, the course transitioned into the introduction of the mock edTPA task. The language and focus then joined the ideas of CGI with the expectation of the edTPA task. This task was broken into individual components to allow PSTs an opportunity to continue working with CGI as they merged these new understandings with a teacher performance assessment task. Therefore the course began with the language of the standards, immersed PSTs into the pedagogical model (CGI), and concluded with a teacher performance task (edTPA).

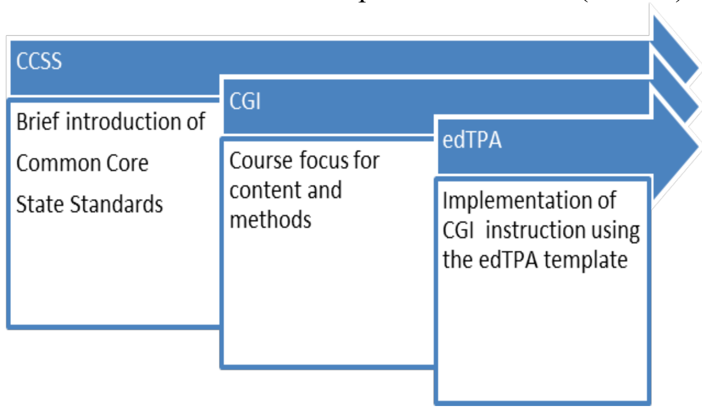

Figure 2. Course Design Overview

Data Collection

This study includes both qualitative and quantitative methods of data collection. Data collection occurred during one semester. The instructor of the course collected any materials related to coursework (i.e. course assignments, daily writings, etc.). Another researcher administered the survey data and conducted six interviews, without the instructor present at either of those events.

Quantitative data presented here were collected during the first and last day of the mathematics methods course using the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI). The MTEBI survey consists of 13 items on the Personal Mathematics Teaching Efficacy (PMTE) subscale and 8 items on the Mathematics Teaching Outcome Expectancy (MTOE) subscale (Enochs, Smith, & Huinker, 2000). The subscales address the two-dimensional aspect of teacher efficacy. The PMTE subscale examines the PSTs' beliefs about their abilities to be an effective mathematics teacher. The MTOE subscale examines the PSTs' beliefs about their abilities to increase student learning through effective mathematics teaching regardless of external factors. This instrument employs a five-item Likert scale, with a higher score correlating with teacher effectiveness. Possible scores on the PMTE subscale range from 13 to 65; MTOE subscale scores range from 8 to 40. These subscales have high reliability (Chronbach's alpha = .88 for PMTE and .81 for MTOE) and represent independent constructs based on confirmatory analysis.

The qualitative data consists of end of the semester semi-structured interviews that were conducted with six PSTs selected randomly from the 33 PSTs in the methods course. The participants were recruited through an email that was sent from the researcher conducting the interviews. The purpose was to elicit conversation around PSTs beliefs, course experiences, and the mock edTPA task. The interview protocol consisted of 11 multi-part questions.

Results

Research question 1: What changes occur in elementary prospective teachers' mathematics teaching efficacy beliefs during a mathematics methods course implementing a mock edTPA task?

Table 1 presents the Likert scale value means and standard deviations as well as those for the PMTE and MTOE subscales. Table 2 shows the analysis of dependent sample t-test, using an alpha level of 0.05. The Likert scale values on the overall MTEBI and the PMTE subscale show a significant increase in teacher effectiveness beliefs. PSTs became more confident in their beliefs about their ability to implement effective mathematics instruction. Therefore, mathematics teaching efficacy beliefs did positively change during the mathematics methods course. The change in scores on the MTOE subscale was not statistically significant, so the slight decline in mean scores should be interpreted as unchanged expectations for student outcomes and the statistically significant change for the overall MTEBI should be attributed entirely to the change in the means for the PMTE subscale.

Table 1:MTEBI Likert Scale Value Means, Standard Deviations, and Mean Differences

	Pre		**Post**		**Change**
Instrument	**Mean Likert Value**	**SD**	**Mean Likert Value**	**SD**	**Mean Difference**
MTEBI	3.54	0.48	3.75	0.40	0.21
PMTE subscale	3.55	0.64	4.31	0.46	0.76
MTOE subscale	3.53	0.61	3.32	0.68	–0.21

Table 2: MTEBI Dependent T-Test Results

Instrument	**T-value**	**p-value**
Overall MTEBI	3.12	.004*
PMTE subscale	7.93	.000*
MTOE subscale	1.91	.065

* Statistically significant difference in the mean for Pre vs. Post.

Research Question 2: What are the perceptions of PSTs about their mathematics teaching effectiveness upon completion of a mathematics methods course implementing a mock edTPA task?

The qualitative interview data indicate that PSTs recognize the importance to teaching effectiveness of assessing and understanding students' mathematical knowledge prior to and during instruction. "I think they should learn based off of what they know" (Participant # 2, interview, December 9, 2014). Another recurring theme was that effective teaching allows for multiple solution strategies to be considered, which was different from the PSTs' own mathematical learning experiences, "I use to think that there was just one way to learn math…. I don't really think that there is one way I saw kids [describes a variety of solution strategies]" (Participant # 3, interview, December 9, 2014). Also, some participants indicated they were able to be effective because they were introduced to resources that they could rely on in their own classrooms such as, "CGI interviews"(Participant #6, interview, December 9, 2014) and "formative assessment" (Participant #4, December 9,2014). Finally, others made general statements about their growing confidence, such as, "I have seen, from the beginning of this course to the end of the course, I have seen a progression in my own math…so I do feel more prepared coming out of it" (Participant #3, December 9, 2014) and "I was terrified to teach math…but now I feel a little more confident" (Participant # 2, December 9, 2014).

Discussion

With the limited research on how edTPA is shaping and changing teacher education it makes sense to begin with considering PSTs' teaching effectiveness beliefs during a time when they are preparing for an experience that will assess how well they are able to analyze their teaching effectiveness during a sequence of mathematics lessons and a re-engagement lesson based on their analysis of student assessment data. As teacher educators consider how to merge teacher performance assessments into their teacher education programs, this study is one example that if a pedagogical model such as CGI has been previously shown to shift pedagogical and efficacy beliefs, then edTPA can become a useful part of the overall methods course experience without unduly dominating such a course. The PSTs perceptions of their effectiveness proved to be strong because of their ability to implement CGI in their field experiences and come back to the university classroom to engage with creating the edTPA Task 4 documents. The field experiences and the shift in beliefs seemed to ease the potential tension about edTPA and how it should be completed during their future student teaching experience.

INVESTIGATION OF MATH TEACHERS' CIRCLE THROUGH A ZONE THEORY LENS

Gulden Karakok
University of Northern Colorado
Gulden.karakok@unco.edu

Diana White
University of Colorado Denver
Diana.white@ucdenver.edu

Math Teachers' Circles (MTCs) are an innovative, problem-solving focused approach to professional development. This model provides teachers opportunities to develop their problem-solving skills as well as help them to communicate with others on classroom implementation of problem-solving activities. As with any professional development with teachers, it is important to explore the impact of this model in terms of teachers' learning and development. In this report we provide our implementation of a zone theory lens provided by Goos as a way to investigate the MTC model. Initial analysis implementing this particular theoretical lens helps us gain insights in ways to improve this new model of professional development activities for future participants.

Keywords: Teacher Education-Inservice; Problem Solving; Mathematical Knowledge for Teaching; Assessment and Evaluation

Introduction

Problem solving is one of the critical topics in mathematics education that has been the focus of research and curriculum reform internationally (e.g., Common Core State Standards Initiatives 2010; NCTM 2000; OECD 2004 & 2010). As its importance in students' learning of mathematics is palpable, in-service teachers also need support in developing and improving their problem solving abilities as well as its classroom implementation (Anderson 2005; Hiebert et al. 1996). One innovative professional development approach to address these areas is the Math Teachers' Circle (MTC) model, which emphasizes developing and improving teachers' problem solving skills in the context of significant mathematical content. It is designed after Math Circles for secondary students, which originated in eastern Europe, migrating to the US in the mid-1980s. Secondary students in these circles engage in solving challenging mathematics problems with guidance from the mathematicians who facilitate these sessions. In this spirit, participating teachers in an MTC engage in solving math problems geared towards the level of teachers, rather than the level of their students, designed and facilitated by mathematicians. During each session teachers solve problems, discuss problem-solving strategies and different solutions, as well as possible implementations of problem-solving activities in their classrooms. Generally, each MTC provides a weeklong summer workshop, followed by monthly evening sessions during the academic year. This model has been gaining momentum in the US, with 71 active MTCs in 36 states. White, Donaldson, Hodge and Ruff (2013) and White (2015) provide additional information about the MTC model.

Being a relatively new model (since 2006), the evaluation of MTCs requires an investigation of effectiveness from various lenses-both theoretical and practice based ones. The purpose of this report is to describe our initial attempt at implementing a theoretical model described by Goos (2009) to explore possible contributions of the MTC models to teachers' development in the area of problem solving.

Theoretical Framing

The evaluation of professional development activities is a complicated task. Many researchers provide practice-based perspectives to design, implement and evaluate professional developments and outline effective practices. For example, Mewborn's (2003) review of research identifies three key elements of successful practices. In general professional developments are stated to be effective if they (1) provide opportunities in which teachers engage with mathematical concepts and also focus on their students' learning of such concepts; (2) are situated in school-context in which teachers could implement and authenticate ideas; and (3) provide opportunities in which teachers discuss issues related to their and their students' learning within a supportive group of participants and network.

These key elements are part of a more theoretical model proposed by Goos (2009), which provides additional aspects contributing to the outlined key elements of effective professional developments. This particular perspective is an extension of Valsiner's (1997) model for understanding learner's development that stems from Vygotsky's Zone of Proximal Development construct (1978).

In their model, Goos et al. (2007) describe three zones, each of which focuses on different aspects of teacher learning and development: the Zone of Proximal Development (ZPD), the Zone of Free Movement (ZFM), and the Zone of Promoted Action (ZPA). The ZPD in this model refers to teachers' *knowledge* and *beliefs* on content and pedagogy. In other words, teachers' development of content knowledge, pedagogical content knowledge, their beliefs about mathematics and about teaching and learning of mathematics are considered within this zone. The ZFM, on the other hand, focuses on "constraints and affordance within the professional context" (p.26). In particular, teachers' *perceptions* related to their profession such as insights on their students' ability, views on curriculum, standards, and assessments they implement, and connections to other teachers and districts, and how such perceptions develop or change through participation in professional development activities are considered in this zone. The third zone, the ZPA, focuses on the *professional development strategies* that are being introduced either formally through structured workshops or informally through communication with other colleagues.

Goos et al. (2007) observed that these zones complement each other in the effort to describe teacher's learning and development. In particular, Goos et al. state, "For teacher learning to occur, professional development strategies [ZPA]must engage with teachers' knowledge and beliefs [ZPD]and promote teaching approaches that the individual believes to be feasible with their professional context [ZFM]" (p. 26).

In this exploratory study, we investigated ways in which the MTC model contributes to participants' learning and development by identifying aspects related to each zone. Though this particular theoretical lens was only implemented in the data analysis phase of the evaluation, this exploration provided insights on improving the planning stages of the professional development model, as discussed in our conclusion.

Methods

Participants and Data

The participants of this study were 129 in-service teachers who attended one of the six MTCs summer workshop hosted during 2011 summer. The number of participants and their years of teaching varied by site, as summarized in Table 1. There were more MTC sites during this particular

Table 1: MTC sites and participants

Site	Number of participants	Years Teaching Mean (SD)	Range
A	23	7.26 (5.2)	1-18
B	20	9.4 (8.8)	0-31
C	16	12.3 (10.3)	0-35
D	19	11.7 (8.7)	0-28
E	20	8.2 (5.3)	1-19

F	27	14.6 (6.9)	2-30
All	129	10.8 (8.0)	0-35

summer; however only six of them both qualified and agreed to participate in this exploratory study. To qualify, a site had to offer at least a workshop of four full days in length and with primarily middle-school level teacher participants, though many also allowed secondary teachers to participate. These sites were geographically diverse. All sites focused on problem-solving activities by engaging participants to solve challenging problems. Some sites also included activities in which participants explicitly discussed pedagogical approaches and implementation of problem solving in their classrooms.

Analysis

In this study we focus on data collected by two instruments: the Learning Mathematics for Teaching (LMT) instrument developed by Hill, Schilling and Ball (2004) and an exit survey developed by one of the authors. All sites administered two subscales of the LMT instrument at the beginning and the end of the workshop. These subscales were used to measure mathematical knowledge for teaching (MKT) of Number Concept and Operations, and Proportional Reasoning. These particular items were used to get an insight on the participants' development of content and pedagogical content as described in the ZPD.

In addition to the LMT instrument, we investigated the ideas relating to the ZPD by qualitatively analyzing the end of workshop exit survey. These questions focused on participants' overall experiences, asking them to comment on their thoughts about the workshop, their learning, other participants' impact on their learning, their anticipation of changing their teaching practices as a result of this workshop, useful aspects of the workshop as well as their comparison of this workshop to other professional developments. Participants' responds were transcribed and analyzed using open and axial coding procedures as described by Strauss and Corbin (1990). Each researcher developed codes that describe participants' experience as a learner and a teacher. These codes were refined by the research team and themes were developed. At the final stage of the analysis, themes relating to the ZPD, ZFM and ZPA from each site were analyzed across workshops to get an insight of the overall experience of all participants.

Results

The LMT instrument was used to explore the participants' development of mathematical knowledge for teaching, addressing aspects outlined in the ZPD. As a condition of using the instrument, we must report standardized scores only by converting raw LMT scores to standardized (z) scores using the scoring tables provided at the instrument-training workshop. An example of the

Table 2: The LMT: Standardized Scores for Number Concepts

Site	Number and Operations		
	Pre	Post	Difference
A	-.41 (1.0)	.06 (1.0)	.48 (.53)*
B	.23 (1.0)	.58 (.74)	.35 (.86)*
C	.12 (.85)	.30 (.91)	.18 (.75)
D	-.50 (.66)	-.21 (.73)*	.28 (.63)*
E	.65 (1.1)	.91 (1.1)	.26 (.72)*
F	.37 (.98)	.56 (.96)	.18(.47)
All	.05(1.0)	.33(97)	.29(.67)*

*Notes.(1)*Scores are standardized and are presented as *M (SD)*. *Pre* = pretest score; *Post* = posttest score; *Difference = Post – Pre*.

(2) *= Planned comparisons showed a significant difference between pre- and posttest scores ($p < .05$).

standardized pre-, post and differences is provided in Table 2 for the Number Concept and Operations.

The analysis of the LMT indicates that the planned comparison t-tests show an increase in the Number Concept and Operations scores that was significant with all sites combined, *M(SD)=.29(.67)*with *p <.00001*.However, we have not observed a similar increase in Proportional Reasoning content that was also administered in the LMT instrument.

In addition, we conducted the repeated measure ANOVA, which revealed a significant main effect of Test Form, $F(1, 112) = 76.31$, $p < .001$. Overall, Proportional Reasoning scores were significantly higher than the Number Concept and Operations scores (M(SD) = .29(.67) and -.10(.67), respectively), and this pattern was consistent across all six sites. The interaction of Test Form x Workshop Site was not significant, $F(5, 112) = 1.46$, $p = .21$.

Table 3: Repeated Measures ANOVA: LMT Standardized Scores

Source	SS	df	MS	F	p
Between subjects					
Site	68.27	5	13.65	5.48**	.00
Error	279.19	112	2.50		
Within subjects					
Test	21.03	1	21.03	76.32**	.00
Test * Site	2.02	5	0.40	1.44	.21
Test (Error)	30.86	112	0.28		
Time	0.96	1	0.96	4.28	.04
Time * Site	0.476	5	0.10	0.42	.83
Time (Error)	25.13	112	0.22		
Test * Time	4.45	1	4.45	18.82**	.00
Test * Time * Site	0.40	5	0.08	0.34	.89
Test * Time (Error)	26.49	112	0.237		

Note. Site = Workshop Site 1, 2, 3, 4, 5 or 6. Test = Number Concepts and Operations or Proportional Reasoning. Time = Pretest or Posttest. ***p* < .01.

There was also a significant main effect of Time Administered, $F(1, 112) = 4.28$, $p = .04$. Post-test scores were higher on average than pre-test scores (M(SD) = .45(.92) and .36(1.05), respectfully). The interaction of Time Administered x Workshop Site was not significant, $F(5,112) = .424$, $p = .83$, indicating that all six sites shared a pattern of differences between pre- and post-test administration and supporting the combination of data across sites for the planned comparisons tests.

There was significant interaction effect of Time Administered x Test Form, $F(1,112)=4.452$, $p<.001$. Overall, there were gains from the pre- and post-test scores for Number Concept and Operations scores, whereas there were losses for the Proportional Reasoning scores (M(SD) = .29(.67) and -.10(.67), respectively),and this pattern was consistent across 5 of the 6 sites. However, the interaction of Test Form x Time Administered x Workshop Site was also not significant, $F(2, 112) = .35$, $p = .889$. This indicates that the pattern of pre- and post-test scores for each form was not significantly different across sites and further supports combining the data across sites for analysis in the planned comparison tests.

The exit survey results were analyzed qualitatively to capture general themes within all zones: ZPD, ZFM, and ZPA. The main themes reflecting ideas that relate to the ZPD were different types of learning such as learning of math content, problem-solving strategies, teaching strategies and overall comments on learning. The themes that captured the ideas referring to the ZFM were teachers' perspectives on student learning, plans for classroom teaching and problem-solving activities and teaching, and the Common Core State Standards perspectives. The main themes observed reflecting the ideas for the ZPA were the challenges that participants experienced during the workshop, collaboration and engagement experience, and general comments on the structure of the workshop.

Responses to the question, "please tell us your thoughts about the workshop," were varied, demonstrating that the culture within the individual sites was unique. However, the dominant themes were reported by the participants mostly related to the ZFM and ZPA, such as collaboration with other teachers; engagement in the workshop activities and perspectives on teaching strategies in the classroom. Even though themes related to the ZPD were also observed, these were not observed in the cross-case analysis. For example, Site A participants reported that learning problem-solving strategies was impactful.

Most participants (64.12%) commented that collaboration with others was the most important support they received during the workshop. This particular theme directly relates to the structure of the MTC model, referring to the ZPA. This theme was observed in response to the question, "please comment how the support you received from others impacted your learning." A participant from Site E commented that the support from others was most impactful in a way that it was, "positive, reflective, [they] bounced ideas off each other, check[ed] mechanisms, asked/answered why—had seen/shared several different approaches to the same question."

Another theme indicating a possible development in the ZPD but also ideas referring to the ZFM was observed in the responses to the question, "Do you anticipate changing anything about how you teach mathematics as a result of the workshop. If so, in what ways?" The majority of participants (63.84%) stated that they learned teaching strategies in the workshop that they planned on transferring to their classroom. An exemplary quote from a participant referring to the ZFM was about this teacher's perspective on student learning is, "I realize that it's ok to give 'hard' problems for students to solve. The process to solve takes patience and, as a teacher, I need to encourage students to be creative in their thinking to build good reasoning."

Participant engagement was the most common theme that highlights the unique structure of the MTC model in area of the ZPA. This theme emerged in response to the questions, "Please comment on any differences or similarities that struck you about this workshop compared with other professsional development workshops you have attended in the past (if applicable)" and "Please comment on what you considered to be the most useful aspects of this week." Participants from workshop Sites A, C, D, E, and F all commented that the MTC workshops were more engaging than other professsional development workshops they had attended. A participant from site F commented that,

> most workshops are how to get children excited about learning. This workshop goes beyond with a chain reaction. The instructor was excited, making the teacher excited, which in turn will make the students excited. Some workshops I have attended in the past, I felt like the teacher link was the smaller part. Each link needs to be equal to gain strength.

The most common theme coming from participants of workshops at sites B, C, and D was in regards to the usefulness of collaborating with other teachers: this was also the most common theme from the combined responses.

Overall, this initial analysis to investigate the MTC professional development model through a zone theory perspective highlights the possible impact that the MTC could provide to participating teachers in the ZFM and ZPA. In addition to the possibility of increasing participants' development and learning of mathematics and mathematical knowledge for teaching the exploration of other zones provides a framework to structure the future MTC workshops.

Conclusion

In this report we shared a theoretical approach to explore the MTC professional development model. The MTC model is an innovative professional development in which participants develop their abilities and beliefs on problem solving which are the main ideas of the ZPD. However, as previous research on effective professional development address the development in the ZPD is not enough to make change in teachers' professions and special focus and investigation are needed on the areas that are highlighted in the ZFM and ZPA. We use this zone theory approach was to gain insights on possible impacts of the MTC model. This particular approach provided a mean to understand aspects such as importance of engagement with other teachers and impacting teachers' personal motivation during their participation. This initial attempt needs further exploration by collecting data from facilitators of each MTC on the structure of the MTCs, observing each MTC during workshops and conducting follow-up interviews and surveys with the participants.

USING WRITING TO ENCOURAGE PSMTS' REFLECTIONS ON AMBIGUITY IN MATHEMATICAL LANGUAGE

Rachael H. Kenney

rhkenney@purdue.edu

Nick Montan
Purdue University
nmontan@purdue.edu

Literature suggests that the mathematical language of teachers impacts a student's understanding of math concepts. When teachers unintentionally use ambiguous language, students' understanding of a subject can be negatively affected. We share background on specific instances in which teachers can create confusion with the language they use, and we investigate both pre-service teachers' and college algebra students' concepts of three common terms in mathematics: Solve, Evaluate, and Simplify by asking both groups to unpack their understanding of these terms through a writing prompt. We compare the language used by both groups in their definitions. Preservice teachers' reflections on their experience with the writing prompt are also examined to identify ways that such a task can help them identify gaps in their own understanding and in their thinking about student learning.

Keywords: Teacher Education-Preservice, Classroom Discourse, Mathematical Knowledge for Teaching

Introduction

By the time students have entered a college mathematics class, we might assume that they have developed a clear understanding of some basic terminology. Similarly, as teachers we might expect that we also have a clear definition in our minds for the words we use in our academic language everyday. However, when pressed to really examine our understanding of certain terms, it is possible that several gaps in understanding may come to light.

Teaching requires a sensitivity to the need for precision in mathematics (Ball & Bass, 2003). Mathematical terms are perhaps more precisely defined than those in many other disciplines (Barwell, Leung, Morgan, & Street, 2005), and ambiguities can only be accepted when there are shared experiences and assumptions across a community of learners (Jamison, 2007). However, we know that simply reading or hearing a precise definition of a mathematical term does not guarantee that a learner will attribute the same given meaning to the term. Meaning-making is dependent on an individual's construction experiences surrounding such mathematical expressions (Brown, 1997). It is important for teachers to consider ways in which they may unintentionally influence students' learning through their own ambiguous use of terminology and academic language in mathematics. Even simple vocabulary can have a large impact on students' understanding (Boulet, 2007; Gay, 2008).

In this study, we discuss the use of a tool for reflection called *writing to learn mathematics* (WTLM) to help preservice teachers not only examine their own understanding of certain vocabulary terms but also investigate how college algebra students understand them. Our study is housed within a unique college teaching seminar that supports the development of preservice secondary mathematics teachers' (PSMTs) knowledge about both mathematics and pedagogy as they work as the instructor of a college algebra course. We are interested in how both PSMTs and college algebra learners define words that they have been using in mathematics for many years. Specifically, we examine the following three questions in this study: (a) How do college students (specifically college algebra students and PSMTs) define the common terms, *solve, simplify, and evaluate* in mathematics? (b) What are PSMTs' reactions when required to interrogate their own understanding of these common mathematical terms? (c) What can PSMTs learn from reading students definitions of the terms?

Background

Ambiguity in Mathematical Language

It is a common misconception in and out of the classroom that mathematics is a subject composed of "arcane rules for manipulating bizarre symbols something far removed from speech and writing" (Jamison, 2007, p. 45). This misconception places mathematics in a negative light. The meaning of mathematics almost literally gets lost in translation as vocabulary and terminology seem to take a backseat to the repetition of procedure and blindly following steps to solve a problem (Boulet, 2007). Jamison (2007) provides one suggestion for why students may struggle in mathematics classes:

> Ordinary speech is full of ambiguities, innuendoes, hidden agendas, and unspoken cultural assumptions. Paradoxically, the very clarity and lack of ambiguity in mathematics is actually a stumbling block for the neophyte. Being conditioned to resolving ambiguities in ordinary speech, many students are constantly searching for the hidden assumptions in mathematical assertions. But there are none, so inevitably they end up changing the stated meaning–and creating a misunderstanding. (p. 47)

The preciseness of math terminology juxtaposed with the implicit, sometimes vague definitions contained in natural language, may prevent students from developing adequate meanings; they are constantly switching between math and every day speaking. Problems may arise especially when there are shared meanings with everyday words, or when vocabulary used in natural language has a very different meaning in the mathematical context (Rubenstein, 2007). Table 1 shows some examples of potential vocabulary problems that teachers may overlook when trying to understand students' conceptual difficulties.

Table 1: Vocabulary Issues (adapted from Thompson & Rubenstein, 2000, p. 569)

Category of Potential Pitfall	Examples
Some words are shared by mathematics and everyday English, but they have distinct meanings.	*number*: prime, power, factor *algebra:* origin, function, domain, radical, imaginary *geometry*: volume, leg, right *statistics/probability*: mode, event, combination
Some mathematical words are related, but students confuse their distinct meanings.	*number:* factor and multiple, hundreds and hundredths *algebra:* equation and expression, solve and simplify *geometry:* theorem and theory *statistics/probability:* dependent and independent events

Students and teachers need to know the meaning of math vocabulary words and terminology in order to communicate in the classroom (Gay, 2008, NCTM, 2000, Thompson & Rubenstein, 2000). More specifically, it is important for teachers and their students to have the *same* (or at least similar) understanding of the words being used to convey ideas, objects, and actions. There is much literature devoted to the development of mathematical vocabulary, particularly in the context of students studying a field of mathematics (e.g., geometry, algebra, statistics) for the first time, or for students learning mathematics in a second language. However, by the time students are in college, we expect them already to have learned the basic vocabulary associated with a topic such as college algebra. In this study, the focus is not on teaching vocabulary, but on probing existing understanding of common vocabulary terms in mathematics.

It is challenging for beginning teachers with little classroom experience to skillfully incorporate academic language for productive discourse. Gay (2008) shares examples of witnessing such challenges when preservice teachers ask students to do such things as “Graph this expression” and “Evaluate 6^3, 12^4, and n^4 if n=3” (p. 218). She suggests the importance of helping pre-service teachers be aware of the impact of their use of vocabulary on their students’ learning and understanding and shares strategies she has used with preservice teachers to help them build their understanding of mathematics terms, such as graphic organizers, concept circles, and the use of analogies. Below, we discuss the use of writing in mathematics as an effective tool for unpacking one’s understanding of the language used in mathematics.

Addressing the Problem

Nathan and Petrosino (2003) posit that, “discursive and reflective methods that are already commonplace in professional development and teacher education programs can serve as the basis for interventions aimed at aligning teachers’ views with accurate models of student reasoning and development” (p. 924). *Writing to Learn Mathematics* (WTLM) is one such method that incorporates writing prompts into content and methods courses to support the understanding and teaching of concepts and procedures. Through writing, learners (including PSMTs) can engage with mathematical content in new ways (Author and colleagues). In alignment with WTLM, careful reflection on written work can influence perspectives on teaching and learning in mathematics. Researchers suggest that giving learners opportunities to write in the content domain can play a major role in helping them to develop their voice in that domain (Kaplan, Fisher, Rogness, 2009; Thompson & Rubenstein, 2000). And can play a significant role in advancing and assessing learning (Inoue & Buczynski, 2011; Miller, 1992). Incorporating writing in the mathematics classroom offers multiple benefits to PSMTs committed to understanding the diverse ways in which students learn, discover, and create.

Research on WTLM focuses heavily on benefits it provides to the students doing the writing (Inoue & Buczynski, 2011). Investigations have also focused on the benefits that teachers can gain from reading their students’ writings in mathematics (Adu-Gyamfi, Bosse, Faulconer, 2010; Miller, 1992, Quinn & Wilson, 1997). In this study, we take this further to look at what teachers can learn from engaging in the writing prompts themselves before giving them to students.

Theoretical Perspectives

We believe that well-developed subject- matter knowledge is critical for effective teacher preparation. However, as PSMTs develop more expertise in their field, they can easily forget what novice students find easy and difficult to learn in mathematics (Nathan & Petrosino, 2003). One reason to explicitly teach WTLM stems from the existence of such *expert blind spots* (Nathan & Petrosino, 2003), where “teachers’ subject-matter expertise often overshadows their pedagogical knowledge about how their novice students learn and develop intellectually in the domain of interest” (p. 906). PSMTs need opportunities to engage with mathematics in ways that interrogate and reframe their current understandings and to perturb their basic idea of “knowing” mathematics. WTLM provides a tool for both expanding content knowledge and assessing students’ understandings of mathematics (Miller, 1992).

Reflective practice is one means of supporting WTLM’s incorporation in the classroom (Quinn & Wilson, 1997). It allows teachers to consider the implementation of novel practices in the classroom (Foss, 2010). When enacted as “a deliberate way of thinking leading to change in action,” (Shoffner, 2008) reflection allows PSMTs to develop and refine the knowledge needed to guide their teaching (Spalding & Wilson, 2002). Thus, reflection can support PSMTs’ understanding of teaching mathematics through consideration of prior understandings, past experiences, and current beliefs (Stockero, 2008).

Working within a constructivist framework where learning is viewed as a process of transformation or modification of existing ideas, we see WTLM and reflection as powerful tools for perturbing PSMTs' existing ways of thinking in mathematics. They provide a way from them to interrogate understanding, enhance their thinking, and reflect on ways in which they and their students understand mathematics.

Methods

The participants in the study were senior PSMTs enrolled in a unique mathematics seminar at a university in the United States where they receive course credit to teach College Algebra. As course instructors, they were fully responsible for teaching the class to 20-30 students three days a week in 50-minute class sessions. They also had the added requirement of attending a seminar (taught by the first author) each class day to discuss pedagogical issues from the day and the mathematics that they would teach next. The College Algebra course was overseen by a course coordinator who designed the syllabus, pacing guide, and common exam and online homework sets. The added responsibilities for the undergraduate teachers were writing lesson plans, creating and grading their own quizzes twice a week, and proctoring exams.

Over the course of a semester, PSMTs were given WTLM prompts related to college algebra topics. In this study, we focus on the first prompt given, which dealt with mathematical vocabulary. We chose to address understanding of the common terms solve, simplify, and evaluate. The prompt given to the PSMTs was stated: **Explain the difference between the directions "Solve, Evaluate, and Simplify" in math problems. Then write an example using each with the expression 3(x+2)-x.** This question comes from a set of writing questions at the end of a chapter in Sullivan and Sullivan's (2004) algebra book. We chose it because of the target courses' focus on algebra and because confusion amongst these terms is mentioned in the literature (Thompson & Rubenstein, 2000).

After writing a response to the prompt in class, PSMTs engaged in collaborative reflection through asynchronous web discussions on a course wiki (c.f., Shoffner, 2008). They were asked to post their prompt response and post a reflection on the experience of answering the prompt, and were required to read and respond to other posts from their fellow PSMTs. They next created a quiz for their college algebra students (referenced below as "students") that included the same WTLM prompt, and posted another reflection on the WIKI to discuss that they had learned from reading their students' responses.

We collected prompt answers and reflections from 31 PSMTs over four semesters. These serve as our primary data source. In Fall 2014, we also collected prompt responses from 185 college algebra students. All data have been analyzed using content analysis to identify patterns in responses (Creswell, 2007) to address the research questions above. Our analysis included an examination of the following: (a) common language used to define the terms; (b) common misinterpretations of the terms; and (c) common themes in the PSMTs' reflections.

Findings

Definitions of Solve, Simplify and Evaluate

We examined the glossaries of several algebra textbooks to see examples of some formal definitions of the terms solve, simplify and evaluate. One McGraw Hill online algebra text gave the following three definitions: *evaluate* means to find the value of an expression; *solve* is the process of finding all values of the variable that make an equation a true statement; and *simplify* means to write an expression in simplest form. In comparison, we found that both the PSMTs and college algebra students used similar language in some of their definitions, but provided many more specific ideas from their experiences with these terms. Additionally, many of the college algebra students (and some PSMTs) struggled significantly with defining evaluate.

Table 2 shows a count of the number of acceptable vs. unacceptable/incorrect definitions.

Table 2: Response Results

	Unacceptable Definition			Acceptable Definition			No Definition Given		
	Solve	Eval	Simp	Solve	Eval	Simp	Solve	Eval	Simp
Students (N=185)	16	133	15	169	30	168	0	22	3
PSMTs (N=31)	1	5	0	30	25	31	0	1	0

Solve was not a difficult term for the PSMTs or students to define. Over 90% of both groups provided an acceptable definition – some formal, some very informal. Table 3 shows the most common language used across both the PSMTs and students. For example, a majority of both groups mentioned that solve involves either finding a value of the given variable (similar to the textbook definition above) or finding an answer/solution to the problem (without specific mention of variables). A small percentage (3.9%) of the students felt that solve and simplify were actually the same thing, and another 7.8% defined solve as producing an "exact" answer – neither of these ideas was found with the PSMTs. Both groups made use of the language of "isolating" the variable or "getting the variable on one side" in their definitions.

Table 3: Results for Solve

SOLVE	Same as Simplify	Find value of variable	Find an answer/solution	Isolate variable	Exact
Students (N=185)	7 (3.9%)	65 (35.7%)	67 (36.8%)	9 (5%)	14 (7.8%)
PSMTs (N=31)	0	12 (38.7%)	8 (25.8%)	7 (22.6%)	0

Simplify was also relatively easy for the both groups to define, with 91% and 100% providing an acceptable response. Interestingly, in their reflections, several PSMTs mentioned this term as the one that gave them the most difficulty. This was due to the fact that they did not know how to define it without using the word "simplify" in their definition. As seen in Table 4, we did find that the most common language used by the college algebra students was to get something into the simplest terms or simplest form, which matches the textbook definition above. However, we also found that 14.6% of the students and 9.7% of PSMTs referred to getting an "equation" in simplest form, rather than an "expression." It is possible that this could be partially explained by how the responders may have been thinking about the purpose the simplification - some members of both groups of learners made reference to a need to simplify first before solving an equation. Thus, their reference to an equation makes sense for them in this context

The most common language in the PSMTs definitions for simplify involved "combining like terms." They were also more likely to mention specific strategies for simplifying such as "factor" or "cancel," while a larger percentage of students used the language of "breaking it down" to describe what was happening. Both groups had members who referred to the idea of "reducing" in their definitions in some way.

Table 4: Results for Simplify

SIMPLIFY	Combine like terms	Reduce	Break it down	Simplest terms/for m	Involves an equation	Factor	Cancel

Students (N=182)	13 (7%)	28 (15.1%)	28 (15.1%)	85 (46%)	27 (14.6%)	20 (10.8%)	1 (0.5%)
PSMTs (N=31)	18 (58.1%)	8 (25.8%)	1 (3.2%)	13 (41.9%)	3 (9.7%)	12 (38.7%)	9 (29%)

Evaluate was the most difficult for both the PSMTs and the college algebra students. Only 16.2% of students provided an acceptable definition of this term, and while 83% of the PSMTs were able to come up with a suitable definition, their reflections after answering indicated that most of them struggled to do so in the task. When members of both groups did have an acceptable definition, it was common to find the language of "plugging in" in their answer. The most common incorrect responses among the students was that evaluate meant the same thing as solve (28.8%) or simplify (10.4%) (see Table 5). Only a small percent (3.7%) used the language similar to the textbook definition above, though all of these students said that evaluate meant to "find a value of the equation" (while eight out of the nine PSMTS who used this language said "find a value of the expression). What we found most interesting where the definitions that attributed a non-mathematical definition of evaluate to this term. Some examples include: "To evaluate an equation is to determine how you are going to solve the given equation;" "evaluate means tell what kind of problem it is"; and "evaluate is to analyze a given expression in order to find further information" (the latter was from the one PSMT who answered with a non-math definition).

Table 5: Results for Evaluate

EVALUATE	Same as Solve	Same as Simplify	Find the value	Non-math definition	Plug in
Students (N=163)	47 (28.8%)	17 (10.4%)	6 (3.7%)	16 (9.8%)	12 (7.4%)
PSMTs (N=30)	2 (6.7%)	0	9 (30%)	1 (3.2%)	10

PSMTs' Reflections After Answering the Prompt and Reading Student's Responses

We next analyzed the PSMTs wiki reflection posts to identify common themes in the ideas that they posted and discussed asynchronously with each other. The left column in Table 6 includes general forms of the most common themes found across the PSMTs' reflections after they answered the writing prompt or after they read their students' answers. These themes are paraphrased from PSMTs' writings, while the quotes in the right column are one example of a direct quote from a teacher that fits the theme. Each one here appeared in some form in more than five different PSMTs' reflections and was therefore identified in our coding as an area of interest.

Table 6: Common Remarks from PSMTs' Reflections

	Theme	**Example Quote**
Reflections on mathematical	I had a hard time differentiating among the three words	"At first, I really had no idea what the differences were between the terms."
	I had a hard time putting my answer into written words	"Once I started writing my ideas down, I felt stupid. I couldn't find the words to describe what the process was for each one."

understanding	I take things like this for granted	I think we are so conditioned to know what to look for we don't look at the directions unless we are confused... If [it says] 3(x+2)-x=0, we'd solve."
Reflections on pedagogy	This activity caused me to think about what I do or my own experiences	"I never realized how much informal language I use, and how I often find myself neglecting the more formal language of mathematics."
	I need to change what I'm doing in class	"I am going to be more strategic with the words I use in class to be sure that my students fully understand and that I am truly meaning what I am saying."
Reflections on student thinking	I can see why students struggle in mathematics	"Grading my quizzes today, I realized that a lot of students tried to factor when the problem was to expand or expanded when they were told to factor. I think if I had not done this prompt before grading, I might have been a little more judgmental. I probably would have thought: Can't these kids read directions?"
	If we change what we're doing, it will be easier for students to learn	"I think that by using the term evaluate, we can get our students to think about a problem more deeply."
	I learned a lot about the different ways that students think about mathematics	"When reading what the students write, I get to see an alternative way of thinking about a problem or a word, which helps me become a better educator."

As seen in the table, the PSMTs' reflections can be grouped into three main categories: reflections on their own mathematical understanding surrounding mathematical language/vocabulary; reflections on their own pedagogy; and reflections on their students' thinking and learning. The most common statement in the reflections (16 out of 31 PSMTs) was that struggling to define these terms made them feel like they were being placed in their students' shoes and that they could empathize with students' struggles. The second most common reflection focused on PSMTs' awareness that they have become too comfortable with terms in mathematics and the realization that they do not tend to pay attention to them in problem solving– instead they felt they usually let the mathematical symbols "tell" them what to do.

Conclusions

Teachers impact students in some obvious ways, but the focus for us is how they unintentionally influence students through ambiguous terminology and practices. Given the emphasis for a focus on developing student conceptual understanding and sense making in mathematics (NCTM, 2000), there is a critical need to understand and support effective practices that PSMTs can engage in to overcome their blind spots and enhance their content and pedagogical content knowledge in secondary mathematics. Our findings suggest that the use of writing prompts that unpack and encourage reflection on existing understandings of common mathematical terms can serve as one such effective practice to use in teacher preparation.

PRESERVICE TEACHERS' FRACTIONAL CONCEPTS IN SOLVING ADVANCED FRACTION PROBLEMS

Mi Yeon Lee

University at Buffalo
jiwonson@buffalo.edu

Talal Arabeyyat
University at Buffalo
talalhas@buffalo.edu

This study investigated how pre-service teachers' fractional concepts are related to solving problems involving advanced fractional knowledge. 96 Participants took a written test including three fractions questions about fraction concept, fraction comparison, and multiplicative relationship involving fraction quantities and composite units. The data were analyzed using an inductive content analysis approach. Findings suggest that many of our PSTs developed limited understanding of fraction sub-constructs and thereby were not able to solve the three problems. Another finding is that when PSTs relied on only one sub-construct such as part-whole, they tend to provide incorrect answers. This finding implies that PSTs' understanding of fractions as measure and operator may be a foundation of solving problems involving advanced fractional knowledge.

Keywords: Teacher Education-Preservice; Teacher Knowledge

Objectives or Purpose of the Study

The purpose of this study is to characterize profiles of the mathematical competence of pre-service teachers in the topic of fractions. Especially this study investigates how pre-service teachers' fractional concepts are related to solving problems involving advanced fractional knowledge. Since Shulman (1986) coined the notions of content knowledge and pedagogical content knowledge, many researchers have investigated what teachers know and how they know about mathematics and teaching mathematics over the past three decades. They reported teachers' insufficient knowledge about teaching mathematics, in particular, elementary in-service and pre-service teachers' lack of understanding about whole numbers, fractions, and fraction operations (e.g., Behr, Harel, Post & Lesh, 1993; Ma, 1999; Mack, 2001; Steffe, 2003).

This line of research studies suggests that teachers should develop a profound understanding of fundamental mathematics (Ma, 1999) and mathematical knowledge for teaching (e.g., Ball, Thames, & Phelps, 2008), which encompasses knowledge that teachers use in teaching practice such as selecting and using effective representations, deftly assessing students' work, and providing appropriate remediation. In particular, teachers' capability to solve problems differently and to use different representations of mathematical ideas is considered to be an important aspect of mathematics education. Empson (2002) highlighted that "the key in fraction instruction is to pose tasks that elicit a variety of strategies and representations" (p. 39) and, that representational models used by teachers (e.g., pizzas, number lines, and fraction bars) engaged and facilitated students' learning of initial fraction knowledge.

However, despite a large number of research studies focusing on teachers' problem-solving, representational knowledge, and computational skills (e.g. Eisenhart, Borko, Brown, Underhill, Jones, & Agard, 1993), several questions still remain unanswered regarding preservice teachers' ability to solve problems, their ability to translate from one mode of knowledge to another, and possible difficulties preservice teachers have in connecting different modes of knowledge. Lester and Kehle (2003) highlighted that "far too little is known about problem solving" and in particular, about teachers' problem solving strategies and their abilities to transfer in problem solving (p. 510). This issue should be addressed in the teacher education of preservice teachers of mathematics at all levels.

As a way to characterize profiles of the mathematical competence of pre-service teachers in the topic of fractions, this study investigates how pre-service teachers' fractional concepts are related to solving problems involving advanced fractional knowledge. The research questions that guided the study were: (1) How do PSTs solve fraction problems and what strategies do they use? (2) How does PSTs' conception of fractions relate to problem solving ability involving advanced fractional knowledge?

Theoretical Framework

Studies on Fractions (Five sub-constructs)

According to research, understanding fractions clearly indicates understanding five possible constructs that fractions can represent (Clarke, Roche, & Mitchell, 2008; Sibert & Caskin, 2006). Although the meaning of part-whole is dominantly used to represent fractions in mathematics textbooks, many mathematics researchers believe that students would understand fractions better when they are exposed to the other meanings of fractions (Clarke et al., 2008). The first construct is *part-whole*, which goes well with an example of shading parts out of a whole. The second construct is *measurement*. Measurement includes identifying a unit length and then iterating the unit length to determine the length of an object. The third construct is *division*. When considering a sharing context, people can connect division to fractions. For example, in the context of finding a person's share to fairly share 3 candy bars with 4 people, each person will receive ¾ of a candy bar. The fourth construct is *operator*. That is, fractions can be used to indicate an operation. For example, when John has $21 and Mary has 2/3 of John's money, Mary's money will be 14 dollars, which indicates 2/3 of 21 dollars. Students who represent "two-thirds the amount of 21 dollars as "2/3 x 21" may have developed a concept of a fraction as an operator. The last construct is *ratio*. That is, fractions can be used to represent part-part ratio or part-whole ratio. For example, when there are four red marbles and seven blue marbles, the ratio 4/7 could be used to indicate the ratio between red marbles (part) and blue marbles (part). Also, the ratio 4/11 could represent the ratio between red marbles (part) and total marbles (whole). In this study, we provided pre-service teachers with three fractions questions, which particularly used part-whole construct and operator construct. According to Usiskin (2007), operator construct is not stressed enough in school curricula although just knowing how to represent fractions using part-whole construct doesn't guarantee knowing how to operate with fractions in other areas of curriculum where fractions occur (Johanning, 2008).

Studies on Teacher Knowledge (MKT and CK)

Shulman (1986) put forward the idea that teachers have specialized knowledge of teaching, which is what differentiates a teacher from a subject matter specialist. This notion is referred to in his article as the distinction between *content knowledge, pedagogical content knowledge,* and *curricular knowledge. Content knowledge* is subject matter knowledge of mathematics. *Pedagogical content knowledge* is topic specific pedagogical knowledge needed to teach mathematics. *Curricular knowledge* refers to educational programs made for the teaching of specific subjects and topics at a given grade level, including instructional materials available in relevant programs, and affordances and constraints in the use of such specific instructional materials (Shulman, 1986). More recently, Ball and her colleagues (1990; 2008) proposed a new term, *Mathematical Knowledge for Teaching* (MKT), which is defined as "a practice-based content knowledge for teaching built on Shulman's (1986) notion of pedagogical content knowledge" (Ball, Thames, & Phelps, 2008, p. 389). Mathematical Knowledge for Teaching focuses on identifying students' mathematical thinking and on the understanding required to teach specific topics in mathematics. MKT distinguishes mathematical content knowledge into three strands: *common content knowledge*, *knowledge at the mathematical horizon*, and *specialized content knowledge*. C*ommon content knowledge* is described as the mathematical knowledge held in common with others who know and use mathematics in various professions or occupations, which is what Shulman meant by his original *content knowledge*. *Specialized content knowledge* is described as mathematical knowledge about the ways that mathematics is taught to students by a teacher. *Knowledge* *at the mathematical horizon* refers to an awareness of how mathematical topics are related over the span of mathematics included in the curriculum.

This study examines pre-service teachers' content knowledge such as specialized content knowledge and knowledge at the mathematical horizon. That is, our study focuses on pre-service teachers' specialized content knowledge in fraction concept (part-whole construct) and fraction comparison, and how this specialized content knowledge of different topics are horizontally related to advanced fractional knowledge, which deals with multiplicative and reversible reasoning involving fractional quantities and composite units.

Method

Participants and Contexts

Data from this study came from 96 PSTs from two different university sites. Participants were either in their sophomore, junior or internship year of elementary teacher preparation programs—one from at a large northeastern university and the other from at a large southwestern in the United States. Each PST was enrolled in an elementary mathematics methods course. Mathematics methods courses were designed to support PSTs' knowledge development for teaching elementary mathematics.

Data Sources

A written task was used for the study, which asks three important fractional knowledge: (1) Fraction comparison (recognizing the difference between the actual numbers and fraction of the number and comparing the size of fractions); (2) fraction concept (the concept of referent units to represent a partial portion of a whole in given area models); (3) Multiplicative relationships involving fraction quantities and composite units (reversible reasoning including composite units of fractions). The provided questions are as follows (see Table 1).

Table 1: Main Task of this Study

1. At both Rivers High School and Mountainview High School, ninth graders either walk or ride the bus to school. 6/7 of the 9th grade students in Rivers High School ride the bus, while 7/8 of the 9th grade students in Mountainview High School ride the bus. If there are 40 9th grade students who walk at Rivers and 25 9th grade students who walk at Mountainview, in which school do more students ride the bus? In which school do a greater fraction of the students ride the bus? Explain your strategies or solutions as much as in detail.
2. For each picture shown below, (i) write a fraction to show what part is shaded. For each picture, (ii) describe in pictures or words how you found that fraction, and why you believe it is the answer.

   (1)  (2) 
3. Merlyn spends $60 of her paycheck on clothes and then spends 1/3 of her remaining money on food. If she $90 left after she buys the food, what was the amount of her paycheck? Explain your solution method as much as in detail. You may use representations (e.g., diagrams, rectangles, number line etc.).

Data Collection and Data Analysis

Three questions about fractions were administered to the entire class in four mathematics methods course sections towards the end of the spring semester in 2014. Qualitative and quantitative analyses were conducted. In particular, for the written response, we used an inductive content analysis approach (Grbich, 2007). We initially organized raw data into an Excel spreadsheet, read all of the responses, and created codes based on the raw data. More specifically, data analysis involved five processes: (a) an initial reading of each PST's response, (b) identifying correctness of the responses, (c) exploring the subcategories under each analytical aspect according to the number of correct responses and their problem solving strategies that PST demonstrated, (d) coding the categories and subcategories, and (e) interpreting the data quantitatively and qualitatively (Creswell, 1998).

Summary of Findings

In this section, we present overall findings from the written task and detailed analysis depending on PSTs' cognitive levels in fractional knowledge. Because we divided the cognitive levels according to the number of correct answers among three questions, it would be helpful to be aware of what fractional knowledge is involved in each three question. The first question is focused on comparing the size of fractions and recognizing the difference of comparing the size of the actual numbers and fractions. To find in which school a greater fraction of the students rides the bus, students need to compare the sizes of the given fractions 6/7 and 7/8 using procedural knowledge or conceptual knowledge. However, to find in which school more students ride the bus, students may use measurement construct by focusing on unit fraction and iterations (multiplicative relationship). That is, considering the given fractions for bus riders at two schools were 6/7 and 7/8, students would be able to know that 1/7 and 1/8 indicates fractions for walkers, which corresponds to the number of students given in the questions, 40 students at Rivers and 25 students at Mountain view. Thus, students can find the number of bus riders by multiplying 40 by 6 or 25 by 7 because 6/7 or 7/8 can be created by iterating a unit fraction, 1/7 or 1/8 six times or seven times, respectively.

The second question is focused on concept of fractions, more specifically, understanding of referent units to represent a partial portion of a whole in the given area models. To find a fraction of shaded parts in the diagram, students need to pay attention to what is considered as a referent unit and how to represent the different sizes of continuously or discontinuously shaded portions using the same referent unit (a whole). Depending on students' cognitive levels, some students could solve this problem by finding the total area or portion of the shaded part or by finding fractions of each shaded portion and adding them together, or by finding a fraction of the smallest portion, setting it as a unit and counting the total number of the unit through iterations.

The third question is focused on understanding of multiplicative relationships and reversible reasoning when composite units of fractions are included. To find the amount of original paycheck, students need to know 2/3 of the remaining money equals \$90 because 1/3 of the remaining money was spent for food. Also, students need to understand that 2/3 is created by iterating a unit fraction (1/3) twice and thus the amount of money corresponding to 1/3 can be found by dividing \$90 by 2. From here, students will be able to easily figure out the amount of money corresponding to 3/3 and so the original paycheck can be found by multiplying 45 by 3 and adding it to 60 via reversible reasoning.

Among the three questions, we think the third problem is most difficult followed by the first and second questions. The third question requires understanding fractions as operators and requires multi-steps to solve the problem. The first question may be solved by either using measurement sub-construct or ratio sub-construct. The second question, which may be easiest, can be solved by relying on part-whole sub-construct. Because each question that we asked was created by focusing on specific fractional knowledge, we first divided PSTs' cognitive levels depending on the number of correct answers and further examined their strategies used to solve the questions. More specifically, we divided PSTs into three categories depending on the number of correct answers. PSTs who got all three correct answers were sorted into level 3, and PSTs who got two questions were assigned to level 2. PSTs with all incorrect answers to the three questions were considered at level 0. 19 PSTs were assigned to level 3 and 36 PSTs were assigned to level 2. Also, there were 28 PSTs corresponding to level 1 and 16 PSTs corresponding to level 0. In the next section, we present each level in more detail.

PSTs at Level 3

PSTs at level 3 demonstrated following features in terms of problem solving strategies and fractional knowledge across the three questions (see Table 1). PSTs at level 3 demonstrated a good understanding of fractions as part-whole, measure, and operator in solving problems. In particular, they tended to often use multiplicative reasoning, which is related to iterations in the measure construct to solve word problems involving fraction quantities. Also, the PSTs showed that they had a clear concept of unknown and were able to create equations to find unknowns based on the concepts of unknown and the understanding of fractions as measure and operator.

Table 2: Features of PSTs at Level 3 in problem solving strategies and fractional knowledge

Level 3	Features
Fractional knowledge	• Understand the part-whole construct of fraction • Understand the measurement construct of fraction by using iteration (multiplicative reasoning) to solve the problems • Understand the operator construct of fraction by considering fractions as a multiplicative operator on knowns or unknowns • Have a concept of unknown and create equations to find the unknowns
Problem solving strategies	• Understand problem clearly • Often use drawing to make better sense of the problem situations • Tend to use multiple ways of solving the problems

Regarding fractional knowledge used to solve each question, in the first question, PSTs at level 3 compared the size of two fractions by using a conceptual strategy (i.e. 1/7 is bigger than 1/8 and thus 7/8 should be greater than 6/7 because 7/8 took out less fraction than 6/7), converting fractions into decimals (i.e. 7/8 [= 0.87] is greater than 6/7 [= 0.85]), or finding common denominators procedurally (i.e. 7/8 [=49/56] is greater than 6/7 [=48/56]). However, to find in which school has more bus riders, most PSTs tended to identify a unit fraction for walker from the given information and use the multiplicative relationship to figure out the number of bus riders at two schools (Figure 1).

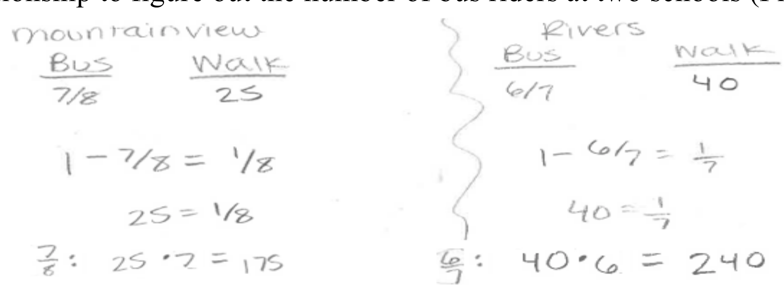

Fig. 1 Solution to find in which school has more bus riders in question 1.

Also, in solving the second question, most PSTs used a strategy to divide all parts into small equal sizes (1/16 or 1/32), set the equal size as a unit, and count the number of iterations of the unit (See Figure 2). This strategy shows that PSTs at level 3 understand measurement construct of fractions.

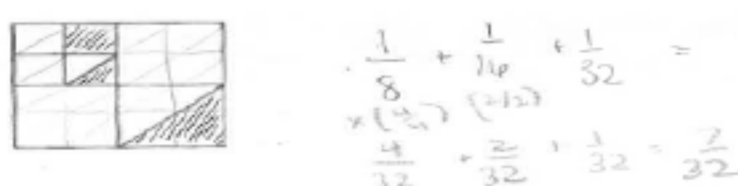

Fig. 2 Solution to find a fraction of shaded parts.

Finally, in solving the third question, two-thirds of PSTs found the amount of original paycheck by using multiplicative relationship from measurement construct of fraction. For example, PSTs first found the amount of money corresponding to 1/3 of remaining money by using the multiplicative relationship that 2/3 can be created by iterating 1/3 twice and the given information that \$90 is 2/3 of the remaining money. Then PSTs added the money spent on clothes (\$60) to the entire remaining money, which consists of 2/3 (\$90) and 1/3 (\$45). Figure 4 presents PSTs' solution method where they use their understanding of unknown and operator construct of fractions. PSTs set variable x as the original paycheck that she wanted to find and then represented the amount of money spent on food as (x-60) × 1/3 by considering 1/3 of remaining money was spent on food after spending \$60 on clothes.

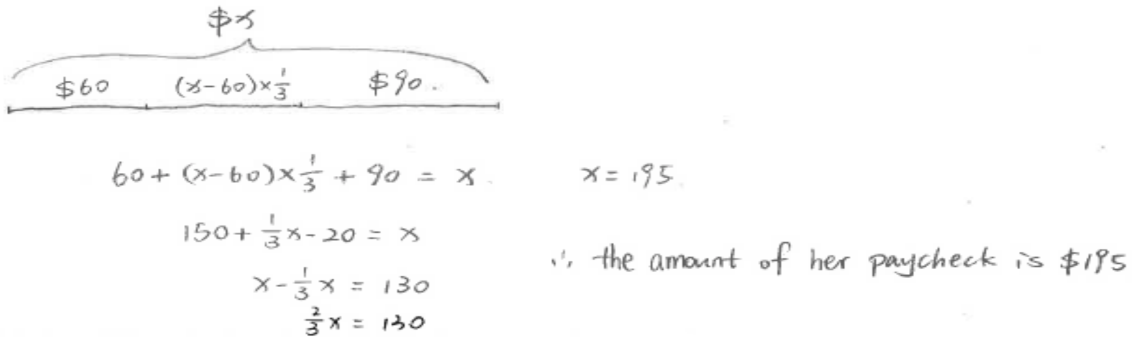

Fig. 3 Solution to use unknown and operator construct of fractions in question 3.

PSTs at Level 2

PSTs at Level 2 got two questions out of the three questions. We divided three sub-categories within level 2 depending on which questions PSTs got. For example, level 2-1 designates PSTs who got correct answers in both questions 3 and 2 (level 2-2: PSTs who got a correct answers in question 3 and 1 / level 2-3: correct answer in question 1 and 2). Although there are three sub-categories in level 2, we consider level 2-1 is highest, followed by level 2-2 and 2-1 due to the problem difficulty, which will be explained in detailed. We observed many similarities between PSTs at level 3 and those at level 2-1. 15 PSTs at level 2-1 demonstrate a good understanding of fractions a measure and an operator. However, these PSTs did not understand the problem correctly to question 1 and provide only one of the two sub-questions. With respect to problem solving strategies, they tended to represent the problem using drawing and solve each problem in multiple ways.

However, PSTs at level 2-2 seem not fully understand fractions as an operator. Although four PSTs provided a correct answer to the question 3, which requires multi-step multiplicative thinking, they often ignored denominators and solved it like whole number problems. 5 PSTs were categorized at level 2-1 where they were not able to recognize known and unknowns in correctly. In solving question 3, they showed difficulty in using measurement concept (e.g., 2/3 is twice of 1/3). In solving question #1, they relied on guess and check by either using given fractions.

PSTs at Level 1

PSTs at Level 1provide only one correct answer and consequently three subcategories exist in this level. For example, level 1-1 indicates PSTs who got a correct answer in question 1; level 1-2 includes PSTs who got a correct answer in question 2, and level 1-3 with PSTs who got a correct answer in question 3). Because each problem requires different level of problem difficulty, we consider PSTs at 1-3 is the highest level followed by those at level 1-1 and at 1-2. 13 PSTs were at 1-1; eight were at level 1-2; and six were at level 1-3. Table 3 shows the features of problem solving strategies and fraction knowledge at this level.

Table 3: Fractional knowledge and problem solving strategies by PSTs at Level 1

Level/Description	Features
1-1: Correct answer to question 1 (Middle)	*Fractional knowledge* • Be able to apply fraction as a ratio and measurement. • Yet, show lack of understanding of fraction as operator/ multiplicative thinking. *Problem solving strategies* • Although some used logical reasoning, rely on guess and check.
1-2: Correct answer to question 2 (Lowest)	*Fractional knowledge* • Develop an understanding of fraction as part whole. • Understand the measurement construct of fraction by using iteration (multiplicative reasoning) to solve the problems. • Lack understanding of fraction as measurement, operator, or ratio. *Problem solving strategies* • In solving # 2, relying on visualization by rearranging all parts together to form one simple fraction or viewing half of 3 squares. • Often do not understand the problem correctly. • Make computational errors/ Misrepresent the multiplicative relationship.
1-3: Correct answer to question 3 (Highest)	*Fractional knowledge* • Have some understanding of multiplicative thinking involving fractions. • However, have limited understanding of fraction as ratio or measurement. *Problem solving strategies* • Tend to use guess or backward/ Often do not recognize the problem correctly. • Misrepresent the second denominators.

PSTs at Level 0

15 PSTs were categorized at Level 0 where none of the answers are correct in the three fraction problems. In Question 1, these PSTs showed limited understanding of fraction as a ratio or measurement by either focusing on only one part of the two. In solving the question 2, they tended to miss the denominator and consider the problem as involving whole numbers. In solving Question 3, they showed lack of understanding of unknown and were not able to construct or solve algebraic equation. In particular, most of these pre-service teachers failed to identify the multiplicative relationship by recognizing the referent unit incorrectly.

Discussion and Concluding Remarks

In this study, we investigated how pre-service teachers solved three fraction problems that require different sub-constructs. By tracing their correctness and problem solving strategies in the three problems, we also explored how PSTs' use of fractional concepts is related to solving problems involving advanced fractional knowledge. First, we found that many of our PSTs developed limited understanding of fraction sub-constructs and thereby were not able to solve the three problems. Another finding is that when PSTs relied on only one sub-construct such as part-whole, they tend to provide incorrect answers. Based on our findings, we hypothesize that PSTs' understanding of fractions as measure and operator may be a foundation of solving problems involving advanced fractional knowledge.

This exploratory case study investigated the role of mindset (i.e., fixed mindset vs. growth mindset) as elementary teachers participated in a professional development focusing on mathematics. Data were collected on two participants with opposing mindsets. Attention was given to their interactions in collaborative group settings as well as their views regarding working with successful and struggling mathematics students. Results indicated that although the two participants engaged in the same professional development activities, their engagement led to different interactions within those activities.

Keywords: Teacher Beliefs; Teacher Education-Inservice

Introduction

To support all students in developing deep mathematical understanding, "students [must] have access to a high-quality mathematics curriculum, effective teaching and learning, high expectations, and the support and resources needed to maximize their learning potential" (National Council of Teachers of Mathematics [NCTM], 2014, p. 59). Although the literature abounds with descriptions of effective teaching and learning (e.g., Franke, Kazemi, & Battey, 2007;NCTM, 2000, 2014; National Research Council, 2001), teacher educators recognize that for most mathematics teachers the classroom practices described in the literature represent a reconceptualization of mathematics teaching (Sowder, 2007). Professional development (PD) is a key mechanism for supporting teachers' development of effective teaching practices (Loucks-Horsley, Stiles, Mundry, Love, & Hewson, 2010;Sowder, 2007) and equity in mathematics.

PD experiences that are sustained, focused on worthwhile tasks, and provide immersion experiences in productive teaching practices can challenge teachers to transform their practice (Elmore, 2002; Hawley & Valli, 1999; Loucks-Horsley et al., 2010). Despite these known characteristics of effective PD, supporting change in mathematics classrooms continues to be daunting (Franke et al., 2007). Cooney (1999) posited that teachers' belief in teaching as an act of giving information to students represents an obstacle to change in the mathematics classroom. Sowder (2007) stated, "Many of teachers' core beliefs need to be challenged before change can occur" (p. 160). Recognizing that a teacher's beliefs influence his or her perceptions of effective instruction (NCTM, 2014;Pajares, 1992), much research on PD has sought to address changes in teachers' beliefs and changes in instructional practice, with varying results (see Philipp (2007)).

Recently, *mindset* has emerged as a term used to describe the belief that either mathematics ability can be cultivated in all students or mathematics ability cannot be changed (Dweck, 2006). NCTM (2014) reported research showing that "believing in, and acting on, growth mindsets versus fixed mindsets can make an enormous difference in what students accomplish" (p. 64). Responding to these different mindsets may be an important notion for progressing the field forward. Just as teachers' differing beliefs influence their PD experiences, we wondered how teachers' differing mindsets influence their engagement in PD experiences. The purpose of this study was to examine how teachers with opposing mindsets interacted with the content of a PD. Specifically, the research question that guided our work was: How do elementary teachers of different mindsets interact in a mathematics-focused PD?

Theoretical Framework

Dweck and Leggett(1988)described a social-cognitive model of motivation and personality that framed a theory of implicit conceptions of the nature of ability based on work in goal orientation and behavioral patterns. This implicit theory and its research base continues to support work in fields including educational psychology and mathematics education (e.g., Aronson, Fried, & Good, 2002; Blackwell, Trzesniewski, & Dweck, 2007; Dupeyrat & Mariné, 2005). The evidence supporting its generalization to other domains (Dweck, Chiu, & Hong, 1995; Dweck & Leggett, 1988) and the instrument used to measure its constructs (Dweck et al., 1995) provided the theoretical framework for this study.

Dweck and Leggett (1988) posited that an individual's implicit assumptions about the nature of an ability lead directly to the type of goals he pursues regarding that ability and the behaviors he exhibits when faced with challenges (Dweck et al., 1995; Dweck & Leggett, 1988). They described the *entity* and *incremental theories*. Individuals assuming an entity theory tended to view attributes as fixed, uncontrollable entities and adopted performance-oriented goals to gain or avoid judgment regarding the ability. In contrast, individuals espousing an incremental theory tended to view attributes as malleable and subscribed to learning goals focused on improvement of the ability (Dweck, 1986; Dweck & Leggett, 1988). These mindsets and their associated goals created "a framework for interpreting and responding to events" (Dweck & Leggett, 1988, p. 260) that promoted observable behavioral patterns when the ability under consideration is challenged. Maladaptive, *helpless* responses characterized by lowered performance and the avoidance of challenges were associated with entity theories. Their adaptive counterparts, *mastery-oriented* responses, were associated with incremental theories and characterized by the pursuit of challenges and persistence when faced with failure (Diener & Dweck, 1980; Dweck, 1975; Dweck & Leggett, 1988).

Although the tenets of implicit theories were initially established through the characterization of an individual's own intelligence, Dweck and Leggett(1988) proposed a framework through which its generalization to other attributes and domains occurred, culminating in the validation of an instrument used to assess individuals' implicit theories for multiple attributes (Dweck et al., 1995). The authors predicted that for any attribute of personal significance, "viewing it as a fixed trait will lead to a desire to document the adequacy of that trait, whereas viewing it as a malleable quality will foster a desire to develop that quality" (Dweck & Leggett, 1988, p. 266). Additional evidence supported that the model holds for generalization to traits beyond the self, such as the character and attributes of other people and the world (Dweck & Leggett, 1988; Erdley & Dweck, 1993). This application of the model suggested further observable characteristics of an individual's interactions based on their implicit theories. Those with fixed mindsets should be seen to reject change in themselves and others and draw simplified conclusions from brief experiences. In contrast, those with growth mindsets should be seen to encourage growth in other individuals and organizations and experience a sense of control relative to their environment (Dweck & Leggett, 1988).

Methodology

To examine the role of mindset in PD, we used case study methodology, specifically a holistic, multiple-case design (Yin, 2014). We viewed this as an exploratory case study, with the purpose "to identify research questions or procedures to be used in a subsequent research study, which might or might not be a case study" (Yin, 2014, p. 238).

This study occurred within a PD project serving 82 kindergarten through sixth grade mathematics teachers. The project was in its second year of external funding and represented a partnership between a university and four rural school districts in a southeastern state. Although the project included academic year meetings and demonstration lessons, the project component of focus in this report was the ten-day summer institute occurring during the second year of the project in which teachers met in grade-level groups (i.e., K–2, 3–4, 5–6) and engaged in immersion and practice-based experiences (Loucks-Horsley et al., 2010), with a mathematical focus on fractions and their operations.

The twelve-item Likert style mindset survey included Dweck et al.'s (1995) nine items related to mindset in relation to intelligence, morality, and world. (For evidence of reliability and validity see Dweck et al.) In addition, we created three survey items pertaining to a teacher's point of view of their students' mathematical abilities. The addition of these items is supported by the work of Dweck and Leggett (1988).

We developed four semi-structured interview protocols along with an observation protocol for data collection. Interview questions related to participants' strong academic students, struggling students, and their role as mathematics teachers working with these students. The observation protocol, employed during observation of participants in PD activities, consisted of six categories: evaluation of situation, dealing with setbacks, challenges, effort, criticism, and success of others. In each category, observable behaviors for each mindset were recorded. Participants were video-recorded during institute activities.

On the first day of the summer institute all teachers completed the mindset survey, which was scored following Dweck and colleagues' (1995) protocol. Four participants representing each mindset were interviewed and then two teachers, Ms. Fitzgerald (fixed mindset) and Ms. Gorman (growth mindset) were selected. Both Ms. Fitzgerald and Ms. Gorman (pseudonyms) participated in the grades 5–6 PD group, which had as its primary focus the modeling of multiplication and division with fractions. At the time of the study, Ms. Fitzgerald, a Caucasian female, had completed eight years as a classroom teacher and Ms. Gorman, an African American female, had completed nine years of classroom teaching.

To analyze the data, we drew on the organization and analysis procedures described by Yin (2014). We developed a case study database for each participant, organizing and compiling all data chronologically. We began by employing an inductive strategy for analyzing participant interviews. This strategy led to the development and refinement of a set of codes representing relevant concepts. In addition, we relied on our theoretical framework to guide the analysis of interviews and observation data, identifying evidence of both fixed and growth mindsets. The validity and reliability of our findings are supported by the use of multiple sources of evidence (construct validity), replication logic (external validity), and a case study protocol (reliability).

Results

In this section, we present the results from our analysis. Each case will be presented separately, organized according to the three themes that emerged during analysis: intelligence, goals, and challenges.

Ms. Fitzgerald (Fixed Mindset)

Intelligence. When asked if intelligence was something that could change, Ms. Fitzgerald stated, "I don't think so. I think it's something that you are born with and what you learn through school is what you learn." During her interviews, Ms. Fitzgerald distinguished between students who were naturally talented at mathematics and those who were talented at literacy:

> I think that you are either literature based or you're mathematically based. . . . The literature-based [students] are slower learners. . . . The mathematically based [students], they can do it through

> computations. They can do it with manipulatives. They can usually draw diagrams.

She also spoke of instructional practices related to students of different ability levels.

> I would give [students in the high ability group] a higher level task and give my inclusion group a lower level task. But all that was aiming towards the same goal. . . . For my inclusion group, I might pull a fourth grade task on perimeter versus my high group, I might pull a sixth grade task. And then my middle group, keep them on target with a fifth grade task. But in the end, we are all working towards the same goal.

Ms. Fitzgerald indicated that students have a tendency to disengage when faced with challenging material, thus leading to behavioral issues. In addition, as she reflected on her own frustration when faced with a challenge, she said: "Now I see how my kids get frustrated. . . . I think that I would back off a little bit if a task seemed to be too difficult for them. I don't want them to get this frustrated."

Goals. Ms. Fitzgerald indicated that she was guided by performance-oriented goals for herself and her students, which was evidenced in three ways. First, Ms. Fitzgerald focused on solutions to problems. She said:

> I would let [the struggling students] do their own models first but we might go to an algorithm a little bit quicker with them and try to work backwards if they can't get the models on their own. Solve the problem and then try to create a model that matches and then hopefully later on they could go to the model first.

Ms. Fitzgerald indicated that if a student cannot draw the model right away, then she has the student find the solution using an algorithm, thus emphasizing the model as another procedure to be learned. Then, the student can use the solution as a means for drawing the correct model.

Ms. Fitzgerald also placed a great emphasis on testing and algorithmic proficiency. She stated:

> I go straight to the algorithm and I would like for my kids to have different ways to do it because when it comes time for [the state's constructed response assessments], they can't just do the algorithm. They have to be able to draw some type of model or picture.

She saw her instructional role in working with the students as guiding them to the answer.

> I have to step away and let them do their thing, not tell them the right answer, step back, let them struggle a little bit, and guide themselves to the correct answer. And if they get it wrong, it's ok. . . . I might give them an easier task the next day, something that's still within . . . the same unit, but something that may be a little easier, not as confusing for them. After that, lead into some instruction because they always have to have some instruction.

Challenges. During the PD, Ms. Fitzgerald faced the challenge of developing models (i.e., either pictorial or concrete representations) for fraction problems involving multiplication and division. Ms. Fitzgerald consistently demonstrated helpless responses. She made statements such as, "I couldn't tell you because I don't know," and "Yeah, but that's probably not right," which indicated a negative self-cognition. In addition, Ms. Fitzgerald offered statements that seemed to be intended to divert away from the discussion such as, "I'm more of an algorithm person," and, "I need to go to the K-2 class and then maybe I can do something in there." When selected to respond during the institute, she would offer statements such as "We're nowhere yet" and "I'm thinking I don't know."

Ms. Fitzgerald expressed continued frustration when faced with the challenge of drawing models. "I can't read the models. I can't draw the models. So I was very frustrated. That made it hard to participate in the tasks and the problem sets." Similarly, Ms. Fitzgerald stated, "Because I've tried – like our problem sets, you have to draw the model, no algorithm and I just look at it and go – oh, I'm defeated again today, I can't do my homework." When asked how she might overcome the challenge, Ms.

Fitzgerald said, “Um, just forge ahead and really try to wrap my brain around it.” She also indicated that more time should be spent “breaking [the model] down and simplifying it to where everybody can understand it.”

Ms. Gorman

Intelligence. When asked if intelligence was something that could change, Ms. Gorman stated, “I look at this as saying people can make mistakes, and you can learn from your mistakes, and you can change.” She explained that although some students understand procedures more quickly, *all* students can gain a stronger understanding of mathematics through struggling with difficult material and exploring and explaining their thinking.

> I think that in the long run they would have a better understanding of math, they would have the critical thinking skills to think through it, whereas some of the others . . . they could do the procedures but couldn't explain why. . . . I had some [high ability] kids who, at the beginning of the year, 'The answer is 24', 'How do you know that?', 'I just know.' They knew the procedures of it, they could tell you the answer, but couldn't explain. It didn't mean anything. . . . I was almost excited when they would get something incorrect because that gave me the chance to help them think through it.

Ms. Gorman’s goal of supporting all students in understanding mathematics led her to describe her instructional practices in working with low achieving students.

> Definitely take some steps back. . . . Let them struggle. . . . to a degree. . . . you don't want them to struggle so much that they're like "I'm done." But to let them struggle to see if they can figure out – a way of persevering through it. And then offer my help and then walk away.

Ms. Gorman described her own struggles in working with high-ability students:

> This past year I had five [high ability] kids, which is a lot to have in one room. They were very procedural and what I found was hard for them was, they were like 'I just know,' but they couldn't visually show me or tell me why. . . . So, with them, having more advanced type tasks, questions, or even be able to have questions to be able to ask them, I think that's one of my struggles. Even though I know I'm supposed to ask advancing and assessing questions, I think that even when I'm looking at it I have a hard time being able to pinpoint what question to ask at that moment quickly and walk away.

Goals. Ms. Gorman’s statements suggested that she was guided by learning-oriented goals, as indicated by her tendency to focus on developing mathematical understanding. She described the role of student exploration and explanation in developing this understanding and linked these to changes in her instructional practice.

> Being able to connect with how they are thinking, I would say it's a lot more engaging, just because I am pulling it out and trying to find manipulatives, and getting the kids to explain their answers, and I've been trying to share with the kids multiple ways that they can get to it, and I usually don't share until they open the door first. So, I kind of build off of their ideas.

She indicated her role in working with students was to ask good questions and serve as a guide.

> So as far as my teaching strategies go, it's just taking some steps back, making sure I'm asking the right types of questions, to get the kids to go in a certain path, so even if they're steering off the wrong way my questioning needs to be correct in that I'm pointing them back in the right direction. If they have no clue at all, you know, just helping them to find that starting point without giving too much. And without them always using my strategy.

Finally, she acknowledged the role of drawing models in supporting the development of mathematical understanding. The models served as a tool for making sense of the mathematics and making connections.

> A lot of times I think . . . the lower kids tend to not have number sense or not really know what the numbers represent. And so with pictures, and things like that--with the labeling--I think that would help them to progress to a better understanding of what it is they're doing.

Challenges. When discussing the challenges associated with understanding the models for multiplication and division of fractions, Ms. Gorman's responses most often could be categorized as mastery-oriented responses. Ms. Gorman attributed her struggles with understanding the models to the fact that she had not been taught these models as an elementary student. She said, "I feel like I'm trying to figure some of these [visual models] out because I was not taught that way. . . . I thought I knew math. I do not know math the way I thought I knew math."

She felt it was important, however, to understand the models so that she could utilize them in her classroom.

> I don't [understand] the pattern blocks. . . . I would not use those in my classroom because I would feel like if I could not explain it to the kids with a clear understanding – because that to me would become one of the tools that they could use to figure out the problem. But they can't use something if I can't explain it efficiently.

During summer institute sessions, she frequently continued to work with one particular model until she felt sure, even as others around her moved on to a different representation.

In reference to the variety of models displayed by her peers, Ms. Gorman described herself as being overwhelmed as her lack of understanding had been exposed and she aimed to understand all of the different models.

> I'm very overwhelmed. Just in the sense of – obviously I know how to divide and multiply fractions – but having to show pictorially how to multiply and divide fractions is totally different. Because I never have really had to do that. . . . And then another thing that was overwhelming is that you are passing these posters around and you are looking and somebody like me whose mind is just constantly going and I see a different way to work out something then I'm like – ooh! You know, I want to work it out this way. And then there's another way. And then another.

She believed that to overcome the challenge she needed more practice with the models. She said, "Before I took it to the classroom I would need some more practice . . . just so I could feel comfortable in what I'm saying, so that they could try it and understand what they were doing."

Discussion and Conclusion

Supporting all students in learning meaningful mathematics is a daunting task, and one that requires a shift in how teachers view effective mathematics teaching (Sowder, 2007). PD represents the primary means towards supporting teachers in developing this view (Loucks-Horsley et al., 2010) and much is known about key components of effective PD (Elmore, 2002; Hawley & Valli, 1999; Loucks-Horsley et al., 2010). The impact of PD is often hindered, though, as a result of teachers' beliefs about instruction (Sowder, 2007). Although much research has examined the role of beliefs in teachers' PD (Philipp, 2007), the role of mindset has only recently emerged and has yet to be examined in this way.

As a result, the purpose of our study was to examine how teachers' mindsets influenced their participation in a PD setting. Throughout the PD, the teachers worked with representing the multiplication and division of fractions with models, a task to which many teachers had not been previously exposed. In this sense, Ms. Fitzgerald and Ms. Gorman were no exception. They each described the uncomfortable feelings associated with not knowing; yet how they responded to this challenge was quite different. Ms. Fitzgerald spoke of frustration, stating continuously that she did not understand the models and that she preferred to utilize algorithms. Ms. Gorman spoke of being overwhelmed, providing statements that demonstrated her persistence in trying to understand the variety of models available.

Additional differences between the two participants emerged when considering the purpose of understanding the models. Ms. Fitzgerald seemed to see the development of a model as an additional process for students to learn; a process that was needed in order to be successful on state assessments. Ms. Gorman indicated that the development of a model supported the development of students' understanding. Interestingly, Ms. Fitzgerald believed that students who understood mathematics made connections among the models and the algorithms. Unlike Ms. Gorman, however, she did not see this as an indication that students struggling with mathematics might benefit from tasks or activities that supported them in making those same connections. Rather, she felt these students did not hold the potential for understanding mathematics and instead needed more practice with the procedures.

These contrasting views influenced the instructional practices described by the two participants. While both mentioned the role of struggle in learning, Ms. Fitzgerald aimed to support her students in avoiding struggle, for example through the use of easier tasks. This practice was likely influenced by her belief in the inability to influence students' mathematical abilities. Rather, each student's achievement level should be identified and then appropriate tasks assigned. Ms. Gorman described the importance of productive struggle in supporting the learning process. Thus, students' mathematical abilities could be shaped by their learning experiences.

Across the three areas in our analysis (i.e., intelligence, goals, and challenges), the differences between views expressed by the two participants can be attributed to their opposing mindsets. Ms. Fitzgerald's propensity to see intelligence as unchangeable is clearly linked to her fixed mindset, along with her performance-oriented goals and helpless responses. Similarly, Ms. Gorman's view that intelligence is changeable combined with her learning-oriented goals and mastery oriented responses is clearly aligned with her growth mindset. As a result, the opposing mindsets resulted in different PD experiences.

The findings for this exploratory case study lead us to ask more questions. First, we believe that Ms. Gorman and Ms. Fitzgerald left the PD with greatly different experiences. How will the differences we observed in Ms. Gorman's and Ms. Fitzgerald's interactions during PD carry over into their classroom practice? In *Principles to Actions*(NCTM, 2014) explicit connections are drawn between growth mindsets and mathematical success for all students. Further, Blackwell, Trzesniewski, and Dweck (2007) reported being able to manipulate mindset. What interventions can we include in PD so that we orient teachers toward a growth mindset? How might findings from these questions impact future PD and even work with pre-service teachers? Finally, how can we help teachers build ways to work productively with students of different mindsets? Knowing that "believing in, and acting on, growth mindsets versus fixed mindsets can make an enormous difference in what students accomplish" (NCTM, 2014, p. 64), we must also continue to follow this investigation into the differences that can be made in what teachers accomplish when attention is given to mindsets.

AN EXPLORATORY ANALYSIS OF A VIRTUAL NETWORK OF MATHEMATICS EDUCATORS

Anthony V. Matranga
Drexel University
avm43@drexel.edu

Emmanuel Koku
Drexel University
emmanuelkoku@drexel.edu

This study is part of a larger research design project that aims to cultivate an online community of mathematics educators. The purpose of this smaller study is to suggest interventions that will further support community cultivation efforts. Social network analytical methods are used to study project participants' interactions in virtual spaces. Investigation focused upon the connectivity of network structure, the most prominent members of the network, the presence of a core-periphery structure and the relationship between participant types and prominence. Analysis suggests that supporting interactions between newly involved and more long-standing participants will enhance community cultivation efforts. And, four participants emerged as most influential in the network, therefore being most effective in controlling and spreading novel information. These participants are suggested to receive additional professional development.

Keywords: Teacher Education-Inservice

Educational research and policy call for mathematics instruction to be student-centered, with a focus on argumentation and negotiation. While these calls were made over two decades ago, classroom instruction still does not reflection this “reform” oriented vision of classroom instruction (Stigler & Hiebert, 1999). One initiative that has shown promise in supporting teachers in shifting instructional orientation from teacher-centered to student-centered is engagement in community. Involvement in community provides opportunities for teachers to critically examine daily instructional issues, analyze student work, and plan mathematics tasks to support learning. While community engagement has been linked with improved instructional strategies (Vescio, Ross, & Adams, 2008), there is a lack in understanding of how to support emergence of teacher communities, particularly those that take place in online mediums.

This study is part of a larger research project that implements and innovative professional development (PD) model designed to cultivate an online community of mathematics educators. Due to extensive interactional data available from the larger study, and a particular focus on structural features of the network, we used social network analysis to investigate the patterns of interactions within the network. Social network analysis is a quantitative analytical method derived from graph theory used to study the structure of social networks (Scott & Carrington, 2011). Taken together, social network analysis can provide data about relationships in social networks that can be informative for future interventions that would not have been evident by other investigatory approaches. From an educational researcher's perspective, structural information about teacher networks is crucial for the implementation of interventions designed to foster community cultivation. For example, if teachers are identified as being sparsely connected, an intervention can be designed to support interaction between these teachers in order to improve the flow and access of information in the network as a whole. Interventions that serve the purpose of the one just mentioned may be critical in the process of cultivating a community of educators. Part of the purpose of this research is to make such suggestions for interventions.

The analytical methods briefly introduced here (and further elaborated in the methods section) serve as the backdrop against which research questions are formulated to focus investigation in this study. Consequently, this study seeks to answer the following research questions:

- What are some of the structural properties of the social network?
- Who are the most central members of the participant network?
- To what extent is a core-peripheral structure present in the network?
- What is the relationship between participant type and centrality?

Literature Review and Conceptual Framework

This study is informed by literature on sociocultural learning theories (i.e. communities of practice and situated learning) and social network theory. These theories provide the conceptual lens to understand the structural relationships in the community of mathematics educators, and provide insights for interventions aimed at improving dissemination of instructional strategies and learning in the MathCom network.

Communities of practice

Communities of practice is a social perspective of learning that hinges learning upon individuals' enculturation into a community through increased participation within a social group. Three characteristics distinguish a group of individuals from a community of practice: mutual engagement, joint enterprise and shared repertoire (Wenger, 1998). Mutual engagement refers to the notion that communities develop and are maintained around engagement in shared practices. Engagement in meaningful activities of a community requires particular competencies that are valued by the community. Understanding of such competencies can be measured by the extent to which one interacts with community members. Therefore, identifying participation patterns both provides a sense of individuals' level of understanding of communal practices and the strength of community structure. Joint enterprise and shared repertoire refer to common goals, beliefs and a shared set of tools, respectively. While evidencing these aspects of community relies on more qualitative research, social network analysis is useful for investigation of mutual engagement to identify patterns of interactions (Wenger, Trayner, & de Laat, 2011).

Legitimate peripheral participation (LPP)

Communities of practice have a particular structure that is conducive to sustaining and maintaining engagement, which can be conceptualize through the lens of LPP. Communities consist of a core group of full participants, or "old-timers" who are experts in the community's practices (Lave & Wenger, 1991). However, if only experts are present, engagement typically becomes stagnant and interactions do not persist. Peripheral participants, or "newcomers", provide new perspectives and fresh outlooks to be considered by old-timers, which facilitates sustained engagement within a community (Lave & Wenger, 1991). Overtime, newcomers follow a trajectory of increased participation in the community, and eventually replace old-timers. The constant interchange of newcomers and old-timers is a core feature of a community of practice. Therefore, identifying places to support interaction between newcomers and old-timers may enhance community cultivation efforts.

Social network analysis and communities of practice

The discussion above underscores a perspective of learning that takes participation in a community as the unit of analysis. Researchers argue that communities of practice are comprised of social networks (Schenkel, Teigland, & Borgatti, 2001). Social network theory focuses upon the relational patterns embedded within a community and groups. In order for group norms to emerge and common beliefs to be present amongst the community, it is important for the social network structure to afford information flow. Recent studies have sought to identify central members—prominent members that have high levels of interaction within the group—in teacher communities to leverage their position in social networks to spread novel information (Daly, 2010). For example, through investigation of the importance of leadership for community success, Tsugawa, Ohsaki, and Imase (2010) conclude that in online communities, centrality can predict an individuals' ability to assume leadership responsibilities. In a similar study that sought to understand the relationship between individuals' centrality and successful implementation of reform, Atteberry and Bryk (2010) provide teachers professional development to act as "coaches" to spread information around school-based initiatives. In doing so, Atteberry and Bryk (2010) used social network analysis to study the relationship between teachers' centrality prior to receiving professional development and the success of the reform effort. They conclude that teachers with higher levels of centrality prior to implementation were more successful in dispersing novel information. In the current study, centrality measures are used to inform which participants, given additional developmental opportunities, may have the most impact on community cultivation.

Methodology

Social network analytical methods are used to investigate the "MathCom" network structure. In the following section these analytical methods are explained along with descriptions of the research setting, participants, data collection and processing, and data analysis plan.

Study Site and Participants

Data for this study is drawn from the MathCom project, which began in 2012. This project is designed to bring together and cultivate a virtual community of mathematics educators across the nation. A primary goal of the MathCom project is to foster mathematics educators' collective engagement in learning of mathematics and pedagogy. Accordingly, participants have been recruited in groups throughout the project as incremental efforts are being made to cultivate community. Over the past two years, multiple mediums of communication have been used as leverage points to support teacher interactions (i.e. face-to-face workshops, online classes and workshops, twitter discussion threads and email list serves) around different content, such as mathematics, instruction and assessment. Therefore, the research setting is in virtual spaces that foster online communication, such as twitter, online courses/workshops, and email listservs.

There are 82 participants (mathematics educators) involved in this study. Taking into consideration whether (and how) they participated in the two face-to-face summer institutes (at the end of Year 1 and Year 2 of the project) that focused on community and instructional development, we can distinguish between 6 types of participants:

- *2013 Fellows (n=12)* were part of the Year 1 institute
- *2014 Fellows* (*n=5*) began in Year 2 *and* were involved in the second summer institute.
- *2013 and 2014Fellows* (*n=12*) participated in both summer institutes.
- *Online participants (n=15)* were those who participated in the Year 2 institute solely via virtual video chat software.
- *Other(n=26)* participants participated strictly via online mediums
- *Staff(n=12)* are teacher educators responsible for virtual interactions with participants and developing project activities

However, given our interest in participants' interactions in the virtual spaces, we focused on the 67 who participated in those spaces.

Data Collection and Processing:

Social network analysis is based on the premise that social life consists primarily of relations and the patterns formed by these relations. Social network analysts study these patterns of interactions between individuals in a network (Scott, 2013). In order to conduct the social network analysis, we examined the records of interactions between participants in each virtual space (twitter, online classes and workshops, email listservs) between May 2013 and September 2014. Participant (*i*) is said to have "talked to" Participant (*j*) if the latter initiated a communication tie to the former. In Twitter, a tie exists if Participant (*i*) included (*j's*) hashtag in the message (Ediger et al., 2010). On email and Blackboard learning systems, a tie is defined if Participant (j) responded to an initial or any other posts/emails from another participant (*i*). From this information, we created one communication matrix that records the interaction between study participants. Each cell (*Xij)* of the matrix takes on a value indicating how frequently (number of times) participant (*i*) directs or initiates a tie to participant (*j*). The resulting 67 x 67 binary asymmetric matrix became the basis/input for all of the structural analysis presented in this paper. The social network analysis software, *UCINET* version 6 (Borgatti, Everett, & Freeman, 2002) was used in all data preparation and analysis. Analysis results are reported as normalized indices. A normalized measurement is one in which the numerical value that results from analysis is standardized so one could compare the particular analytical result to other networks with different sizes.

Data Analysis Plan

This study uses four social network analysis measures (i.e. density, centralization, centrality and core-periphery) (Borgatti & Everett, 2013; Kadushin, 2011) to address the research questions and describe the communication structure of the MathCom network. First, density and network centralization measures allow us to address the first research question: *what are some of the structural properties of the MathCom Network? Network density* describes the general level of cohesion in a graph (Scott, 2000). The centralization score describes the extent to which the flow of information is organized around particular individuals or groups of individuals. Second, centrality analysis is employed to answer the second research question: *who are the most central members of the MathCom network?* Centrality is used in social network analysis to identify important nodes or those that occupy influential positions in a network. Three variants of centrality measures are used in this study: in-degree, out-degree and betweenness centrality (Freeman, 1979). *In-degree* centrality measures the ties an actor receives from others, while *out-degree* centrality measures the ties an actor directs to others. Betweenness centrality is a measure that indexes the number of times a participant falls on the shortest path between two participants in the network. Third, we employ a core-periphery model to examine the extent to which core-peripheral structures are present in the MathCom network (Question 3). This method bifurcates the network into a discrete model consisting of two classes. Fourth, distinguishing levels of centrality for participant types is also of interest (Question 4). We used specialized Analysis of Variance (ANOVA) tests for social network data to examine the differences in centrality by participant type (e.g. whether 2013 fellows are more central then 13 & 14 fellows).

Findings

Research Question 1: What are some of the structural properties of the MathCom network? To address this question, density and centralization measurements were used to give information about network connectivity. The MathCom network resulted in a density of 8.3%. Out of the 5,852 possible directed edges in the network, 488 of these edges are present. The network centralization analysis resulted in a measure of 0.222. This indicates that the MathCom network is more representative of a network that has centrality evenly distributed throughout the network than one that is controlled by a few central members. Density and centralization give an overall representation of the structure of the network. And in this case illustrate that over the 15 months in which this data was collected, close to 500 connections were made and certain central members are potentially emerging as a centralization score of .222 indicates there is some heterogeneity among centrality in the network.

Research Question 2: Who are the most central members of the MathCom network? As will be recalled, in-degree and out-degree centrality scores index the level of activity of participants in the communication network. On average, the top 10 participants have normalized out-degree scores of about 1.082, which is about 10 times larger than the average out-degree scores for the middle ten participants (0.111), and ninety times larger than the scores for the bottom ten participants (0.0117) respectively. On an individual level, participants 11018, 11006 and 11003 are the most active participants: actors 11006 and 11018 for instance have an outdegree score that is about 35% higher than the next highest out degree in the network. The indegree analysis yield similar results to those of outdegree: actors 11006, 11018 and 11003 have the highest normalized indegree centrality scores. Betweenness centrality analysis also yields actors 11018, 11006 and 11003 falling in the top ten, however actor 11016 also yielded a high betweenness centrality score. While actor 11016 did not have as high a valued in/out-degree score, her dichotomized indices where among the highest. Given the importance of betweenness centrality for indicating potential for leadership qualities and the control of information, actor 11016 is considered as one of the most central members.

The above analysis suggests that actors 11018, 11016, 11006 and 11003 are the most central members in the network. Each of the identified actors are 2013 and 2014 fellows, meaning they have been a part of the project since it began in 2013, a year longer than other members that began participation in 2014. Over a year of the project, the identified actors will have had many more chances to participate than those that began in 2014, therefore being a possible reason for their increased centrality. However, based on centrality alone, and drawing from previous research, this analysis suggests these are the most central members and should receive additional professional development opportunities.

In addition, in this analysis staff members are omitted in identification of the most central actors. For example, staff members 1 and 7 are present in the top ten of each centrality measure, however they are left out of this analysis. Part of the purpose of this research is to provide additional professional development opportunities for participants that are identified through social network analysis as most influential in the network. Therefore, identifying staff members that are most central does not support research goals; although, staff members are included in analysis as part of the 67 individuals because many interactions occur between staff (who act as role models) and participants, thereby disseminating best practices in mathematics pedagogy.

Research Question 3: To what extent is a core-peripheral structure present in the network? To address this question, we fitted a categorical core-periphery model to the MathCom data. The core-periphery analysis provided sub-group densities, which can be used to examine the connectivity, between/within, the core and periphery groups. The density profiles also help evaluate the extent to which the derived groups approach an ideal core-periphery structure where 100% of ties are expected between core members, 0% between peripheral members, and most of the connections expected between the core and periphery members. The core-to-core density of the MathCom network is 59%, the core to periphery is 16.7%, the periphery to core is 9.6% and the periphery to periphery is 3.2%. Although this network does not completely approach an ideal core-periphery structure (and few are expected to be), the analysis indicates the presence of a core periphery structure in the network (see Figure 1).

Of the 15 participants in the core of the network, 9 are 2013 & 2014 fellows, 2 are 2013 fellows, 3 are staff, and 1 is an "other" participant that was not part of either institute but was rather active in online classes. The high concentration of 13 & 14 fellows in the core of the network is expected, due to increased opportunities to participate throughout the life of the project. Thus, participation in the summer institute seems to be related to communication activity in the network. The staff members in the core of the network are also reasonable results due to their frequent activity in twitter and email. However, a rather interesting result is participant 13010 falling into the core, as she was not part of either institute. Further research will explore the position of participants such as 13010.

Research Question 4: What is the relationship between participant type and centrality? The analysis above suggests that there are variations in centrality of participants in MathCom. One determinant of this communication activity is participant type (whether they are 2013 Fellows, 2013-2014 Fellows, etc.). Table 1 displays the results of an ANOVA permutation model examining the differences in mean (betweenness, outdegree and indegree) centrality of participants by participant type. The ANOVA analysis shows that 2013 & 2014 fellows have the highest centrality means in each category. Their average betweenness, outdegree and indegree centralities are about 3 times larger than the next largest mean. For example, the mean out degree centrality for 2013 fellows is 0.2452, while that of 2013 & 2014 fellows is 0.7148, which is 2.9 times larger then the 2013 fellows. Second, 2014 fellows have substantially lower in/out-degree (valued and dichotomized) than 13 & 14 fellows. For example, the in/out degree of the 2014 fellows is 14.8% and 10.6% of the 13 & 14 fellows, respectively. These findings illustrates a clear divide in the amount of participation between the two groups: with the 2013 & 2014 fellows much more active than 2014 fellows.

Discussion

Network structure

The above analysis clearly shows the presence of a core and periphery in this network. While the core-periphery analysis will “force” members into the two categories regardless of the nature of the connections in the network, the density measures suggest a rather densely connected core (59% of the potential connections are present) and a rather sparsely connected periphery (3.2% of the potential connections are present). In the ideal core-periphery structure the core-to-core density is 100% and the periphery-to-periphery density is 0% (Borgatti & Everett, 2000). While the results shown here are not quite representative of the ideal core-periphery network, the divide suggested by Borgatti and Everett is a theoretical model rarely (if ever) observed in practice.

Lave and Wenger (1991) suggest a core-periphery structure is critical to sustaining productive interactions within a community while maintaining the structure of a community. In particular, they note that constant interaction between core and peripheral members is critical for knowledge creation and distribution in a community. In consideration of this guiding theory, results of this study are used to identify connections that should be fostered between core and peripheral members to ensure the suggested interactional patterns. Through intervention, members that have been most recently introduced to the MathCom network (e.g. 2014 fellows) and are in the periphery, will be connected with members in the core that have been part of the project for a longer period of time (e.g. 2013 and 2014 fellows). Furthermore, as the periphery begins to decrease in size due to peripheral members beginning to evolve into more centrally located members in the community; new participants should be gathered in order to maintain the core-periphery structure.

Centrality

Recent literature suggests that higher levels of centrality in networks increase individuals’ likelihood of spreading novel information throughout the network (Atteberry & Bryk, 2010). In addition, Tsugawa, Ohsaki, and Imase (2010)mention that high levels of betweenness centrality are indicative of leadership qualities. Therefore, providing additional professional development opportunities to the most central actors may be an effective way of spreading novel information throughout the network in this study. The results of this study suggest that actors 11003, 11006, 11016 and 11018 should be given additional developmental opportunities in order to become "coaches" within the network that engage in practices with others to promote development of student-centered instructional strategies.

Conclusion

This study illustrates a quantitatively driven approach to enhancing professional development efforts. Social network analytical methods were used to identify opportunities for intervention that may have otherwise gone unnoticed. In particular, this investigation has evidenced the presence of a core-periphery structure and has identified 4 individuals that are most central in the MathCom network. These results provide justification for (1) providing professional development to specific individuals in the network, and (2) fostering relationships between specific groups of individuals in the network.

In this report, we will consider in-service elementary school teachers' noticing of the mathematical practice: justification. This study is part of a larger project evaluating the efficacy of a three year professional development built around attending to student thinking and promoting mathematical habits of justifying, generalizing and making sense. Noticing justification is a complex task requiring attention to both the (1) mathematical content and strategies and (2) the nature of the argument provided by a student. We have found that teachers' struggle to attend to both aspects simultaneously and offer a framework for considering teacher noticing of mathematical practices.

Keywords: Classroom Discourse; Teacher Education-Inservice; Reasoning and Proof; Standards

Reform curriculum and standards frequently treat mathematics as a dichotomous subject consisting of both content and practices (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010; National Council of Teachers of Mathematics, 2000). Teachers are expected to foster classrooms not just based on mathematical content goals, but that also promote practices such as justification and generalization. However, practice goals often remain more mysterious. For example, many teachers lack an understanding of just what justification is and how it would look if a student was engaged in justification (Knuth, 2002; Simon & Blume, 1996). *Professional noticing* is a lens for making sense of what teachers attend to in their classrooms, how they interpret student strategies and build upon them. We consider teacher noticing of justification in the context of a professional development (PD) designed to transcend particular mathematical content and focus teachers on the mathematical practices that support and sustain students' development and learning of mathematics. We attend to teachers' noticing of justification, considering the interplay between noticing of justification practice and content-specific mathematical strategies.

Noticing

Noticing in a professional setting is both a lens for making sense of what teachers see in the complex setting of a classroom and a skill to be developed in PD for current and pre-service teachers. Much of the work on noticing stems from Mason's (2002) *intentional noticing*. Intentional or professional noticing differs from everyday noticing as to what is attended to and how it is interpreted is influenced and focused by the professional experience and knowledge of the individual. Jacobs, Lamb, and Philipp (2010) developed a framework for teachers' professional noticing of children's mathematical thinking consisting of: *attending to children's strategies, interpreting children's understandings*, and *deciding how to respond on the basis of children's understandings.*

We build on Jacobs, Lamb, and Philipp's work to consider not just children's mathematical thinking related to content and strategies, but also as it relates to general mathematical practices. We are considering practices to be mathematical activity that is not dependent on particular mathematical content, bur rather is embedded in all areas of mathematics such as the practices of justifying or generalizing. For this report, we will focus on the practice of justification.

Justification

Justification is an essential practice in mathematics classrooms listed in both the Common Core State Standards for Mathematics (CCSS) (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) and the National Council of Teachers of Mathematics (NCTM) Principles and Standards for School Mathematics (National Council of Teachers of Mathematics, 2000). Our usage of mathematical practice will reflect the usage found in the CCSS where mathematical practices describe ways in which students engage in the discipline of mathematics. Justification is of particular importance as it provides "a means by which students enhance their understanding of mathematics and their proficiency at doing mathematics..." (Staples, Bartlo, Thanheiser, p. 447). Justification provides a means to *both* deepen understanding of various mathematical content and develop mathematical practices.

Despite its importance, defining justification is a perilous task. Our definition will most closely follow Stylianides (2007) definition of a proof:

- It uses statements accepted by the classroom community (set of accepted statements) that are true and available without further justification;
- It employs forms of reasoning (modes of argumentation) that are valid and known to, or within the conceptual reach of, the classroom community; and
- It is communicated with forms of expression (modes of argument representation) that are appropriate or known to, or within the conceptual reach of the classroom community. (p. 291).

Within the PD, we define *justifying* as:

Reasons with meaning of ideas, definitions, math properties, established generalizations to:

- *show why an idea/solution is true*
- *refute the validity of an idea*
- *give mathematical defense of an idea that was challenged*

As in Stylianides' definition of proof, justification derives its meaning from building on established facts in order to present a mathematical argument. However, in the PD, the emphasis switches from the product (a proof or justification) to the act of justifying. In this way, a student may be engaged in justifying even if his or her reasoning is incomplete or incorrect.

Previous work has shown that teachers and pre-service teachers may struggle to differentiate between justifications and non-justifications both when evaluating and creating their own justifications. Knuth (2002) found secondary teachers often evaluated non-proofs including empirical arguments as valid justifications for general cases. Pre-service teachers also often consider purely empirical arguments justifications for the general case (Stylianides & Stylianides, 2009; Martin & Harel, 1989). Simon & Blume (1996) illustrated that pre-service teachers provided alternate information when pressed to justify such as citing a rule for its efficiency or relying on procedures in place of a mathematical rationale. In light of these results, the noticing of student justification practices in classrooms is a challenging task. Lo and McCrory (2010), identified four factors necessary for teachers to promote justifying activity: (1) Knowing what counts as a valid justification for a given answer; (2) Familiarizing oneself with the struggles elementary school students may have; (3) Understanding how mathematical topics connect across operations and number systems; and (4) Knowing how to teach in a way that supports mathematical reasoning. (p. 150). These factors highlight some of the complexity involved for teachers to promote justifying activity. While the PD aims to address all four factors, we will be focusing on the first factor. Knowing what counts as a justification (and recognizing justifying activity) serve as an important aim when promoting justification.

Attending to justification practices provide an extra layer of complexity to the already complex situation of making sense of students' mathematical thinking. Noticing justification requires both attention to content and practice. That is, there must be mathematical content to be justified. However, mathematical content alone is insufficient; justification also requires an argument to provide a *why* for mathematical claims and decisions. For example, consider the task in Figure 1.

> [School Name Redacted]'s PTA provided 12 celery sticks, 17 carrot sticks, and 7 apple slices. If each student took 3 snack pieces, how many students would have a snack?

Figure 1: Task from Cycle 4

A non-justification for the solution of twelve students might be:

> "I added 12, 17, and 7. 12+17 is 29. 29+7 is 36. Then 36 divided by 9 is 12. So 12 students would get snacks.

While the student is explaining *how* they arrived at the answer, they are not providing any rationale for *why* this procedure produces the correct answer. There is mathematical content in this example, but no evidence of the practice of justification.

In contrast, a justification for the solution of nine students might be:

> "There are 12 of one snack, 17 of one snack and 7 of another. I could add all of the snacks together to find the total number of snacks since the types of snacks do not matter, which would be 36. Because division tells me how many groups of three are in 36, I could divide the 36 by 3. This would tell me how many groups of three snacks fit into 36 snacks. So 12students could each have three snacks."

In this example, the student used their knowledge of addition and justified why totaling the different snacks would be appropriate. They then justified their division decision by using the known definition and connecting to the context. By connecting to a known meaning, they not only used an operation, but provided a justification for it. The mathematical content and argumentation were both aspects of the excerpt.

The Setting and PD

The PD takes place at an elementary school in a mid-sized urban district that is engaged in a three year PD for third to fifth grade teachers. The PD uses a *Studio Model* where one teacher (the studio teacher) works with a consultant to plan math lessons and then opens their classroom to the other teachers while teaching this lesson. The remainder of the third to fifth grade teachers (resident teachers) help plan the lesson, observe the enactment, and then debrief the lesson. At this elementary school, the third to fifth grade teachers engage in a yearly summer course (3 days) and five studio cycles throughout the year. These cycles include two days of PD sessions. Day one consists of leadership coaching with the principal and planning with the studio teacher. Day two involves all third to fifth teachers and consists of working together to do mathematics related to the lesson, planning and enacting the studio lesson and then debriefing the lesson. For this study, we are going to focus on the first year of the PD with attention to the lesson debriefs.

The central focus of the PD is to get all students to habitually justify and generalize in order to make sense of mathematical problems and ideas. To this end a set of *Habits of Mind* (such as working through stuck-points), *Habits of Interaction* (such as critique and debate), and *Mathematically Productive Teaching Routines* are the focus of the PD throughout the first year (Foreman, 2013).

Resident teachers' attention is focused on student discourse, in particular on discourse related to justifying and generalizing during the studio lesson. The teachers are provided with observation tools to help focus their attention (see Figure 2). The teachers are encouraged to write down discourse they observe during the lesson within the categories of: *procedures/facts, justifying,* and *generalizing.* After the lesson is enacted, the teachers engage in discussion around the various discourse they noticed and characterize them with respect to the three categories provided. In the discussion they are asked to justify their categorizations. Using this tool helps teachers focus/attend to children's discourse rather than other aspects of the classroom.

Teacher ______________________________ Grade/Class________________ Date______________ Page_____

STUDENT DISCOURSE OBSERVATION TOOL

PF USING PROCEDURES/FACTS	**J** JUSTIFYING	**G** GENERALIZING
No evidence of reasoning • Short answer to a direct question • Restating facts/statements/rules • Showing or asking for procedures *Uses meanings, definitions, properties, known math ideas to describe reasoning when:* • Explaining ideas & methods • Questioning to clarify • Noticing relationships/connections But ***doesn't show why*** the ideas/methods work	*Reasons with meanings of ideas, definitions, math properties, established generalizations to:* • Show why an idea/solution is true • Refute the validity of an idea • Give mathematical defense for an idea that was challenged	*Reasons with math properties, definitions, meanings of ideas, established generalizations, and mathematical relationships as the basis for:* • Making conjectures about what might happen in the general or special cases or • Justifying a conjecture about what will happen in the general or special cases

Methods

A member of the research team was present at each of the PD sessions and took detailed field notes. In addition, all PD sessions were video recorded. The field notes from year 1, provided the starting ground for identifying instances when teachers discussed student discourse and how it pertained to justifying, generalizing and procedures/facts. These episodes were then transcribed for analysis. Transcripts were analyzed for any instance of noticing during discussions of characterizing discourse. Each instance (measured as a turn in conversation) was then considered in light of whether the teacher noticed (1) the mathematical content, (2) the character of the discourse (justifying, generalizing, or procedures/facts), and (3) what evidence was provided for their interpretations and descriptions. The analysis focused on describing and interpreting aspects of noticing (rather than responding to student thinking), as the PD focused first on these aspects during year 1.

Results and Discussion

Each of the following excerpts comes from a teacher response when asked to share a piece of discourse from their discourse observation tool after the lesson. Teachers were prompted to characterize the discourse in terms of justifying, generalizing and procedure/facts. We begin each section by sharing the teacher-selected piece of discourse and then analyzing it.

Teacher Noticing 1 (Cycle 1)

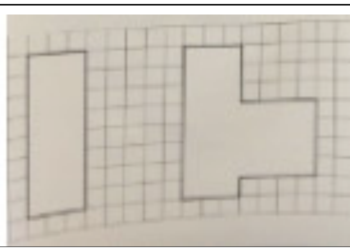
> Teacher: They [a pair of students] were very much engaged with each other and happily exchanging their different ways of looking at the problem.

No mathematical content or practices. This quote exemplifies noticing that is general and does not provide evidence of student discourse or any interpretation of mathematical content or practices. This teacher was commenting on level of engagement without evidence. She did note that they had different ways of looking at the problem, but without evidence, this statement does not reflect noticing of the mathematics in terms of content or practice. Because of the PD's structure (and the observation tool's focus), teachers were nearly always focused on students rather than teachers. However, this focus often swayed to their noticing of student affect rather than mathematical discourse.

Teacher Noticing 2 (Cycle 1)

> Teacher: I still think he's doing that justifying, defending the idea about that whole corner thing. I heard such awesome things, like, "How?," "I know because…," and then he's explaining, and then "I disagree, how did you get this number?" "Well, because you said this, this, this…did you know it was going to be this number" "Look. You said…" and he showed him on the paper!"

Noticing mathematical practice without content. The above noticing was of two students engaged in discussion as to whether the corners of the perimeters in Figure 3 should count once or twice in the total. The student used toothpicks to illustrate that a corner contributes two sides to the perimeter total. In this case, the teacher has noticed the practice of justification, but the evidence provided does not connect to the mathematical content. This noticing might be considered *keyword* justification noticing. While the teacher appeared to notice that a mathematical argument was being made, she did not report any student discourse that was mathematically focused. Noticing justification in this manner might reflect any number of justification conceptions and does not directly connect back to the definition of justifying being utilized in the PD. With the content of what follows, "I know because," an interpretation of justification lacks warrant. The "because" could be followed by a justification or it could be followed by a procedural explanation. Prior to attending to student mathematically thinking, it is unlikely a teacher could recognize justification beyond what might be a superficial interpretation.



What 2 observations are you going to share with your partner and why does it make sense?

Figure 3: Task from Cycle 1

Teacher Noticing 3 (Cycle 2)

> Teacher: But, then [student 1]– I really thought it was great when [student 1] on her own –cause we were just flipping it [a triangle] [motions upside down] you know what the kids would think

as right side up because we gave it to them “upside down” [air quotes] so he [student 2] thought it if you flip it, it’s right side up so when she [student 1] turned it lengthwise, “well does that look like it to you?”

Noticing mathematical content without practice. In this excerpt, a teacher is noticing the mathematical content. Students were asked to identify if various shapes were triangles. Many students felt that whether or not a shape was a triangle related to orientation (see Figure 4). In this exchange, one student recognized and rotated a triangle to provide an argument that the top was in fact a triangle. The teacher noticed this exchange including interpreting that the students were focused on orientation. In this excerpt, some *evaluative* comments were made such as, “I really thought this was great.” Despite the prompt to characterize this discourse, this teacher did not consider whether there was justifying, generalizing or using facts/procedures. This was a fairly typical response type within a subset of teachers. It is unsurprising that a teacher’s focus might be solely on making sense of the students’ mathematical strategies, especially if attending to students’ mathematical thinking is a shift from their typical teaching. Interpreting the nature of the discourse and making sense of the mathematical understandings requires attending to two different (though interrelated) facets of a complex situation.

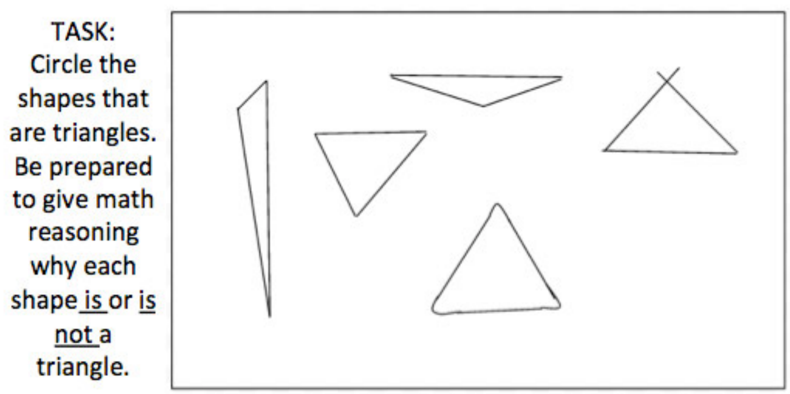


Figure 4: Task from Cycle 2

Teacher Noticing 4 (Cycle 4)

Teacher: [Student 1] was arguing with girl next to him [student 2] that she was wrong because she had the two and one remainders and the numbers added up to 11 even though [student 2] had 12 up there. They were focused on the remainders. He had 12 and knew he was right. When he talked to the whole group, it was when he said, “2 remainders plus 1 remainders equals 3” and he goes, “three divided by three equals one more group.” As soon as he said it out loud, you could see the light bulb flash and he was smiling and he told the girl next to her she’s right. The other girls said [inaudible]. He was having the whole conversation justifying it to himself.

Noticing mathematical content and practice. In this excerpt, the teacher is describing a debate between students based on the remainder from the prompt in Figure 1[1].The teacher in this case provided specific evidence of the mathematical discourse that included both content and interpreting the character of the discourse. While the connection between the mathematical content and characterizing of practice was tenuous, this excerpt represents one of the only cases of a teacher identifying a justification with concrete evidence. This might reflect both the complexity involved in attending to both aspects, but also the fact that this data is from the first year of the PD implementation. At this point, the teachers are in the beginning phases of attending to student reasoning in a meaningful way.

A Framework for Noticing Mathematical Content and Practices

We summarize the four different ways teachers notice justification in Table 1.

Table 1: Framework for Noticing Mathematical Content and Practices

	Does not notice mathematical practices	**Notices mathematical practices**
Does not notice mathematical content and strategies	Statements are general in nature and contain no evidence of students' mathematics.	Statements may provide evidence of students engaged in a practice but no mathematics content is included.
Notices mathematical content and strategies	Statements include evidence of students' mathematical strategies and content-specific interpretations.	Statements include evidence and interpretation of both content and practices.

Attending to and promoting student justification may require a high level skill-set including both a knowledge of the nature of mathematical justification paired with being able to notice and make sense of students' mathematical thinking and strategies around content. The characterizing student discourse tool provides both a tool for writing down discourse (which focuses teachers on students), and provides a stable definition for the discourse types of: *generalizing, justifying* and *using procedures/facts.* As teachers learn to notice their justifications, their conceptions of justifications should continue to develop. At the same time, characterizing discourse (with evidence) necessarily requires understanding of students' mathematical thinking around given content. In this way, characterizing discourse is a way to promote attending to students' mathematical thinking and making sense of their reasoning.

Our analysis of Year 1 data, provided insight into the current state of teacher noticing of practices such as justification and generalizing. Noticing justification is an incredibly complex skill requiring both a deep understanding of elementary mathematics content and understanding of justification as a mathematical practice. The teachers in our study frequently attended to one or the other, but rarely created robust interpretations of student discourse that addressed both the character of the discourse and the mathematical content understandings. In fact, there were no examples of attending to both during the thirty minute debrief discussions in the first three cycles.

Based on this analysis, we were able to illustrate examples of what teachers notice when told to focus on characterizing discourse in terms of justifying, generalizing, and procedures/facts. Prior to extensive professional development, teachers were not able to characterize discourse using evidence. Further, we argue that noticing practices is a difficult and complex task due to the requirement to notice not just mathematical practices cues, but also notice mathematical content. Finally, we have introduced a framework that has helped to organize and make sense of the way teachers were noticing to student discourse. We conjecture that teachers will continue to shift from noticing only certain facets of student discourse to an integrated view of mathematical content and practice through Year 2 and Year 3 of the professional development.

Endnote

[1]The division problem could be solved in one of two ways. The snacks could be first summed to arrive at the total number of snacks, and then divided by three. Alternately, each snack type could be divided by three first, leaving remainders of two carrot sticks and one apple slice.

THE UNINTENDED CONSEQUENCES OF A LEARNING TRAJECTORIES APPROACH

Marrielle Myers
Kennesaw State University
mmyers22@kennesaw.edu

This case study, which is a part of a larger design study, examines teachers' uses of learning trajectories (LTs) in diverse classrooms. Specifically data were collected and analyzed for evidence of equitable use of LTs and learning trajectory-based instruction (LTBI). Qualitative analysis revealed that the use of LTBI did not guarantee equitable instructional practices. Moreover, a number of deficit-oriented themes emerged in one case.

Keywords: Learning Trajectories; Equity and Diversity; Teacher Beliefs; Teacher Education-Inservice

Introduction

Research has demonstrated that professional development (PD) that focuses on students' mathematical thinking can lead to changes in teachers' practice (Kazemi & Franke, 2004; Sowder, 2007). Learning trajectories (LTs) are gaining prominence as a representation of students' mathematical thinking, and are thus being used in professional development projects nationwide. While initial results of LT-focused professional development projects are positive, these results have not yet been teased apart to investigate if these benefits are present for traditionally underserved students.

In this paper, I present findings from a case study of teachers that participated in a yearlong professional development project focused on LTs. I begin this report with a brief discussion about learning trajectories. I focus this discussion on how research on LTs has developed over time, specifically in relation to their use in classroom instruction. I follow with a discussion of the theoretical framework that guided this study. I describe the context of the study (location and professional development) and present findings from one case that was particularly interesting and problematic. I conclude this report by discussing implications of the findings.

Background

Over the past two decades, a number of scholars have written about and argued for the use of LTs in mathematics and science education (Battista, 2004; Brown, Clements & Sarama, 2007; Clements & Sarama, 2008; Clements, Wilson & Sarama, 2004; Clements & Sarama, 2008; Confrey et al, 2009; Duncan, Rogat & Yarden, 2009). While the terminology differs (e.g., learning progressions vs. learning trajectories), many of these scholars agree that LTs have the potential to transform the teaching-learning process. LTs have shown promise because they: simultaneously attend to specific skills as well as broader concepts; they attend to how student thinking develops over time (NRC, 2007); they are empirically developed from work with students; and they attend to probable pathways students may take as well as common misconceptions in their mathematical development (Confrey, 2006).

Research on LTs has occurred along three primary fronts: a) developing and validating LTs in different mathematical strands (Battista, 2006; Clements & Sarama, 2007; Maloney & Confrey, 2010); b) using LTs to design curriculum and assessment (NRC, 2007); and c) exploring the ways teachers use LTs in instruction (Bardsley, 2006; Edgington, 2012; Mojica, 2010; Wilson, 2009). Regarding the latter, previous research on LTs has shown promise. Using knowledge of student thinking as represented by LTs, teachers have: a) set goals based on students' developmental level (Clements, 2007); b) described student work with greater detail (Wilson, 2009); c) assessed students more effectively (McKool, 2009); and d) anticipated students' strategies as well as misconceptions (Edgington, 2012). What remains unexamined is whether or not *all* students benefit from the promise of LTs as well as how teachers use their knowledge of LTs with traditionally underserved students. Specifically, are LTs used equitably?

Theoretical Framework

To examine whether or not LTs were used equitably in the classroom, I framed this study using Gutierrez (2007) equity framework. In this and other work, she articulates four dimensions of equity: access, achievement, identity, and power. Because Gutiérrez' initial framework was developed from her work with high school math departments and school districts, my first step in this work was to re-conceptualize this framework at the classroom level. Additionally, I conjectured ways in which teachers *might* use LTs to promote access, identity, achievement, and power. Table 1 represents a conjecture of the ways in which teachers might use LTs in to promote equitable instruction (Myers, Sztajn, Wilson & Edgington, in review).

Table 1. Conceptual Framework for LTBI and Equity (E-LTBI Framework)

	Teachers use their knowledge of LTs and LTBI to:
Access	Design instruction and instructional tasks such that they are accessible for all students.
	Identify and use up-to-date research based materials and technology
	Be accessible to and attend to all students in the class.
	Foster classroom discussions such that all students can participate and engage.
	Provide all students with opportunities to engage in rigorous mathematics.
Achievement	Set high, yet appropriate, academic standards for all students.
	Unpack and build upon their students' prior mathematical knowledge and use it as a basis for understanding more meaningful and complex mathematics.
	Select and use a variety of forms of assessment (e.g., formative, summative, projects, class discussions) to gauge student achievement.
Identity	Support the development of a robust mathematical identity
	Listen to and consider students out-of-school experiences and design instructional activities that incorporate elements from their homes and communities.
	Validate the use of students' own algorithms and strategies to solve problems.
	Assist students to build connections between the mathematics they learn and the broader world/society.
	Encourage students to engage in mathematical tasks according to their preferences and participate in mathematical discourse in ways that are comfortable for them.
Power	Ensure that students have voice in the classroom.
	Position students as experts in the classroom (this includes things they know in school and things they know from outside of school).
	Allow students to solve problems that are relevant to them (these problems can exist inside or outside of school).
	Encourage all students to present, justify, and defend their mathematical ideas/arguments.
	Help students to see themselves as sources of mathematical knowledge.

Methods

The Learning Trajectories Based Instruction (LTBI) project is a multi-year design project that examined teacher learning of LTs and how LTs were used in instruction (Sztajn et al., 2012). The participants in this case study represented a subset of teachers in a larger design study. The research question under investigation for the case study was: In what ways do teachers use LTBI to promote access, achievement, identity, and power in their instruction? In this report however, I address a smaller research question: *How do deficit perspectives manifest in the context of an LT-focused professional development project?*

Context

Learning trajectory-based instruction is defined as instruction that situates LTs at the center of the teaching practice (Sztajn et al., 2012). The goals of the larger LTBI project were to (1) explore the impact of LTs on elementary teachers mathematics instruction; (2) build a conceptual model of instruction that is centered on LTs; and (3) confront teachers' stereotypes of students (van Langenhove & Harré, 1999) by focusing on what students can do (as seen in LTs) and building upon it through supportive classroom practices (instead of focusing on what they cannot do).

The professional development began with a 30-hour summer institute in which participants learned about Clements and Sarama's (2009) LTs for early number and counting, addition and subtraction problem types, Smith and Stein's (2008) five practices for mathematical discourse, as well as formative assessment. Because the content of the LT was dense, the LTBI research team organized multiple LTs from Clements and Sarama's work into what we called "Learner Profiles"(Myers, Sztajn, Wilson & Edgington, in review). These profiles—named perceptual child, direct modeling child, counting on child, place value child and multi digit child—provided a way for teachers to "chunk" information about students and created a broader perspective. Teachers participated in an additional 30 hours of PD throughout the school year where they engaged in professional learning tasks related to both the content of the LT and its use in instruction. These tasks included watching clinical interviews, analyzing samples of students' work, curriculum evaluation, and task design. Participants also conducted a number of activities with their own students, which served as the basis for project discussions.

While there were a number of initial conjectures from the project related to teacher learning, discourse, and positioning/stereotypes, three of these conjectures were particularly relevant to this case study. First, the LTBI team conjectured that the learner profiles would be a more manageable grain-size for teachers and offer them a productive way to talk about "where" their students were mathematically. Second, the LTBI team conjectured that LTBI could support teachers' focus on individual students and help teachers design instruction that meets their needs based on their current conceptions. Finally, the LTBI team conjectured that teachers would reduce their use of the words "low" and "high" to describe their students and begin describing their mathematical work using language from the LT.

The partner school for this study was a small elementary school in a suburban district in the southeastern United States. The enrollment was 370 students and the five-acre campus was situated in the heart of a historic district. Demographic data indicated that 36.2% of students are considered economically disadvantaged and 27.1% of students had limited English proficiency.

Participants

Seven teachers participated in the larger design study described above. Because the content of the learning trajectory focused on early number knowledge (including counting), four K-1 case teachers were selected for additional research. Case teachers participated in four interviews and three classroom observation cycles during a four-month period. At the start of this case study, the teachers had completed 40 hours of the professional development. The remaining 20 hours of PD occurred concurrently with the case study.

For the purpose of this paper, I focus on one case “Elizabeth.” At the time of the study, Elizabeth had 15 years of teaching experience. She was in her fourth year teaching kindergarten and had been teaching at the partner school for nine years. Elizabeth was selected as the focal case for this paper because she demonstrated a deficit orientation throughout the PD project.

Data Sources and Analysis

Data sources for this case study consisted of student mathematical portraits, interviews, classroom observations, and field notes. The mathematical portraits consisted of questions related to how teachers use LTs to: solicit evidence of students’ mathematical understandings, set goals for students, and create mathematical opportunities for students. These portraits were created so that the researcher could examine the ways in which teachers talked about individual students as well as groups of students. The mathematical portraits were revisited at each interview during the course of the study. Interview protocols addressed each dimension of the E-LTBI framework and additional questions were added as themes emerged during the study. An observation protocol was also developed to address the E-LTBI framework as well as other aspects of equitable instruction (Author, 2014).

Data analysis occurred in two phases: ongoing and retrospective. The goal of on-going analysis was to understand emergent themes as they related to the E-LTBI framework. All interviews and field notes were reviewed immediately and notes were made regarding preliminary themes. Both pre-determined and open coding was used during ongoing analysis. The pre-determined codes consisted of the four dimensions of the E-LTBI framework (access, achievement, identity, and power) as well as the LTBI instructional practices (task/learning goal, anticipate, monitor, select/sequence, and connect). While pre-determined codes resulted from the research questions and the LTBI instructional model, open coding allowed for the emergence of new themes. The following codes were developed during open coding: curriculum, high vs. low students, comparing, literacy, usefulness of LTs, using “high” students as exemplars, deficit orientations, and motivation. During retrospective analysis both within-case and cross-case analysis were conducted (Merriam, 1998).

Results

While a number of themes emerged during the data analysis, one particular manifested throughout Elizabeth’s case. At different periods during the study, Elizabeth displayed a deficit perspective towards certain students in her classroom. In some cases, she actually used language from the trajectory to justify her beliefs. Here, I present a number of examples that highlight Elizabeth’s deficit orientations as well as how she failed to use LTBI equitably.

Tracking

In my opening interview with Elizabeth, I asked her to talk to me about where each of her students was currently working in the learning trajectory. Elizabeth chose to group her students into four groups. She labeled these groups, “…lower group, next up from low, not quite counting on, and higher group.” Later in the study, I again asked Elizabeth to talk to me about her students and where they were working in the trajectory. Although the LTBI team conjectured that teachers would describe groups of students using mathematical evidence from the LT, this was not the case with Elizabeth. Throughout the study, she continued to use language of “low” and “high” and only described her “high” students with LT language.

Not only were these labels of “low” and “high” problematic, but also the demographics of the students that fell into these two groups were alarming. Of Elizabeth’s 17 students, eight of them were in the two “lower” groups and the remaining nine students were in the “higher” groups. Of the eight students in the lower groups, six were Hispanic, one African-American, and the other was White. Of the nine students in the “higher” groups, seven were White, one African American and one Hispanic. Throughout the course of the study, the only student that moved out of the lower track (according to Elizabeth’s assessment) was the one White student. As you will see in the coming examples, Elizabeth used LTBI to provide opportunities for her “higher” students while her “lower” students were denied the benefits of LT-based instruction.

This particular finding is problematic because one conjecture from the project was that teachers could use knowledge of LTBI to focus on individual students and design instruction to move them forward. At the conclusion of the study, Elizabeth indicated that her students in the higher group continued to achieve, while those in the lower group did not.

Access

One aspect of the LTBI PD was a focus on creating high demand tasks with multiple entry points. Teachers had opportunities to examine a variety of tasks and modify them such that students at multiple levels of the LT could access the task. When I asked Elizabeth to explain how she ensures that her tasks are accessible by students at various LT levels, she indicated that the students at the lowest level needed step-by-step instructions. Specifically, she stated:

> You take it step-by-step and for each step you plan for them not understanding it possibly. And for the ones it’s not accessible because they just don’t comprehend it…[make] sure through the activity progressively each step is accomplished and comprehended and then move on to the next step. Check for comprehension at the lowest level and once that’s clear, move to the next step.

In this example, Elizabeth indicated that the learning trajectory could be used as a rigid checklist to monitor students’ progress. In contrast to our discussions about using LTs develop open tasks that were accessible for students working at different profile levels; Elizabeth indicated that students at the lowest level needed more procedural tasks.

Another important component of access was that teachers would use LTs to design rigorous tasks for students at all LT levels. When I asked Elizabeth about how she used the LT to design these opportunities, she stated:

> I remember. . .. we do set appropriate academic standards, and I think since our last meeting when I mentioned that we thought that the idea of them counting to 100 and counting to 100 by tens would be pretty much asking too much but we did it every day and now a good majority of them can. Not successful for I’d say 50% of the class but we work it into. . . I work things into my daily routines so they got daily practice, and those that could achieve it at least have the opportunity to try and the opportunity to practice.

In this example, Elizabeth indicated that rigorous goals were appropriate for those that “could achieve.” Throughout the study, Elizabeth offered some students opportunities to be challenged mathematically, while those that were “lower on the trajectory” or “floundering” were given rote tasks.

Achievement

A focus of the achievement dimension is that teachers could use LTBI to set short- and long-term goals for individual students, assess their progress, and design instruction that builds upon students’ individual conceptions as identified in LTs. During a pre-lesson observation, I asked Elizabeth to think about the skills her students had demonstrated in class and how she would build upon students’ conceptions. Elizabeth responded:

> They have learned to count to ten, which is great because they didn't do that before. I'm trying to think. They don't have a number sense and…I guess it's hard to say what they do have, honestly, I guess because I worry so much about what they don't have. But they have gained since the very beginning of the year and just being able to count to ten, and even to twenty. Not completely accurately but they know if they put one number after the other, they're seeing things in order. I guess I should be more positive but really they're . . .. I don't know how to express it in a positive way. I worry that they don't grasp just the whole idea of numbers and amount, and why it's important.

This example highlights tension Elizabeth felt. While she was able to identify some progress that her students were making, her primary focus was what students did not know. She focused more on skills that the students did not demonstrate and she did not use the LT did not provide her with the agency to develop appropriate instructional plans.

Identity

In the identity dimension, teachers use their knowledge of LTs to solicit and validate various approaches to tasks. Another element of this dimension is that teachers help students build connections between in-school mathematics and out-of-school mathematics. When I asked Elizabeth how she could facilitate this in her classroom, she stated:

> I don't think they have the ability to really grasp say, say I think maybe fourth, fifth grade demography and geography. That might be something a little bit more of a mathematical connection but for their level and I'll introduce grander ideas or bigger numbers and they kind of get it but I think my kids who are challenged with second language and also just the beginning of number sense, they can't get it.

In this statement, Elizabeth indicates that English language learners or students developing number sense could not "get it." This statement also highlights that Elizabeth was unwilling to think of out-of-school mathematics in relation to her students lived experiences. Rather, her example of out-of-school mathematics was demography or geography.

Power

A key component of this dimension is that teachers see the mathematical potential of all of their students, allow them to take ownership of their ideas, and position them as experts in the classroom. As we were discussing the concepts of positioning students as experts, I asked Elizabeth to recall and example she previously shared with me of a student who counted and tapped her chin as she counted to keep track of the number. I suggested to Elizabeth that this could be an example where she could allow this student to share her counting method with the class. Elizabeth responded:

> Usually they can't express it because they don't have . . . They don't know what they're doing. They've just seen adults do it and they think that's counting…I assume some type of counting method that is used in that country, but I usually would ask them about it and they could continue doing that if it helped them . . .. But I wouldn't encourage the rest of the class to start doing it too. I just said this is the way we're going to do it here and if that's the way you do it, you can do that, that's fine.

I asked Elizabeth if she could think of an example when she would position students as experts and allow them to take ownership of ideas in the classroom. She provided the following example:

> We just had a center – a subtraction center – that was manned by Paul, Natalie and Jared. Natalie had her first grade workbooks and she asked me if she could have a center during math time that

if people were done they would be able to visit the math center and practice subtraction because she knew how to do it and she wanted to teach them how to do it.

Later in this conversation I asked Elizabeth to think of other students that she could position as experts or different types of expertise that existed in her classroom. She shared another example about Paul. These examples demonstrate Elizabeth's belief that only some students can be seen as experts in the classroom. The student referenced in the first example was one of Elizabeth's "lower" students. Paul, Natalie, and Jared on the other hand were her top three students. Throughout the study, I asked Elizabeth to share examples of students taking ownership of ideas in the classroom or demonstrating expertise. For Elizabeth, only her "high" students were referenced. These examples indicate that the trajectory was not enough to help Elizabeth see all students as possessors or knowledge therefore allowing all students to be experts.

Discussion

My goal for this paper was to present an important "unintended consequence" that emerged as a result of a professional development project. While other teachers in the case study exhibited growth/progress/demonstrated change, Elizabeth did not. Using the LT as a tool to focus on the students' individual thinking did not disrupt Elizabeth's beliefs about who could and could not do mathematics. While Elizabeth did demonstrate findings from other studies of LTs (e.g., using LTs to set goals for students), these findings did not cut across all subgroups of students in her class.

Previous work has shown promise that when content-focused PD and issues of culture, privilege and power are fully integrated; teachers can begin to acknowledge the contributions of all students and deficit orientations can be dispelled (Battey & Chan, 2010). Elizabeth's case presents a critical challenge for the field. When teachers have strong deficit perspectives, those beliefs will carry over to their professional development experiences. Therefore, although teachers may engage in new and innovative pedagogies, not all students will benefit from this new professional knowledge. This case highlights the fact that although Elizabeth was able to use elements of the LTBI in her instruction, they were not implemented equitably. Therefore, to avoid unintended consequences of content-only focused PD, teacher educators must consider simultaneously addressing issues of culture, power, and privilege.

In this study, we considered how middle school teachers understood the relationship between fractions and ratios. We used two instruments to collect data from 11 teachers and relied on Knowledge in Pieces as a lens for considering understandings teachers have and how coherent those understandings are. From our analysis, we developed three main findings: participants did not have a single definition for ratios; they used specific vocabulary when discussing ratios; and their language evoked additive strategies rather than multiplicative relationships. Further, we concluded that they each had a number of knowledge resources, but that those resources may not yet be well-connected to each other. This has implications for professional development.

Keywords: Teacher Knowledge; Middle School Education; Rational Numbers

Purpose & Background

In middle school mathematics, teachers are asked to teach an array of concepts for which they may have only limited understanding. One such area, proportional reasoning, has increased in prominence and emphasis by being considered its own content domain in the Common Core State Standards for Mathematics (National Governors Association & Council of Chief State School Officers, 2010). Despite the importance and richness of the proportional reasoning domain there has been a disproportionate focus on it in research (Lamon, 2007). The limited research available on teacher knowledge of proportions indicates that like students, teachers struggle with proportional reasoning (e.g., Akar, 2010; Harel & Behr, 1995; Orrill & Brown, 2012; Orrill & Kittleson, in press; Orrill, Izsák, Cohen, Templin & Lobato 2010; Post, Harel, Behr, & Lesh, 1988; Riley, 2010). Strikingly, in one study, Post, Harel, Behr, & Lesh (1988) found that their sample of teachers in grades 4-6 were unable to correctly respond to ratio and proportion items developed for students in those grades. In fact, on the ratio items, the 167 respondents answered less than 50% of the items correctly.

Lamon (2007) explained that proportional reasoning is one of "the most difficult to teach, the most mathematically complex, the most cognitively challenging, the most essential to success in higher mathematics and science, and one of the most compelling research sites" (p. 629). Despite this there is little research on teachers' understandings of proportional reasoning (Ben-Chaim, Keret, & Ilany, 2007; Lamon, 2007; Lobato, Orrill, Druken, & Jacobsom, 2011). Existing research suggests that proportional reasoning is conceptually difficult for teachers. This is, in part, because it is possible to rely on rote algorithms such as cross multiplication to get correct answers while overlooking the multiplicative nature of the relationship (Berk, Taber, Gorowara & Poetzl, 2009; Lobato et al., 2011; Modestou & Gagatsis, 2010; Orrill & Burke, 2013). Researchers have also suggested that teachers hold naïve conceptions about proportions (Canada, Gilbert, & Adolphson, 2008; Lobato et al., 2011). For instance, Canada, Gilbert, and Adolphson (2008) found that in a sample of 75 pre-service teachers only 28 were able to reasonably interpret a unit rate (e.g., amount per dollar) as useful for determining which package was a better buy when comparing two different size packages of ice cream.

Past research indicates an important link between the amount of knowledge a teacher demonstrates and its organization (Bédard & Chi, 1992; Ma, 1999; Orrill & Shaffer, 2012). For instance, Orrill and Shaffer (2012) found that the least expert teacher in their study demonstrated many ideas about ratios and fractions that were not interconnected while the most expert teacher introduced many ideas that co-occurred more frequently, suggesting stronger connections between them. We hypothesize that these stronger connections are an indicator of greater coherence. This finding is consistent with research in cognitive psychology that suggests expertise requires both an accumulation of knowledge and organization of that knowledge (Bédard & Chi, 1992). It is also consistent with seminal work in mathematics education such as Ma's study (1999) that showed that teachers with more connections between their mathematical knowledge resources were better able to interpret a variety of mathematical situations. As highlighted by Thompson, Carlson, and Silverman (2007), teachers with incoherent understanding can only teach disconnected facts. In contrast, a teacher with coherent understanding has the potential to support students in developing coherent understandings. Thus, coherence is a salient aspect of teacher knowledge (e.g., Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Kaasila, Pehkonen, & Hellinen, 2010; Ma, 1999).

Two concepts that are important to proportional reasoning are fractions and ratios. Past research has found that the relationship between these two important concepts is not always clear (Clark, Berenson & Cavey, 2003; Sowder, Philipp, Armstrong, & Schappelle, 1998). This may, in part, be because of the organization of textbooks that frequently provide limited guidance on the definition of ratios and fractions and that deal with multiplicative structures in discrete unconnected ways, such that topics like the relationship between ratios and fractions are not shown or discussed (Clark et al., 2003; Sowder et al., 1998). These issues suggest that it is entirely plausible that teachers hold multiple knowledge resources about the relationship between fractions and ratios that are not coherently organized.

This study contributes to the growing knowledge base focused on teacher understanding by considering one aspect of proportional reasoning: relationships between fractions and ratios (e.g., Lobato & Ellis, 2010). Specifically, we considered the following questions: (1) how do 11 middle school teachers understand the relationship between ratios and fractions; and (2) how coherent are their understandings?

Theoretical Framework

Coherent & Robust Understandings

A coherent and robust understanding of ratios for middle school teachers must go beyond that of their students (Clark et al., 2003; Lobato & Ellis, 2010). Teachers need to understand that a ratio is a comparison of two quantities, where quantity is defined as "a measurable quality of an object-whether that quality is actually quantified or not" (Lamon, 2007, p. 630). A teachers' understanding of ratio should go beyond ways to express it, to include the understanding that a ratio is a multiplicative comparison and not an additive comparison (Lamon, 2007; Lobato & Ellis, 2010; Sowder et al., 1998). This is a critical understanding as the concept of ratio is considered crucial for the transition from additive to multiplicative reasoning (Sowder et al., 1998). Teachers need to be able to discern whether students are using additive or multiplicative reasoning (Sowder et al., 1998).

It is also important for teachers to understand the relationship between ratios and fractions. A fraction is more than simply a part-whole relationship. Fractions can be interpreted as a part-whole comparison, measure, operator, quotient, and ratio (Lamon, 2007). A common notion that students have is that all ratios are fractions – which is a limited conception given that ratios can be part-part relationships and given that a ratio is a comparison of two quantities, thus not a value that can be placed on a number line (Clark et al., 2003; Lamon, 2007; Lobato & Ellis, 2010). Teachers should both understand the relationship between fractions and ratios and have the ability to identify students' limited understandings to justify or refute them (Lobato& Ellis, 2010). And, teachers need to know that in many cases ratios can be meaningfully reinterpreted as fractions (Lobato & Ellis, 2010). For instance, in a salad dressing that is 2 parts of vinegar and 5 parts of oil, the ratio 2:5 expresses not only the part-part comparison, but also the multiplicative relationship—that there is 2/5 as much vinegar as oil.

Knowledge in Pieces

We rely on the Knowledge in Pieces theory (KiP; diSessa, 2006) for this study. KiP asserts that individuals hold understandings of various grain sizes that are used as knowledge resources in a given situation (Orrill & Burke; 2013). For novices, these knowledge resources are not well-connected to each other. As expertise develops, interconnections allow more knowledge resources to be invoked in appropriate situations. KiP offers a unique lens for exploring the development of expertise, which is dependent on the extent of the *coherency of knowledge* (Orrill & Burke; 2013). By coherency of knowledge we refer to multiple knowledge resources that are connected in robust ways allowing for *in situ* access to the resources. Coherence, combined with a robust set of knowledge resources, allows teachers to deal with complex situations in more efficient ways. This is consistent with previous research on expertise (e.g., Bédard & Chi, 1992), and Ma's (1999) concept of profound understandings of mathematics. We hypothesize that as a teacher develops coherence among knowledge resources, the teacher will be more fluent at teaching and doing mathematics.

KiP represents a departure from the deficiency model traditionally used in the study of teachers' knowledge. Much prior research has focused on what knowledge teachers do not "have" and the misconceptions that they do display. In contrast, KiP assumes that teachers have a wide variety of knowledge resources available to them, but that those resources may not be well connected. KiP also allows for identification of additional resources that could be important for a teacher to develop.

Methods & Data Sources

The participants were 11 middle school teachers (6 females) ranging from 1 to 18 years of experience from multiple schools within a single state. Data were collected from two interviews. One, the LiveScribe interview, was a paper-based protocol with think-aloud prompts that included 23 items. We mailed the interview protocol to the participants along with a LiveScribe pen, which recorded their spoken words as well as marks they made on their paper. The second source of data was from a 90-minute videotaped clinical interview including 18 items conducted with each participant. All recordings were transcribed verbatim to capture the knowledge resources evoked by the participants. We analyzed the data by focusing on the knowledge resources the teachers demonstrated on these tasks (not those resources they did not use). We used open coding (Corbin & Strauss, 2007) to identify codes for knowledge resources.

Interview Tasks

For the current study, we considered participants' responses to four tasks that focused specifically on the relationship of fractions and ratios. The Triangle task (Table 2), from the LiveScribe interview, explored teachers' understandings of the multiplicative relationship between the two sides of the triangle. All the other tasks were drawn from the clinical interview. Tasks 2 and 3 focused on situation related to salad dressing shown in Table 2. In Task 2, participants are asked to respond to one teacher's approach to making sense of the situation using an algorithm to find equivalent fractions. We then asked the teachers, "What does 2:5 mean as two-fifths? What is there

2/5 of in this situation?" Task 3 asked the participants to react to other teachers' responses to Task 2 as shown in Table 2. We considered only the second bullet point, "fractions and ratios are the same

Table 2: Interview Tasks

Task 1 Triangle Task
Some students in Mr. Warren's class have noticed that the ratio of 3 feet to 24 feet simplifies to 1 to 8. They also know that this ratio can be written as 1/8. However, they get confused about what the fraction 1/8 means in this situation.  a) What does the 1/8 mean in this situation? b) How would you explain that to your students?
Task 2? Oil & Vinegar Situation
Alexi made a batch of salad dressing using 2 tablespoons of vinegar and 5 tablespoons of oil. She would like to make a much larger batch that preserves the ratio of vinegar to oil. If she uses 15 tablespoons of oil, how much vinegar should she use?
Task 3 Teachers' responses to the oil & vinegar situation
• "I know that 6 is $\frac{2}{5}$ of 15. So I guess there's a two-fifth there." • "Fractions and ratios are the same thing." • "$\frac{2}{5}$ is a ratio here not a fraction. A fraction is a part-whole relationship like 2 T vinegar to 7 T of salad dressing, which is $\frac{2}{7}$ not $\frac{2}{5}$." • "I wonder if it has something to do with finding how much vinegar I would need for 1 part oil or how much oil for 1 part vinegar?"

thing" for this analysis. Finally, Task 4 asked each participant whether they believe fractions and ratios are the same. (Note: there are 4 participants who did not respond to Tasks 2 and 3 due to time constraints in the clinical interview).

Results

In our analysis, we found three main results related to our questions of how 11 middle school teachers understand the relationship between ratios and fractions; and how coherent those understandings are. First, the participants did not share a unified definition of ratios. Second, these participants used specific vocabulary to discuss ratios that differed from their fraction vocabulary. Finally, these participants relied on language that evoked a build-up strategy rather than language that suggests multiplicative relationships.

Multiple Definitions

Consistent with previous research (e.g., Clark et al., 2003), these participants seemed to draw from multiple knowledge resources in defining the relationship between ratios and fractions. The knowledge resources we saw among the 11 participants were comparison of two concepts, part-part and part-whole relationships, context as differentiating, and equivalence. For example, five participants focused on the similarity between the representations of fractions and ratios in talking about the relationship of the two concepts. For instance, Greg said in response to Task 3,

> Fractions and ratios are the same thing…I mean, a ratio can be written as a fraction, but again, you could write this as 2/7ths. … when you're thinking about it as a ratio it's important to define what you're comparing what the numerator and denominator are.

Mike and Alan also mentioned the idea of "comparing two things to each other" (Mike).

Nine participants relied on discussions of part-part and part-whole relationships. Bridgett and Alan both relied on the idea that ratios are part-part whereas fractions are part-whole, without clarifying whether ratios could be part-whole. For example, Bridgett explained, "When we first introduce ratios we say it's a part over a part and then we say for fractions it's a part over a whole." Allison, Ella, Mike, Larissa, and Greg added that ratios can be part-whole relationships. For instance, Allison explained that ratio is part-part but "sometimes it can be a part to whole relationship" as in the relationship of "the vinegar to the whole recipe" in Task 2.

A third set of knowledge resources considered context as differentiating ratios and fractions. David and Greg both discussed the need for using units (labels) with ratios. David asserted that fractions and ratios are the same except, "… with a fraction you don't need a unit. A ratio you should have some type of unit… you don't just put numbers." Larissa considered the need for context through word problems as a differentiating characteristic. She stated, "When I'm dealing with fractions I don't necessarily see it as a ratio unless it's in a word problem form."

Equivalence was the final knowledge resource on which participants drew. Greg, David and Ella explained that the 1/8 in Task 1 is a ratio rather than a fraction by referring to equivalent ratios. For instance, Greg explained that 1/8 is "the ratio between the two legs" and that we also could have "1-to-8, 2-to-16, 30-to-240, and those would still have the same ratio." Larissa, Ella, Greg and Allison relied on the use of similar triangles to demonstrate that all triangles similar to the given one have the same ratio as the original triangle.

Ratio Language

For these 11 participants, ratios evoked certain phrases. Most common among these was the phrase "for every", which was used by nine of the participants. For example, in describing the relationship in the Task 1 David said, "For every one foot on the short side of this triangle you have eight feet on the long side of this triangle." Similar language was used by six participants and two others used this language in Task 2.

We also noted that many participants used "*a* to *b*" when describing ratios versus "*a* out of *b*" or "*a*-*b*ths" language when describing fractions. For example, Ella justified her assertion that there is not a two-fifths in the oil and vinegar situation saying, "the two-fifths is not like two to five… like it is just fundamentally part to part. Pretty much all ratios are." Care in using differentiating language use was not consistent for all the participants.

Build-up Language

Our third main finding focused on the language selected by the participants. There was pervasive use of language that suggested additive reasoning. In particular, we found that10 of the 11 teachers used some variation of "for every" in their response. For example, when responding to part B of Task 1, Bridgette stated, "so every time you go up one you should go out eight points." This suggested a build-up strategy in that every time you add one to the short side, you add 8 to the long side. Another suggestion of additive reasoning came in statements of uncertainty about multiplication versus addition. For example, Allison noted, "for every one unit on one side the other side has eight times that unit. I almost said eight plus, but then that wouldn't work if it was eight plus so it has to be eight times that unit." This suggested a tie to addition for this participant. Only Autumn avoided use of this language in her responses.

Conclusions

We examined 11 teachers' understandings of the relationship between fractions and ratios and how coherent those understandings were. The lack of a dominant focus for ratios and fractions suggests that students may be hearing a number of different definitions from their teacher. This is consistent with previous research and could partially be attributed to a wide array of definitions presented in textbooks (Clark et al., 2003) as well as to a lack of a single definition of these concepts in the field (Lamon, 2007; Lobato & Ellis, 2010; Vergnaud, 1988). For our research, the use of these resources raise questions about the coherence of teachers' knowledge. Holding many definitions that do not seem well-connected could suggest knowledge structures that are not robust enough to support an array of student thinking. For instance, if these teachers tell students that ratios are part-part relationships whereas fractions are part-whole relationships students may infer that ratio cannot be part-whole. Teachers with coherent and accurate resources for the relationship of ratios and fractions may be better able to support students in developing coherent understanding of these concepts.

We saw that language and context both seem to be important in considering knowledge resources for ratios and fractions. Many of the participants relied on certain phrases when discussing ratios. The participants were not consistent with these phrases and some used them interchangeably, which obscures the coherence or lack thereof of the concepts. Thus, language and context seem critical for the development of coherency of knowledge in this domain.

We found that several important aspects of a coherent and robust understanding of ratios and fractions were not evoked by the teachers. For example, not all described ratios as a comparison of two quantities. Also only five participants were able to reason about the relative value of one quantity to the other and six participants were unable to reinterpret a ratio as a fraction in Task 1. These teachers seemed to have access to knowledge resources for fractions and ratios, but relied only on ratio understanding in some cases.

This study considers areas in which participants may lack coherence in their understandings. For example, part-whole discussions only happened in the context of the oil and vinegar situation. In contrast, build-up strategies, which are more elementary (Lamon, 2007), were found across the tasks. For a coherent understanding, we would expect to see strong connections between consistently used knowledge resources comprising a robust understanding of ratios.

Scholarly Significance

Teachers need robust understandings of mathematics to support students' learning (e.g., Baumert et al., 2010). However, little research has been done on teachers' understandings of proportional reasoning to uncover how they conceptualize the relationship between fractions and ratios. Knowing how teachers understand the mathematics they teach has practical implications for guiding the development of effective support opportunities for teachers.

The teachers in our study have access to a variety of knowledge resources for fractions and ratios, but they have not necessarily developed coherent connections between those resources. Returning to the idea that expertise refers to having more structured knowledge (Bédard & Chi, 1992), this work unveils some possible connections between knowledge resources that teachers rely on when differentiating between ratios and fractions. More research needs to be done to highlight the kind of knowledge and the organization of the knowledge needed for teaching ratios and fractions.

SECONDARY MATHEMATICS METHODS COURSES: WHAT DO WE VALUE?

Mathematics teacher education has been criticized, both internally and externally, for failing to identify shared practices and goals within teacher preparation programs. Work has begun to address this criticism at the elementary level but less exists at the secondary level. This paper reports on a national survey with responses from 116 secondary mathematics methods course instructors from colleges and universities. The purpose of the survey was to identify those topics, or "touchstones," in secondary methods courses that are widely valued. The survey asked participants to rank 41 potential "touchstones" of secondary mathematics methods courses on a scale from one to five according to those touchstones they value most in their methods courses. The results were quantitatively and qualitatively analyzed looking for important characteristics that would spur discussion about shared goals in secondary teacher preparation.

Keywords: Teacher Education-Preservice; Mathematical Knowledge for Teaching

Teacher preparation is striving for continual improvement, motivated both internally and by critiques from external entities. Within the teacher preparation community, scholars and practitioners consistently press for self-improvement through adherence to guiding principles (Grossman, Hammerness, & McDonald, 2009), attention to the needs of schools and communities (Darling-Hammond, 2006), and emphasis on evidence-based practices as shared through venues such as the *Mathematics Teacher Educator* journal. External groups, such as some economists (e.g., Harris & Sass, 2011) or the National Council on Teacher Quality, have also called for reform, citing the difficult-to-detect effects of teacher preparation programs on beginning teacher performance. There are counterarguments, however, to the external critiques (e.g., Heller, Segall, & Drake, 2013). For example, it is unwise to condemn university-based teacher preparation programs in general when they vary widely in their specific features.

Some of these varied features are the quantity or quality of field components, course requirements, the content of required courses, and the alignment and integration of various aspects of a preparation program. In mathematics teacher preparation, specifically, some scholars (Ebby, 2000; Youngs & Qiang, 2013) have focused on the importance of prospective teachers' field experiences and the alignment between those experiences and the kinds of mathematics instruction advocated in methods courses. Others have called for more content courses for prospective mathematics teachers (Conference Board of the Mathematical Sciences, 2012) or for thoughtful integration of mathematics subject matter in pedagogical methods courses (Burton, Daane, & Giesen, 2008; Steele & Hillen, 2012). These subject-specific teaching methods courses—in which prospective teachers develop skills and pedagogical content knowledge essential to them developing effective, ambitious, and manageable classroom practices—are commonly a central component of teacher preparation programs (Sowder, 2007) but the number, format, and foci of these courses vary widely from institution to institution (Kidd, 2008).

This study focuses specifically on the topics addressed in mathematics teaching methods courses because these courses are largely under the control of mathematics teacher educators and so can be a focused area of improvement to complement larger-scale programmatic efforts. We address secondary methods courses because of our experiences at this level and because it is less studied than methods courses at the elementary level. This study involved a survey of 116 methods instructors from across the United States for the purpose of determining what topics they value for inclusion in secondary mathematics methods courses. We sought to determine the extent to which secondary mathematics methods instructors agree in their valuations and to identify topics that are broadly valued by instructors that may potentially serve as shared foci, or what we refer to as *touchstones*, for these courses. By analyzing and discussing responses from a large number of mathematics teacher educators, we can, as a field, work to clarify and bring needed coherence to the curricula of these methods courses.

Background

With regard to research on mathematics methods course, much of the past work focused on courses for prospective elementary teachers. Mewborn (1999) and Ebby (2000), for example, analyzed prospective elementary teachers' reflections on and connections between these courses and their concurrent field experiences. Swars and colleagues (2009) traced changes in prospective elementary teachers' beliefs and specialized content knowledge as they progressed through a two-course methods sequence that had associated field experiences, finding that shifts in the prospective teachers' beliefs about mathematics teaching and learning and their sense of efficacy with mathematical content could be traced to specific features of the methods courses. Ball and colleagues (2009) have also worked on features of elementary methods courses, developing and studying curricula for such courses that include high-leverage teaching practices and aim to develop mathematical knowledge for teaching.

At the secondary level, some scholars have developed textbooks for methods courses (e.g., Posamentier & Smith, 2009; Rock & Brumbaugh, 2013) and there is a wide range of studies that examine specific topics within the context of methods courses (e.g., Stump, 2001) but not a great deal of research focused on the overall content of secondary methods courses explicitly. Two exceptions to this lack of research on methods courses overall are the work of Markovits and Smith (2008) and Steele and Hillen (2012), both of which deal with content-focused methods courses that integrate pedagogical development with the development of mathematical knowledge for teaching through "discernible mathematical and pedagogical storylines that are tightly connected" (Steele & Hillen, 2012, p. 54). For the present study, it is important to note that one principle for designing content-focused methods courses is to choose a narrow focus on a specific mathematical topic or pedagogical process. This choice, then, becomes centrally important to the methods course and the advocates of content-focused methods courses do not explicitly specify what those focal topics or processes should be. Our study is complementary because it concerns the specific topics that one might choose to include in a secondary methods course but it does not specify how one might design a coherent course around the chosen topics.

Currently, there are many different topics addressed in secondary mathematics methods courses (Arbaugh & Taylor, 2008; Kidd, 2008). In an article about elementary programs that applies equally well to secondary programs, Ball and colleagues (2009) argued that the lack of a shared professional curriculum for teacher preparation means that "[s]tudent teachers' learning opportunities reflect the orientations and expertise of their instructors and cooperating teacher" rather than "common agreements about the preparation required for initial practice" (p. 459). Although the lack of common agreements is certainly a concern, the diversity that currently exists provides a rich set of resources to draw upon as we work to establish common agreement.

To guide the field in drawing upon those resources and achieving systematic improvement, Arbaugh and Taylor (2008) laid out a framework adapted from Borko (2004). Their framework identifies three phases of research phases. The first phase involves studying a single course or single teacher preparation program. The second phase involves studying a single course or a single program feature that is enacted in multiple teacher preparation programs. The final phase compares multiple programs with varying features across multiple sites. Arbaugh and Taylor (2008) pointed out that "the vast majority of work in mathematics teacher education fails to surpass Phase 1" (p. 5). The research in Phase 1 provides a valuable literature base for the field, but the present study moves into Phase 2 by focusing on a specific program feature—secondary mathematics methods courses—across the United States and Canada. This is not to say that our study is the first endeavor into Phase 2 with respect to methods courses. Indeed, Taylor and Ronau (2006) analyzed 58 methods course syllabi from members of the Association of Mathematics Teacher Educators (AMTE) and found considerable variation in the types of assignments included on the syllabus and the stated goals and objectives for the courses. The present study complements Taylor and Ronau (2006) by focusing on topics within secondary mathematics methods courses rather than assignments and broad learning goals and by relying on instructor survey responses which can capture more than what is encoded in a syllabus.

We use the term "touchstone" to refer to potentially agreed-upon topics for inclusion in secondary mathematics methods courses. This term has historical roots in the notion of a physical, public stone to which community members could bring their precious metal to verify its authenticity. In our usage, we imagine a set of touchstones as a community-developed, public resource to which instructors could refer as they design and develop their own courses. We chose to use "touchstone" rather than the term "standard" because "standard" conveys an official or authoritative quality that we do not intend. Rather, if this initial work of identifying potential touchstones for secondary mathematics methods courses leads to a well-defined set, we intend for the set to form a resource that instructors have the option but not the obligation to adopt.

Toward that end, this study addresses the following questions: Which potential touchstones do instructors of secondary mathematics methods courses value the most highly? Which potential touchstones are valued to significantly different extents by different instructors?

Method

Survey

Drawing on seminal research in the field related to mathematics teaching and teacher education (e.g., Arbaugh& Taylor, 2008; Schoenfeld & Kilpatrick, 2008; Swars et al., 2009) as well as our own experiences with secondary mathematics methods courses, we compiled a list of potential touchstones to be used in a survey for methods instructors. Examples of these touchstones are "Enacting mathematical tasks," "Formative assessment," and "Digital tools and technologies (e.g., calculators)." We piloted this list with approximately 20 instructors and asked whether items could be removed or whether items we had omitted should be added. Revision then yielded a list of 41 potential touchstones (see Appendix) that we used for this study. Our goal for the list was to balance comprehensiveness and specificity by covering a full spectrum of topics without overwhelming survey respondents with an inordinate number of options or with options that were too closely related to allow for meaningful distinctions.

We chose to supply a predetermined list of touchstones rather than ask open-ended questions because an open-ended approach would have likely led to a wide variety of phrasing and terminology in the responses and possible idiosyncrasies of meaning, as described by Kidd (2008), that we would then have to interpret and categorize with possible concerns for the internal validity of the analysis. We recognize that, with a predetermined list, respondents also have to engage in interpretation of what we mean with various phrasing of the touchstones, but we felt there would be less variability in the respondents' interpretations as readers of touchstones than there would be in their responses as writers of touchstones. Furthermore, it is possible that, when responding to an open-ended question, a respondent may inadvertently omit a topic that is actually quite valuable to them only because they did not happen to bring it to mind in the few minutes they were responding to the survey. With the predetermined list, we were able to go through a multi-step process to assure that there were no serious omissions and we also included an open-ended item at the end of the survey asking respondents to list any touchstones that they highly value but were not on the list. Finally, the predetermined list lessened the time demands on the respondents and thus likely increased the response rate.

The survey was administered electronically with the following prompt: “Please tell us how important you feel it is for each of the following content items to be valued and addressed by secondary mathematics methods courses for preservice teachers.” The 41 touchstones were then listed with a five-point Likert scale ranging from “Not important” to “Very important.” We chose to ask about the instructors’ values rather than about their actual practice because the latter may elicit what instructors feel obligated to teach or what they are able to address in a limited timeframe rather than what they value in an ideal sense. In addition to the open-ended item about missing touchstones, there was also an open-ended item for general comments. The survey then gathered demographic information including professional title, secondary methods teaching experience, and academic home (e.g., college of education, department of mathematics).

Participants

The survey was sent to the approximately 940 members of AMTE, with the invitation email explicitly asking for responses from those involved in secondary mathematics methods courses. An item on the survey was used to verify that respondents were secondary methods instructors as opposed to other members of AMTE. Members of AMTE were chosen because the association is professional peers within the field who would most like participate and find value in the results of this study. It should be noted that AMTE’s membership is not necessarily representative of all mathematics teacher educators in the United States but rather those who are active with regard to professional organizations of teacher educators. Thus our results should not be construed as the representative values of secondary mathematics methods instructors in general. The results, however, can be interpreted as representing the values of many of the leaders in mathematics teacher education and those likely to be involved in shaping future directions in the field.

We received 129 responses and included 116 responses in the analysis. Of these, 70 were from individuals in colleges of education and 36 were from individuals in mathematics departments. The remaining 10 individuals had either joint appointments or another situation.

Data and Analysis

The data were analyzed using quantitative and qualitative methods as the data included numerical and free responses. First, the data were compiled on the 41 touchstones to determine basic descriptive statistics (mean, standard deviation) to understand which touchstones participants valued the most and the least. Independent t-tests and analyses of variants (ANOVA) were used to determine if certain groups separated by department or professional title varied significantly in how they valued any of the 41 touchstones. Second, the free responses were qualitatively analyzed to determine what touchstones participants perceived as missing and to identify themes in any of the additional comments offered.

Results

Due to space limitations, only the overall valuations of the touchstones and comparisons according to academic home will be reported in this paper.

Descriptive Statistics

Table 1 lists the 41 touchstones ordered by mean values. Note that every touchstone had a rating above 2.5 out of 5, which lends internal validity to the set of potential touchstones. Nineteen of the 41 touchstones had means within one standard deviation of the highest-rated touchstone and 0

Table 1: Touchstones Ordered by Mean Value

Touch stone	Description	Mean	St. Dev.
TS4	understanding of practice/process standards (e.g., CCSS, NCTM, NRC)	4.71	0.56
TS16	multiple representations of mathematical ideas	4.68	0.57
TS28	attending to student thinking and using student ideas to push understanding forward	4.68	0.58
TS35	mathematical knowledge for teaching	4.68	0.64
TS8	adapting, choosing, and generating mathematical tasks	4.61	0.59
TS20	productive classroom discourse	4.59	0.61
TS9	enacting mathematical tasks	4.55	0.68
TS6	lesson and unit planning	4.53	0.67
TS7	cognitive features of mathematical tasks	4.48	0.67
TS3	understanding of content standards (e.g., CCSS, state, district, school)	4.48	0.68
TS17	the relationship between conceptual and procedural knowledge	4.47	0.68
TS11	formative assessment (on-going assessment)	4.44	0.74
TS29	motivating students to persevere and take risks	4.36	0.76
TS36	reflection on practice and development as a professional educator	4.35	0.69
TS10	informal assessment (e.g., observation, conversations with students)	4.34	0.79
TS5	choosing and writing instructional goals	4.28	0.8
TS21	positive classroom culture	4.26	0.79
TS37	repertoires of effective mathematical teaching practices and pedagogical tools	4.22	0.74
TS18	pedagogies that address different types of knowledge and skills (e.g., procedural, conceptual, strategic, declarative)	4.17	0.83
TS25	digital tools and technologies (e.g., calculators)	4.14	0.72
TS34	mathematical content knowledge	4.13	0.91
TS30	nature of problem-solving	4.11	0.81
TS23	roles of the mathematics teacher (e.g., teacher as guide, teacher as lecturer)	4.11	0.84
TS26	analog tools and technologies (e.g., manipulatives)	4.05	0.78
TS14	issues of equity, status, fairness, and social justice	4.05	0.93
TS24	mathematical applications or mathematics in context	4.03	0.84
TS12	summative assessment to assess student understandings	3.98	0.78
TS15	needs of underrepresented populations	3.98	0.95
TS1	curriculum vision	3.91	0.86
TS2	knowledge of written curriculum materials	3.81	0.81
TS31	students' metacognitive skills	3.78	0.81
TS27	classroom management that supports cultural and learning goals	3.77	0.95
TS40	learning theories and applications to practice	3.73	0.89
TS22	sociomathematical norms	3.73	0.95
TS19	relationship between participation structures (e.g., pair work, complex instruction) and cultural and learning goals	3.72	0.97
TS33	personal and societal beliefs about teaching and learning mathematics	3.62	1.07

TS13	expectations, purposes, and design of homework	3.61	0.88
TS39	teaching theories and applications to practice	3.54	0.88
TS38	read educational research	3.38	0.9
TS32	history and nature of mathematics	3.09	0.94
TS41	do educational research (e.g., Action Research)	2.78	1.07

touchstones had a mean near the “not important” or “less important” ratings, indicating that the respondents tended to value a large portion of the potential touchstones. Only 32 out of 116 respondents made any suggestion of additional touchstones and most were singular suggestions (e.g., working with parents). Seven additional touchstones were suggested by at least two respondents. One related to reflecting on practice was mentioned in some form 5 times and another related to learning trajectories was mentioned 4 times.

Comparison by Department

Focusing on respondents from colleges of education or mathematics departments, and using an alpha level of 5%, we found statistically significant differences between the valuations of five touchstones (see Table 2). As there were nearly twice as many participants in educational departments (70) to those in mathematics departments (36), assuming equal variance was not possible in every case. Thus we ran independent *t*-test comparisons with equal variance assumed or not assumed as appropriate according to Levene’s statistic ($p<0.05$).

Table 2: Touchstones that varied significantly by respondents’ department

Touchstone	TS3	TS9	TS10	TS14	TS15
Description	understanding of content standards (e.g, CCSS, state, district, school)	enacting mathematical tasks	informal assessment (e.g., observation, conversations with students)	issues of equity, status, fairness, and social justice	needs of underrepresent ed populations
Equal Variance	Not Assumed	Not Assumed	Assumed	Not Assumed	Not Assumed
***t*-score**	3.399	-2.288	-3.258	-3.205	-3.601
df	96.557	62.510	104	53.573	55.199
***p*-value**	0.001	0.026	0.002	0.002	0.001
Education Department Mean	4.429	4.686	4.529	4.271	4.271
St. Dev.	0.627	0.627	0.583	0.779	0.779
Mathematics Department Mean	4.778	4.361	4.028	3.611	3.556
St. Dev.	0.422	0.723	1.000	1.103	1.054

Table 2 shows that understanding content standards (TS3) varied significantly, with participants from mathematics departments valuing it more than participants from colleges of education. On the other hand, enacting mathematical tasks (TS9), informal assessment (TS10), issues of equity, status, fairness, and social justice (TS14), and needs of underrepresented populations (TS15) were valued more highly by those in colleges of education than in mathematics departments.

Discussion

The purpose of this study is to spur conversation amongst mathematics teacher educators about what we value with regard to topics in secondary mathematics methods courses. Based on our survey results, part of this conversation can be the idea of a set of touchstones for secondary methods courses, possibly consisting of those items valued most highly by our respondents. We found the notion of preservice secondary mathematics teachers coming to understand process standards (NCTM, 2000) or the Standards for Mathematical Practice (NGO & CCSSO, 2010) to be valued the most highly. Also valued very highly were the notions of using multiple mathematical representations, attending to student thinking and student ideas, and developing the preservice teachers' mathematical knowledge for teaching. These touchstones and others align with ongoing national efforts focused on mathematics education in general, such as the National Council of Teachers of Mathematics' (2014) *Principles to Actions*, which laid out eight effective teaching practices that are largely consonant with the highest rated touchstones.

Our results also confirm past work (e.g., Taylor & Ronau, 2006) showing that mathematics teacher education as a field places high value on a wide range of topics and activities. Although the set of touchstones covers a vast array of topics, each of which could easily warrant extended attention and development, results show nearly all of it being valued for inclusion in secondary methods courses. In other words, we may as a field be a bit too ambitious, especially considering the issue of limited time with which to address these touchstones in methods courses specifically. This concern was raised several times in the comment section of our survey and thus is worth discussing. One way to address the time constraints is to move certain touchstones to other facets of teacher preparation programs besides methods courses. Another way to address time constraints is to remove some of the lesser-valued touchstones from consideration, perhaps because they are unnecessary, such as having preservice teachers read or conduct empirical research, or because they are better suited for development for inservice teachers, such as the role of sociomathematical norms in classrooms or the applications of learning theories to practice. To be clear, we are not suggesting specific remedies for this dilemma, but the results presented here can form an empirical basis on which to make these decisions rather than relying solely on the idiosyncrasies of individual instructors as critiqued by Ball and colleagues (2009).

This study is a modest effort in Phase 2 of Arbaugh and Taylor's (2008) roadmap for research on mathematics teacher education. We have gathered input from methods instructors from across the country, representing many different teacher preparation programs. Yet, future research can go further to gather more detailed data to allow for the examination of the ways in which respondents interpreted the touchstones presented here. Moreover, future research could bridge the gap between what we value for methods courses in an ideal sense and what is actually occurring in the methods courses. Some of this work is already underway via the Mathematics Teacher Education Partnership (MTEP), which is a consortium of secondary mathematics teacher educators from 30 states and 69 universities formed to coordinate improvement of secondary mathematics teacher preparation. The results presented here can inform MTEP and other similar efforts to identify what we value in the field and what we want to emphasize with preservice teachers in the limited opportunities that we have to interact with them.

Acknowledgments

We thank the Service, Teaching, and Research (STaR) program and the Association of Mathematics Teacher Educators for facilitating this study and we thank the Southeastern Conference faculty travel grant program for their financial support.

REASONING QUANTITATIVELY TO DEVELOP INVERSE FUNCTION MEANINGS

Teo Paoletti
University of Georgia
paolett2@uga.edu

Researchers have argued that students can develop foundational understandings for a variety of mathematical concepts through quantitative reasoning. I extend this research by exploring how students' quantitative reasoning can support them in developing meanings for inverse relations that influence their inverse function meanings. After summarizing the literature on students' inverse function meanings, I provide my theoretical perspective, including a description of a quantitative approach in the context of inverse relations. I then present one student's activity in a teaching experiment designed to support her in reasoning about a relation and its inverse as representing the same relationship. The student's quantitative reasoning supported her in developing productive meanings for inverse function, although this required her to reorganize her understanding of various mathematical ideas.

Keywords: Cognition; Teacher Education-Preservice; Design experiments

Researchers have indicated students can leverage reasoning quantitatively to develop meanings for various mathematical topics before developing more formal mathematical understandings (Ellis, Ozgur, Kulow, Williams, & Amidon, 2012; Johnson, 2012). Researchers using a quantitative reasoning lens have also provided important insights into students' learning of a variety of secondary mathematics topics including specific function classes (e.g. linear functions (Johnson, 2012; P. W. Thompson, 1994) and exponential functions (Ellis et al., 2012)). A natural extension of this body of research is to explore how students' quantitative reasoning influences their notions of relations (or functions) and inverse relations prior to and concurrently with thinking about specific function classes. In this report, I summarize the research on students' inverse function meanings then propose ways of thinking that have the potential to support students in developing productive inverse relation and inverse function meanings. I present important aspects of a student's activities from a semester-long teaching experiment designed to support her in developing such meanings. I conclude with implications stemming from this work and directions for future research.

Research on Inverse Function

Vidakovic (1996) presented a genetic decomposition for inverse function (i.e. a description of how students might learn a concept, including methods for constructing their schemes). She proposed that students develop inverse function schemas in the following order: function, composition of functions, then inverse function. She conjectured students could coordinate all three schemas and develop inverse function meanings through this coordination. Whether implicitly or explicitly, many researchers (Brown & Reynolds, 2007; Kimani & Masingila, 2006; Vidakovic, 1997) who have examined students' inverse function meanings have maintained an emphasis on composition of functions as critical to students developing productive inverse function meanings. However, these same researchers noted that students often carry out techniques for successfully determining representations of inverse functions (e.g., determining an inverse function analytically) without connecting these techniques to function composition. As a consequence, students (and teachers) hold compartmentalized inverse function meanings, typically related to executing specific actions in analytic or graphing situations (Brown & Reynolds, 2007; Kimani & Masingila, 2006; Paoletti, Stevens, Hobson, LaForest, & Moore, in press). Moreover, Paoletti et al. (in press) reported that pre-service teachers, when given a function meant to represent a context, struggled to interpret the contextual meaning of the inverse function they constructed. Collectively, these researchers' findings suggest that current approaches to inverse function have been ineffective in supporting students in developing productive inverse function meanings. Complicating the matter, and as I argue in more detail below, researchers predominately treat students construction of 'inverse function' meanings as distinct from their function understandings (e.g., Vidakovic's genetic decomposition), as opposed to approaching 'inverse function' as developing hand-in-hand with 'function'.

Theoretical Framing

I explore the possibility of supporting students developing inverse meanings via reasoning about quantities and relationships between quantities (i.e. reasoning quantitatively). A *quantity* is a conceptual entity an individual constructs as an attribute of an object or phenomena that allows a measurement process (P. W. Thompson, 1994). As an individual associates two varying (or non-varying) quantities, she can construct *quantitative relationships* (Johnson, 2012; P.W. Thompson, 1994); an individual engages in *quantitative reasoning* as she constructs and analyzes these relationships (P. W. Thompson, 1994).

Using a quantitative reasoning lens, I conjectured that if a student constructed a relationship between two quantities (e.g., quantities A and B) that did not entail some conceived causation between the quantities, the student could choose one quantity to be the input of a relation (e.g., A input, B output) while anticipating that the inverse relation would involve choosing the other quantity as the input (e.g., B input, A output). With respect to graphing relations and inverse relations in the Cartesian coordinate system, a student who understands relations in ways compatible with this could interpret a single graph as representing both a relation and its inverse. Engaging in such reasoning requires the student to anticipate choosing either axis as representative of an input quantity; researchers (Moore & Paoletti, 2015; A. G. Thompson & Thompson, 1996) have defined such reasoning as bidirectional reasoning. Although this type of reasoning may seem trivial, Moore, Silverman, Paoletti, and LaForest (2014) illustrated that students are often restricted to reasoning about the quantity represented along the horizontal axis as the input.

By focusing on a relationship between quantities, the 'function-ness' of a relation and its inverse is not critical. A student can describe a relation and its inverse without (necessarily) being concerned if either represents a function. Moreover, the student understands that the choice of input-output quantities does not influence the underlying relationship that the associated functions or relations describe. Whereas this approach does not foreground function (or composition of functions) as critical to developing inverse meanings, I conjecture a student who develops understandings compatible with those described would have little difficulty making sense of the formal definition of inverse function that relies on composition of function (e.g., understanding if $B = f(A)$ and $A = f^{1}(B)$, then $f(f^{1}(B)) = f(A) = B$ and $f^{-1}(f(A)) = f^{1}(B) = A$).

Methods

I conducted a semester-long teaching experiment with two undergraduate students, Arya and Katlyn (pseudonyms). I focus this report on Arya's activity. Arya was a junior who had successfully completed a calculus sequence and at least two additional courses beyond calculus. The teaching experiment consisted of three individual semi-structured task-based clinical interviews (per student) (Clement, 2000) and 15 paired teaching episodes (Steffe & Thompson, 2000). I used clinical interviews to explore Arya's function inverse meanings without intending to create shifts in her meanings. I used the teaching episodes to pose tasks and questions that I conjectured might perturb Arya's meanings, leading her to make accommodations to her meanings to resolve her perturbations.

I used the combination of clinical interviews and teaching episodes to explore Arya's mathematical activity, to build models of her mathematics, and to investigate the mathematical progress Aryamade over the semester (Steffe & Thompson, 2000).

In order to analyze the data, I used open (generative) and axial (convergent) approaches (Strauss & Corbin, 1998) in combination with conceptual analysis(P. W. Thompson, 2008)to develop and refine models of Arya's mathematics. Initially, I analyzed the videos identifying episodes of Arya's activity that provided insights into her meanings. Using these identified instances, I generated tentative models of her mathematics that I tested by searching for activity that corroborated or refuted my models. When Arya exhibited novel activity that contradicted my models, hypotheses were made to explain this activity including the possibility that this new activity indicated fundamental shifts in her operating meanings. Through this iterative process of creating, refining, and adjusting hypotheses of Arya's meanings, I was able to not only characterize her thinking at a specific time or situation, but I was also able to explain transitions in Arya's meanings throughout the teaching experiment.

Task Design

I focus this report primarily on one task (*Graphing sine/arcsine task*, Figure 1), which a research team designed to support the pair of students in developing productive inverse relation meanings via reasoning bidirectionally. Relevant to this report, the first two parts of this task involve the students creating graphs of the sine (Graph 1) and arcsine function (Graph 2). The third prompt asks the students to consider how they could use Graph 1 to represent the arcsine function. The prompt also asks the students to consider if Graph 1 and Graph 2 represent "the same relationship." I conjectured by asking the students to foreground the "relationship" represented by both graphs, they might engage in reasoning bidirectionally in order to conceive Graph 1 and Graph 2 as representing both the sine and arcsine functions (or relations).

Graph 1:	Create a graph of the sine function with a domain of all real numbers. What is the range?
Graph 2:	Using **covariation talk**, create and justify a graph of the arcsine (or inverse sine) function.
Prompt 3:	Can you alter (**do not draw a new graph**) Graph 1 such that it represents the graph of the arcsine function? Does this graph convey the same relationship as the second graph? How so or how not?

Figure 1: Graphing sine/arcsine task

Results

For brevity's sake, I highlight important instances in Arya's activity in order to describe her thinking including shifts in her thinking. I first describe Arya's activity (most relevant to this report) during the initial clinical interview in order to characterize her meanings prior to the teaching episodes. I then provide data from four consecutive teaching episodes in which Arya addressed the prompts in the *Graphing sine/arcsine task* for various relations.

Results from the initial clinical interview

When given a function's graph and asked to determine a graph of the inverse function, Arya switched the coordinate values (e.g., a point (a, b) from the original curve became (b, a) on the inverse curve). When asked to determine the inverse of a function represented analytically, Arya switched the variables and solved for the previously isolated variable (heretofore referred to as switched-and-solved) (e.g., the inverse of $y = x + 1$ was $y = x - 1$). I also gave Arya a function defined analytically that converted degrees Fahrenheit to degrees Celsius (i.e., $C(F) = (5/9)(F - 32)$ and asked her to represent the inverse function. She switched-and-solved obtaining $C^{-1}(F) = (9/5)F + 32$. When asked to interpret the meaning of the inverse equation, Arya considered again switching the variables (e.g., $F(C) = (9/5)C + 32$), but rejected the resulting equation because it defined the same relationship between degrees Fahrenheit and Celsius as the original equation and function. I inferred from Arya's activity that she anticipated a function and its inverse function represented relationships that differed in some way other than a choice of defining input-output quantities (e.g., having different graphs or defining a different relationship).

Also of note from the interview, Arya exhibited activity in multiple problems that I took to indicate she was restricted to reasoning about the horizontal axis as representing a function's input. For instance, when given the graphs in Figure 2 and asked "Are these graphs the same or different?" Arya argued, "[the graphs are] showing the same thing but in a different way… this [*Figure 2a*] is what is happening to distance as time is going on." Then describing Figure 2b, Arya stated, "As you change your distance… the time is moving forward." In this and other cases, Arya maintained considering the horizontal axis as representing a function's input or the independent quantity of a relationship.

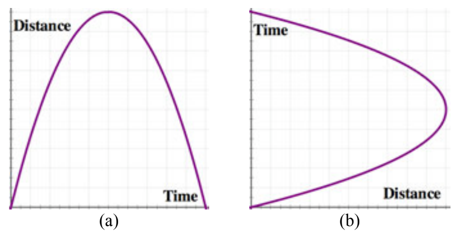

Figure 2: Double parabolas problem: Are the graphs the same or different?

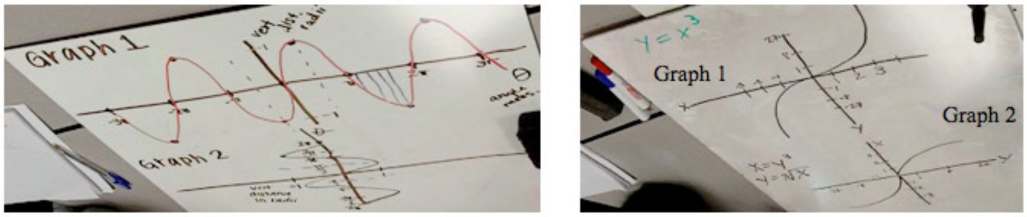
Considering sine and arcsine

Nine days prior to the first teaching episode exploring the *Graphing sine/arcsine task*, Arya and Katlyn constructed the sine function as a relationship between an angle measure (input) and a vertical segment length above the horizontal diameter measured relative to a circle's radius (output) in a circular motion context (see Moore (2014)). Upon my giving the students the *Graphing sine/arcsine task*, they reproduced the graph of the sine function (see Figure 3a, Graph 1). Arya then leveraged her understanding of switching the coordinate values to graph the arcsine relation (e.g., the point ($\pi/2$, 1) became (1, $\pi/2$), see Figure 3a, Graph 2). The students labeled the horizontal and vertical axes in Graph 2 'vertical distance' and 'angle measure', respectively. I then questioned the students about "what [the] two graphs are representing?" Arya responded, "They're showing the same relationship, but this [*pointing to Graph 2, Figure 3a*] shows… if you're changing your vertical distance on your graph, what [*pointing to θ-label on the vertical axis*]radian measure that corresponds to. And this shows [*pointing to Graph 1, Figure 3a*] if you're changing your angle measure what vertical distance that corresponds to." As during the *Double parabolas problem*, Arya *described* the graphs as representing the same "relationship," but her interpretation of each graph relied on the horizontal axis as representing the input quantity (e.g., the quantity that she first envisioned varying or caused the other quantity to vary).

With both students content in their explanations of the two graphs, I asked them to consider the third prompt with the hopes of raising the underlying difference between their understandings of the graphs. Katlyn first wrote the analytic equation $\sin^{-1}(y)= \theta$ near Graph 1 and described interpreting Graph 1 with the vertical and horizontal axis representing the input and output quantity, respectively, of the arcsine relation. Arya responded, "I don't know if that, can you do that?" Katlyn's claim contradicted Arya restricting a function's input to the horizontal axis. As the interaction continued, Arya attempted to refute Katlyn's reasoning. But, as she attempted to do so, Arya continually returned to her understanding that Graph 1 represents the same distance-angle measure pairs regardless of which axis is denoted as a function's input. She concluded, "I don't see anything mathematically incorrect. I don't see it."



(a) (b)

Figure 3: Graphs of (a) the sine and arcsine functions and (b) a cubicand its inverse

By focusing on both graphs as representing, “Vertical distance and angle measure… the relationship between the two,” Arya reorganized her meaning for interpreting graphs. Specifically, as Arya addressed the third prompt in the *Graphing sine/arcsine task* and Katlyn’s claim, she had to consider whether graphs unquestionably represented the input quantity on the horizontal axis or if this was a common practice of graphing. Once Arya understood that graphs could be interpreted with either axes as representing the input (i.e., reasoned bidirectionally with respect to axes), she understood a single graph as representing both a relation and its inverse. By the end of the second teaching episode, Arya exhibited this understanding multiple times with respect to both Graph 1 and Graph 2, leading me to conjecture she had constructed the sine and arcsine relations as representing the same relationship between angle measure and vertical distance.[1] Moreover, she understood that a graph of the sine relationship simultaneously represented a graph of the arcsine relationship, and vice versa.

Considering a decontextualized function

I designed the third teaching episode to explore how Arya might extend her reasoning with the sine and arcsine relations to a relation or function represented by a decontextualized equation ($y(x)= x^3$). For instance, I was unsure if she would continue to reason about a relation and its inverse as representing the same underlying relationship, particularly when graphed, or if she would encounter perturbations due to the different context and the chance that she might use her switch-and-solve technique (on the previous task they maintained a quantitative referent for each variable rather than switching the variables). After graphing $y= x^3$ (Figure 3b, Graph 1), the pair switched-and-solved to obtain the inverse rule $y=x^{1/3}$. They were unsure how to graph this equation so I suggested they recall their activity from the previous sessions. In response, they labeled the horizontal axis y, the vertical axis x, and they constructed Graph 2 (Figure 3b) by considering how y changed (along the horizontal axis) for changes in x (along the vertical axis) so that they maintained the same x-y relationship of Graph 1. That is, when drawing Graph 2, their focus was not on the equation $y=x^{1/3}$, but instead the relationship between the varying values x and y as depicted in Graph 1.Arya argued, “all the same information is in both graphs.” Compatible with the outcome of the prior two teaching episodes, Arya’s (and Katlyn’s) graphing activity indicated that she anticipated that a relation (or function) and its inverse represented the same relationship between quantities that could be represented graphically in multiple ways.

Due to my perceived discrepancy in their Graph 2 and the equation they had determined, I asked Arya to write an equation for Graph 2. She pointed to the equation $y = x^{1/3}$ but quickly noticed Graph 2 (Figure 3b), as labeled, did not represent an equivalent relationship between the varying values x and y. Because of this, Arya relabeled the vertical axis y and the horizontal axis x so that Graph 2 represented, “This equation [*pointing to* $y = x^{1/3}$].” Although Arya’s newly labeled graph represented the equation $y=x^{1/3}$, she immediately experienced another perturbation. Given her new axes labels, she noted that Graph 1 and Graph 2 did not represent the same relationship between the varying values x and y. Hence, Arya realized that her switching-and-solving activity was inconsistent with her activity in the previous teaching episodes where she maintained the relationship between the quantities (i.e., variables).

As Arya was unable to reconcile her perceived inconsistency between switching-and-solving and maintaining the relationship between quantities (or variables) in both Graph 1 and Graph 2, I directed her to address the third prompt believing this may support her in considering the relation in *Graph 1* as simultaneously representing the inverse relation, and that she might then note that her Graph 2 was merely the result of using variables arbitrarily. Consistent with her activity interpreting Graph 1 in Figure 3a as the arcsine relationship, Arya described two ways of interpreting Graph 1 in Figure 3b by considering either the horizontal or vertical axis as her input. Although Arya had no difficulty reasoning bidirectionally with respect to the axes in Graph 1, this did not support her resolving the differences she perceived between Graph 1 and Graph 2 (Figure 3b) due to the discrepancy introduced by her use of variables.

Contextualizing the function

As Arya began to question the validity of her activity when graphing the arcsine relation, and based on my interpretation that she did not realize that switching-and-solving requires using variables arbitrarily, I attempted to give contextualized meanings to the variables in order to support Arya in reflecting on her use of variables. I rewrote the given equation as $V = s^3$ and asked Arya to consider the equation as representing the volume of a cube (V) for a given side length (s) with the caveat that we could have negative side length and volume values. When considering the context, Arya labeled both Graph 1 and Graph 2 in a way that maintained both the relationship between volume and side length and the variable referents; in Graph 1 she labeled the horizontal axis *side length* and the vertical axis *volume* and in Graph 2 she labeled the horizontal axis *volume* and the vertical axis *side length*. Although Arya maintained the relationship between side length and volume in both graphs, this did not alleviate her perturbation as she remained unsure how this related to her switching-and-solving activity.

To support Arya in considering a way to relate her activity maintaining the relationship between quantities (and maintaining variable referents) with her switching-and-solving activity, I raised the idea of using the variables arbitrarily. I wrote the equations $y = \sin(x)$ and $y = \arcsin(x)$ next to two unlabeled Cartesian coordinate systems. I asked the pair to describe how they would label each coordinate system for the given equation and what quantity each variable would represent in each case. Katlyn stated she would use the conventional x-horizontal, y-vertical axis labeling and that for the $y = \sin(x)$, x would represent angle measure but in $y = \arcsin(x)$, y would represent angle measure. Arya questioned, "Why do we do that?… It doesn't make sense… Just because we want this to be our input [*pointing to x in the equation* $y = x^{1/3}$] and that to be our output [*pointing to y in* $y = x^{1/3}$]? I feel like that's really the only…It's [*referring to switching the variables*] just so you can call your input x and your output y."

Although Arya identified that switching-and-solving maintained calling the input quantity x, this did not resolve her perturbation. For instance, Arya leveraged reasoning bidirectionally to question the need of a second graph if a relation (or function) and its inverse were meant to represent the same relationship between quantities, saying, "If they gave me this graph [*Graph 1*] and wanted me to find the information, with this [*the vertical axis*] as the input I certainly could… I could turn my head and look at it [*Graph 1 with the vertical axis as input*] and understand what that means. There's still no reason for this [*pointing to Graph 2*] graph. So… like when you switch then you're saying something new." Arya maintained that her switching-and-solving technique resulted in 'something new', which was incompatible with her anticipation that a function or relation and its inverse maintain the same relationship.

Through much of the remainder of the last two teaching episodes, Arya experienced a state of perturbation as she attempted to relate her quantitative meaning for inverse to her switching-and-solving activity. By the end of the fourth teaching episode, Arya understood using variables arbitrarily (e.g., switching the quantitative referents of variables) to relate these meanings but continued to question why this would be done if a function and its inverse were meant to represent the same relationship. Arya's activity in contextualized situations, along with her reasoning bidirectionally with respect to the axes and her reasoning about variables as arbitrary, supported her in reorganizing her meanings for inverse relations (and functions). In later interactions, Arya maintained that a relation (regardless of if the relation was a function) and its inverse represented the same relationship and that in order to make sense of switching-and-solving she had to use the variables arbitrarily to represent the quantities under consideration (although she continued to question why she was taught to switch the variables).

Discussion and Concluding Remarks

By the end of the teaching experiment Arya understood that a relation and its inverse (regardless whether the relation was a function in the formal sense) represented the same relationship. However, developing this understanding was not trivial; it required Arya to reorganize her meanings for interpreting graphs (e.g., which axis could represent the input quantity), her meanings for variables (e.g., changing the quantitative meaning of x depending on the function under consideration), and her inverse function meanings (e.g., a function and its inverse represent something different). Whereas previous researchers have focused on students' and teachers' developing inverse function meanings via their understanding of function composition, these results provide insights into a different approach to inverse functions (or relations). To develop an understanding of a relation and its inverse as representing the same invariant relationship, the student in this study had to consider and reflect on various meanings she maintained (e.g., graphical conventions, interpreting variables, inverse procedures). As she reflected on her activity including her coordinating relationships between quantities, the student reorganized her meanings for various mathematical ideas so that she could adequately address the prompts in the *Graphing sine/arcsine task* (as well as all previous problems she was able to address). Previous researchers have indicated students can leverage quantitative reasoning to develop foundational meanings for various mathematical topics (Ellis et al., 2012; Johnson, 2012), and these results indicate students can reorganize already developed meanings via quantitative reasoning, although this process is not trivial.

In this report, I focused on Arya's development of inverse relation (or function) meanings via her reasoning quantitatively about relationships. Arya's activity had the potential to influence other meanings as well, including her function meanings. Future researchers may be interested in exploring how quantitative and/or bidirectional reasoning has the potential to support students in developing foundational function meanings. Additionally, this work examines the activity of a student who had already developed meanings for inverse function. Researchers may be interested in exploring how students who have not had formal instruction in functions and inverse functions (e.g., middle school students) could develop meanings for (inverse) function via their reasoning about quantities as these results indicate that such an approach has the potential to support students in developing productive inverse meanings.

Endnote

[1]Arya did discuss restrictions to the graphs in Figure 3(a) such that both Graph 1 and Graph 2 would represent functions regardless of chosen input quantity, but she typically worked with the arcsine relation (a multi-valued function).

"I DON'T THINK I WOULD TEACH THIS WAY": INVESTIGATING TEACHER LEARNING IN PROFESSIONAL DEVELOPMENT

Priya V. Prasad
University of Texas at San Antonio
priya.prasad@utsa.edu

Can professional development (PD) have a profound and lasting effect on participating teachers? The purpose of this study was to understand how teachers learn new mathematics content in professional development in order to contribute to the open question of how PD affects teachers' actual instructional choices in the classroom. Teachers were followed from a content-based PD program into their classrooms and their content knowledge was probed in each context. Data was analyzed from the perspective of motivation theory. Findings show compelling links between teachers' motivations, their conceptions of their students, and the nature of their knowledge of algebra. These links have broader implications for conceptualizing in-service teacher learning.

Keywords: Teacher Education-Inservice; Teacher Knowledge

Research on the professional development (PD) of mathematics teachers depends heavily on the question of what kinds of knowledge teachers need in order to teach mathematics effectively. After Shulman's (1986) introduction of the idea of pedagogical content knowledge and its subsequent refinement, researchers interested in both preservice and inservice teacher education have developed a clearer idea of what types of knowledge teachers needed to develop (Grouws & Shultz, 1996). However, defining the types of mathematical knowledge teachers need is only the first step in fostering that knowledge in teachers. Although the field has struggled to define and measure the effectiveness of PD without using teacher self-reports or student achievement data, there is no doubt that such an endeavor relies on understanding how teachers use concepts learned in professional development in their own classrooms. The purpose of this study was to investigate the ways in which teachers participating in content-based professional development made connections between the mathematical content of the PD program and their own mathematics instruction.

Background

The professional development of teachers is just one stage in the overall education of teachers and often comes at a time when teachers have settled comfortably into their practice (Feiman-Nemser, 2010). According to Feiman-Nemser, research has viewed teachers at this stage in two ways, either having already settled into a basic style and resistant to efforts aimed at change or constantly changing (with or without the help of professional development) in order to become more effective with students and to gain professional satisfaction. This study is done with the second view in mind, positing that professional development is one way of guiding or channeling the change teachers already are invested in making. However, according to previous research, the effectiveness of any program aimed at changing instructional practice must rely on how well such programs align with a teacher's preexisting beliefs about teaching, learning and mathematics (Arbaugh, Lannin, Jones, & Park-Rogers, 2006; Chapman, 2002; Thompson, 1984).

Due to the increasing diversity of teachers' mathematical backgrounds, educating inservice teachers produces issues very similar to those faced when educating diverse learners (Adler, Ball, Krainer, Lin, & Novotna, 2005). However, while some facets of professional development reflect the dynamics of a mathematics classroom, such as an instructional triangle consisting of interactions between nodes representing the professional development instructors, the participating teachers and the mathematics content (Borko, 2004), teachers constantly consider their own students–even while attending to their own learning–creating an instructional rhombus with the fourth node representing the teachers' real or hypothetical students (Nipper et al., 2011). However, Nipper et al. found that tension between the teachers and the content of the professional development arose as teachers realized that the mathematics content of the program was not content that they could directly use in their own classrooms.

Previous research has identified particular design features that characterize effective professional development: sustained learning over a period of time, active learning by teachers, examples from classroom practice, collaborative activities, modeling effective pedagogy, opportunities for reflection, practice and feedback, and focus on content (Boyle, White & Boyle, 2004; Hill, 2004). Ross, Hogaboam-Gray, and Bruce (2006) found that a professional development program which incorporated all these features resulted in a significant increase in student achievement on an external assessment. However, Marra et al. (2010) argue that individual design features are not as important the interactions between these features. Thus, they propose the orientations framework for classifying professional development programs. Based on their framework and the meta-study they conducted, they conclude that the most effective orientations of professional development are either completely or partially content-driven. This conclusion is echoed by Sowder, Philipp, Armstrong, and Schappelle (1998), who found that teachers appreciated when attention was paid to learning mathematics content. Sowder et al. found that changes in mathematical knowledge prompted changes in instruction, but this was mediated by teachers' comfort level with the content. Moreover, increased understanding of the mathematics they were teaching prompted the teachers to have greater expectations for their students' mathematical learning and changed their views about the centrality of curriculum materials and the quality of the classroom discourse. Content-driven professional development has also been shown to support student achievement (Hill, Rowan, & Ball, 2005; Saxe, Gearhart, & Suad Nasir, 2001).

However, while much research has been done to identify effective professional development, most of it relies on teachers' self-reporting of aspects of professional development that they liked and what instructional changes they have made (Marra et al., 2010). Less work has been done in understanding how teachers use the knowledge gained in professional development and how that knowledge leads to instructional change.

Theoretical Frameworks and Research Question

This study adds to the existing knowledge by applying the frameworks of motivation theory to analyze teachers' participation in and engagement with professional development. There are four major frameworks that make up the foundation of motivation theory as applied to the classroom: expectancy-value theory, self-efficacy beliefs, goal orientation and attribution theory (Karabenick & Conley, 2011). In the context of education, these describe students' willingness to engage with school tasks. According to expectancy-value theory, the effort a student expends on a task depends on whether he thinks he will be successful at the task and on whether he believes that success on the task will result in a valued reward – either internal or external. A student's self-efficacy determines her assessment of her own abilities, interpreting her past failures and successes in order to set her own personal goals and define success for herself based on those self-determined goals. The character of the goals set by the student for himself also affects the student's level of effort. Two different goal orientations produce different patterns of effort and perseverance: performance goals are goals that rely on affirmation from others and can result in low effort from students with low-self efficacy, while learning (or mastery) goals are goals defined by gaining new skills or new knowledge, potentially prompting students with low self-efficacy to learn from failure and try again. Finally, a student's attribution of failure or success to either effort or ability also affects her motivation to attempt or to persevere in completing a task.

However, as teacher learning is different in character than student learning, applying motivation theory to teacher learning narrows the focus of this framework in order to allow for a more nuanced discussion of how teachers' self-efficacy and subjective task values can influence their participation in professional development. Karabenick and Conley (2011) use motivation theory to investigate teachers' motivation to participate in professional development, situating teacher motivation within the context of a PD program by tying motivation to the ways in which teachers participate in the program and enact the practices recommended by the program. They extend a framework for teachers' choices developed by Watt and Richardson (2007). The studies by Karabenick and Conley (2011) and Watt and Richardson (2007) both rely on a framework for value developed by Wigfield and Eccles (2000), which classifies four different types of value:

> *interest value* is the enjoyment the individual derived from performing the task; *utility value* is how the task relates to future goals; *attainment value* is the importance to the self of doing well on a task, linked with identity (in this case teacher identity); and *cost*, which refers to the accumulated negative aspects of engaging in the task, including anticipated emotional states (performance anxiety, fear of failure), and the amount of effort required to succeed at the task. (Karabenick & Conley, 2011, p. 11).

Expectancy-value theory relies on the intertwined concepts of self-efficacy and value, both of which have been studied extensively with regard to students, but are only beginning to be explored with teachers. This study, like others that apply a motivation theory framework to the processes and concerns of teaching (Karabenick & Conley, 2011; Watt & Richardson, 2007), primarily relies on the lenses of expectancy-value theory and self-efficacy theory, with other constructs in motivation theory referenced if relevant.

This study attempts to contextualize the choices teachers make with respect to their own learning within professional development, as well as their use of content from PD in their own classrooms. This paper will address the findings related to the following research question: what influences mediate teachers' alignment with the mathematics content of professional development and connections they make between that and the mathematics content of their classrooms?

Methods

These qualitative case studies were conducted within a three-year part-time degree for middle school mathematics teachers with elementary certification run by a large research university in the southwestern United States. This program had a heavy focus on mathematical content and included four required mathematics courses: number & operation, algebra, geometry, and probability and statistics, each of which was team-taught through the university by a research mathematician and a high-school teacher. After completing the program, participants are awarded a Master of Arts degree in Middle School Mathematics Teaching Leadership from the university. The general orientation of the program would be classified as content-driven (Marra et al., 2010). Three participating teachers, each of whom had at least five years of teaching experience in either middle or elementary school, were chosen from a single cohort of the professional development program after that cohort had finished the program's algebra course.

Data was collected in four major stages: 1) during the Spring 2012 semester as teachers participated in the professional development algebra course, 2) after the end of the algebra class, 3) during the 2012-2013 academic year as the teachers began their first year of teaching after finishing the algebra course, and 4) during the Fall 2013 semester. Data collected from the first stage of the study was made up of observations of the PD algebra course at the university. Special attention was paid to the instructors' mathematical decisions and perspectives of algebra. Stage two of the study included a post-class task-based interview where teachers were asked to reflect on the experience of the algebra class and their attitudes about the content, as well as the program as a whole up to that point and then to pedagogically unpack five mathematical content questions taken from the algebra course. The third stage of the study asked teachers to open their practice and their classrooms to observation by the researcher. Teachers were asked to identify lessons for observation which they saw as connected to the content covered in the professional development algebra class. Teachers participated in pre- and post-observation interviews in order to chart the teacher's intentions more specifically by focusing on a particular mathematical topic. Also, the teacher was asked to identify explicitly the connections she saw between the lesson she was teaching and the content covered in the professional development algebra class. The final stage of the study was a follow-up interview that asked teachers to contextualize this PD experience with their other PD experiences and within the greater narratives of their careers.

Non-task-based interview data from the second and fourth stages of data collection and relevant tangential comments from the third stage were analyzed within the value framework developed by Wigfield and Eccles (2000) in order to produce a motivational portrait of each teacher. This was done by isolating references teachers made to their reasons for participating in the PD program, statements that revealed their attitudes toward particular concepts, and any other remarks that revealed aspects of their affect. While many of these pieces of data were explicitly prompted by actual interview questions, some telling comments arose amidst other portions of the interviews. The task-based portion of the second stage of data collection and the mathematical observations and interview excerpts from the first and third stages were analyzed for the algebraic perspectives put forward by the teachers or PD instructors. This was done by placing solutions within contrasting frameworks for algebra established by Pimm (1995), Kaput (2008) and Kieran (2007). Teachers' written work from the task-based interviews was used in conjunction with the interview transcripts to provide further clarification.

The importance of motivation theory to this study became apparent after a cursory analysis of the data. Teachers' reasons for participating in the PD program appeared relate strongly with their initial expectations for the program and its usefulness to their teaching, prompting the explicit use of motivation constructs in analyzing the data.

Findings

This paper will focus on one teacher: Felicia. At the start of her progress through the content-based PD program, Felicia was beginning her tenth year in the profession. Her confidence in her mathematical ability was very high, often referring to herself in interviews as a "math person," and saying that, as a teacher, "Math has always been my thing. And I think I'm really really strong in it, so I teach to my strength." Felicia did not think the mathematics in the PD program would be much of a challenge for her, an opinion she retained throughout most of the program. Felicia's motivations for enrolling in the PD program were a mix of personal and professional goals. Her eventual career goal was to move into administration, and she was hoping that a Master's in Middle School Mathematics Teaching Leadership, paired with a Master's in Educational Leadership, would help propel her into more leadership positions. Although her interest in mathematics created some amount of interest value in the PD program, Felicia mostly held utility value for the program, as she felt it would help her career. Felicia also had a high level of self-efficacy as a teacher of mathematics: "I think the level that I'm at and where I am with classroom management and building those relationships with the kids, I think I'm there. There's a lot of things I can still learn from older teachers, but then again too, I have a different – better – different way of doing it that I think is better."

Felicia's overall contentment with her mathematical abilities (especially in algebra) and instructional style led her to expect that she would not be prompted to change as a mathematics teacher due to her participation in the PD program. The nature of the utility value that she held for the PD program – professional, not practical – also signals her expectation that the content of the PD program (and specifically the PD Algebra course) would hold mainly interest value for her. Moreover, her idea of "relevant" content was very narrow: the mathematics had to directly mirror the mathematics her students would be expected to learn. Felicia referred multiple times to the fact that she taught sixth grade and that most of the content of the PD Algebra course was not appropriate for sixth-grade students. Moreover, Felicia viewed her own ongoing mathematical development mainly as an opportunity to develop more and better "tricks" or solution strategies for traditional algebraic tasks. Otherwise, Felicia described her gains from the PD program as mostly personal: "I like math... I mean, honestly, that's what it comes down to. I like math, and I like some of the times it was a challenge and I was like, ooh! Something new let's go find out how to do it, it was for me. Because I'm a math nerd. It's a challenge. Some of the things were challenges."

While the PD instructors emphasized certain perspectives of the algebraic concepts and encouraged teachers to explore those perspectives, during the task-based interview, Felicia fell back on her previous understandings of algebra to solve the given problems. For example, consider the following item from the task-based interview:

> Construct a function with the following properties if possible or explain why it would not be possible.
> 1. One element in the domain and four elements in the range.
> 2. Four elements in the domain and one element in the range.
> 3. Four elements in the domain and four elements in the range.

Felicia's solution to this item relied heavily on her visualization of functions in the Cartesian coordinate plane. She concluded that the first set of properties could not describe a function, since "technically, if you're graphing it, it'd be a vertical line, and it won't pass the vertical line test, so it won't be a function." Similarly, she identified the second set of properties as a horizontal line, so it would describe a function that was not one-to-one. The third set of properties described a one-to-one function, "because for every unique domain there's a unique range." In her pedagogical analysis of this task, Felicia connected her solution strategy with how she thought students would approach the task, asserting that seeing (or knowing) graphical representations of the sets of properties given would make this task easier for students to complete. Although she brought up the "circles" representation of functions (i.e. the map-between-sets representation) that was emphasized in the PD Algebra course as another possible visual representation that might be meaningful for students, Felicia admitted that she did not find much meaning in that representation herself, and that she was unlikely to present it to students. She explained her conception of functions as follows: "When it comes to functions, I automatically think of something that can be graphed or can't be graphed. I don't think of the circles like we were taught in class." Although she said that the more abstract visual representation of functions was new to her, it is clear that this representation held little meaning for her, since she followed the previous statement by saying, "I don't think I would teach it this way because I'm not comfortable with it. I would go directly to the graph, because graphing is an easy way to see it." Felicia referred multiple times to graphical representation being "easier" to understand – either for herself or for her students.

Felicia's work on and reflection about all the tasks in the task-based interview diverged a great deal from the PD instructors' presentation and development of the concepts. For three of the tasks, Felicia used or advocated the use of numerical solution strategies, making her mathematical perspective of those tasks non-algebraic (Kaput, Blanton, & Moreno, 2008). In general, the PD instructors did not encourage the teachers to use numerical solutions, choosing instead to focus teachers' attention on algebraic structure. In fact, Felicia's work only reflected the mathematical perspective of the PD Algebra course on one task, possibly because she had no other solution strategy outside of the one she had learned in the PD Algebra course. Even her emphasis on the Cartesian-coordinate-graph-representation of functions to the exclusion of the more abstract map-between-sets representation placed more weight on a representation that the PD instructors introduced almost as an afterthought in that unit. Felicia's lack of alignment with the development and presentation of mathematics in the PD Algebra course provides an important context for understanding how she viewed algebraic content in the PD Algebra course and its relevance to the algebraic content of her own classroom.

Felicia's conception of her role as a teacher (and especially in her role as an interventionist) was as a provider of different strategies for her students. She considered her job to be finding different ways of teaching the material, stating that the "traditional" methods and algorithms "don't really work for this generation." She also equated "better ways" of teaching the material with showing students different strategies for approaching problems. As a result, Felicia considered the main utility of content-based professional development to be as a way to help her learn or create different strategies and algorithms to teach her students:

> *Felicia*: [The PD courses] have helped me realize the reason why it works, or the reason behind the actual math, the algorithms or the operations or whatever. So it helps me develop a trick, per se, that the kids might get a little bit easier than the traditional here's how you do it type of thing.

In turn, she would then present the alternate algorithm or strategy to her students. Unfortunately, Felicia did not see many opportunities in her classroom to develop different strategies or alternate explanations with respect to the content of the PD Algebra course.

In one episode from the observations of Felicia's classroom, a student asked her for help with the one-step equation: $v - 3.7 = 8.78$. Felicia's interaction with the student around this problem reflected this belief about professional development, since she did not in any way mirror the PD instructors' approach to similar problems, which were discussed extensively in the PD Algebra course:

> *Felicia*: I explained to her: a number minus this number is going to give me this number right? And she's like, yeah. I'm like, okay, so what are we going to do with this number that we're minusing? And at first, she said subtract. And I'm like, so wait a second, if I subtract that number from [the answer], I'm gonna get a smaller number right? She said yeah. And I'm like, but if we have a smaller number over here, for the variable, is that gonna make sense that you subtract something and get a bigger number? She's like, no. And I'm like, so... She said we were going to add it to it, and I'm like, okay why? And she was like, because we want a bigger number over in the variable spot than we do over in the equals spot. In other words, of course.

Notice that Felicia emphasizes the relative sizes of the known numbers, implying that the operation of subtraction should diminish the unknown.

> *Felicia*: So, I'm like, good, good, good. So I'm like, well look at this, it's the opposite of the operation that's happening to that number, to the variable, to other side, right? She's like, yeah. I said, so whenever you do this, you're going to do the opposite of what's in there to isolate the variable…and I'm like, what's negative 3 point blah blah blah plus that same number, and she's like zero. I said, okay, well that's gone. All we have left over here is the variable, and then we add this over here and that's how we get our answer.

Felicia uses this emphasis to highlight the use of opposite operations in order to isolate the unknown. The PD instructors' emphasis throughout the first unit of the PD Algebra course was on the importance of equivalence when working with equations, a concept that Felicia barely uses in her explanation of the problem. In the PD Algebra course, the PD instructors emphasized the *transformational* aspects of tasks involving solving equations (Kieran, 2007). In this transcript, Felicia conceptualizes the task as a *generational* one for the student; although the equation in question is already formed, Felicia focuses the student on the unknown v in order for the student to reason about the relationship between v and the other two numbers. In essence, she prompts the student to reason backwards from the given equation to the formation of the equation. Although the PD instructors encouraged meaning-building with expressions in the PD course, they did not emphasize meaning in the solving of algebraic equations. Moreover, Felicia prompted the student to do some numerical reasoning with respect to the possible size of the unknown. This reflects Felicia's own work in the task-based interviews, where she would diverge from the presentation and development of algebra from the PD Algebra course in favor of numerical reasoning.

Discussion and Implications

These examples, when put into the context of Felicia's motivational structure, have serious implications for understanding how teachers learn new mathematics content in content-based professional development. Sowder, et al (1998) recognized that teachers' retention and usage in the classroom of new content relied in part on how comfortable they were with the content to begin with. However, the example of Felicia introduces a new dimension to our understanding of how teachers learn. Although Felicia's mathematical self-efficacy was very high and she was comfortable with particular approaches to the content, her largely utility value for the PD course seemed to strongly influence how she approached new and unfamiliar content. Her tight focus on her students (which reflects the findings of Nipper, et al (2011)) prompted her to filter all the content in the PD Algebra course through her perception of what would be useful to her students.

The frameworks of motivation theory present us with a different perspective through which to examine teachers' participation in professional development. Further study on professional development done through this lens may illuminate new considerations for the designers and facilitators of content-based PD programs.

This study reports teachers' insights and challenges after one year of adopting a curricular material designed to move students through carefully engineered, small steps and encourage learners through success and accessible challenges. The analysis of interviews showed that teachers 'followed' the material in different ways, not necessary in-line with its underlying principles. Two of these principles—bonusing and breaking down concepts into smaller elements—were particularly difficult for many teachers, suggesting the need of a specific teachers' mathematical knowledge.

Keywords: Mathematical Knowledge for Teaching; Elementary School Education; Teacher Education-Inservice (Professional Development); Teacher Knowledge

Introduction

While there is extensive research on both mathematics teachers' knowledge and the quality of curricular materials, the number of studies combining these two factors is limited. In an effort to address this gap, Charalambous and Hill (2012) reported a multiple case study suggesting that curricular materials can increase quality of instruction if they are supported and followed properly. Understanding the relationships between mathematics teachers' knowledge, curricular materials, and student performance would inform policy decisions regarding adoption and implementation of new resources, as well as the design of corresponding professional learning opportunities for teachers.

This paper analyzes one case of an elementary school adopting new curricular material and engaging teachers in corresponding professional learning over the course of one year. The study was conducted as part of a broad, longitudinal project, the Math Minds Initiative, involving a school district in western Canada, researchers from the University of Calgary, and the JUMP Math (2015) organization. The initiative focused on a particular school with a history of low performance in mathematics. The purpose of the initiative was to improve mathematics teaching and learning at the elementary level and to understand the relationship between curricular resources, teachers' knowledge and students' performance. We are interested in what teachers need to know in order to teach mathematics well, and how this knowledge can be supported through access to particular resources and related teacher professional development. As design-based research, this study draws on multiple sources of data informing next steps in the initiative. However, the focus of this paper is on teachers' experience of adopting the JUMP Math program. Specifically, we address the question: what were the insights and challenges perceived by teachers during the first year that all teachers at the school adopted the JUMP material?

Understanding teachers' insights sheds light on teachers' learning through the year, as well as knowledge required to adopt the JUMP Math materials. Teachers' challenges during this project provide information about the knowledge required not only for the adoption of the material, but also for quality mathematics instruction in general.

Curricular Material and Mathematics Knowing for Teachers

Teachers' disciplinary knowledge of mathematics has been a focus of research since the 1970s. With an initial emphasis on formal mathematics content, over the last few decades, the main interest has shifted to more varied aspects of mathematics knowing such as access to a diversity of meanings for concepts, beliefs on the nature of the subject matter, and how knowledge is enacted in the classroom (Davis & Renert, 2014; Thompson, 2015). While there are efforts to measure this knowing through tests, such as the instrument proposed by Thompson, we concur with Davis and Renert's argument that such knowing includes an open disposition and cannot therefore be readily measured with tests and other instruments. Two features of this disposition are relevant for this report. First, teachers have to be responsive to students' mathematical conceptions and misconceptions. They should be continuously aware of students' potential interpretations of a concept. Second, school mathematics is not limited to standard definitions, notations and algorithms such as those reflected in a program of studies. Teachers should be open to enact mathematics as a creative, emergent activity, which involves mathematical explorations and inquiry beyond textbooks that may result in insights not only for students, but also for teachers.

Teachers draw from a variety of resources including textbooks, teachers' guides, online material, electronic devices, and the community (Clark-Wilson et al. 2014; Gueudet, Pepin, & Trouche, 2013; Gueudet & Trouche, 2009). Following Gueudet, Pepin and Trouche, we conceive the adoption of curricular material as a creative act: "teachers' work with resources includes selecting, modifying, and creating new resources, in-class and out-of-class" (p. 1003). Gueudet and Trouche proposed the term *documental genesis* for the evolving process of the manner in which teachers use a resource. A *document,* for a particular teacher in given moment, consists of a resource and a scheme of utilization. As the scheme of utilization changes over time, a document is dynamic, whereas the resource may remain unchanged. The process of document genesis is twofold: "The *instrumentalization* dimension conceptualizes the appropriation and reshaping processes … .The *instrumentation* dimension conceptualizes the influence onthe teacher's activity of the resources she draws on [emphasis added]" (Guedet & Trouche 2009, p. 205). Most recently, Gueudet et al. (2013) considered a collective dimension of document genesis including joint work on selecting and adapting educational resources. We extend the idea of document genesis to a more ecological perspective in which the community includes not only other teachers, but also the research team and professional learning facilitators. The teacher participants are *coupled* with the researchers and facilitators in a process of mutual influence (Preciado Babb, Metz, Marcotte, 2015). In this sense, our perception as researchers of curricular material is also influenced by our interactions with teachers and informed by the data collectively gathered and analyzed for research purposes.

The Math Minds Initiative

The Math Minds Initiative is a five-year project started in 2012. While the school district provided a research school as a main focus for the study, the team from the University of Calgary provided professional support to teachers from this school as well as from other schools in the district. The JUMP Math organization contributed the mathematics program as well as further support for professional learning. During the first year of the initiative, two teachers started mid-year to use the program with no further support. In 2013 all the teachers were required to adopt JUMP Math as official curricular material and to attend the corresponding professional development sessions through the year.

The curricular material provided by JUMP Math consisted of teachers' guides, an assessment and practice book for each student, and access to pre-designed SmartBoard slides. Additionally, students were provided with individual mini-whiteboards—a suggestion from the research team to assist with the continuous assessment recommended by the resource package.

JUMP Math Principles

The Canadian version of JUMP Math is based on both the *Western-Northern Canadian Protocol for Collaboration in Education* (WNCP, 2006), which provides guidelines for the curriculum in several provinces in Canada, and the Ontario program of studies. The teachers' guide (Mighton, Sabourin, & Klebanov,2010) provides lesson plans with references to each particular outcome in the corresponding program of studies—WNCP or Ontario. The lesson plans correspond to the assessment and practice book and include individual and group activities and explanations. The guide shows teachers how to introduce one concept at a time, explore concepts and make connections in a variety of ways, assess students quickly, extend learning with extra bonus questions and activities, and develop problem-solving skills. It also provides support material for each strand.

The JUMP Math program is based on a number of principles, including confidence building, guided practice, guided discovery, continuous assessment, rigorously scaffolded instruction, mental math, and deep conceptual understanding. While the assessment and practice book consists of sequences of exercises, the teachers' guide has numerous suggestions for engaging students in discovery and problem solving. The guide also encourages students' independent thought and work: "When you feel your students have sufficient confidence and the necessary basic skills, let them explore more challenging or open problems" (Mighton et al. 2010, p. A-5). The JUMP material shows teachers how to break the material into steps and assess component skills and concepts. It teaches "fundamental rules, algorithms, and procedures of mathematics for mastery, but students are enabled to discover those procedures themselves (as well as being encouraged to develop their own approaches) and are guided to understand the concepts underlying the procedures fully" (p. A-6).

Despite the seemingly direct approach to instruction, every lesson in the teachers' guide refers to at least one problem solving strategy, including: looking for patterns; changing into a known problem; reflecting on other ways to solve a problem; doing a simpler problem first; making and investigating conjectures; using mental math and estimation; representing; guessing, checking and revising; selecting tools and strategies; using logical reasoning; justifying the solution; and revisiting conjectures that were true in one context. An important component of the program is *bonusing,* which involves extensions of concepts and skills in each lesson. The teachers' guide advises teachers to "be ready to write bonus questions on the board from time to time during the lesson for students who finish their quizzes or tasks earlier" (Mighton et al. 2010, p. A-8). Lessons in the teachers' guide include examples of such questions, and teachers are encouraged to create their own. Strategies to create bonus question include: change to larger numbers or introduce new terms or elements; ask students to correct mistakes; ask students to complete missing terms in a sequence; vary the task or the problem slightly; look for applications of the concept; look for patterns and ask students to describe them.

Method

The Math Minds Initiative is design-based research (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) that includes the implementation of the curricular material, as well as professional development aimed at improving mathematics literacy in a school with a long history of low achievement—as well as other schools in the district. The initiative also aims at further research and theory on mathematics teacher knowledge. The research project includes multiple sources of data such as video-recorded lessons, class observations, longitudinal results of the Canadian Test of Basic Skills (CTBS, Nelson 2014), and interviews with teachers and students. In this paper we present the analysis of six semi-structured interviews with teachers who taught during the school year 2013-2014 at the research school. Examples of the interview questions are: What specific advice would you give to new teachers joining Math Minds? Have you found [JUMP Math] materials to be helpful? Restrictive or difficult? To what extent did you follow the teachers' guide? SmartBoard lessons?

Workbook? In what ways did you improvise / extend / elaborate? Have you found [JUMP Math] principles helpful? Restrictive or difficult? What are your goals or priorities for improving your teaching of math?

Transcripts of the interviews were coded using NVivo with a particular focus on the manner teachers used the resources to capture the documentation process. The initial codes were compared each other, forming broader categories. Four major categories resulted from the analysis, which included the codes with higher prevalence. These categories are consistent with class observations conducted by different members of the research team.

Results

We present the results in four sections, corresponding to each major category. While the first category refers to how teachers used the material in general, the other three are more specific to JUMP Math principles. Excerpts from the interviews are included as evidence to support our findings.

Document Genesis

Teachers claimed that they followed the teachers' guide and used JUMP Math materials consistently at the beginning. Some tried to fully complete all the pages in the assessment and practice books that applied to the official program of studies and to use all of the associated lessons in the teachers' guide and, often, all of the associated SmartBoard slides. This is evident in the following excerpt:

> *Teacher:* Whereas I think when you first begin, you feel like, okay, I've got to go through each one, and it just wasn't working. So again, it's just the experience and sort of knowing, okay—and obviously previewing the slides and saying, okay, we don't—we can skip this one, or this—unless they're really struggling or—and just being able to know where can I stop and how much do I really need to go through all of this.

While it was clear for teachers that some slides or parts of a lesson would have to be selected, the motivation for such decisions varied. The previous excerpt suggests that the teacher made the decisions based on assessment of students' struggles. However, other motivations included both time pressures and a-priori judgments that some steps were not needed, as is evident in the following excerpt:

> *Teacher:* Towards the end, when I was trying to catch up a bit, I was taking the teacher guide and I was looking at the outcomes and what our curriculum outcomes were, and if it was like … number sense … in four lessons, then I would look at those four lessons, see what the big picture was, because then I could condense them maybe to two lessons instead of four.

A third type of motivation identified in the interviews was familiarity with another, previously used resource. One teacher commented that it was easier to use a resource she was already familiar with, as long as it was similar to what was suggested in the JUMP Math materials:

> *Teacher:* Well I have one that's very similar that will still teach the same outcome, but it's a different game in a little bit of a different way…. Taking what I've had from my past as a teacher, because it worked, it was good. Is it the activity in the JUMP lesson? No, but it worked. And so it would save me some time that way, because it does take a lot of time to prep for these, so I would have something like that, maybe use that game instead.

Finally, another manner in which teachers used the material was to select pages from the practice book for bonusing:

Teacher: I try to follow [the teachers' guide] exclusively. The SmartBoard lessons, like I say, some of them—if they're very hands-on, I will use a lot of them. … I just make sure that I've looked through [the material] and then I just pull up those two or three that I need. And the workbook, I look at it: is this going to be for everybody or is it going to be a bonus page?

This last excerpt shows a decision based on two JUMP Math principles: continuous assessment and bonusing.

Continuous Assessment

All teachers mentioned continuous assessment in the interviews. They also consistently referred to the use of the small whiteboards to assess students in-the-moment. Overall, the material seemed to impact teachers' knowledge regarding this fine-grained presentation of concepts and procedures, as well as the corresponding assessment practice. Continuous assessment not only served to break the content into small pieces, so everybody understands the concept, skill or instruction in class, but also to inform decisions about whether to skip parts that might already be mastered. These decisions, however, seemed to be more difficult to make, as suggested in the following teacher's comment:

*Teacher :*I feel like I need to speed up. I don't know. I need to become better at just moving on and not getting hung up on things and being able to recognize when we can move on and at the same time—and so it's not—at the same time, not compromising that in-depth study of things. Like knowing where, hey, they got it, we can go. We don't need to keep doing this.

Breaking down into smaller steps and constantly assessing students was particularly relevant to a teacher who had been a successful mathematics student:

Teacher: I was very successful in math as a student, and I just get it, and I find it difficult to do those microsteps back as to how to make it simpler for the kids and simplify it. And when I taught it that way, I'm like, oh my God, I don't know how to teach it a different way, because I just get it. And so I don't see a different way to get there, and I think that's my biggest challenge because I've never struggled with math. As a student, I was very, very successful, but that makes teaching math harder, because I don't know how to attack a problem from a child's perspective.

This excerpt is consistent with Davis and Renert's (2014) notion of the teacher being an expert who is able to appreciate the struggles of a novice.

Bonusing

All teachers made reference to bonusing. However, all but one claimed that finding and creating bonus questions and tasks was challenging. Although the teachers' guide shows how to create bonus questions and the assessment and practice book has bonus questions, one teacher perceived the need to find bonus questions beyond the material:

Teacher: You need to find bonus questions often from a variety of other sources beyond the JUMP resource in order to find the proper challenge for each individual child.

This comment also highlights a perceived need to personalize bonus questions. The following statement reflects a similar assumption:

Teacher: Coming up with really good ones has taken a lot of time, a lot of effort. But I feel now I've got a better idea of kind of what works for the kids as well and also just realizing not every kid's going to have the same bonus question, right? Like you're going to change the bonus question based on the kid and kind of the extra challenges that they need.

In contrast, the teacher who found it easy to create bonus questions claimed:

> *Teacher:* Everybody is so engaged in the workbooks and so it gives me an opportunity to continually assess their learning and because there—there is generally enough in the workbook that everybody has enough to do, and it's easy. Having said that, it's very easy to create challenges from—because of the way that the questions are structured, because of the way the work is structured. It's very, very easy to just create challenges on the spot for those who need it. And in a lot of cases, the students will create challenges on their own—their own challenges.

For this teacher, bonus questions and tasks were easy to create on the spot by following the structure of questions in the material. The excerpt also suggests a culture of self-bonusing in her classroom.

Inquiry and Problem Solving

Teachers consistently indicated a lack of opportunity for problem solving or inquiry in the JUMP Math approach. However, most of them indicated that going through the mini-steps was necessary, and that the program did this very well. An example of a teacher's perception on inquiry in the material follows:

> *Teacher:* And when I—and as far as inquiry goes, that is our direction in education in the next ten years, and as soon as I heard that, I thought, well, JUMP doesn't lend itself to inquiry. But in thinking about it, it certainly can, it just has to—it's maybe how we're going to start praising things but once again, I still think we—we need the foundation before we can even [missing word?] an inquiry.
> And so my struggle this year is sometimes should it—should I just do like an inquiry lesson or should I stick with my microsteps, but I want to do the microsteps because I'm learning so much about what I missed teaching them. So to me, right now, that's more important and maybe we throw in an inquiry day on Fridays or something. Throw in everything and just give them an open-ended question and maybe change that next year. It's just this year I'm just sticking to my recipe.

In the previous excerpt, the teacher gave second thought to the possibility of including inquiry in the JUMP Math approach. However, the last comment regarding sticking to the recipe suggests that she did not see inquiry addressed in the material.

There was a particular comment regarding students not being used to more complex, or multistep problems:

> *Teacher:* So all of a sudden, when [students] had to do this sort of a—in a way, it was a multistep problem, whereas the vast majority of this program is very one step questions and these microsteps. So as soon as you throw a multistep problem at them, I was very surprised at how many kids were just like, whoa, what am I going—how do I solve this? And there was just no—not even an attempt to work through the problem.

Overall, teachers' perceptions of inquiry and problem solving seem to be contrary to the problem solving strategies included in the teachers' guide.

Discussion

The analysis of teachers' interviews presented in this paper yields several conclusions regarding the interactions of the classroom resources and mathematics knowledge for teaching. First, the analysis of document geneses showed that teachers' interpretation of what it means to follow JUMP

Math were very different. The initial approach of having all students cover all the material contrasts with the approach based on assessing students and selecting pages from the assessment and practice book for bonus. The latter approach seems to be more aligned with the philosophy of the program.

Second, all the teachers made reference to the incremental steps and to continuous assessment. In particular, the use of the mini-whiteboards supported continuous assessment during class. It is particularly interesting that the teachers who claimed having no problem with mathematics when she was a student found it difficult to break concepts into smaller steps. The use of the resources enabled this realization; however, the resource did not seem to enable her to deconstruct concepts appropriately. This suggests that even if teachers know that the resources were designed around microsteps, they may experience difficulty in breaking concepts and skills into smaller elements themselves. This research finding is consistent with a most recent analysis of teachers' perception of scaffolding in the year proceeding the interviews reported in this paper. Sabbaghan, Metz, Preciado Babb, and Davis (in press) found that teachers with less experience in the initiative tended to use traditional strategies for scaffolding—such as modeling and coaching—in contrast to teachers with more than one year in the initiative who considered micro-level scaffolding strategies.

Third, even though the teachers' guide provides advice on bonusing, most teachers found this very challenging. The idea of bonusing has been evolving during the Math Minds initiative. The research team has compiled examples from teachers implementing the program. The team has also identified connections to the literature on intrinsic motivation, shaping the collective understanding of the bonus principle of the JUMP Math program. Moreover, in contrast to the teachers' guide's emphasis on creating bonus for early finishers, Mighton (2007) also advised to consider bonus questions for everyone: "I always make up special bonus questions for the most challenged students, too, so they can feel that they are doing harder work as well" (p. 106). We have come to perceive bonusing as a strategy for both fostering a positive attitude towards mathematics and deepening mathematical understanding.

The longitudinal results for student performance on the CTBS tests—omitted in this paper due to limited space—showed a significant improvement after one year of adopting the JUMP Math program (Metz, Sabbaghan, Preciado Babb, & Davis, in press). This was particularly reflected in students who initially had low performance. However, scores leveled or decreased for some students with initially high performances. Our principal hypothesis for this situation is that it might be attributed to teachers' lack of confidence in creating bonus questions for students. This hypothesis is supported by the fact that the students of the one teacher who reported confidence with bonusing showed significant improvement across the board (Preciado Babb, McInnis, Metz, Sabbaghan, Davis, in press).

Finally, the general agreement that a resource like JUMP Math does not include inquiry contrasts with the problem solving strategies included in each lesson in the teachers' guide. This is probably due to a strong focus on the assessment and practice book instead of the suggested activities in the guide and the SmartBoard slides. The research team considers that both bonusing and the selected sequence of tasks (Metz, et al., in press) in the assessment and practice book afford opportunities for mathematical inquiry. There is, therefore, a need to better understand the mathematical knowledge required for bonusing and for breaking down concepts into smaller elements.

THROUGH THEIR EYES: EARLY CHILDHOOD TEACHERS AS LEARNERS AND TEACHERS OF MATHEMATICS

Sue Ellen Richardson
Purdue University
richa114@purdue.edu

Laura Bofferding
Purdue University
lbofferd@purdue.edu

We explore early childhood teachers' lived experiences learning and teaching mathematics with young children, adding finer-grained context and detail to broader research descriptions. We interviewed ten early childhood teachers in a university laboratory school about their mathematics training, classroom mathematics curriculum, who controls their mathematics curriculum, and their mathematics teaching and learning philosophies for young children. Analysis included coding for Bourdieu's (Grenfell, 1996) social field theory. Results highlight social factors that influence what early childhood teachers do and teach, such as standards, regulations, administration, research, university organization, parents, and children. Teachers worked with autonomy and competence; mathematics teacher educators should leverage early childhood teachers' interest in young children.

Keywords: Early Childhood Education; Teacher Knowledge; Teacher Beliefs; Pre-School Education

Purposes

Early childhood education, for children ages birth to age eight (NAEYC, 2013), is changing due to advances in neuroscience (Shonkoff & Phillips, 2000) and greater public awareness of the effects and benefits of early childhood education (Grunewald & Rolnick, 2006). In the past, early childhood teachers taught little mathematics to children, so they received limited or no professional development related to mathematics instruction (National Research Council [NRC], 2009). This left teachers with limited knowledge and experience with mathematics, mathematics pedagogy, and the mathematical processes and thinking strategies of young children (Early, Maxwell, Burchinal, Bender, Ebanks, Henry, et al., 2007; Sarama & Dibiase, 2004). Therefore, limited research exists concerning early childhood teachers' mathematics knowledge as derived from their experiences and the mathematics they plan for and identify in the activities and centers they create for children. While large-scale studies of early childhood teacher characteristics focus on teacher demographics, training, working conditions, and years and experiences in the field, finer-grained studies are required to give context to teachers' lives and work in order to inform teacher educators, policy-makers, and other stakeholders who develop training and policies for the evolving early childhood field (Early et al., 2007; NRC, 2009). In particular, researchers should examine sources that early childhood teachers draw on to make decisions and judgments about their mathematics instruction (Brown, 2005).

In this study, we examine finer-grained interview data that adds detail and context to these broader descriptions of early childhood teachers' training and that captures social and cultural influences on what teachers do and think in their teaching. In addition, we highlight aspects of early childhood teachers' attitudes, knowledge, and practice that are affected by their varied professional development opportunities and activities (Pianta, Barnett, Burchinal, & Thornburg, 2009). Our study attempts to give voice to often unheard or hidden early childhood teachers and addresses gaps regarding the mathematics that they plan for and identify in activities by recording their lived experiences and concerns regarding the learning and teaching of mathematics (Early et al., 2007; Brooks, 2007). We hope to provide a counter-narrative to one that portrays early childhood teachers as lacking in mathematics knowledge and understanding, both in their own thinking about mathematics and in their understanding of the mathematical thinking of the children in their classrooms.

Theoretical Perspectives and Background Literature

Bourdieu's Social Field Theory

Because the knowledge-beliefs – we consider beliefs a form of knowledge – with which early childhood teachers operate emerge from social and cultural influences (Pajares, 1992), it is appropriate to look at the work and characteristics of early childhood teachers through a sociocultural lens (Edwards, 2003). Bourdieu developed a sociological perspective that can be used to objectively study early childhood teachers' relations, actions and the evolution of their dispositions for teaching mathematics (Grenfell, 1996; Grenfell, 2012; Noyes, 2004).We use his constructs of *habitus, field,capital*, *mechanisms of change,* and *structures*. Next, we describe Bourdieu's constructs using examples from early childhood education.

The *field* of early childhood education. A *field* is a social context involving a network of structures, relations, laws for functioning and specific institutions (Grenfell, 1996; Grenfell & James, 2004; Noyes, 2004). Fields exist on a continuum between heteronomy and autonomy based on the degree to which they can generate their own dilemmas rather than unknowingly reproduce repressive power structures or be affected by external forces. The working environment (or *field*) of early childhood teachers includes different groups of collaborators. Social structures are created between teachers, between teacher and parents, and between teachers and the children in their classrooms. Teachers *structure* the *field,* i.e., the classroom environment and activities, for the children, considering what they know about the children and the implicit feedback the children give (Cadwell, 1997).

Several authorities influence the early childhood field. The National Association for the Education of Young Children (NAEYC),professional organization for the field, provides guidance through publications, position statements, conferences, and accreditation. Those who teach young children refer to "developmentally appropriate practice," (Bredekamp & Copple, 1997), a framework developed by NAEYC to guide those in the early childhood field, both nationally and world-wide, for the best research-based practices regarding young children's learning and development. Also, state early childhood standards play a central role in the lessons that teachers plan (FSSA, 2006). These authorities act as *mechanisms of change* (Grenfell & James, 2004) by changing, for example, what early childhood teachers are required to teach.

Ways of shaping early childhood teachers' knowledge (*habitus*). *Habitus* is a set of dispositions or tendencies that are created in and by individuals' social interactions, and shape and orient how they see the social world (Grenfell, 1996; Grenfell, 2012; Noyes, 2004). Early childhood teachers' habitus is influenced by professional development opportunities and their teaching experiences. Training opportunities for both in-service and pre-service early childhood teachers range from no mathematics courses, courses not specifically related to the mathematics of young children (i.e., college algebra), content courses related specifically to the mathematics of young children, methods courses focused on the mathematics of and pedagogy of teaching young children, and general early childhood curriculum courses that include some content and pedagogy for teaching mathematics (NRC, 2009). Professional development previously focused on developmentally appropriate curriculum and the importance of play (Bredekamp & Copple, 1997; NRC, 2009), but now includes research on children's thinking and learning and using technology to provide training and support to full-time teachers who are part of a large, diverse workforce (NRC, 2009; Sarama & DiBiase, 2004). Research-based interventions have also shaped early childhood teachers' knowledge for teaching (Herron, 2010; Jung & Reifel, 2011).In addition, early childhood teachers' practices are influenced by the experiences they have as teachers, such as working with children and families from different socioeconomic backgrounds and under various state requirements (Lee & Ginsburg, 2007).

Knowledge-beliefs (*capital*). *Capital* refers to different types of assets that individuals possess, such as economic, status, position, or knowledge (Grenfell & James, 2004; Grenfell, 2012; Noyes, 2004). Examining teachers' beliefs is often used to learn about what teachers do and think in their teaching (Pajares, 1992). Pajares described beliefs as created through a process of enculturation and social construction, thoroughly intertwined with knowledge. For example, teachers' beliefs changed after implementing constructivist instructional strategies, evidence that beliefs are grounded in social experiences (von Glasersfeld, 1993, as cited in Philipp, 2007, p. 276). Although we can participate in shared physical and social experiences, our individual understandings of these shared experiences are unique to each of us, not consensual (Philipp, 2007). Because teachers operate as if their beliefs regarding mathematics, teaching, and learning are true for themselves, they operate as if knowledge and beliefs are a single construct (Beswick, 2010). Therefore, as knowledge is constructed from experiences, so too are beliefs.

The literature on early childhood teachers' knowledge-beliefs about mathematics includes general survey information as well as small qualitative studies. Early childhood teachers tend to support more social-emotional development rather than the development of children's mathematical thinking (NRC, 2009). Knowledge-beliefs focus on when children are ready to begin mathematics instruction, as early as age 2 (Sarama & DiBiase, 2004). Counting, adding, subtracting, and shapes constitute the most necessary mathematics topics. Teachers ordered mathematics activities with counting first, followed by sorting, numeral recognition, patterning, number concepts, spatial relations, making shapes, and measuring. They use manipulatives, number songs, and games to accomplish their objectives, but not workbooks or software. Teachers preferred that children explore mathematics activities and engage in open-ended free play rather than large-group lessons. Misconceptions that early childhood teachers hold about young children's mathematics teaching and learning focus on which young children are ready for mathematics education and the content of curriculum, classroom environment, and mathematics assessments; and they might be overcome with sustained research-based professional development(Lee & Ginsburg, 2009).

Mechanisms of change. Change mechanisms challenge the status quo and indicate the amount of autonomy a field possesses. Mechanisms can be internal or external. In order to understand what teachers do, we need to understand both the evolving fields in which they are situated and the nature of their evolving habitus. Disjunction is a *mechanism of change* that teachers experience between the structuring of their habitus and current field, causing change in their practice (Noyes, 2004).

Structures. Structures explain how field, habitus, and capital interact, and are both the product and source of tensions, described as "structuring and structured" (Grenfell, 2006, p. 293). Because habitus cannot be seen, the relational structures that underlie practice and knowledge-beliefs must be explored (Grenfell, 2012).

Women, Their Work, and Mathematics

This study joins other studies that document women as participants in mathematical activity in their work within a traditional female context, such as sewing or caring for young children (i.e., Hancock, 2001). A goal of this study is to allow the teachers to make sense of their own thinking, and to correct the invisibility and distortion of their experiences by giving voice to their multiple perspectives and ways of knowing, creating more knowledge and a broader picture, as each woman's experience tells something different and valuable (Brooks, 2007). Lather (1988) cautioned that by attempting to explain others' lived experiences, the others' reality would be violated. In other words, we will only attempt to explain the teachers' lived experience, knowing that this is just our own understanding of the teachers, not a replica of their experience.

Research Questions

Using a portion of data from a larger research study, we investigate the following research questions: What experiences do early childhood teachers have learning and teaching mathematics? What do these experiences mean for their teaching mathematics with young children? What can their stories of lived experiences as learners and teachers of mathematics tell early childhood teacher educators, policy makers, and other stakeholders?

Methods

Participants

A purposive, convenience sample was recruited from an early childhood development laboratory school at a Midwestern state university. Ten early childhood teachers volunteered. Table 1 includes their education, years at the center, and teaching assignments.

Table 1: Participant and Classroom Descriptions

Classroom Team	Teacher	Position	Degree	Years at Center	Classrooms	
					# of Children	Ages (years)
Ducks	**D1**	Head	BS ECE	17	20	3 – 5
	D2	Associate	BS Child Dev	11		
	D3	Assistant	AS EC Dev	6		
Eagles	**E1**	Head	MS C&I/BS ECE	16	20	3 – 5
Squirrels	**S1**	Head	BS Child Dev	22	14	2
	S2	Student Teacher	BS ECE	Just Hired		
Tigers	**T1**	Head	BS Child Dev	5	14	2-1/2
Koala Bears	**K1**	Head	MS Child Dev	19	14	2-1/2 – 4-1/2
	K2	Associate	BS Ed Studies	1		
	K3	Assistant	CDA Credential	6		

Data Collection Process

Here, we report on one of three data collection activities of the larger study, initial semi-structured interviews with classroom participant teams regarding their experiences learning and teaching mathematics. Because teachers collaborate on planning and implementing curriculum, initial interview data was gathered from each teaching team (see Table 1). During one-hour interviews, teams were asked to describe their training related to teaching early childhood mathematics; classroom mathematics curriculum, activities, and experiences; issues related to who has control over mathematics curriculum in their school setting; and philosophy regarding teaching and learning mathematics with young children. Researchers used a semi-structured interview protocol that was developed from literature (Frid & Sparrow, 2009; Lee & Ginsburg, 2009) and prompted teachers for additional information during interviews as needed.

Analysis

Several rounds of analysis were conducted in order to gain a sense of the underlying "web" (Grenfell, 1996) of relations and tensions (Clandinin, Murphy, Huber, & Orr, 2009) that teachers experience as they learn and teach mathematics. First, each transcript from the initial interviews was divided into chunks expressing a cohesive idea focused on the same idea or activity. Each chunk was coded using Bourdieu's constructs of habitus, field, structuring structures, capital, and mechanisms of change, with subconstructs generated from the data (Grenfell, 1996; Grenfell, 2012; Grenfell & James, 2004); teachers' experiences learning and teaching (Early, et al., 2007; NRC, 2009); and mathematics content (FSSA, 2006). Anecdotal snapshots of each classroom were developed, and short narratives of each teacher were created that included a timeline and dominant themes found in their individual transcripts. From these pieces, we developed narratives of the teachers as learners and teachers of mathematics with young children, along with their philosophies.

Results

The data describes autonomous early childhood teachers affected by external forces as they teach and learn, through interactions with children and adults.

Bourdieu's Social Field Theory "Web"

Habitus and experiences. Teachers described experiences in their classrooms that have affected their teaching habitus (Grenfell, 2012). For example, E1 and D2 explained that they did not like geometry as students and had trouble learning it (structured structure), but as early childhood teachers, they have learned about geometry with and from the children and found engaging geometry activities (structuring structure). T1 explained that most of the children in her classroom of 2-1/2-year-olds speak English as a second language (structured structure), so she has adjusted her learning activities to use multiple media to share new words with the children (structuring structure). T1 also noted that most of the teachers at the center obtained their degrees from the university (structuring structure), which she says explains why many teachers sing the same songs and do many of the same activities (structured structure).

Social fields and power. Teachers alluded to social fields that exert power on their practice and in their classrooms (Grenfell, 2012). S1 and E1 noted that the center is part of a university, and therefore, they teach pre-service teachers in practicums and student teaching, in addition to the children in their classrooms. They also noted that the state department of education has made changes in center and teacher licensing regulations that have affected the early childhood education field in which they work; all of the teams reported that standards exert control over their practice, both in what they plan and how they record and communicate their plans. Most teachers referred to components of NAEYC that influence their practice, including accreditation, developmentally appropriate practices, and state and national conferences. K1 and T1 mentioned that parents expect their children will have fun and receive academic instruction, while D1 indicated that parents share their concerns about their children with her. Most of the teachers noted that children exert control in their classrooms in various ways, as their interests and development/age drive curriculum, and through interactions and language.

Capital and knowledge-beliefs. All of the teachers talked about learning about mathematics with young children from their methods courses, conferences, other professional development, and other teachers. They all also discussed their ideas about what constitutes mathematical activity. For example, teachers in the Duck room incorporate patterning into their line up routine. Veteran teachers appreciated the new knowledge that D3 and S2 brought to their classrooms from their recent coursework, as well as knowledge gained from early childhood research. Half the teachers (K1, S1, S2, D2, D3) described instances of gaining knowledge from working with the children. The teachers all use their knowledge of the curriculum and typically developing children to integrate mathematics into the daily schedule.

Mechanisms of change. E1 described a major event in the history of the school that challenged the status quo immensely and has caused a great deal of disjunction for her. Previously, two early childhood settings co-existed on the university campus, one providing child care and the other operating as a laboratory school that provided instructional settings for undergraduate students and research opportunities. Recently, the school and center merged, and the department under which they operated has been subsumed into another department, resulting in less observation time with young children and fewer connections to research, both as participants and implementers. S1 also mentioned fewer undergraduate students working in the center and conjectured that the economics of working in the early childhood field affected the number of students in the program. Degree programs that an assistant (D3) and a student teacher (S2) are completing have affected activities in the Ducks and Squirrel classrooms, such as by adding mathematics to everyday contexts (mathematizing). Several teachers mentioned that they experienced change in their practice after having the opportunity to put theories learned in coursework or training into practice with children.

Interactions between habitus, field, and capital – Structuring & Structured Structures. The data also includes examples of the field of the teachers using their capital in their interactions with the children. The teachers described mathematics activities and materials they created for the children and classroom environment. These practices are the result of teachers' experiences and knowledge of young children, interacting with external forces including center rules, standards, NAEYC accreditation, state regulations, and the university. The teachers acknowledge children's reactions to the activities and materials as they provide the next activity or materials, or introduce the activity to children in a future classroom. This example of a structured and structuring structure can be explained by Maton's (as cited in Grenfell, 2012, p. 51) equation: [(habitus)(capital)] + field = practice. The teacher has power imposed on her by the outside fields, while she exercises power and capital in her classroom, all the while adjusting her practice according to feedback she receives from the children.

The teachers' experiences as *learners* of mathematics were often frustrating, leaving the teachers feeling that they were "not good at math," "math was hard," and "math was not my favorite subject." However, their experiences *teaching* math with young children have been rewarding, leaving the teachers feeling that "this math is fun," and they want the children to continue having "fun" experiences with math so they grow up to enjoy it, develop positive dispositions toward mathematics (unlike some of the teachers), and succeed as students and mathematicians. It is interesting to note that eight of the ten teachers in this study were seasoned veteran teachers, with five to 22 years of experience. However, the two novice teachers in our study reported more positive experiences learning mathematics than the veteran teachers. Perhaps their stories point to improvements in K-12 mathematics since the veteran teachers were in those learning environments.

Women, Work, and Mathematics

Double consciousness (Brooks, 2007) means that women know their own lives, work, and knowledge, but they also know the dominant culture's knowledge as well because they have to navigate between both. For the early childhood teachers, this means that they know their own experiences and thinking about mathematics. They also have a sense of the "finished product," the mathematics created by the dominant male culture the children in their care will eventually be expected to know. They work back and forth between the two different experiences of mathematics, the math that they find "fun" and "enjoyable" with and for young children, and the mathematics they know the children will eventually be expected to learn. Teachers also work between their training and experiences in child development and requirements of the standards, many stating that the standards "validate" the choices they previously made based on their knowledge of children and development.

Conclusions

Although the veteran teachers in our study described many negative and less-than-productive experiences as K-12 and college mathematics learners, all of the teachers in our study currently draw on their experiences with young children and more recent research-based professional development and state standards in their practice as early childhood mathematics teachers. In descriptions of their work, teachers expressed autonomy, confidence, and competence. Their initial habitus upon entering the field of early childhood education has evolved during interactions with the children in their classrooms, their families, professional development activities, and state standards. Despite acquiring a negative habitus while learning mathematics, they all now enthusiastically teach mathematics with young children, planning activities based on their understanding of early childhood mathematics and the children's development and interests.

This study illuminates several social factors that influence what early childhood teachers do and teach, such as standards, center regulations and administration, research, university organization, parents, and children. Some factors affected all teachers at a center in a similar way, such as the use of standards, while other factors only affected individual teachers, such as each teacher's training. Implications are that early childhood teachers may benefit from examining their early experiences learning mathematics and the role those experiences have on their teaching. Teacher educators might ask preservice teachers to examine these early experiences and then provide tasks that support them to reflect on and integrate new information with their knowledge-beliefs developed earlier (Brown, 2005). They might also highlight the fixed nature of structures such as standards and ask preservice teachers to consider ways they could adjust their notions of practice.

The results from our study suggest that both veteran and novice early childhood teachers bring a lot of capital to their work, which should be respected by stakeholders, including early childhood teacher educators and policy makers. In addition to appreciating veteran teachers' capital, teacher educators might emphasize to their students that, although novice teachers expect to learn from veteran teachers, the capital novice teachers bring to teaching is often appreciated by veteran teachers. Our results also suggest that grounding math methods or content training in experiences *with* young children could engage early childhood teachers when they feel less competent about the training subject, such as geometry with young children. This would connect and value the work that these women do with young children with more formal mathematics.

This paper examines the possibilities of using standardized assessments to assess elementary and secondary novice teachers' skills with leading problem-based mathematics discussion. The findings reveal that our standardized assessments were able to elicit and reveal variations in skills across teachers; provide fine-grained detail about the performance of particular teachers for feedback purposes; and account for existing classroom norms. This suggests that such tools could be useful in assessing and supporting beginning teachers.

Keywords: Teacher Education-Preservice; Instructional Activities and Practices; Assessment and Evaluation; Classroom Discourse

Theoretical Framing

The preparation of beginning teachers has received increased attention in recent years with calls to ensure that beginners are prepared to take responsibility for all students' learning upon entry to the teaching force. This call has spurred changes towards preparing beginners to <u>do</u> core tasks of teaching. In a number of teacher preparation programs, course content is shifting to focus on high-leverage teaching practices such as eliciting and interpreting student's thinking and leading discussions (Ball, Sleep, Boerst, & Bass, 2009; Davis & Boerst, 2014; McDonald, Kazemi, & Kavanagh, 2013). This shift means that teacher education programs must also develop ways to assess the <u>doing</u> of teaching. Many current assessments of teaching, including observation tools (e.g., Danielson, 2011) and portfolios (e.g., Darling-Hammond, 2010), offer information about beginning teachers' skills with respect to broad domains of work like planning, instruction, or assessment. But we need additional tools to improve estimates of beginners' skill with particular practices of teaching.

One practice that has received considerable attention in teacher education is the practice of leading a discussion in mathematics. Mathematics discussions are important for supporting students in developing conceptual understanding (e.g., Michaels, O'Connor, & Resnick, 2008) and learning disciplinary norms and practices (e.g., Lampert, 2003; Yackel & Cobb, 1996).For these reasons, a number of current efforts are focused on helping novice teachers learn to enact this complex practice (Boerst, Sleep, Ball, & Bass, 2011; Lampert et al., 2013). Given this, teacher educators will also need ways to assess novices' skill with leading mathematics discussions, beyond relying on plans for leading a discussion, reflections, or analysis of others' enactment (e.g., through video analysis).

Many factors beyond sheer skill influence novices' enactment of specific practices. As teachers lead whole class discussions, for example, factors related to students, the content, and the environment, matter for the unfolding of the discussion (Cohen, Raudenbush, & Ball, 2003). Teachers' knowledge of the content, the "discussability" of the mathematics task, students' prior experiences participating in discussions, and teachers' knowledge of and relationships with their students all shape how discussions play out. All of this can make it difficult to appraise novices' skills in ways that are comparable and fair. We sought to investigate whether it is feasible to design a standardized assessment that is capable of: (a) eliciting and revealing variations in skills across teachers; (b) providing fine-grained detail about the performance of particular teachers for feedback purposes; and (c) accounting for existing classroom norms. Below we begin by articulating and specifying what we mean by a "mathematics discussion" then turn to the describing the assessment development.

Work of leading a discussion

We grounded our assessment development in a particular decomposition (Grossman et al., 2009) of the practice of leading a mathematics discussion. We define classroom discussion as "a period of relatively sustained dialogue among the teacher and multiple members of the class" in which students respond to and use one another's ideas to develop collective understanding (TeachingWorks, 2015).Our decomposition is informed by research on practices for orchestrating productive discussions (Smith & Stein, 2011), the concept of talk moves (Chapin, O'Connor, & Anderson, 2013), and research on decomposing practices so that novices can learn them (Boerst et al., 2011). We differentiate *discussion-enabling practices* (Boerst, Moss, & Blunk, 2009), such as anticipating student thinking and monitoring student work, and *discussion- leading practices* used to manage a discussion, such as eliciting student thinking. We distinguish between three stages of the discussion: launch, orchestration, and conclusion. The launch comprises the work a teacher does to frame the discussion (Engle, 2006) and is separate from the actual setting up of the task. Within each stage, teachers engage in particular discussion-leading practices. For example, orchestration includes practices such as *eliciting contributions* and *probing student thinking*. Figure 1 shows our decomposition of discussion-leading, as well as examples of discussion-enabling practices. Within each discussion-leading practice, we further identify techniques (Boerst et al., 2011), including particular talk moves.

Figure 1: Decomposition of Leading a Mathematics Discussion

Assessing beginning mathematics teachers' discussion leading practice

Because beginning teachers are more often assessed on their ability to plan, we set out to design an assessment focused squarely on the interactive work of leading a discussion. We also wanted the assessment to be classroom-based, since so much of the work of leading a discussion involves responding to student thinking in the moment. We wanted our assessment to elicit and capture both a range of and variation in performance, as well as provide fine-grained detail about the demonstrated skills of individual teachers. Because we intended to use the assessment in real classrooms, it was important that it account for variations in classroom norms and grade levels.

With these goals in mind, we developed parallel elementary and secondary assessments to be implemented in novice teachers' classrooms. Simultaneously, we sought to design the assessments with as much standardization as possible to allow for comparing teachers' performances. Because discussion-enabling practices are critical to the work of preparing for a discussion (e.g., Jackson, Garrison, Wilson, Gibbons, & Shahan, 2013), we provided supports for teachers to prepare for the discussion so that our assessment could focus squarely on their discussion-leading skill. Both the elementary and secondary level assessments required teachers to lead problem-based mathematics discussions, in which students work on a mathematical task and then participate in a discussion about their work on the task. We selected mathematical tasks that have been extensively piloted in K-12 classrooms and can be found in existing materials (Ball & Shaughnessy, 2014; Mathematics Assessment Resource Service, 2012). Table1 provides an overview of each of the tasks. These tasks offer opportunities to compare and connect a range of solutions, strategies, or approaches, which represents one discussion structure (Kazemi& Hintz, 2014). The tasks were also selected because they focus on high-leverage mathematics content (Ball & Forzani, 2011), can be used across grade bands, and because we conjectured that they could be implemented as a "drop-in lesson" without necessarily being connected to the current instructional focus of a classroom.

Table 1: Elementary and Secondary Mathematics Tasks

Elementary: You will lead a discussion of solutions to the problem, "Make number sentences for 10," a problem with multiple solutions. The students will first work independently or in pairs on the problem. Then, you will lead a discussion of the task. The goal of the discussion will minimally be to elicit several solutions to the problem and to have students explain why they are or are not solutions and to notice similarities and differences among the solutions. The focus for your discussion will vary depending on student solutions. A table of possible student solutions is included to help you organize your discussion.	*Secondary:* You will lead a discussion of solutions to the problem "Proofs of the Pythagorean Theorem?" The students will first work on the task, then you will lead a discussion of the task. The task asks students to evaluate several attempts at proving the Pythagorean Theorem. The goals of the discussion include eliciting several solutions to the problem, ensuring that the merits and limitations of each solution are explained, and identifying features of a strong mathematical proof. It is not necessary to complete a standard proof of the Pythagorean Theorem.

By specifying the mathematics tasks, we sought to control for the variation that would arise if teachers led discussions on different topics. This was important for achieving our goal of designing a tool that could compare performances. Prior experiences teaching methods courses led us to believe that providing a discussable task was a support that could enable the assessment to focus on assessing teachers' discussion-leading skills.

Grades 2-3	
Generate number sentences for 10 using multiple operations determine whether the value of a proposed expression is 10 listen to classmates and provide justification for agreeing or disagreeing with specific explanations begin considering the idea of infinitely many solutions make a claim regarding the number of possible solutions with justification	Students will likely generate number sentences for ten that move beyond integer pairs that sum to 10 (e.g. 1 + 9). Their expressions are likely to contain multiple terms and are likely to incorporate subtraction, although some students may need prompting The types of expressions that students might generate include: 1 + 1 + 1… = 10, 2 + 3 + 5 = 10, 11 – 1 = 10, 83 – 73 = 10 Students might notice number patterns that allow them to generate many expressions quickly, e.g. 12 - 2, 22 - 12, 32 - 22…. Students may also incorporate multiplication and division. If students use subtraction, multiplication and/or division, they are likely to think that there is a very large finite number of solutions to the problem . Students may state that the number of solutions to the problem is infinite.

Figure 2: Support for Differentiation of Learning Goals and Anticipating Student Thinking

We also built in supports around other discussion-enabling practices. For example, the assessments included supports for understanding the mathematics, anticipating student thinking (Smith & Stein, 2011), and adapting the task for different grades. Figure 2 shows an excerpt of the support materials for differentiating the goals of the task and anticipating student thinking. Both assessments also included lesson plans with suggested timing, participation structures, and guidance for setting up the task.

We also developed a scoring tool that could be used to analyze and assess videos of teachers' leading these discussions. This tool was designed to focus on the discussion-leading practices core to our decomposition of the work: launching a discussion, eliciting responses, probing students' thinking, orienting students to one another's contributions, making contributions to the discussion, recording/representing content, and concluding the discussion. Our tools also focused on specific techniques. These techniques were selected for their importance to skillful beginning teaching. For example, "orienting students to the contributions of peers" had five associated techniques: (1) students are prompted as needed to talk to the whole class; (2) the teacher poses questions to students about others' ideas and contributions; (3) students are asked to comment on, add to, or restate other students' ideas; (4) listening is supported by moves that ask all students to respond to one another's work; and (5) students are encouraged to listen, and respond to maintain productive and focused interactions. We included this level of detail in the scoring tool to reflect our decomposition of practice and to meet the goal of developing an assessment that would allow us to capture differences in performance across and within performances. Importantly, we were assessing teachers' skills in responding to student contributions, not whether students responded in a particular way (e.g., students might not respond to a well-formulated question intended to probe their thinking).

In developing the scoring tool, we recognized that there are many ways to score or assess instruction, including rubrics that differentiate levels of performance in particular domains. We chose to use threshold statements to record the presence or absence of particular techniques with respect to a defined threshold. This choice motivated the goal of using of the tool for identifying whether teachers were enacting techniques in the different practices. This format could be particularly useful in identifying patterns across groups of teachers as well as within an individual teacher's performance. Additionally, we built in a "not applicable (N/A)" choice because some specific techniques may not be needed in particular cases. Finally, we developed a section that captures common issues that may arise in discussions. A codebook was developed with definitions of each technique, examples of what it was, and examples of what it was not.

Methods

We piloted the assessment with 17 first-year teachers (9 elementary teachers across grades 1-5 and the 8 secondary teachers across grades 7-12). We recruited a diverse sample of teachers with respect to grade level, school district, and teacher preparation program. The purpose of the pilot was to gather data from a range of first-year teachers and was not intended to be representative of all first year teachers. We provided the plan for the discussion and gave participants 45 minutes to prepare.

The discussion was video-recorded by the research team. One camera was set up in the back of the classroom and focused on teacher and student interactions. Discussions ranged from approximately 15 to 45 minutes in length, although the full lessons were longer. Participants also completed a background survey indicating their prior experience and training in discussion leading practices. All teacher names used in the subsequent sections are pseudonyms.

The analysis of the discussions was conducted by the research team through independently watching and scoring each video using the tool described previously. Then the team, comprised of members with expertise in both elementary and secondary mathematics teaching, met together to discuss the scoring and reach a final consensus. When there were discrepancies across scores, the full team examined the video and resolved the issue, referencing the codebook as needed. A subset of the videos (>20%) was additionally coded by a trained rater, yielding an inter-rater agreement of 85% (Miles & Huberman, 1994).

Findings

We analyzed the 17 discussions to examine how well the assessment was able to: (a) elicit and reveal variations in demonstrated skills across teachers; (b) provide fine-grained detail about the performance of particular teachers for feedback purposes; and (c) account for existing classroom norms. We address each of these in the following sections.

Eliciting and revealing variation in demonstrated skills

In looking across all performances elicited by the assessment, we found that the scoring tool was able to reveal a range of skill with respect to all of the discussion leading practices. For example, within the domain of orchestration (including the practices of eliciting, probing, orienting, and making contributions), the assessment and tool revealed skills that varied from a minimum of three demonstrated techniques to performances that revealed use of all 15 techniques associated with orchestration. Additionally, the assessment and tool was able to elicit and reveal a range of performance within each discussion leading practice. For example, Table 2 shows a range of performance on each of the four discussion leading practices used during the orchestration stage of the discussions.

Table 2: Range of performance within discussion leading practices

	Eliciting	*Probing*	*Orienting*	*Contributing*
Range of techniques	1/3 to 3/3	0/4 to 4/4	0/5 to 5/5	1/3 to 3/3

Our study suggests that the assessment and scoring tool are capable of revealing variation in performance. We found that the tool was capable of revealing variation in skills at multiple levels, including higher-level variations between discussion leading practices and more fine-grained variations in performance within particular discussion leading practices. As an example of this variation, within this sample, teachers demonstrated greater skill at eliciting student thinking than probing student thinking or orienting students to the contributions of peers. All of the elementary teachers demonstrated skill with every eliciting technique/move, and six out of eight secondary teachers did as well. In contrast, only two out of 17 teachers engaged in all aspects of orienting, many of them engaged in only some aspects, and a few teachers engaged in almost no orienting. This means that the tool enabled us to discern differences in the skills of groups of novice teachers with respect to discussion-leading practices.

The assessment and scoring tool were also able to capture fine-grained variations of performance within particular discussion-leading practices. For example, with the practice of *probing student thinking*, which included four different techniques, 14 out of 17 teachers engaged in probing students' mathematical processes, while only nine teachers probed students' understanding of key mathematical ideas. For example, one secondary teacher, Ms. Mason, first elicited student ideas about which of three attempted proofs of the Pythagorean Theorem is most valid and complete. A student replied "In attempt number one, you have to find the area of the squares in order to get the triangle in the middle". Ms. Mason responded by probing the student's process, "Okay, how do I find the area of a square?" The tool showed that almost all of her probing focused on process. In contrast, another secondary teacher, Mr. Jacobs, probed both for student process and understanding. In one case, as students were defending their choice of one potential proof as being the best, a student said "I said that number two…it explains things. There's a lot of information". Mr. Jacobs responded, "What do you mean by the most information?" probing the students' understanding of what "information" meant in the context of a proof. This suggests that the structure of the scoring tool used with the discussion assessment data was able to highlight differences in teachers' demonstrated skill with particular practices.

Providing fine-grained detail about the performance of particular teachers

The assessment and scoring tool were able to elicit and capture variations of performance within teachers' discussions. To illustrate this capability, we describe what the scoring tool revealed about the performance of one fourth grade teacher. Mr. Weber launched his discussion efficiently and framed the mathematics to be discussed, although he did not have all students' attention before beginning. Within the practice of eliciting, Mr. Weber enacted all of the techniques that we sought to capture, including eliciting multiple solutions/strategies. He demonstrated less skill in the practices of probing and orienting, posing no questions that probed students' processes or understanding. Mr. Weber also did little to orient students to each other's contributions. He occasionally reminded students to listen to each other and asked for signs of agreement/disagreement with a contribution, but he did not ask students to comment on, add to, or restate others' ideas. Mr. Weber did enact techniques within the practice of making contributions. He revoiced and asked questions to engage students in substantive discussion of the key ideas; however, the mathematical contributions he made did not enrich the core ideas of the discussion nor did they keep the discussion focused on the learning goals. Throughout he demonstrated skill with recording and representing content as he recorded students' number sentences on the board, although he did not always attend to the mathematical accuracy of his records. Mr. Weber concluded by taking stock of the discussion and worked to support students in remembering that they had determined that there could be infinitely many solutions to the task. This highlights how the assessment and scoring tool allowed us to capture detail and nuance within individual teachers' practice.

Accounting for classroom norms

Across the performances the scoring tool appeared to be able to account for variations in existing classroom norms. In some classrooms, students added on to another's thinking and spoke to the whole class without prompting from the teacher. The designation of N/A allowed us to recognize that students were doing these thing while still acknowledging that the teacher did not visibly employ moves that supported students in participating in this way. Yet, only two techniques received a substantive number (>3) of N/As. This indicates that the assessment and tool were able to elicit and capture demonstrated skill with the majority of the techniques. The two techniques that were frequently coded as N/A were (1) supporting students to speak to the whole class and (2) supporting students to listen to contributions of peers. Both techniques are used in the service of *orienting students to the contributions of peers*. The high frequency of N/A suggests that the standardized assessment and scoring tool may not be suitable for systematically eliciting and capturing teachers' skill in this area.

Discussion and Implications

We examined the utility of using a standardized assessment to assess novices' discussion-leading practice. The assessment and tool prompted and captured a range of performance and revealed variations across groups and within individual discussions. We also found that it was able to account for existing classroom norms.

To consider the implications of these findings, we begin by acknowledging the limitations of how we designed and piloted the assessment and scoring tool. One limitation is that the assessment and tool are grounded in a particular decomposition of the practice of leading a discussion. A different decomposition might reveal different capabilities of the assessment and scoring tool because if teachers are more familiar with other decompositions of the practice, they may perform differently. A second limitation concerns the design of our scoring tool, which used threshold statements, yielding information about the presence or absence of each technique within a practice. This meant that the scores did not always distinguish the quality or quantity of teachers' enactments above the threshold. Finally, these analyses did not consider the validity of the assessment with respect to whether it accurately reflects a teacher's typical practice. Despite these limitations, our findings suggest that a standardized assessment of discussion-leading practice can reveal important information about teachers' skill. As we were not intending to make claims about this sample of teachers or a larger population of novice teachers, the small sample was appropriate for our goals. However, the variations in performance that are used to illustrate the capabilities of the assessment and tool cannot be interpreted as representing the skills of a larger population of teachers.

This standardized assessment accomplished many of our design goals. Its ability to capture a range of skill and to distinguish patterns across groups and within individual teachers' performances could make the assessment and scoring tool useful in teacher education. Teacher educators and programs could use such assessments to track teacher candidates' growth over time and to identify areas of strength and weakness with respect to the practice, which would allow for targeted support and program-level curriculum design. The use of scaffolds for particular parts of a lesson also showed promise for allowing the assessment to focus on a single instructional practice.

Additionally, the subject matter standardization allowed for comparison across performances, as well focusing the assessment squarely on discussion leading practices through providing standardized supports. Standardized mathematics content supported the efficiency and manageability in using both the assessment and scoring tool, as scorers did not need to familiarize themselves with the content and task of each discussion. Even with standardization of content and content supports built into the materials, there were instances in which subject matter knowledge appeared to be a factor in teachers' discussion-leading practice. In these cases it was unclear whether we were accurately capturing a teacher's skill with discussion leading or whether we measured indirectly his/her use of content knowledge in teaching. Subsequent work will need to take this into consideration.

We found that the practice of recording and representing content was challenging to assess using this assessment. Although the assessment materials asked teachers to record student contributions and other relevant mathematics, a number of elementary and secondary teachers involved students in the recording or relied completely on student-generated records. This may have been a reasonable choice given existing norms and routines and in some cases it appeared to support students in providing explanations to the class, but this choice made it difficult to see evidence of how these teachers record content. The materials may not have specified clearly enough that while students often contribute to recording, the assessment was asking teachers to record contributions. Future versions of the assessment will need to keep this challenge in mind; we see several different possibilities for addressing this challenge.

Future research could consider how well the assessment of novices' discussion-leading practice corresponds to their typical practice when leading discussions. Another important direction will be to further take up the questions about the role of subject matter knowledge in assessing teachers' skill with discussion-leading practices. Finally, further research could also investigate the impact of scaffolding materials for novices with different conceptions of what makes a mathematics discussion.

NOTICING STUDENT MATHEMATICAL THINKING IN THE COMPLEXITY OF CLASSROOM INSTRUCTION

Noticing students' mathematical thinking is recognized as a key element of effective instruction, but novice teachers do not naturally attend to and make sense of student thinking. We describe a design experiment in which prospective teachers were engaged in analysis of minimally edited classroom video in order to support their ability to notice important student mathematical thinking within the complexity of classroom instruction. We discuss evidence of prospective teachers' learning in five iterations of the intervention, including the extent to which they developed a focus on students' mathematics, changes in the ways they discussed that mathematics, and the extent to which they focused on instances of student mathematics that had potential to be capitalized on to support student learning. Aspects of the intervention that seemed to support teachers' noticing are discussed, as well as future directions for the work.

Keywords: Classroom Discourse; Design Experiments; Teacher Education-Preservice

Research has shown that a key distinction between novice and expert teachers is their ability to notice what is important in complex classroom situations (Berliner, 2001). Because teachers' use of student thinking has been identified as a key element of effective instruction (e.g., NCTM, 2014) and has been linked to increased student learning (Fennema, Carpenter, Franke, et. al, 1996), one particularly important focus of teacher noticing is student mathematical thinking. However, research suggests that teachers, particularly novices, do not naturally attend to and make sense of student ideas (Jacobs, Lamb, & Philipp, 2010). Fortunately, noticing student mathematical thinking is a skill that can be learned (e.g., Jacobs, et al., 2010; Sherin & van Es, 2005) and has thus become a focus in many teacher preparation programs.

Many recent prospective teacher noticing interventions, focused on what has been termed *professional noticing of children's mathematical thinking* (Jacobs, et al., 2010), have supported noticing through analysis of student written work (e.g., Fernández, Llinares, & Valls, 2013; Haltiwanger, & Simpson, 2014) or short video excerpts of one-on-one student interviews (Schack, Fisher, Thomas, et. al, 2013). This work has also typically focused on student thinking related to specific mathematical content, for example, proportional reasoning or early numeracy. Evidence across these interventions suggests that prospective teachers' noticing skills can be successfully developed in "environment(s) in which the number of salient features was limited and, therefore, a manageable focus for discussions" (Schack, et. al, 2013, p. 395). Mathematics classrooms, however, are not limited in the scope of what might be noticed. This raises questions of whether prospective teacher noticing can be supported in a more complex context that simulates that of classroom noticing, and whether prospective teachers' professional noticing skills can be developed using classroom artifacts that include a range of mathematical foci.

Evidence suggests that using classroom video as a medium to promote professional noticing might be enhanced by providing a way to scaffold teacher noticing, such as targeted questions or a framework (e.g., Roth McDuffie, Foote, Bolson, et al., 2014; Santagata, 2011). Santagata (2011), for example, found that posing targeted questions to focus teachers on the relationship between a teacher's actions and students' learning of mathematics supported teachers in providing more in-depth analyses of these interactions. Similarly, Roth McDuffie and colleagues (2014) found that providing carefully designed prompts supported prospective teachers in higher level noticing, including making connections between key components of teaching and learning. In short, research suggests that specific prompts support the noticing of what is valued within classroom interactions. This study builds on this work by examining the use of an explicit analytic framework to scaffold prospective teachers' mathematical noticing.

In this study, we examine the effects of an intervention designed to promote prospective teachers' noticing of student mathematics that could be used by a teacher to support students' understanding of the mathematics. In particular, we focus on the following research questions: (a) In what ways does prospective teacher noticing change as a result of the intervention?; and (b) How do variations in the viewing framework appear to affect prospective teacher noticing?

Theoretical Framework

Consistent with Jacobs and colleagues (2010), we aim to promote the *professional noticing of [student]'s mathematical thinking*. We follow their definition of this practice to include three interrelated skills: (a) attending to student thinking, (b) interpreting what students are saying mathematically, and (c) deciding how to respond. In this study, we focus on just the first two components of the practice. Our choice of this noticing focus stems from its close connection to our goal of helping prospective teachers learn to enact *ambitious teaching* (Lampert, Beasley, Ghousseini, Kazemi, & Franke, 2010)—"deliberately responsive and discipline-connected instruction" (p.130) that supports all students in developing deep understanding of mathematics.

Although our work is firmly grounded in the noticing of student mathematics, we also take the perspective that not all instances of student mathematical thinking have the same potential to enhance student learning. Thus, we focus specifically on noticing instances of student thinking that have significant potential to be used during the lesson to support the learning of important mathematics. In particular, we draw on Leatham, Peterson, Stockero, and Van Zoest's (2015) definition of **M**athematically Significant Pedagogical **O**pportunities to Build on **S**tudent **T**hinking [MOSTs] as occurring at the intersection of three characteristics: (a) student mathematical thinking, (b) significant mathematics, and (c) pedagogical opportunity. The MOST analytic framework uses two criteria to determine whether an instance of student thinking embodies each of these characteristics. For student mathematical thinking the criteria are that there is sufficient evidence to reasonably infer the student mathematics and that one can articulate a mathematical point closely related to this student mathematics. The significant mathematics criteria are that the mathematical point is appropriate for the mathematical development level of the students and is central to mathematical goals for their learning. The pedagogical opportunity characteristic requires that the student mathematics creates an opening to build on student thinking to help develop an understanding of the mathematics and that the timing is right to take advantage of the opening. Instances that satisfy all six criteria, and thus all three required characteristics, are MOSTs (see Leatham et al., 2015 for more details). In this study, the MOST analytic framework was used as a tool to focus participant noticing.

Methodology

The Intervention

The participants in the study were 17 prospective mathematics teachers (PTs) enrolled in an early field experience course between fall 2011 and fall 2014. They participated in the study in five cohorts, each with three to four PTs. Each PT was assigned to observe a local, experienced secondary mathematics teacher's classroom. Participants recorded videos of mathematics lessons in these classrooms on a rotating basis; over the course of each semester, efforts were made to collect video from a range of grade levels with varied mathematical topics. The instructional portions of the classroom video were left mainly unedited for analysis, although portions in which students could not easily be heard were removed. The PTs and researchers used the Studiocode (SportsTec, 1997-2015) video analysis software to individually analyze one video each week, marking mathematically important moments a teacher should notice in the classroom. The PTs included a description of why they chose each moment. The researchers met weekly to agree on instances that were MOSTs in the video and to discuss the instances PTs had identified as important, including which instances would be discussed at a weekly group meeting among the PTs and researchers. These group meetings were facilitated by the first author and focused on building PTs' skills in noticing mathematically important moments.

Because the intervention was conceived as a design experiment (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003), the specific scaffolding activities varied by semester. All of the PTs were initially prompted to identify *mathematically important moments that a teacher should notice during a lesson*, with the definition of this construct left open ended to provide baseline data for PT noticing. All of the cohorts except cohort 5co-developed labels in the weekly group meetings to describe and categorize types of mathematically important moments. These labels drew on Stockero and Van Zoest's (2013) pivotal teaching moment categories, but the categories were not made explicit to the PTs. After the creation of these labels, PTs assigned labels to moments they marked in subsequent videos. Each cohort was introduced to a variation of the MOST framework at some point during the semester. This framework evolved over the four years of the study, so cohorts 1 and 2 used a general version of the framework in which the MOST criteria were only loosely defined in terms of student thinking, important mathematics, and pedagogical opportunity. Cohorts 4 and 5 used the most explicit, analytical version of the framework as defined in Leatham and colleagues (2015). The MOST framework was introduced to the first four cohorts five to six weeks into the semester and to cohort 5 two weeks into the semester. After the introduction of the framework, PTs were expected to focus on moments in the videos that were MOSTs, as defined by the version of the framework available at the time. Cohort 5 was pushed to most explicitly discuss each characteristic of the framework.

Data Collection and Analysis

The study data was the PTs' video analyses and video recordings of the weekly meetings. To analyze how the PTs' noticing changed during the intervention, we analyzed the video instances the PTs had marked and their reasoning. APT's written description of an instance received the most weight. When available, aPT's label and what (s)he said about the instance in the meeting were also considered. To minimize the possibility that PTs influenced each other's thinking, the meeting commentary received more weight if a PT was the first to speak about an instance.

The unit of analysis was a PT-identified instance. Drawing on frameworks used in previous research (Stockero, 2008; van Es & Sherin, 2008), each instance was coded for the agent of the PT noticing and the level of specificity with which the mathematics was described. If there was any student focus in an instance, an additional code was assigned to describe the nature of the PT's noticing of the student(s). Figure 1 gives the coding categories, definitions and codes.

Coding Categories	**Description**	**Codes**
Agent	Who or what was the focus of the noticing*	Teacher (T), Teacher/Student (T/S), Student/Teacher (S/T), Student Group (Sg), Individual Student (Si), Math (M)
Math Specificity (MS)	Whether and how the mathematics is discussed	Non-math (NM), General Math (GM), Specific Math (SM)
Nature of Noticing (NoN)	For instances with some student focus, what about the students was attended to	Affective Interaction, General Understanding, Mathematical Interaction, Noting Student Math (NSM), Analysis of Student Math (ASM)
*Student-teacher interactions are coded as teacher/student if the teacher is the primary focus and student/teacher if the		

student is the primary focus

Figure 1:Coding Framework

To give a sense of some of the key codes that we will discuss, consider the three instances in Figure 2. These all focus on the same instance of an individual student's thinking so were all coded as Si for the agent. Although instance 2 is focused on a student mathematical question, we have no idea what the related mathematics is, so it was coded GM for math specificity. The mathematics is discussed in a much more specific way in instances 2 and 3, however, so these were coded as SM. Instances 1 and 2 describe the important student mathematics, but do not go beyond this, so were coded as a NSM focus. Instance 3 on the other hand, is making sense of why the student asked the questions she did, so was coded as an ASM focus.

	Description of Instance	**MS**	**NoN**
	I think that this is a very good question that is necessary to further learning (making examples similar). The student describes her question in depth to infer her thinking.	GM	NSM
	Student is curious as to why they need to divide by the determinant to find the inverse [matrix] in this example, but not in the previous example.	SM	NSM
	[S]he does not know why we are multiplying by 1/2 in one example and not the other. The student does not understand that they have to multiply by 1/det[A], probably because the multiplication of 1/det[A] was not shown in the previous example because the det[A]=1. We {we]re multiplying the matrix [d -b –c a] by 1, which is trivial. The students should understand that if two matrices multiplied together give the identity, that they are inverses of each other.	SM	ASM

Figure 2:Coding Examples

In the analysis process, each PT-identified instance was individually coded by either two or three researchers. The researchers then met to reconcile the coding; when there was disagreement about one or more codes for an instance, the instance was discussed among the group until agreement was reached. In cases where two researchers were unable to reconcile their coding, the third researcher was brought into the discussion to help resolve any coding differences.

Results

The goal of the intervention was to promote the noticing of instances of student mathematics that have the potential to be capitalized on during a lesson to support student learning. Thus, our analysis focused on the extent to which we were able to promote such noticing. We discuss both changes in the PTs' noticing as a result of the intervention, as well as the extent to which the PTs met our "target" for noticing: individual students, specific mathematics, and noting or analyzing student mathematics. In this discussion, *baseline* refers to the PTs' noticing in the first two videos each semester, before there was any attempt to focus their noticing. *Final* refers to the noticing in the last four videos each semester—an indication of the PTs' most refined noticing. We use four videos to report the final noticing because most of the PTs noticed significantly fewer instances in these later videos. In fact, PTs noticed an average of 8.8 instances per video early on, and less than half that amount (3.75 instances/video) in the final four videos, an indication of becoming more selective about the instances deemed important to notice.

Agent

Table 1 shows the percent of PT noticing focused primarily on students (coded Sg, Si, or S/T), primarily on the teacher (T or T/S), and on the mathematics itself in the baseline and final data. At the start of the intervention, a significant percent of the PTs' noticing was focused primarily on the teacher in the video, and to a lesser extent, on the mathematics itself. This non-student focused noticing accounted for between 25% and 81.2% of the baseline noticing. Except for cohort 1, 51.0% or fewer of the instances noticed by the PTs in the baseline data had a primary student focus. At the end of the intervention, however, the majority of each cohort's noticing was focused on the students in the video, ranging from 85.5% to 100% of instances.

Table 1: Participant Noticing by Primary Agent

		Cohort 1	Cohort 2	Cohort 3	Cohort 4	Cohort 5
Primary Student Focus	Baseline	75.0%	46.7%	51.0%	18.8%	28.4%
	Final	88.9%	100.0%	90.0%	98.3%	85.5%
Primary Teacher Focus	Baseline	22.7%	33.3%	42.9%	59.4%	62.5%
	Final	9.5%	0.0%	6.0%	1.7%	14.5%
Math Focus	Baseline	2.3%	20.0%	6.1%	21.9%	9.1%
	Final	1.6%	0.0%	4.0%	0.0%	0.0%

Although the primary focus on students was encouraging, we were particularly interested in the extent to which PTs focused on individual students and their mathematics. Thus, we further analyzed the subset of instances with a primary student focus to determine whether the PTs' focus in these instances was on individual students, groups of students, or student-teacher interactions (Table 2). At the start of the intervention, each cohort's student-directed noticing was either focused mainly on groups of students (cohorts 1, 2, and 5) or on student-teacher interactions (cohort 4); cohort 3's noticing was evenly split between the two. With the exception of cohort 1, the PTs' final noticing was primarily focused on individual students (79.7% to 90.3% of instances), indicating that the intervention was successful in focusing the PTs on what individual students were saying or doing during the lesson.

Table 2: Primary Student Noticing

		Cohort 1	Cohort 2	Cohort 3	Cohort 4	Cohort 5
Individual Students	Baseline	39.4%	21.4%	16.0%	38.9%	4.0%
	Final	37.5%	90.3%	84.4%	79.7%	85.1%
Groups of Students	Baseline	51.5%	57.1%	44.0%	16.7%	68.0%
	Final	8.9%	9.7%	11.1%	6.8%	8.5%
Student/Teacher	Baseline	9.1%	21.4%	40.0%	44.4%	28.0%
	Final	53.6%	0.0%	4.4%	13.6%	6.4%

Focus of Noticing

Instances with any student focus (coded Si, Sg, S/T and T/S) were also coded to characterize what about the students the PTs had noticed. As a reminder, the goal was to focus PTs' attention on what students were saying mathematically, so the target was noting or analyzing the student mathematics, with analyzing deemed to be the higher-level of the two foci. Due to space constraints, we discuss just these two noticing foci.

There was a wide difference in the percent of the student-focused instances coded as either noting or analyzing student mathematics for each cohort in the baseline data (Table 3). The first two cohorts had a total of 47.5% and 46.4% of such instances coded with one of these foci, while the latter three cohorts had a significantly lower percent, ranging from only 2.3% to 20.4%. In the baseline data, only cohort 2 demonstrated any analyzing; this was all attributable to just one PT. All of the cohorts increased their noticing with these two foci. In fact, with the exception of cohort 1, the final data shows that 85.5% or more of the PTs' student-centered noticing was coded as noting or analyzing student mathematics, with noting instances accounting for the majority of the instances for cohorts 2, 3 and 4, and a more even split between noting and analyzing (47.3% and 38.2%, respectively) for cohort 5. Cohorts 2 and 5 demonstrated the highest percentage of analyzing, but again, cohort 2's analyzing was largely attributable to one PT. Cohort 5's percent of analyzing was not only the highest among all cohorts, but was also more consistent among the PTs in the cohort. Collectively, the data suggests that the intervention was successful not only in focusing the PTs' attention on students, but also on the important mathematics that came from these students in the lessons. More specific versions of the framework were generally more effective in supporting noticing. The higher percent of analysis by the last cohort also suggests that providing a framework earlier in the intervention and engaging PTs in a more structured use of the framework better supported noticing than earlier iterations of the intervention.

Table 3: Participant Student-Centered Noticing Focus

		Cohort 1	Cohort 2	Cohort 3	Cohort 4	Cohort 5
Noting Student Math	Baseline	47.5%	32.1%	20.4%	15.6%	2.3%
	Final	59.0%	76.7%	78.0%	89.8%	47.3%
Analyzing Student Math	Baseline	0.0%	14.3%	0.0%	0.0%	0.0%
	Final	1.6%	20.0%	8.0%	8.5%	38.2%

Specificity of Mathematics

The specificity of the PTs' noticing indicates whether and in what level of detail the mathematics in an instance was discussed. Non-mathematical noticing was present in the baseline data for all cohorts and was most prevalent for cohort 5, with 39.8% of their noticing focused on non-mathematical features of classroom interactions (Table 4). There was no non-mathematical noticing present in the final data, however. Perhaps surprisingly, most cohorts discussed the mathematics in a specific way more than half of the time from the start (between 52.5% and 75% of instances), although cohort 5 only did so 29.5% of the time in the baseline data. All of the cohorts maintained or became more specific in their discussion of the mathematics through the intervention, with the final three cohorts most consistently discussing the mathematics in a specific way in the final data and cohort 5 showing the most significant change in specificity. This again suggests the benefit of a more explicit analytic framework.

Table 4: Specificity of Participant Noticing

		Cohort 1	Cohort 2	Cohort 3	Cohort 4	Cohort 5
Non-math	Baseline	15.0%	10.7%	2.0%	3.1%	39.8%
	Final	0.0%	0.0%	0.0%	0.0%	0.0%
General Math	Baseline	32.5%	14.3%	38.8%	26.0%	30.7%
	Final	24.6%	26.7%	12.0%	13.6%	5.5%
Specific Math	Baseline	52.5%	75.0%	59.2%	70.8%	29.5%
	Final	75.4%	73.3%	88.0%	86.4%	94.5%

Noticing of MOSTs

An additional measure of PT learning was whether they became better able to identify instances of student mathematics that had potential to be used to support student learning of mathematics—that is, instances that were MOSTs. Table 5 gives the percent of the instances that PTs marked that coincided with instances the researchers identified as MOSTs. As seen in the table, all of the cohorts increased in the percent of moments that aligned with the researchers' moments, but the data needs to be interpreted with caution. Ongoing analysis is focused on determining whether the PTs talked about these instances in a way that indicates they were focused on the student mathematics, rather than for some other reason.

Table 5: Participant Noticing of MOSTs

	Cohort 1	Cohort 2	Cohort 3	Cohort 4	Cohort 5
Baseline	60.0%	32.1%	44.7%	25.0%	17.0%
Final	86.9%	66.7%	68.0%	67.2%	67.3%

Discussion and Conclusions

The findings of this study add support to a growing body of research demonstrating that it is feasible to develop prospective teachers' professional noticing skills. In fact, we developed these skills at the start of a teacher preparation program, when the prospective teachers had very little knowledge of students to draw upon. Key differences between this and many other interventions are that the noticing intervention used longer unedited classroom video recorded in local teachers' classrooms and focused on a range of mathematical topics, depending on the topics of the recorded lessons. Thus, these findings suggest that there may not be a need to narrow either the scope or length of classroom artifacts used to develop noticing skills (i.e., use short transcripts or video clips), nor the mathematical focus of the noticing activities.

The data also showed a general trend that when a more explicit analytic framework was provided, the PTs came to discuss the mathematics in a more specific way, and more often noted and analyzed what the students in the video were saying mathematically. Although the total percentage of instances in which the PTs noted or analyzed student mathematics was a bit lower for cohort 5, they and cohort 4 showed the greatest increase in these foci from beginning to end of the intervention. Furthermore, cohort 5 reached the analyzing level in 38.2% of all instances in the final videos—significantly more than any other cohort. These findings suggest that, although using even a loosely defined framework can support prospective teacher noticing (cohorts 1 and 2), using a more structured framework can significantly improve the outcomes of a noticing intervention. The fact that cohort 5 was given the framework earlier and was prompted to use the framework in a more structured way likely also enhanced their learning, although additional analysis is necessary to confirm whether this is the case.

Although the findings are noteworthy, there are still open questions that need to be addressed. For instance, we do not yet know how the participants' interactions with each other during the weekly meetings or the facilitation of these meetings supported the PTs' noticing, nor have we yet examined the PTs' proposed teacher responses to identified moments. Ongoing work is also focused on understanding how the noticing skills developed during this intervention transfer to noticing student ideas during the PTs' own instruction. Addressing questions such as these holds potential for helping novice teachers learn to enact the type of student-centered instruction the field has been striving to achieve (e.g., NCTM, 1989; 2014).

A TOOLBOX FOR SUPPORTING EARLY NUMBER LEARNING IN PLAY: MOVING BEYOND "HOW MANY'?

Anita A. Wager

parksamy@msu.edu

This paper explores the ways preschool teachers orchestrate instructional environments to promote mathematical play related to early number and, how they intervene during play to promote children's engagement with early number. We highlight these practices to identify resources for the growing numbers of early childhood teachers. This is important as many prospective and practicing teachers do not have access to the knowledge of teaching that supports young children's math learning because of the constraints of mathematics methods courses and the dearth of research on early childhood mathematics in mathematic education journals – particularly in-depth attention to early number and teaching mathematics in play.

Keywords: Early Childhood Education; Number Concepts and Operations; Teacher Education-Preservice

One of the most important challenges for young children in mathematics is gaining fluency with foundational concepts related to number, which include developing an understanding of the number word list, 1-to-1 correspondence, cardinality and related concepts like subitizing, and relationships of more, less, and the same (National Research Council, 2009). Generally, children develop understandings of these number concepts from ages 2 to 6 (Ibid.), meaning that the early years of public schooling are important to helping children master more advanced concepts, such as conceptual subsidizing (decomposing larger sets into easily identifiable subsets), and to helping children who come to school without mastery of early skills related to number quickly catch up. Increasingly, research has demonstrated that early and successful mastery of these early number concepts is predictive of later success in mathematics in particular and in schooling more broadly (e.g., Duncan et al., 2007; Jordan Kaplan, Locuniak & Ramineni, 2007). For example, in a large-scale longitudinal study, Duncan and colleagues (2007) found that early math skills are better predictors of later school success than measures of reading, attention skills, or socio-emotional behaviors, with little difference across gender and socio-economic status. More specifically, in a study of low-income families, Ramani, Row, Eason and Leech (2015) found that caregivers' engagement of children in activities aimed at teaching about number and caregivers' use of advanced number talk predicted children's understanding of cardinality, ordinal relationships, and early arithmetic. Additionally, Ramani and colleagues found no relationship between demographic variables, such as parent education, home language, or family income and children's knowledge of the number core.

Other research has shown that adults' intentional engagement of children around the number core, particularly in relation to constructs, such as cardinality and subitizing, improves children's understandings of these concepts. For example, Gunderson and Levine (2011) found that children's understanding of cardinality increased when adults counted sets and labeled them simultaneously (e.g., "1,2,3. That's 3.") in comparison with counting or naming sets in isolation. In a study of three-year-olds, Mix and colleagues (2012) found similar results. This body of work, generated primarily by developmental psychologists, demonstrates the importance of attending to early number and suggests that there are particular strategies that early childhood teachers could draw on to promote children's mastery of the number core. Yet, relatively little attention is paid to early number in mathematics education research, particularly in relation to teacher education practices for prospective elementary teachers (Parks & Wager, 2015).

Indeed, none of the studies cited above about the importance of early number concepts for predicting later mathematical success were published in mathematics education journals. In a recent review of 20 years of mathematics education and early childhood education journals, we found that only 28 of the 239 articles published about early childhood mathematics attended to the number core at all. In addition, the mention of early number concepts in many of these 28 articles was quite cursory – often an aside to a broader discussion. In fact, cardinality was explored in depth in only one article; 1-to-1- correspondence was explored in two articles, and subitizing was examined in four. (As a point of comparison, 66 articles mentioned fractions, 11 in some depth, and this was within a dataset of articles identified as attending to pre-K-Grade 3 contexts). In addition, only three articles concerned with early number concepts focused on strategies for helping preservice or practicing teachers support children's early number learning (Schack et al, 2013; Tirosh, Tsamir, Levenson & Tabach, 2011; Tsamir et al, 2013), which suggests a need for greater attention to developing strategies to help teachers promote early number understandings.

Recent increases in publically funded prekindergartens and staffing of these programs with teachers who have been certified in elementary education makes this need more pressing. In the 2012-2013 school year, 28 percent of four-year-olds in the US were enrolled in state-funded preschool programs (Barnett, Carolan, Squires & Brown, 2013). More than half of the states require that teachers in these prekindergarten (pre-K) programs have four-year degrees in education, which means they have likely learned to teach mathematics in university methods courses. Given current interest in universal pre-K (Barnett et al., 2012), these numbers are likely to increase, resulting in greater numbers of future pre-K teachers in elementary mathematics methods courses across the country. Additionally, given the lack of attention to early number in research (and anecdotally on methods course syllabi), future kindergarten teachers almost certainly also need more support in attending to early number than they have been getting in typical mathematics methods coursework.

In addition to requiring more in-depth attention to early number (and geometry), these future pre-K and kindergarten teachers also need strategies for helping their children maximize opportunities to learn mathematics in play settings in the classroom. Recommendations for best practices in early childhood settings almost universally include calls for time for play, which promotes cognitive development, language learning, and social growth (Copple & Bredekamp, 2009). Typical classroom play materials, such as blocks, games, and toy collections, offer potentially rich opportunities for children to learn and practice early number concepts (Wager & Parks, 2014; Seo & Ginsburg, 2004; van Oers, 2010); however, without teachers who intentionally intervene to mathematize play by attaching mathematical language to play, scaffolding more complex play, and directing student attention toward potential mathematics, children are unlikely to get the full benefits from their mathematically oriented play (Ginsburg, 2006; Graham, Nash & Paul, 1997). Yet, there is also little attention to teaching strategies for mathematizing play in the research literature. In the review described above, we found only one study (Eberly & Golbeck, 2001) that focused on understanding ways that practicing or preservice teachers learned about or implemented strategies to mathematize play.

In order to address these gaps in the literature, this study draws on a rich library of data from two broader studies in order to identify productive strategies that practicing preschool teachers used in order to promote mathematical play in their classrooms and to mathematize that play for children. The research questions guiding our analysis were: How do preschool teachers orchestrate their instructional environments to promote mathematical play related to early number? And, how do these preschool teachers intervene during play to promote children's engagement with early number concepts?

Theoretical Framework

In this study, we take the perspective that early number learning develops not only as a result of maturation, but is significantly influenced by context and engagement with knowledgeable others (Vygotsky, 1978). Although Piaget is best known for his stage theories of development, which argue that children move through predictable stages of learning (e.g., going from more concrete to more abstract understandings of quantity) as they mature (Piaget, 1962), Piaget also did not believe that these stages operated independently of the environment or of social interactions with others (Piaget, 1964). Similarly, Vygotsky argued that adults can and should provide instruction that "marches ahead of development" (Vygotsky, 1962, p. 104) to foster children's learning.

This perspective is important because it means that rather than waiting until a child is "developmentally ready" for a particular mathematics concept, teachers must take responsibility for guiding children toward new understandings. In relation to early number, this means that primary grade teachers should not simply wait until understandings of the number core develop before beginning instruction in early arithmetic nor should they assume that children who come to school without competence with cardinality, 1-to-1 correspondence, and subitizing will develop these skills by engaging with instruction aimed at early arithmetic. Rather, they must both create instructional environments that foster children's growth in relation to these early number understandings and engage in intentional instructional practices that will move children along the developmental continuum (Parks, 2015). Both Vygotsky (1968) and Piaget (1962) saw play as an important context for these kinds of instructional interactions, both because play is motivating for children and because it encourages exploration with physical objects, which often leads to more sophisticated understandings of quantity.

Mode of Inquiry

The analysis presented here is drawn from data collected in two broader studies, both aimed at understanding mathematical learning and teaching in early childhood classrooms. Both studies were designed within a tradition of interpretive research that values attention to meaning-making by participants and understanding the role of context in human interactions (Erickson, 1986; Graue & Walsh, 1998). The first study provided an intervention of sorts as teachers engaged with professional development explicitly designed to support their understanding of mathematics learning in play-based pre-K classrooms, whereas the second study observed existing phenomena – what math was happening. Thus, we have examples from teachers who were supported to think about math in pre-K and from a teacher who was not.

The first study involved a Professional Development (PD) program designed to promote culturally and developmentally responsive early number teaching. The project team designed, facilitated, and studied the PD for three cohorts of pre-K teachers who were teaching in a local districts' new 4-year-old kindergarten. Each cohort took four graduate courses over a two-year period. Data included audiotaped group discussions and artifacts from the course, interviews with teachers, and bi-weekly observations in a subset of participants' classrooms. For the current analysis, we focused on artifacts – in particular, 51 learning stories (narrative assessments of young children's learning, Carr, 2011) teachers wrote to identify what they noticed and how they responded to children's mathematics engagement in play.

The second study was a longitudinal examination of the mathematical experiences of a cohort of children as they moved from preschool to Grade 1 in a rural public school. Data included video of classroom events, assessment interviews, and out-of-school engagements, as well as interviews with teachers and parents. For the current analysis, we focused on video data collected in the preschool classroom of mathematics-related interactions in both formal and informal settings. The teacher in this pre-K was an experienced, white, female teacher with more than 15 years of experience in pre-K and kindergarten. The majority of children in the cohort were African American (13 out of 16) and all children in the cohort came from low-income families.

For this analysis, we identified episodes in both sets of data that had been previously coded as involving cardinality, 1-to-1-correspondence, and subitizing as well as adult interactions. We then coded these episodes as relating to organization of the instructional environment or intervention in the moment. Then, each of these sets of data was analyzed (by each researcher and through conversation and writing with each other) to identify strategies used by the teachers in both studies to promote students' understandings of early number.

Findings and Discussion

We found that teachers engaged (or had the opportunity to engage) children in rich math interactions in three instructional spaces: (a) activities purposefully planned for whole class engagement in math; (b) play with math-like materials in the room or in specific math centers (e.g. board games, counting manipulatives) and; (c) during play that might not obviously be seen as mathematical (Wager, 2013). For each of these instructional spaces we provide vignettes from classroom observation (either ours or reported by the teacher) and identify strategies teachers used.

Planned activities

Teachers in both projects planned activities that were purposefully designed to engage children in counting related activities, although teachers in the professional development project were more likely to design activities where children routinely got to handle objects as they practiced counting. In the classroom observed without intervention the most frequent counting activities involved reciting the number sequence, singing a song prompted with cards to practice number recognition, and counting during calendar time, when only the teacher or a single child handled objects while counting.

Activities when children could handle objects and count typically occurred during transitions, meals, or other routines such as morning meetings. Sometimes these were whole group activities while other times individual children 'led' the activity for the class. A common practice among teachers was to start each class period by having a child count how many children were present. In the following examples we see how a teacher supports a child who is still working on 1-to-1 correspondence and another who is moving toward problem solving. In Vignette 1, Betty reflects on her observation of Bob counting his classmates during circle time. The children had been doing this activity for about six weeks.

> *Vignette 1:* When I asked [Bob] to count how many children were sitting in the circle, he was not exactly sure where to start. With a little guidance he started with the child that was sitting next to me. He counted with 1:1 correspondence tapping each child on the head, however, he skipped one girl and she said, "hey you missed me". He turned to me and looked confused. He started again and I encourage him to slow down. He skipped another child and then the aide assisted him so he could finish counting all the way around. *(Betty, Counting Children)*

In the next example, Marley shares how she supported Sam to make counting his classmates a more challenging activity. She had previously noticed that Sam would write addition problems on a dry erase board and ask, "how much is this?"

> *Vignette 2:* I asked Sam to first count the girls and then count the boys as I wrote the numbers on the easel. I used this opportunity to also explain what the + and = signs mean. After I recorded the numbers I had all the children stand up to be counted showing that 5 girls plus 6 boys equals 11 children all together. *(Marley, Math problems…)*

Snack time is another space that teachers engaged children in counting activities. Sadie had a snack helper in her class whose job was to count out 14 plates and put 4 orange slices on each plate.

> *Vignette 3:* I helped Clara with the first plate, working to count out 4 orange slices. She put 3 slices on the second plate, then counted the number on the first plate and the number on the second plate and asked me, "that the amount?" When I asked her what she thought, she put on more on to make 4. Then on the 4th plate she put 5 slices and asked again. I helped her take one orange slice away, using the words more, less, and take away, until she discovered the plates had the same amount. *(Sadie, Clara's Snack Task)*

The teachers in these vignettes used a variety of strategies to support children's early number development. In vignette 1, Betty recognizes that Bob can count using 1-to-1 correspondence to about 3 or 4 before he switches to rote counting. Her strategy was to encourage Bob to slow down so he could match a number to each child that he taps, and ultimately have an adult count with him. In vignette 2, Marley modeled a joining problem by using a practice the children regularly engaged with in the class. In vignette 3, Sadie does not directly tell Clara whether she is right or wrong but rather asks her what she thinks. Sadie then modeled how to compare sets. Both Sadie and Marley modeled strategies for children using math vocabulary.

Math games and materials

Preparing the environment for children to engage with learning is a critical aspect of any early childhood classroom, and certainly true for mathematics learning. Yet providing materials and organizational structures that encourage interactions around math is not enough. We found in both of our studies that teachers provided varying levels of support to children as they played with math games and activities. All the classrooms had several math games both teacher-made and commercial. In addition, teachers made decisions to highlight the mathematical nature of materials. For example, Sarah organized collections of small toys, such as cars and animals, on a shelf along with a balance. By placing these objects in proximity, she encouraged her students to engage with them in a mathematical way. Vignette 4 describes the impact of Sarah's decision to organize unifix cubes in sticks of 8, rather than loose in a bucket.

> *Vignette 4:* Clay sat down among a pile of unifix cubes that other children had been playing with and began, without prompting to organize them into sticks of 8. He began by touching each cube as he counted it to ensure he had the correct amount. After he made a few sticks of 8, he started using his previous sticks as points of comparison, holding up a new stick and then removing two cubes when he noticed that it was too long. After watching Clay for a moment, two other boys began to make sticks of 8, touching each cube as they counted.

Sarah intentionally asked the students to keep the unifix cubes in sticks of 8 (a number chosen because it was the number of spaces on their bingo cards) because she knew it would provide opportunities to practice meaningful counting whenever the cubes were cleaned up; however, she did little to deepen students engage with these cubes across the year, such as changing the goal number for the size of sticks or asking students to articulate the strategies for composing sticks from smaller groups of blocks or comparing finished lengths. Sarah, who did not receive professional development around early mathematics and who reported that she'd had little preparation around the counting core in her preparation program, was not as adept as the teachers receiving PD as recognizing mathematics in play and intervening to highlight it for children, as demonstrated in the next vignettes.

In analyzing teachers' interactions when playing games with children or observing children play the games, we were particularly interested in those examples of teachers finding alternative ways to ask ‘how many’ or go beyond asking ‘how many’. The ways in which teachers did this included general comments about sets that encouraged the children to count such as “wow, that is a lot” or asking which one has more when children had more than one set of objects. In vignette 5, Betty observes John at the math center working on a Counting Book.

> *Vignette 5:* On the first page, he wrote the numeral 4 and then stamped 4 stamps. On the second page he wrote 1-10 saying each number to himself as he wrote. I asked him, “what did you write”, he told me the numbers up to 10. I asked, “how many will you stamp” and he started stamping and counted each one up to 10. On the next page he stamped 7 stamps, counted them and wrote the number 7. Then he stamped on more and stopped. I asked, “what now”. He crossed out the 7 and asked me how to write 8. I showed him a picture of the numeral 8 and he tried it. *(Betty, How Many Stamps?)*

In this next vignette, Chela describes how Kiki used the balance scale to count and compare various objects in the room. Kiki had filled the cups with different objects from the science table, putting insect and spider counters in one and one-gram yellow weights in the other. Then using a chart that Chela had made for children to compare the number of objects in different sets, Kiki lined up the insects on one side and weights on the other.

> *Vignette 6:* In a very precise manor, Kiki had lined up the yellow grams and commented, “wow this is lots!” At this point I prompted him to also line up the insects and spiders, which Kiki thought was a great idea. Kiki had a difficult time knowing for certain which one had more, but thought that it was the yellow grams because there were lots. I asked him how he could know which was more and he counted each. *(Chela, Measurement and Balance Activity)*

In Vignette 5, Betty asks the question ‘how many’ but does so in a way that encourages action to count out rather than how many are already in a set. She also asks John ‘what now’ so that he could choose between crossing out a stamp or changing the numeral. In Vignette 6, the nature of the materials Chela has in class encourage the practice of counting. By asking the child how he could find out which set had more, she encouraged him to think of counting rather than directing him to do so.

Mathematizing Play

Perhaps one of the most challenging responsibilities that early childhood teachers face with respect to supporting math learning is mathematizing the activities children engage with in free play. To do this effectively, teachers must recognize the mathematics that children are engaging with and make in-the-moment decisions to support further learning. We found examples of situations in which teachers were able to recognize and respond to math in a variety of classroom environments. In Vignette 7, Sadie observes Clara in the housekeeping area as she was making food for her friends. Clara was the mom and her friends were her babies.

> *Vignette 7:* They all started talking about birthdays and her babies said they needed 4 ‘cupcakes’ because they were 4 years old, or 5 ‘cupcakes’ because they were 5. She counted 4 cupcakes for one of her babies and 5 for the other. When I was invited over to share in the birthday festivities, I was given a plate and a pile of food. I asked how many cupcakes I had and Clara counted 8 of them and stopped (there were more pieces on my plate). When I said I want 2 cupcakes because I am 2, Clara removed some pieces of food off my plate and left me with 2 and said “there, now lets sing”. *(Sadie, Clara’s Counting Kitchen)*

In Vignette 8, Sadie observed Sam using 3D shapes to build “a huge castle”. Although play with shapes could be coded as mathematical materials, in this situation we are examining the interaction around counting and thus we coded this as play. There was considerable conversation about the different shapes Sam used for his castle. Here we pick up where Sadie's reflection shifted to a discussion of counting.

> *Vignette 8:* While the conversation continued we talked about the various heights of his towers. He counted with 1:1 correspondence up to 4, which was the tallest tower. He noticed that the lower tower was only 2 shapes tall and compared them saying "this one is shorter than that one." We talked about how the tallest tower did not have the most shapes. *(Sadie, The Castle King)*

Vignette 7 provides a wonderful example of how teachers can enter children's play to support mathematical thinking. Clara was already counting and showing evidence of 1-to-1 correspondence and cardinality but Sadie was able to push on this without disrupting the play by having Clara think about how to remove enough 'cupcakes' to leave Sadie with two. Sadie could have taken this further by asking how many cupcakes Clara took off her plate. In vignette 8, Sadie joined Sam in his castle building and raised questions about the height of his towers, which encouraged him to compare heights, count, and ultimately see that more blocks did not always mean a higher tower.

Not surprisingly we found more instances when teachers recognized the opportunity to mathematize but did not do so in the moment or did not engage with mathematics at all, despite the opportunity to do so. For example, students in Sarah's classroom routinely built tall towers of blocks and argued with each other about whose was the largest, but the teachers in the room never intervened to ask the children to find out. Similarly, while mathematical games were available, teachers did not intervene to teach children the rules of the games, which would have supported mathematical thinking, but instead let them play however they wanted, which often resulted in play-acting with the pieces (intellectually valuable, no doubt, but unlikely to lead to development of the skills highlighted in the number core).

Implications

The vignettes provide examples of how teachers who have had PD explicitly focused on early number were able to provide activities and materials, and respond to children's engagement in these activities, materials, and play in order to support early number development. In interviews and classroom discussion about the PD, each of these teachers shared that they would not have attended to math in these ways without the PD. The purpose of the above is not to argue for the effectiveness of the particular PD but to see the possibilities of early number engagement when teachers are supported to develop the skills for these interactions. Many of our prospective teachers do not have this opportunity because the constraints of programs are such that mathematics methods courses are intended to cover a broad grade band and the early counting is often left out. Without more research in mathematics teacher education journals on the practices that support early math and the content knowledge required, our future early childhood teachers will not be able to engage in these kinds of interactions and the children in their classrooms will not interact with the math thinking that research shows is important.

In this paper, we describe teachers' learning of an instructional practice related to launching a cognitively demanding task. Using a multi-case study design, we analyze eight teachers' participation in a rehearsal of the instructional practice in professional development and the ways these teachers enacted this practice in their classroom instruction. Our findings suggest that what teachers attended to in their rehearsal related to their classroom practice and the degree to which the cognitive demands of the task were maintained.

Keywords: Teacher Education-Inservice

Introduction

As a model of teaching, student-centered mathematics instruction supports students in engaging in tasks that build conceptual understandings, communicating and evaluating mathematical reasoning, and making connections among mathematical concepts. Such instruction has been shown to lead to increased student learning (Fennema et al., 1996; Boaler & Staples, 2008) and may address issues of equitable instruction for traditionally marginalized students (Myers, 2014). Though a consensus among researchers suggests that expert teaching involves understanding and using students' thinking to guide instruction (Bransford, Brown, & Cocking, 2000; Darling-Hammond, 2008; Kilpatrick, Swafford, & Findell, 2001), mathematics teaching in the US remains largely teacher directed, focused on procedures, and marked with few opportunities for intellectual engagement (Stigler & Hiebert, 2004; Wiess et al., 2003).

Professional development (PD) that relates new learning to teachers' practice can influence their instructional strategies (Darling-Hammond et al., 2009; Goldsmith, Doerr, & Lewis, 2013), yet many teachers have difficulties implementing new instructional strategies in their teaching. In PD, mathematics teacher educators (MTEs) have found that guiding frameworks for instructional practices are often insufficient to support teachers in enacting new practices in their classrooms (Boston & Smith, 2009; Munter, 2014). Recently, work around *rehearsal* in pre-service teacher education is showing promise as an approach for assisting novice teachers in learning and enacting student-centered instructional practices (Lampert et al., 2013). Our research adopts rehearsal as a pedagogy for supporting teacher learning of new instructional practices for a PD setting. In this paper, we aim to describe the ways a group of practicing secondary mathematics teachers attended to instructional moves for one student-centered instructional practice through rehearsal in PD. Specifically, our research is guided by the question: *in what ways does teachers' participation in rehearsal of an instructional practice in PD relate to their enactment of the practice in their classrooms?*

Background

A critical foundation for student-centered mathematics instruction is students' engagement with cognitively demanding mathematics tasks. Stein, Grover, and Henningson (1996) described the cognitive demands of a mathematics task as "the kind of thinking processes entailed in solving the task" (p. 461) and offered a framework for categorizing tasks as low and high cognitive demand. Their research showed that though teachers may begin instruction with a cognitively demanding task, the demands of the task often decline during implementation. Stein and Lane (1996) reported that the greatest gains in student learning occurred in classrooms where cognitively demanding tasks were implemented and maintained during instruction.

MTEs have developed frameworks for assisting teachers in maintaining the cognitive demands of tasks (e.g. Smith, Bill, & Hughes, 2008; Smith & Stein, 2011). Recently, Jackson and colleagues' (2013) investigated the relationship between task setup at the beginning of a lesson and the quality of the culminating discussion. They identified four factors that related to its implementation which were the degree to which: key contextual features were made salient; key mathematical concepts were highlighted and examined; a common language that supported contextual and mathematical elements of the task was developed; and the mathematical integrity of the task was maintained. We consider the practice of launching cognitively demanding tasks as paramount to teachers success in maintaining the cognitive demands of a task.

Theoretical Perspectives

We conceptualize PD as a boundary encounter (Sztajn et al., 2014; Wenger, 1998) where both the teaching and MTE communities bring distinct practices and identities. In a boundary encounter, teachers and MTEs come together to exchange knowledge by interacting around representations of knowledge that carry meaning in both communities called boundary objects. Members from differing communities introduce, negotiate, and integrate elements of their own practice as they interact and make new meanings of the boundary object together. From this perspective, teacher learning is taken as changes in their participation in the boundary encounter and the presence of new aspects of practice in their classroom teaching.

In PD, MTEs design professional learning tasks (PLTs) to facilitate participation around boundary objects (Edgington et al., 2015). Grossman and colleagues (2009) characterized PLTs as representations, decompositions, and approximations of practice. Representations, such as video or model lessons, refer to the ways MTEs make visible particular aspects of teaching. Decompositions refer to partitioning practice for in depth study, such as introducing a lesson or responding to students' thinking. Approximations of practice refer to opportunities for novices to engage in a particular practice, such as analyzing written work. Rehearsal is a particular kind of approximation of practice that supports novices by providing opportunities to learn about, practice, and reflect upon important aspects of practice while receiving in-the-moment feedback. Emerging research on the use of rehearsal has demonstrated its effectiveness in supporting teacher candidates in enacting particular instructional practices (Lampert et al., 2013;Tyminski, Zambak, Drake, & Land, 2014).

Building from this research, we design learning opportunities around boundary objects for instructional practices in our work in PD. We use a sequence of PLTs that begins with a representation of practice (e.g. experiencing a model lesson) followed by a decomposition of a particular aspect of that representation (e.g. debriefing the facilitation of a task). Next, we design a PLT that allows teachers to approximate the specific practice (e.g. rehearsing that practice with peers). One such PLT is a rehearsal. In our work, rehearsals have three interrelated components: teachers *rehearse* a particular instructional practice with their peers; receive in-the-moment *feedback* to support learning the practice; and *reflect* on their rehearsing and observations.

Methods

Our multi-case study investigates how teachers' participation in rehearsal relates to their classroom enactment of one student-centered instructional practice – launching cognitively demanding mathematics tasks. Case study research is useful for understanding a phenomenon bounded by a particular context and aims for its detailed description (Stake, 1995). To answer our research question, we first examined case teachers' participation in rehearsals and subsequent enactment in their classrooms. Next, we conducted a cross-case analysis to identify trends across case teachers rehearsals and enactments of launching cognitively demanding tasks.

Context and Participants

Our study is part of a multiyear PD and research project investigating secondary mathematics teachers' learning of student-centered instructional practices. The 108-hour PD was designed for a 10-month period, beginning with a 60-hour summer institute followed by 20 hours of face-to-face meetings and 28 hours of online work throughout the school year. In the summer institute, we shared several research-based frameworks for instructional practices that served as boundary objects through sequences of PLTs described above. As a part of the school year meetings, teachers were asked to plan and teach several student-centered lessons in their classrooms. This study focuses on teachers' learning the practice of launching cognitively demanding tasks.

Building from Jackson et al.'s (2013) four factors, we articulated a framework for the practice of launching cognitively demanding tasks. For us, the purpose of the practice is to ensure that students understand the mathematical goal of the task and can engage productively when the task is implemented without lowering its cognitive demands. The framework describes five instructional moves for launching: allowing think time (TT); checking for understanding (CU); addressing barriers for engagements (AB); sharing approaches (SA); and ensuring students can begin the task (BT). Allowing time for students to think about what the task is and what mathematical approaches they might take enables students to formulate a plan and identify additional information or questions they may have. Prompting students to share their interpretations of the problem ensures that students understand the task's mathematical goal. Addressing barriers provides an opportunity to resolve issues that may prevent students from engaging with the mathematics of the task during implementation, such as contextual questions, uncertainties about terminology, or mathematical skills not directly related to the goal of the task. Sharing approaches encourages multiple strategies and representations to be made public and allows students who may not have an approach to hear other's ideas. Ensuring that students can begin the task gauges whether enough students are confident about their approaches for the class to productively and collectively engage.

In the summer institute, each teacher completed one rehearsal to approximate launching. For each, three participants simulated "students" based on profile cards that outlined particular understandings, strategies, or barriers to engagement. One participant served as "teacher" and rehearsed launching the task. A MTE served as facilitator and provided in-the-moment feedback to the teacher while they rehearsed. Upon conclusion of each teacher's rehearsal, all participants reflected on what they learned by rehearsing and observing. During the school year, participants planned and taught student-centered lessons in their classrooms. These enactments served as a basis for continued reflection and discussion during the school year PD meetings.

Seventeen teachers from four suburban and rural school districts in the Southeastern United States volunteered and received a stipend for participation in the PD. Of the twelve teachers completing the PD, ten completed the activities used for this research, with eight teaching tasks of high cognitive demand. These eight teachers served as cases for this study.

Data Sources and Analysis

Data consisted of transcribed video recordings of the rehearsals and classroom enactments and written reflections following the rehearsals. We specified our unit of analysis as a teacher's talk turns in the transcripts and their written responses to reflection prompts. For the within-case analysis, we first coded each of these units in relation to the boundary object (TT, CU, BA, SA, and GS) to identify moves from the launching framework. Four researchers collaboratively coded the units for one of the eight case teachers, discussed discrepancies, clarified code definitions, and reached consensus. The remaining cases were double coded independently by members of the research team who then met and resolved discrepancies. This procedure allowed us to characterize each teacher's participation in the rehearsal in relation to classroom enactment.

For the cross-case analysis, we first used constant comparative methods (Strauss & Corbin, 1998) to identify noticeable trends relating teachers' participation in the rehearsal with their enactments. Next, we used a subset of the Instructional Quality Assessment (IQA) rubrics (Junker et al., 2006) related to Academic Rigor to determine the quality of the instructional task (AR1) and its implementation (AR2). After reaching agreement on three classroom videos with the IQA rubrics (IRR 88%), we used the IQA to rate the remaining lessons. To assess whether the cognitive demands of the task were maintained in the lessons, identical scores on AR1 and AR2 were taken to indicate that the cognitive demands of the task were maintained; a decreased in scores indicated a decline. Together, these two approaches allowed us to understand the relationships across teachers' participation in the rehearsal, their enactments in classrooms, and the maintenance of the cognitive demands upon task implementation.

Findings

Our cross-case analysis identified three trends in teachers' launches of cognitively demanding tasks. During rehearsal, teachers' launches varied in attention from addressing barriers to engagement to ensuring students' understanding. This variation corresponded to the degree to which their classroom launch attended to students' thinking and the degree to which the cognitive demands of the task were maintained. Instructional moves made in each teacher's rehearsal and enactment, and the maintenance of cognitive demands are summarized in Table 1.

Table 1. Instructional moves and related maintenance of cognitive demands.

	Rehearsal					Classroom Enactment					
Case	**TT**	**CU**	**AB**	**SA**	**BT**	**TT**	**CU**	**AB**	**SA**	**BT**	**Cog. Demand**
Eli		X	X	X	X	X	X	X	X	X	Declined

Amy			X			X	X	X	X	X	Maintained
Ann		X	X			X	X	X		X	Maintained

Removing Barriers

Cal, Eli, and Mia used a variety of the instructional moves from the launching framework during rehearsal. Though they demonstrated the ability to use the moves as a tool to support them in launching, their launches had a marked emphasis on addressing barriers of context and language. During rehearsal and feedback, teachers' focus on barriers prevented them from the ultimate goal of launching– ensuring student understanding so that students may begin the task productively. Similarly, their reflections centralized the importance of addressing barriers without attention to the overarching goal of launching. For example, Eli began his rehearsal with the question, "Are there any words you do not understand?" He continued to focus on seeking out contextual and language barriers throughout his rehearsal despite feedback that encouraged him to move forward. The facilitator attempted to redirect Eli to move beyond barriers by saying, "So let's assume that issue is resolved and move on from there." He persisted with moves to clarify context through the end of the rehearsal. In his reflection, Eli stated, "What do you do when the issues don't go away? Redirect them with another question?" His primary focus on removing barriers overshadowed the ultimate goal of ensuring understanding and allowing students to engage with the task.

In their classroom enactments, Cal, Eli, and Mia demonstrated most of the launching moves. They proactively sought to resolve ambiguous features they anticipated would prevent students from making progress on the task. Though they were successful in addressing contextual and language barriers, this preemptive approach directed students' attention toward the mathematics central to the task, endorsed particular strategies, or supplied particular mathematical tools that resulted in a clear path for students to take to solve the problem. Additionally, in all three of these cases, the cognitive demands of their task declined. For example, Cal's lesson was organized around a task about landing an airplane with a goal of using trigonometric ratios to solve problems. Prior to introducing the task to his students, he discussed the context of plane flight and drew students' attention to mathematical features important to the task.

C: So what do you think as a pilot flying a plane or making a landing – what kind of math is going through a pilots head or should he be thinking about?
S1: A lot. The angle that the plane has to – the angle that you have to have the plane at when you're landing it.
C: The boy mentioned angles. What have we been talking about for 7 days? [S: Angles] Great. What else?
S2: Triangles.
C: How does a triangle work when you're flying a plane? How would it relate to flying a plane? How would it relate to flying a plane?
S2: Cause you're using the degrees.
C: Okay. Degrees.
S3: How high it goes?
C: Alright. How high you're going.
S4: How fast you gotta be going.
C: Speed. Okay, what else?
S5: How far you have until you gotta be up in the air.
C: Okay. So we've heard angles, triangles, speed, height. Okay. When you get this, keep your pencils down. Take a few seconds to read over it. Read over this, see what questions you might have after you read it.

In his attempt to contextualize the task prior to introducing it, Cal's attention to barriers he anticipated included the mathematical ideas central to his learning goals. His launching moves directed students towards a specific approach without allowing them the opportunity to consider other possibilities. During implementation, his students used triangles and trigonometric ratios as discussed in the launch to solve the task. The lack of ambiguity along with teacher-endorsed mathematical strategies led to a clear path for students to solve the task.

Though the rehearsal provided opportunities for them to try most of the launching moves, there was a marked emphasis on addressing contextual and language barriers. In their classrooms, their launching practice removed the ambiguities of the task that they anticipated and supplied students with the key mathematical concepts needed for the task. We infer that their focused attention toward removing barriers to engagement and supporting students in accomplishing the task successfully related to the lowering the task's demands.

Emphasizing Understanding

Ema, Pat, and Tea also demonstrated many instructional moves from the launching framework during the rehearsal, but their participation differed in significant ways. Their rehearsals centralized the importance of ensuring students' understanding by integrating requests to re-voice the problem with responses to contextual or language difficulties that emerged. In their reflections, they noted the importance of students understanding the problem, addressing barriers, and making sure students could begin the task. For example in Ema's rehearsal, the first five questions she posed focused on ascertaining whether the "students" understood the problem. When a contextual barrier emerged from this questioning, Ema paused and the facilitator questioned her thinking. She responded, "in my head, I'm thinking I have to go back to what the problem is, but it was a good time to go ahead and get that [context barrier] out of the way." In her reflection, she noted the struggle of ensuring understanding while not overemphasizing aspects that were peripheral to the mathematical goal of the task in a timely manner.

In their classroom enactments, Ema, Pat, and Tea used all of the launching moves. Their emphasis on ensuring student understanding in the rehearsal led to moves that elicited and responded to their students' thinking about the task as it arose in the launch discussion. They worked to refine students' understanding of the task through questions like, "in your own words, what is the problem asking us to do?", clarifying terminology and contextual information, sharing different ideas about how to approach the task, and checking to make sure that students felt confident to begin working on the task. As an example, Pat began her lesson by allowing students time to think and discuss the problem. While listening to this discussion, she noted different students' questions and then strategically introduced them to the whole class.

P: Okay, I was asked a couple of good questions so I want to make sure that everybody hears the answers to them. Roman, will you ask your question first?
S1: Do you have to find out how much, how many toothpicks it takes to build all of the figures combined or just 1 individual?
P: Okay, do you all understand what Roman's question is?
S2: Yea, like the 8th or all of the 8 together.
P: So he is asking, are you trying to find the number of toothpicks in general for just the 8th or the 8th, the 7th, the 6th… the 2nd, and the 1st all together. Which one do you think that we're trying to find?
Ss: [multiple responses aloud] "The 8th," "all of them", etc.
P: Just the 8th? [multiple responses aloud, "No," "Yea"] So from the… let's come to a consensus of what we think overall. I've heard a lot of people say just the 8th. Which one do you think would make more sense? When you're normally trying, would you be finding, if you're trying to find your square, do you really care about all of the squares that came before it? [Students "no!"] Or just the specific square?
S3: Just the specific square.
P: Just the specific square. So let's go with the assumption that we're only trying to find that specific square. Ok Zack, what was your question?

Pat's launch continued by introducing other questions for whole class discussion, addressing contextual barriers as they arose, and ensuring that one member from each small group was confident to begin. Her integrated use of the launching moves suggests her attention to ensuring students understood the problem so that they could productively engage with the task.

The rehearsal provided opportunities to use the launching moves with a goal of ensuring understanding. In their classroom enactments, they addressed context and language barriers as they arose in discussion, had students share a variety of strategies for approaching the task, and verified that students could engage with the task. We infer that their attention toward ensuring students could engage with the mathematics of the task by eliciting and responding to students' ideas supported the maintenance of the cognitive demands of the task.

Removing Barriers to Emphasizing Understanding

Amy and Ann did not demonstrate many of launching moves during the rehearsal. Similar to Cal, Eli, and Mia, they focused almost exclusively on addressing barriers of context and language. Yet in their reflections, both noted the importance of not leading students through a launch and to leave the essential mathematical question open for students to resolve. In Ann's self-reflection, she stated that she learned, "how difficult it is to not directly lead the student to the solution." Similarly, Amy's reflection emphasized the difficulty of addressing "student misconceptions without leading their thinking too far into the task."

In their classroom enactments, Amy and Ann used most of launching moves to both respond to students' thinking as well as highlight anticipated barriers related to context and language. They provided time for students to think about the problem, probed to ensure students' understanding, and verified that all students could begin the task. Amy prompted students to publically share the approach they were going to use for the task.

For Amy and Ann, their attention when launching shifted from addressing barriers in rehearsal to emphasizing students' understanding in enactment. The rehearsal provided opportunities to reflect on the importance of listening and responding to students rather than leading to a particular approach. Their rehearsal was similar to Cal, Eli, and Mia – both teachers responded to students' thinking as well as highlighted anticipated barriers related to context and language. However, their enactments were more like Ema, Pat, and Tea. Their launches allowed students to engage with the mathematics of the task and maintained its cognitive demands.

Discussion

Our findings describe three ways secondary mathematics teachers participated in rehearsal of launching cognitively demanding tasks, enacting the practice in their classrooms, and whether the practice maintained the cognitive demands of the task. For teachers focused on removing barriers during their launches, their participation in the rehearsal related to instructional moves that lowered the cognitive demands in their lessons. For others focused on ensuring students' understanding, their participation led to a use of the framework in ways that maintained the demand. For Amy and Ann, participation in the rehearsal sensitized them to the importance of attending to students' thinking and led to launches that maintained task demands.

Our findings suggest that rehearsals are a viable pedagogy for MTEs to address the "problem of enactment." Opportunities for teachers to rehearse, receive feedback, and reflect on instructional practice may assist them in enacting the practice with students. Our results underscore the importance of clearly communicating both the moves and the purpose of a particular instructional strategy in PD. We urge PD designers and facilitators using rehearsals to carefully consider how they communicate the purpose of an instructional practice and align feedback and reflection opportunities with this purpose.

PRE-SERVICE TEACHERS' UNDERSTANDING OF FRACTION OPERATIONS: PROVIDING JUSTIFICATION FOR COMMON ALGORITHMS

Ashley N. Whitehead
North Carolina State University
anwhiteh@ncsu.edu

Temple A. Walkowiak
North Carolina State University
tawalkow@ncsu.edu

This study examined pre-service elementary teachers' change in their understanding of fraction operations while taking a mathematics methods course. Specifically, their explanations and justifications for common algorithms for multiplication and division of fractions were coded using an existing framework (SOLO; Biggs, 1999) for the assessment of understanding. Results indicated that most students made improvement in terms of their level of understanding around fraction algorithms. Implications for mathematics teacher educators are discussed.

Keywords: Elementary School Education; Teacher Education-Preservice; Mathematical Knowledge for Teaching; Reasoning and Proof

Currently, the amount of conceptual understanding pre-service elementary teachers hold around common algorithms is weak (Ball & Bass, 2002; Simon, 1993); however, a push for conceptual understanding is being deemed necessary for all students (CCSSO, 2010; NCTM, 2000; Stylianides, Stylianides, & Philippou, 2007). This means that pre-service elementary teachers need to hold a deeper understanding of common algorithms if their own elementary students are expected to understand the meaning behind each algorithm (Ball & Bass, 2002; Ball, Thames, & Phelps, 2008). Although previous studies have focused on elementary teachers' conceptual understandings (Simon & Blume, 1996; Yackel & Cobb, 1996) more work is needed around fraction algorithm understanding and how teachers justify those algorithms for their students. The current study aims to begin to fill that void.

The purpose of the study was to examine how pre-service elementary teachers provide explanation and justification for algorithms around fraction operations. Specifically, the two research questions were: (1) What are pre-service elementary teachers' levels of understanding of algorithms for the multiplication and division of fractions *before* and *after* experiencing instruction focused on fractions in a mathematics methods course?; and (2) How do pre-service elementary teachers *change* in their level of understanding of the algorithms?

Theoretical Framework and Related Literature

This study draws on the work of Skemp (1976) who defined the ideas of relational versus instrumental understanding. According to Skemp (1976), relational understanding is equivalent to conceptual understanding such that it is knowing *why* something happens, whereas instrumental understanding is similar to procedural understanding such that it is taking a rule and using it without understanding. In the past twenty years, there has been much attention to developing relational understanding in pre-service teachers (e.g., Ball, 1990; Ball & Bass, 2002; Simon, 1993;). Researchers have noted the specialized content knowledge that is specific to the work of teaching (Ball, Thames, & Phelps, 2008) and have emphasized that in order for teachers to be able to answer students' questions of "why," they must have a more robust relational understanding than that of their students.

One such study, performed by Eisenhart et al. (1993), followed Ms. Daniels, a student teacher who tried explaining the "invert and multiply" rule to a student in her class and abandoned the explanation midway through when she realized the example she was using pertained to multiplication, not division. Another study, performed by Ball (1990), gave the example of Allen, an elementary education major who also struggled with the "invert and multiply" rule for division of fractions and could not generate an example that did not reference multiplication. Much of the challenge for our work as mathematics teacher educators is to prepare pre-service teachers to answer these types of questions effectively and not give the reasoning "because it's the rule". To do so requires the development of a deep conceptual understanding of the mathematics for pre-service teachers.

To measure understanding in mathematics, researchers have typically used open-ended assessments and interviews that then must be analyzed. One analysis tool, and the tool used in this study, is the Structure of the Observed Learning Outcome Taxonomy (SOLO; Biggs, 1999) as displayed in Figure 1. The nature of the SOLO Taxonomy is one such that student learning is examined as they move from a lower level of understanding to a higher, more abstract, level of understanding. As students progress through the levels, they retain the traits from the previous level; in other words, each level builds on the previous. According to a study performed by Ball (1990), pre-service teachers' mathematical understandings typically are found to be at the Unistructural level where they are simply reciting algorithms in their explanations to students.

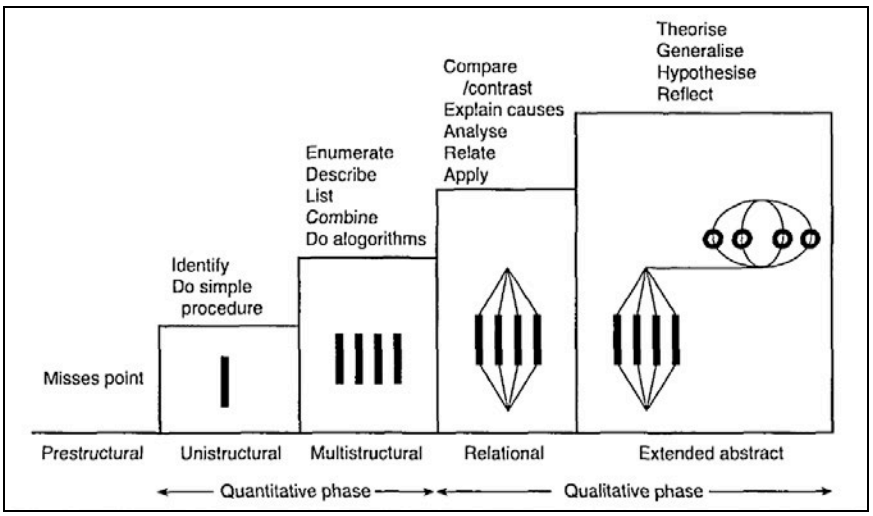

Figure 1: SOLO Taxonomy(Biggs, 1999, p. 67)

With the continued emphasis on conceptual understanding in documents such as the National Research Council's *Adding it Up* (2001) and in the Common Core State Standards for Mathematics (2010), there is a need to better understand pre-service teachers' conceptual understanding so we can better prepare them for their future work. Furthermore, historically, fractions have been difficult for both children and adults in the United States (Lamon, 2005). This speaks to the need for further research focused on fraction operations and namely pre-service teachers' understanding of them, as is in the case in the current study.

Methods

Participants

The participants in this study were forty-eight juniors in an elementary education program who were enrolled in a mathematics methods course, the second in a two-course sequence and focused on multiplicative reasoning in grades 3-5. Data was collected from two sections of this course, which were taught by a total of four instructors, two teaching one section and the other two teaching the other section. All lessons were created as collaboration between the four instructors; therefore, all students experienced the same tasks and activities during the class sessions. Of the students enrolled in the methods course, 96% had taken one or two Calculus courses, either in high school or at the college level, or they had taken *Calculus for Elementary Teachers,* which focuses on a conceptual understanding of Calculus-related topics. The mathematical background of these students is important to note because the focus of this paper is on the pre-service teachers' conceptual understanding and level of justification they can provide to students. One can see from the level of mathematics achieved by these students that they have experienced the content they will be expected to teach; however, they may or may not be able to explain the ideas conceptually.

Intervention

After the pre-service teachers completed the pre-assessment, they participated in a five-week unit of instruction during which they learned about algorithms for fraction operations and also had opportunities to examine student work. Examples of tasks completed during the instruction period are shown in Figures 2 and 3.

Misconceptions with Fraction Multiplication

1. Maisy draws a picture like the one shown to depict3 $\cdot \frac{4}{5}$. Maisy concludes from her picture that

$$3 \cdot \frac{4}{5} = \frac{12}{15}$$

Because 12 pieces out of 15 are shaded. Is Maisy right? If not, where is her reasoning flawed?

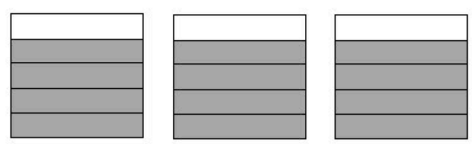

Figure 2: Misconceptions with Fraction Multiplication. Adapted from Sybilla Beckman "Mathematics for Elementary Teachers" fourth edition.

Popcorn Problem #1 **Name** ______________________________

At the Carolina Popcorn Shoppe, the managers direct their employees as to how much popcorn constitutes a serving when a customer orders one. There are currently 6 cups of cheese popcorn at the serving counter. How many servings can be made if the customer is given:

a. ½ cup of cheese popcorn?

b. ¼ cup of cheese popcorn?

c. 1/6 cup of cheese popcorn?

d. 1/3 cup of cheese popcorn?

e. 2/3 cup of cheese popcorn?

f. 3/4 cup of cheese popcorn?

g. 5/6 cup of cheese popcorn?

Solve this problem using pictures or another tool.

Can you write a mathematical equation to represent your model?

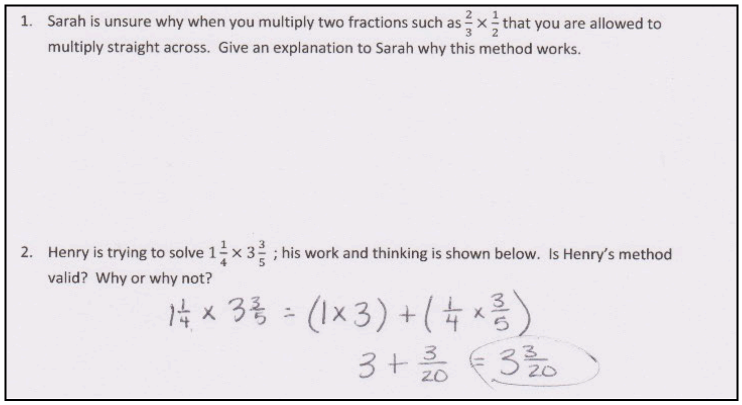
Describe the pattern that you notice, if any, across the sub-questions a-g.

Figure 3: Building Towards the Fraction Division Algorithm.

The activities were selected to build pre-service teachers' conceptual knowledge of fraction-based algorithms as well as their ability to recognize common student errors relating to fraction multiplication and division. Class readings were also given to help further pre-service teachers' understanding related to the given topics.

Measure

Before and after the instructional sequence, participants were asked to complete an assessment (see Figures 4 and 5) related to algorithms for fraction multiplication and division. Prior to instruction, the participants had not worked with multiplication and division of fractions in either of their methods courses.

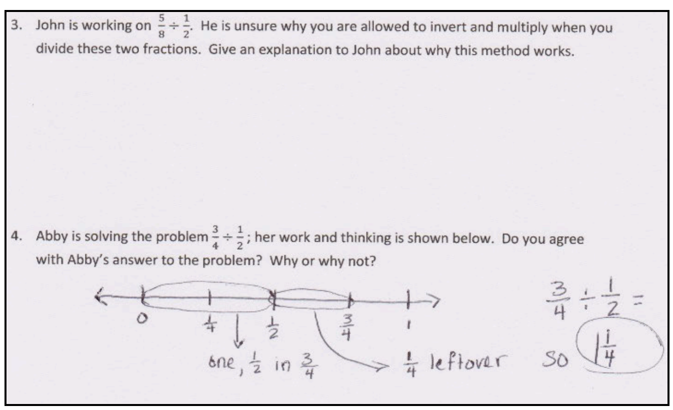


1. Sarah is unsure why when you multiply two fractions such as $\frac{2}{3} \times \frac{1}{2}$ that you are allowed to multiply straight across. Give an explanation to Sarah why this method works.

2. Henry is trying to solve $1\frac{1}{4} \times 3\frac{3}{5}$; his work and thinking is shown below. Is Henry's method valid? Why or why not?

$$1\tfrac{1}{4} \times 3\tfrac{3}{5} = (1 \times 3) + \left(\tfrac{1}{4} \times \tfrac{3}{5}\right)$$
$$3 + \tfrac{3}{20} = 3\tfrac{3}{20}$$

Figure 4: Questions 1 & 2 from Pre/Post Assessment regarding fraction multiplication.



3. John is working on $\frac{5}{8} \div \frac{1}{2}$. He is unsure why you are allowed to invert and multiply when you divide these two fractions. Give an explanation to John about why this method works.

4. Abby is solving the problem $\frac{3}{4} \div \frac{1}{2}$; her work and thinking is shown below. Do you agree with Abby's answer to the problem? Why or why not?

Figure 5: Questions 3 & 4 from Pre/Post Assessment regarding fraction division.

Analysis

Answers were coded according to the levels of the SOLO taxonomy with numbers from 0 to 4 assigned to each of the levels, with Preoperational being a 0 and Extended Abstract being a 4. Two independent raters coded 25% of the pre- and post-assessments in order to check for inter-rater consistency. 98% of the two raters' codes were either exact matches or within one scale point of each other (with 76% exact match agreement). Table 1 provides an example for each level in the SOLO taxonomy as well as a justification for the assigned code.

Beyond the example in Table 1, we now provide a general overview of the coding scheme. Responses coded as the Prestructural level meant the pre-service teacher misinterpreted the question or did not provide an answer. The Unistructural level meant the pre-service teacher did not explain, but instead recited the algorithm to the student as a means of justification. In terms of examining student work, they identified something was wrong, but could not pinpoint exactly where the mistake was occurring. The Multistructural level meant the pre-service teacher recited the algorithm, but gave a further justification for the specific example; however, the justification was not complete or was

Table 1: Examples of Student Responses for each Level.

SOLO Taxonomy Level	Example of Student Response	Justification for SOLO Level
Preoperational (0)		Incorrectly answered the problem.
Unistructural (1)		Recited the rule of turning the mixed numbers into improper fractions.
Multistructural (2)		Recited the rule, but began to display signs of conceptual understanding in the reasoning of estimating the answer.
Relational (3)		Understood the numbers were not fully decomposed and wanted to teach Henry how to view the problem in terms of an area (array) model.
Extended Abstract (4)	N/A – an example might include generalizing the problem to that which includes variables instead of numbers.	No examples of student work provided.

incorrect. In terms of examining student work, the pre-service teacher described what had been done and identified the student's mistake. Within the Relational level, the pre-service teacher provided an explanation in which the idea was fully explained conceptually in terms of the specific example. In regards to examining student work, they correctly identified the problem and explained what it meant in terms of the particular example. Finally, the highest level of justification was the Extended

Abstract in which the pre-service teacher gave a generalized proof in terms of variables, and explained the student's method in terms of a generalized approach.

Results

For question #1 on the assessment, the average score was a 0.50 on the pre-assessment and a .96 on the post-assessment (change of 0.46) on a scale of 0-4. Question #2, resulted in a 0.63 for the pre-assessment and a 1.15 for the post-assessment (change of 0.52) on a scale of 0-4. Question #3 resulted in a 0.40 for the pre-assessment and a 0.77 for the post-assessment (change of 0.37) on a scale of 0-4. Question #4 resulted in a 0.71 for the pre-assessment and a 1.46 for the post-assessment (change of 0.75) on a scale of 0-4. A total score for the entire pre-assessment was .56 and a 1.08 for the post-assessment. A paired t-test was performed for each question with 95% confidence, and all questions showed statistically significant improvement from pre to post assessment (all p-values < .05). A breakdown of the count of students for each level and question for the pre and post assessment is shown in Table 2:

Table 2: Count of Students in each Level and Question.

SOLO Taxonomy Level	**Question #1**		**Question #2**		**Question #3**		**Question #4**	
	Pre	**Post**	**Pre**	**Post**	**Pre**	**Post**	**Pre**	**Post**
Preoperational (0)	34	20	19	13	30	28	25	19
Unistructural (1)	7	13	28	19	17	9	17	7
Multistructural (2)	4	12	1	12	1	5	1	3
Relational (3)	3	3	0	4	0	6	5	19
Extended Abstract (4)	0	0	0	0	0	0	0	0

As one can see from Table 2, no student was classified as Extended Abstract. This may have been because the course did not focus on formal proof and the questions were worded in such a way that they did not suggest giving a formal proof. Before instruction, students typically fell between Preoperational and Unistructural. In other words, pre-service teachers either did not know how to explain the problem to the student or they just simply recited the algorithm. After instruction, most students were between Unistructural and Multistructural; therefore, many students were still reciting an algorithm, but several were also making sense of the algorithm conceptually. The most improvement occurred on question #4 regarding Abby's invented solution to dividing fractions. Many students on the post-assessment recognized the answer of $1\frac{1}{4}$ was not correct because the leftover $\frac{1}{4}$ piece referred to a whole of 1 and not a whole of $\frac{1}{2}$. Therefore, the leftover $\frac{1}{4}$ piece was actually $\frac{1}{2}$ of the whole of $\frac{1}{2}$.

Discussion

In terms of the course, the students were not asked to work formal proofs, but instead use an example to explain a rule in mathematics; therefore, it was expected that no student would fall in the extended abstract category. Second, the questions were given to the student in terms of a particular example and they were asked to explain to the student why the algorithm worked. There might have been students who fell into the Extended Abstract category if the questions were reworded more generally, such as: "explain why the algorithm for multiplying fractions works".

Additionally, the results found from the study hold true with the study performed by Ball (1990), such that prospective teachers' "notions of mathematical explanation seemed to mean restating rules" (p. 138). Although there was a positive increase in levels, work needs to be done to better develop pre-service teachers' conceptual understanding. Finally, some of the increase in scores may have been attributed to fraction division being discussed during the same day of the post-assessment due to time restraints in the course. If the study were performed again, a period of time should be given between the instruction and the post-assessment to check for continued understanding beyond the day of instruction. .

Elementary teachers need to have a deep understanding of the material in order to "handle certain mathematical issues that may arise in the classroom and recognize rudimentary versions of mathematical [proof] in their students' arguments" (Stylianides et al., 2007, p. 148). By strengthening pre-service teachers' conceptual knowledge of mathematics and helping them form solid justifications as to why procedures work, the difficulties secondary students face when they are abruptly introduced to proof in the upper grades may be diminished (Stylianides, 2007). Therefore, in order to improve our education system, we need to improve teachers' knowledge of mathematical content as well as their overall concept of justification (Ball & Bass, 2002; Toluk-Uçar, 2009). The ways in which this can be achieved were highlighted throughout this paper such as: providing more courses in explanation and justification, spending more time on difficult topics, explaining in detail why algorithms work, and providing examples of teachers who teach conceptually through videos or classroom observations. Additionally, more courses involving various elementary mathematics topics are needed to improve pre-service teachers' conceptual understanding.

This paper only touched upon instruction given to students for a fraction-related unit. More research needs to be done to see how students provide justification for other mathematical algorithms, not just for fractions. Also, further research is needed to investigate whether higher-level mathematics courses are a factor in pre-service teachers' ability to justify solutions to students or if there are other factors involved. Finally, interviews of students who performed at the Relational level would be beneficial to see if those students could move into the Extended Abstract level with more time and guidance. Overall, instruction in this study was successful in helping to improve students' scores between levels of the SOLO taxonomy. Therefore, instruction seems to be one stepping stone in helping pre-service teachers in their endeavor to become proficient in explanation and justification.

In this mixed methods study, we use positioning theory to analyze teachers' professional discussions about students' mathematical work over the course of 60 hours of professional development focusing on a learning trajectory. After identifying a category of speech actions that suggested student learning is limited by their age or grade level, a quantitative investigation revealed that teachers' discussions grew to include elements of the learning trajectory over time. A subsequent qualitative analysis revealed changes in the structure of these discussions, where teachers came to recognize and use students' prior experiences in instruction, and student learning was more influenced by prior experiences than their age or grade level.

Keywords: Learning Trajectories (or Progressions); Teacher Education-Inservice (Professional Development)

Introduction

Teachers' professional conversations about students often focus on what students cannot do (Franke & Kazemi, 2004) and take evaluative perspectives (Visnovska, Zhao, & Cobb, 2006). Such a focus may lead to limited expectations of students (Rosenthal & Jacob, 1968). In this mixed methods study, we examine teachers' discourse in a professional development setting to consider the ways their learning of a framework for students' mathematical thinking can foster changes in their discourse. We use positioning theory (van Langenhove & Harré, 1999) to frame an analysis of 60 hours of professional development discussions among 22 elementary teachers and examine how certain discourse patterns related to students' ages or grade levels changed during the yearlong professional development. Specifically, our research answers the question: *In what ways does teacher learning of a mathematics learning trajectory relate to changes In their discursive patterns about students as mathematics learners ,and themselves as mathematics teachers, I na professional development setting?*

Background and Theoretical Framework

Professional development (PD) based on students' thinking results in changes in teachers' discourse (Horn, 2007; Kazemi& Franke, 2004). As teachers learn details of students' mathematical strategies, their discussions shift from a focus on students' struggles to more nuanced discussions that attend to students' strategies and levels of sophistication in students' mathematical thinking (Kazemi& Franke, 2004). Teachers' use of more refined language to describe the complexities of student mathematics supports teachers in incorporating student thinking into their model of practice (Horn, 2007). Some researchers have explicitly used student thinking to structure the discourse in a professional development program. For example, Battey and Chan (2010) worked to counteract metanarratives about race and mathematics learning by drawing teachers' attention to student thinking and what students can do—as opposed to what they cannot do. A focus on student thinking led to changes in teachers' discourse about students as they began to base their claims about students in evidence of students as mathematical thinkers instead of assumptions formed by other characteristics.

van Langenhove and Harré (1999) proposed positioning theory as an approach to understanding how psychological phenomena are constructed through social interactions in conversations. In contrast to the “roles” people take in interaction which may be static and limiting, positions in conversations are dynamic, negotiated in the moment, and may be accepted or contested. They argue that conversations can be understood through an examination of three mutually constitutive constructs called positioning-triads: the intention of a speech action (speech acts), positions, and storylines. Whereas speech actions are the actual words that one says, speech acts are the meanings intended by the speaker and are taken up in conversation. Speech acts in conversations tend to follow particular patterns called storylines, which refer to narratives that exist within a culture. Storylines provide a socially constructed image which participants in the conversation use to interpret each other’s actions and positions. Speech acts relative to a particular storyline lead to positions, or the ways these speech acts may be heard by other participants. Positioning can be interactive, where speech acts along with a particular storyline frame another person as competent/incompetent, powerful/powerless, etc., or reflexive, where a speech act frames one’s self in a particular away, such as unknowledgeable, skilled, agentic, etc. Together, speech acts, storylines, and positions describe a structure of conversations and provide a way to understand shared meaning in social interactions.

Researchers in mathematics education have used positioning theory in a variety of ways, including studies of student interactions (e.g., Langer-Osuna, 2011) and classroom interactions (Herbel-Eisenmann and Wagner, 2010). Suh, Musselman, Herbel-Eisenmann, and Steel (2013) used positioning and storylines to study nine teachers’ talk in PD and revealed how teachers’ speech acts positioned students and themselves in relation to teaching and learning. They identified two particular storylines present in the PD discussions related to “low students.” First, teachers’ discussions followed an “institutional tracking” storyline, where students in less advanced mathematics tracks were unlikely to move to take advanced courses. Second, discussions followed an “individual maturation” storyline, where students’ lack of maturity prevented them from being successful in mathematics. In both storylines, students were positioned with characteristics that were beyond the teachers’ control, thus limiting teachers’ self-positioning as agents of change. They report that when teachers were introduced to a new storyline, they positioned students differently and themselves with more agency.

Suh et al.’s (2013) work both demonstrates the utility of positioning theory to examine teacher discourse in PD as well as the possibility of changing discursive patterns about students through the introduction of new storylines. Our research aimed to understand the degree to which teacher learning about a learning trajectory (LT) affected the discursive patterns in PD. Specifically, we focused on speech actions, speech acts, storylines, and positions in teachers’ discussions about students’ mathematical work to understand the ways their learning of a LT affected their conceptualizations of students as learners and themselves as teachers.

Methods

Our study used an exploratory sequential mixed methods design to investigate the changes in teachers’ discursive patterns about students as mathematics learners (Teddlie & Tashakkori, 2009). We followed a two-phase approach. First, we investigated whether teachers’ learning of the LT affected their discussions of students’ mathematical thinking through a quantitative analysis of their speech actions. Next, we investigated qualitatively teachers’ discussions by examining changes in the speech acts, positioning, and storylines over time to understand the ways teachers’ discourse patterns incorporated the LT.

Context

Our study is a part of the Learning Trajectory Based Instruction (LTBI) project, a multiyear PD and research project that investigated teacher learning of students' mathematics LTs and an instructional model where LTs provide guidance for teachers' instructional decisions (Sztajn et al., 2012).LTs are mappings based on empirical research and represent the ways student thinking within a specific mathematical domain evolves over time (Daro, Corcoran, & Mosher, 2011). They outline the partial understandings, common alternative conceptions, and expected tendencies of how learning proceeds in relation to particular forms of instruction (Confrey 2009).

In the first implementation of the PD, we shared Confrey's (2012) equipartitioning LT with teachers and sought to understand how their learning of the LT affected the ways they conceptualized students as mathematics learners and themselves as mathematics teachers. The equipartitioning LT describes how students' informal understandings of fair sharing might evolve to an understanding of partitive division, including students' strategies and common errors related to fairly sharing collections, wholes, and multiple wholes to produce equal-sized groups or parts. The 60-hour PD was designed for a 12-month period, beginning with a 30-hour summer institute during which participants engaged in professional learning tasks (PLTs) that included video analysis of students' working through mathematical tasks, videos of classroom instruction, and analysis of students' written work. Throughout the year, teachers and researchers met monthly after school to discuss the implementation of instructional tasks with their students and refine their understanding of the LT. The PD ended with a two-day follow-up summer meeting.

The research team partnered with one elementary school in a mid-sized suburban school district in the Southeastern United States. The school had approximately 600 students, 35% Caucasian, 29% Hispanic, 25% African American, 7% Asian, and 4% other; 54% of the children qualified for free or reduced lunch. Twenty-two K-5 teachers completed the project at years end.

Data Collection and Analysis

Data sources included video and audio recordings of teachers' discussions while engaging in 21 selected PLTs that focused teachers on students' mathematical thinking. During the summer, teachers engaged with various practice-based artifacts to learn about students' thinking of equipartitioning. During the school year meetings, teachers discussed various classroom-based activities aimed at eliciting and understanding their own students' thinking. Recordings for these 21 PLTs, totaling 41 video and 55 audio files, were transcribed.

During the PD, patterns in teachers' discussions about students' mathematical work began to emerge, often attributing students' lack of success to their grade level or age. Statements such as, "we don't do that in third grade" or "he is low," revealed some of the narratives about students as learners that were accepted and used in the group. We conceptualized these statements as categories of speech actions related to storylines that were used to position students as mathematics learners and themselves as mathematics teachers. Upon completion of the PD, we developed a codebook to identify these speech actions based on the field notes collected during implementation (Wilson, Edgington, Sztajn, & Decuir-Gunby, 2014). Four codes defined the categories and described teachers' speech actions as suggesting student learning is dependent upon their: Ability/Achievement; Age/Grade; Effort; and Luck. In this paper, we focus exclusively on speech actions related to Age/Grade.

Phase one. For the quantitative analysis, we specified the unit of analysis as a speech action. Four independent coders first identified speech actions related to Age/Grade (85% inter-rater reliability). To understand if learning the LT resulted in changes in their speech actions, the research team revisited the coded units for evidence from the LT. Evidence was taken to be both explicit use of LT terminology (e.g., direct reference to the LT structure, specific student strategies described within the levels) as well as implicit where teachers used less formal language to describe ideas from the LT. In both cases, these units were assigned an additional code of LT, resulting in three variables: Age/Grade with LT, Age/Grade without LT, and total Age/Grade. Next, we organized the total speech actions within each of the 21 PLTs chronologically (see Table 1). We hypothesized that as the PD progressed, teachers' speech actions would increasingly include references to the LT and thus subjected each variable with its associated time to Spearman rank-ordered correlation tests of significance.

Phase two. To understand the ways and the extent to which teacher learning of the LT resulted in changes in speech acts, positioning, and storylines in the PD, we identified episodes in teachers discussions, that is segments of discussion around one idea that begins when a speech action is made and taken up by other participants in the discussion (Harré & van Langenhove's, 1999). We then used a constant comparative method (Strauss & Corbin, 1998) to discern themes across all episodes, meeting regularly to discuss emerging patterns, deviations from those patterns, and reconcile them with the data. We considered the resulting themes as storylines teachers used to conceptualize students as mathematics learners and themselves as mathematics teachers. Next, we applied the positioning-triad as an analytic tool to the episodes to understand the ways, and extent to which, teacher learning of the LT resulted in changes in the storyline and positions across the PD. For each PLT, two members of the research team summarized the speech acts, teachers' positioning of themselves and students, and variations in the storyline for all episodes occurring during the PLT. The entire research team then looked across the summaries to mark shifts in teachers' discussions as the PD proceeded and understand the ways the LT affected teachers' discursive patterns.

Findings

Results from the two phases of analysis indicate that teacher learning of a LT affected the discursive patterns about students as mathematics learners in a PD setting. First, we show how the speech actions related to Age/Grade changed quantitatively over time. We then qualitatively examine how the speech acts, storylines, and positions changed.

Phase one analyses indicated that teachers' speech actions related to Age/Grade remained present throughout the PD ($n = 143$; $\rho = -0.052$; $p = 0.411$). Further, speech actions related to Age/Grade that also used the LT significantly increased over time ($n = 40$; $\rho = 0.352$; $p = 0.059$). For the subset coded no LT, no significant decrease was found ($n = 103$; $\rho = -0.079$; $p = 0.367$). These findings confirm our hypothesis that, as the PD unfolded, teachers learned about the LT and came to use LT-language in Age/Grade discussions of students as mathematics learners. These analyses show that teachers' speech actions changed, yet they do not characterize the changes in positions or storylines used to conceptualize students as mathematics learners.

Phase two analyses focused on the episodes related to Age/Grade in order to examine positioning and storylines. As seen in Table 1, a total of 46 episodes related to Age/Grade occurred in the focus PLTs. Table 2 summarizes the speech acts, storylines, and positions across these episodes. Whereas the initial storyline of the discussions indicated that age and grade level are key influences of student learning, the storyline changed such that students' prior experiences influenced learning. Though teachers' speech actions still referred to age and grade, these actions were intended more as descriptions of the student. Teachers began the PD by positioning themselves as one who had experiences with students and expertise to make sense of students' mathematics but had no instructional recourse if a student did not meet their age or grade level expectations, because students' capacities to learn were limited. Over time, teachers began to note that students had experiences, beyond their age or grade level, that they may bring to instruction, and began to indicate that they could include these experiences in their instructional decisions. Eventually, teachers positioned students as having resources that support their mathematics learning and could tailor their instruction to make use of these resources. In what follows, we provide two episodes to illustrate these shifts.

Table 1. Number of Age / Grade speech acts and episodes by Time and PLT.

Table 2. Number of Age/Grade episodes & related speech acts, storylines, and positions.

PLT	N	Speech Act Examples	Storyline	Teacher Positioning	Student Positioning
1-3	13	"I would have expected that from the third grader"	Learning is limited by a student's age or their grade level	Teachers have expertise in understanding students and have expectations based on age / grade level	Students' age or grade level are expected to be successful at certain mathematics
5-12	17	"That radial cut has not appeared yet…kids have the idea from [their] experience that it's supposed to look like a triangle"	Learning is influenced by age or grade level and prior experiences	Teachers have expertise and expectations but recognize the role of prior experiences	Students have prior experiences beyond their age or grade level that influence learning
13-21	16	"We think that because kids are older, they've had experiences, but that's not necessarily true"	Learning is influenced prior experiences	Teachers can use students' prior experiences to support learning	Students' prior experiences are resources that support their learning

As an example of initial positioning during the summer institute (PLTs 1–3), the following example occurred during the first task (PLT 1). Teachers viewed two clinical interviews of two students completing a series of equipartitiong tasks where they were sharing 24 coins among four and three people (Wilson, Edgington, & Confrey, 2010). The following episode was part of a group discussion about what they described as surprising about the students' work:

G1: Well, the kindergartner did what I thought starting back over with a pile in order to move from four to three. I thought that. But she surprised me with what she did after that.
A1: Well, the most surprising thing was that she seemed to know quickly that it was eight. And I was trying to decide if that was just a guess or if it was an intuitive understanding because she did seem to even recognize that if you took the six coins that the fourth person had, you could distribute those three ways and have eight. She almost seemed to know that intuitively –[D5 agreeing] – which I would never have expected.
D5: No. Me neither.
A1: I would have expected that from the third grader and yet I felt dismayed that formalized classroom mathematics education had stifled her, so that she [G1, D5 agreeing] didn't see it at all that way and immediately suggested that you couldn't do it because three was an odd number.
G1: Right - and there would be some leftover.
A1: You know? Certainly the five year old wasn't encumbered by that. [D5 agreeing] She probably -- she might know odd from even, but that wasn't part of the discussion.
G1: Yeah, that –
A1: was a real stumbling block for the third grader, I thought.

As teachers explained students' mathematical approaches in this discussion, they used the grade levels or age of the students to support their expectations and understanding of what the student did. Speech acts, such as "The kindergartener did what I thought…but surprised me when", "which I never would have expected…I would have expected that from the third grader", and "the five year old wasn't encumbered," positioned themselves as competent in inferring students' mathematical understanding based on their expectations of students at a particular grade level or age. Simultaneously, students were positioned according to these expectations in comparison to students of other age or grade levels, resulting in teachers' surprise. Taken together, the teachers' speech acts and positions follow a storyline that students' mathematical understandings are defined by their age or grade level.

As the PD progressed through the fall (PLTs 5-12), PLTs were based on students' written work and videos of whole classroom instruction. Although teachers' speech acts still referred to students' ages or grade levels, they began to include terminology and ideas from the LT to describe student thinking in more detail. For example, in an episode where teachers were examining a set of student work, one teacher commented, "Developmentally, that radial cut has not appeared yet…kids have the idea from [their] experience that it's supposed to look like a triangle. But when they're dividing, we only had one that actually tried to use those radial cuts." The teacher attributed students' lack of success on the task to their age (development), but also recognized that students' experiences influence their thinking. In such episodes, teachers continued to position themselves as competent in understanding students' thinking but began to expand their explanations beyond age or grade level to include other students' experiences. In turn, students were positioned as having experiences that may support them in learning. These nine episodes followed a storyline that shifted from learning being limited by age and grade to include opportunities to learn and prior experiences also influencing student learning.

By January (PLT 13),a stable positioning-triad emerged in the episodes related to Age/Grade and persisted for the duration of the PD. At this point, speech acts incorporated ideas from the LT and referred to age and grade level not as a limiting factor for learning, but as a descriptor. These 16 episodes followed a storyline where students' prior experiences affected learning, teachers positioned themselves as able to use those experiences as resources for instruction, and students were positioned as bringing resources to instruction. To illustrate, the following example episode from the summer follow-up in June occurred as teachers revisited the two clinical interviews from the example above.

A4: If we believe learning is along this trajectory and it's this path way and they need to have these things earlier on before they can get to these things, then it does seem that age is less relevant. Yes, they have more experiences so hopefully they're getting there.

D4: Yeah, isn't it both? Because they don't necessarily have to have- it's not really linear. I mean, they can jump certain things, you know, levels.

[one speech act omitted from the episode]

D3: I liked what D4 was saying about like with age, we often link that to experiences, that because they're older, they've had more experiences. And so I think a lot of what we do is that we do learn from our experiences and we often make the assumption that because kids are older, they have consistently had experiences and they've learned through that. But I don't think that's necessarily true when you look at home backgrounds that kids come from or look at being in a different classroom or a different school, different things like that. That's going to come into play. So each child comes to the table with a different set of experiences. And so that's where like sometimes the high kids do surprise us because they don't know something. Because maybe we've made that assumption before and not provided them with those experiences, or those experiences have always been done for them at home.

Teachers' speech acts incorporated ideas from the LT (e.g. "trajectory," "levels") and referred to age and grade level, not as a limiting factor for learning, but as a descriptor. The storyline suggests that student learning is influenced by prior experiences and opportunities and is not limited to their age and the expected school experiences for students at particular grade level. Teachers positioned themselves with agency – they could provide learning opportunities for students that draw upon, or even provide, such experiences as resources to foster learning. Students were positioned as having these resources that could be used when learning mathematics.

Discussion

Learning the LT changed teachers' discursive patterns about students as mathematics learners and themselves as teachers. Similar to Suh et al.'s (2013) individual maturation storyline, we found a storyline with elementary grades' teachers that a student's age or grade level limits their learning. Yet in our study, teachers grew to acknowledge and use prior experiences as a resource for supporting learning rather than viewing students' learning as bounded by their age or grade level. Thus, we conclude that learning a framework for students' thinking may led to changes in the ways teachers position students from a more strengths-based perspective. Further, such learning may support teachers' agency.

A MULTI-YEAR STUDY OF THE IMPACT OF A PROBLEM-SOLVING FOCUSED PROFESSIONAL DEVELOPMENT ON TEACHER LEADERSHIP

Jan A. Yow
University of South Carolina
jyow@sc.edu

Diana White
University of Colorado Denver
Diana.White@ucdenver.edu

This study explored the connections between teacher leadership and a professional development model focused on problem-solving, Math Teachers' Circles (MTC). Surveys were completed by 213 MTC participants resulting in three years of data across multiple sites. A mathematics education leadership framework provided a data analysis tool. Findings suggested MTCs did impact participant teacher leadership, as survey results attended to all three areas of leadership from the analysis framework.

Keywords: Middle School Education; Teacher Beliefs; Teacher Education-Inservice; Teacher Knowledge

Objectives & Purpose of Study

With the implementation of the Common Core for State Standards in Mathematics (CCSSI, 2010), the need for mathematics teachers to be learners and leaders in mathematics education is stronger than in the past. Mathematics teachers are being called upon to not only improve their own mathematical content knowledge and how to teach that content, but also to lead students, parents, colleagues, administrators, and communities in understanding and meeting the new standards presented in the CCSS. Math Teachers' Circles (MTCs) are one form of professional development that may help teachers reach these standards for teaching and leading.

In this study, the researchers highlight the potential of MTCs to develop mathematics teacher leaders. Both are experienced MTC leaders, and they use their knowledge of MTCs, of teacher leadership, and of teacher professional development—augmented with quotes from national surveys of MTC participants—to highlight the potential of MTCs to develop mathematics teacher leaders.

After preliminary background on MTCs, their history, and sample problems, the authors use the PRIME Leadership Framework (NCSM, 2008) as a lens with which to view the work of MTCs. The paper ends with some concluding remarks on growing MTCs as a means for teacher leader development.

Math Teachers' Circles

MTCs are a form of professional development, aimed primarily at middle school math teachers, which tap into the instinct that mathematicians have to share their love of mathematics with others. This makes MTCs an accessible entry point for mathematicians interested in starting to work with teachers and for teachers interested in working with mathematicians to learn more mathematics through problem solving. With the advent of the CCSS, this partnership is particularly timely for both parties.

The canonical model for an MTC involves a leadership team consisting of two mathematicians, two middle school math teachers, and one administrator. After attending a summer training workshop, teams spend a year securing funding and then launch their own MTC the following summer, generally with a 4-5 day residential workshop. Academic year sessions follow, generally about three per semester, with each 2-2.5 hours in duration. Each MTC tailors this basic model to meet the needs of their local setting.

Sessions typically begin with a leader presenting a rich problem that fosters exploration involving multiple levels of deep mathematical content. As the session develops, problems lend themselves, for example, to discussions of symmetry, algebraic representations and functions, and arithmetic and algebraic properties like the commutative, associative, and distributive laws. From a problem-solving perspective, problems may lend themselves to the techniques of "ask a simpler question" and "work backwards." Related to the CCSS, it requires teachers to use most, if not all, of the Standards of Mathematical Practice as they explore the various facets of the problem.

A final key feature of some problems is the "low-threshold, high-ceiling" property. That is, an entry-level problem requires minimal mathematics background to understand and begin to explore it, yet it can be connected to research-level mathematics. In addition to in-depth explorations, participants also investigate shorter problems. For example, the following two problems can be discussed in a meaningful way in about 30 minutes: (1) What is the last (units) digit of 7^{503}? (2) What are the last two digits of ^{503}?

Computing either of these by hand would be quite cumbersome, and plugging them into a calculator provides an estimate in scientific notation, but does not help directly with finding the last few digits. Thus, one needs to use mathematical reasoning, in particular concepts of place value and the process of multiplication, to both find and justify a pattern for the last tens and units digits of the powers of 7 that allows one to answer each question. In working through these problems, teachers work directly with content relevant to their students, but at a level that develops their own mathematical reasoning skills. Fernandes, Koehler, and Reiter (2011) and Donaldson, et al. (2014) provide a more in-depth discussion of a problem unfolding in a MTC session, while White (2015) provides a more in-depth description of one MTC.

In addition to working on engaging mathematical problems, many MTCs include sessions or portions of sessions that directly connect to the classroom. These comprise diverse topics such as effective questioning strategies, how to translate lessons learned in MTCs to the classroom, and how to implement the CCSS. Two valuable texts the authors have found to help lead some of these sessions are Boaler and Humprey's (2005) *Connecting Mathematical Ideas: Middle School Video Cases to Support Teaching and Learning* and Burago's (2010) *Mathematical Circle Diaries, Year 1: Complete Curriculum for Grades 5 to 7.*

A somewhat unexpected (at least to the original organizers) consequence of the MTC program has been the development of teacher leadership. This was first discovered on a national survey of MTC participants in 2010, where a surprising number of respondents made comments that indicated that they had emerged as informal or formal leaders in their schools or districts. Moreover, they attributed this to their participation in MTCs. In the remainder of this paper, we discuss how MTCs connect directly with the PRIME Leadership Framework (NCSM, 2008), augmenting our narrative with illustrative quotes from participants.

Literature Review & Theoretical Framework

Need for Teacher Leaders

Reform documents emphasize K-12 students should be learning mathematics through problem solving (National Council of Teachers of Mathematics [NCTM], 2000; CCSSI, 2010).Mathematics Standards call for students to discuss, collaborate and justify their thinking through engaging tasks (NCTM, 2000; CCSSI, 2010) and for teachers to support such work (NCTM, 2014).

Despite this push for reform, middle school mathematics teachers still often teach content in traditional teacher didactic manners emphasizing textbooks and lecture (Grouws & Cebulla, 2000; Kent, Pligge, & Spence, 2003; Weiss, Pasley, Smith, Banilower, & Heck, 2003). With so many barriers to instructional change (Anderson, 1996; Roehrig, Kruse & Kern, 2007), teachers need to feel empowered to make changes to their instruction that benefit student learning (Fullan, 2001).

Professional Development

Professional development is one avenue for empowering teachers to make changes. Effective professional development should build teachers' content knowledge, immerse them in authentic experiences, address beliefs, involve collaborative communities, and provide long term support (Darling-Hammond, Chung Wei, Andree, Richardson, & Orphanos, 2009;Johnson, 2006; Loucks-Horsley, Hewson, Love, & Stiles, 2003). Flowers and Mertens (2003) described a need for professional development specific to middle school teachers' content and student learning needs. Teachers who attended professional development experiences longer than 8 hours and connected to other school-based initiatives reported the experiences improved their teaching while shorter unconnected experiences did not (Flowers & Merten, 2003). Other studies show long-term professional development of more than 80 hours is needed for teachers to enact inquiry-based practices (Porter, Garet, Desimone, & Birman, 2003). Professional development focused on mathematical problem solving increases teachers' content knowledge and improves pedagogical strategies (Anderson & Hoffmeister, 2007). MTCs are designed using these research-based characteristics: focused on building teacher content knowledge through problem solving strategies, was long-term, and involved building collaborative communities between teachers, mathematics educators, and mathematicians. This study further investigated the connection between high quality professional development and teacher leadership (Yow & Lotter, 2014).

Teacher Leadership

Due to teacher influence on student learning (Darling-Hammond, 1999), developing teacher leadership in mathematics education is one of the most important factors in schools (Pellicer & Anderson, 2001). Dozier (2004) defined teacher leaders as "good teachers who influence others." Before the phrase teacher leadership (Barth, 2001; Lieberman & Miller, 2004), teacher empowerment was the phrase used to describe a similar construct: teachers believing they had the "skills and knowledge to act on a situation and improve it" (Graham & Fennell, 2001; Short, 1994). Subject specific teacher leadership is a recent phenomenon; professional organizations define educational leaders in teaching (NBPTS, 2010; NCTM, 1991). Characteristics specific to mathematics teacher leaders are described in the literature (Langbort, 2001; Miller et al., 2000; Yow, 2007); however, few empirical studies exist (Webb, Heck, & Tate, 1996; Yow, 2010). Therefore, our research question asked *How does teacher involvement in a Math Teachers' Circle impact their enactment of teacher leadership?*

Theoretical Framework

The National Council of Supervisors of Mathematics (2008) developed the *Principles and Indicators for Mathematics Education Leaders* (PRIME) leadership framework responding to a lack of attention to the importance of school leadership in improving teaching and learning (Spillane, Halverson, & Diamond, 2004). The framework "aims to describe actions for mathematics education leaders across all settings, preK-12, in all its complexity" (NCSM, 2008, p. 2). We see teachers as educational leaders closest to student learning and therefore choose to focus on their data.

The framework lists specific actions that fall along a continuum of three stages of leadership growth. The continuum includes knowing and modelling leadership (leadership of self) as stage 1, collaborating and implementing structures for shared leadership on a local level (leadership of others) as stage 2, and advocating and systematizing improvements into the wider educational community (leadership in the extended community) as stage 3 (NCSM, 2008, p. 2). With this focus on leadership in mathematics education, we employed this framework as our data analysis tool.

Methods

Data was analyzed from a national survey distributed to all MTCs in 2010 and to the authors' local MTCs in 2013 and 2014. Collectively, 213 participants completed the survey measuring MTC teacher impact. The survey contained Likert scale and open-response items asking teachers to rate and address their gains in mathematical content knowledge, attitudes and dispositions toward mathematics, classroom instructional practices, and professional activities. Data was analyzed through the three areas of leadership put forth in the PRIME Leadership Framework (NCSM, 2008). As shared earlier, the framework consists of: Stage 1 Leaders, considered ***Leadership of Self*,** "know and model" good teaching practices in their own classrooms; Stage 2 Leaders, considered ***Leadership of Others***, "collaborate and implement" these good teaching practices with all students and other teachers and administrators; and Stage 3 Leaders, considered ***Leadership in the Extended Community***, "advocate and systematize" these good teaching practices on a larger scale helping to create instructional change at the district, state, national, or international level. At each stage, leaders are respected for the self-knowledge, influence of others, and advocacy on a larger scale, respectively.

Data was coded using the above three foci. For example, when teachers mentioned impact of MTCs on their own practice, those comments were coded as *Leadership of Self.* Comments that reflected MTC impact on collaborative work, such as "we all worked as a team to try and learn together," or encouraged teachers to invite others to learn with them (e.g., "I've started bringing my colleagues from the department to the Circles as well") were coded as *Leadership of Others*. Lastly, comments were coded as *Leadership in the Extended Community* when they spoke to the impact of MTCs on teachers expanding their sphere of influence to a larger community: "I have started giving presentations at meetings and conferences, have become the mentor for new math teachers, and am peer reviewer of math activities for the classroom at my level for the region."

Results, Discussion, and Conclusions

Findings showed MTC participant responses attended to each of the three stages of leadership put forward in the PRIME Leadership Framework.

Stage 1: Leadership of Self

MTCs allow teachers to develop their content and pedagogical expertise, change practice, and take risks (Yow, 2007), all part of leadership of self. A prerequisite to knowing and modeling good teaching practices is knowing and understanding the content and the disciplinary practices of mathematics. With the advent of the CCSS, many teachers are being asked to teach in ways that are often quite different from how they were taught. MTCs provide an opportunity for teachers to take on the role of learners of mathematics, and to revisit what that role looks and feels like. In fact, in initial end-of-workshop surveys of the MTC program, comments about being back in the role of a learner of mathematics were so prevalently cited as a benefit of MTCs that it was incorporated as a question on the most commonly used end-of-workshop survey form, and has been widely reported at conferences as one of the key outcomes of MTCs.

Math Teachers' Circles focus on building teacher content knowledge through problem-solving while also strengthening teachers' problem-solving skills and fluency with implementing the CCSS Standards of Mathematical Practice. They also learn the habits of mind and the disciplinary practice of mathematics, whereby the "answer" in not always known and uncertainty followed by exploration is the norm. As noted by one participant, "I have not participated in a workshop where I as a person have to struggle through, and the presenter did not share the correct answer." Often times, "answers" to the problems are not immediately given to participants at the end of problem-solving sessions so they can continue to grapple and discuss the problem. This directly addresses the first mathematical practice of perseverance in the CCSS (2010).

Teachers see what is modeled in the MTC and develop their pedagogical expertise in their own classrooms:

> In the meetings, they deliberately have us talk about our techniques and approach to the problem. When we think out loud as a group, we start to see patterns, and together we think about tools we can use. When possible, I like to integrate this approach in my classroom, giving my students the tools they need to figure out an overarching problem and then letting them chip away at it collectively until they figure it out.

MTCs provide an opportunity for teachers to be Stage 1 Leaders by allowing them to improve their own content knowledge as well as problem-solving skills. MTCs allow teachers to work in community to learn mathematics and solve problems that they can then implement in their own classrooms. "My classroom teaching has become more student-centered and engaging. Students are working together and discussing problems in groups, or exploring individually before sharing with a larger group."

Stage 2: Leadership of Others

MTCs focus on building community and learning how to solve problems alongside colleagues which lends itself to Stage 2 Leadership of Others by "collaborating and implementing." One teacher noted

> We all worked as a team to try and learn together…As different participants have different backgrounds and learning styles, the group work revealed to be very effective because we used our previous knowledge and our personal ways of seeing, interpreting and solving each problem. The support and the conversation with other members of the circle were always positive and enriching.

Teachers become a part of a community of learners within the MTC and then use this structure to begin similar communities at their schools. Seeing the model of mathematical discussion among the mathematicians, mathematics teacher educators, and teachers helps teachers learn how to facilitate mathematical discussions with their own colleagues. They gain a broader sense of what it means to be a part of a mathematics education community: "I feel that working on mathematics with my colleagues gives me a wider perspective on how to view mathematics and what it means to teach mathematics."

MTCs provide the opportunity for teachers to be Stage 2 Leaders by their returning to their schools and sharing what they learned with their fellow teachers and administrators. For example, following the intensive summer workshop, teachers invited colleagues from their schools to join us at our monthly Saturday meetings so they could see for themselves the types of mathematics and problem-solving in which we engaged. Some of these guests came to more than one Saturday meeting to extend their own learning and take what they were learning back to their schools and classrooms. In addition, one of the mathematics teacher educators invited her preservice teachers to come to the Saturday sessions. Their visit introduced them to current practicing teachers and offered them an opportunity to see what types of professional development are available to teachers and how they may incorporate such problem-solving approaches into their own future classrooms. One teacher wrote, "I've started bringing my colleagues from the department to the Circles as well, and that helped them realize that there really is something to this approach. It's also helped us cohere as a group back at school, and our students benefit immensely."

Stage 3: Leadership in the Extended Community

MTCs provide an opportunity for teachers to be Stage 3 Leaders by their sharing what they have learned on a larger scale. For example, teachers from MTCs have presented at state mathematics conferences. During these presentations, teachers advocate for strong instructional practices by explaining what happens during MTC meetings and then present rich problems that they themselves have spent time solving with their students. They discuss the rich mathematical content of the problem and the mathematical directions they or their students may take to solve the problem. One teacher shared, "I have started giving presentations at meetings and conferences, have become the mentor for new math teachers, and am peer reviewer of math activities for the classroom at my level for the region."

Because MTCs often span several schools and school districts, teachers are able to interact with an extended community of math teachers within a region and increase their ability to systematize the practices used in MTCs. This leads to teachers building a wider network of colleagues with whom to learn and collaborate: "Participating in the MTC meetings has encouraged me to network with others and attend conferences with them." This newfound agency of being a member of a professional community also builds confidence in MTC participants, which results in taking on more of a leadership role in areas outside of their classrooms as well: "[Being a part of an MTC] has given me the confidence to step into more of a leadership role and a role in developing curriculum and lesson plans." Another participant who has become an instructional coach credited MTCs with helping in her job transition. "My leadership role in our math circle has correlated directly with my role change in my district from classroom teacher to teacher leader (instructional coach)." Strengthened by belonging to a professional mathematics education community empowers teachers to be mathematics teacher ambassadors (Yow, 2007) charged with telling others about the work they are doing in the MTCs and in their classrooms with students.

Concluding Remarks

MTCs provide a valuable professional development experience for mathematicians, mathematics teacher educators, and mathematics teachers. A powerful outcome of MTCs is the sense of community and broader understanding teachers gain of mathematics and the mathematics education community as a result of their participation. Even more, they provide an opportunity to develop mathematics teacher leaders by offering teachers the opportunity to develop in the areas of leadership of self (e.g. developing their content and pedagogical expertise, changing practice, and taking risks), leadership of others (e.g. becoming a part of a learning community), and leadership of the extended community (e.g. teaching their colleagues).

MTCs have the potential to impact mathematics teacher leadership on a national level given there already exists a national community and network of MTCs. Preliminary research has already been published on MTCs (White et al., 2013) and their relationship to mathematical knowledge for teaching. Also, Marle, Decker, and Khaliqi (2012) report that at one MTC, after a year of participation, classroom observations showed increases in the use of inquiry-based learning and in pedagogical content knowledge. More research is needed among long-standing MTCs to measure how extended participation in an MTC aides the continued evolution of a mathematics teacher leader from Stage 1 leadership to Stage 3 leadership (NCSM, 2008).

This paper briefly describes a lesson analysis tool, and its embedded conceptual framework, designed to help teachers analyze their mathematics instructional practice from a culturally responsive standpoint. The tool consists of six dimensions: cognitive demand, depth of knowledge and student understanding; mathematical discourse; power and participation; academic language supports for English learners, and cultural/community funds of knowledge. These six dimensions have theoretical underpinnings in culturally responsive pedagogy and pedagogical content knowledge.

Keywords: Equity and Diversity; Teacher Education-Preservice; Teacher Education-Inservice

This brief report describes a lesson analysis tool, and its embedded conceptual framework, designed to help teachers analyze their mathematics instructional practice from a culturally responsive standpoint. The Culturally Responsive Mathematics Teaching – Lesson Analysis Tool (CRMT6-LAT) consists of six dimensions: (a) cognitive demand, (b) depth of knowledge and student understanding, (c) mathematical discourse, (d) power and participation, (e) academic language supports for English learners, and (f) cultural/community funds of knowledge and social justice (Aguirre, et al., 2012). These six dimensions have theoretical underpinnings in culturally responsive pedagogy and pedagogical content knowledge, and an empirical basis in research that has documented positive effects on mathematical learning and identity development. The tool can be used to analyze real-time, videotaped, or written lessons, or to support lesson planning, reflection, and refinement. The power of this tool is its combined multi-dimensional focus on traditionally separate constructs of equitable mathematics instruction.

Theoretical Framework

Culturally responsive mathematics teaching (CRMT) is an equity-based instructional approach that integrates attention to mathematics, mathematics thinking, culture, language, and power to comprehensively support and strengthen student mathematics learning, engagement, and positive mathematics identity development (Aguirre & Zavala, 2013; Leonard et al, 2010). CRMT reflects the scholarship intersection between culturally responsive pedagogy and pedagogical content knowledge. Gay (2000) argues that culturally responsive pedagogy "simultaneously develops, along with academic achievement, social consciousness and critique, cultural affirmation, competence and exchange; community building and personal connections; individual self-worth and abilities and an ethic of caring (p.43-44)." Pedagogical content knowledge is the specific knowledge needed to teach content, including knowledge about the purposes of teaching mathematics, children's content understandings or misunderstandings, curriculum, and instructional strategies and representations (Grossman, 1990). Both literatures are robust in teacher education yet rarely connected to help support instructional practices needed to advance the mathematical learning of today's youth.

CRMT6-Lesson Analysis Tool

To help mathematics teachers teach from a culturally responsive approach this tool supports the comprehensive examination of teaching practice including lesson design, implementation, and reflection. The full tool, available from the TEACH MATH (Teachers Empowered to Advance Change in Mathematics) website, includes a reflection prompt for each dimension as well as rubric-style descriptors with progressive scores 1-5 reflecting a range of practices.

Cognitive Demand

From a culturally responsive stance, providing all students with access to high cognitive demand tasks is an equity issue. Research consistently finds that students who are placed in "lower" mathematics classes, and who are members of non-dominant groups, are less likely to be exposed to mathematical tasks that demand higher order thinking (Mosqueda, 2010; Oakes, 2005).

Depth of Knowledge and Student Understanding

This dimension highlights how knowledge and understanding are expressed in mathematics lessons, through activities such as reasoning, explaining, justifying, and engaging in complex problem-solving. Research shows that when teachers support mathematical learning by attending, interpreting, and responding to students' mathematical thinking, student understanding deepens (Carpenter, Fennema, Peterson, Chang, & Loef, 1989).

Mathematical Discourse

Mathematical discourse is an important component of deepening and communicating mathematics understanding. Research shows that all children, including young children and children learning mathematics in another language can showcase their mathematical knowledge when given opportunities to participate in mathematical discussions (Celedón-Pattichis & Turner, 2012; Herbel-Eisenmann & Cirillo, 2009; Turner & Celedón-Pattichis, 2011; Yackel & Cobb, 1996).

Power and Participation

Important considerations for understanding and supporting student participation are issues of power, status, and authority in the classroom. The way (whether intended or not) a teacher positions students as valuable contributors or "uninvited guests" can determine who has legitimate mathematical authority in the classroom (Spencer, 2006; Turner et al, 2012; Yoon, 2008). Developing worthwhile mathematical tasks that promote mathematical thinking, have multiple entry points, and tap into a wide range of knowledge can help to minimize status issues and foster a shared authority over mathematics (Featherstone, et al, 2011; Horn, 2012).

Academic Language Supports for ELLs

Academic language is vital to the way students learn and communicate their understanding of mathematics (Moschkovich, 2010). Therefore it is important to consider the instructional supports needed to facilitate student development and use of academic language. This is particularly true for students who are learning mathematics in an additional language (Celedón-Pattichis & Ramirez, 2012; Civil & Turner, 2014). This dimension focuses attention on lesson structures and language scaffolding strategies (e.g. revoicing, use of cognates, graphic organizers, realia) that support academic language development especially for students learning English as another language.

Cultural/Community Funds of Knowledge and Social Justice

This dimension highlights the important mathematical knowledge and practices that occur outside of school in children's homes and communities, specifically cultural funds of knowledge (Gonzalez, Moll, & Amanti, 2005). Examples of connections to children's funds of knowledge include mathematical investigations of family/community gardens, sewing techniques, family budgeting practices, as well as practices of community businesses such as auto painting, flower shops, fire stations, and *mercados* (Civil, 2007; Civil & Kahn, 2001; Taylor, 2004; Turner, Varley Gutiérrez, Simic-Muller, & Díez-Palomar, 2009). Mathematics is an analytical tool to make sense of socio-political issues that impact their world and life experiences including issues of civic engagement, overcrowding, and fairness (Gutstein, 2006; Turner & Strawhun, 2007).

Lessons Learned From Project Uses of the Tool

The central aim of TEACH MATH is to transform mathematics teacher education so that teachers will be equipped with powerful tools and strategies to increase student learning and achievement. We have used the CRMT6 tool with new teachers in several ways:

Analysis of lessons in mathematics methods classes. Prospective teachers have used the CRMT6-LAT tool to analyze a lesson they designed and/or taught during the mathematics methods course. Based on their analysis, prospective teachers wrote a critical reflection describing the strengths and limitations of the lesson and specific ideas for improvement supporting teachers to simultaneously synthesize different dimensions of culturally responsive mathematics teaching.

Observation of practice. The tool was also used when observing lessons during student teaching. Used in this way, the tool enabled the mathematics teacher educator to understand which dimensions of culturally responsive mathematics teaching prospective teachers felt confident with, which dimensions might warrant further exploration, and which dimensions were still quite challenging for them to attend to in lesson planning and implementation.

Providing targeted feedback to early career teachers. As part of our longitudinal study, we also observed and provided targeted feedback to early career teachers using this tool. For example, to support professional learning and growth, we encouraged teachers to select two dimensions from the CRMT6-LAT. The most prevalent choice was mathematical discourse (30% of observations) followed by cognitive demand (17%), power & participation (16%), depth of knowledge (14%), academic language (12%); funds of knowledge (11%), suggesting teacher hesitancy to focus on the equity-oriented dimensions addressing language, culture, and power.

Conclusion

There is a need for pedagogical tools, such as the CRMT6-LAT, that help teachers to be culturally responsive with content area teaching. These tools need to be analytical, applicable, and flexible in order to maximize pedagogical discourse about mathematics teaching and learning and support a robust and equitable instructional practice in mathematics. The CRMT6-LAT is such a tool.

Students come to the learning of categorical association with many misconceptions. The purpose of this study was to determine the effectiveness of novel curriculum materials to improve mathematics teachers' knowledge of students' conceptions regarding categorical association. Results showed that prior to use of the materials, teachers' knowledge was mostly limited to variations on one misconception. Following use of the materials, they were more broadly aware of a number of different misconceptions and improved their ability to analyze categorical data for association.

Keywords: Teacher Knowledge; Data Analysis and Statistics

Background

Statistical association is one of eight big ideas in statistics (Garfield & Ben-Zvi, 2004). This is reflected in the inclusion of the study of categorical data for association in curriculum documents such as the Common Core State State Standards for Mathematics (Standards 8.SP.4 and HSS-ID.B.5) (CCSSI, 2010) and the Guidelines for Assessment and Instruction in Statistics Education Report (Franklin et al., 2007). Researchers (e.g., Batanero, Estepa, Godino, & Green, 1996; Watson and Callingham, 2014) have established that students have great difficulty and many misconceptions when analyzing bivariate categorical data presented in contingency tables for association. For students, Batanero et al. (1996) and Watson and Callingham (2014) found the following misconceptions to be most prevalent:

- Deterministic (D): Students conceive of association from an 'all-or-none' perspective: all cases must show an association with no exceptions in order for an association to exist. These students believe that the cells in the two-way table that do not agree with the association should have zero frequency.
- Unidirectional (U): Students believe association only occurs when it is direct, and do not recognize that inverse association is possible. These students tend to give more relevance to positive cases than negative cases that confirm a given hypothesis.
- Localist: Students examine only a part of the data-often the cell with the highest frequency (L-S) or only one conditional distribution (L-RC)-to determine if an association exists.
- Ignore the data (I): Students ignore the data at hand and instead use their previous theories/knowledge about the variables under investigation to decide if they are associated.
- Lack of Proportional reasoning: Students compare frequencies rather than percents in their analysis (P-S), or claim that one cannot compare two groups of unequal sizes (P-M).

Students come to the learning of categorical association with conceptions, including the misconceptions described above. Teachers tasked with teaching students the topic of categorical association need to make their teaching responsive to students' various conceptions of it. This can be supported through knowledge regarding what students may think about particular content topics and how this thinking can progress, known in the Mathematical Knowledge for Teaching theoretical framework (Hill, Ball, & Schilling, 2008) as Knowledge of Content and Students (KCS). Thus, the purpose of this study was to determine the effectiveness of novel curriculum materials to improve mathematics teachers' KCS for teaching categorical association. This manuscript presents preliminary results from a larger study concerning the effectiveness of the materials to develop mathematics teachers' knowledge for teaching statistics more broadly.

Method

Forty-two teachers in statistics and education courses at three large universities in the United States during the Fall 2014 semester participated in the study. Eight were in-service teachers and the remaining were pre-service teachers. All participants were enrolled in a course that utilized new curriculum written by the first two authors of this report. The curriculum materials were designed to develop the knowledge teachers need to teach categorical association, including KCS. One section that focused on KCS in particular was based on Batanero et al. (1996) and Watson and Callingham's (2014) identification of common misconceptions in interpreting contingency tables. It presented real excerpts of students' reasoning about contingency tables and asked the teachers to do three things: describe each student's misconception, look for relationships between pairs of students' misconceptions, and respond to the student as his or her teacher. After the teachers discussed the misconceptions, the instructor provided the formal terms for the identified misconceptions (e.g., unidirectional). The homework for this section asked the teachers to (a) write their own definitions of three of these misconceptions and (b) create a short classroom lesson plan (not including homework or exam assessments) to address at least two of the misconceptions.

This manuscript reports results from the first item on a pre- and post-assessment designed to evaluate teachers' knowledge for teaching categorical association (Figure 1). It required participants to write a correct response and distracters for a multiple choice question (adapted from Batanero et al., 1996) about association between categorical variables. The directions emphasized the idea that distracters should reflect common student misconceptions about an item, allowing participants to exhibit their knowledge of an array of empirically-observed student tendencies when dealing with the content. This empirical grounding helped make the item an authentic means for eliciting participants' KCS (Hill, Ball, & Schilling, 2008) in regard to categorical association.

Analysis of the responses began with three of the authors independently coding teachers' answer choices as Correct (C) (corresponding to the correct answer on the item, which they were directed to write as an answer choice) or one of the misconceptions included in the curriculum materials. Any that did not fit these categories were classified as Other (O). The use of the coding scheme was piloted with a subset of six teachers' answer choices. Based on the pilot results, the coding scheme was expanded to include new categories for common responses: 1 –Students treat the problem as a one variable problem, looking at the marginal distribution for one of the variables only; N- Students believe that there is not enough information to determine if there is an association. All of the coding categories except N are grounded in research regarding common student misconceptions. In the next phase of analysis, all teachers' pre-and post-assessment answer choices and associated reasoning provided on the assessment task were coded. After comparing codes, any discrepancies were resolved through discussion by the coders and a final code was determined.

Now, imagine that you are writing the answer choices for an eighth-grade multiple choice test item. Th item itself is shown below, without any answer choices. Write several answer choices so that one is correct, and so that the others are distracters that reflect common student misconceptions about the assessment item. Explain the erroneous student thinking that would lead to each distracter, as well as the sound student thinking that would lead to the correct answer choice. Keep listing distracters until you have exhausted your knowledge of student thinking patterns about this type of item:

In a medical center 500 people have been observed in order to determine whether the habit of drinking caffeinated beverages has some relationship with high blood pressure. The following results have been obtained:

	High blood pressure	No high blood pressure	Total
Drinks caffeinated beverages	180	120	300
Does not drink caffeinated beverages	120	80	200
Total	300	200	500

Using the information contained in this table, would you think that, for this sample of people, high blood pressure is associated with drinking caffeinated beverages? Select the best explanation from the choices below.

Figure 1: Assessment Item 1

Results

The analysis of the responses provided to represent the correct answer choice for the item revealed that 69% of the teachers provided a correct answer with sound reasoning on the pre-assessment. This rose to 95% on the post-assessment, providing evidence that the curriculum materials improved teachers' abilities to analyze a contingency table for association.

Table 1 presents the results of an analysis of the responses meant to be distracters for the item, representing common student misconceptions identified by the teachers in the study. The percent reported in the table identifies the percent of the total responses each misconception was referenced for that assessment (pre or post). Multiple copies of the same code per student are counted multiple times.

Table 1: Identification of Common Student Misconceptions on Assessment Item 1

Misconceptio n	P-M	P-S	I	U	L -S	L -RC	I	1	N	O	s um	c ount
Pre	6 %	3 %	4 %	1 %	9 %	4 8%	2 %	1 8%	2 %	8 %	1 00%	1 17
Post	8 %	3 %	6 %	0 %	1 4%	3 4%	1 0%	9 %	1 %	1 6%	1 00%	1 14
Change	2 %	0 %	2 %	- 1%	5 %	- 14%	8 %	- 9%	- 1%	8 %		

The L-RC misconception was predominant on the pre-assessment, identified in nearly half (48%) of the 117 distracters written by the participants. In fact, 22 of the 42 participants applied the L-RC misconception in different ways (i.e., different rows and columns were isolated) to write multiple distracters on the pre-assessment. Interestingly, for those 13 teachers who provided an incorrect response for the correct answer choice on this item, 7 of them had the L-RC misconception themselves. A related misconception, 1, was the second-most common misconception identified on the pre-assessment, accounting for 18% of the distracters.

L-RC was still the most commonly identified misconception on the post-assessment, but it declined to be identified in approximately one-third (34%) of the distracters and was only used multiple times by 9 of the participants. Instead, the teachers on the post-assessment shifted to increase their identification of I, L-S, D, and P-M misconceptions. Few identified the U misconception on either assessment, but that is as expected given that the item displays a table with no association. A preliminary paired analysis showed essentially the same results as those presented above.

Discussion

This study found that prior to instruction many teachers understood that students commonly mistakenly analyze a contingency table for association by focusing on a single row or column-whether in the body of the table (L-RC) or in the margin (1). In addition, that misconception was also held by 17% of the participants prior to use of the curriculum materials and they generally were unaware of other misconceptions. Thus, an implication of this work is the need for teachers to have learning experiences specific to their knowledge for teaching categorical association. The curriculum materials evaluated in this study were effective at providing such learning experiences, facilitating teachers' learning of how to correctly analyze a contingency table for association and increasing their KCS with respect to their recognition of student difficulties with the topic (particularly the L and I misconceptions). Future work will involve more detailed analysis of the responses classified as O in this study (which accounted for 16% of the post-assessment responses) and connecting the results regarding this first item on the assessment to the results of the other three items to give a more complete picture of the participants' KCS for teaching categorical association before and after use of the curriculum materials. Also, based on this study's results, adaptation of the curriculum materials will be made to draw teachers' attention toward less commonly recognized student misconceptions.

This qualitative study examined how preservice secondary teachers with strong content backgrounds reported using their content knowledge in beginning teaching. Data included 3 interviews with 4 preservice teachers enrolled in a one-year master's program designed for content experts. Interviews spanned their teacher education program and first year of teaching. We mapped how participants described using their content knowledge to the construct of mathematical knowledge for teaching (MKT). We found that participants used various aspects of their MKT in making pedagogical decisions and providing explanations.They struggled to use their knowledge to make content accessible to their students. Participants' confidence in their content knowledge obscured the need for them to develop knowledge of content and students.

Keywords: Mathematical Knowledge for Teaching, Teacher Education-Preservice

In recent years, several agencies have offered certification programs to content experts in STEM fields to become high-quality teachers of mathematics (e.g., Robert Noyce Scholarship, National Science Foundation's STEM-TP). The assumption underlying these programs is that, given a strong content background, this population of preservice teachers needs only coursework in pedagogy and a teaching practicum to be prepared to be highly qualified teachers (Selke & Fero, 2005). Our research is directed towards understanding how prospective teachers' strong STEM background contributes to their teaching. This population is of interest because of their in-depth content knowledge and how they might call on that knowledge in teaching. Our institution has created an intensive one-year master's program leading to secondary mathematics teacher certification for those individuals who have earned an undergraduate degree in a STEM discipline. We are reporting how the prospective mathematics teachers in one cohort of program candidates described using their content knowledge in teaching.

Framework

Content knowledge is a necessary but insufficient prerequisite for effective mathematics teaching (Ball, Thames, & Phelps, 2008; Monk, 1994). Effective teachers also need pedagogical knowledge (Brown & Borko, 1992; Goos, 2013).Research tells us that both extensive subject-specific content knowledge and pedagogical knowledge are needed for teaching mathematics(e.g., Ball et al., 2008). Rather than considering teacher knowledge as a distinct knowledge of content *or* of pedagogy, a critical component of teacher knowledge is the interaction between content *and* pedagogy, what Shulman (1986) termed *pedagogical content knowledge* (PCK). PCK goes beyond *knowing how to teach*. It involves creating and analyzing multiple representations; making the subject accessible, yet challenging; increasing critical thinking skills; and aiding students in their understanding of broad mathematical concepts (Shulman, 1986).

Ball (2003) expanded Shulman's construct in context of teaching mathematics. What she termed *mathematical knowledge for teaching* (MKT) is composed of both subject-matter knowledge and pedagogical content knowledge. Subject matter knowledge is subdivided into *common content knowledge* (CCK), *specialized content knowledge* (SCK), and *knowledge of the mathematical horizon*. CCK refers to the ability to do mathematics accurately and efficiently, whereas SCK involves the mathematical skills that are unique to teaching, such as assessing the generalizability of students' nonroutine strategies. Pedagogical content knowledge contains subcategories of *knowledge* *of content and students* (KCS), *knowledge of content and teaching* (KCT), and *knowledge of content and curriculum*. KCS includes the ability to anticipate student thinking and misconceptions, and KCT includes the development, selection, and sequence of content to achieve a particular goal. In this study we considered how participants' called on different aspects of their MKT in beginning teaching.

Program

Our teacher preparation program is for STEM professionals and for outstanding recent college graduates with degrees in STEM fields, who want to earn a master's degree in teaching and middle (Grades 4–9) or secondary (Grades 7–12) teacher certification in mathematics or science. During one full academic year teacher candidates complete coursework on curriculum, learning, adolescent/child development, content-specific methods, and making connections between STEM disciplines and Grades 4–12 school mathematics and science. Three distinctive program features provide context for this paper:1) courses focused on all STEM content areas and the connections among them, 2) a year-long student teaching placement, and 3) meetings of candidates, mentors, and program faculty throughout the year to build relationships, discuss candidates' progress, and engage in professional development.

Methods

We collected data on 4 mathematics teacher candidates (hereafter participants)from the same cohort and 3 of their mentor teachers. All participants were seeking initial licensure for Grades 7–12 mathematics, had earned their bachelor's degree within the previous two years, and had prior informal teaching experience (e.g., tutoring, teaching assistants). Data were collected through 3 interviews: at the outset of their teacher preparation program(first), at the end of the year-long internship (second), and at the end of their first year of teaching (third). We asked participants to describe the connections among their backgrounds and work experiences in relation to their STEM content knowledge and current teaching. We interviewed their mentor teachers once about their mentees' backgrounds, teaching styles, and educational philosophies. At least two researchers independently open-coded transcripts. From the coded transcripts, we identified salient themes. We also examined the mentor interview transcripts for confirming or disconfirming evidence of these themes.

Results

Participants called on various aspects of their MKT in several ways and with a range of success: to make pedagogical decisions about what and how to present content, to provide multiple explanations and in-the-moment adjustments, and to unpack content to make it accessible for Grade 4–12 students.

Content Informs Pedagogical Decisions

Several participants described both large-scale curricular decisions and small-scale pedagogical decisions that were informed by their aspects of their CCK and KCT. The participants spoke positively of their decisions concerning both what was taught and how it was taught. For example, Alex described how his CCK affected what he taught:

> Being able to understand, like understand where everything comes from, is really important. I think it's only helped me, because you have to pick and choose what you're going to spend the most time – or … perceive to be most important, right. And you also have to weigh does it matter if … the students understand this to a certain level? (Alex, third interview)

Gerald used KCT to determine how he supplemented the textbooks saying, “My textbook will break [a problem] down differently [than I will]. I’ll show both ways [to the students]” (second interview). In other instances, Gerald, drawing on CCK to inform his KCT, explained:

> Are you going to mark off points if it’s not in standard form, like exponents going from greatest to least? I said, for Algebra I it’s not important. It’s really only important when you’re dividing polynomials. I was like if [students] get it in any form, I’ll take it. (second interview)

Others used their KCC to provide a better sense of “what was the most important thing that [students] had to understand” and their KCT to consider “how to make that [concept] clear in many different ways” (Jennie, second interview). Similarly, Alex used CCK to explore his own understanding, saying, “It's always important for me to understand what's going on [with particular content],” and KCC to determine “what do they really need to understand right now?” (second interview). Jennie credited her CCK for providing the ability to see the connection between disciplines, but we say that she relied on her *knowledge of the mathematical horizon*.

Participants used KCT and KCS to make decisions about how they taught. All participants developed long-term projects and/or connected applications of mathematics to student interests. Jennie used CCK and KCC to create a project-based lesson integrating mathematics and science. To develop students’ conceptual understanding, Reagan called on KCT to create lessons with real-world applications that required students to discover, explain, and justify common mathematical algorithms. Using KCS, Alex drew on students’ interests by using the popular game, Angry Birds, as a context for mathematical modeling of flight paths with parabolas, applying concepts of physics, and comparing paths with lines of best fit; stating “all of[creating the project] came through my math background” (Alex, second interview**).**

Content Informs Explanations and In-The-Moment Adjustments

Participants also gave positive reports of specific ways that their CCK helped them make in-the-moment pedagogical adjustments and provide alternate explanations. Reagan referred to the power of her CCK in managing the unexpected questions and providing multiple explanations:

> I think that majority of teaching is about the content and the fact that I’m a content expert…I can explain concepts in multiple ways. Kids can ask me questions that are not entirely related to what we're talking about and I can give them answers or let them know that I’m going to look them up….I can answer questions students ask all the time..… Also, I’ve had poor teaching moments where there has not been enough planning and prep time put into classes. It is easier to on-the-fly talk about things as well. (second interview)

Jennie agreed saying that because of her knowledge of mathematics “I think I am better able to explain things and give different examples” (second interview). Additionally, Reagan used her CCK to elaborate off-the-cuff on topics of interest to students: “There’s a lot where they’ll say, ‘Hey is that related to this?’ And I know whether or not it is and I can talk to them a little bit more and I can give them more applications and when is this used” (second interview).

Making Content Accessible to Students

What the participants referred to as “present[ing] [content] to the kids in a way that was at their level” (Jennie, third interview), Reagan described as the “biggest stumbling block related to my education” (third interview).It was in this pedagogical skill that we found their CCK was an inadequate substitute for their limited KCS. Gerald was challenged by “breaking the math down” and was forced to “rethink what I did in high school and what I've learned throughout” (second interview). Gerald’s mentor noted these struggles as well: “the only thing is with him being at such a high level sometimes it has been very difficult to bring it back down to the level that some of these kids are at." Similarly, Jennie's mentor observed that though "the content for her was somewhat simple," she struggled in "bringing learning [the content]…down to the eighth grade level. And display[ing] the content in an understandable way to the students." Jennie continued working on this struggle in her first year of teaching,"I found myself at the beginning of the year kind of teaching above them," and noted the dissonance between their knowledge and her own, "I assumed going into it that they knew more than they actually knew, because of where I was at" (second interview). Reagan explained:

> I'm struggling with ways to explain what seems elementary to me … I think that that's been my biggest frustration because I am so familiar with the content that it doesn't make sense to do it any other way. (second interview)

Though participants became aware that "not everybody see[s] it like I see it," they still focused on making content accessible by breaking down problems "into extremely small steps" (Gerald, third interview).They began to recognize that they needed to consider the mathematics they were teaching from the perspective of their students. At this early time in their teaching career, their KCS was underdeveloped and their only pedagogical strategy for making content accessible was decomposing content into smaller, manageable pieces. In taking this approach, they may have inadvertently overemphasized a procedural view of mathematics while underemphasizing the development of conceptual understanding.

Conclusions

In programs tailored to prospective teachers with strong STEM backgrounds, it is commonly assumed that they have in-depth understanding of content and, hence, their programs focus primarily on pedagogy. However, our participants' general pedagogical focus did not fully support them in making connections between their content knowledge and pedagogical preparation. We suspect that our participants' struggles (e.g., making content accessible) were the result of a lack of PCK, in particular KCS. One remedy is to provide teacher candidates who have content expertise with early experiences that make them aware that CCK does not provide all that is needed for MKT. There is, however, an underlying challenge in implementing this remedy: their initial confidence in CCK obscured the need to develop their PCK. Hence, there is a need for experiences that disturb their complacency regarding content to motivate them to attend to their KCS.

MATHEMATICS STUDENT TEACHERS' DEVELOPMENT OF PEDAGOGICAL CONTENT KNOWLEDGE: AN INTEGRATIVE-TRANSFORMATIVE PROCESS

Lin Ding
Hong Kong Institute of Education
lding@ied.edu.hk

Allen Yuk Lun Leung
Hong Kong Baptist University
aylleung@hkbu.edu.hk

How mathematics student teachers (MSTs) develop their pedagogical content knowledge (PCK) during their preparation is an important question to teacher educators. This proposal is based on the first author's Ph.d dissertation on the changes In Chinese MST's PCK over two years to further discuss the changes in the interrelationships among components of PCK. The PCK in this study was defined as three components--- knowledge of students (KOS), knowledge of teaching (KOT) and content knowledge (CK). The focus of this proposal is the changes regarding the interrelationships between KOT and KOS, and KOS and CK. The types of these changes are reported by examples, and a discussion is made on a hypothesis model on interpreting MSTs' PCK development from an integrative and transformative perspective.

Keywords: Mathematical Knowledge for Teaching; Teacher Education-Preservice

Research Background

Pedagogical content knowledge (PCK), first proposed by Shulman (1986), as an important indicator of teaching competency, continues to attract attention of researchers from different disciplines. PCK has been described as the unique teaching knowledge that distinguishes teachers from scholars in a given subject. A number of studies in PCK have focused on its definition and components, and its development within individual cognitive domains. These studies suggested that PCK composes of several major knowledge components, for example, knowledge of learners, teaching, curriculum and content (e.g., Tatto et al., 2008). However, for the development of PCK of mathematics teachers, there remains to be further explored on a specific model to explain its change. In the field of science teacher education, integrative and transformative perspectives were adopted to interpret science teachers' PCK and PCK development (e.g., Gess-Newsome, 1999).The transformative model views PCK as the transformation of different constructs into a unified form, while the integrative model assumes that PCK does not exist as an epistemic entity, rather it is an incorporation of accessible knowledge components such as knowledge of students. This proposal tries to provide some insights on a possibility of a hypothetic model- an integrative and transformative process to explain (pre-service) mathematics teachers' PCK development.

Theoretical Framework

The general ideas of integrative and transformative point of views can be considered as promising in applying the field of mathematics teacher education. It can be found that for those, who classified the PCK into different components, might have the tendency to adopt integrative perspectives to understand PCK where it is understood as a mixture of different knowledge components. In addition, another strand tending to interpret mathematics PCK as a derivation of mathematics subject matter knowledge (SMK). For example, in knowledge quartet (KQ) model (e.g., Rowland, et al, 2005) described the different levels of melting between mathematics knowledge and teaching .The integrative and transformative perspectives also have the potential in explaining the process of PCK development especially among mathematics pre-service teachers. Since there existed studies to document the difficulties and dilemmas that pre-service teachers met in mathematics teaching in relationship to their teaching knowledge (e.g., Inoue, 2009; Kinach, 2002). These difficulties and dilemmas, in some extent, reflect pre-service mathematics must experience a process from possessing unified and unstable PCK (i.e., separate PCK components) to an integrative and mature PCK unit. For example, Even (1993) found that insufficient SMK might lead to MST's adoption of teaching strategy for an emphasis on procedure mastery rather than on conceptual understanding. Some isolated literatures documented pre-service or novice teachers' teaching explanation and representation reflecting fragmentary and unstable teaching knowledge (Charalambous, Hill, & Ball, 2011; Inoue, 2009). Inoue (2009) reported that the MSTs under studied basically possessed SMK for solving mathematics problem, but a majority of them could not give pedagogically meaningful representation to support students to understand the concept. However, few studies in the past documented the process of MSTs' PCK development, in particular, how the different components of PCK becomes a unified one. PCK in this study is consisted of *knowledge of teaching*(KOT), *knowledge of students*(KOS) and *content knowledge*(CK). This proposal tries to interpret the identified types of interrelationships between KOT and KOS, and between KOS and CK through integrative and transformative perspectives.

Methods

This proposal is built on a portion of the first author's PhD dissertation on tracing changes in the PCK of a group of Chinese MSTs during the final two years of their four –year teacher education. The selected preparation program aimed to nurture future secondary mathematics teachers. To capture MST's PCK change, both quantitative and qualitative approaches were adopted. In this proposal, only the data collected from three video-based interviews (the qualitative approach) were focused. Three video clips were selected from Hong Kong TIMSS video study to serves as prompts for stimulated recall. Three teaching topics were selected: Three-term ratio (R3), Distance formula (DF), and Pythagoras theorem (PT). The video clips were edited with research purpose, including a coherent teaching process on teaching the key content of the topic, and students' responses reflected from either blackboard exercises or questions. The detailed content and major snapshots representative of student blackboard work of the video clips, and the interview questions about KOS, KOT and CK categories will be elaborated during the presentation. All 36 video-based interviews (6 PSTs* 3 topics* 2 stages) were recorded and transcribed verbatim by the first author. Data collected from the three video-based interviews were examined and analyzed. A total 20 questions (10 KOT questions, 7 KOS questions and 3 CK questions) across three topics were discussed in this proposal. The MSTs' response to each question in each stage was analyzed in terms of a level (either one among Low, Intermediate and High). In this proposal, the interrelationships between KOT and KOS, and between CK and KOS were examined and major types of these changes are presented.

Results

Changes in Interaction between KOT and KOS

In general, for KOT and KOS interaction, the changes reflected in Stage Two indicated the development of a degree of awareness of student learning trajectory in designing teaching strategies. The KOS revealed in the six STs' KOT are mainly general knowledge about students' characteristics and interests, and their perception on students' effective learning including developing learning habits, standardized ways of solving mathematical problems. The three types of changes are illustrated below and the specific examples will be shown in presentation.

Type 1: Regarding students' comprehension as an important measurement of the effectiveness of teacher instruction. The commonality in MSTs' commentaries on teacher instruction in Stage Two was that the MSTs showed a more careful analysis of the teacher's instructions in the video clips to strategize on how teacher instruction can match student comprehension. This confirms a transition from a more teacher-directed teaching approach shown in Stage One to a more student-centered teaching approach that was evident in Stage Two where student comprehension was regarded as an important measurement of the effectiveness of teacher instruction.

Type 2: Facilitating students' development of learning and thinking habit through teaching. Five STs displayed this type of change which refers to STs' concern about students' development of a learning habit. Phrases such as "experiencing by themselves", "learning habit" and "standardized methods for solving mathematics problems" were used in STs' responses to KOT questions. All examples of this type of change reflect MSTs' concern about students' examination performance which can be seen as a kind of integration between KOT and KOS.

Type 3: Taking students' interest and prior knowledge into account when designing teaching strategy. This type of change was mainly identified among MSTs whose paired responses improved from Low to Intermediate level in Stage Two. In general, in Stage One, these MSTs showed little or no awareness of the students' interests or prior knowledge. In Stage Two, they began to integrate student concerns into their teaching approaches like encouraging student participation, offering fewer abstract exercises and more real-life examples, activities with manipulatives and sensing student diversity. In addition, the idea of creating real-life examples or scenarios was widely used by the MSTs in considering their strategies in Stage Two.

Change in the Interaction between CK and KOS

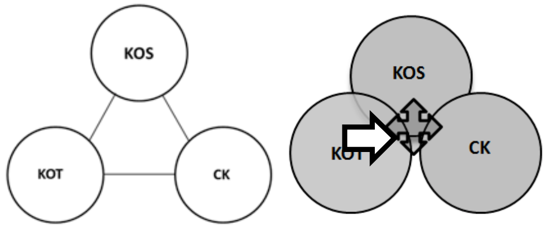
For the interaction between KOS and CK, the two types of KOS-CK change reported related to the changes in how MSTs attributed students' mistakes, difficulties and confusions. Compare to the interaction between KOT and KOS, the interaction between KOS and CK seemed to plays a more important role in terms of promoting these MSTs' PCK development in a more advanced level. With the involvement of CK, MSTs' KOS became more content-specific and tend to focus on students' mathematical thinking. In particular, MSTs were able to elaborate their thinking of students' thinking which was a KOS-CK interaction.

Type 1: A shift from a focus on the correctness of students' answers to the interpretation of students' mathematical thinking. Two STs displayed this type of change. In the Stage One, they focused on correctness of students' answers, but paid more attention to why the student thought that way from a mathematical perspective in Stage Two. For example, one MST tried to analyse why a student made a mistake by examining the sequence of content topics in the curriculum, while the other more able to interpret explicitly students' thinking process such as what caused student confusion.

Type 2: Developing a more sophisticated interpretation of student's thinking from a mathematical standpoint. Three STs showed this type of change. In Stage One, these MSTs inclined to either characterize the student's method as simple trial and error or make a quick conclusion of students' thinking based on their observation from video clips. In Stage Two, these MSTs were able to reinterpret students' methods from a mathematical perspective, or evaluate the students' thinking in terms of mathematical learning trajectory.

Discussion

The analysis above in identifying major types of changes through the paired responses supports the emerging of connections between KOS and KOT and between KOS and CK in the MSTs' PCK development during the period under studied. It was found that both the relationships between KOT and KOS and between KOS and CK became more integrated. The MST's awareness of relationships among teaching strategy, student perspective and mathematics increased and the boundaries between these knowledge domains became less rigid. The current evidences focused on relationships between KOT and KOS and between CK and KOS, these types of change suggest an integrative-transformative PCK model to explain these MSTs' PCK evolution process from a relatively integrative compartmentalized PCK to a transforming PCK with its components interacting and merging, which can be visualized as Figure 1.



MSTs Stage One PCK MSTs Stage Two PCK

Figure 1: An integrative compartmentalized PCK with three components evolves into a transforming PCK with several components interacting and merging

The tentative model proposed in this study highlights the interactive relationship among three PCK knowledge domains, and suggests the possibility of PCK transformation trajectory. This model has heuristic value in terms of helping teacher educators to think deeper about potential developmental trajectories for a better design of training courses. This study is an initial attempt to build a PCK model and evidences were provided to support its soundness. More discussion will be made in the presentation.

Research suggests that teachers' knowledge and beliefs about teaching and learning mathematics are among the key factors for effective teaching. This study explores the extent to which K-12 mathematics teachers' educational beliefs and mathematics knowledge for teaching (MKT) have an impact on students' math achievement. The effects of students' prior math achievement and teachers' years of experience and mathematics degrees earned were also examined. Hierarchical regression analysis results indicated that prior achievement was a significant student-level predictor of mathematics achievement. Teachers' MKT and teaching experience also had a significant effect on the relation between prior achievement and current achievement. Results may have implications for teacher professional development programs as well as education policies at both district and state level.

Keywords: Mathematical Knowledge for Teaching; Teacher Beliefs; Teacher Education-Inservice; Teacher Knowledge

Purpose of the Study

A significant body of research highlights the integral role that teachers' domain-specific knowledge for teaching and their educational beliefs about teaching have on their knowledge development, decision-making and planning, and instructional practices (e.g., Pajares, 1992; Philipp, 2007). Adding to this line of research, this report extends our findings from a larger study that examined both antecedents and outcomes of teachers' beliefs about teaching and learning mathematics (Ekmekci, Corkin, & Papakonstantinou, 2015) by connecting teachers' beliefs and their mathematical knowledge for teaching (MKT) to student outcomes. Specifically, the current study is guided by the following research questions: (a) to what extent does a student's prior mathematics achievement relate to their subsequent mathematics achievement, (b) to what extent do teacher-level characteristics (e.g., experience, beliefs, and MKT) relate to students' math achievement, and (c) to what extent do the effects of student-level factors on math achievement vary by teacher-level characteristics?

Literature Review

Teachers' personal and domain-specific educational beliefs should not be overlooked in the evaluation and development of effective instruction (Stipek, Givvin, Salman, & MacGyvers, 2001). There are various types of educational beliefs that math teachers possess such as self-efficacy beliefs, locus of control beliefs, and epistemic beliefs about mathematics that influence their instructional approaches (e.g., Stipek et al., 2001). Teachers' self-efficacy can be defined as the degree to which teachers believe they can successfully perform teaching-related tasks within a particular domain or context (Enochs, Smith, & Huinker, 2000). Teachers' locus of control may be defined as the extent to which teachers attribute student outcomes (i.e., achievement) to themselves or other (external) factors (Hofer & Pintrich, 1997). Epistemic beliefs can be perceived as beliefs about the nature of knowledge—i.e., where it comes from, its essence, and how one comes to know (Muis, 2004).

Prior studies have found a strong association between teachers' beliefs and students' achievement-related outcomes (e.g., Goddard, Hoy, & Woolfolk-Hoy, 2000; Love & Kruger, 2005). However, the vast majority of these studies focused on only one type of belief (e.g., self-efficacy) and failed to scrutinize the collective impact of different types of beliefs on student achievement. Moreover, the relation between teachers' domain-specific beliefs and student outcomes has not been adequately addressed in previous research.

In addition to teachers' educational beliefs, MKT, defined as "the mathematical knowledge that teachers use in classrooms to produce instruction and student growth" (Hill, Ball, & Schilling, 2008, p. 374), has been found to positively relate to student performance (Hill, Rowan, & Ball, 2005). While previous findings indicate that each of the aforementioned beliefs and knowledge are associated with student achievement, no studies were identified that examined the varying effects of each of these beliefs on students' mathematics achievement. Questions remain as to whether certain educational beliefs have stronger effects on students' mathematics achievement compared to other educational beliefs. Preliminary findings suggest that certain beliefs may play a more important role in student achievement in mathematics given that Ekmekci, Corkin, and Papakonstantinou (2015) found that among these three beliefs, a teachers' epistemic beliefs about mathematics is the strongest predictor of a teachers' MKT, which is a reflection of their instructional practices (Hill et al., 2008).

In terms of teachers' professional background, years of teaching experience has been positively associated with teacher quality (see Rice [2003] for review; 2010). A second teacher background variable that has been linked to student achievement is teachers' educational background in the subject matter that they teach. The majority of the research that examines the influence of educational background in a teaching discipline assesses its impact on student-related outcomes (Barry, 2010). Given the significant relations that have been found between teachers' educational and experiential background with student achievement, the current study will examine the extent to which teachers' beliefs and MKT explain the variation in student performance after accounting for these variables.

Conceptual Framework

The conceptual model in Figure 1 provides a representation of our multilevel research design. Arrow A displays the direct link between the student's prior math achievement (level-1) and math achievement as the outcome variable. The main effects of the teacher-level variables (level-2) on math achievement are depicted by arrow B. Arrow C represents the effects of teacher-level variables on the relation between students' prior math achievement and current math achievement (e.g., does the predictive value of prior achievement change by level of teacher experience?).

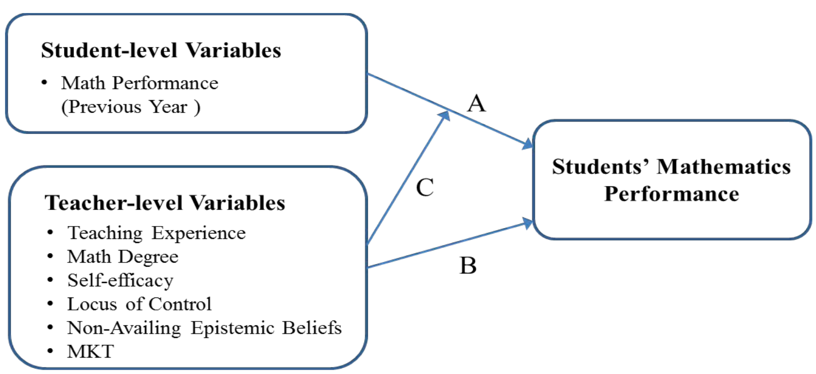

Figure 1: Conceptual Model of the Study

Methodology

The teacher-level data for this study has been collected as part of a project that was partially funded by Teacher Quality Grants Program at the Texas Higher Education Coordinating Board under Grants #496 and #531. For the past two years, consistent measures were administered to assess teachers' educational beliefs after a summer campus program (SCP)—a three-week intensive professional development program aimed at improving mathematics teachers' MKT. Participating teachers took a post-survey on the last day of the SCP assessing teachers' self-efficacy for teaching mathematics, internal locus of control, and non-availing epistemic beliefs about mathematics. The teachers also took the Learning Mathematics for Teaching (LMT) assessment, a standardized assessment that measures MKT (Hill, Ball, & Schilling, 2008), on the last of day the program. More specifically, elementary teachers took El NCOP 2008 scale and middle and high school teachers took MS PFA 2007 scale.

In addition to these measures, teacher level variables included professional background variables such as years of teaching experience and whether teachers had earned a mathematics degree. Student level data requested from the school district included student scores on a standardized mathematics test that was administered at the end of the academic year. The ongoing study will continue to collect data from 2014 teachers and students. Although 2014 teacher data is readily available, since the student achievement data for this cohort is not available yet, this brief only reports the findings for the 2013 cohort.

Among the 51 K-12 teachers who participated in the 2013 SCP, 76% were female; 39% were African American, 30% Hispanic, 20% White, 10% Asian, and 2% other. Students' ethnic background breakdown in the school district is as follows: 29% are African American, 58% Hispanic, 9% White, 10% Asian, and 2% other. About 25% were high school teachers; 25% were middle school; and 50% were elementary teachers. We used SPSS to conduct Linear mixed effects (multilevel regression) analyses. The complete between-teacher model is as follows:

Level-1 (student level): $Y_{ij} = \beta_{0j} + \beta_{1j}(\text{PriorMathAchvmt})_{ij} + r_{ij}$

Level-2 (teacher level): $\beta_{qj} = \gamma_{q0} + \gamma_{q1}(\text{MathMajor}_j) + \gamma_{q2}(\text{TEACHEXP}_j) + \gamma_{q3}(\text{Self}-\text{eff}_j)$
$+\gamma_{q4}(\text{LocusOfControl}_j) + \gamma_{q5}(\text{Epis. Beliefs}_j) + \gamma_{q6}(\text{LMT}_j) + u_{qj}$

Results and Discussion

The results showed that teacher-level variation accounted for 22% of the variation in math achievement (Model 1: Unconditional Model). Table 1 displays the results for the within-teacher (Model 2) and between-teacher (Model 3) models predicting the student achievement outcome. Findings showed that the only significant stand-alone predictor was students' mathematics achievement in the previous year (corresponds to Arrow A in Figure 1). None of the three types of teachers' beliefs were significantly associated with student achievement in math (Arrow B). Whether teachers' had a mathematics degree or not was also not significant (Arrow B). However, teachers' LMT scores and years of experience both had a statistically significant effect on the relation between prior achievement and current mathematics achievement (Arrow C). This implies that the predictive value of prior achievement on students' mathematics achievement varies by teachers' MKT and teaching experience. More specifically, higher MKT (i.e., LMT scores) and greater years of teaching experience strengthens the relation between students' prior and current mathematics achievement. Although statistically not significant, teachers' beliefs were positively associated with students' math achievement.

These results suggest that teacher educators should pay close attention to developing teachers' math knowledge, especially MKT. Urban school districts may consider hiring more experienced teachers to boost their students' academic achievement. Lastly, teacher preparation programs should look for ways to offer more mathematics content and methods courses to improve their MKT.

Table 1: Linear Mixed Effects Model Results

Independent Variable	Model 2 Coeff.	Model 2 *SE*	Model 3 Coeff.	Model 3 *SE*

STANDARDIZED ASSESSMENTS OF DISCUSSION LEADING PRACTICE: ARE THEY VALID MEASURES?

Leading mathematics discussions is an important practice for beginning teachers. Assessments designed to determine skill with this practice are critical. But it is important to determine if such assessments yield performances that correspond with teachers' typical discussion leading practice. In this paper, we investigate the validity of one standardized assessment that was designed to assess novices' skill with discussion leading practices, providing evidence of its alignment with typical practice. Analyses suggest that a standardized assessment has the potential to accurately reflect teachers' typical discussion leading practice and provide opportunities for teachers to use additional practices.

Keywords: Instructional Activities and Practices; Classroom Discourse; Assessment and Evaluation; Teacher Education-Preservice

The assessment of teacher candidates' skills with core practices of teaching, such as leading a discussion, is crucial as teacher education shifts toward preparing beginners to do these core tasks of teaching (Ball & Forzani, 2009; McDonald, et al, 2013). As part of a larger project, we are developing a standardized assessment of beginners' skill with leading mathematics discussions. We use "standardized" to refer to having teachers lead a discussion with a provided mathematics task, and an accompanying lesson plan, including instructional goals. However, one may wonder if this standardized assessment will yield performances that differ from "typical" practice when leading discussions. This study investigates the concurrent validity of the assessment by examining how novices' performances on the standardized assessment corresponded with how they lead discussion in regular classroom practice.

Leading a discussion is challenging and complex with many interacting practices at play. Given the complexity, we sought to standardize some of these practices in order to assess others. To determine where to standardize, we turned to a particular decomposition of the work of leading a mathematics discussion that draws on research around practices for orchestrating discussions (Smith & Stein, 2011) and talk moves (Chapin et al, 2013). As illustrated in Figure 1, our decomposition distinguishes between three stages of discussion: launch, orchestration, and conclusion. Within each stage, teachers engage in discussion-leading practices using particular techniques (Boerst et al., 2011), including talk moves.

Discussion Enabling	Discussion Leading		
Anticipating student thinking Setting up the problem Monitoring student work	**Launching**	**Orchestrating** - Eliciting - Probing - Orienting - Making Contributions	**Concluding**
	Recording		

Figure 1: Decomposition of Leading a Mathematics Discussion

We chose to focus the assessment on discussion-leading practices and to standardize the discussion-enabling work by providing scaffolds similar to those teachers might encounter in curricular materials including the task (Figure 2), lesson plan, and anticipated student thinking. We then developed an assessment of beginning elementary teachers' skill with leading mathematics discussions that asked teachers to do the following:

> *You will lead a discussion of solutions to the problem "make number sentences for 10" with an eye to the similarities and differences among presented solutions. Your goal is to elicit several solutions to the problem and to have students explain why they are or are not solutions and to notice similarities and differences among the solutions. Depending on the level of your students, your discussion may also focus on the number of solutions to the problem. You may modify the lesson as necessary for your students.*

The task was selected to engage students across grades and skill levels with opportunities to generate and compare solutions.

The assessment includes a scoring tool designed around the stages of work and practices outlined in Figure 1. This tool further decomposes the practices into related techniques, which represent a sample of possible techniques that we selected as crucial for beginning practice. For example, *orienting students to the contributions of peers* occurs during the orchestration stage of the discussion and is specified by five techniques such as "the teacher poses questions to students about other's ideas and contributions." In developing this tool, we recognized that there are many ways to score or assess instruction, including rubrics that differentiate levels of performance. For the purposes of identifying correspondence of techniques used by teachers in their typical practice with those used in an assessment, we chose to record the presence or absence of each technique in relation to a given threshold. A choice of N/A (not applicable) was built into the tool to recognize that some techniques may not be needed depending on the norms of the classroom. To investigate the degree to which a standardized assessment of discussion leading practices yields performances that correspond with the same teachers' typical practice, we piloted this assessment with 9 first through fifth grade elementary teachers and also documented a mathematics discussion that they led as a part of their regular classroom practice.

Methods

The participants in this study were nine first-year elementary school teachers who served as a proxy for candidates at the end of their program. We sampled teachers from a range of grade levels (1-5), school districts, and teacher education programs. While we sought a diverse sample to elicit variation in performance, this sample is not meant to be representative of all first-year teachers. Data sources for this study include video recordings of a discussion led as a part of regular classroom practice (observation discussion) and the assessment discussion. Observations were captured in order to compare typical discussion leading practice with teachers' assessment performance. Teachers were given the assessment described above and were encouraged to spend no more than 45 minutes preparing. Observations were conducted prior to the assessment discussion so that teachers' typical practice would not be influenced by the assessment.

To investigate the concurrent validity of the assessment, we used the developed scoring tool to analyze both the observation and assessment discussion videos. Multiple members of the research team scored all of the videos. For this study, scoring refers to recording the presence or absence of particular techniques at a particular threshold. Any discrepancies were resolved through discussion and reference to the codebook. A subset of the discussions (> 20%) was coded by a trained rater, yielding an inter-rater agreement of 85%. All nine individual teachers' scores were compared for consistency between the observation and assessment discussion both at the level of discussion leading practices and at the level of the techniques associated with them. We coded the techniques and the discussion-leading practices for whether teachers received the same rating in both contexts or not. Changes in use of techniques from "not present" on the observation to "present" on the assessment will be referred to inconsistent favoring the assessment. All teacher names used in the subsequent analyses are pseudonyms.

Findings

To examine the correspondence between the assessment discussion and teachers' typical discussion leading practice, we first describe the patterns of consistency that we found across the sample and then use cases of three teachers to illustrate some of the nuances of these patterns. Overall, when comparing individual teachers' use of particular techniques across observation and assessment, we found that many techniques were used across both contexts. Additionally, many of the techniques that were not used on the observation were used during the assessment. When examining performances at the practice level, we found that *eliciting student thinking* and *concluding* the discussion were well matched with most teachers matching or showing more skilled performance during assessment on all techniques. To get a clearer picture of the correspondences between performances on the assessment and observation, we consider the practice of *orienting students to one another's thinking.* When we compare the use of particular orienting techniques, we find that the techniques were often different across performances; in other words teachers used different orienting techniques across contexts, lowering the number of matching techniques used. However, Figure 2, which shows the number of orienting techniques that received a score of N/A and present for both instances of instruction, highlights that at the level of the discussion leading practice, teachers were fairly consistent in the number of different orienting techniques that they were using with inconsistencies favoring use of more techniques in the assessment. For example, T25 used four orienting techniques in both the observation and assessment discussions, and also earned one N/A in both instances, showing high levels of consistency across discussions.

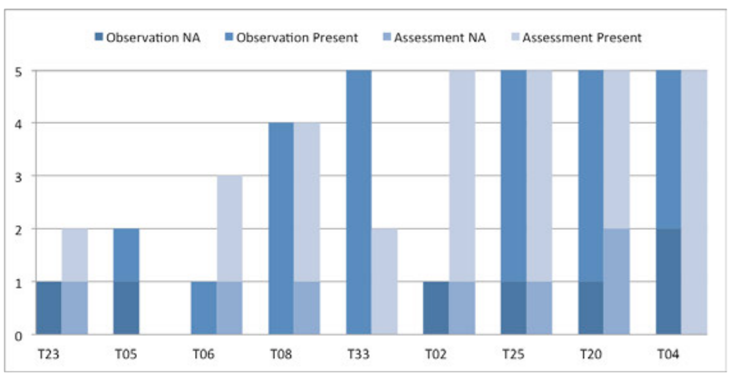

Figure 2: Orienting techniques across observation and assessment contexts

Cases of comparing teachers' discussion leading practice

To further illustrate the findings, we selected three teachers representing different cases of technique use: consistent (T08), inconsistent, favoring the assessment (T02), and inconsistent, favoring the observation (T33).

Consistent. Ms. Bryan (T08) presents a case of a teacher whose performance was consistent across contexts. In both discussions, her *launch* engaged students in the key mathematical work, though in neither case was she efficient. In both instances she consistently *elicited student thinking* and *probed* for both process and understanding. One area of her orchestration that varied slightly was around *orienting*. Though she did the same number of orienting techniques in both instances, the techniques she used varied slightly.

Inconsistent, favoring the assessment. Mr. Dawson (T02) performed significantly better on the assessment than the observation. His *launch* and work around *eliciting student thinking* was quite similar in both instances but in all other areas he did demonstrated more skill on the assessment. Most notably, his work around the practice of *orienting students to one another's thinking* increased from no orienting during the observation to use of all five techniques during the assessment discussion. We noted that his treatment of the content in his observation, recording the mass of objects in different units, did not seem discussion-worthy. We wondered if his choice of task and content impacted his performance.

Inconsistent, favoring the observation. Ms. Jordan (T33) performed significantly better in some areas during the observation that she did on the assessment. In both cases she launched the discussion efficiently with a tight mathematical focus and was able to elicit and probe student thinking. However, she did much more work orienting students to the contributions of others during the observation. We noted that in her assessment discussion, Ms. Jordan made critical errors while attempting to respond to a student contribution. This prompted us to wonder if her content knowledge impacted her use of particular techniques.

Discussion and Implications

In this investigation of the concurrent validity of a standardized assessment of beginning teachers' discussion-leading practice, we found that the assessment was reflective of teachers' discussion-leading practice in their typical instruction in many cases. When this was not the case, inconsistencies favored better performance on the assessment. This may mean that the scaffolds built into the assessment could support beginners and show their potential to utilize discussion-leading practices even if they are not yet consistently using them in their typical practice.

The findings suggest that the standardized assessment could reflect teachers' typical discussion leading practice and could reveal better performances when provided with scaffolds, (e.g. the lesson plan appeared to support beginners' ability to conclude a discussion). This indicates that the assessment may make visible teachers' potential to use the discussion leading practices given the right supports and content. Although we did not set out to account for differences in performances, we did observe a number of interesting features of lessons with discrepancy including the role of the task, subject matter knowledge, and learning opportunities built into the assessment. Future research could examine systematically the ways in which these and other factors contribute to differences in performances.

Although there were several limitations to the study including the sample, the limited number of observations, and the design of the scoring tool around a particular decomposition of discussion leading practice with threshold statements, the findings suggest that a standardized assessment has utility for assessing beginners' skills and should be further investigated.

PROSPECTIVE TEACHERS' SENSE MAKING

Carla Gerberry
Xavier University
carla.gerberry@xavier.edu

Lindsay Keazer
Central Connecticut State University
lmkeazer@gmail.com

This study explored how prospective elementary teachers described their past experiences engaging in the first of the Common Core Standards for Mathematical Practice, which requires students to "make sense of problems and persevere in solving them." Through a process of grounded theory we found that prospective teachers' responses varied between whether or not they described the problem solving process as one that relied on non-routine thinking, or as a process of following prescriptive steps. Just under one third of the 41 students gave examples of the practice that demonstrated an understanding of solving problems as a sense making process, and many cited that this happened in the contexts of "geometry" and "word problems". These findings suggest that teachers' past experiences may have afforded few opportunities to engage in this practice, and teachers may need support in developing new understandings.

Keywords: Teacher Education-Preservice; Standards; Elementary School Education

Objectives

The Common Core State Standards (CCSS) (NGA, 2010), adopted by the majority of U.S. states and territories, include Standards of Mathematical Practice (SMP) that describe practices students should develop when learning mathematics. A challenge currently facing many prospective teachers is that the Standards for Mathematical Practice (SMP) require them to learn to teach mathematics in ways distinct from how they learned mathematics. We sought to examine how prospective teachers interpret the SMP through the lens of their previous experiences with mathematics. In this study we focused on the first SMP, which requires students to "make sense of problems and persevere in solving them." More specifically, we investigated the following question: What are prospective teachers interpretations of the CCSS.MP.1 based on their past experiences?

Perspectives

In this study we focus on the first SMP because it is a core practice with broad application to all levels of mathematics. This practice emphasizes student thinking and persistence through solving non-routine problems, which contrasts traditional ways of learning mathematics through rote memorization and an emphasis on skill over understanding.

One enduring challenge in mathematics education is how teachers (and teacher educators) can be responsive to the various conceptions of mathematics held by their students. The literature of the field supports that an emphasis on reasoning and sense making should be inherent in all mathematics learning (e.g., NCTM, 2009; Schoenfeld, 2009), but in order to teach in this manner teachers themselves need a conceptual understanding of mathematics (e.g., Ball, Hill, & Bass, 2005). Prospective teachers in the U.S. may not be adequately prepared to teach the demanding mathematics curriculum required by the Common Core State Standards (Education Policy Center, 2011), and many of them may hold conceptions of mathematics that do not easily align with the SMP.

Prior to entering teacher education programs, prospective teachers have spent many years as students in mathematics classrooms, often learning mathematics in ways that do not align with current standards. Lortie's (1975) theory of "apprenticeship of observation" suggests that a teacher's past experiences observing and engaging in learning as a student are a major contributor to how they learn to teach. Prospective teachers' understandings of mathematics and teaching are strongly influenced by their past experiences as students of mathematics. If they did not develop a conceptual understanding of mathematics, they may have difficulty interpreting the Mathematical Practices, and struggle to support their future students in developing them.

In this study we explored prospective teachers understandings of how they had engaged in the practice described in CCSS.MP.1 in their past experiences as a mathematics student. We took a grounded theory approach (Glaser and Strauss, 1967) in this study because there were no existing frameworks with which to analyze the data.

Methods

Context

This study was conducted in two sections of a Number Theory content course designed for prospective elementary and middle school teachers at a private university in the Midwest. Prospective teachers were in their freshman or sophomore year and this was their first mathematics course at the university. The population consisted of 41 prospective teachers: 38 females and 3 males.

Data

The data collected for this study were from an online survey given prior to the first day of class. We asked demographic questions as well as items pertaining to attitudes and beliefs. The focus of this study was on how pre-service teachers make sense of the first Common Core Mathematics Standard through the lens of their past experiences as prospective teachers. More specifically, the survey asked prospective teachers to read the description of CCSS.MP.1 and think about what it meant to them. "Describe any past experience you have had as a student of math, in which you feel like you participated in a way that met this standard." The description of CCSS.MP.1 that was provided to the prospective teachers is available at http://www.corestandards.org/Math/Practice/.

Analysis

Qualitative data pertaining to prospective teachers' understanding of the CCSS.MP.1 were imported into an Excel spreadsheet with all identifiers removed. The two co-authors began the grounded theory process (Glaser and Strauss, 1967) by reading and rereading all prospective teachers' responses, and engaging in constant comparison to search for possible themes. We met to discuss our initial observations and concluded that an observable variation between responses was whether or not the individual described the problem solving process as one which relied on non-routine thinking, or as a process of following prescriptive steps. After discussing this variation, the co-authors separately returned to the data and categorized responses according to these two categories. This categorization was done by reading and rereading responses and underlining words or phrases that indicated an understanding of problem solving as either a thinking process, or a process of relying on prescriptive steps. After both authors conducted this analysis separately, we met to discuss our categorization and to examine together the responses that were particularly difficult to classify. This process of categorizing, sharing, and discussing helped us to further clarify our understanding of the criteria that differentiated responses in each category.

The prospective teachers' responses that we categorized as demonstrating an understanding of the practice were those who indicated that thinking and reasoning was an integral part in coming to a mathematical solution. Some examples of phrases used by prospective teachers that indicated the importance of their own reasoning to help them arrive at solutions were: "thinking about the problem critically and from different angles", "support our answers", "problem solve and explain our reasoning to how we got our answers". Responses that we did *not* categorize as demonstrating an understanding of the practice fell into one of two cases: a) they indicated a reliance on rules, steps, and procedures to arrive at a solution rather than their own thinking, or b) they were vague and lacked enough detail to make a determination. When responses emphasized prescriptive steps and did not indicate the use of their own thought processes in arriving at a solution, it fell short of offering enough evidence to indicate understanding of CCSS.MP.1. Once all responses were categorized according to whether or not they indicated an understanding of the practice, we conducted further analysis by reading and rereading the responses within each category, and noting themes that emerged within each group. In the following sections, we describe the findings.

Results

Of the 41 responses, 13 prospective teachers demonstrated an understanding of CCSS.MP.1 as representing a thinking process. All 13 of the responses that we categorized as "understanding" indicated that the prospective teacher saw this standard as being about a thinking process in which the ideas and strategies come from the student (i.e., "I had to figure out…"). Student-centered thinking was indicated through verbs and phrases such as: *plan, questioning, pondering, discovering, think out, thoroughly considers the question, determine the best way to solve.* In 9 of the 13 responses, prospective teachers mentioned the existence of "different methods" to solve. Four of those responses also mention a goal of trying to come up with the best solution or determine the best way to solve the problem. Three of the responses included a reference to a geometry course, and 4 responses referenced "word problems" as contexts in which they had participated in the practice in the past.

Of the 41 prospective teachers who completed the survey, the remaining 28 did not show ample evidence to demonstrate an understanding of CCSS.MP.1 as a thinking process. In 15 of these 28 cases, the prospective teacher restated phrases directly from the standard or gave a vague response and did not provide any elaboration on what the standard meant to them or how they had experienced it. In 13 of these 28 cases, we categorized the response as "procedural," because they described the problem solving process as one that attempted to minimize it to a procedure. Another theme that surfaced from our analysis was that 7 of the 28 responses emphasized the importance of checking and rechecking their work using multiple methods. In the presentation, we will support findings with examples of prospective teachers' responses.

Discussion/Conclusions

Just under a third of the prospective teachers were able to show evidence of understanding that CCSS.MP.1 was about a student-centered thinking process, by giving examples and drawing on their past experiences. Of those prospective teachers who showed evidence of understanding CCSS.MP.1, about half of them referenced either geometry or word problems as contexts in which they had had opportunities to participate in this standard in the past. These findings suggest that prospective teachers' past experiences may have offered them little opportunities outside of those two contexts to engage in the practice promoted by CCSS.MP.1.

Current emphases on problem solving across the field of mathematics education focus on "reasoning and sense making" (NCTM, 2009) and "make sense of problems and persevere in solving them." These ideas clearly delineate the need for students to develop their own thinking strategies for working through non-routine problem solving, and necessitate that these practices become a part of "every mathematics classroom every day" (NCTM, 2009, p.5) instead of limited to narrow contexts such as geometry and word problems.

There is risk that prospective teachers who do not conceptualize mathematics as a discipline of reasoned sense making may not understand the importance of developing students' thinking strategies, and may attempt to reduce problem solving to procedural steps. Close to one third of the prospective teachers we surveyed interpreted CCSS.MP.1 as describing a problem solving process that could be minimized to a procedure. They emphasized activities such as circling, highlighting, underlining, and double checking rather than activities that have the potential to scaffold the development of students' own thinking strategies.

This is a time of transition for teacher educators as we develop our programs to prepare teachers for new expectations established by the Common Core. The findings from this study are significant as they illuminate prospective teachers' early understandings of the first SMP, and identify a need for teacher educators to support further development of their understandings of the SMP that they will be responsible for promoting in their future classrooms.

Without extra support, teachers (both prospective and practicing) are limited to the examples provided within the Common Core documents. Past experiences may not have provided them with the relevant conceptions and understandings needed to enable them to generalize the meanings of each of the SMPs. Thus, mathematics teacher educators should explore ways to help prospective teachers understand these ideas through engagement in mathematical inquiry and subsequent reflection aimed to help them understand the thinking processes that should be an inherent part of doing mathematics.

Further research is needed to explore ways of supporting the development of prospective teachers understandings of these ideas, and to examine the conditions that help prospective teachers come to see mathematics as a sense making process.

REFLECTING ON A DECADE OF CURRICULUM DESIGN: THE IMPORTANCE OF SETTING THE TONE

Theresa Grant
Western Michigan University
terry.grant@wmich.edu

For over a decade I have led a collaborative effort to develop, enact and revise curriculum materials for a Number and Operations course for prospective elementary teachers (PTs). A main focus of this course is on justifying one's thinking by relying on elementary-age appropriate meanings of numbers and operations, rather than rules. This article summarizes some of the key aspects of the curriculum development project, changes in the style and content of the curriculum, and recommendations for the importance of tone setting guidance for PTs and their instructors.

Keywords: Teacher Education-Preservice; Number Concepts and Operations; Curriculum; Mathematical Knowledge for Teaching,

Framing the Issue

Although the issue of what knowledge teachers need to teach has been debated since teacher education programs began, there has been a surge in the intensity and depth of the conversation in the last few decades. Most notable are two recent efforts, both based on a systematic examination of practice. Ball and colleagues have been working on developing a theory of the mathematical knowledge need for teaching by analyzing the work of elementary mathematics teaching (e.g., Ball, Bass & Hill, 2004; Hill, Rowan & Ball, 2005). Other efforts are geared at designing mathematics education courses for PTs by adopting a collaborative, systematic and iterative process of lesson development, analysis and refinement (e.g., Ball, Sleep, Boerst & Bass, 2009 and Berk & Hiebert, 2009). While some consider this to be the work of teaching, Berk & Hiebert (2009) highlight the similarities between this work and design research.

For over a decade I have led a similar project focused on developing and revising the Number and Operations course for PTs that facilitates the ability to justify one's thinking in ways appropriate for elementary students. This work began in 2003 when I was one of the main authors on the NSF-funded *Understanding Mathematics Deeply for Teaching (UMDT)* project (Flowers & Rubenstein, 2003 – 2007). A main product of this project was a set of instructor notes including a 1-page overview of the lesson (Brief Notes), and a set of Detailed Notes of varying length, but typically 10+ pages. Interspersed among activity descriptions were stand-alone essays called Teacher Notes (loosely modeled after a similar feature from the *Investigations in Number, Data and Space* curriculum, TERC, 1998). These included activity-specific notes, such as examples of student work and related mathematical issues, and more general notes on issues like social norms, sociomathematical norms (Yackel and Cobb, 1996), and tone setting for new topics. [Although I have found no literature defining tone setting, practitioner articles discuss suggestions for tone setting activities. The idea is to find an activity that conveys and motivates the goals of a course and introduces students to class norms.]

Following this project, I led my institution's efforts to continue to develop these materials in an incremental way. Our cyclical process included weekly meetings and impromptu conversations about the lessons that all instructors would use, and suggestions for future alterations. This work was also informed by research conducted with colleagues on PTs' understanding mathematics (e.g., Lo, Grant & Flowers 2008, Lo & Grant, 2012).

Setting the Tone for a Meaningful Approach to Mathematics

Over the years I have come to more fully appreciate the difficulties faced by PTs in both embracing the course goals and making the necessary shifts in thinking. Thus in the summer of 2012, I abandoned the idea of accomplishing tone setting in the first class (or two), and instead created a new 4-week unit to address the multi-faceted issue of setting the tone for making this fundamental shift from rule-based to meaning-based thinking. The new unit was designed to support PTs as they built a new foundation for doing mathematics, while simultaneously working on their understanding of number. Foci included: recognizing when rules are being invoked; generating and exploring age-appropriate meanings; and learning to focus on meanings by generating and analysing diagrams of problem situations before solving them. As we experimented with the new unit over four semesters, the Instructor Notes remained relatively sparse. With the new unit solidified, I devoted a portion of my sabbatical to generating detailed Instructor Notes and reflecting on how the curriculum had changed over the last decade.

Methodology

I structured my work on Unit 1 in three phases: 1) immerse myself in the activities; 2) refine the activities and create detailed Instructor Notes; 3) compare the resulting unit with the first few weeks of the *UMDT* curriculum. Since I was not teaching during my sabbatical, I invited an experienced mathematics education instructor to participate in more intense variation of our curriculum design process – thus providing a means of immersing myself in the activities. I chose an instructor who was essentially new to the course (she had not taught it in over 10 years), but not new to teaching PTs, nor new to working collaboratively on curriculum design for PTs. My goal was to: 1) reflect on the activities and their function in the unit; 2) identify sticking points of both instructors and PTs as they navigated the first unit, and 3) use this information to refine activities and create detailed Instructor Notes. For every lesson in Unit 1, I offered pre-lesson planning, observed the lesson, and had post-lesson discussions with the instructor. During and immediately after each observation I recorded my own reflections.

The process of creating detailed Instructor Notes and analyzing field notes from observations, interviews, and my own reflections, was a cyclical one. For each identified theme, I considered how to most effectively address it in the Instructor Notes; and in the course of writing up each activity, I reflected on its relation to larger themes. At several points I consulted with the instructor about sticking points and developing themes. Drafts of the Instructor Notes were shared with several instructors for feedback. Once satisfied with the newly designed Instructor Notes, they were compared to those from the original *UMDT* project, both for content and style.

Results and Discussion

The Instructor Notes: An Overview

Many of the suggestions raised by the instructor for inclusion in the Instructor Notes were not surprising: expected student responses; suggestions for what ideas to pursue and which ones not to pursue; a clear sense of the goals of each individual activity, and how this related to overall unit and course goals. Although this kind of information had been included in some Instructor Notes, particularly for well-established activities, it did not necessarily exist for every individual activity, particularly those in the new first unit. Furthermore, in instances where such information was included, the format of this information greatly impacted its usefulness. For example, there were some activities for which I provided a written description of expected student work. In discussing one such activity, it was clear that this description had little impact or staying power, however when I drew pictures to match these descriptions, the instructor quickly understood the important issues raised by the different approaches. Finally, it was also clear that a better organizational system was needed facilitate the quick location of particular information while teaching.

After making these and other alterations to Unit 1, I compared the notes to those from the original *UMDT* project. The new Instructor Notes were of similar length and maintained many of the original features of the notes, with some new features added including activity-specific goals. Also notable was a difference in the number and type of activities. In the original course, there were typically fewer activities in one 100-minute class. For example, Day 1 had been one activity: grappling with the reasoning behind the divisibility rule for 4. This was not an easy task for PTs and required a great deal of understanding and skill to facilitate in such a way that students stayed engaged without becoming discouraged. The current content focus of the first lesson is on even and odd numbers – something that is more accessible to many than proving divisibility rules. The lesson is also divided into three related, though separate activities. In addition, there is a distinct shift from generally open-ended activities with broad goals, to open-ended activities that are more focused on achieving specific goals, particularly in the first unit. This transition was due to a recognition of PTs need for more focused activities to make issues more clear, as well as instructors expressed needs for more clear and specific goals.

Broader Issues: A More Nuanced Approach to Norms, Goals and Tone Setting

Two broader sticking points emerged from the analysis of the data, particularly for classes 1 through 4: the unproductive use of generic teaching moves; and a need for a "big picture" view of the first unit. Consider the following generic teaching moves that could be considered standard moves in a stereotypical "student-centered classroom":

- A reluctance to tell anything, accompanied by the assumption that generalizations/insights/conclusions will always be articulated by students.
- Encouraging the sharing of many ideas, rather than delving into a few in greater depth.
- An overreliance on general why questions (e.g., *What do others think?* or *Can anyone add to this*?), rather than questions designed to help focus PTs on particular issues.

The result of these moves was that important mathematical ideas were not always pursued <u>and</u> many activities wound up taking twice the amount of time intended. My conversations with the instructor indicated that the richness of individual tasks, and the lack of prior knowledge of how PTs react to the task, led her to lose focus on the goal of a particular task. Which brings me to the second, related sticking point: the critical role of having clear goals for individual tasks, how these relate to the goals for the lesson/unit/course as well as the progression PTs go through as they learn to do mathematics meaningfully.

As I worked on the cyclical process of writing Instructor Notes and considering these broader sticking points, I returned to the impetus for creating the new Unit 1: the need for a more detailed and multi-faceted approach to setting the tone for PTs. I realized that the Instructor Notes needed to provide explicit suggestions for doing so, thus better setting the tone for instructors. In the original *UMDT* notes for the first day, there had been a Teacher Note titled *Expectations and Initial Tone Setting*, containing a sample script of how an instructor might explain the goals of the course and their relation to expected norms. In the newly created Instructor Notes, tone setting was supported in a multitude of ways: 1) all goals for activities were refined, and activity descriptions were altered to more clearly reflect goals; 2) whenever possible, summary suggestions were included pointing out the relationship between the activities on a particular day and both course goals and PTs future work as teachers. These additions were designed to help set the tone for both PTs and their instructors as they worked on individual activities. In addition, more general Teacher Notes were created to deal with bigger issues, most notably, two general Teacher Notes addressing the two main sticking points: *Confronting the Taboo of Teacher Telling* and *Confronting the Sanctity of Student Sharing*. As the titles suggest, the notes were aimed at confronting extreme views of a "student-centered" classroom and highlighted the struggles PTs face in moving from rule-based to meaning-based mathematics in the area of number and operation, thus setting the tone for instructors.

Conclusions

One of the enduring challenges of mathematics education is preparing PTs to teach K-12 students to reason mathematically. Many things contribute to this dilemma, including a lack of agreement on what it is that PTs need to know. While progress is being made, a recent national survey of those teaching mathematics content courses for PTs concludes that as a group, these individuals "likely have not had opportunities to think deeply about important ideas in elementary mathematics, and most institutions do not provide training and/or support for these instructors" (Masingila, Olanoof, & Kwaka, 2012, p.357). Thus it is imperative that we create educative materials for this varied population. I propose that in addition to features common to the university-based curriculum projects cited earlier (e.g., specific learning goals, rationale for the activities, expected student responses, etc.), careful attention must be paid to providing the kinds of tone-setting guidance necessary for students (PTs) and their instructors alike to navigate the complex process of basing mathematical work on reasoning rather than rules.

SITE-BASED MATHEMATICS METHODS COURSEWORK: THE DEVELOPMENT OF ATTITUDES AND THEORY-PRACTICE CONNECTIONS

Thomas E. Hodges
University of South Carolina
hodgeste@sc.edu

Cindy Jong
University of Kentucky
cindy.jong@uky.edu

This paper reports on the development of attitudes about mathematics, as well as the construction of theory-practice connections among elementary preservice teachers engaged in site-based mathematics methods coursework. Using the attitudes scale from the Mathematics Experiences and Conceptions Surveys, preservice teachers engaged in site-based methods coursework had more negative entering attitudes than control groups, but demonstrated higher growth rates at two subsequent time points. Further, preservice teachers were able to saliently describe theory-practice connections during reflections on the site-based experience.

Keywords: Affect and Beliefs; Teacher Education-Preservice

This paper focuses on the designs and outcomes of field-based mathematics methods coursework organized around opportunities for elementary preservice teachers (PST) to make solid, lasting theory-practice connections using an apprenticeship model. The design of such courses is predicated on the notion that live demonstrations, engagements and reflections on work with real students in classroom settings provide critical experiences on which theory practice connections are constructed {c.f. \Cochran-Smith, 1999 #457}. When mathematics methods courses are taught onsite in elementary schools, PSTs are offered ongoing opportunities to explore strategies that support children's mathematical thinking under the guidance of their methods course instructor and the classroom teacher {Hodges, 2014 #534}. After working directly with children or witnessing a live teacher demonstration, PSTs return to their methods classroom with their methods instructor to engage in immediate reflective conversations that help them learn to theorize from practice.

Objectives of the Study

Little is known about the impact site-based courses have on PSTs conceptions of mathematics teaching and learning, nor the types of theory-practice connections PSTs are able to construct through their participation in such contexts. Consequently, we undertook an exploratory mixed-methods design aimed at unpacking PSTs development as a consequence of their experiences in the site-based methods course. The Mathematics Experiences and Conceptions Surveys [MECS] (Jong & Hodges, in press) were administered to (n = 38) PSTs at three time points: (a) at the beginning of mathematics methods coursework; (b) at the end of mathematics methods coursework; and (c) at the conclusion of the student teaching semester. The MECS measure, in part, PSTs attitudes towards mathematics. Since attitudes are felt less intensely, and are more apt to change than beliefs {Philipp, 2007 #160}, we focused our attention on the attitudes scale as growth might be more readily visible over the short duration of a methods course and/or the student teaching experience. Additionally, the MECS contain contextualized sets of experiences items which help to explain any changes in attitudes as a consequence of prior and/or ongoing experiences within teacher education. Additionally, we drew upon artifact collection and analysis to explore the types of theory-practice connections PSTs developed as they participated in the site-based design.

The overall aims of this research were to (a) determine what, if any, changes occur in attitudes towards mathematics over the duration of the site-based mathematics methods course and into student teaching; (b) compare changes in attitudes among those engaged in the site-based course to populations of students which participate in a more conventional campus-based coursework; and (c) explore the types of theory-practice connections PSTs are developing within the site-based design. This focus contributes to the knowledge base on mathematics teacher development by observing both affective and cognitive aspects of experimental site-based PST mathematics methods course designs.

Perspectives

The MECS measurement of attitudes focuses on participants' ways of feeling and thinking about mathematics, maintaining a focus on PSTs enjoyment of and inclination to see mathematics as a worthwhile activity from both teaching and learning perspectives. Many elementary PSTs enter teacher education coursework with negative attitudes towards mathematics {e.g. \Connor, 2011 #387}. Our own work has suggested that elementary PSTs attitudes towards mathematics are strongly linked to their experiences in K-12 classrooms, and can be positively influenced through attention to methods experiences centered on reform practices in mathematics education (Jong & Hodges, in press). Ultimately, subcomponents of the affective domain, including attitudes, influence PSTs orientations to their own classroom in relation to students' mathematical thinking, use of curriculum materials, and student achievement (Philipp, 2007).

Given the link between attitudes and attention to reform practices in methods coursework, we wished to maintain a dual focus on the development of attitudes alongside the types of theory-practice connections PSTs were able to make. Theory-practice connections were considered in two ways: (a) those that analyze the instructional routines present in mathematics classrooms; and (b) those that investigate students' thinking about mathematics within classrooms. As an example, observations of instructional routines often focused on Smith and Stein's {, 2011 #446} *5 Practices for Orchestrating Productive Mathematics Discussions*, as these practices have shown significant promise in their ability to attend to critical features of inquiry-based mathematics instruction. Examples of the types of frameworks that investigate students' mathematical thinking include students' (a) views of the equal sign {Falkner, 1999 #442}; (b) levels of geometric thought {Wu, 2005 #565}; and (c) placement along an equipartitioning learning trajectory {Confrey, 2009 #564}.

Methods

The data presented here include thirty-eight PSTs enrolled in mathematics methods courses at one university in the United States during fall 2013. MECS-1 was administered during the first week of class while MECS-2 was administered during the final week of class. MECS-3 was administered following full time student during the spring 2014 semester. The Rasch Rating Scale Model was selected to create a common metric and rating scale. MECS-1 was selected for anchoring and subsequently the rating scale thresholds from MECS-1 were anchored using additional coding in a Winsteps control file. The attitudes scales from MECS-2 and MECS-3 were reanalyzed with the item and rating scale in place. Once quality control checks for stability, reliability, and fit were completed, the anchored items scales for MECS-2 and MECS-3 were deemed valid. Subsequently, more traditional parametric tests could be completed on the logit values. Data from the university of interest were then compared to data from two other institutions where MECS were administered at each time point. The other institutions, however, offered their mathematics methods coursework in a conventional campus-based course. We followed quantitative analyses with a qualitative thematic analysis of PSTs narrative reflections on theory-practice connections constructed during methods coursework.

Results

Results of the mixed methods design are organized sequentially by data type.

Quantitative Analyses

Results of an RM-ANOVA analysis indicated significant changes ($p < .001$) in all pairwise comparisons from MECS-1 (.522), to MECS-2 (1.296), to MECS-3 (1.928) among those enrolled in the site-based methods courses. Similar growth occurred in those enrolled in campus-based methods coursework at comparative universities. Furthermore, using Levine's test of homogeneity, there were no statistically significant differences between site-based and campus-based attitudes at any of three time points. Mean values for each university are presented in Table 1.

Table 1: Mean Attitudes Scores by University

University	MECS-1	MECS-2	MECS3
Site-Based	.522	1.296	1.928
Campus-Based 1	.540	1.012	1.322
Campus-Based 2	.711	1.303	1.979

Despite a lack of statistical significance between groups, the site-based methods mean values were lowest among the three institutions, yet exceeded the attitudes scores of campus-based 1 and were nearly identical to campus-based 2 at the end of the methods course. Further, the site-based attitudes maintained high levels of growth, along with campus-based 2, at the conclusion of the student teaching semester.

Qualitative Analyses

During observations of the experienced classroom teacher and their methods course instructor, PSTs maintained a five practices evidence log detailing the extent to which the classroom teacher and their instructor attended to each practice. These evidence logs provided a shared context to discuss mathematics lessons during debriefing sessions. Analyses suggest that PSTs were able to attend to the five practices in their observations, and could note "missed opportunities" in the experienced classroom teacher's attention to each practice. Observing these "missed opportunities" resulted in discussions of lesson modifications that would lead students to important mathematical understandings. Further, PSTs were able to generalize effective teacher moves that encourage the development of productive sociomathematical norms {Yackel, 1996 #227} towards argumentation. The following quote from a preservice teacher is indicative:

> Discussions should focus on students' thinking (both correct and incorrect) to develop instruction and help make applicable connections through representations. I learned using these resources that structure is essential in scaffolding appropriate math discussion. This discussion is important in supporting students in taking risks and asking questions to further their own understanding.

Three themes were developed through analyses of PST's responses to experiences focused on students' mathematical thinking: (a) differentiating instruction, (b) the use of curriculum materials; and (c) attention to multiple representations. The frameworks often highlighted misconceptions in core prerequisite knowledge, which supported PSTs in seeing that instruction must address holes in conceptual understanding, even if instructional guides and materials assume such knowledge. The following quote is illustrative of students' attention to representation of prerequisite knowledge:

> All of the students I interviewed seemed to have a clear understanding on moving from symbol to picture. They all knew how to shade in an area model. One pattern I noticed was that all three students had difficulty moving from picture to symbol. This made me think they were better at partitioning than unitizing fractions.

Discussion

The use of MECS indicated significant growth in PSTs attitudes over the duration of the mathematics methods course and into student teaching. The growth in attitudes among those engaged in site-based coursework was not statistically different from that of comparative campus-based courses. This finding is in and of itself important. Much like many comparative studies of reform mathematics curricula, which provide a "do no harm" comparison to traditional curricula, this study indicates that experimental site-based methods courses provide analogous growth across in attitudes across the teacher education program. Furthermore, we find that although not statistically significant, those engaged in site-based methods courses did show higher growth rates than comparative institutions.

The link between attitudes development and reform mathematics experiences in methods courses is clear. Given PSTs' direct attention critical aspects of reform instruction, the development of those attitudes might well be linked to certain critical experiences embedded in the site-based design. Although only an initial step, unpacking the design of methods courses, particularly carefully crafted theory-practice connections provided here, continues to be a fruitful area of research in mathematics teacher education.

MAINTAINING QUANTITATIVE COHERENCE: PRESERVICE ELEMENTARY TEACHERS' EXPLANATIONS USING CONCRETE REPRESENTATIONS

Erik Jacobson
Indiana University

Mark Creager
Indiana University
macreage@indiana.edu

Fetiye Aydeniz
Indiana University
faydeniz@indiana.edu

In this study, we asked 19 preservice elementary teachers who had completed content courses and were enrolled in a methods class first to solve multidigit addition and subtraction problems and then to demonstrate how they would explain the same solution to a child using base ten blocks. We found that even those with conceptual understanding of place value and multidigit arithmetic faced challenges providing explanations using base ten blocks that children would be able to understand. In particular, only some gave explanations with base ten blocks that had quantitative coherence—that is, the meanings associated with concrete objects and their transformation remained stable across the explanation. Additionally few PSTs' explanations corresponded with their initial solution because they did not coordinate the sequence of representation transformation with the sequence of their initial solution.

Keywords: Teacher Knowledge; Elementary School Education; Instructional Practices

Providing instructional explanations that students can understand is a critical part of teachers' work. Teachers who know what a clear explanation involves and can perform one themselves are better able to orchestrate a discussion that functions as a student-voiced explanation. Leinhardt (1987) contrasted the instructional explanations of novice and experts and provided a description of the key features of expert explanations. High quality explanations address a specific student audience by using representations that students understand, featuring strategic examples, avoiding errors, and highlighting important connections. Existing studies of preservice teachers have documented generally poor facility in explaining a wide range of mathematical ideas, including standard multidigit algorithms (e.g., Ma, 1999; Thanheiser, 2009).

In this study we identified features of preservice teachers' (PSTs) explanations involving base ten blocks that would prevent or impede student understanding. By interviewing PSTs who had already completed a sequence of content courses and were enrolled in a methods class, we were able to interview many participants who had conceptual understanding of place value yet still offered problematic explanations. Our study addressed this research question: *What challenges do preservice elementary teachers face providing instructional explanations with concrete representations?* We found that PSTs may not maintain quantitative coherence in their use of concrete representations and also may not coordinate their actions with the concrete representation and the sequence of the solution they aim to explain.

Theoretical Framework

In this study we envision teaching that is responsive to various conceptions of mathematics. In particular, we assert that instructional explanations that use representations are accessible to a wide range of students only if the underlying quantitative meanings of the representations and of the ideas that are being explained are made explicit and connected. According to Smith and Thompson (2008), quantities are constituted in people's conceptions of measurable attributes of objects, events, or situations. For example, in a situation where a girl started with 187 seashells, picked up more, and finished with 400, using *quantitative reasoning* (Thompson, 1994) could involve thinking about the situation as a starting amount, an unknown change, and the final result. Starting with 187 and keeping track of how many must be added on before arriving at 400 is a solution that might be generated from such quantitative reasoning. In contrast, we use *numeric reasoning* to refer to calculating and either not selecting calculations based on quantities or not explicitly connecting the component values and results of calculation to corresponding quantities. To extend the seashell example, someone reasoning numerically might subtract 187 from 400 to find the answer but not be able to provide a quantitative meaning for subtraction (e.g., subtraction as take away) that makes sense in the problem situation. While the differences may seem subtle, numeric reasoning without an understanding of the associated quantitative relationships can result in difficulties selecting appropriate calculations and in difficulties interpreting and using the results of calculations (Lobato & Siebert, 2002). We consider explanations to be *quantitatively coherent* if the quantitative meanings associated with concrete objects and their transformation remained stable across the explanation. Additionally, we argue that explanations must follow an appropriate sequence to be understandable for children.

Methods of Inquiry

In Fall 2014, we recruited 20 PSTs at a large public university in the Midwestern United States enrolled in two sections of a methods course. They had completed one content course in number and operation and a second in geometry and measurement. The interviews took place before multidigit addition and subtraction was discussed in the methods class. The first author was the instructor of one section of the methods course, and conducted semi-structured (e.g., Bernard, 1994) hour-long interviews with each pair of PSTs. We present data from 17 PSTs work on two tasks and 2 PSTs worked on only one task. One PST arrived late and did not work on either task. The first task was "187 plus what number is 400?" The second task was "Find 120 plus 96." Participants were first asked to explain their solution to the problem and then to demonstrate how they would explain the same solution to a child using base ten blocks. A main goal of the interviews was to examine how teachers' coordinated their initial solutions with their explanations of these solutions using base-ten blocks. The authors watched the videos and reviewed the transcripts many times. In each pass, we examined talk, gesture, and inscription for evidence of what the PSTs were thinking.

Analysis and Findings

For each task, we report representative cases and summarize findings for all participants.

Task 1: 187 Plus What Number Is 400?

To solve the problem, 16 of the PSTs used the standard algorithm for subtraction and 3 PSTs used different methods. When using blocks to explain their solutions, 12 of the PSTs maintained quantitative coherence and 7 did not. None of the explanations, however, corresponded in sequence with the initial solution supposed to be explained.

Erin did not maintain quantitative coherence. To solve the first problem for herself, Erin wrote the missing value equation 187 + __ = 400 and then used the standard algorithm for subtraction. She crossed out the digits 4, 0, and 0 writing 3, 9, and 10. Then she subtracted by place value starting with the ones to find the answer 213. She checked her work by adding 213 and 187 using the standard algorithm for addition to get 400. When asked to explain her strategy with base ten blocks, Erin counted out a collection for 187 using one flat, eight rods, and seven cubes. Erin then asked if she should "show 400 and then breaking it down" to which the interviewer agreed. She made a pile of 4 flats and stated she would show subtracting the 187 from the 400. She then removed 2 flats from the 400 pile to form a new pile and then took one rod and three cubes from the bank of extra material and placed them on top of the two flats she had moved. Two flats remained in her original pile, and she placed these back in the bank. She stated that the pile with 187 and the other with 213 would combine to make 400.

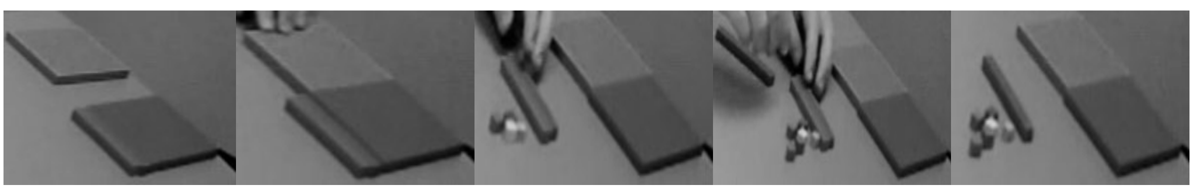
Abby maintained quantitative coherence. Abby initially solved the problem using the same method as Erin. To explain her solution using blocks, Abby laid out 4 flats to represent 400 and she stated she wanted to "take away 100, 80, and 7". To do this she removed 1 flat, traded a second flat for 10 rods and removed 8 of them, and finally traded a rod for 10 cubes and removed seven of them. She described her result as "200, 10, and 3 which would be 213".

Interpretation. Erin's explanation with blocks did not have quantitative coherence because the single rod and three cubes she used to form 213 came from the bank of extra material rather than from the collection representing 400. Abby's explanation did have quantitative coherence in that she used equivalent trades with the bank and constructed 213 by removing 187 from the initial collection of 400. However, her explanation using blocks did not correspond with her initial solution because she reversed the sequence of ones, tens, and hundreds. Thus, we judged that neither PST used blocks to explain her initial solution in a way children could understand.

Task 2: Find 120 Plus 96.

Of the 17 who worked on the task, 14 used the standard algorithm and 3 used different methods. When using blocks to explain their solution, 14 PSTs maintained quantitative coherence and 3 did not. Only 7 PSTs gave explanations that corresponded in sequence with their initial solutions.

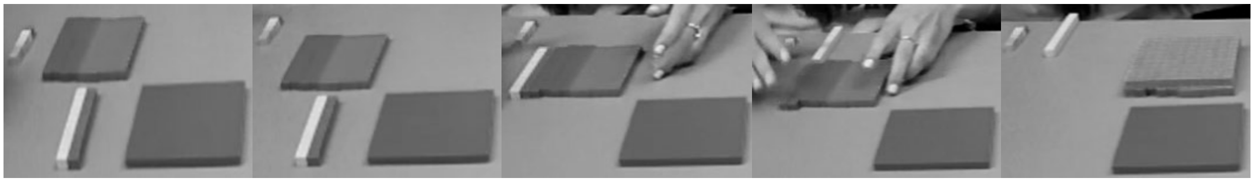
Alan did not maintain quantitative coherence. To solve the second problem, Alan said he first "rounded up" 96 to 100, added 100 to 120 to get 220. He then subtracted 96 from 100 to get 4 and finished by subtracting 4 from 220 to get 216. To explain his solution using blocks, Alan formed a collection of 1 flat and 2 rods. He placed 1 more flat below this (Figure 1a). He pointed to the single flat, held up 4 cubes, and said he "could not really get 96" so he added 4 to it and showed 100. He put the 4 cubes in his hand back in the bank of extra material. Next, he moved the single flat next to the collection of 120 (Figure 1b). He then moved the 2 rods from the collection to the side and put 4 cubes from the bank next to them (Figure 1c). He said, "I would take the 20 minus 4 to just get 16." He then moved in 2 cubes and 1 rod from the bank (Figure 1d) and removed 2 rods to leave a collection of 16 next to the two flats (Figure 1e).



a. b. c. d. e.

Figure 1: Alan's Representation of 120+96 with Base Ten Blocks

Cara maintained quantitative coherence. Cara used the standard algorithm to solve the problem initially. She wrote 120 above 96, wrote 6 in the ones place on the third line, noted 1 above the 1 in 120, wrote 1 in the tens place on the third line, and finally wrote 2 in the hundreds place. When Cara was asked to explain her solution, she formed a collection for each addend, one positioned above the other. The upper collection had 1 flat and 2 rods, and the lower collection had 9 rods and 4 cubes. In each collection, she organized the different blocks in sub-groups ordered from left to right and vertically aligned (Figure 2a). She then said 0 plus 6 would be 6 and moved 6 cubes down (Figure 2b), and that 2 tens plus 9 tens would be 110 and moved 11 rods together (Figure 2c). She moved one rod down, and slid the remaining 10 rods left and underneath the flat from the first collection, covering them with a flat from the bank (Figure 2d & e). She said the final answer was 216.



a. b. c. d. e.

Figure 3: Cara's Representation of 120+96 with Base Ten Blocks

Interpretation. Alan's explanation did not have quantitative coherence because he said "twenty minus four" and then used the same 4 blocks (originally representing "minus four") with another 2 cubes and 1 rod from the bank to form a collection representing 16. Cara's explanation had quantitative coherence because the meanings of the blocks in her original collections remained stable throughout her explanation. The new flat from the bank covered up 10 rods, effectively replacing them. Unlike Abby on the previous task, Cara's explanation directly corresponded to her initial solution. We judged that Cara's explanation of her initial solution could be understood by children but that Alan's explanation of his initial solution could not.

Conclusion

We found that PSTs who have completed content courses still struggle to provide understandable explanations using concrete representations. To be understood, instructional explanations that involve concrete representations require that transformations of the concrete representation correspond to the sequence of the solution that is being explained. Moreover, quantitative coherence must be maintained to provide instructional explanations that are numerically accurate, grounded in representations, and build from students' intuitive and informal strategies. Only 6 explanations of the 36 we analyzed maintained quantitative coherence and corresponded with the sequence of the initial solution that was supposed to be explained. Our finding suggests that an important goal for elementary mathematics methods classes is supporting PSTs in maintaining quantitative coherence when using concrete representations and may require explicit focus on the sequence of representation use.

ELEMENTARY TEACHERS' PERSPECTIVES ABOUT THE TENSIONS OF TEACHING MATHEMATICS THROUGH ART AND MUSIC

Crystal Kalinec-Craig
University of Texas at San Antonio
Crystal.kalinec-craig@utsa.edu

In order to help more children to be successful in mathematics, teachers are searching for new ways to leverage children's out-of-school knowledge and experiences while teaching mathematics, specifically with regard to contexts of art and music. The following paper details a subset of a larger phenomenological pilot study about seven elementary teachers as they worked with three artists to craft mathematics lessons that incorporate art and music. The presentation will detail how Kara and Miranda, two third grade teachers, discussed the tensions of teaching elementary mathematics through art and music. Implications for future research and practice regarding the practicality these lessons will be discussed.

Keywords: Elementary School Education; Instructional Activities and Practices; Teacher Education-Inservice

Objectives and Background for the Study

Research in mathematics education suggests that many students, particularly those in traditional classrooms, feel disconnected from their in-school mathematical learning (Greer, Mukhopadhyay, Powell, & Nelson-Barber, 2009). To help more students be successful in mathematics, teachers can explicitly incorporate students' out-of-school knowledge and experiences into their practice (Turner, Gutierrez, Simic-Muller, & Diez-Palomar, 2009). Research frameworks such as those on culturally responsive mathematics teaching (Bonner & Adams, 2012; Gay, 2000), children's multiple mathematical knowledge bases (Turner et al., 2012), and STEAM education (Science, Technology, Engineering, Art, and Mathematics) has provided concrete examples of how teachers might contextualize their practice in the familiar experiences of their students. Research-based frameworks that leverage children's familiar experiences and knowledge for teaching mathematics are particularly important for children who are not typically successful in traditional classrooms (Greer et al., 2009). When teachers use more authentic, non-traditional contexts of art and music, as related to the diversity of children's particular cultures and native languages, more students might learn mathematics more easily (Courey, Balogh, Siker, & Paik, 2012). The purpose of this study was to explore the perceptions of seven elementary teachers as they learn to craft tasks, related to mathematical concepts of fractions and geometry, within Latin@ children's knowledge and experiences with art and music. (It should be noted that the author is using "Latin@" specifically to honor those who do not identify as male or female.) The guiding research questions for this pilot study ask: (1) Prior to the Te'ALaMO (Teachers, Art from Latin@ cultures, and mathematical MOdeling), how did teachers utilize art and music as a context for teaching elementary mathematics, and (2) during the Te'ALaMO, what affordances, tensions, and/or implications for future practice do the teachers describe when considering art and music as a context for teaching elementary mathematics? For this particular brief research report, the authors will focus on the experiences of two third grade colleagues, Kara and Miranda.

Methodology

Te'ALaMO was designed as a qualitative, phenomenological study (Creswell, 2007) that explored the experiences of seven in-service teachers as they learned from a musician, an actress, and a muralist about how to integrate elements of art and music in their mathematics instruction during the summer of 2014. The setting for the study was in a large city in a south-central area of the U.S. where the author is a mathematics teacher educator at a large urban university. Three pre-K, three third grade, and one fifth grade teacher were purposefully recruited for the study from schools that serve large populations of Latin@ children and non-native English speakers and that were nearby a Latin@ community cultural arts center, where the workshop was housed. Prior to the workshop, the teachers discussed their beliefs and prior experiences about using art and music to teach mathematics and then worked on activities with the artists that situated mathematics within playing mariachi music, acting, and designing murals. The research team conducted focus group interviews and collected observational field notes of the activities, teachers' quick reflections at the conclusion of each day regarding their experiences, and an optional demographic survey about the teachers' backgrounds. The researchers also created transcriptions of video and audio recordings of the participants during the workshop.

Because phenomenological research is described through the perspective of the participants, findings based on the data analysis emerged from the teachers' experiences during Te'ALaMO. Data analysis began by reading the transcripts and observational field notes and identifying the ways in which teachers discussed how and why (or why not) they might use art and music as a context for teaching mathematics. Memos (Creswell, 2007) about these emerging themes were created for each day of the workshop and across all three days. The researchers compiled and compared their detailed memos about the teachers' experiences regarding the affordances and tensions of using art and music to teach mathematics as a way of conducting member checks of their findings.

Preliminary Findings

Over the course of the three-day workshop, the teachers learned about mariachi music, performance art, and murals with respect to teaching elementary mathematics concepts such as rational number operations (e.g., equivalent fractions, ratios and proportions) and transformational geometry (e.g., shape attributes, patterns, reflections). As an example, the musician and teachers compared how the structure of music note values (e.g., whole notes, half notes, and quarter notes) was similar to how elementary teachers might introduce the meaning of creating and operating on fractions equivalent to one whole (e.g., one whole note is the same duration as two half notes or four quarter notes when played at the same tempo; 1 = 2/2 or 4/4). Later, the Chicana actress described the nine equal sectors of a performance stage and how this these sectors referred to the actors' relative stage position. Finally on the last day, the muralist extended the discussion about rational numbers by helping the teachers to use proportions and scale to replicate a small picture on a larger poster board.

Many of the teachers like Kara and Miranda, two third grade teachers in the workshop, already utilized some elements of art and music in their daily practice as a mathematics teacher (e.g., children illustrating mathematical representations through drawings, singing songs to help memorize basic facts, students learning about area and perimeter by creating their name in block letters on graph paper). Throughout the workshop, Kara and Miranda were two vocal participants who discussed at length about how the challenges and tensions that they might face if they wish to situate more of their mathematics teaching within the contexts of art and music.

Preparing Students for Standardized Testing While Developing Their Flexible Mathematical Thinking

Although Kara and Miranda discussed many ways that they used art and music to address elementary mathematics concepts with their students, they still recognized that the pressures of standardized testing could be in conflict with their goal to help children develop a flexible understanding of mathematics. Because Kara and Miranda taught in a grade level that was subject to statewide standardized testing, they assumed that other colleagues might not agree that art and music could be a viable context for helping children to learn mathematics. Specifically Kara stated:

> It's hard to sell something like this [teaching mathematics through art and/or music] to other people if you don't have, like, evidence. You know? Especially, when you teach a [name of the standardized test] grade. Oh my God. It's…it's, well 'how's it going to affect the data?' That's like [laughs], always on everybody's mind. But, just with, especially with the first day Te'ALaMO, the [mariachi] music, I could see how much higher order thinking is involved when you're having to count and clap…

In this moment, Kara concluded that she felt the pressure of using art and music to teach elementary mathematics when each moment of her practice as a teacher needed to be tied to some measurable outcome or goal as it related to the state's standardized test. Kara continued her thought by claiming that even though she felt pressure of the standardized test, she still maintained her belief that art and music could help her students to develop a flexible understanding of mathematics. She stated that

> I think a lot of, well, even what we're trained on is that sometimes it's you're teaching the child how to think in ways that they're not used to, and sometimes that's hard, you know? They're being assessed in a certain way, but we're training them to think this one way, and then it's hard for them to think differently. So, giving them all these avenues to express the same sort of idea, you know, I think is important. And I think, you know, as teachers when we come to things like this, we have to be advocates for it at our own campus, you know? I think it's hard to do at third, fourth, and fifth grade, because… You can get other teachers on board with this sort of model [of teaching mathematics through art and music].

Kara concluded that she could address this tension of creative teaching while preparing her students for the yearly standardized test if more of her colleagues adopted non-traditional methods of teaching mathematics by leveraging elements of art and music.

Finding Resources for Implementing Mathematics Lessons that Incorporates Art and Mathematics

Miranda, Kara's colleague at the same school, agreed with Kara's belief that art and music could serve as a flexible context and proposed that she could also address the required elementary standards across multiple content areas. At first, Miranda suggested that art and music " might open some avenues for some of them [the students], you know, and show them how the art can be integrated into math, and engineering, and science, and you know, you can find it everywhere. I think it's, it's fantastic for the kids." Then after the muralist concluded her session on using proportions and scale to create murals from smaller pictures, Miranda reiterated her perception on the final day of the workshop when she stated that

> And I find that I use art, I integrate it a lot with social studies because it's easier…like when we're studying, let's say Cinco De Mayo You know, where we can talk about the history and then we can make something. They make it, a piñata. And so I have two grades. I have my social studies, you know my actual… about the history, and what they wrote in their journals, you know, that grades then I also have an art grade. But now with this [the mural lesson in the workshop], I can integrate it with math.

Miranda described how she already leveraged her Latin@ students' particular students' out-of-school knowledge and experiences (e.g., Cinco De Mayo and piñatas) while teaching social studies, history, art, writing. Now after the mural activity, Miranda could see how she might use a mural about Cinco De Mayo and piñatas that could help her address her mathematics standards as well.

Shortly after the muralist's activity, Kara and Miranda mentioned yet another challenge to implementing similar lessons like the mural activity with their students. Specifically, Kara stated "materials and supplies. Some schools are, you know, really, uh, considered wealthy, right? You get to go into the supply room and get whatever, and then, not all campuses are like that." Because all of the teachers who participated in the workshop worked at schools that served children from mostly economically challenged communities, Kara in particular recognized that although she could teach a lesson that addressed multiple state standards by utilizing elements of art and music, she would have a challenge of finding enough supplies and resources for these lessons.

Implications and Conclusion

As teachers find new ways to support their students' mathematical thinking, they are exploring new contexts by which to connect their lessons to children's out-of-school mathematical knowledge and experiences (Gay, 2000; Wager, 2012). Findings from this study suggest that elementary teachers are working to negotiate both the inherent challenges and potential opportunities for situating their instruction within the contexts of art and music. More research is needed to explore the potential tensions and challenges that teachers might face if they elect to use art and music as a context by which to teach mathematics, particularly with the growing popularity of STEAM education. Furthermore, more research is needed explore how teachers can successful negotiate the challenges with the affordances of using art and music to teach mathematics so that more children develop a flexible understanding of mathematics that is connected to their out-of-school knowledge and experiences.

PROBLEM-SOLVING: ANALYZING NARRATIVE GENRE ASPECTS OF PROSPECTIVE MATHEMATICS TEACHERS' DISCOURSE

Janet M. Liston
The University of Arizona
jliston@math.arizona.edu

This paper reports on an empirical study that examined the language and word choices of three prospective teachers (PTs) of secondary mathematics as they facilitated group discussions with elementary PTs. In the context of a university elementary mathematics content course, groups of PTs collaborated to solve problems involving whole-number and fractional operations. This paper reports on the participation in one such activity that asked PTs to find fractional parts of pattern-block designs. Through a narrative-genre framework, I analyzed how particular language choices of the facilitators functioned to help PTs make sense of problem-solving tasks.

Keywords: Teacher Education-Preservice; Classroom Discourse; Problem Solving

Purpose of the Study

Communication process standards, published by the National Council of Teachers of Mathematics (NCTM, 2000), have emphasized that students should communicate their mathematical thinking clearly and use mathematical language to express ideas precisely. From these ideas we can construe that teachers need to understand how language is used to diagnose student thinking, compare that thinking with desired mathematical understandings, and give appropriate responses through mathematical discourse. However, according to Schleppegrell (2012), using aspects of mathematical language necessary to help all students learn and construct meaning is a key challenge for prospective teachers (PTs). One reason may be that PTs lack classroom experiences and opportunities to converse with students about mathematical ideas. Additionally, PTs may not yet see a need for care in their expression and word choice.

In response to the above and a concern for issues of equity in mathematics education, I draw on the social nature of learning mathematics and argue that language is a primary tool that structures participation discourse practices (Halliday, 1978). And if language can be viewed as the principal resource for making meaning in the classroom, in what ways does this happen? How do particular choices of words function to communicate meaning, negotiate understanding, and invite participation in mathematical discussions? The purpose of this paper is to contribute to the scarce literature on the preparation of secondary mathematics PTs as related to awareness of their language choices and the impact of those choices on student understanding and sense- making. Through a narrative-genre perspective of language, I report findings that explicate ways in which this structure of language is appropriate to the facilitation of mathematical discourse.

Theoretical Perspectives

One way that studies have illuminated important facets of language-use in mathematics is with a semiotic perspective. Language can be described as a semiotic system because it involves sets of meaningful choices in human learning and meaning-making (Halliday & Matthiessen, 2004). According to Eggins (2004), when making a choice of language, what someone says gets its meaning by being interpreted against the background of what could have been said in a particular context – but was not.

While much of mathematical meaning is communicated through the expression of signs and symbols, the use of words and grammatical structures associated with these representations remains the fundamental processes for a *shared construction* of mathematical meaning (Halliday &

Matthiessen, 2004). Different language structures trigger different resulting behaviors, or *functions*, based on the particular choices made. This has been described as a functional-semantic approach to language which explores both how people use language in different contexts, and how language is structured for use as a semiotic system (Eggins, 2004). In alignment with a semiotic perspective, I have drawn on Labov and Waletzky's (1997) six stages of narrative-genre for discourse (see Table 1) in an analysis of PTs' language choices as they facilitated problem-solving discourse in group discussions. Here I focus my attention on the question: In what ways do secondary PTs facilitate and structure mathematical discourse through their choices of language and words?

Table 1: Six Stages of Narrative Genre Adapted for Mathematical Discourse

Stage	Name		Narrative Speech Function	Associated Examples of Mathematical Speech Function
1.	Abstract	A	Here, the facilitator cues the listeners that there is a story to tell.	"This task is about…" "You will be asked to…"
2.	Orientation Or Launch	O	Here, the facilitator presents necessary preliminary information needed to understand the problem.	"In this task, we know about…" "Think about this task based on your own experiences with…"
3.	Complication	C	Here, the facilitator introduces one or more problems that need to be solved.	"But we don't know for sure if…" "I didn't think we needed to…"
4.	Evaluation	E	Here, the facilitator makes clear what needs to be accomplished, why the audience should keep listening.	"I have a feeling that you are thinking…" "We still need to continue to…"
5.	Resolution	R	Here, the facilitator helps release the tension and sort out the problem.	"What you say makes sense to the problem…"
6.	Coda or Re-launch	C / R	Here, the facilitator refers back to the theme of the first stage and restates the problem.	"If you remember, we also need to…" "This only addresses part of what we need to do…"

Data Sources and Analysis

This study took place in a content course for PTs of elementary mathematics. Four secondary PTs volunteered to facilitate group discussions because they wanted to strengthen their abilities to communicate effectively with others whose perspectives of what it means to 'do mathematics' might differ from their own. Despite apparent differences in elementary and secondary curriculums, there are overlapping algebraic and geometric concepts, and novice teachers in high schools are often asked to teach beginning algebra and geometry courses. The primary source of data came from audio-recorded mathematical dialogues between 16 elementary PTs in the course (hereafter referred to as students) and the four secondary PTs (hereafter referred to as *facilitators*). Four students and one facilitator comprised each group.

Audio-recordings of six problem-solving activities were distributed over 15 weeks, resulting in 24 transcripts total. Additional data (interviews/debriefs) helped me pay specific attention to each facilitator's personal recollection of the problem-solving events. As the instructor, I chose tasks specific to the course's curriculum involving whole-number and fractional operations.

T his paper highlights an analysis of three transcripts of audio-recordings in which three groups (each with a different facilitator) discussed the task: *The yellow hexagon pattern tile is 3/2 of the area of a second pattern tile design. Use pattern tiles to make what could be the second pattern design.* These three transcripts were selected from a larger set of classroom observations collected over one spring semester. Using Labov and Waletzky's (1997) six stages of narrative-genre analysis, I systematically coded excerpts of each facilitator's language choices, which were then analyzed as to how closely they followed the narrative-genre scheme of *abstract (A), orientation (O), complication (C), evaluation (E), resolution (R), coda (C/R)* (see Table 2). Subsequent interviews and debrief sessions provided insight into the ways that particular excerpts of language choices functioned to direct and structure meaningful discourse.

Table 2: Order of Narrative-Genre Codes Used by Facilitators

Facilitator																						
Brice	A	O	C	C/R	E	C	C	E	C/R	C	C/R	E	C/R	E	C	C/R	E	C	E	R	C	R
Beatrice	O	O	O	E	E	R	E	C	R	E	R											
Linda	O	C	E	E	R	C	C/R	C	E	C	R	E	R	E	R							

Findings

The codes revealed that the facilitators structured discourse in different ways. Overall, Brice was more successful helping his group realize that the second shape would consist of two blue rhombi (or four green triangles). The number of coded excerpts revealed that Brice had more verbal interaction with his group, and that he structured those interactions in a way that restated the task (*coda/re-launch*, C/R) for his group five separate times. Each time, he used a different choice of words which functioned to draw attention to various aspects of the task's goals–that is, needing the yellow hexagon to be 3/2 of the area of the second shape. This refocused the group's thinking and helped to put a spotlight on what still needed to be accomplished. The following excerpt demonstrates one of Brice's C-E-C/R cycles; Brice restated the task's goal in this excerpt because his evaluation did not connect in a way that made sense for the student:

> *Student:* Okay, so we broke that [the yellow hexagon] into three [equal parts] with the blue ones (rhombi), right? Now there's 3/2s, so don't I need-? Now what? [*Complication* because the PT does not connect her idea to the new design asked for in the task.]
>
> *Brice:* So you're saying that this [the PTs' new design of two blue rhombi] would be the whole…and that we're going to make three halves, so if I were to add (two blue rhombi) plus half of this again, it would equal this (the yellow hexagon)? [*Evaluation*]
>
> *Student:* What do you mean?
>
> *Brice:* So remember, you are to make sure the yellow hexagon is three of the half-parts that make up the new design. [*Coda/Re-launch]*.

Beatrice and Linda did not structure their discourse as closely to the narrative scheme as Brice did. The codes revealed little use of the *re-launch* stage (one *re-launch* used by Beatrice and none used by Linda). Consequently, the group members lost focus and conversation slowed. Linda's evaluations were vague (she self-reported not wanting to give out too much information) and included such language as "you're getting close" and "I like your idea". While encouraging in nature, those words did not structure the discourse towards promoting further thinking about the task. Beatrice self-reported that she felt at times "unconnected" to the group's ideas and therefore, felt safer in telling them how she was thinking. Beatrice told her group "what they're trying to tell you is that the hexagon is the larger part of a whole. So the whole is going to be smaller than the hexagon, right?" These words served to inform the group members how to think and consequently stopped any further thinking about the relative sizes of the two designs.

Discussion and Conclusion

Mathematics education researchers and linguists (e.g., Halliday & Matthiessen, 2004; Herbel-Eisenmann & Otten, 2011) have brought increased attention to the ways that language functions to make meaning in mathematical activities. For this study I defined *successful facilitation* of mathematical discourse not necessarily by the lengths of conversation or whether groups found solutions, but more by the ways in which the facilitators' words helped the students make sense of the task and take up peers' ideas. In analyzing discourse patterns revealed in this study, I determined that a facilitation cycle of *complication,* followed by *evaluation* and then by *coda/re-launch* [C-E-C/R] was more successful than other cycles of discourse. Additionally, this study suggested that the C-E-C/R cycle may not only be a use of language, but also a way of thinking. That is, this cycle reflected the facilitators' thinking about the task and also served to re-focus the group's thinking about the task. Brice's use of this cycle ("let's go back and think about how the yellow hexagon has to compare to the new shape we're trying to build") functioned to lead the students to find a solution that made sense. Mathematical discourse plays an important role in this way by shedding light on the functions of various language choices and how those choices structure discussions and thinking towards making meaning (Barton, 2008).

Moschkovich (2010) has maintained that teachers need to create and sustain environments for learning and what takes hold across tasks and practices in these environments. As both elementary and secondary PTs endeavor to use reform pedagogy and communicate effectively with students, an understanding of how their own language choices structure discourse and shape meaning-making aspects of understanding mathematics becomes important. Through an analysis of data from a linguistic perspective, I was led to posit that a narrative-genre analysis could help both PTs and teacher educators identify structures of language-use that facilitate discourse effectively. Further research into how discourse structures connect with and promote students' thinking about mathematical tasks can help teacher educators better prepare PTs to facilitate mathematical discussions in the classroom. Analyzing word choices through Labov and Waletzky's (1997) narrative framework has the potential to shed light on why some mathematical conversations stall and others result in deeper connections of mathematical ideas.

In trying to promote equitable mathematics education systems, we see a need to aim at developing the role of allies when we work with mathematics teachers and students. With the goal to better understand what being an ally *means and what* ally-work *involves, we review literature outside of mathematics education that describe how allies support more equitable systems. In this report, we synthesize this work in order to engage the mathematics education community in discussing how we might do this work.*

Keywords: Equity and Diversity, Teacher Education-Inservice, Affect and Beliefs

Although the term "stakeholder" has been common when referring to those that have a vested interest in education, such as parents, teacher educators, and community members, we expand the function of a stakeholder by focusing on "allies" in our work in schools. Mathematics education research clearly shows that the system of schooling and mathematics education result in inequitable practices and experiences for many students (e.g., Martin, 2009), aspects of education that the idea of stakeholder does not address. Thus, this brief research report focuses on a conceptual exploration of *ally* and *ally-work* to address issues of equity in mathematics education. As Hand (2003) has argued, mathematical teaching and learning for students from dominant versus nondominant racial, ethnic, linguistic, and socioeconomic backgrounds have resulted in visible "participation gaps" in mathematics classrooms. We believe these disparities must be understood in terms of the distribution of opportunities to learn (OTL) (Gresalfi & Cobb, 2006).OTL are not dependent upon students alone, but on an equitable system that may ensure powerful mathematics learning for minoritized student groups (Martin,2009;Moschkovich,2010). *Fair distribution* of OTL for diverse students is promoted through an "equitable system", which refers to intersecting levels of synergistic support for these students (Hand, Penuel, & Gutiérrez, 2012). This systemic support can be augmented through the engagement of *allies* in disrupting systems of privilege and oppression in education (e.g., Swalwell, 2012; Tatum, 1994).

We review literature outside of mathematics education to explore what being an *ally* means and what *ally-work* involves. We synthesize this literature in order to engage the mathematics education community in discussing how we might do this work. We do this not only because we think the idea of allies deserves conceptual attention in mathematics education but also because we are hoping to negotiate and study an equitable system in an urban district with the goal of promoting a fair distribution of OTL for students who have experienced longstanding marginalization in mathematics education and for the teachers who teach them.

Being an Ally and Ally-Work

We synthesize a series of definitions and stances. First, we describe the roles and functions of an ally. Second, we present some challenges and tensions described in the consulted literature.

Ally-Work is Cyclical (Inward-Outward) and Expansive (Collaborative)

Jenkins (2009) and Clark (2010) define who an "ally" is by comparing similar ideas like "advocates," "anti-work," and "agents," juxtaposing the levels of social justice commitment, empathy, and action. Accordingly, these authors argue that allies are people strongly oriented at supporting oppressed groups. Allies' stances stem from an awareness of the systemic forces that maintain oppression and how these systems inherently disadvantage others. Allies' stances first work inwards by recognizing their "unearned privileges" in a community; then their work and stances expand outwards by embracing their "obligations of privilege" (Clark, 2010, p. 707).

Contrastingly, Jenkins (2009) describes an advocate as a defender, one who pleads for a cause. An advocate may speak up but may or may not engage in action. Similarly, Clark (2010) characterizes "the mere silencing of hate-talk" as "anti-work" (p. 712). Advocates' work represents a type of anti-work through the process of interrupting acts of oppression against marginalized people, actions that are effective in the presence of advocates. These changes, however, are situational and temporary. Jenkins also contrasts ally-work with an agent's work. An agent is a person with power to act and force change. "Agents may or may not identify with the community or group on whose behalf they are acting. Agents orient themselves toward action and go beyond developing empathetic relations or vocal oppositions; they work to create change within dimensions of society in which they may or may not have power (p. 28). Furthermore, Philip et al. (2014) define *ally* as a discursive position that educational scholars of color take in their work with teachers by a humble approach of learning from teachers, addressing issues of racism with teachers at school, and helping them understand the impact on students of neoliberal reforms. Additionally, scholars with teaching experience are *allies* with nuanced understanding of the teachers' work through own experience, or *teacher solidarity.*

As a result, ally-work encompasses the work of an advocate and an empathic co-worker, an agentive work that is cyclical and expansive. As a cyclical process, it starts through an inward questioning and internal transformation of dispositions. Then, this renovated perspective expands outwardly to others in joint action to support change. Ally-work addresses a twofold change, first by inviting others to engage in a "critical dialogue and discussion, interrogating perceived lines of difference and [then] inquiring into the possibilities for creating productive alliances across these lines" (Clark, 2010, p. 705). Through this dialogue participants have "an opportunity to come into contact with likeminded others and find social support for their struggles" (DeTurk, 2006, p. 44). Then a mutual and intercultural understanding is built through "perspective taking and corresponding changes in participants' beliefs, attitudes, and behavior" (p. 47). A relational identity nurtures a genuine empathy that naturally leads to action and to effect changes. Clark argues that ally-work implies a conscious decision to combat disadvantages and inequities by strategically combining self-awareness, empathy, commitment, and action to promote change.

Ally-Work Encompasses an Identity of Tensions and Relative Power

Being an ally represents "an identity that is achieved by acting on the moral imperatives of pursuing social justice and validating differences" (DeTurk, 2011, p. 575).In their support of marginalized groups in relation to sex, race, or any other social identity, allies make use of their social and cultural capital to effect change and influence others. This means that their social identities matter in their context of action. In the U.S. context, DeTurk (2011) asserts that" being White, male, heterosexual, able-bodied, fluent in English, or otherwise equipped with such capital, are relatively powerful in their capacity to influence others" (p. 577). For example, an African American man described how a Black ally needs the support or "validation" of a White person because a White person's social and cultural capital is privileged by the system (DeTurk, 2011). Thus, allies' successful efforts to confront racism and sexism depends" on how much power they had in a given situation" (DeTurk, 2011, p. 578).

Nevertheless, DeTurk (2011) complicates simplistic perspectives on power, arguing that power is fluid, multifaceted, and contingent. So, in-group members like African American persons "could act as allies to Whites by interrupting anti-White prejudice" (p. 584). Likewise, an ally self-identifying as a gay man could promote closer connection as an ally to other gay men. Furthermore and equally strong might be when a heterosexual man is an ally of a gay-men group. But overall the matching of these different power dynamics highlights the contextualized, fluid, and yet systemic nature of power. Membership to a social and cultural group does not determine an absolute power or lack thereof. Allies aware of these dynamics need to develop tactics and alliances that crisscross different groups to support each other.

A tension in being an ally concerns preventing allies' risk (i.e., personal safety, relationships, or status) because, at times, allies can feel their personal wellbeing is threatened (DeTurk, 2011). A greater ethical and moral tension is related to speaking for others or overprotectiveness. Allies asserted that taking actions, of speaking for others, might disempower those who are to be empowered and thus, reinforce oppression. DeTurk (2011) warns that overemphasis on dialogue might highlight mainstream values as well, and the demanding of such procedures might reinforce a laden procedure that only serves "enlightened self-interest" (p. 584). Thus, negotiations need careful procedures.

Finally, Kelly and Chapman (2015) introduce the term "adversarial ally" to identify an issue in ally-work for those in disadvantage. An ally might "unambiguously harm a client and in another moment unambiguously help that same person" (p. 48). Specifically to the context of health services, people with disabilities have limited options for health care. So though patients might experience these services as helpful and necessary, they also may experience them as harmful and oppressive. The adversarial aspect of being an "ally' in this situation is that despite health professionals' stance of empathy and caring action towards people with disabilities, their uncritical support for and work in an oppressive system that limits health care options for people in need, perpetuates an inequitable system.

Being an Ally in Education and Mathematics Education

Although an increasing percentage of school children in the United States are children of color, poor, and from homes where family members speak languages other than English—all potential sources of privilege and oppression—mathematics teachers (MTs) and mathematics teacher educators(MTEs) remain fairly homogeneous along these demographic lines (Hollins & Guzman, 2005). Thus, thoughtful attention to how these differences matter in mathematics classrooms and professional development is necessary. Actions of ally educators in their classrooms oppose the disadvantages that some students may have by providing "extra time and attention towards those in need" (p. 708) and including curricular content that challenges normative notions. Only through explicit and critical action will ally-work promote just, equitable, and safer spaces for diverse students. For example, many teachers feel that it is necessary to take corrective action in order to help students of color to acquire mainstream American English, without acknowledging these student's identities and where they come (Clark, 2010).Ally-work actions need to be critically assessed through equity lenses as the OTL mathematics include not only what students learn, but also how they learn it (Esmonde, 2009).

MTEs seeking to promote equitable systems in mathematics education would benefit from ally-work beyond roles as advocates or agents. Developing an intercultural communication with MTs and students could help with constructing an alliance built on mutual understandings and promoting and sustaining generative action. We would need to become *allies with* MTs, students, and each other.

Our goal would be to learn from one another through participatory action research, and accordingly adapt our work so that MTs work with us, and each other, as agents of change in their own classrooms by making curricular adaptations responsive to their students' interests and needs. Building dialectic relationships and transferring them into collective action are central points in ally-work.

In our presentation, we expand on these ideas in order to prompt discussion about the role of allies and ally-work in mathematics education. For this, we will provide transcripts of our team's reflections. As MTEs, we believe acknowledging power is crucial. Being aware of the relative power of our social and cultural capital can guide us to examine and contextualize our actions. In our work with MTs and students, the success of our roles and relationships must be re-evaluated on a regular basis and contrasted with the expectations and goals of students and MTs. Tensions must be embraced as learning sources and opportunities to develop stronger connections with others. If tensions do not emerge, an exhaustive examination of our stances and actions is required. Likewise, diversity should be constantly addressed not only related to race, culture, language, and gender, but also academically in how we define what counts as mathematics.

THE MATHEMATICS NEEDED BY ELEMENTARY TEACHERS: DO TEDS-M AND MET II AGREE?

Edward Silver
University of Michigan
easilver@umich.edu

Jillian P. Mortimer
University of Michigan
jbpet@umich.edu

We investigated the relationship between two representations of mathematical knowledge for teaching: the Mathematical Education of Teachers II (MET II) report and the Teacher Education and Development Study in Mathematics (TEDS-M) knowledge assessment. Expert raters matched MET II specifications to TEDS-M items, finding a suitable match for almost every item. Inter-rater agreement was high for mathematical content expectations, but much lower for mathematical practices. Ratings indicated that TEDS-M released items mapped onto some but not all MET II content domains. The findings suggest that the two representations are well aligned in some respects though not in others.

Keywords: Teacher Knowledge; Standards; Elementary School Education; Assessment and Evaluation

Purpose

A longstanding argument in the educational research literature holds that teachers' knowledge is related to students' achievement in mathematics. However, there has been a lack of detailed examination of the ways in which and the extent to which different specifications agree or disagree about the mathematics knowledge that teachers need in order to be effective. Such examination is essential to identifying commonalities and sharpening points of disagreement, both of which are critical to moving the field forward both in research related to teacher knowledge and in the development of programs to prepare novices to be effective teachers.

In this study we examined the alignment between two representations of essential knowledge for mathematics teachers: the Teacher Education and Development Study in Mathematics (TEDS-M) knowledge assessment for elementary teachers (using the released items) (Tatto, 2013) and the Mathematical Education of Teachers II (MET II) report (including the essential ideas (EIs) for elementary and middle grades teachers and the Common Core Standards for Mathematical Practice (SMPs)) (CBMS, 2012). Understanding the ways in which and extent to which these two representations align should benefit researchers and practitioners alike.

Conceptual Foundation

Our study rests on and draws from two distinct research literatures: scholarship on mathematical knowledge for teaching (MKT) and studies of alignment between and among key elements of educational systems. Each is briefly summarized in this section.

Teachers' Mathematical Knowledge

Shulman (1986, 1987) is widely credited with drawing attention to teachers' knowledge and how the ways teachers know content might differ from the ways it is known by other professionals. As it has become known in mathematics education, MKT has been theorized and studied from a variety of perspectives including efforts to specify the nature and structure of the knowledge needed for effective teaching of mathematics (e.g., Ball & Bass, 2000; Davis & Simmt, 2006), and the relationship among teachers' mathematical knowledge, their instructional decisions and practices, and student achievement (e.g., Hill, Rowan & Ball, 2005). This corpus of scholarship illustrates the value of having both theoretically derived conceptions of knowledge for teaching and empirically validated assessments that reliably test such knowledge.

Alignment

The concept of aligning standards and assessments gained momentum in school mathematics with the advent of the NCTM standards (NCTM, 1989). Webb (2002) outlines four criteria that can be used in alignment studies between state academic standards and assessments and are a subset of his criteria of content focus: categorical concurrence, depth-of-knowledge consistency, range-of-knowledge correspondence, and balance of representation. The focus of our analysis in this study was categorical concurrence.

Methods

Expert Raters

In order to explore the alignment between the TEDS-M elementary knowledge assessment and the MET II EIs and SMPs we solicited the judgments of four experts in mathematics and mathematics education. We chose two who had been involved in creating and/or reviewing items for the TEDS-M assessment and two who were among the authorship team for the MET II document. Each pair included one mathematician and one mathematics teacher educator (MTE). The selection of expert raters was purposeful in that it allowed us to probe the possible influence of the raters' prior familiarity with one of the representations (TEDS-M vs. MET II) or their professional training (mathematician vs. MTE).

The Rating Task

Each expert rater was given the released TEDS-M assessment items, the MET II EIs for elementary and middle grades teachers, a description of the SMPs, and a recording tool. For each item the expert raters were asked to identify, if possible, an EI and a SMP that best fit the item. There was an "Other" option for instances when a rater judged that an item pertained to a particular domain but did not fit with any of the specific EIs; raters also had an option to identify primary and secondary EIs or SMPs in cases where more than one applied. We conducted follow-up interviews with individuals and pairs of raters to probe the raters' thinking for selected items and to gather their impressions of the rating procedures.

MET II Essential Idea and SMP Agreement

Expert raters could be paired based on their document affiliation (TEDS-M or MET II) or their professional training (MTE or mathematician). This resulted in four different pairs: TEDS-M, MET II, mathematicians, and MTEs, with each rater belonging to two pairs. Agreement between pairs regarding the EIs was calculated in three mutually exclusive ways: Identical Agreement (IA) was the percent of cases where rater pairs assigned exactly the same EI to a test item; Domain Agreement (DA) was the percent of cases where two expert raters disagreed on the exact EI that fit a test item, but the EIs they assigned were within the same domain; and Secondary Agreement (SA) was the percent of cases where expert raters disagreed on both the primary EI and MET II domain that fit an item, but one rater in a pair identified the primary EI of the other expert rater as a secondary EI. We similarly calculated instances of rater agreement for SMPs, except that the DA category was not applicable to SMPs because they are not organized by domains. Because the agreement categories were mutually exclusive, we were also able to sum across categories for each pair of raters to obtain a percent of Total Agreement.

Representation of MET II EIs in the TEDS-M Knowledge Assessment

Following the agreement calculations, we examined the representation of MET II domains within the released TEDS-M items by grouping all of the EIs by domain to give a more manageable picture of the representation of the kinds of content included in the assessment

Results

The Rating Task

In 99% of cases expert raters were able to assign either a specific MET EI or a rating of "Other" within a domain to TEDS-M items. Additionally, expert raters were able to assign SMPs to TEDS-M items in 90% of the cases.

Agreement Between Raters on MET II Essential Ideas and Mathematical Practices

Table 1 shows the types of agreement for different pairings of expert raters when assigning EIs and SMPs to TEDS-M assessment items. The percent of Identical Agreement was near 50% for all rater pairs. Given that there are 42 different EIs, assigning the exact same EI to TEDS-M assessment items around half of the time is a high level of agreement. Two rater pairs had exceptionally high Total Agreement, and the other two had acceptably high agreement of this type. On the other hand, the extent of Identical Agreement and Total Agreement for SMPs was considerably lower.

Table 1: Inter-rater Agreement for EIs and SMPs by Rater Pair and Type of Agreement

Agreement Type	MET II Pair	TEDS-M Pair	MTE Pair	Mathematician Pair
MET EIs				
IA	56%	44%	44%	47%
DA	32%	24%	27%	15%
SA	3%	6%	21%	18%
Total	91%	74%	92%	80%
SMPs				
IA	21%	35%	29%	24%
SA	21%	0%	9%	3%
Total	42%	35%	38%	27%

Representation of MET II EI Domains in the TEDS-M Knowledge Assessment

There was variation in the degree to which MET II domains were represented in the released items. EIs in the domains of "Measurement and Data," "The Number System" and "Expressions and Equations" were assigned more than 25 times. In contrast, none of the EIs in "Counting and Cardinality" and "Number and Operations-Fractions" were assigned to any TEDS-M released item. Additionally, EIs in "Statistics and Probability" were assigned in only four instances.

Discussion

Through this examination of the relationship between the TEDS-M knowledge assessment and MET II expectations we found that experts were able to assign MET II EIs to TEDS-M assessment items with high inter-rater agreement. This suggests that the MET II document and the TEDS-M assessment are viewed by experts as depicting a similar view of the mathematics content knowledge needed by elementary teachers. The highest levels of agreement were found for the MET II and the MTE pairs.

Though the expert raters also mapped SMPs onto almost all TEDS-M items, they exhibited far less agreement. In fact, the percent of Total Agreement for SMPs was lower than the percent of Identical Agreement for EIs for all four rater pairs. As there are only eight SMPs one might expect the levels of agreement to be higher for SMPs than for EIs. On the other hand, the SMPs are not described in either the MET II or the CCSSM documents at the same level of detail that characterizes the description of content expectations. In follow-up interviews the raters noted both that many of the assessment items seemed to align with multiple SMPs and that it was more challenging to identify a primary SMP than was the case for EIs. The highest level of agreement was found for the MET II pair, and the lowest was for the mathematician pair. The low agreement between the mathematicians is surprising given the presumption that SMPs are fundamental to doing mathematics.

Another noteworthy finding was the unevenness of the correspondence of TEDS-M items to MET II content domains. Raters judged very few items to be related to EIs in the domain of statistics and probability, and there was a complete absence of items tied to EIs in the domain of fractions. Because these two domains are foundational in elementary mathematics education, this finding needs further examination to see if it is attributable simply to unfortunate omissions in the selection of publicly released items or if it reveals a limitation in the content coverage of the TEDS-M assessment.

Given the array of different conceptualizations and assessments of knowledge needed to teach mathematics, a careful examination of similarities and differences seems wise to inform both research and teacher education. A clear understanding of different conceptualizations of what teachers need to know to be successful will support researchers to study this knowledge and teacher educators to nurture its development. The study reported here is a first step in what we hope will be a larger scale effort to interrogate and integrate across disparate views of the mathematical knowledge needed to teach elementary school mathematics.

SIMULATING TEACHING: NEW POSSIBILITIES FOR ASSESSING TEACHING PRACTICES

This paper argues that successful practice-based teacher education requires innovations in assessment that can better inform preservice teachers and those who prepare them. Such assessments must focus directly on specific teaching practices of novice teachers, as well as offer opportunities to assess the use of content knowledge for teaching. Simulations, an assessment type used in other professional fields, hold promise as one means for gathering data about and providing feedback on teaching. To explain how this could work, we describe an assessment that focuses on preservice teachers' ability to elicit and interpret a student's mathematical thinking, and we appraise what it makes possible.

Keywords: Assessment and Evaluation; Instructional Activities and Practices; Teacher Education-Preservice

The Need for Assessments of Practice

The increasing focus on specific instructional practices in initial teacher preparation means that there is a need to develop ways to assess preservice teachers' teaching in new and more precise ways. Assessing preservice teachers' ability to describe, analyze, or reflect on practice does not provide sufficient insight into their development. Further, novice teachers need specific feedback about their practice (Grossman, 2010).

Assessment of teaching practice is not new in teacher preparation. Approaches have focused on appraising preservice teachers in real context of practice, such as in field placements and during student teaching, and have included microteaching, field-based performance tasks, and systematic field observation of lessons (e.g., Hamerness, Darling-Hammond, & Bransford 2005; NCATE, 2003). In field-based assessments, however, contextual factors affect preservice teachers' performance. Although context is a reality of practice, field placement contexts are unique for each preservice teacher, which makes it more difficult for teacher educators to obtain reliable estimates of their preservice teachers' teaching capabilities. For example, our teacher preparation program, like many, used interviews conducted in their field placements to assess our preservice teachers' skill with eliciting and interpreting student thinking. They probed children about their mathematical thinking and then they later analyzed the interviews to make claims about the children's understandings (Sleep & Boerst, 2012). Using video records, instructors were able to see and provide feedback on the types of questions posed, how well they attended to and used children's mathematical ideas, as well their manner with the children. We were also able to assess the quality of their interpretations of the children's thinking. However, issues of fairness arose because some children were less forthcoming with their thinking than others and required different sorts of probing questions to elicit their thinking. Further, because instructors did not know the children themselves, they could not determine whether the preservice teachers were accurately uncovering children's thinking. As a result, it was also not possible to detect patterns in preservice teachers' skills overall within the program. This paper describes work we have been doing since 2011 to develop and investigate the use of simulations as a complementary form of assessment that can address some of the shortcomings of previous approaches.

The Use of Simulations in Professional Preparation

Simulations are used in many other professional fields. In many medical schools, doctors in training engage in simulations of physical examinations, patient counseling, and medical history taking by interacting with "standardized patients," adults who are trained to act as patients who have specified characteristics. Evaluation of medical students' interactions with standardized patients makes possible common appraisal of candidates' knowledge and skills. In medicine, simulations have been used for formative assessment for over 40 years and are currently used in high-stakes medical licensure examinations (Boulet, Smee, Dillon, Gimpel, 2009). In nursing schools, simulations are used to develop and practice clinical skills, including skills difficult to develop and practice on an actual patient. Many of these simulations make use of mannequins (robots) that can be programmed to behave in particular ways and to exhibit particular symptoms. Simulations have not been widely used in education, for either learning opportunities or assessment purposes. There are beginning to be examples of programs using them to support the learning of skills such as managing a classroom (Dieker, Straub, Hughes, Hynes, & Hardin, 2014*),* conducting a parent conference (Dotger & Sapon-Shevin, 2009), and school leader development (Dotger, 2014); however, the use of simulations for assessment has been limited.

A Simulation Assessment of Skill with Eliciting and Interpreting Student Thinking

To concretize ideas of simulations in assessing teaching practice, we turn now to describe an assessment that we developed and are now using of preservice teachers' ability to elicit and interpret student thinking. The assessment makes use of a standardized student (i.e., someone playing the role of a student) and takes about 25 minutes to complete.

In the first part of the assessment, preservice teachers are given a copy of the standardized student's work on a problem (see Figure 1) and they have 10 minutes to prepare for an interaction with one standardized student about her work. Because the student's work produces the correct answer, the task is to determine how the student reasoned about the problem and what she understands. Students can use an array of methods different from those familiar to adults, and an important task of teaching is to probe and make sense of students' mathematical processes and understanding, both when they seem obvious and when they do not. This is particularly demanding for novice teachers who are likely to know less about non-standard approaches.

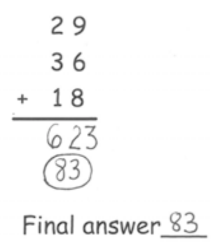

Figure 1.A Student Work Sample on an Addition Problem

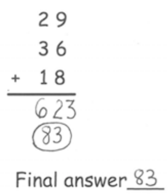
In the second part of the assessment, preservice teachers have five minutes to interact with the standardized student. Preservice teachers are told that they should elicit and probe the standardized student's thinking to understand the steps she took, why she performed particular steps, and her understanding of the key mathematical ideas involved. To ensure consistency, the role of the standardized student is guided by carefully articulated rules for reasoning and responding, including responses to questions that are commonly asked, referred to as the "student profile" (see Figure 2). In this case, the student uses an alternative algorithm to solve the problem. The student added the digits in each column, starting with the tens. The student interpreted the 623 in the written work as 6 “tens” and 23 “ones” and produced the final answer of 83.

In the third part of the assessment, the assessor asks a series of questions to elicit the preservice teacher’s interpretation of the student’s process and her understanding. Further, the preservice teacher is asked to predict, based on what the interaction revealed, how the student would solve 27 + 48 and what she would understand about several key mathematical ideas.

Student work:



General orientation to responses:
- do not make basic facts errors
- give the least amount of information that is still responsive to the preservice teacher’s question
- if a question is confusing, say something like, “What do you mean?”
- do not write unless you are asked to write

The student:
- uses the column addition method, except that the student is working from left to right
- correctly applies the column addition method for solving addition problems
- can use the same process to solve addition problems with more than two digits, understands when/why/how to “combine”
- has conceptual understanding of the procedure (e.g., “six hundred and twenty-three” is not the answer because we have to combine the tens)
- is thinking about 623 as 6 tens and 23 ones
- can tell that the sum of 83 is reasonable

Specific responses (*a subset of them*):

Preservice teacher prompt	*Response*
What did you do first?	I added the tens: 2 + 3 + 1 and I got 6.
How did you get from 623 to 83?	I had to combine the 6 and the 2.
Why did you need to combine those numbers?	Because they’re both tens.

Figure 2.An Excerpt from the Standardized Student Profile

The assessment is scored using checklists with the criteria for proficient performance, including both mathematical and pedagogical aspects as it is being completed. Criteria for eliciting are keyed to specific parts of the task (e.g., probes for why the student combines the 6 and the 2) as well as how the preservice teacher takes up specific things that the student did or said. The interpreting criteria focus on the accuracy of the explanation of the student’s thinking and the use of evidence to predict the student’s performance on a similar problem.

Features of the Assessment Situation

In designing assessment scenarios, we make choices about the authenticity and familiarity of the context. Although the teaching context itself is a simulation, some features are nonetheless authentic. For example, the student work is ambiguous with respect to the student’s process (e.g., How did the student get from 623 to the final answer of 83?) and understanding of the core mathematical ideas (e.g., What does the student interpret the “623” to mean?). This means that preservice teachers cannot know in advance how the interaction will unfold. In addition, just as in actual classroom practice, the interaction occurs in real time, which requires teachers to generate questions on the fly in response to the student.

The inauthentic aspects of the assessment actually enable more systematic evaluation of skills. First, all preservice teachers elicit student thinking about the same mathematics content, which avoids the issue of some content being easier or harder to elicit student thinking about. Second, that our preservice teachers are all interacting with a standardized student means that we are able to see their skills under the same conditions. Third, we are able to focus this particular assessment squarely on eliciting and interpreting student thinking, not on other aspects of teaching — also important — such as building relationships with students.

What Simulation Assessments Can Offer

Simulation assessments present one promising possibility for improving assessment of teaching practice. We use these in our program to learn about how our preservice teachers are developing and how we can support improvement in their skills. But we also assess their skills on entry to the program and this, too, has been useful. One year, for example, we found that almost all our entering preservice teachers asked about the student's process for solving a mathematics problem; however, fewer than half of them asked about the student's understanding. Further, they rarely posed follow-up problems (6%) to confirm the student's process or understanding. When asked to produce a problem that could be used to confirm the student's approach, only 54% of preservice teachers were able to generate a numerical example that would present the same conditions as the original problem. These baseline data provided crucial information as we set out to develop our preservice teachers' skills. We are also finding that these assessments support us in providing more detailed and specific feedback to our preservice teachers that can help them improve their practice. In our current work, we are continuing to investigate the validity and practicality of simulation assessments, including exploring their feasibility and design entailments. We are also conducting validation studies that examine the relationship between performances in simulations with performances in classroom contexts.

SUPPORTING TEACHERS USING APPROPRIATE TOOLS STRATEGICALLY: A PRACTICAL FRAMEWORK FOR SELECTING AND REVISING DGS TASKS

Milan Sherman	Charity Cayton	Kayla Chandler
Drake University	East Carolina University	North Carolina State University
milan.sherman@drake.edu	caytonc@ecu.edu	kcchand2@ncsu.edu

Given the implications of high cognitive demand tasks for student learning, we sought to determine how to support teachers in selecting or designing tasks that use Dynamic Geometry Software to support students' high-level thinking. We discuss the development of a practical framework for supporting teachers in this important work of teaching. The framework integrates Sinclair's Design Principles (2003) and the amplifier and reorganizer metaphor for technology use (Pea, 1987) in order to assess the role of technology in relation the thinking requirements of a task. Following the description of the framework and its development, we discuss results regarding how pre- and in-service teachers used the framework to evaluate and revise tasks found in current Geometry textbooks.

Keywords: Technology, Teacher Education-Preservice; Teacher Education-Inservice; Teacher Knowledge

The Common Core State Standards in Mathematics identify students' ability to use appropriate tools strategically as an important mathematical practice. We believe a similar principle applies to teachers: that they must be discerning users of technology in considering how to effectively achieve certain mathematical goals with their students. However, there are few practical tools available to assess the role of technology in a given task. One lens for analyzing a technology task is the way it supports students' mathematical thinking. Research on student learning shows that students who engaged with tasks requiring high levels of mathematical thinking demonstrated a greater ability to problem solve, make connections, and communicate their thinking than those who did not (Stein & Lane, 1996). Thus, it is important to support teachers in selecting high-level tasks to implement with their students. This paper describes a framework for selecting and revising technology tasks to support students' high level mathematical thinking, and efforts to implement it with teachers.

Theoretical Framework

Dynamic geometry systems (DGS) support the learning of important mathematics (Hollebrands & Dove, 2011) and support students' mathematical thinking (Sherman, 2014; Cayton, 2012). We have analyzed numerous mathematical tasks that use DGS in order to better understand the role of technology in supporting students' mathematical thinking. In this section we describe the theoretical and research bases guiding our development of a framework to help teachers judge the potential of a DGS task to encourage students' high-level thinking.

Sinclair's Design Principles

An important principle of using technology strategically for mathematics instruction is that the inclusion or exclusion of technology within a given task should depend on mathematical goal(s). Only then can a teacher decide which tools, technological or otherwise, may be most effective in accomplishing that goal. Sinclair (2003) describes design principles related to how the *sketch*, i.e., technological representation of mathematical objects, and associated prompts for students' activity, should depend on the goal of the task. We use these principles to identify three overarching goals for students' mathematical activity: making mathematically meaningful observations, mathematical exploration, and fostering curiosity/modifying thinking. Along each dimension, technology plays a role in achieving the goal, and the metaphor of using technology as an *amplifier* or a *reorganizer* provides a way to describe the role that technology plays.

Amplifier and Reorganizer Metaphors of Technology Use

Pea (1987) introduced the metaphors of amplifier and reorganizer to distinguish two ways in which technology may be used to support students' thinking. As an *amplifier*, technology can make a task more efficient by performing computations and generating representations quickly and accurately, but the focus of students' activity is not essentially changed. As a *reorganizer*, technology can transform students' activity, supporting a shift in students' mathematical thinking to something that would be difficult to achieve without it. With respect to the goals for students' mathematical activity above, technology use as a reorganizer is interpreted to mean that DGS plays an essential role in achieving these goals. We integrated the design principles with the amplifier/reorganizer distinction into a single framework (Figure 1) to evaluate the role of technology with respect to each goal (row) (for more detail regarding the development of the framework and an example of how it may be used to analyze and revise a task, please see Sherman & Cayton (in press)). The framework is intended to serve as a practical tool to support teachers in assessing how the use of technology supports particular goals for students' thinking and reasoning, and to suggest ways in which a task might be revised in order to accomplish certain goals more effectively.

		Technology Used As	
		Amplifier Students could achieve the same goal without the technology	**Reorganizer** The mathematical goal of the task would be difficult to achieve without DGS
Goals	**Question**	**Use of Design Principles**	
Make mathematically meaningful observations; look for invariant relationships.	Do the sketch and prompts use the dynamic affordances of DGS in a way that would be difficult or impossible to replicate without it?	Students create multiple static examples, either by construction or dragging, and reason from those static examples, e.g., students are prompted to make observations or generalizations based on a table or static measurements without reference to the sketch.	The sketch allows for continuous dragging, and students are guided to examine measurements or relationships dynamically. Students are required to make or explain observations or generalizations dynamically in terms of the sketch.
Mathematical exploration; use appropriate tools strategically.	How does technology support mathematical exploration?	Sketch and prompts guide students to investigate the same example or set of examples to explore mathematical connections or invariances. Freedom with respect to dragging does not provide alternative paths if students are all investigating the same example.	Sketch and prompts allow students to explore based on individual observation of mathematical concepts, connections or invariances within the sketch. The sketch supports students' mathematical exploration by providing alternate paths.
Foster curiosity and modify thinking; make and test conjectures; use appropriate tools strategically.	Does the sketch provide feedback? Do the prompts encourage or require students to use feedback?	Experimentation is limited by restrictive construction or does not provide feedback to allow students to explore their own conjectures; or prompts do not explicitly guide students to test conjectures.	Sketch and prompts support experimentation; sketch provides feedback or allows students to test and refine conjectures. Prompts explicitly guide students to use the sketch to test conjectures.

Figure 3: DGS Task Framework

Implementing the Framework with Teachers

In order to better understand how mathematics teachers make sense of the framework, and how it supports their ability to critically examine and describe various uses of technology, we introduced the framework to teachers and had them use it to analyze three tasks and make suggestions for how the tasks might be revised. The contexts for this study include a teacher education course and two professional development courses at three different universities. Data was collected in spring and summer of 2014. Participants included a total of 25 pre-service and in-service teachers with a range of teaching experience.

Results

The way in which teachers' used the framework to evaluate the three tasks we presented them with are summarized in Table 1. (The tasks can be found at the following links: Intersecting Chords: http://tinyurl.com/lhb7acw, Exploring Properties of Polygons: http://tinyurl.com/mkhho55,and Trapezoid Midsegment: http://tinyurl.com/k9vw3d2) The expert evaluation reflects the authors' assessment of each of these tasks along the dimensions represented in the framework in Figure 1.

Table 1: Teachers' Evaluations of Three Tasks

Task: Intersecting Chords		**Expert**	**April**	**July**	**August**
Mathematically Meaningful Observations	Amplifier	x	5	4	11
	Reorganizer		3	0	2
Mathematical Exploration	Amplifier	x	7	4	13
	Reorganizer		1	0	0
Foster Curiosity and Modify Thinking	Amplifier	x	7	3	13

Mathematically Meaningful Observations	Amplifier		4	1	3
	Reorganizer	x	4	3	10
Mathematical Exploration	Amplifier	x	5	3	3
	Reorganizer		3	1	10
Foster Curiosity and Modify Thinking	Amplifier	x	5	2	3
	Reorganizer		3	2	10

Discussion

In our discussions with teachers, we found that the differences in how they categorized a task along each dimension related mostly to interpretation of the prompts. For example, the Midsegment Trapezoid task includes the prompt *Drag point A or point B to change the shape of trapezoid ABCD. Do not allow segment AD to intersect BC. What do you notice about EF and (AB+DC)/2?*Some teachers interpreted this prompt as requiring students to drag continuously, and thus called it a reorganizer along the first dimension of the framework. Others, however, thought the prompt was asking students to engage in a "drag and stop" action, which would merely generate another example, and categorized it as being an amplifier. Since the prompt is not explicit, we believe either interpretation is valid. From a teacher education perspective, we believe that this ambiguity provides a pedagogical opportunity in understanding this dimension of the framework, i.e., that continuous dragging leverages the dynamic affordances of DGS.

Other discrepancies between teachers were also noted. For the first dimension, practicing teachers with more years of experience often categorized a task as an amplifier, citing the fact that they had taught that particular concept without technology for many years. Thus, teachers did not necessarily focus on if DGS was needed to accomplish the goals for students' mathematical thinking within a task. Along the second dimension, teachers tended to focus on the open-endedness of the task rather than the role of DGS in supporting the open-ended features of the task. In response to this issue we revised the framework to be more explicit about the criteria for this dimension. For the third dimension, teachers assumed students would check their conjectures without an explicit requirement to do so leading them to categorize tasks as reorganizer even if an explicit requirement to check conjectures was not present. As students rarely check their conjectures spontaneously, it is included in the framework as an explicit requirement in the prompts.

Implications for Teacher Education

The value of this practical framework is directly related to its effectiveness in supporting teachers' use of DGS to engage students in mathematical reasoning and sense making. Our current results demonstrate that the framework was useful in helping teachers understand distinctions in how DGS might support student thinking, and that teachers were able to use it to critically evaluate tasks that incorporated the use of DGS. Raising teachers' awareness of the idea that DGS can be used in a variety of ways that may or may not promote students' mathematical thinking is an important step in helping them to use DGS more strategically. Fostering this awareness and providing sustained opportunities to move beyond evaluation to revising and creating DGS tasks that support students' mathematical thinking represents an important element of mathematics teachers' technological pedagogical content knowledge (TPACK) (Niess et al., 2009) that this framework has the potential to address.

This study examined preservice elementary teachers' selection of mathematics tasks for English language learners (ELLs) following a three-week field experience. For each of the first three weeks of the field experience, the preservice teachers were provided with cognitively demanding tasks for which to plan a lesson for a one-on-one session with an ELL. In the fourth week, the preservice teachers were asked to select their own tasks. Through the use of a qualitative document analysis methodology, we found that the preservice teachers attended to their ELL's culture, language, and mathematics to varying degrees when selecting tasks. Further, they included a number of visual representations to accompany the tasks. The findings suggest that further preparation is needed to help preservice teachers select appropriate tasks for ELLs.

Keywords: Teacher Education-Preservice; Equity and Diversity; Curriculum

English language learners (ELLs) comprise the fastest growing demographic in U.S. public schools (Wolf, Herman, & Dietel, 2010). ELLs are a culturally, economically, and linguistically diverse group of students who can benefit from particular instructional strategies in the mathematics classroom. Many teacher preparation programs in states with historically small proportions of ELLs do not address strategies for teaching ELLs. In fact, though it has been estimated that nearly every teacher in the U.S. has at least one ELL student, less than one third of teachers have been prepared in effective teaching strategies for ELLs (Ballantyne, Sanderman, & Levy, 2009). These realities have contributed to the persistent achievement gap (Fry, 2008) between ELLs and their native English-speaking peers.

Shulman (1986) described particular aspects of knowledge needed for teaching, including curricular knowledge. He referred to these aspects collectively as pedagogical content knowledge (PCK). Magnusson and colleagues (1999) later expanded on the notion of curricular knowledge. This expansion described two categories of this knowledge: knowledge of goals and objectives and knowledge of specific curricular programs and materials. Knowledge in these areas is an important aspect of practice for which teachers must be prepared. Because tasks determine students' learning opportunities (Kloosterman & Walcott, 2010), the selection of appropriate curricular resources for students is a crucial component of a teacher's work.

Although there is some literature related to mathematics curricula and ELLs (e.g., Campbell, Davis, & Adams, 2007; Pitvorec, Willey, & Khisty, 2011), a review of the literature on preservice teachers (PSTs) did not reveal any studies related to their selection of mathematics tasks for ELLs. In this study we examined four PSTs' selection of tasks for ELLs following three weeks of an ELL-focused field experience. The following question guided the study: *What are the characteristics of the tasks PSTs selected for ELLs following a specialized field experience?* As we were interested in the particular tasks selected, we focused on the first of Stein, Grover, and Henningsen's (1996) three phases through which tasks transition: the tasks as represented in the curriculum materials. Attending to this phase is important because teachers' decisions to select particular tasks can limit or expand students' learning opportunities in the classroom.

Methods

The data for this study were from a larger study investigating a four-week field experience for four, elementary PSTs. This field experience paired each PST with an ELL student in weekly meetings. For the first three meetings, the research team provided the PSTs with a cognitively demanding task. The PSTs were then asked to write up a lesson plan for implementing the task with their ELL. The PSTs were allowed to modify or adapt the task in any way they saw fit. In the fourth meeting the PSTs were asked to select their own task to use with their ELL. For each meeting we had video recordings of the meeting, video recorded pre and post interviews, the PSTs' lesson plans, and the PSTs written reflections.

In this study we focused on the fourth and final meeting of the PST and ELL pairings because we were particularly interested in the features of the PSTs' selected tasks. We conducted a document analysis (Bowen, 2009) in conjunction with an inductive coding scheme to analyze the data. This began with open coding (Strauss & Corbin, 1990) the lesson plans and interview transcripts for each PST to identify initial themes related to the features of the PSTs' selected tasks. Axial coding (Strauss & Corbin, 1990) was then used to further refine these themes.

Findings

The PSTs were asked to adapt an existing task or to develop a task of their own for the fourth week. Two of the PSTs elected to create their own tasks and the other two adapted an existing task. In the following sections we discuss the common features of all four tasks to better understand the factors to which PSTs attended to in support of ELLs.

Connection to Culture and Context

Within three of the four tasks, there was evidence that the PSTs attended to the task context for their ELLs. This occurred in one of two ways: focusing heavily on the ELL's culture in selecting a task or on a context that the PST thought would be familiar to the ELL, but not necessarily tied to their particular cultural background. Morgan and Hannah adapted their tasks based on their ELLs' cultural background. Morgan's task was situated within an apartment context, which she believed Ho-Min would be familiar with, saying "I did try and figure out what kind of living arrangements he may have been used to [in S. Korea]." Hannah took a different approach and included a Korean name in the problem and made use of her knowledge of Hwa-Young's upbringing in Japan by selecting a common Japanese dessert, imagawayaki, for the task. This was very successful in gaining Hwa-Young's interest in the task. Hwa-Young even exclaimed, "Imagawayaki is my favorite dessert, too!" Fiona focused on common contexts with which she thought Jin would be familiar, saying "[I] tried to do common things, using food and like soccer and basketball, which I know he liked." Morgan and Hannah seemed to select culturally relevant contexts for their students based on their knowledge of their student's, while Fiona selected contexts devoid of Asian culture. In contrast to these cases, the fourth PST, Kimberly, did not attend to Kyong-Tae's cultural interests or contextual familiarity. The task she selected was familiar to her because it was going to be on her methods course exam the next day. She described her opportunity to work with Kyong-Tae on the task as "totally beneficial."

Attention to Mathematical Content

In three of the four tasks selected, there was evidence that the PSTs attended to the ELLs' mathematical levels when selecting tasks. They did this in two ways. First, they selected tasks appropriate for the grade level of the student. For example, Hannah focused her task on 4th grade fraction ideas for her 4th grade ELL. This approach of matching the task to grade level standards was different than the approach Morgan and Kimberly used. When explaining her choice of task, Morgan stated that she focused on area "because he [her ELL] said he liked area, I'm thinking he, at least, has some experience with it or knows how it works." Similarly, in light of Kimberly's prior interactions with Kyong-Tae and his seemingly advanced mathematics level, Kimberly selected a task related to middle grades geometry. Kimberly and Morgan's selections seemed to be influenced heavily by their knowledge of their students, while Hannah instead relied on grade level expectations.

In contrast to these cases, Fiona did not appear to attend to the mathematical content in choosing her task. Fiona's task consisted of mathematical activities that, during implementation, did not pose much of a challenge for Jin. Although Jin was in the fourth grade, Fiona selected tasks that consisted largely of single step addition, subtraction, and multiplication. Her task selection was driven by her desire to have an interaction that was "more fun than the other tasks when he was like sitting down and working through it. I hope he finds it fun."

Attention to Language

There is evidence that all the PSTs attended to language within their tasks. Morgan paid substantial attention to language, saying she "tried to keep the wording pretty short and simple" while adding in certain words like "dresser" in the prompts to help "expand his [English] vocabulary." Further within the lesson plan, Morgan identified how she would provide linguistic support for words if they became problematic. For example, she stated "if he is struggling with the word 'entire,' [she would] motion that the carpet has to be placed throughout the whole room." Kimberly's attention to language was evident in her choice of an entirely oral task. She explained her decision to do this in her pre-interview: "I would be verbally giving him directions, that this might be more challenging for him to pick up on the cues, but it is probably a lot more similar to what he sees in school." She also anticipated linguistic challenges by preloading vocabulary at the start of the task.

In contrast, Fiona and Hannah's attention resulted in problematic language in their written tasks. Fiona did not anticipate challenges that Jin may face with terms such as digit and number, and therefore did not have a plan for how to support Jin. Hannah's task had multiple spelling errors, multiple verb tenses used within a single problem, and overly complex or incoherent sentences. For example, within one activity, Hannah used eat, uneaten, ate, eaten, and left over to describe what happened to a dessert. In all cases, the PSTs paid attention to language; however, in some instances, this attention did not support their ELL's language development or lessen linguistic demands.

Inclusion of Visuals

Three of the PSTs included visual representations in their task. Hannah included pictures of desserts, identified as a modification intended specifically for Hwa-Young, and stated, "instead of having her draw her own pictures, I make sure that I had a picture for her." Morgan's inclusion of a bedroom diagram was also seen as a support for her ELL, identifying in her lesson plan that she would "walk him through what each picture represents" and point to various places in the diagram to assist with linguistic challenges (e.g. unfamiliarity with 'carpet'). Morgan further adapted the visual presentation of the task by increasing the amount of white space. Kimberly's supports included drawing a table and diagram of a circle on the whiteboard prior to Kyong-Tae's arrival, which she saw as supporting him during her orally administered task. In contrast to these three PSTs, Fiona included no visual supports for Jin. It is not known why she chose to do this and is in contrast to her behavior during the first three weeks.

Discussion

We examined PSTs' task selections for ELLs with whom they were familiar. Each PST used their knowledge of their ELL to select tasks that positively impacted their student's success. However, at times, these selections seemed to be problematic or misguided. When selecting mathematically appropriate tasks, the PSTs primarily selected activities based upon their student's grade level, and not from their prior knowledge of the student's mathematical ability. In all cases, the selected task did not pose substantial mathematical challenges or exhibit characteristics of high cognitive demand tasks (Stein et al., 1996). Although the PSTs had classroom instruction on cognitively demanding tasks, this was insufficient for impacting the level of cognitive demand of self-selected tasks for students with whom they were familiar.

When adapting language for their selected tasks, two of the PSTs were successful at anticipating and planning for linguistic challenges. Although all the PSTs had been adapting language during the prior three weeks, this, in conjunction with their coursework, was insufficient at fully developing their skills in anticipating and planning for language. This is evidence that PSTs need further practice at anticipating and planning for language within curriculum materials for ELLs.

Our findings indicate that completing a four-week field experience with an ELL in conjunction with coursework is insufficient to fully prepare PSTs to work with ELLs. Further research is needed to better understand how to support and prepare PSTs for their work with ELLs in their future classrooms. It is our hope that this study will encourage others to further investigate how teacher educators can better prepare PSTs, and potentially in-service teachers, for working with and supporting ELLs in the mathematics classroom.

EXAMINING METHODS FOR STUDYING MATHEMATICAL KNOWLEDGE FOR TEACHING

Rachel B. Snider
University of Michigan
rsnider@umich.edu

Over the past 20 years researchers have made progress in understanding mathematics teachers' knowledge. Although the field has made advances in measuring mathematical knowledge for teaching (MKT), much is left undiscovered about the nature of this knowledge. This is due in part to the many challenges inherent in studying MKT, which is multifaceted and inextricably tied to practice. This paper investigates methods around the study of MKT by looking at tasks from three cognitive interview studies. It focuses on how the tasks and the pedagogical contexts within them influence what can be learned about the different facets of MKT. This paper has implications for future studies that seek to investigate the nature of MKT.

Keywords: Mathematical Knowledge for Teaching; Research Methods; Teacher Knowledge

Introduction

Over the past 20 years, researchers have made progress in understanding the knowledge entailed by the work of teaching mathematics and in measuring mathematics teachers' knowledge. Although these studies have conceptualized such knowledge and found valid ways of measuring teachers' knowledge, there is still much left to learn about the nature of this knowledge. This is because this knowledge is multifaceted, involves multiple layers of reasoning, and inextricably tied to practice (Putnam & Borko, 2000). Many researchers have sought and created measures of teachers' knowledge, yet few have looked closely at the nature of this knowledge. One line of research that has looked at the nature of this knowledge stems from Ball and colleagues' work on *mathematical knowledge for teaching* (MKT). Their research group has used extensive records of practice to build and test hypotheses about the nature of mathematics teachers' knowledge (Ball & Bass, 2003). This work has led to an understanding of some of the mathematical demands of teaching mathematics, yet many facets of MKT are still not known. Moreover, this is complex work that cannot be easily replicated without copious data from mathematics classrooms, and a group of researchers with broad, multidisciplinary expertise in teaching, mathematics, and cognition. What is needed is a better understanding of how to study MKT. Such an understanding would allow more researchers to analyze the complex mathematical knowledge and work that occurs in teaching, leading to a better understanding of the unique knowledge demands of teaching mathematics. This paper investigates methods around the study of MKT by looking at tasks from three studies that investigated MKT using cognitive interviews. The differing types and structures of tasks across the three studies affect teachers' responses and the types of knowledge that are made visible. This affords the ability to look at how the tasks themselves and the pedagogical contexts within them influence what can be learned about the different facets of MKT from each task.

Theoretical Framework

This study draws on the theory of *mathematical knowledge for teaching* (MKT), the knowledge needed to carry out the work of teaching (Ball, Thames, & Phelps, 2008).This notion of MKT builds on Shulman's (1986) conceptualization of pedagogical content knowledge. Pedagogical content knowledge, which resides at the core of expert teaching, is a teacher's ability to turn content knowledge into pedagogically powerful forms that can be adapted to students' varying abilities, prior knowledge, and backgrounds (Shulman, 1987). MKT includes both subject matter knowledge and pedagogical content knowledge. Included within subject matter knowledge is a category of content knowledge unique to teachers. Other mathematics professionals use mathematics in a compressed and finalized form, but teachers must interpret, understand, and share the uncompressed versions of mathematics knowledge that their students learn and use. Knowing mathematics in these multiple uncompressed forms and mapping between them is a subset of mathematical knowledge unique to teachers (Ball et al., 2008).

This study draws on a situated perspective of knowledge and practices. In this perspective, embedded within knowledge are fundamental links to the situations in which it was learned and is used (Brown, Collins, & Duguid, 1989). Teachers' "professional knowledge is developed in context, stored together with characteristic features of the classrooms and activities, organized around the tasks that teachers accomplish in classroom settings, and accessed for use in similar situations" (Putnam & Borko, 2000, p. 13). In this view, teacher knowledge is inextricably linked to the contexts, tasks, and practices of teaching. Therefore, knowledge and practices can vary across settings. Several examples exist in the literature documenting teachers whose mathematical knowledge differed between teaching and non-teaching contexts (Borko et al., 1992; Hodgen, 2011; Ma, 1999; Thompson & Thompson, 1994).

Methods

This paper presents a qualitative study using tasks and responses from three different studies designed to investigate MKT using cognitive interviews (Desimone & Le Floch, 2004). In the first study, nine experienced geometry teachers were interviewed while solving nine multiple-choice MKT-Geometry tasks, three problems in each domain: knowledge of content and teaching, knowledge of content and students, and specialized content knowledge.

The second study was designed to address a range of teaching practices and mathematics content. For each task, participants were presented with a classroom situation and asked to take on the role of the teacher. This included providing feedback on student work and using it to further instruction, creating formative assessment, and designing learning goals for a lesson. Twelve experienced teachers ranging across grades K-12 participated in this study.

Ten high school Algebra II teachers participated in the third study. The tasks in this study were focused on the teaching practices of giving explanations and selecting examples and on the content of rational expressions and equations. In each task, participants were either asked to pick examples to teach a particular topic, such as simplifying rational expressions, or to give an explanation for students of a particular concept, including solving a rational equation.

While each study was focused on investigating MKT in the context of particular mathematics content and teaching practices, this paper presents a broader analysis across all three studies of the ways in which the tasks used in each study shaped what could be learned about MKT from the tasks and interviews in each study. Each task and its associated responses were analyzed around the ways in which the pedagogical context and details of the task, as well as the type of response participants were asked for, shaped the facets of MKT that were made visible.

Results

The four findings that emerged from the analysis are described below with examples.

Task Type

Different types of tasks can allow different facets of teachers' MKT to be made visible. For example, several tasks from the second study asked participants to evaluate student work. For each task participants were asked to craft their own response. Because of the open-ended nature of the task, participants were more likely to draw on knowledge they would use in doing this task in their own teaching. In contrast, one of the tasks from the first study asked participants to evaluate incorrect student work and determine the student's error. This task provided four options for participants to choose from. By providing the possible student misconceptions, the knowledge that could be seen was constrained to the choices given.

Although intended to reveal participants' knowledge of student thinking, a task that asks participants to evaluate student work can surface gaps in participants' mathematical knowledge. For example, one task asked participants to evaluate a student's construction of a geometric figure. The student work was missing a description of how one component of the figure was drawn, making it incomplete, but not incorrect. A few of the participants made mathematically incorrect statements about the student's final figure, revealing gaps in their own mathematical understanding. If the participants had instead been asked to construct the figure themselves, this knowledge may not have been revealed.

Task Structure

Small changes in the tasks can reveal or obscure facets of teachers' knowledge. For example, one of the early task designs in the third study presented participants with ten problems from which to select examples for teaching simplifying rational expressions. In pilot interviews, participants spent a significant amount of time solving all of the problems, which made visible their mathematical reasoning. However, the work they engaged in was less authentic to the work of teaching and the knowledge used in doing the task was not reflective of how they might actually select examples in their own planning. The task was revised to present participants with a list of 30 problems. The list was similar to one teachers might find in their textbooks or online, and also included a list of answers. Participants who were presented with the later version of the task began by evaluating the features of the problem, including the final answer. While many of the participants worked through a few of the problems after they had selected them, none of the participants solved all of the problems. By changing the task, the work participants did in solving it more closely resembled the work of teaching, providing a better window for viewing MKT.

Another example comes from the second study. One of the tasks presented participants with student work on a permutation problem. Participants were first asked in writing what they noticed about the student's work. They were also asked to provide feedback to the student and how they might wrap up the problem with the whole class. By asking participants in writing what they noticed before they provided written feedback to the student, the task was unknowingly focusing participants on aspects of the student work they might have otherwise overlooked and distorted the ways in which they would actually engage this work in practice. Removing this question in written form provided a better understanding of how participants evaluate student work and provide feedback on it.

Mathematical Detail

One task from the first study presented a problem that involved finding the measure of an inscribed angle given other known angle measures. Four student solutions were given, all of which ended with the correct value, but provided different levels of detail. Participants were asked to determine which solution was incorrect. One solution made a mathematical jump, associating the value of two unrelated angles. The other answers used correct mathematical reasoning to reach a correct answer, including dividing the measure of the central angle in half to find the measure of the inscribed angle that intercepts the same arc. However, none of the students mentioned that the measure of the inscribed angle was half the measure of the arc it intercepts. Because the problem focused on inscribed angles, several participants interpreted these responses to be incorrect, even though they were designed by researchers to be correct.

Context Unrelated to MKT

Other details in the problem context can cause teachers to respond to a task without drawing on the MKT the task intended to elicit. On one task, participants attributed an incorrect response to the verbal mode of communication instead of the student's underlying misconception. In another case, participants chose an activity based not on the underlying mathematics, but on the tools students would use in the activity.

Conclusion

Creating tasks to study MKT is not straightforward. The types and structures of cognitive interview tasks, as well as the pedagogical contexts in those tasks can affect the facets of MKT that are made visible. Other task features also matter. Tasks that most closely resemble the work of teaching have the potential to better probe MKT. When participants respond in unexpected ways to a task, small changes to better approximate the work of teaching may enable participants to draw on their MKT as they do in teaching. Further, teachers' content knowledge may be better accessed indirectly through a teaching situation than through mathematics problems. While there is much left to consider around methods for studying MKT, the methodological considerations discussed in this paper provide a starting point for understanding how best to investigate MKT.

EXAMINING PROSPECTIVE TEACHERS' ABILITY TO NOTICE AND ANALYZE EVIDENCE OF STUDENTS' MATHEMATICS LEARNING

Sandy M. Spitzer
Towson University
sspitzer@towson.edu

Christine M. Phelps
Central Michigan University
phelp1cm@cmich.edu

One way to strengthen the impact of teacher education, and thus address an enduring challenge in improving education, may be to teach prospective teachers (PTs) to systematically study and improve their teaching. In particular, a key skill for teachers is to appropriately notice and evaluate evidence of student understanding. In this study, we examine PTs' analyses of student learning in a lesson transcript, and compare these analyses across populations. Results indicate that prospective secondary teachers conducted higher quality analyses than prospective elementary teachers, but both populations of PTs overestimated students' understanding within the lesson transcript. Implications of this study suggest a link between mathematical knowledge and analysis skills, and indicate the need to explicitly teach analysis skills to PTs.

Keywords: Teacher Education-Preservice; Teacher Knowledge

One of the most persistent and enduring challenges for teacher educators and educational researchers is the difficulty of designing teacher education programs which produce strong and long-lasting positive effects on their graduates. Multiple researchers have suggested that one way teacher education can have long-lasting effects is by preparing prospective teachers (PTs) to be lifelong learners who become better teachers over time (Fieman-Nemser, 2001; Hiebert, Morris, & Glass, 2003). However, more research is needed on how to best achieve this goal.

One model for lifelong learning from teaching is composed of a cycle of four skills meant to be repeated systematically on a lesson or unit. This cycle, which is theoretically informed by the work of Hiebert, Morris, Berk, and Jansen (2007), is known as a *lesson experiment*. The skills of the cycle are intended to help teachers structure a personal or collaborative analysis of their own teaching in terms of its effectiveness in helping students meet specified learning goals. These skills are: (1) setting mathematical learning goals for students; (2) collecting and analyzing evidence of students' achievement of those mathematical learning goals; (3) developing cause-effect hypotheses that connect teaching to students' achievement; and (4) revising teaching based on the hypotheses to better improve students' opportunity to learn (Hiebert, Morris, Berk, & Jansen, 2007). Using these skills may help teachers both improve a lesson or unit and develop a mindset for thinking about teaching in terms of student learning (Phelps & Spitzer, 2012). Lesson experiments allow teachers to analyze and learn from their own teaching, systematically improving over the course of their career. Thus, helping PTs learn to conduct lesson experiments might be one way to strengthen the impact of teacher education programs. Learning more about how PTs might acquire and use the lesson experiment skills is an essential step in addressing the enduring challenge of designing effective teacher education programs.

Objectives of the Study

Research suggests that without explicit instruction, PTs hold a variety of misconceptions about analyzing teaching, and while they can enact some skills of the lesson experiment model, these skills are fragile and context-dependent (e.g. Morris, 2006; Spitzer, Phelps, Beyers, Johnson, & Sieminski, 2011). However, this research has mostly been conducted with prospective elementary teachers. Little work has been conducted to examine these skills in practicing teachers or in prospective secondary teachers, and no existing research compares these skills across different populations of teachers. This lack of knowledge limits our ability to successfully prepare teachers at all levels who will be lifelong learners.

In an ongoing research project, our goals are to begin to address these research gaps by investigating teachers' ability to analyze and evaluate evidence of student achievement of mathematical learning goals, and compare them across several populations. In particular, in this paper we will present the results of a quantitative analysis of prospective elementary and secondary teachers' evaluations of a sample lesson transcript in terms of student thinking and learning. The research questions for this analysis are: *How do PTs evaluate evidence of student understanding in a lesson transcript? What differences exist in the evaluations of evidence among elementary and secondary PTs?*

Methods

This project employed a mixed-methods approach in which participants completed an online survey including both open-ended and multiple-choice type questions eliciting their analysis of a sample transcript of a 5th grade mathematics lesson. This paper focuses on the quantitative portion of the study, while future analyses will investigate the open-ended responses.

Participants

Participants included PTs enrolled at either of two large comprehensive universities, one in the Mid-Atlantic region and the other in the Midwest. Participants were recruited through email, word of mouth, and announcements in classrooms, and received a token gift card as a thank you for participating. Fifty-four PTs responded to the invitation and completed the survey. This sample includes 36 prospective early childhood or elementary teachers (including 4 prospective elementary teachers with a specialization in mathematics), 5 prospective middle grades teachers with a specialization in mathematics, and 13 prospective secondary teachers with a specialization in mathematics. 87% of participants were female; 22% had completed at most one year of college, 58% had completed 2 or 3 years, and 20% had completed 4 or more years.

Measures and Analysis

To assess participants' evidence analysis abilities, we designed a task asking participants to read a transcript of a 5th grade lesson on comparing decimals using the conceptual ideas of decimal place value. The content was chosen specifically to be accessible to all participants (elementary and secondary) and because place value underlies so many important ideas of school mathematics. The learning goal of the lesson, which was prominently displayed at the beginning of the transcript, was "*Compare two decimals to the thousandths place based on meanings of the digits in each place* (National Governors Association, 2010, CCSSM 5.NBT.3.b)."

The sample lesson transcript featured teacher direct instruction, students working on problems individually, and whole-class discussions and was divided into six sections, each featuring a different student response or teacher action, and a lesson conclusion. Of the six transcript sections, two were designed to provide some evidence of student understanding (one of a misconception and one of some conceptual understanding) and the other four provided no evidence of student understanding of the learning goal. These included a student who used a procedure to compare decimals (appending zeros) but without evidence of understanding that procedure (Section A), a conceptual explanation by the teacher accompanied by student thumbs-up (Section B), a student who provides only the correct answer with no explanation (Section C), and a student who used an alternative method (converting to fractions and using a calculator) to compare decimals without reference to place value ideas (Section D).

Participants were directed to read the entire transcript first and then were presented with the sections individually. After participants read each section, they were asked "What can you tell from this section about how well the students understand the learning goal?" and chose from three options:

0: I can't tell from this section if the students understand the learning goal or not.
1: I can tell a little from this section about the students' understanding (or lack of understanding) of the learning goal.
2: I can tell a lot from this section about the students' understanding (or lack of understanding) of the learning goal.

Participants were then asked open-ended follow-up questions asking what mathematical ideas students understood (or did not understand) and what evidence from the transcript convinced them. Last, participants chose which part of the transcript they thought told them the most about student understanding. For this question, they could choose any of the six sections or the lesson conclusion, which featured mostly teacher talk with students nodding.

For analysis here, we focus only on participants' quantitative ratings of each of the four transcript sections that provided no evidence. A rating of "can't tell" was coded as a 0, "tells a little" as a 1, and "tells a lot" as a 2. Because each section provided no evidence of student understanding, lower ratings indicate a higher-quality analysis of the evidence (i.e., "can't tell" is the best response for each of these sections, and "tells a little" is better than "tells a lot").

Results

The average rating across all four sections was 1.36 (SD = 0.41), indicating that most PTs felt that these four transcript sections consistently told them something about students' understanding. Because these four sections were all specifically designed to provide no evidence of student understanding, this indicates that PTs are overly generous in their estimations of evidence. We first consider the kinds of evidence that PTs found most compelling. Table 1 shows participants' ratings for each of the four different sections.

Table 1: Participant's Ratings of Transcript Sections

	Percent of respondents choosing each rating			
Transcript Section	"Can't tell"	"Can tell a lot"	"Can tell a little"	Mean Numerical Score (*SD*)
A: Procedural Explanation	2%	74%	24%	1.72 (*.49*)
B: Teacher Instruction	35%	28%	37%	0.93 (*.80*)
C: Correct Answer	23%	36%	41%	1.13 (*.76*)
D: Alternative Method	6%	72%	22%	1.67 (*.58*)

From this table, it is clear that participants most highly rated those sections which contained a student explanation of some kind (either of a procedure or alternative method), even though neither of those explanations related to the mathematics of the learning goal (place value). In particular, only one participant recognized that a procedural explanation does not provide evidence of conceptual understanding. Participants expressed the most skepticism about a section containing only teacher instruction, but even for this section, 65% of PTs believed that the transcript provided at least a little evidence of student understanding.

Interestingly, when directed at the end of the task to choose the section which told them the most about student understanding, participants looked more favorably on teacher instruction and non-verbal student responses as evidence of learning. 20% of participants chose Section B as telling the most, and another 17% chose the lesson conclusion, which also included mostly teacher talk and students nodding. Only 20% of PTs chose one of the two sections which did provide some evidence of student thinking.

We were also interested in the differences that might exist in evaluations between different populations of PTs. The data suggests that prospective secondary (middle and high school) teachers demonstrated significantly higher quality analyses of this transcript than prospective elementary (and early childhood) teachers (Primary $M = 1.49$ ($SD = 0.32$), Secondary $M = 1.10$ ($SD = 0.45$), $p < .01$). It is likely that this difference is related to higher levels of mathematics knowledge among prospective secondary teachers; future analyses of this data will investigate this relationship more closely. We also hypothesized that PTs who had completed at least one methods course would conduct higher-quality analyses than PTs who had not. However, this relationship did not prove to be the case, as there was no significant difference found (Methods $M = 1.37$ (SD = .34), No methods $M = 1.35$ ($SD = 0.49$), $p = .88$).

Discussion

The PTs in this sample generally overestimated the evidence of student learning, particularly in cases where the student gave some kind of explanation. Those PTs who had completed a methods course performed no better than other PTs, suggesting that general knowledge of pedagogy does not automatically improve evidence analysis skills. However, secondary PTs did better than elementary PTs, suggesting mathematics knowledge may matter in analyzing evidence. Overall, these results indicate that more explicit instruction in evaluating evidence of student learning in mathematics may be needed. Future research is also needed in order to better investigate the link between mathematics knowledge, pedagogical knowledge, and the ability to analyze evidence. The results of this study provide a first look at one method for responding to the enduring challenge of effective teacher preparation. This research, and future research, will improve our ability to give all teachers the skills needed to become lifelong learners of teaching.

Preparing to Teach Algebra (PTA) Project gathered data about opportunities to learn to teach algebra provided by secondary teacher education programs. In sharing our findings, we use structures from the Mathematical Knowledge for Teaching (MKT) framework (Ball & Bass, 2003). The MKT framework is one way of situating the ways in which teacher education programs support preservice mathematics teachers in developing necessary knowledge types for teaching algebra. Using the MKT framework as an analytical framework is not straightforward, however. The framework must be interpreted and individualized to the study of algebra and to the opportunities to learn to teach algebra that we found. We present our struggles, the evolved framework, and our results in this session.

Keywords: Teacher Education-Preservice; Mathematical Knowledge for Teaching; Algebra and Algebraic Thinking; Instructional Activities and Practices

Introduction

Teacher preparation programs should provide opportunities which support the development of specific types of knowledge needed for teaching mathematics, especially at the secondary level (e.g., McCrory, Floden, Ferrini-Mundy, Reckase, & Senk, 2012). This study is part of the *Preparing to Teach Algebra (PTA)* project which explored opportunities provided by secondary mathematics teacher education programs to learn about algebra, teaching algebra, issues of equity in algebra context, and algebra, functions, and modeling standards described in the Common Core State Standards for Mathematics. For this presentation, we address the question: *What types of knowledge do secondary mathematics teacher preparation programs support when they provide preservice teachers (PSTs) with opportunities to learn to teach algebra?*

Theoretical Framework

Ball and Forzani (2009) suggested that teacher preparation programs, including those preparing mathematics teachers, should change their curricular focus from what teachers know and believe to "the actual tasks and activities involved in the work" (p. 503). In exploring opportunities provided to preservice algebra teachers, we face a challenge to situate opportunities within a particular theoretical framework. The MKT framework offers a categorical system of knowledge types needed for successful mathematics teaching and focuses on knowledge in practice (Ball & Bass, 2003). Several researchers have made efforts to measure MKT outside of practice, suggesting that knowledge development can be supported during teacher preparation (e.g., Herbst & Kosko, 2014). In this presentation, we share our use of the MKT framework (e.g., Ball, Thames & Phelps, 2008) to better understand how intended opportunities to learn to teach algebra might support knowledge for teaching algebra.

Method

PTA project collected data from three secondary mathematics teacher education programs in the form of interviews with instructors of required mathematics and mathematics education courses at each institution, along with relevant course materials. We focused our current analysis on opportunities to learn to teach algebra, coding data in pairs of researchers. In this presentation, we analyze opportunities reported by instructors and found in their instructional materials to investigate aspects of MKT included in courses at each institution and across the three programs.

Results

In the following sections, we discuss our operating definitions of different aspects of the MKT framework. We present some preliminary results from our use of the MKT framework. Here, we focus on five aspects of MKT: *specialized content knowledge, horizon content knowledge, knowledge of content and students, knowledge of content and teaching,* and *knowledge of content and curriculum* (each defined below).

Specialized Content Knowledge (SCK)

Specialized content knowledge (SCK) can be described as knowledge that teachers need to unpack mathematical concepts and to interpret student work, especially in terms of unique approaches or solutions, that similarly qualified persons outside of mathematics teaching may not need (e.g., unpacking and relating the area and volume formulae for different shapes) (Ball et al., 2008). SCK enables teachers to delve into content from multiple perspectives, allowing them to explain concepts in multiple ways or follow students' reasoning (Ball et al., 2008).

For the purposes of this study, we refer to SCK learning opportunities as including: (a) unpacking particular aspects of mathematical concepts (including derivations, history, and proof), (b) evaluating and interpreting student arguments and solutions, (c) recognizing and valuing alternative solutions from instructors and colleagues, and (d) exploring teaching-related mathematical ideas. For example, a History of Mathematics course instructor at Kappa University expressed her desire for PSTs to appreciate the complexities present in many of the algebraic ideas they take for granted, and how historical struggles can be predictors of student struggles. She gave them opportunities to investigate these struggles by studying the process and timeline taken to develop and standardize concepts such as function notation. As the instructor noted, “Some of these early algebraic things are ideas that are really quite sophisticated and it makes sense for students to stumble.” We classified these opportunities as SCK because of the opportunities for PSTs to learn about the history and complexity of algebraic concepts and notations which could impact student understanding.

Horizon Content Knowledge (HCK)

According to Ball et al. (2008), horizon content knowledge (HCK) refers to teachers’ understanding of how particular mathematical content is connected throughout the K-12 curriculum and to college mathematics. For our analysis, we focused on opportunities PSTs had to learn about how middle school mathematical topics (e.g., variables) can be used in high school topics (e.g., exponential functions) or how college mathematics relates to secondary content.

For example, a Discrete Mathematics instructor at Kappa University wanted to provide mathematical knowledge for PSTs to see where the secondary content fit into the larger mathematical landscape. For instance, the instructor mentioned that PSTs learned when it was appropriate to allow complex number solutions to quadratic equations. We coded this example as HCK because the instructor described how teaching algebraic content varies at different levels.

Knowledge of Content and Students (KCS)

In Ball et al. (2008), Knowledge of Content and Students (KCS) is described as "knowledge that combines knowing about students and knowing about mathematics" and specifically supports teachers in tasks that require "an interaction between specific mathematical understanding and familiarity with students and their mathematical thinking" (p. 402). Ball et al. described elements of KCS as including knowledge about students' thinking, interests or motivations, as well as common student conceptions and misconceptions.

In looking for examples of KCS from our data, we considered activities that emphasized anticipating or predicting with respect to student thinking, mathematical understanding, and motivation. For example, the Secondary Mathematics Methods instructor at Beta University emphasized gathering and interpreting data on student thinking: "Okay, you can't just gather information about right and wrong answers. So … in this system of linear equations, they were able to find the intercept. What does that mean? Do they understand what that means?" At Gamma University, the Algebra in the Curriculum instructor mentioned asking PSTs to look at written student work and anticipate what support the students would need by answering, "[H]ow can you support, from the written work what can you see as far as what are the [algebraic] habits of mind that those students need help with?"

Knowledge of Content and Teaching (KCT)

Ball et al. (2008) described Knowledge of Content and Teaching (KCT) as an important component of PCK; they proposed that this type of knowledge "combines knowing about teaching and knowing about mathematics" (p. 401). PSTs need opportunities to learn KCT in their secondary mathematics programs; we found evidence of such opportunities in our case study programs. For example, the Modeling in the Curriculum instructor at Gamma University included a textbook analysis as a course assignment. He asked PSTs to choose a textbook and find where matrix multiplication was addressed in the book. PSTs then discussed, "How are the different books doing it? What are the advantages, disadvantages?" This activity required students to grapple with both mathematical and pedagogical ideas in order to make decisions about both how to introduce particular mathematical topics and how to sequence concepts or activities associated with the topic. The Probability and Statistics instructor at Beta University emphasized that she provided her students with multiple opportunities to visualize and interpret data. She modeled this as a pedagogical strategy for those students who will be teachers as their future students will likely benefit from seeing data in various ways as well. Again, this strategy engages PSTs in what Ball et al. (2008) refer to as "an interaction between specific mathematical understanding and an understanding of pedagogical issues that affect student learning" (p. 401).

Knowledge of Content and Curriculum (KCC)

From Ball et al. (2008), KCC is the category of PCK focused on issues related to mathematics curriculum, specifically knowledge of the available programs and instructional materials designed to teach a certain topic at a particular level. KCC also includes considerations related to the affordances and complexities of selecting curriculum within a determined context. According to Shulman (1986), there are two additional types of curricular knowledge: lateral curricular knowledge and vertical curricular knowledge. The former is about the knowledge of the curriculum taught in a different subject area. The latter is related to the knowledge about the curriculum in the same subject area that has been used during previous years, as well with that that will be used in subsequent years.

For example, the Modeling in the Curriculum instructor at Gamma University reported that "[o]ne of the things that we do, actually when we do matrices. I have them each grab an Algebra II or secondary math textbook, I don't know if you have seen the math ed room, but there's tons of books

(...), so they kinda grab books and we discuss how are the different books doing it, what are the advantage, disadvantages."

Discussion

We are investigating the use of the MKT framework to analyze our OTL data from courses at three secondary mathematics teacher preparation programs. Although the MKT framework is appropriate to analyze future teachers' OTL about different types of knowledge for teaching, utilizing the MKT lens to make sense of our data has not been a straightforward process. These areas of knowledge are not discrete (as acknowledged by its developers) and many instructors design OTL to address multiple areas in connection with one another. For example, we were unclear about the categorization of an OTL in Abstract Algebra at Kappa University. The instructor reported that he had students in the course teach each other the abstract content by going to the board to explain homework questions to each other, presenting alternative solutions to problems, and working in groups in class. An argument for including this example in KCS is that by teaching each other the content, PSTs may be developing their abilities to anticipate what their classmates know or will struggle with and that may translate to their future students. On the other hand, the PSTs are not explicitly supported in anticipating their classmates' (or future students') thinking, motivation, or struggles. Therefore, we tentatively decided to categorize this OTL as SCK rather than KCS. Textbook analysis activities also proved challenging to categorize. They might seem to be obvious cases of KCC given their direct relationship to curriculum. However, we found instances in which this categorization was less clear. The example described in the KCT section above serves to illustrate this difficulty, as the students analyzed textbooks in order to investigate treatment of matrix multiplication and to consider advantages and disadvantages of different approaches; this analysis seemed more closely related to the descriptions provided for KCT than KCC.

In this session, we will describe analytic challenges inherent in using the MKT framework, present our evolving conceptions of the MKT categories, and share preliminary analysis results. We will engage our audience in discussions about our definitions, analytic decisions, and next steps in our analysis. We will share preliminary findings from three teacher preparation programs, which will help other teacher educators strengthen their programs. This presentation will help researchers who plan to use the MKT framework as an analytical framework for types of knowledge of algebra teachers.

CAN I TEACH MATHEMATICS? A STUDY OF PRESERVICE TEACHERS' SELF–EFFICACY AND MATHEMATICS ANXIETY

Kathleen Jablon Stoehr
Santa Clara University
kathy.stoehr@gmail.com

Amy M. Olson
Duquesne University
olsona@duq.edu

This paper presents two studies (qualitative and quantitative) with the shared goal of exploring preservice teachers' (PSTs') experiences of mathematics anxiety and self-efficacy for mathematics teaching. Findings indicate that PSTs experience high levels of mathematics anxiety, impacting current learning and preference for teaching the content, as well as the development of self-efficacy for teaching mathematics and conceptions of ideal teaching. Findings regarding anxiety (fear) of evaluation and concern about being able to inspire students in their future classrooms converged across studies.

Keywords: Mathematical Knowledge for Teaching; Teacher Education–Preservice

Mathematics education researchers agree that a confident and competent mathematics teacher is a vital necessity in the classroom (Oswald, 2008). Yet many elementary preservice teachers (PSTs) and in-service teachers experience relatively high levels of mathematics anxiety (e.g., Beilock Gunderson, Ramirez, & Levine, 2010; Swars, Smith, Smith, & Hart, 2007), and have histories of confronting anxiety and feelings of failure in mathematics during their own K-12 experiences (McGlynn-Stewart, 2010; Sloan, 2010). Further, definitions of mathematics anxiety suggest a relationship between anxiety of failure and self-beliefs such as self-efficacy (Trujillo & Hadfield, 1999). In efficacy theory, mathematics anxiety may be a source of physiological arousal that impedes the development of positive self-efficacy. Importantly, Lee (2009) found in a study of PISA results that mathematics anxiety and self-efficacy for mathematics were independent predictors of mathematics performance, indicating the need to not only measure them separately, but to understand how they differentially impact mathematics learning and achievement.

Thus, in this study, mathematics anxiety is investigated as a potential source of negative physiological arousal that impacts, but is not synonymous with, self-efficacy for teaching and learning mathematics. To the extent that PSTs feel anxiety when contemplating teaching mathematics (or learning mathematics content and pedagogy deeply enough to be effective in teaching mathematics), their experience of self-efficacy for teaching mathematics is negatively impacted (Bursal & Paznokas, 2006; Swars, Daane, & Giesen, 2006). However, there are some indications that experiences gained in mathematics education methods courses can help decrease mathematics anxiety (Gresham, 2007; Vinson, 2001). Yet little is known about what aspects of courses are efficacious in reducing mathematics anxiety and how these effects can be maintained. Thus, we undertook both a quantitative and qualitative exploration of mathematics anxiety and self-efficacy experienced by PSTs with the goal of further understanding how these perceptions impact PST education.

Methods and Data Sources

This paper reports on both a qualitative and quantitative study to explore different aspects of PSTs' experiences of mathematics anxiety and self-efficacy. PSTs were recruited while enrolled in their teacher preparation programs at a southwestern university. The PSTs who participated in the qualitative study (n = 3*)* were recruited during the 2010-2012 academic yearswhile participating in a larger ongoing research project, [TEACH MATH] that follows PSTs from their preparation programs and into early career classrooms. PSTs in the quantitative study (n = 53) were recruited during the

2013-2014 academic year. Participants in both studies were primarily interested in teaching early elementary (39.6%) or upper elementary (45.3%) grade levels and thus planned to teach all core subjects, including mathematics.

For the qualitative study, the participants (Estelle, Phoebe, and Roxanne) were selected because their mathematics autobiographies (an assignment written for their mathematics methods course) spoke clearly and powerfully about feelings of mathematics anxiety. Additional data such as individual and group interviews as well as semi-structured prompts were collected over the course of three semesters during their methods courses and student teaching. An iterative analysis (Bogdan & Biklen, 2006) was used to demarcate the narratives that pertained specifically to mathematics anxiety and self-efficacy. For each participant, narratives were identified within text passages that included key words specific to anxiety and self-efficacy. An emergent coding scheme (Marshall & Rossman, 2006) was utilized to organize and sort each participant's narratives.

For the quantitative study, PSTs were recruited from teacher education courses to participate in an evaluation of online teacher professional development for elementary mathematics. Quantitative anxiety measures [based on the Hopko (2003) and Hadley & Dorward (2011) revisions of the *Mathematics Anxiety Rating Scale - Revised*], self-efficacy measures [based on the *Mathematics Teaching Efficacy Beliefs Instrument* by Enochs, Smith, & Huinker (2000)], subject area preference measures, and amount of vicarious experience PSTs had in classrooms were collected at pre-post. This study reports on baseline measures (prior to exposure to the professional development content).

Results

Qualitative Findings

All three of the women viewed mathematics as a content area to learn as students and to know as teachers, but one that held little appeal for them. Estelle saw mathematics as something that she could not escape (i.e., that mathematics was "everywhere"). Phoebe found mathematics to be a subject area that she *strongly* disliked and believed she was just not a "math person." As a result, she often reached for the comfort of her non-math status to diminish others' high expectations of her in this content area. Roxanne viewed mathematics as "a sore subject." Having spent her lifetime trying to pass mathematics classes despite not understanding the content, Roxanne had few ideas about mathematics other than mathematics was a subject to be endured. In other words, all three women spoke of mathematics as a requirement in their academic and professional lives, but not as a rich discipline they looked forward to learning or teaching. Based on the patterns of findings over three semesters of data collection, PSTs who experience high levels of mathematics anxiety and low perceptions of self-efficacy can learn to gain an understanding of the content, but they often limit (self-handicap) their opportunities to expand their mathematics understanding.

Further, the PSTs' experiences with mathematics anxiety and self-efficacy shaped their views of the ideal mathematics teacher. For Estelle, the ideal mathematics teacher was one who would never embarrass students in front of the class, who would be truly interested in all students' mathematical thinking (not just the smart students), and who would hold high expectations for all students. In other words, the best mathematics teacher would not let students hide behind a "wall" of feigned understanding; nor would she make them wish they could. For Phoebe, the ideal mathematics teacher was one who would explain mathematics concepts and problem-solving methods in multiple ways and who would thus create a learning environment in which there were multiple ways to be a "math person." For Roxanne, the ideal mathematics teacher was one who would provide opportunities for students to actively engage in mathematics, regardless of their mathematics ability so their focus would not be on just "getting through" the content. Thus the findings indicate that experiences in learning mathematics and learning to teach mathematics influence how future teachers imagine the qualities of the ideal mathematics teacher.

Quantitative Findings

In general, PSTs rated their mathematics learning anxiety and mathematics teaching anxiety similarly ($h = .04$), with the average scores on both scales falling between "a little" and "a fair amount" of anxiety in response to items. On both scales, anxiety was highest for items set in an evaluative context. In contrast, efficacy beliefs were quite high for both learning and teaching, although PSTs felt higher efficacy for learning ($h = .16$). Item averages indicate that students tended to fall between "agree" and "strongly agree" with statements about their efficacy to learn (with the lowest efficacy for learning to inspire students in mathematics), while they fell somewhere between "uncertain" and "agree" on statements about their efficacy to teach.

Based on efficacy theory, it was hypothesized that mathematics anxiety and vicarious experience in the program would predict PST self-efficacy, which would in turn predict preference for teaching mathematics. A mediation model(using PROCESS 2.11; Hayes, 2013) was found to be significant; $R = .55, F(3, 48) = 7.33, p < .001$, with $R^2 = .31$, and CI 95% [.12, .50]. Results indicated that the mathematics anxiety ($b = -.33, p = .001$) and vicarious experience ($b = .12, p = .017$) significantly predict self-efficacy, self-efficacy significantly predicts subject area preference ($b = .83, p = .013$), but anxiety ($b = -.44, p = 0.059$) and vicarious experience ($b = .05, p = 0.658$) do not significantly predict the outcome with the mediator in the model. Thus, self-efficacy appears to mediate the relationship between anxiety, vicarious experience, and subject area preference. The indirect effect of mathematics anxiety on subject area preference is -.27 (Boot 95% CI [-.64, -.08]), and the indirect effect of vicarious experience on subject area preference through self-efficacy is .10 (Boot 95% CI [.02, .25]).

Discussion

Based on the literature, it was hypothesized that PSTs would respond with relatively high levels of anxiety and low levels of self-efficacy for teaching mathematics as has been demonstrated in other studies. While anxiety was high across the studies (especially around contexts of evaluation and failure), efficacy was higher in the quantitative study than expected and inconsistent with the ways PSTs talked about their future teaching in the qualitative study. However, the PSTs in the quantitative study felt most efficacious about their ability to learn, rather than teach, the content. Given the relatively low level of real classroom experience these PSTs had, uncertainty is probably a healthy response and is certainly consistent with self-efficacy theory, which asserts that the efficacy of novices remains fluid until such time as individuals have had successful (or unsuccessful) mastery experiences upon which to base their beliefs. It is further consistent with the qualitative findings that suggested the PSTs were greatly concerned about their abilities to become good mathematics teachers.

An interesting finding across both studies was that PSTs were concerned about their ability to inspire students in mathematics. In the quantitative work, PSTs reported lower self-efficacy for helping their students become interested in mathematics, motivating them when they lost interest, and helping build connections with families to improve student achievement in mathematics. In the qualitative work, the "ideal" teacher is clearly represented as one who can help even anxious students feel comfortable in learning mathematics. Clearly, PSTs need more support to develop skills and confidence in motivating and inspiring students to be comfortable and engaged in mathematics.

CONNECTING THEORY AND PRACTICE IN MATHEMATICS TEACHER EDUCATION: AFTER SCHOOL PROGRAMS AS PROFESSIONAL DEVELOPMENT CENTERS

Jessie Store
Alma College
storejc@alma.edu

Meeting the goals of rigorous curriculum requires providing professional development (PD) that challenges existing notions of teaching mathematics. It requires nurturing shifts from teacher-centered norms to classroom norms centered on student thinking. This paper reports a PD design that used after school programs, and supported student mathematical thinking and a shift towards student centered practices. Effects on student learning, as well as on teacher practices were based on analysis of classroom videos, written artifacts, curriculum materials, and field notes.

Keywords: Teacher Education-Inservice; Elementary School Education; Design Experiments

Objectives

Good's (2010) report of normative classroom practices from 1968 to 2008 revealed that despite changes in the curriculum standards to emphasize discourse, critical thinking, and problem solving, the normative teaching practices continue to be teacher centered. Lack of significant changes in teacher practice show that PD opportunities have not been very effective. Students continue to underperform in critical thinking and problem solving areas. For example, the National Assessment of Educational Progress (2013) showed that from 1978 to 2012, number of 17-year-old students in US that demonstrated understanding of algebra and multistep problem solving skills has never been above 8%. Meeting curriculum goals is constrained by teachers' weak knowledge and the school environment (Ball, Thames, & Phelps, 2008), placing great demands for improvements of teacher education and support. As Guskey (2009) explained, "no improvement effort in the history of education has ever succeeded without thoughtfully planned and well-implemented PD activities designed to enhance educators' knowledge and skills" (p. 226). Furthermore, Marrongelle, Sztajn, and Smith (2013) insisted that "we need studies that open the black box of PD and provide rich descriptions of the nature of the work in which teachers engage that does or does not lead to improved knowledge, beliefs, or habits of practice" (p.209). The objective of this paper therefore, is to contribute to this area of high need by reporting a mathematics PD design.

Perspectives and Methods

Sztajn (2011) discussed the need for standards for reporting mathematics PD research. These standards are necessary because of the uniqueness of mathematics PD research and for clarity when reporting features that affect the effectiveness of the PD. Sztajn recommended reporting theoretical perspectives, goals, context, and its structure.

Theoretical Perspective

This study draws from Greeno's (2003) situative perspective of knowing. Development is a product of interaction of the individual, interpersonal, and the social systems. Acquired knowledge facilitates one's participation in a community, and because "individual mental structures certainly change as part of this learning" (Sawyer & Greeno, 2009, p.364), such knowledge can be transferred from one community to another. Development and practices are influenced by the norms of the social systems; normative teacher practices are therefore a reflection of the affordances and constraints of school systems. Implications of this include a focus on content, tools (e.g., instructional materials), discourse communities, and viewing teaching as learning in practice. Based on this framework, the situative research question for the current study is: What are the affordances and constraints of this PD design?

Program Goals and Context

The current mathematics PD had two interrelated primary goals. The first goal was to support elementary school students' mathematical understanding through engagement in generalizations and justifications about mathematical patterns. The second goal was to develop pedagogical and content knowledge through theory and practice.

Six schools and 12 teachers with 6-25 years of teaching participated. Three of the school were title 1 schools with 76.67% to 99.55% students classified as poor and about 30% students were below their grade level in mathematics. For the nontitle 1 schools, about 58% of the students were poor and 14% were below grade level in mathematics.

Program Structure

This program was structured into different recursive phases. Teachers worked on pattern finding activities like in figure 1 during PD. They discussed different student strategies, watched videos of students working on the tasks, analyzed student work, and discussed best practices to support students. The teachers met with the professional developers three times for 90 minutes each meeting during this phase. In the second phase, the teachers taught classes of about 15 students who were in grades 3-5 who voluntarily enrolled in this program. They taught twice a week for 90 minutes each time for five weeks. These lessons started with an outdoor physical activity and were followed by pattern finding activities. The teachers were provided with curriculum materials including lesson plans. Phase 3 was similar to phase 1. However, during this phase, teachers reflected on their classroom experiences, and discussed the affordances and constraints in their classrooms. Teachers also made recommendations to the professional developers on the structure and content of the activities for their students.

If one person sits on each side of a square in this pattern, how many people would sit around a train of 100 squares? How many people would sit around a train of *any* number of tables. Write your rule. How do you know your rule will always work?

1 2 3

Figure 1: An example of pattern finding tasks for On Track program.

This pattern of phases continued until the teachers had three teaching (five-week) sessions distributed over a year. Two interviews, at the end and during one of the teaching sessions, were conducted with each teacher. Recordings of the interviews, classroom activities and materials, were analyzed qualitatively and quantitatively to identify the constraints and affordances.

Results and Substantiated Conclusions

Student Learning

74% of the generalizations that students wrote were explicit (i.e. students wrote correct rules for finding the nth term of the pattern-finding activities) which in this study was considered the highest possible reasoning level. The percentage of explicit generalizations, however, differed from task to task. Multiple regression analysis showed a significant positive relationship between the student growth in the End of Grade state math exams and students' explicit generalizations from this study at a p value of less than .0001 (Maher and Berenson, 2013). That is, this program supported students learning within it, and highly correlated with performance in mathematics end of year exams. Moreover, most teachers reported a positive change in students' persistence and development of habits of using different strategies.

Teacher Learning

Teachers reported that doing the math activities in the PD and teaching with the same task contributed to their knowledge more. Teacher Jane said:

> I am (now) able to see and develop what kids might do, what problems kids might run into, and how they might think. It is also interesting to me because I am like maybe they will come up with something different from the way I approached it.

Teachers reported a shift from teacher-centered practices and notions in which activities are very structured and questions funnel student responses. Teacher Mary reflected: " *I have learned doing this program that too often we tell the kids instead of asking them and giving them time to arrive at the answer*." Further, more, Liz felt that

> The program has been an interesting experience, just teaching math in a way that we do not teach in schools where you are not rushed to make them come up with an answer. It is like just do what you are capable of doing and just pushing kids but not like leading them, but just letting them do it for themselves.

The shift towards student-centered teaching was also attributed to the affordances of the after school settings especially the flexibility of how much time teachers could allocate to activities. On reflecting on her practice, teacher Deb said:

> I think I have changed from the beginning of the program to this last session because at first I was so used to having a long list of objectives. You got to cover this, you have got to do this real quick, so I think I was pushing a little bit with the kids at first. But I have come around to a little bit of –here it is, see what you can do with it and just asking them questions and not trying to lead them.

Observations aligned with reports of changes in teaching practice. Teachers became more at ease with practices such as encouraging students to question each other, requiring students to make their reasoning accessible to their peers, and encouraging finding relationships between different strategies. However, teachers did not develop some critical habits easily. One notable difficulty in the change of teaching practices which the teachers reported and the research team observed was the development of habits of creating or taking up opportunities to ask for powerful justifications. The teachers discussed the likely student justifications, appreciated the justifications with more explanatory power for all cases, and identified critical questions that will stimulate students to think of powerful justifications. For example, for the task in in Figure 1, the rule for n number of tables is $2n + 2 = s$ where s is the number of seats. Asking how the variable $2n$ and constant $+2$ connect to the question was one of the critical questions. However, teachers tended not to ask the critical questions but instead asked, "how did you get your answer" as the main way of asking for justification. As a result, describing the steps for the strategies was the most socially accepted justification scheme in these classrooms.

Significance

PD remains at the center of reform efforts, especially now as we transition to the Common Core State Standards. There is a critical need to learn what and how teachers learn in PD settings, and the impact on student learning. This study contributes to this need by reporting the PD design and it's impact. Classrooms already have ways of teaching and doing mathematics that may not support PD goals or reform efforts. This PD design removes teachers from these settings and support them in afterschool settings in which teachers can flexibly focus on student thinking, and re-establish norms and notions to develop teaching habits that align with reform goals without some constraints of schools and regular classrooms. Of course, one important goal of this PD is for teachers to transfer their PD teaching practices to their regular classrooms.

FACTORS INFLUENCING SUSTAINED TEACHER CHANGE: A COLLECTIVE CASE STUDY OF TWO FORMER PROFESSIONAL DEVELOPMENT PARTICIPANTS

Christine Taylor
North Carolina State University
Christine_Taylor@ncsu.edu

This study considers professional development (PD) effectiveness by examining sustainability of teachers' change. The instrumental collective case describes two teachers' classroom instruction three years after the completion of a PD focused on mathematics discourse. A strong alignment between the PD's goals with the teachers' school culture was one factor in the teachers' continued use of elements from the PD. Teachers also continued to emphasize core elements of the PD, including valuing student talk as a way of mediating student thinking.

Keywords: Teacher Education-Inservice; Elementary School Education; Classroom Discourse"

Although 99% of US school teachers reported attending professional development (PD) in 2011 (NCES, 2013), it is unclear how teachers engage with professional learning experiences and change practice over time. Current work studying PD effectiveness suggests effective PD is sustained over time, focuses on content, and occurs within a community of practice (Garet et al., 2001; Boston & Smith, 2009; Desimone, 2009; Louis, Marks, & Kruse, 1994). Yet many current measures of effectiveness only examine teachers while they are participating in the professional development. Those measures of effectiveness fail to examine the lasting effects of professional development over time.

This study joins an emerging field of work that addresses an often neglected measure of PD effectiveness: *sustainability* of teacher change. For the purposes of this study, I adapt definitions from Fishman et al. (2011) and Franke (2001). *Sustainability* is defined as a teacher's continued use of the intervention in ways congruent with developers' intent after resources and support for such practices have been withdrawn.

Others' work in sustainability shows what features of PD result in sustained teacher change. Preliminary results suggest these features include teacher group cohesion, communities of practice, teachers' perception of the usefulness of the intervention, alignment of the PD with current practice, and alignment with other stakeholders' expectations of instruction (Hodges & Cady 2013, Fishman et al., 2011; Franke et al., 2001; Coburn, 2003; Gutierrez & Penuel, 2014).

This instrumental collective case study (cf. Stake, 1995) describes two teachers' mathematics instruction three years after the completion of a professional development program. It seeks to answer the overarching questions: In which ways did teachers sustain PD ideas into their practices or not? From the teachers' perspectives, what factors affected sustainability of the professional development ideas? Specifically, what classroom aspects of Project AIM have been sustained? What grade level team aspects of Project AIM have been sustained? What aspects of Project AIM beyond the second grade team have been sustained?

Theoretical Framework

Professional development intends to facilitate teacher change over time. Researchers have examined teacher change within the context of creating and adapting new knowledge (Franke 2001). I adapt a Vygotskian framework, like that described by Gallucci, Van Lare, Yoon, & Boatright (2007). It includes the following steps:

- Individual *appropriation* of particular ways of thinking through interaction with others
- Individual *transformation* and ownership of that thinking in the context of one's own work
- *Publication* of new learning through talk or action
- The process whereby those public acts become *conventionalized* in the practice of that individual and/or in the work of others (p. 296)

Methodology

As this is a sustainability study, I provide a brief description of Project AIM, the initial professional development program in which the participating teachers engaged. During the 2011-2012 school year, 26 teachers participated in a year-long, forty-hour professional development. The professional development was offered in a large Southeastern U.S. school district. Conditions of participation in the PD included teaching second grade and attending in school teams. The professional development had a focus on "math talk" or mathematics discourse.

Study participants were selected from the pool of 26 teachers who formerly participated in Project AIM in the 2011-2012 school year. By design, the PD required teachers to attend with colleagues from their grade-level school teams. In order to examine teacher group cohesion, this study follows two teachers who work together. These two teachers from Barnes Elementary were members of a group of three who attended PD together and continued to teach together in second grade after the completion of the Project AIM PD. These teachers represent two individual case studies.

Data sources for the study consist of a set of baseline data from the 2011-2012 PD year and follow-up data collected during the 2014-2015 school year. The PD year data include written pre- and post- beliefs questions and a math lesson artifact package for each teacher. The follow-up data include a follow-up math lesson artifact package, a semi-structured interview, a team focus group, and two lesson cycle observations for each teacher. Data analysis involved an iterative approach outlined in Decuir-Gunby et al. (2011), where theory, data (the participants' own words), and research goals (interest in sustainable elements of professional development) inform the code development.

Results

Barnes Elementary follow-up

Nora and June teach together at Barnes Elementary, a school with strong emphasis on Paideia seminars. Teachers at the school regularly engage their students in group discussions across subjects.

Nora. At the time of the professional development, Nora, a white female, was in her second year of teaching second grade. She earned her Bachelor of Science degree in Elementary Education. Nora valued students' comfort level when describing important attributes of math talk. By the end of the PD, she had some specific strategies to establish that comfort: building up strategies throughout the year and using question stems.

Since the completion of the PD, Nora has engaged in many additional professional learning activities. She has completed a Masters degree in Education. She is active in the National Paideia Center by attending conferences and presenting seminars. She has also taken on a number of leadership roles in her county and school; she writes and reviews math lessons for the county, while her school leadership includes serving on her school's magnet committee and serving as grade chair.

June. At the time of the professional development, June was in her eleventh year teaching at Barnes. Of her ten previous years teaching, three were in third grade and seven were in second grade. She earned her undergraduate degrees in Elementary and Special Education. At the beginning of the PD June valued student comfort as the most important aspect of math talk. By the completion of the

PD, she expressed other aspects of math talk as more important: questioning, high-level tasks, and active listening.

Since the completion of the PD, June has continued to actively work in her school mentoring newer teachers. She is passionate as she discusses her continued love for second grade. She has attended multi-disciplinary conferences that align with her school's Paideia scholarship.

Cross-case Analysis

Initial results suggest that there are multiple aspects of the professional development still being implemented and adapted three years after the completion of the PD. Some of these are found in the following table:

What aspects of Project AIM PD have been sustained in participating teachers' classrooms?

Sustained Aspect of the PD	Example
The PD introduced some specific strategies to begin to scaffold student talk in the classroom	Teachers learned a strategy called "Bet Lines" during the PD and have continuously used that strategy in much the same way as it was presented in the PD.
The PD emphasized careful planning for instruction, including selection of high-demand tasks.	One teacher now critically examines "challenge" tasks in curriculum materials, selecting and modifying tasks so that they will be of high cognitive demand.
The PD emphasized that small group work is a time when more students have the opportunity to participate.	One teacher reflected that her students with limited language skills were more engaged in pair work than with whole group work. Rather than "checking out" during whole group discussion, the opportunity to speak with a partner promoted talk.

This presentation focuses on how teachers continue to value student talk as a way to reveal thinking. June and Nora both discussed the importance of student talk. June reflected on the PD's alignment with her school's philosophy: "[W]e're not necessarily a STEM school, but we do a lot of STEM thinking. So a lot of it is just constantly using the discourse and explaining your thinking and the kids questioning and so it's constantly kind of tied together in some ways."

There was evidence of this in June's classroom, as she encouraged discussion and critical thinking in all subjects, including math. During her classroom instruction, June pushed her students by using probing questions. She also scaffolded students' interactions by encouraging them to disagree respectfully or ask one another clarifying questions.

Nora also reflected on the importance of student discussion as a way to mediate understanding: "We are starting number sense now. You know, that's so important in second grade, the major work that we do, and I wanna make sure that every kid understands it, but sometimes you have to kinda let that go and hope that maybe they will understand it better when they're hearing conversation and hearing their peers share. You have to, kind of, take away some of the control from me and give it to the kids."

There was evidence of Nora putting these ideas into action in her classroom. During one classroom observation, students were assigned rotating roles for their small group work. (This was one strategy for talk presented in the PD.) One student's role in each group was the questioner. Nora provided the questioner with some possible questions to ask relevant to the activity. As she and her class discussed the lesson at the end of the class, Nora asked her class which of the three roles had helped the students best understand the math activity. Many expressed that being the questioner had helped them to understand the task better.

Conclusion

This study shows that a strong alignment of PD goals with teachers' administrative goals allows teachers to engage with and sustain professional development ideas long after the professional development has completed. In fact, teachers expressed that Project AIM fit naturally in to the work they were already, not feeling like doing the work of the PD was "just one more thing." Future professional development should consider alignment with current administrative goals in order to make their work relevant to teachers for years to come.

TEACHER BUY-IN FOR PROFESSIONAL DEVELOPMENT: 4 DISTINCT PROFILES

Jodi Fasteen
Portland State University
jfasteen@pdx.edu

Eva Thanheiser
Portland State University
evat@pdx.edu

Kathleen Melhuish
Portland State University
melhuish@pdx.edu

Professional development (PD) provides an opportunity for teachers to grow in their practice, but this growth is mitigated by teachers' buy-in for the PD. We examine factors that affect teacher buy-in for PD, creating profiles for 4 different levels of buy-in. Thematic analysis based on field notes from the first year of a sustained PD focused on improving mathematics instruction showed that individual teacher buy-in was affected by (a) the teacher's view of mathematics, (b) the teacher's view of their students, and (c) the teacher's perceived need for growth in their own practices.

Keywords: Teacher Education-Inservice; Teacher Beliefs

In this report, we explore different ways in which elementary school teachers interact with a high-quality, sustained, district-wide professional development (PD) for mathematics teaching, *MathematicsStudio PD* (Foreman, 2010). How teachers interact with a PD depends on various factors, including (a) their beliefs about mathematics, (b) their views of their students' mathematical capabilities, and (c) their beliefs about their own need to grow in their teaching practices.

Perspectives / Theoretical Framework

Darling-Hammond et al. (2009) synthesized research on PD in education, noting that "effective professional development is intensive, ongoing, and connected to practice; focuses on the teaching and learning of specific academic content; is connected to other school initiatives; and builds strong working relationships among teachers" (2009, p. 5). Likewise, in her summary of successful PD, Klingner (2004) advocates for long-term support for teachers rather than one-shot PD. Klingner notes the importance of a community of practice, of administrative and mentor support, and opportunities to observe demonstrations of the target practices. She lists the following factors as contributing to teacher buy-in for PD: (1) grassroots support from teachers (as well as support at administrative levels), (2) teacher involvement in planning of the PD, and (3) transfer of ownership from the PD providers to the teachers.

The PD in this study was designed to align with Darling-Hammond et al.'s (2009) characteristics of effective PD. However, the PD was district-wide and opt-in to participate in the PD happened at the school level rather than the individual teacher level, thus support from teachers was not grassroots in all cases as advocated by Klinger (2004). Given that school- and district-wide PD is a common feature of in-service teacher education, it is worthwhile to investigate teacher buy-in for PD that they did not select for themselves. Because buy-in for PD is linked to teacher implementation of research-based practices, understanding what affects buy-in may allow PD providers to have a stronger impact on the teachers they serve. For the purpose of this paper, we define *buy-in* for PDas active engagement with and support of the PD.

Underlying Principles of the *Studio PD*

The *Studio* PD advocates for student-centered classrooms where activity centers on mathematical sense making, reasoning, and understanding by all students. All students are to engage in discourse that focuses on sense making, justifying, and generalizing mathematical ideas. In this way, mathematics is not treated as a set of rules, but rather as an interconnected and logical structure (Hiebert, 1986). However, teachers have been shown to frequently view mathematics as a "fixed set of factors and procedures" (Smith III, 1996, p. 392). As noted by Smith, this view of mathematics often occurs in conjunction with teaching that is primarily prescriptive in nature where teachers tell the mathematics rather than have students explore and engage in mathematics themselves.

Beyond just seeing mathematics as more than a set of procedures, teachers must also see students as being capable of engaging in mathematical habits and practice. The professional development advocates for a growth rather than fixed mindset (Dweck, 2007). A teacher with a fixed mindset might feel that only their “strong” students were capable of engaging in mathematics. One has a fixed amount of intelligence and no amount of work will change that. A growth mindset approach changes focus from intelligence to effort where anyone is capable of learning and improving.

Underlying the PD is the assumption that teachers are reflective practitioners. That is, the teachers are asked to reflect on their teaching and consider how they might grow in their practice. However, this presupposes that teachers have a disposition for changing their teaching. We posit that teachers must feel there is a need to grow to engage fully in the PD.

Methods

Data for this project comes from a large-scale study looking at the efficacy of a 3-year PD in an urban school district. For this study, we focus on the first year of the PD, which began with a 3-day summer workshop on best practices for teaching mathematics and then included 5 two-day PD sessions situated within each school spread across the school year. Each of these two-day sessions included a morning of leadership coaching with the principal, an afternoon of PD with the studio teacher (a resident teacher who opened her classroom for facilitated observations by the other resident teachers), and a full day of PD with the studio teacher and other resident 3-5th grade teachers. The first year of the PD focused on the *Mathematical Habits of Mind and Interaction*(Foreman, 2010), a set of metacognitive skills for engaging with mathematical ideas and problems, in conjunction with the *Mathematically Productive Teaching Routines*(Foreman, 2010) which support student engagement in the Habits. Posters of the Habits were prominently displayed in each classroom.

Researchers observed each PD session and took detailed field notes at two case study schools. The PD sessions were also video-recorded and relevant sections transcribed for analysis. The field note data was analyzed using thematic analysis (Braun & Clarke, 2006). To examine the varying levels of buy-in and engagement among the teachers, the data was analyzed to look for trends across teachers.

Results & Discussion

Variations in teacher buy-in for the PD were linked with two primary characteristics: alignment of the underlying principles of the PD and the teacher beliefs about students and mathematics, and teachers’ own perceived need to grow. Table 3 shows four different types of buy-in based on these primary characteristics. While the profiles for high and low buy-in had clear-cut relationships with belief alignment, mid-level buy-in took a number of forms. We present two teachers with mid-level buy-in: Kim and Nina. Kim’s beliefs about mathematics and children aligned with the principles of the PD, however, her buy-in was mitigated by an inconsistent perceived need to grow in her practice. Nina’s beliefs and perceived need to grow fluctuate leading to varying levels of engagement and support of the PD. In this report we focus on the teachers’ perceived need to grow due to space limitations.

Table 3 Four profiles of teacher buy-in for PD, focusing on two attributes of teacher beliefs

Teachers	Cora	John	Kim	Nina
View of mathematics and their students	Aligned	Not aligned	Aligned	Conflicted
Perceived need to grow in their own practice.	Yes	No	Conflicted	Conflicted

Buy-In	High	Low	Mid	Mid

Kim can be described as seeing mathematics as a sense-making subject and a context for rich student discourse, viewing her students as capable of engaging in the Mathematical Habits advocated by the PD, and generally being conflicted about her perceived need to grow.

In terms of her perceived need to grow Kim often felt she was already engaging in the practices advocated by the PD (demonstrating low buy-in). By advocating for reflection and alterations in teaching, she felt the PD providers were challenging her status as a professional.

> I think most of things we are [already doing]. I feel like, … like we feel like [we are treated as if we] were incompetent or something, you know. [The PD should recognize] that we have to feel that some of these things we do! … it's not like right now we are all the sudden changing our teaching skills or our teaching strategies, you know.

However, Kim also recognized the PD as useful (demonstrating high buy-in) when she found that it provided her with tools that she saw as immediately applicable in her classroom to solve one of her problems of practice. For example, consider Kim's reflection on a discussion protocol discussed in the PD:

> Well, I think with this particular strategy [having students interpret and compare their responses with each other], it's great because ... you are made to look at someone else's problem and explain to the other person what it is. So, it makes them [the children] become truly the listener and then maybe by doing that you are clarifying … your idea or seeing things, you know, so they are processing.

In contrast to Kim, Nina waivers in her fundamental beliefs. She fluctuates between seeing mathematics as a set of rules or a sense-making subject and whether she sees her students as capable of engaging in the mathematical habits advocated by the PD or not. Her perceived need to grow is mitigated by her doubts around her mathematical ability and her doubts of her own efficacy when transitioning away from a *teaching as telling* model (Smith III, 1996) towards a student-centered classroom.

In terms of her perceived need to grow, Nina recognized some positive effects of the PD and she wavered between seeing teaching as something to be refined/improved and reverting to her "traditional" approach. She explained:

> I'm still old-school, I am learning it with the students. I think I need as much practice as they do. ... I've got to just make it work better next year. I'm practicing [to engage students in sense-making] and I see how it is working for everyone, especially the slower student who thinks math a little less quickly as others.

In this statement, Nina's conflicted beliefs are evident by her self-label as "old school" but are in conflict with Nina seeing that the changes advocated by the PD are working for students (demonstrating a high level of buy-in). While Nina appears to be positively approaching change, she also explains she reverts back to her prior teaching style when students are not meeting her expectations (low buy-in).

> Once they can't reach it [sense-making], I'm like, 'Okay, this is how we did it in 5th grade' because back in the day we didn't get to talk. We had to do, do, do – … So I show them how I did old-fashioned math that got us to Einstein, to build a rocket and everything else. Now, we're talking math and talking math and talking math and sometimes they don't get it through the language.

Nina engaged in the PD and attempted to make changes to her classroom. She responded positively to the potential effects of the new teaching routines and student mathematical habits when she saw evidence that her struggling students found success. However, when facing doubts of efficacy, she often abandoned the practices advocated by the PD.

Conclusions/Take-Away

In order for high quality professional development to be useful, the teachers receiving the PD must buy-into the PD and take on the work in their own teaching practice. This is particularly true in the case of district-wide PD which is not self-selected by each teacher. The teacher profiles provided insight into what teacher buy-in may look like and how individual teacher differences may lead to differing levels of buy-in within the same PD. It may be difficult to generate teacher buy-in if their beliefs about mathematics and related pedagogy do not align with those advocated by the PD. When aligned, teachers can look to the PD to support their teaching practice. When unaligned, teachers may choose not to incorporate the principles of the PD into their practice. Additionally, we found that a perceived need to grow in teaching practice was a mitigating factor for buy-in. If a teacher is willing to acknowledge problems of practice in her own classroom and she is willing to try new teaching techniques, then a district-wide PD can provide welcome support for growth. If teachers believe they are already doing well enough, they may have little motivation to engage with "yet another" district-wide PD. Therefore, we advocate that PD providers consider how to actively leverage teachers' own perceived needs when designing and enacting PD.

60 PSTs engaged in the practice of professional noticing of children's mathematical thinking of one student's work in finding ¼ of a set of 8 baseball cards. While PSTs were mostly successful (> 65%) when examining the facets of professional noticing as individual skills, < 50% of PSTs were successful in mobilizing all three in a coordinated manner.

Keywords: Teacher Education-Preservice; Elementary School Education; Instructional Activities and Practices

Educational approaches have suggested effective instruction should build upon students' ways of understandings mathematics (NGA & CCSSO, 2010; NCTM, 2014). Professional noticing of children's mathematical thinking (Jacobs, Lamb, & Philipp, 2010) is a construct that has been introduced and used frequently as a framework to understand the ways in which teachers attend to, interpret, and respond to children's mathematical thinking (e.g., Dietiker et al, 2014). Professional noticing has been described as a difficult practice to develop, but also as one that can be learned. In this paper, we present our analysis of PSTs' responses to a pedagogical activity designed to engage them in professional noticing within a fraction context.

Theoretical Frame

Our "Baseball Card Problem" activity design drew on the work of Jacobs and her colleagues (2010). Professional noticing is comprised of three related skills: attending to children's strategies, interpreting children's understandings, and responding to children. Our activity provided a sample of student work along with specific questions designed to examine PSTs' processes of professional noticing within the context of a fraction multiplication problem. Fraction operations have long been considered to be the most difficult topic for elementary teachers to both understand and teach effectively (e.g. Ball, 1990); similarly often demonstrate "limited understanding of the meaning of multiplication and division of fractions" (Armstrong & Bezuk, 1995, p. 87).

Methods

Data came from 72 PSTs from two different university sites during the 2011-2012 academic year. Each was enrolled in an elementary mathematics methods course jointly designed and delivered by a sub-set of the authors. Within the section of our course addressing making sense of and responding to student work, we have designed activities to support the development of PSTs' professional noticing of children's mathematical thinking (Jacobs, Lamb, & Philipp, 2010); specifically in the area of responding by posing a subsequent problem (Tyminski et al., 2014). The Baseball Card Problem was set within Tracey's 4th and 5th grade, multi-age classroom, in which she posed the following problem:

> Dustin has ______ baseball cards. He gives ¼ to his friend. How many baseball cards did he give to his friend?
>
> 8 24 44 60 100 144

Part I of the activity addressed Liev's (pseudonym) work finding ¼ of 8 baseball cards (Fig. 1).

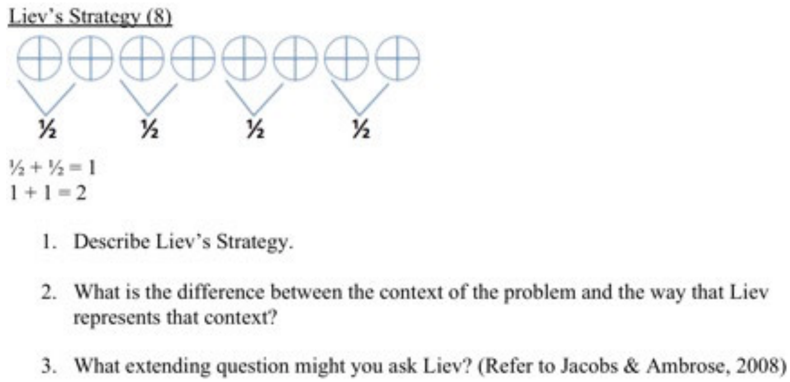

Figure 1: Liev's Written Response to the Baseball Card Problem

We associated question 1 with the skill of attending, question 2 with interpreting, and question 3 with responding. We specifically asked PSTs to respond by using an extending question, as outlined in a course reading, *Making the Most of Story Problems* (Jacobs & Ambrose, 2008).

Analysis

From the 72 PST responses, we selected a random sample of 12 from across the three sections of classes and included responses from both university sites. The authors utilized these 12 responses using open and emergent coding techniques (Strauss & Corbin, 1998) in order to develop and refine a coding scheme for the remaining 60 responses. The authors began by individually and independently reading through the 12 sample responses and creating a coding system for the responses to questions 1 and 2, which were negotiated and agreed upon. Question 3 was to be coded using *a priori* codes from Jacobs & Ambrose (2008). Once codes were established the second and third authors independently coded the responses for the remaining 60 PSTs. Reliability rates for each question were greater than 81%.

Results

We present results of PSTs' responses to the questions, including representative samples as well as a holistic view of PSTs' practice within this example of professional noticing.

Question 1

Question 1 asked PSTs to describe Liev's strategy. We coded PSTs' responses on a scale of 0-3. We next present descriptions of each code along with a representative example for each. All PST names are pseudonyms. Leah's response was coded as 0 as it was an incomplete description of Liev's work., "Liev has divided each of his baseball cards (which are round) into fourths and is giving one-fourth of each card to his friend". Erica's response was coded as 1 as it contained both correct and incorrect information.

> Liev is dividing each card into four equal parts. He then combines¼ of a circle to ¼ of another circle to show 2/4 of 2 circles is the same as ½ of 2 circles. He shows that ¼ of 8 circles will give him ½ of 4. He then joins the 4/2 to get 2.

Joan's response was correct, but omitted a key piece of information; it was coded as 2, while Angela's response was coded as 3 as it was correct, complete and precise:

> Liev draws eight circles to represent the eight baseball cards. He then divides each circle into fourths. Once he has divided the circles into fourths, he adds ¼ of the first circle to ¼ of the second circle and gets one half. Once he has done this for all of the circles, he adds ½ and ½ to

> get a sum of one. He then adds 1 and 1 to get a final answer of two. However, he does not take into account that Dustin gives away two WHOLE cards. By the work provided here, Liev makes it seem that Dustin is giving ¼ of each one of the eight cards to his friend.

Across the 60 PSTs, 25% of responses were coded as 0, 10% were coded as 1, 46.7% were coded as 2, and 18.3% were coded as 3. In all, 65% of PSTs' responses were scored 2 or above, indicating they had a complete or mostly complete and correct description of the student work.

Question 2

Question 2 was asked to support PSTs' interpretation of Liev's thinking beyond the fact he arrived at the correct answer. The context of the problem involves sharing baseball cards, but Liev's solution strategy involved cutting each card up into four equal pieces and giving his friend ¼ of each of the 8 cards. Although his answer is correct, his solution path does not make sense within the context of the problem. We coded PSTs' interpretation of this situation on a scale of 0 – 2, where 0 represented an incorrect interpretation, 1 indicated a correct interpretation with no detail concerning area models versus set models, and 2 indicated a correct interpretation with details. Michelle's is an example of one coded as 0:

> He is trying to find ¼ of 8 baseball cards, but when solving the problem it looks as if he took ½ of the baseball card to solve the problem but still looks as if he divided the 8 cards into four groups. The context of the problem was figuring out ¼ of 8 baseball cards. Therefore, it would make more sense if he would have divided the 8 circles into 4 groups and just took two from that instead of adding the ½ and ½.

Hazel's response was a correct interpretation, but contained little detail as to the mathematics of the situation, "He cuts up the baseball cards into ¼, but in real life you would not do that because then the baseball cards would have no value or make sense". We considered Norah's response an exemplary representation of a 2:

> The context of the problem is that Dustin is giving ¼ of his baseball cards to his friend. He is giving his friend a part of the set, not a part of each piece of his set. Liev does not divide the set into equal whole parts. He divides each part in the set into fourths. In other words, when giving baseball cards to a friend one would not give a piece of each card away. They would give whole cards. Liev does not make that connection to the context of the problem.

Of the 60 responses, 28.3% were coded 0; 40.0% were coded 1; and 31.7% were coded 2. Roughly ⅔ of PSTs correctly interpreted the situation

Question 3

Question 3 asked PSTs to respond to Liev by posing an extending question, as he was able to arrive at a correct answer. We coded only the first question PSTs included in their response according to the four categories from Jacobs & Ambrose (2008, p. 263). Considering the disconnect between the task context and Liev's approach, PSTs who asked a question to promote reflection on the child's current strategy (n = 32) seemed appropriate. We also viewed extending questions encouraging Liev to consider solving the problem another way (n = 19) as an appropriate response for the situation. There were no responses coded as 3, since Liev wrote number sentences, and the concerns most PSTs had were with his approach, not his symbolic representations. Nine PSTs responded with follow up problems for Liev. Of these, 3 PSTs suggested trying the same number choice, but with an easier fraction (½), suggesting that asking for one-half of the cards would encourage Liev to think about splitting the set into two equal parts, a response that seems appropriate. The remaining 6 PST did not suggest follow up problems that we considered appropriate based on Liev's thinking. In all, 90% PSTs responded with an appropriate extending question.

A Holistic View

We believe that the three skills must also be viewed holistically if we wish to understand PSTs' abilities to engage in this practice. We conducted a process of filtering PSTs' responses to determine how many engaged in each of the three skills in an appropriate and connected manner. We considered responses to Question 1 coded as either 2 or 3 as being successful in attending to Liev's work (n = 39). We considered responses for Question 2, coded 1 or 2 to be successful in interpreting Liev's work (n = 30). For Question 3, responses coded 1 or 2 were deemed as appropriate, along with the 3 PSTs who posed new questions using ½. In all 45% of PSTs successfully engaged in the professional noticing of Liev's work in a connected manner.

Discussion and Implications

The examination of PSTs' responses to individual skills within the construct of professional noticing reveal this group of PSTs was largely successful as all percentages were greater that 65%. However, when we took a holistic perspective of PSTs' responses, only 45% of PSTs were successful engaging in the three skills appropriately and in concert. The differences within the individual skills and the holistic view raise questions for future study.

THE DEVELOPMENT OF MATHEMATICS INSTRUCTIONAL VISIONS: AN EXAMINATION OF ELEMENTARY PRESERVICE TEACHERS

Temple A. Walkowiak

anwhiteh@ncsu.edu

The purpose of this study was to examine the development of preservice elementary teachers' visions of high-quality mathematics instruction as they progress through their teacher preparation program. Four case study participants were purposefully selected based upon whether their experiences with school mathematics as a child were predominantly positive or negative. Interviews were conducted at three time points, and the resulting data were analyzed for similarities and differences across participants. Findings indicated similar vision trajectories for those with the same type (positive or negative) past experiences in mathematics. Implications for elementary teacher preparation programs are discussed.

Keywords: Elementary School Education; Teacher Education-Preservice; Affect and Beliefs; Teacher Beliefs

Over the past five years, there has been a call for rigorous, well-designed, longitudinal studies of teacher preparation programs. (e.g., American Association of Colleges for Teacher Education, 2010; Cochran-Smith & Zeichner, 2010). Teacher preparation programs have come under fire, as evident in the recent suggestion by the U.S. Secretary of Education, to tie the "effectiveness" of teacher preparation programs to the assessment outcomes of graduates' K-12 students. Potential policies such as this speak to the importance of a carefully studying how preservice teachers develop on various constructs. Results of such studies can inform modifications to existing programs, and simultaneously, the findings can likely demonstrate impact of programs on other constructs beyond K-12 student assessment outcomes. The current study aims to begin to fill the void in the literature by examining how elementary preservice teachers develop in their visions of high-quality mathematics instruction over the course of their undergraduate preparation program. While there has been work on practicing teachers' development of visions (e.g. Munter, 2014), the current study focuses on preservice teachers and is particularly fitting for this population since "visions" implies a view of their future work as elementary teachers.

Teachers' visions, as outlined by Hammerness (2001) are "a set of images of ideal classroom practice" (p. 143); the development of instructional visions cannot be separated from past experiences (Hammerness, 2001). Typically, elementary teachers do not choose their occupation due to a love of mathematics, unlike secondary teachers of mathematics. Elementary teachers may recall their childhood experiences with school mathematics as positive, or they may describe negative experiences. Since past experiences matter for the development of instructional visions, the work of the current study is warranted. The specific research questions guiding this study were: (1) How do elementary preservice teachers with positive childhood experiences in school mathematics develop in their vision of high-quality mathematics instruction over the course of their teacher preparation program?; (2) How do elementary preservice teachers' with negative childhood experiences develop in their vision of high-quality mathematics instruction?; and (3) What are the similarities and differences in the development of instructional visions across all teachers?

Theoretical Framework and Related Literature

The current study draws on the framework proposed by Hammerness (2001) on teachers' visions and on more recent work by Munter (2014). Hammerness (2001) noted that teachers' visions tend to vary across focus (what are the areas of focus as they describe their vision), range (how narrow or broad is the articulated vision), and distance (how far or close the vision is to their actual practice). The current study examines the first of these ideas – on what the preservice teachers ***focus*** as they describe their visions of high-quality mathematics instruction. Drawing on standards-based practices in the mathematics education literature, Munter (2014) developed a framework for examining the role of the teacher on five progressively sophisticated levels: motivator, deliverer of knowledge, monitor, facilitator, and more knowledgeable other. As one moves up the levels in the framework, the descriptors are more aligned with a vision of standards-based mathematics teaching practices.

Methods

Participants

Participants were purposefully selected from a larger sample of 19 preservice elementary teachers who were participating in a larger grant-funded study (Project ATOMS) focused on program

Table 1: Participants' Childhood Experiences in School Mathematics

Participant	*Experiences*	*Quote*
Felicia*	Positive	"I've always loved math, it was, I think it was my always my strong point in elementary school. I was really good, but it was the way it was taught to me, it was purely memorization, but I was so good at that. So, I I didn't understand why other people were getting frustrated and I just completely understood, you have a formula plug and chug. So, that was always my favorite homework to do."
Adrienne*	Positive	"Math has always been my favorite subject. It's always been a thing that kind of comes easy to me. I like working with numbers and filling out equations and puzzles and stuff like that. It's something that's always interests me, so I've always enjoyed math."
Paul*	Negative	"Math is a, oh God, and Dr. Smith* would probably just cringe but it's, that's just, it's no, I never had that one teacher that made me be like oh, math is the answer to everything, it was, like I said, I just kind of flew under the radar. I could do my multiplication table, I mean, I could, I mean, I wasn't amazing at them, but AIG I had a teacher named Ms. Rutherford* and she was the scariest woman on earth and I think that made me also shy away from it cause she was so mean, she would push us and push us but there was no reciprocation, no caring…So, I've always been the one that was kind of on the lower end of math and I never took calc in high school cause I didn't, I didn't want to push myself so that was kind of me."
Terri*	Negative	"Math was a huge source of frustration for me, mostly because I, I think it was because I was really good at everything else, I was a really good student but I wasn't really quick with math and math took a little bit more effort and I attributed to me not being good at it and me failing so the timed multiplication quizzes I would get really stressed out about those, those were always just really hard, I hated them and once we got into long division I had a teacher who was actually a teacher who influenced me a lot in other ways but she only explained it to me one way and she would not explain it to me any other ways and I just didn't get it and that just made me hate math and from then on I just hated math, like I would go home and cry doing my homework."

*Names are pseudonyms.

evaluation. The four participants were selected based upon their articulation of their own experiences with school mathematics as a child. Two of the participants (Felicia and Adrienne) had positive experiences with school mathematics. In contrast, the other two participants (Paul and Terri) described negative experiences with school mathematics from their childhood. Table 1 presents each participant along with quotes describing their childhood experiences in mathematics.

Data Sources

The data for this study comes from three interviews among a larger set of interviews completed with each of the participants. The three interviews included an introductory interview at the beginning of their full-time enrollment in professional studies courses (beginning of junior year), a midpoint interview completed halfway through their professional studies courses (end of junior year), and a final interview completed just before graduation from the program (end of senior year). The analysis was not limited to, but primarily focused on participants' responses to two questions: (1) Describe a math lesson in an elementary school classroom that you would consider to be effective and explain why you consider it to be effective; and (2) What the teacher does and what the students are doing during mathematics instruction are really important. Describe what you think the teacher should be doing most of the time, and describe what you think the students should be doing most of the time.

Analysis

This study used a qualitative, case study research design. The pair of preservice teachers with positive experiences in school mathematics constituted one case; the other pair made up the second case. There were two levels of analysis: (a) an analysis of each case (or pair of teachers), and (b) a cross case analysis (Yin, 2009). The framework presented by Munter (2014) served as the foundation for coding and for analyzing patterns within a case and across cases.

Findings

RQ #1: Case #1 → Positive Childhood Experiences with School Mathematics

Both Felicia and Adrienne ended their preparation programs with descriptions of their instructional visions as the teacher as "facilitator." In other words, in their descriptions, they tended to focus on the teacher as promoting student-student discourse and probing students as needed as they work in small groups. For example, Felicia said the ideal lesson would be:

> Just the students having really good discourse and not just working through a ton of like procedural problems, but having two or three where they are really able to have all those conversations and make sure that they are really like working as mathematicians and explaining their thinking, talking it out, showing multiple representations and then the teacher is there as a facilitator walking around in between groups listening to what's being said and interjecting when necessary.

At the midpoint of the program, both participants also viewed the teacher as "facilitator." For example, Adrienne said,

> I feel like the teacher needs to possibly pose a problem or a question and then the kids need to discuss it and they need to not only think about it themselves, so maybe kind of do like a think pair/share thing where they're thinking about it and then they're sharing with their partner to kind of and when they're sharing that you could always kind of purposely pair them.

The participants differed at the beginning of the program. Felicia started the program describing the teacher as a monitor in which she described the teacher sharing some knowledge but giving students opportunities to apply the knowledge while the teacher monitors the small group work. In contrast, Adrienne started the program with the teacher having the role as motivator and deliverer of knowledge. She said,

> I would say the teacher would need to first of all be excited about what they were teaching about. Second of all, actually explaining what they are doing not just presenting them with a set of procedures and going off of it but actually explaining why they have to do that and why they have to, why they get the answer.

RQ #2: Case #2 → Negative Childhood Experiences with School Mathematics

Paul and Terri both ended the program describing the teacher as a monitor in which the teacher still disseminates knowledge to the students but gives the students the chance to practice or apply that knowledge in small groups while the teacher monitors. For example, Terri said,

> There should be some direct instruction… I don't… not… not a lot of up front full class instruction. Um, the teacher should be explaining things uh, not from a procedural point of view from the beginning obviously, it should be um, teaching the foundational skills and teaching why things are in questioning and encouraging a lot of discourse throughout the classroom. Asking kids to explain and justify their thinking. The kids should be working in groups. Um I think there should be a good mix of independent work and working groups where there should be a lot of collaboration.

Terri remained at the "monitor" level throughout her teacher preparation program in the description of her vision, but Paul started as describing the teacher as a motivator and deliverer of knowledge when he says, "enthusiasm, enthusiasm, you got to, you got to show the kids this is fun" and moved to describing the teacher as monitor at the midpoint of the program.

RQ #3: Cross-Case Analysis

With the exception of Terri, all participants progressed in their visions of high-quality mathematics teaching. Both participants who had negative experiences during childhood mathematics ended the program describing the teacher as a monitor, whereas the two participants with positive experiences ended the program describing the teacher as a facilitator, which is more aligned with standards-based instruction.

Discussion

It seems understanding our students' backgrounds and experiences in school mathematics is important for our work as mathematics teacher educators. We are not attempting to generalize to the larger population; however, the themes among these four participants in their articulation of their instructional visions suggest backgrounds do matter, particularly in how they progress along a standards-based vision of high-quality mathematics instruction.

This study addresses the continuation of a teacher noticing project as we ask: How does preservice teachers' noticing develop in a mathematics content course for teachers that incorporated unique opportunities for the PSTs to analyze middle grade students' work? In a previous study (Warshauer, Strickland, Hickman,& Namakshi, 2014), we learned that preservice teachers enrolled in a mathematics content course improved their knowledge of content and students as well as their content knowledge as measured by the Learning for Mathematics Teaching instruments (Hill, Schilling, & Ball, 2004). Our aim is to now investigate the relationship between that growth and a specific writing intervention targeting the preservice teachers' noticing of middle school student thinking.

Keywords: Teacher Education-Preservice; Mathematical Knowledge for Teaching; Teacher Knowledge

Purpose and Introduction

Recognizing teacher quality as critical to student learning, the National Research Council (2010) underscores the importance of strengthening teacher preparation programs. University preparation of future teachers typically includes coursework in school subject areas (mathematics in our case), in education and methods, as well as classroom observation, student teaching, and other field experiences (NRC, 2010). Inspired by research that suggests *teacher noticing* can be developed (Miller, 2011), we designed our study to examine how such development might take place in a mathematics content courses for teachers at a university.

In a previous study (Warshauer et al., 2014), we learned that PSTs enrolled in a mathematics content course improved their knowledge of content and students (KSC) as well as their content knowledge (CK) as measured by the Learning for Mathematics Teaching (LMT) instruments (Hill, Schilling, & Ball, 2004). We began the investigation of the relationship between that growth and a specific intervention in the form of writing assignments (WAs) targeting the PSTs' noticing of middle school student thinking. We purposefully chose a WA-based noticing study rather than the more common video-based studies (Sherin & van Es, 2009) because we wanted to reduce the complexities that occur in most classrooms (e.g., teaching moves) and provide a static object that the PSTs would examine for their noticing assignment. Furthermore, assessing homework and paper-based work by students is a common aspect of instructional practice and therefore a natural context for focusing on student thinking. For each WA, the PSTs engaged in a mathematical task during class in groups, participated in whole class discussion of their strategies, and were then given a packet of middle school students' work on that same task and asked to analyze the students' thinking; this was enacted for three rounds with new tasks each round. This proposed talk addresses the continuation of the project as we ask: *How does PSTs' teacher noticing develop in a mathematics content course that incorporated unique opportunities for the PSTs to analyze middle grades student work?*

Theoretical Framework

Research shows that *teacher noticing* is a critical element for effective teaching (Sherin, Jacobs, & Philipp, 2011). We use the definition of *teacher noticing* proposed by Jacobs, Lamb, and Philipps (2010) as three interrelated skills consisting of attending to student's strategies, interpreting student thinking, and deciding on how to respond based on student understanding. *Principles to Action* (NCTM, 2014) includes the mathematics teaching practice, "elicit and use evidence of student thinking" (p.11), and emphasizes the use of evidence of student thinking as an effective practice that informs teaching and supports learning. In particular, what teachers attend to and how they interpret students' mathematical thinking is consequential to the decisions they make in their teaching of mathematics (Jacobs, Lamb, & Philipp, 2010).

A role of mathematics teacher education is to develop teachers' mathematical content knowledge (Hill, Sleep, Lewis, & Ball, 2007) by providing experiences for PSTs to deepen their conceptual understanding of mathematics (Ball, Hill, & Bass, 2005) and to assess students' mathematical work (Hiebert, Morris, Berk, & Jensen, 2007). Philipp (2008) contends PSTs benefit from learning "…about children's mathematical thinking concurrently while learning mathematics." (p. 8). In doing so, Philipp and his colleagues (2007) found that the PSTs were more motivated to learn mathematical concepts beyond just the procedures in order to teach students mathematics for understanding. While studies suggest that *teacher noticing* can be developed (Miller, 2011), findings from Jacobs et. al. (2010) indicate that *teacher noticing* develops with deliberate practice involving particular experiences. Previous studies have explored PST *noticing* in methods courses and student teaching. An important question to investigate, therefore, is how a content course, taken earlier in their program, could be a fruitful environment for starting a trajectory of *noticing* that can develop as PSTs progress through their certification courses and experiences.

Methods

The study reported here was nested within a larger mixed methods project conducted in 2014 over a 14-week semester at a state university in the southern United States. Participants included 128 elementary and middle school PSTs enrolled in six sections of a mathematics content course focused on number and operations. The only selection criteria for the participants were their enrollment in the course and that they gave consent. We report on the qualitative analysis of data related to only eight PSTs who were selected because their first WA seemed to place them in a lower or higher category of noticing based on our rubric.

We used three WAs spaced throughout the semester and interviews to investigate our research question: *How does PSTs' teacher noticing develop in a mathematics content course that incorporated unique opportunities for the PSTs to analyze middle grades student work?* The *writing* intervention was unique in that it was implemented in a content rather than a methods course or later in the PSTs' teacher preparation experience such as student teaching. Each WA cycle began with class time for the PSTs to collaboratively solve a problem-based task intended for the middle grades curriculum (Schoenfeld, 1999) and then discuss their solutions as a whole class. Afterwards, PSTs were provided packets of middle grade students' work (ranging from four to six students per WA) on the same task. The PSTs were instructed to analyze the student work at home and write a paper addressing each student's understanding (or lack of) while providing evidence from the student work to support their claims. Guided by the coding described by Sherin, Jacobs, and Philipp, (2011), we developed a scoring rubric for assessing the PSTs attention to the *noticing* components of *attending* to and *interpreting* student thinking.

Task-based interviews with the eight focus PSTs were conducted at the end of the semester in which they were asked to analyze a single student's work from WA1 that had not been previously assigned. The interviews concluded by prompting PSTs to reflect on what they had learned via the

WAs. To analyze the interviews we used open coding (Strauss & Corbin, 1990) to determine themes that arose from the transcripts of the eight PSTs' interviews with a focus on how they interpreted the WAs in relation to their teacher preparation development.

Results

We report our findings from two main sources to shed light on our research question: *How does PSTs' teacher noticing develop in a mathematics content course for teachers that incorporated unique opportunities for the PSTs to analyze middle grades student work?*

Using data from all 128 PSTs in a multiple-regression model, we examined the effect of their WA1, WA2, Pre-CK and Pre-KSC scores on their Post-CK and Post-KSC scores, respectively. In both models, PSTs' scores on Pre-CK and WA2 were significant. This suggests that by the time the PSTs enacted WA2, they had improved their noticing and this was correlated with their CK and KSC post-scores. Also, in both models, pre-CK was the strongest predictor of their post-LMT scores.

Our findings from the eight focus PSTs' WA data suggest: (1) Among the PSTs with Low levels of attending and interpreting there was a lack of content-specific insights; (2) The growth among PSTs with High levels of noticing varied little across the three WAs possibly due to a ceiling effect; (3) PSTs frequently used subjective accounting **for** and not accounting **of** student work (e.g. attributing errors to "laziness") (Mason, 2002); and (4) Slight growth detected in noticing skills with enriched descriptions of student work from WA1 to WA2 or from WA2 to WA3 in five out of eight focus PSTs.

Upon analyzing the PSTs' interview data, we found four main themes. (1) PSTs found it helpful to hear a variety of their peers' strategies during the in-class problem solving of WA tasks when later attending to and interpreting the student work; (2) WAs were a challenge, as the PSTs had never done anything like this before; (3) PSTs paid closer attention to students' explanations and did not just evaluate students' answers in order to determine what students understood; and (4) Instructor feedback guided PSTs on what to look for in subsequent WAs.

Conclusion and Implications

Analysis of the interview data suggests that PSTs have had little experience with examining student work prior to this course. The WAs therefore created opportunities for PSTs to engage in the important instructional practice of examining student work to understand what the students were thinking and understanding in addition to learning the mathematical content related to the students' work. Through their own enactments of the WA task problems in class, the PSTs began to think of and appreciate the multiple approaches to problems. This seems to have informed the PSTs that students, too, might approach problems differently. The WAs appear to support the development of *teacher noticing* with a focus on student thinking. The challenges faced by the PSTs appear to stem from lack of experiences in writing about students' mathematical thinking, particularly for students who showed little work. A WA format rather than a video, for example, gave PSTs an opportunity to review the student work at their own pace and refer to class notes and other resources to reflect upon and write about their noticing. However, PSTs initial interpretations relied more on their own experiences than possible mathematical reasoning based on students' work. In other instances, they used non-mathematical bases such as students' laziness, sloppiness, or being in a rush as reasons for the work or lack of work on the students' papers. Instructor feedback of the WAs and PSTs' reflections on their previous ones hold promise as supports for PSTs' development of *teacher noticing*. In a continuing project, we plan to follow a cohort of PSTs from this study to examine the development, if any, of their *teacher noticing* as they progress beyond the content courses into subsequent teacher preparation courses as well as conduct a quasi-experimental study controlling for WAs.

DESIGNING SIMULATED STUDENT EXPERIENCES TO IMPROVE TEACHER QUESTIONING

Corey Webel
University of Missouri
webelcm@missouri.edu

Kimberly Conner
University of Missouri
kachz9@mail.missouri.edu

In this paper we share preliminary outcomes from the first enactment of a set of "simulated student" experiences designed to improve preservice elementary teachers' ability to recognize and pose "high leverage" questions in response to students' mathematical thinking. Implications for future iterations are discussed.

Keywords: Teacher Education-Preservice; Instructional Activities and Practices; Teacher Knowledge

Purpose

The purpose of the study is to develop and study an instructional intervention aimed at helping preservice elementary teachers (PSTs) develop their skill in specific teaching practices. In this paper we describe how a "simulated student" tool can support PSTs in developing the skill of asking questions that extend or build on students' mathematical thinking. This project responds to recent calls in mathematics education for better defining the specific practices involved in teaching mathematics and shifting emphasis in teacher education from simply developing knowledge about teaching to providing structured opportunities to practice carrying out this work (Ball & Forzani, 2009).

Theoretical Framework

We see teaching as highly situated, which means that "how a person learns a particular set of knowledge and skills, and the situation in which a person learns, become a fundamental part of what is learned" (Borko et al., 2000, p. 195). One implication of this view is that if preservice teachers are going to draw on the knowledge and skills that they gain in their education courses, their learning experiences need to simulate real teaching. This means creating "approximations of practice" (Grossman, Hammerness, & McDonald, 2009) that provide low-risk situations for novices to try, fail, and learn from their practice. A simulated student provides such opportunities as well as a standardized experience that can be studied and refined over multiple iterations.

Jacobs, Lamb, and Philipp (2010) described the teaching practice of *noticing student thinking*, which includes making decisions about how to respond to students when they exhibit different kinds of mathematical thinking. One way that teachers respond to student thinking is by asking questions, although little is known about how teachers develop the ability to ask effective questions. One of the central goals of this project is to understand how the development of this skill can be supported through a simulation that approximates a teaching situation.

Methods

Design-based research

Design-based research assumes that instructional contexts consist of complex, interwoven parts that are not isolatable; thus design approaches do not attempt to control confounding variables. Instead, they seek to characterize with a high degree of specificity the situation in which an instructional design is implemented, as well as capture multiple measures of different outcomes and a detailed record of alterations to the design over multiple cycles (Collins, Joseph, & Bielaczyc, 2004). Thus far, we have completed one complete implementation cycle, which includes three distinct simulated student experiences, a reflection, and a pre-post assessment.

Context

The participants were recruited from five sections of an undergraduate mathematics course for elementary teachers offered at a large university in the Midwest region of the United States. Much of the mathematical attention of the course is focused on fractions, including operating on quantities and making sense of the unit (Chval, Lannin, & Jones, 2013). The intervention was included in the required assignments for the course and consisted of a set of three "experiences," a reflection assignment, and a pre- and post-test. Fifty-four PSTs participated in all parts of the intervention and gave consent for their work to be collected and used in the research project.

Design

The experiences were designed to provide opportunities for the PSTs to interact in a limited way with a virtual elementary student. Using the online Lessonsketch platform, the PSTs viewed a storyboard representation of a portion of a mathematics lesson withthe roles of teacher and studentsplayed by nondescript cartoon characters. The simulated students convey information to the PST through speech bubbles and facial expressions and follow pre-established paths determined by choices made by PSTs.

An "experience" consisted of a series of tasks and choices. First, PSTs were asked to solve a mathematical task and describe what main mathematical ideas were embedded in the task. Then they viewed the storyboard lesson, which ended with a representation of student thinking containing a critical conceptual "error" closely related to the content of the course (Chval, Lannin, & Jones, 2013) For example, in one experience the cartoon teacher highlighted a students' response to the task in Figure 1, saying "Susan said there were three fourths of the two brownies shaded. I'm curious about what you think. Is Susan correct?" After a time of partner discussion, Matthew was called to the front of the class to share his thinking. He responded, "I don't think Susan can be right, because they are cut in half, not in four squares."

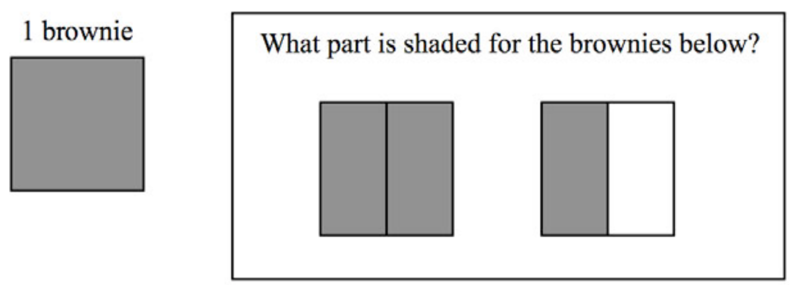

Figure 1: The Brownies Task (from Chval, Lannin, & Jones, 2014)

After viewing an episode, PSTs were asked to interpret the student's thinking and write a teacher question in response. Next they were asked to select from a list of between two and six questions, explain why they believed the question they chose would be effective, and describe how they expected the student to respond. Then they viewed the student's response.

We designed teacher questions to fall into one of two categories, *high leverage* and *low leverage*, drawing on characteristics described in NCTM's *Principle to Actions* (2014). High leverage questions are those that "build on, but do not take over or funnel, student thinking," "make mathematical thinking visible" (p. 41), and target specific ideas rather than general. See Table 1 for examples from the Matthew experience.

Table 1: Examples of question types and student response

	Teacher Question	Matthew's Response
High Leverage	What do you mean about the four squares? Can you show me how that would look?	[draws picture of the two brownies, each split into four squares]. "These are fourths. Susan is wrong because she said THIS [pointing to a half-brownie in the original diagram] is a fourth, when it is really a half."
Low Leverage	If you put the two brownies together, how many pieces would it be cut into?	"Each one is cut into two pieces."

In each experience, the PST was given an opportunity to see a response from the student to their question, and then they would evaluate the question with one of three choices:

1. It was a good question; it accomplished what I wanted it to accomplish
2. It was a good question, but [the student] didn't respond in the way I expected
3. It was maybe not the best question; I should have asked something different

Finally, the PST was given an opportunity to "go back in time" and ask a different question. In the Matthew experience, PSTs wererequired to contrast responses to a high leverage question with responses to a low leverage question, and then say which question they believed was better.

Outcomes

The chart in Figure 2 shows how *low leverage* questions were evaluated after PSTs viewed the students' response. In general, PSTs tended to claim that the low leverage question they chose was good, even though they were often unsatisfied with the student's response. Often, they expected that their question would lead to a resolution of the student confusion, or at least a correct solution to the task. For example, PSTs made statements such as, "I think the question got across the point I was trying to make but Matthew seemed to not process what I was asking." These results seem to suggest that, by themselves, our designed student responses did not generally help PSTs move away from low leverage questions.

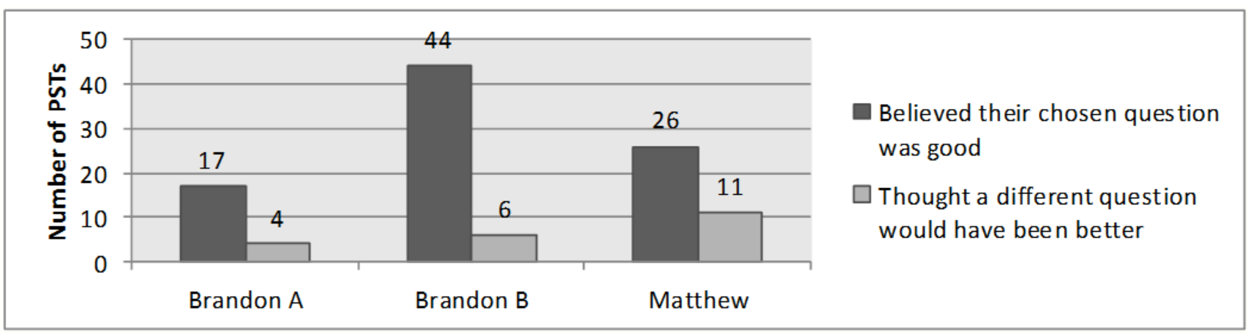

Figure 2: PSTs' evaluations of low leverage questions after viewing the student response

Recall, however, that in the Matthew experience PSTs were given the additional opportunity to see Matthew's response to a high leverage question. Of the 37 PSTs who initially chose the low leverage question, 16 preferred the high leverage question after viewing both responses, while only 3 preferred their initial question (18 indicated no preference). Of the 16 PSTs who preferred the high leverage question, 10 had reported that they still liked their low leverage question *until* they saw the second response.

We conjecture that the opportunity to directly contrast the effect of the two questions was an important design component of the Matthew experience. This is supported by some of the PSTs' evaluations of their questions. After seeing Matthew's response to the initial question, one PST said, "It was a good question and that's where his thinking is wrong but he still isn't thinking of the two brownies as a whole. He is still just looking at a single brownie and seeing one half." But after viewing Matthew's response to the second question, this PST decided that the high leverage question was better: "I didn't realize that if you split up each brownie into 4ths and color in three fourths of each that it would still be three fourths. So technically Matthew is correct too I guess which I never thought about it but still Susan is correct also and he needs to understand that concept too." This example shows a PST not only learning from Matthew's response to the high leverage question, but also recognizing and appreciating that the response helped the PST better understand the relationship between Matthew's and Susan's ideas. This change seemed to be facilitated by the opportunity to see Matthew's response to both questions.

Discussion

Our analysis of our initial outcomes has suggested that an important design feature of our simulated student intervention was the opportunity to directly contrast student responses to high and low leverage questions. That is, simply showing a students' response was not enough to help PSTs recognize the limitations of their initial selected question. This seemed to be because PSTs' default criterionfor an effective question was that it should resolve student confusion. It was only when they saw two questions thatdid not result in resolved confusion that they could look past this criterion and search for other value in the student's response.

This observation suggests that more direct contrasts would continue to help PSTs move towards high leverage questions. That is, in order to help them attend to characteristics of high and low leverage questions, we need to design student responses that are invariant in terms of characteristics PSTs tend to value (e.g., resolving student confusion), but variant in terms of the leverage characteristics (e.g., funneling student thinking versus building on student thinking). This is consistent with the idea that variation needs to be systematically coordinated to help learners differentiate between the ideas they are intended to learn (Marton & Pang, 2006). In the future, we plan to continue to refine our experiences to provide such patterns of variation and invariance to continuedeveloping the skill of asking high leverage questions.

ANALYZING COHERENCE OF TEACHER'S KNOWLEDGE RELATING FRACTIONS AND RATIOS

Travis Weiland

In this study we used Epistemic Network Analysis (ENA) to highlight connections among knowledge resources that middle school mathematics teachers evoked while relating fractions and ratios. The findings discuss how these groups were formed using ENA and discuss the differences in the connections of the participant's knowledge resources in each group. Implications for using ENA to understand teacher knowledge are included.

Keywords: Teacher Knowledge; Middle School Education; Rational Numbers

Introduction

Over the past decade, interest in teachers' mathematical knowledge has been a focus for many researchers (e.g. Hill, Ball, & Schilling, 2008; Thompson, Carlson, & Silverman, 2007). Despite the complexity of researching this domain, researchers have made headway in understanding critical elements of teacher knowledge. For example, researchers have found that there is an important link between the amount of knowledge a teacher has and its organization (Ma, 1999; Orrill & Shaffer, 2012). This aligns with research on expertise that suggests expertise in a domain requires both a certain amount of knowledge and particular organizations of that knowledge (Bédard & Chi, 1992).

Despite the compelling argument that knowledge organization matters, very little research has focused on such organization. In this study, we use Epistemic Network Analysis (ENA; Shaffer et al., 2009), to explore connections between knowledge resources that teachers evoke. For this study, we were interested in investigating how ENA can be used to investigate the connections of teachers' knowledge resources for differentiating between fractions and ratios.

Theoretical Framework

We rely on Knowledge in Pieces (KiP; diSessa, 2006) to explore teachers' knowledge. KiP asserts that the learner holds understandings of various grain sizes that are used as knowledge resources in a given situation (Orrill & Burke, 2013). We posit that as teachers develop their expertise, more connections among resources allow more knowledge resources to be invoked in appropriate situations. Thus, coherence refers to multiple knowledge resources that are connected in robust ways allowing for *in situ* access to the resources. Coherence, combined with a robust set of knowledge resources, allows teachers to deal with complex situations efficiently. This is consistent with previous research on expertise (e.g., Bédard & Chi, 1992).

We chose to focus our study on the relationship between fractions and ratios, which are key concepts in the domain of proportional reasoning (Lamon, 2007). Despite the importance of the relationship between fractions and ratios in proportional reasoning, there has been little research on how teachers differentiate between the two (Clark, Berenson, & Cavey, 2003).

Methods & Data Sources

This study is part of a larger study of middle school teachers' knowledge of proportional reasoning. The participants included 8 licensed middle school teachers (5 female) ranging from 1 to 18 years of experience (med=11.5) from multiple schools. Data were collected from two interviews. The interviews were recorded and transcribed verbatim for each participant.

The four tasks analyzed for this study asked participants about the relationship between fractions and ratios. The first task addressed the multiplicative relationship between the two sides of similar triangles. The second task asked participants to interpret and respond to four teachers' explanations about a 2:5 ratio of vinegar to oil in a salad dressing. The third task had participants consider the concept of equality in proportional situations. The fourth had participants consider the difference between ratios and fractions by presenting a non-standard ratio-combining situation.

Data Analysis

Analysis for this study relied on ENA (Orrill & Shaffer, 2012; Shaffer et al., 2009). For each utterance (typically a response to a single question posed by the interviewer), binary coding was used: a 1 indicates that a particular knowledge resource (see Table 1) was used in the utterance and 0 indicates that it was not. In terms of our theoretical frame these codes represent the pieces of knowledge resources observed.

Table 1: Selected Qualitative Codes of Knowledge Resources That Emerged From Data

Fraction Ratio Concepts (FRC)		
Fraction is part/whole	FRC 1	Refers to fractions as representing a part-whole relationship.
Ratio is part/part	FRC 2	Talks about ratios as being a part-part relationship.
Ratio is part/whole	FRC 3	Talks about ratios as being a part-whole relationship.
Fraction Ratio Differentiation (FRD)		
Context / Units	FRD 1	Uses context or units as a distinguishing feature of fraction or ratio.
Symbolic Representation Use (SRU)		
Mathematical Reasoning with Symbols	SRU 2	Uses a symbolic representation to reason about the relationships within the problem as part of the problem-solving process.
Uncategorized (UC)		
Task Interpretation	UC 1	Talks about what the task description means. Makes sense of what he or she is being asked to do not just answering the question. This includes making sense of symbols like in the case of the free throw problem.
Attending to Context	UC 2	Uses numbers and quantities that are accompanied by labels, directly related to context. In contrast to the use of decontextualized numbers.

ENA took the coded data and placed it into a matrix, broken into vectors by item. This allowed every co-occurrence of the code within a task to be captured. These co-occurrences were then translated into three-dimensional graphs in which the codes are placed relative to their frequency across the dataset, thus allowing variance to be seen. Equiload graphs (Figures 1 & 2) were generated for each participant that showed the co-occurrence of the codes for that participant. The thickness of the lines connecting the vertices indicated the relative frequency of the co-occurrences of those codes.

From a KiP perspective, ENA offers a tool for looking at coherence when it is defined as connections between knowledge resources within the same task. We would expect teachers with more coherent understandings to have one or more very strong pairings of codes in their equiloads, whereas teachers with less coherence would have weaker connections between resources drawing on a wide array of knowledge resources.

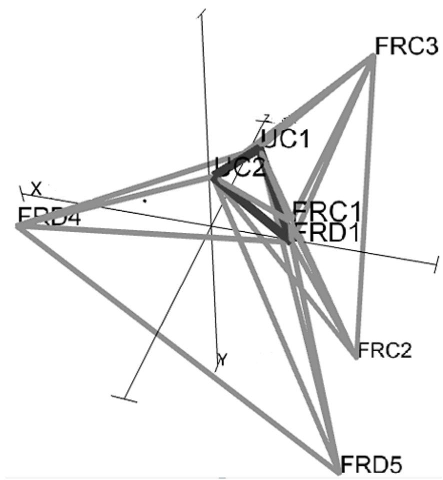

Figure 1: Allison's Equiload Graph

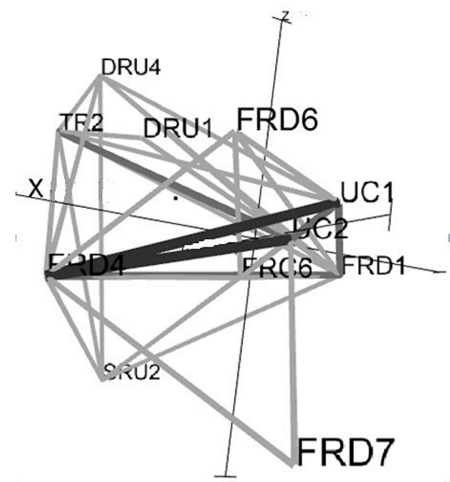

Figure 2:Autumn's Equiload Graph.

Results

Our analysis of the ENA equiloads suggested possible differences in the participants' use of resources. Because our dataset is small and this is exploratory work, we initially separated our participants into groups (Table 2), based on their response to a hypothetical teacher's statement that "fractions and ratios are the same".

Table 2: Participant Groupings

	Participants	Grouping Characteristic
Group 1	Ella, Bridgette, Allison, Mike	Participants rely on fractions as part whole relationships and on ratios as part to part relationships
Group 2	Alan, Larissa	Participants rely on ratios as part to part relationships
Group 3	Autumn, David	Participants do not use either of the knowledge resources above in connection with other knowledge resources

Differences between Group 1 and Groups 2 and 3

Group 1 attended to thinking about part-part and part-whole relationships in discussions of ratios and fractions. For instance, Allison's graph (Figure 1) shows *ratios are part-part*(FRC2), *ratios are part-whole* (FRC3), and *fractions are part-whole* (FRC1)relationships have many connections to one another as well as other resources such as *task interpretation*(UC1), *context*(UC2), and *context/units*(FRD1). In contrast, Alan, Larissa, Autumn (Figure 2)and David's graphs showed no connections to any part-part or part-whole knowledge resources.

We also found differences in the way teachers in group 1 used knowledge resources compared to those in groups 2 and 3. For example, Allison (Figure 2) relied on fewer connections than Autumn (Figure 3). However, Allison's connections drew more on resources related to fraction and ratio concepts (FRC) and fraction and ratio differentiation (FRD). Autumn drew from many different resources useful for problem solving, rather than relying on content knowledge resources. We interpreted Allison's repeated reliance on the same knowledge resources to be a sign of coherence.

Thus, Autumn could be considered less coherent than Allison in terms of the knowledge resources she used.

Resources that differentiate group 2 from group 3

The difference between groups 2 and 3 was not as clear. However, we noted some important differences. The main difference between participants in groups 2 and 3 was their use of the idea that *fractions are part-whole* (FRC1)and *ratios are part-part* (FRC2)relationships. Both Alan and Larissa in group 2 relied on these resources in their responses. In group 3, Autumn never used either idea to respond to any of the tasks and David used these ideas in a single utterance.

Scholarly Significance

Teacher knowledge is critical for supporting student learning, however it is important to consider not just the amount of knowledge, but coherence (Orrill & Shaffer, 2012). ENA has proven to be a useful approach in analyzing the connections of teachers' knowledge resources in conjunction with the KiP framework. This research is a first step in using an analysis method new to the field of mathematics education to contribute to our understanding teachers' knowledge for differentiating between fractions and ratios and to the domain of proportional reasoning.

MODIFYING CHILDREN'S TASKS INTO COGNITIVELY DEMANDING TASKS FOR PRESERVICE ELEMENTARY TEACHERS

This paper expands upon previous work on task development by Tobias et al. (2014), which identifies an eight-step task design process for selecting, modifying, and reflecting upon the implementation of children's mathematical tasks with preservice elementary teachers. Here we explicate the modification step, which includes altering children's tasks to be appropriately challenging and offer opportunities for teachers to move beyond their incoming conceptions. We provide examples of modifications we made to a children's fraction comparison task and discuss the goals we targeted to increase the task's level of cognitive demand. We share results from our analysis of 61 preservice elementary teachers' written work on this task and reflect upon the effectiveness of our modifications.

Keywords: Teacher Education-Preservice; Elementary School Education; Rational Numbers

"What students learn is largely defined by the tasks they are given," (Hiebert& Wearne, 1993, p. 395). Thus, mathematics teacher educators (MTEs) are faced with the challenge of designing and implementing high-quality tasks that can help preservice elementary teachers (PSTs) develop deep and flexible knowledge for teaching mathematics. Our task design research team is comprised of six MTEs from six different universities in the U.S., a collaboration that resulted from a PME-NA working group on PSTs' knowledge for teaching.

Background

Our work is based on the task design cycle developed by Liljedahl, Chernoff, and Zazkis (2007). We have modified their framework to integrate the suggestions made by Yackel, Underwood, and Elias (2007) for drawing tasks from K-12 curricula and modifying them for use with PSTs. This process for task design is meant to provide PSTs with opportunities to view the development of mathematical concepts in the same way their future students will. Not only can this practice support PSTs in developing their knowledge of curriculum, but also by connecting the work PSTs do in teacher education courses to their future work in elementary classrooms we can increase task *authenticity*. Students who experience more *authentic* tasks (i.e., those they consider to be valuable, worthy of their effort, and relevant to their future profession) demonstrate higher levels of achievement (Newmann, King, & Carmichael, 2007).

As MTEs select particular children's tasks to use with PSTs, it is important that they consider the intellectual demands of the tasks and whether (and how) PSTs will have opportunities to engage in high-level thinking and reasoning. Tasks that would pose a high-level of *cognitive demand* (Stein, Smith, Henningsen, & Silver, 2009) for children will not necessarily be high-level for PSTs. Therefore, children's tasks may need to be modified to provide PSTs with an appropriate level of challenge.

Task Development

Our team has collectively developed a fraction comparison task for PSTs by selecting and modifying a children's task from a common U.S. elementary curriculum (Russell et al., 2008; for further discussion see Tobias et al., 2014). The original fifth-grade task provides children with four pairs of fractions and asks, "Which is greater? Solve the problems below and explain or show how you determined the answer" (see Table 2 for original problems). Based on prior experience and research regarding PSTs' use of fraction comparison strategies (e.g., Yang, Reys, & Reys, 2009), PSTs tend to be most familiar with algorithmic procedures (such as converting to decimals or percents or finding common denominators); hence, we anticipated that the PSTs in our classes would tend to use such procedures, as opposed to more reasoning-based methods for comparing fractions. Thus, to increase the cognitive demand of this task we developed learning goals to help PSTs develop conceptual knowledge of fractions as numbers and compare fractions using multiple reasoning and sense-making strategies (see Table 1).Our modifications were led by the following three goals: (a) *discourage familiar (algorithmic) procedures*, (b) *develop multiple fraction comparison strategies based on reasoning*, and (c) *create opportunities for PSTs to reason about fractions greater than one and with benchmark values other than one*. At least two goals were targeted in the modification of each problem (see Table 2).

Table 1:Targeted Fraction-Comparison Reasoning Strategies

Strategy Name	Abbreviation	Example Application
Same Number of Pieces	SNP	4/7 > 4/9, since the fractions have the same number of pieces (four) and sevenths are larger than ninths
Benchmark Value Between	BVB [#]	7/5 > 5/7, because 7/5 > 1 > 5/7
Distance from a Benchmark Value	BVD [#]	4/5 > 3/4, because 4/5 is 1/5 less than one and 3/4 is 1/4 less than one; since 1/5 < 1/4, 4/5 is closer to one than 3/4
Greater Number of Larger Pieces	GLP	8/11 > 7/13, because 8/11 has more pieces (8 > 7) and its pieces are larger (elevenths are larger than thirteenths)

Table 2: Modifications to Problems from Original Children's Task

#	Original Problem	Modified Problem	Intended Strategy
1	7/10 or 3/5	7/10 vs. 8/9	GLP
2	7/8 or 9/10	8/9 vs. 12/13	BVD [1]
3	4/3 or 3/4	24/7 vs. 34/15	BVB [3]
4	3/8 or 1/3	3/7 vs. 6/11	SNP or BVB [½]

For problem #1, we replaced 3/5 with 8/9 to discourage the use of common denominators (by renaming 3/5 as 6/10) and elicit the GLP reasoning strategy. When paired with 7/10, the fraction 8/9 creates an opportunity for PSTs to reason about the fractions' numerators and denominators simultaneously to see that 8/9 is greater than 7/10 because it has more pieces (8 > 7) and its pieces are larger (ninths are larger than tenths). In problem #2, we kept the format of the original problem, which compares fractions that are each one piece less than one whole. This problem type can help PSTs reason about fractions by comparing their distances to a common benchmark value. However, to discourage the use of common denominators and percents, we replaced both fractions with a pair that has odd and relatively prime denominators. Since these fractions are 1/9 and 1/13 less than one, and 1/9 is larger than 1/13, the distance from 12/13 to one must be shorter than that from 8/9 to one, making 12/13 the greater fraction. Although BVD [1] could have been used to solve the original problem, we anticipated that our PSTs' familiarity with these fractions would lead to their use of percents or decimals or a reliance on drawing pictures. For problem #3, we maintained the original goal of comparing fractions to a benchmark value lying in between them, but by selecting larger fractions with relatively prime denominators (and ones that are not reciprocals of one another) we intended to discourage familiar procedures and create opportunities for PSTs to reason about fractions greater than one and with benchmark values other than one. As for problem #4, our modified version serves to develop multiple fraction comparison strategies: SNP (3/7 = 6/14, which is less than 6/11) and BVB [1/2] (3/7 < 1/2 < 6/11). In all, our task included ten problems, these four modified from the original task and six others we created. In this paper we will only discuss the four problems above (for further discussion of all ten problems see Tobias et al., 2014).

Methodology

Our task was enacted by three of the research team's MTEs in their respective mathematics content courses for elementary PSTs across four classrooms (n=61). PSTs were explicitly instructed not to use common denominators or calculators on the task. PSTs worked on the task in groups with their peers during class time while the MTEs facilitated individual conversations with students and groups as they monitored the class. The PSTs' written work on the task was collected after group work, but prior to whole class discussions during which the four reasoning strategies (SNP, BVB, BVD, and GLP) were explicated and named. PSTs' responses to each problem were coded by at least two MTEs with respect to: (a) the strategy used (or attempted to use) to compare the given fractions,(b) whether the strategy used (or attempted to use) was one we intended to elicit, and (c) whether the problem was answered correctly (for further discussion see Thanheiser et al., accepted).

Results

Results indicate that PSTs used a variety of strategies in solving the four modified problems and were mostly successful (for each problem at least 85% of responses received were correct). At the same time, not all PSTs solved the problems using the strategies we intended(see Table 3). Some used more familiar algorithmic strategies, such as finding common denominators and converting to percents, while a small amount applied additional valid strategies.

Table 3: PSTs' Responses to our Modified Problems

#	Modified problem	Intended strategy	Number of responses received (% out of possible n=61)	Responses with correct answer (%)	Responses using or attempting to use target strategy (%)	Responses using common denominators (%)	Responses using conversions to decimals/percents (%)
1	7/10 vs. 8/9	GLP	52 (85%)	98%	6%	10%	10%
2	8/9 vs. 12/13	BVD [1]	53 (87%)	85%	68%	0%	8%
3	24/7 vs. 34/15	BVB [3]	43 (70%)	95%	77%	2%	5%
4	3/7 vs. 6/11	SNP; BVB [½]	59 (97%)	98%	8%; 58%	3%	2%

Discussion and Conclusion

Our modifications to problems #2 and #3 proved to be successful at addressing our first goal, to discourage familiar (algorithmic) procedures, as only 8% and 7% of PSTs who answered these problems, respectively, did so by finding common denominators or converting to percents or decimals. However, 10% of all PSTs who solved problem #1 used common denominators, while an additional 10% converted to percents or decimals. We note that our selection of denominators in problem #1 (10 and 9) did not impede the finding of a common denominator and 7/10 lent itself to easy conversion to percent and decimal form; thus, this problem will require readjustment. We also note that cross multiplication may be another familiar algorithmic procedure, yet we only received one application of this strategy in a response to problem #4.

Our second goal was to help PSTs develop multiple fraction comparison strategies based on reasoning (i.e., SNP, BVB, BVD, and GLP). Problems #2, #3, and #4 were successful in eliciting BVB and BVD strategies from a majority of PSTs. Problem #4 was much more successful at eliciting BVB [1/2] than SNP (58% and 8% of responses, respectively), while two PSTs solved this problem using BVD [1]. The strategy that was least successfully elicited was GLP, with only 6% of PSTs who responded to problem #1 having identified 8/9 as having a greater number of larger pieces than 7/10. Although 98% of responses were correct, we found frequent use of procedural strategies (20%), one PST who used BVB [3/4], and several who claimed that 8/9 was "obviously" larger than 7/10, without providing much detail about their thinking.

Our third goal, to create opportunities for PSTs to reason about fractions greater than one and with benchmark values other than one, was met by our careful selection of fractions in problems #3 and #4. As mentioned above, the majority of responses to problem #4 utilized a benchmark value of 1/2.For problem #3, 95% of the responses received correctly stated that 24/7 > 34/15. We note that this problem was only answered by 70% of the PSTs, but due to its position as last of the ten problems, we believe the low completion rate was an issue of time and not content.

In conclusion, mathematics tasks designed for children can provide an authentic foundation for MTEs when developing tasks for PSTs. This paper does not exhaust all modifications required when using children's tasks with PSTs, but offers insight into ways to increase cognitive demand to provide PSTs with an appropriate level of challenge. By reflecting on PSTs' work on our task, we found that many of our modifications were successful at increasing cognitive demand by developing PSTs' conceptual understanding of fractions, while encouraging them to justify their reasoning and use multiple comparison strategies. Other modifications will require readjustment and further evaluation as we continue to develop this and future tasks for PSTs.

PRESERVICE SECONDARY MATHEMATICS TEACHERS' APPLICATION OF THEOREMS AND ABILITY OF WRITING GEOMETRY PROOFS

Tuyin An
Purdue University
ant@purdue.edu

Keywords: Reasoning and Proof; Geometry; Teacher Education-Preservice

It is widely accepted by the field of mathematics education that proof and reasoning should be integrated into students' mathematical experiences across all grades and across a breadth of content areas (National Council of Teachers of Mathematics, 2000; Schoenfeld, 1994; Yackel& Hanna, 2003). In spite of the important role of proof in mathematics curriculum, a substantial number of secondary learners encounter difficulties with proof in school mathematics (Chazan, 1993; Senk, 1985). Mathematics educators have pointed out that students' low achievement and misconceptions in proofs may actually be caused by teachers' ineffective instructions (Schoenfeld, 1994; Senk, 1985).In order to ensure secondary students' learning and understanding of proof, secondary teachers' knowledge of proof needs to reach to a certain level. Teachers should be able to "Develop and evaluate mathematical arguments and proofs" and "Select and use various types of reasoning and methods of proof" (National Council of Teachers of Mathematics, 2003, p. 1).

The goal of the study is to look in-depth at the nature of preservice secondary mathematics teachers' (PSMTs) learning of geometry proofs in order to help them develop their proof writing ability more effectively. To reach this goal, the following research question will be addressed by using a collective case study design: How do tasks designed specifically to target the application of theorems in geometry build PSMTs' ability to use these applications in proof writing?

A pre and posttest design will be used to collect evidence of the impact of the theorem application tasks on six PSMTs' proof writing ability. The task-based learning sessions (TLSs) are developed for helping the teachers gain familiarity with the application of geometry theorems. The entire data collection for each participant consists of three phases: a pre proof writing test, three TLSs, and a post proof writing test. The theoretical tool, Principles of the Application of Theorems, is comprised of three aspects of applications: using diagrams, words and symbols, analyzing given proofs, and analyzing given conditions. The principles are used for developing and analyzing the tasks for TLSs. A small-scale pilot study will be conducted to test all the data collecting instruments before the official data collection. Results of the study might be able to provide suggestions for the design of undergraduate level geometry courses and other in-service proof training programs.

Keywords: Teacher Education-Preservice; Equity and Diversity

As the population in the United States becomes more diverse, we see a pressing need to build teacher education programs to better prepare elementary mathematics and science teachers to teach students from diverse backgrounds in equitable and culturally responsive ways. According to the InTASC standards, "Teachers must have a deeper understanding of their own frames of reference (e.g., culture, gender, language, abilities, ways of knowing), the potential biases in these frames, and their impact on expectations for and relationships with learners and their families" (p. 3). At the same time, recent research has shown practice-based strategies, such as rehearsals, can support change in teachers' pedagogies (Lampert, Beasley, Ghousseini, Kazemi & Franke, 2010). To address this need and the research on learning, we combined virtual and traditional environments in an innovative, new, rehearsal-based course for elementary education majors that will "authentically" engage prospective teachers in practice-based rehearsals with diverse learners in ways that are typically not possible in traditional courses.

The purpose of this poster is to describe the steps underlying the development of a course that seeks to provide opportunities for prospective teachers to 1) develop an awareness of their hidden biases and stereotypes of who can and cannot do mathematics and science and 2) rehearse alternative responses and practices that serve students of diverse social identities more equitably.

The course centers on a virtual school where teacher candidates experience teaching students from diverse backgrounds and rehearse culturally responsive, practice-based instruction within the safe space of the university classroom. The virtual school environment was constructed using OpenSim, a free, open source, multi-platform 3D virtual world. For the virtual school, the prospective teacher designs her/his own personal "teacher" avatar (a visual representation of a person). In addition, each prospective teacher assumes the "identity" of a student avatar. We developed the elementary student avatars to represent a diverse set of students' identities and created detailed background profiles of each student avatar. By participating in this course and the virtual school, teachers will develop deeper understandings of and be better prepared to meet the needs of all students in their classrooms.

Prospective teachers will have the opportunity to rehearse interactions with students of color, identify personal biases, and enact equitable teaching practices. The use of a virtual platform in this way has the potential to significantly reshape approaches to culturally responsive teacher preparation at our University and more widely.

CREATING CONDITIONS FOR EQUITY: A CASE OF TEACHER-LED CULTURAL CHANGE ENABLING DISTRICT-WIDE DETRACKING IN MATHEMATIC

Evra Baldinger
UC Berkeley
evra@berkeley.edu

Lisa Jilk
University of Washington
jilklisa@uw.edu

Nicole Louie
UC Berkeley

Keywords: Equity and Diversity; Policy Matters; Teacher Education-Inservice

Research has established that tracking in secondary schools is a pernicious barrier to equity (Lucas, 1999; Oakes, 2005; Oakes, Wells, Jones, & Datnow, 1997; Wells and Serna, 1996). This poster tells the story of a district-wide, ambitious detracking effort in mathematics, which is taking place in a large, urban school district on the West Coast of the United States. It is a story of carefully crafted, teacher-led change meeting with national reforms to set the stage for district leadership to roll out a plan for equity and excellence that eliminates tracking in mathematics from Kindergarten through the 10th grade.

In this poster, we share the design of the ambitious, multi-component, six-year professional development (PD) effort, as well as evidence that it has supported a shift in discourse in mathematics departments around the district and in the district-wide mathematics community to focus on the varied, often hidden ways in which the district's diverse students are all mathematically "smart." We describe the ways in which this cultural shift met with ideas from the Common Core State Standards in Mathematics to provide the context within which detracking mathematics was both sensible and possible, from the perspective of district leadership and the school board.

As we write this paper, the district is engaged in a heated and public argument about what mathematics instruction should be available to different groups of students. As the district leadership works to defend its detracking efforts against stakeholders who stand to lose positions of privilege (e.g. through elimination of the "honors" track), it continues to lean on the community of mathematics educators committed to excellence and equity that has been fostered by this professional development effort.

The poster describes the evolution of the PD from its inception in the 2009-2010 school year until now, including ways in which it has attended to the development of (a) classroom practice, (b) departmental communities organized to collaborate around a shared vision, (c) district-wide community of mathematics educators committed to equity, (d) district capacity to sustain the effort without participation from outside supporters. The effort began modestly–a week-long workshop for 24 teachers in Complex Instruction–and has evolved into a multi-level PD effort involving 17 schools and more than 120 teachers.

Our hope is that this poster will foster discussion across our community about how systemic, research-based change toward equity can be strategically supported to overcome immense institutional, cultural, and political barriers.

PRE-SERVICE TEACHER NOTICING OF STUDENT PROBLEM SOLVING STRATEGIES

Sonalee Bhattacharyya
Texas State University
sb1212@txstate.edu

Keywords: Teacher Education-Preservice

There is a need for high quality, effective mathematics teachers recognize and use a variety of problem solving strategies. Professional noticing has been identified as a critical component of teacher preparation, and this skill can be developed through practice (Miller, 2011). To examine this development, I ask "What do Pre-service teachers (PSTs) notice about specific problem solving strategies as they examine student work on a rich problem-solving task?"

Jacobs, et. al have found that professional teacher noticing, although nonroutine, can be learned and supported by professional development (Jacobs, Lamb, & Phillip, 2010). Allowing pre-service teachers to work with multiple representations of word problems can diversify the approaches taken to the problem (Ozdemir & Reis, 2013). This study examines a small piece of this in looking at what PSTs notice about student problem solving strategies.

The participants are PSTs in a mathematics content course as part of a teacher preparatory program at a large university. The participants completed a task involving finding the number of matches involved in a round-robin tennis tournament, and were given student work on this task to analyze in writing, focusing on student thinking and instructional strategies. What problem solving strategies PSTs are noticing, and how they are interpreting these strategies is the focus of the analysis. The writing assignment was given as part of a larger study on teacher noticing.

Initial results reveal that the PSTs focused on, described, and interpreted student problem solving strategies. Other PSTs incorrectly interpreted strategies or made unfounded suggestions, such as rereading the problem. The implications are that PSTs need practice and tools to understand student problem solving strategies, and are willing to do so. Further research is needed to determine the effect of these types of exercises on PSTs growth in terms of their own problem solving toolkit, and their interpretations of students' strategies.

MATHEMATICS TEACHERS USING DATA IN PRACTICE: EXAMINING ACCOUNTABILITY AND ACTION RESEARCH CONTEXTS

Jillian M. Cavanna
Michigan State University
cavannaj@msu.edu

Keywords: Teacher Education-Inservice; Assessment and Evaluation

Recently, there has been a press for the use of data and evidence in schools. There is, however little research that provides insight into the specific practices used by teachers or into the influences of school and policy contexts on teachers' daily uses of data (Little, 2012). Current accountability policies require teachers to use particular data to answer questions posed by administrators and school boards outside the classroom. In contrast, when conducting action research, teachers pose their own questions and use data to seek their own answers to problems in their classroom. Examining teachers' work within the contexts of: (a) their school and its accountability policies, and (b) their work as teacher researchers, offers insights into potential conflicts for teachers using data and evidence in practice. This poster presents preliminary findings from a dissertation study about the ways mathematics teachers use and make sense of data and evidence, addressing the questions: (a) *What data do teachers select or identify as valid evidence?* and (b) *How are teachers making sense of data in relation to school accountability policies and action research efforts?*

This presentation builds from relevant literature related to teacher data use, teacher action research, and teacher agency. I use the theoretical framework developed by Coburn and Turner (2011) to support the understanding of how teachers use data in practice. The four interrelated categories of this framework, include: (1) interventions to promote data use, (2) organizational and political context, (3) processes of data use, and (4) potential outcomes. Coburn and Turner build primarily from Sensemaking Theory and interpretivist traditions, to which I add critical considerations of teachers' agency and power.

The participants of this study include four mathematics teachers at a diverse suburban middle school in the Midwest, US, along with their mathematics coach and administrators. These teachers engaged in a yearlong action research study group focused on improving their practices related to mathematics classroom discourse. The group met 1-2 times monthly to discuss progress and analyze findings related to their collected data. My data sources include: (1) semi-structured interviews with participants across the year; (2) video and audio recordings of all action research study group sessions; and (3) copies of student work identified by participants. I use techniques of grounded theory (Strauss & Corbin, 1990) to generate themes across *what* data teachers identify as valid evidence. I also adopt a dialogic perspective of language use (i.e., Wortham, 2001) and I use narrative discourse analysis techniques to determine *how* teachers discuss and make sense data and evidence. Early analyses suggest that teachers' uses of data vary between action research and accountability contexts and that administrators' and teachers' implicit understandings of quality data use often conflict and may impact teachers' agency.

Keywords: Classroom Discourse; Instructional Practices; Teacher Education-Preservice

Over 20 years ago, the *Professional Standards for Teaching Mathematics* (PSTM) (NCTM 1991) identified critical elements that support meaningful learning. In particular they detailed the centrality of 'classroom discourse,' the use of full class discussions to make mathematical meanings, reasoning, and justifications public and shared. Hiebert et al. (1997) continued to clarify the PSTM elements as well as giving more detail to the social culture of the classroom and its relation to equity and accessibility. Yackel and Cobb (1996) provided nuanced analyses of classroom discussions that distinguished *social* norms for general participation from expectations of mathematical thinking which they called *socio-mathematical* (SM) norms. SM norms focus on mathematical reasoning as the clear intention of classroom sharing, questioning, explaining, and justifying. The Standards for Mathematical Practice of the *Common Core State Standards* (CCSSI, 2010) continued to emphasize these same norms by expecting students to produce mathematical arguments and to understand and critique those of others. Recommendations for teachers concur that teachers themselves need an orientation to these norms (CBMS, 2012).

Despite the research and recommendations on SM norms, we have found it challenging to provide future teachers opportunities to experience these norms first-hand. Further, mathematics educator colleagues have asked for more details on how to make these norms routine in their content courses for pre-service teachers (PSTs). To address these concerns, our team investigated the specific classroom steps an experienced instructor took to initiate elementary PSTs into SM norms. Fall, 2014 we used a mathematics course for PSTs as a case study to examine how SM norms were introduced. We adapted and enhanced a framework from Elliott et al. (2009) to analyze video recordings, field notes, instructor interviews, student surveys, and student mathematical work from the course. We found that orienting PSTs to one another's reasoning was central in beginning to establish SM norms. In this poster we share some of the specific initial practices. For example, an instructor may invite PSTs to analyze and build on a peer's incomplete strategy or representation and reach a solution as a whole group. Preliminary results indicate that, as SM norms become more routine, PSTs begin to challenge each others' mathematical ideas, openly share their confusions, and ultimately use meanings rather than rules to justify their solutions.

EMPOWERING PRE-SERVICE TEACHERS TO ENACT EQUITY PEDAGOGY

Theodore Chao
The Ohio State University
chao.160@osu.edu

Eileen Murray
Montclair State University
murrayei@mail.montclair.edu

Keywords: Equity and Diversity; Teacher Education-Preservice; Elementary School Education; High School Education

Teachers must develop dispositions of advocacy if they are to teach mathematics for equity and social justice (Gutiérrez, 2013). We discuss how to use the research on mathematics teaching for equity and social justice to facilitate pre-service teachers' development of advocacy dispositions. We hope to facilitate discussion on how to develop equity and social-justice dispositions among PSTs within single-semester college methods, content, or connections courses.

Our framework starts with three pillars outlined in NCTM's recent research brief on equity: *Reflecting*, *Noticing*, and *Engaging in Community* (Chao, Murray, & Gutiérrez, 2104). For reflecting, PSTs engaged with the Multicultural Mathematics Dispositions Framework by White, Murray, and Brunaud-Vega (2012) to self-reflect on their own dispositions. For noticing, PSTs analyzed video case studies of students using Jacobs, Lamb, and Phillipp's (2010) noticing framework to attend to, interpret, and respond to students' mathematical thinking. Finally, for engaging in community, students used Agruirre, Mayfield-Ingram, and Martin's (2013) work to learn about students' community knowledge and then build mathematical lessons that invited and honored their students' knowledge. Finally, PSTs read Gutíerrez's (2013) work to explore counter narratives and practices of creative insubordination to connect to the oppression of marginalized peoples.

We piloted this work at two sites. The first author worked with over 60 elementary PSTs in a methods for mathematics teaching course. The second author worked with over 60 secondary PSTs in a mathematics content class connecting traditional content and methods courses for PSTs (2013).

Our preliminary analysis of how PSTs developed dispositions for equity and social justice through these courses showed that, while teachers still had difficulty connecting mathematical thinking with their students' community knowledge, they did end up creating mathematical tasks that showcased societal inequity. For instance, one lesson had children analyze traffic stops data in Ferguson by race, which allowed children to unpack the goals of the #BlackLivesMatter movement. We hope our poster invites discussion in how other educators and researchers explore ideas of equity and social justice within math teacher education.

FOCUSING TEACHER SELF-CAPTURE VIDEO TASKS USING SPECIFIC PROMPTS TO SUPPORT TEACHERS' ENGAGEMENT WITH STUDENT THINKING

Elizabeth B. Dyer
Northwestern University
elizabethdyer@u.northwestern.edu

Keywords: Teacher Education-Inservice; High School Education

Video-based professional development (PD) is an ever more popular way to support teachers' adoption of reform-oriented practices, particularly in engaging with student mathematical thinking (Borko, Koellner, Jacobs, & Seago, 2011; Tripp & Rich, 2012). Much of the video-based PD studied uses researcher-captured video, but relatively little work has examined teacher-captured video (Dyer, 2013; van Es, Stockero, Sherin, van Zoest, & Dyer, in press). This poster examines two types of self-captured video tasks designed to engage teachers in identifying student mathematical reasoning: noticing tasks and experimental tasks.

The noticing tasks were used to prompt teachers to notice and reflect on particular events in the classroom in the midst of teaching. The video equipment used by teachers allowed them save video of an event after it happened. Some of the prompts given to teachers included capturing moments when students shared thinking that the teacher could not make sense of in the moment, and moments when students made productive connections that the teacher did not anticipate.

While the noticing tasks focused on spontaneous moments during teaching, the experimental tasks are based teachers experimenting with an aspect of their practice. Each experimental task asked teachers to plan and try something new in their teaching and capture it on video. Some examples of experimental tasks asked teachers to develop questions to uncover the details of student thinking and modifying a task to incorporate students' real-world experiences.

Data from 11 secondary mathematics teachers participating in PD designed around these two types of tasks were examined using an open coding focusing on teachers' reactions to the two types of tasks. The findings suggest that the teachers preferred the experimental tasks over the noticing tasks. However, across the debriefing discussions in the group sessions it was clear that the noticing tasks provided teachers with a new frame to guide their noticing in the classroom related to the specific prompts of the task. Additionally, teachers commented that these tasks were particularly useful to examining moments that were too complex to unpack while teaching. Finally, from a teacher educator's standpoint, both tasks often provided a unique window into teachers' thinking about the specific prompts (e.g. what moments teachers believed showcased student reasoning), as well as what those moments looked like in different teachers' classrooms. These findings suggest that while noticing tasks may be productive tasks for teacher learning, they may require more effort and be more stressful for teachers than the experimental tasks.

This study investigated the connections between students' misconceptions and teachers' instructional practice. We examined four elementary teachers' experiences in implementing a fractions unit they designed collaboratively as part of a 40-hour summer professional development (PD) program. These teachers were participants in a three-year project focused on improving teachers' mathematical knowledge for teaching (MKT) through a series of monthly workshops, coaching and co-teaching experiences. In particular our goal was to examine the ways in which teachers' instructional practices serve to strengthen or resolve students' misconceptions.

The teachers created a fraction unit to address students' misconceptions in summer professional development sessions and implemented it in their classroom. The main data sources such as videos from the unit development PD, teachers' implementation of the unit, the debriefing sessions following the implementation, and students' task-based interview videos were analyzed using grounded theory (Corbin & Strauss, 2008).

Our findings suggest that teachers were able to identify students' misconceptions about fraction concepts from interview videos and also to design a unit to address them. However, in the process of implementing the designed unit, the teachers demonstrated some difficulties in engaging students' appropriately in reasoning about fractions and addressing students' misconceptions about the whole concept and the benchmark strategy. We attributed the possible reasons to teachers' weaknesses in using precise mathematical language to indicate fraction quantities, in probing students' thinking behind responses, and in making appropriate instructional decisions to address students' misconceptions in the moment of teaching, which all related to core components of MKT, specifically knowledge of content and teaching (KCT) (Ball, Thames, & Phelps, 2008). This study also highlights possible connections between students' misconceptions, the use of inappropriate mathematical language in teaching and teachers' struggles to focus classroom discussions to emphasize key mathematical ideas (Sleep, 2012).

USING ARGUMENTATION TO INVESTIGATE THE IDENTITY AS TEACHER OF A PROSPECTIVE TEACHER

Carlos Nicolas Gomez
University of Georgia
cgome00@uga.edu

Keywords: Teacher Education-Preservice; Research Methods; Affect and Beliefs

The development of an identity as a teacher-of-mathematics requires more than internal reflective work. The "rational other" (Gee, 2001) is necessary to provide feedback as to whether the actions, activities, or discourse of the individual are being interpreted as desired. Snow and Anderson (1987) call identity work the acts or activities one partakes in to define oneself in a context. Identity work can take many different forms whether it is through appearance and manner (Goffman, 1959), or embracing and distancing oneself from roles (Snow & Anderson, 1987). Acts of identity work are discursive moves used in an attempt to convince the rational other of the ownership of certain traits, beliefs, or knowledge that make up one's identity.

Specifically for prospective teachers of mathematics, identity work refers to the actions taken to convince the other that they are teachers-of-mathematics.

For this poster, I focus on the participant's discursive identity or D-Identity (Gee, 2001). D-Identities include the ways that one may characterize her or himself and how others portray the person. Recognition then becomes crucial in the development of an identity. "If an attribute is not recognized as defining someone as a particular 'kind of person,' then, of course, it cannot serve as an identity of any sort" (Gee, 2001, p. 109). Identity work will be different depending on the community he or she is looking to be recognized as belonging to. Prospective teachers must conduct identity work to argue the ownership of a teacher-of-mathematics D-identity. In general, arguments are the way one attempts to convince another that something is true. Argument in its basic form is made of three components: (a) claims, (b) warrants, and (c) data. In this poster, I explore the identity work of a prospective elementary teacher as she discursively enacts her D- Identity in an interview setting. I explore how she argues the ownership of particular traits.

Additionally, I describe the use of an argumentation lens on social identity of a prospective elementary teacher.

The framework breaks down the participant's claims, evidence provided, and her anticipatory statements used to argue her social identity as a teacher-of-mathematics. Eyre's (pseudonym) claims were categorized by the level of ownership or the discursive strength behind the claim.

The criteria for ownership were determined by the use of I-statements, hedges, and intensifiers. Evidence was separated into either anecdotal or belief-based, and anticipatory statements were categorized as being used to provide more details, recognize limitations of teaching, or defensive/protective moves (Goffman, 1959). In this poster, I share the social identity of Eyre I was able to construct using this framework. Her social identity included the centralization of an equity position and the strong desire for student engagement. Implications for teacher education programs are also discussed.

TEACHER CANDIDATES' RESPONSES TO A NON-STANDARD STUDENT SOLUTION ON AN ALGEBRAIC PATTERN TASK

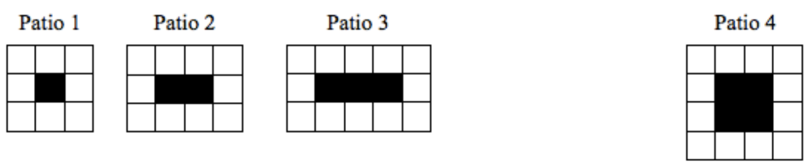
Dana Grosser-Clarkson
University of Maryland
dgrosser@umd.edu

Elizabeth Fleming
University of Maryland
fleming1@umd.edu

Keywords: Algebra and Algebraic Thinking, Teacher Education-Preservice

An enduring challenge facing teacher educators is how to prepare teacher candidates for more ambitious teaching practices. One response has been to help teachers focus on student thinking, which requires teachers to elicit and respond to student thinking (Franke, Webb, Chan, Ing, Freund, & Battey, 2009). However, this can be especially challenging when student thinking does not align with teacher'smathematical thinking.

This poster presents 15 teacher candidates' responses to a non-standard student solution to a pattern task in a secondary mathematics methods course. Teacher candidates were asked to explore the *Tiling A Patio* problem by extending the pattern shown below (Smith & Stein, 2011, p. 19). They were then provided with a non-standard student solution (see Patio 4) and asked to create a fictional dialogue between themselves and the student who created that pattern.



Initial results show teacher candidates were responding to student thinking by posing various types of questions, which were coded using Driscoll's (1996) question type framework. Fourteen of the 15 teacher candidates began their fictional dialogue by *prompting mathematical reflection* and asking students how they arrived at their pattern.However, none of the teacher candidates followed their initial prompt with a question that would *elicit algebraic thinking*. A closer examination of these questions shows that 11 of the teacher candidates were in fact *orienting* and more specifically *funneling* (Herbel-Eisenmann & Breyfogle, 2005) students toward a pattern that matched the candidate's own thinking. A whole-class discussion following the creation of the fictional dialogues showed that many candidates believed there was a single correct answer to the pattern task and did not try to unpack the student solution to see potential value in the response (e.g., cheaper patio). These results suggest that providing teacher candidates with pattern tasks that allow for multiple solutions may help teacher candidates focus on student thinking, while also challenging their conceptions about mathematics.

DESIGNING PROFESSIONAL LEARNING TASKS FOR LEARNING TO POSE PROBING QUESTIONS

Naomi Jessup
UNC-Greensboro
njallen@uncg.edu

Jared Webb
UNC-Greensboro
jnwebb2@uncg.edu

P. Holt Wilson
UNC-Greensboro
phwilson@uncg.edu

Keywords: Teacher Education-Inservice; Design Experiments; Instructional Activities and Practices

Teachers' questioning practices have been shown to support students' explanations, clarify teachers' understanding of students' mathematical thinking, and increase student learning (Webb et al., 2009). Research suggests that all students in the classroom benefit when teachers pose sequences of probing questions after students' initial explanations; however, this practice is often difficult for teachers (Franke et al., 2009). Following recommendations of Grossman et al. (2009) that urge teacher educators to work with teachers on problematic aspects of practice, researchers are exploring *rehearsal* as a pedagogical strategy to work with prospective teachers in university-based methods courses (Lampert et al., 2013). Rehearsal as an approximation of practice supports novice teachers by providing opportunities to learning about, practice, and reflect upon important aspects of practice while receiving in-the-moment feedback from teacher educators. While still emerging, this research on the use of rehearsal to support prospective teachers in enacting the complex work of teaching is promising.

Our research explores rehearsal as a teacher educator pedagogy for working with practicing teachers and shares findings from a pilot design experiment seeking to create and refine rehearsals that support teachers' learning to pose probing questions. We explore the research: *What factors influence teachers' learning to focus on responding to students' mathematical thinking with probing questions in rehearsal tasks?* Working with three middle/secondary teachers in three 1.5-hour professional development (PD) sessions highlighting recent research on teacher questioning, teachers engaged in rehearsals focused on questioning related to students' understanding of functions. Our initial conjecture was that teachers' familiarity with the instructional task affects teachers probing questions. Data consisted of video recordings of sessions, written teacher reflections, post-rehearsal interviews, and our conjecture log. We used constant comparative methods (Strauss & Corbin, 1998) to analyze our data and concluded with a revised conjecture: *Familiarity with the instructional task and its learning goal, mathematics knowledge for teaching, knowledge of students, the degree to which teachers had time to anticipate students' conceptions and errors, and the supporting activities of the PD affects teachers probing questions.* Our findings suggest that mathematics teacher educators should attend to these factors as they explore rehearsals in PD.

UNDERSTANDING ELEMENTARY SCHOOL TEACHERS' PERSPECTIVES ON CHILDREN'S STRATEGIES FOR EQUAL SHARING PROBLEMS

Naomi Jessup	Amy Hewitt	Victoria Jacobs	Susan Empson
UNC-Greensboro	UNC-Greensboro	UNC-Greensboro	The University of Texas at Austin
njallen@uncg.edu	alhewitt@uncg.edu	vrjacobs@uncg.edu	empson@austin.utexas.edu

Keywords: Teacher Education-Inservice; Teacher Knowledge; Rational Numbers; Elementary School Education

Over the past several decades, the growing research base on children's mathematical thinking has provided a way for teachers to structure what they see and hear so that they can better respond to children's ideas in the midst of instruction. Research has also shown that learning is enhanced when teaching is focused on children's thinking (Wilson & Berne, 1999). In this study, we worked with teachers who were learning about children's fraction thinking, and our goal was to investigate how teachers thought about children's thinking. In much the same way that understanding children's thinking has helped teachers honor and build on children's thinking, understanding teachers' perspectives can help those trying to support teachers' development.

We explored teachers' initial perspectives on children's strategies for equal sharing problems in which the answer is a fractional amount. Prior to professional development on fractions, teachers in grades 3–5 analyzed written work for 12 student strategies for the following problem: *Six children are sharing 16 brownies so that everyone gets the same amount. How much brownie can each child have?* Coding involved an iterative process of analyzing video- or audio-recorded discussions of groups of teachers who were asked to order strategies in terms of sophistication.

We identified five perspectives teachers used in deciding levels of sophistication of children's strategies: (a) whether leftover items were partitioned; (b) whether whole items were distributed prior to any partitioning; (c) whether the largest possible partitions were used; (d) whether fraction notation was predominantly used (vs. drawing); and (e) whether the answer was in the form of a mixed number (vs. an improper fraction or informal notation). Some of these perspectives were consistent with research on children's fraction thinking (Empson & Levi, 2011) such as when teachers viewed strategies involving partitioning of leftovers as more sophisticated than those which ignored leftovers. Other perspectives, while reflective of traditional curriculum sequencing, were inconsistent with research on children's fraction thinking such as when teachers viewed distributing whole brownies prior to any partitioning as more sophisticated regardless of the nature of the partitions. For example, partitioning all items strategically (e.g., linked to the number of sharers) was viewed as less sophisticated than distributing wholes and then using a more basic partitioning (e.g., repeated halving). Implications for researchers and professional developers include understanding teachers' starting points and potential confusions as well as appreciating the need to honor and build on these perspectives.

MATHEMATICS TEACHER LEARNING THROUGH INSTRUCTIONAL PRACTICES

Hee-jeong Kim
University of California, Berkeley
hj_kim@berkeley.edu

Keywords: Teacher Education-Inservice; Research Methods

This study investigates how mathematics teachers' instructional moves create opportunities for them to learn about student thinking and mathematics content. In particular, it addresses the *role of assessment in teaching and learning*, by focusing on how specially-designed *formative assessment lessons (FALs)* can be used as a mechanism for teacher professional development.

Learning and development in the workplace is a central ongoing experience for any professional, including teachers (Cohen & Ball, 1990; c.f., Schön, 1983). However, there is little research on teacher learning and development *through* practice; most research on teacher learning and development focuses on teachers' cognitive processes as viewing learning *from* formally organized contexts (e.g., teacher education programs or PD workshops) or focuses only on the social relationships and/or environment *within* a community (e.g., shift in participation within communities of practices). This study aims to fill this gap, and investigates how teachers learn and develop through practice by adapting a socio-cultural developmental framework (c.f., Saxe, 2012) to analyze the process of how mathematics teachers develop new teaching practices to accomplish their own pedagogical goals.

To explore teacher learning and development through practice, this study focuses on two 7th grade mathematics teachers (Ms. Lee and Ms. Janet) and their classrooms as the teachers attempted to implement formative assessment practices by using innovative curricular support materials (e.g., *FALs*) and participating in professional development sessions over the course of one school year. The analysis compares the two teachers' classroom practices, focusing on how Ms. Lee's instructional moves afford the means of teachers' making sense of the content—proportional reasoning—and student thinking of the content, while Ms. Janet's instructional moves do not afford the same kinds of learning opportunities. Preliminary findings illustrate that particular *forms* of instructional practices that are supported in professional development sessions serve different *functions* in two teachers' classrooms (see the "form-function" relationship in Saxe, 2012) and it has different impacts on longitudinal shifts in practices. In the poster, I will provide more information and examples of what forms of instructional practices were supported and how their implementations served different types of functions, and how it shifts or not.

This study has critical implications for mathematics teaching and learning. First, the analytical categories identify and suggest particular practices that support teachers in incorporating formative assessment in their instruction, such as making effective use of student mathematical thinking during instruction. Second, unpacking the process of teachers' developing new instructional practices provides insights on how to better support teachers' professional development and teacher learning.

kmckenne@udel.edu

Keywords: Teacher Education-Preservice; Affect and Beliefs

An important role of mathematics content courses [MCC] during elementary teacher preparation is to help prospective elementary teachers [PSTs] relearn elementary mathematics more deeply while experiencing the type of teaching mathematics educators hope they will practice in their future classrooms. However, research suggests PSTs bring their own sets of beliefs and attitudes that affect what they learn from such programs. There are times when such entering beliefs "are not quite contextualizing, illuminating, and helpful, so much as they are powerful, potentially misleading, and unproductive as resources for learning the principles we hope to teach" (Holt-Reynolds,1992, p. 327). For example, when attending a thoughtfully planned course designed to engage them in rich mathematical thinking, some PSTs are resistant to explore, create, or prove mathematical ideas (Boaler, 2002). Experiencing dissonance, tension, and frustration, many PSTs "react to the course in a perfunctory manner" (Phillip, et al., 2007, p. 439). If PSTs' prior beliefs about learning are at odds with the goals and demands of such coursework, they can create barriers to their personal growth during teacher preparation.

The purpose of this study was to better understand how PSTs perceive opportunities intended to develop their mathematical knowledge for teaching. One hundred fifteen participants who had completed one, two, or three MCC for PSTs completed an electronic survey that measured their perceptions of the relevance of the coursework as well as the appropriateness of specific types of tasks or pedagogical strategies they encountered throughout the coursework.

Findings revealed PSTs' perceptions of the relevance of the MCC and the course learning goals appeared to be associated with their views about the pedagogical strategies typically employed in the MCC. PSTs who viewed one or more pedagogical strategies, and in particular, productive struggle, as *onlysometimes appropriate* [*SA*] consistently reported more unproductive MCC views in terms of course relevance and perceptions of course learning goals than their peers who viewed such strategies as *always appropriate*[AA]. Furthermore, PSTs who indicated *productive struggle* is *only SA* for MCC were twice as likely to view additional pedagogical strategies in the same way compared to those PSTs who found a pedagogical strategy, but not productive struggle, as only *SA* for the MCC. Analysis of open-ended responses from PSTs who perceived one or more pedagogical strategies as *only SA* suggested PSTs desire greater guidance during sense making activities, as well as instructor verification before moving on from a task. Rather than viewing cognitively demanding activities that provide opportunities to make sense of mathematics as potential learning experiences, responses revealed PSTs' overall concern for the unnerving feelings of confusion and frustration prompted by such episodes of struggle.

UNDERSTANDING THE PRACTICE OF TEACHING FOR EQUITY

Laura McLeman
University of Michigan-Flint
lauramcl@umflint.edu

Eugenia Vomvoridi-Ivanović
University of Southern Florida
eugeniav@usf.edu

Keywords: Equity and Diversity; Teacher Education-Preservice

While mathematics teacher educators (MTEs) have described their approaches to preparing teachers to incorporate equitable instructional strategies in mathematics (e.g. Aguirre, 2009), there has not been a systematic examination of how MTEs prepare teachers to effectively teach mathematics to diverse student populations (McLeman & Vomvoridi-Ivanović, 2012). This type of examination will help support MTEs to develop practices that integrate issues of race, class, gender, language, culture, or power in their mathematics teacher preparation courses.

Our goal is to obtain an initial understanding of how MTEs who make issues of equity a priority in their practice facilitate this kind of work. Our research questions are:

- How do MTEs who make equity a priority in their instructional practice conceptualize equity in their teacher preparation courses and how is this reflected in their course syllabi?
- What challenges do MTEs who make equity a priority in their instructional practice face when teaching mathematics methods courses and how do they work towards resolving these challenges?

We analyzed 23 MTEs' responses to a brief survey and their course syllabi. Utilizing components of grounded theory (Glaser & Strauss, 1967), our findings suggested a mismatch exists in the way MTEs conceptualize equity and the way it is addressed in their course syllabi. Further, our findings also suggested there is a mismatch between the nature of the challenges MTEs face and the nature of the resolutions they employ to work towards resolving these challenges.

SOURCES OF INFLUENCE ON THE CURRICULAR CHOICES OF SECONDARY MATHEMATICS PRE-SERVICE TEACHERS

Katherine Miller
The Ohio State University
miller.7837@osu.edu

Azita Manouchehri
The Ohio State University
manouchehri.1@osu.edu

Keywords: Teacher Education-Preservice; Teacher Knowledge; Curriculum

An enduring challenge in mathematics education is the need to understand the types of knowledge and reasoning that teachers need (Ball, Thames, & Phelps, 2008; Breyfogle, Roth McDuffie, & Wohlhuter, 2010; Shulman, 1986). Novice teachers are being evaluated in ways that affect their own career and will soon be evaluated in ways that affect their teacher preparation program (Teacher Preparation Issues, 2014). To serve our secondary mathematics pre-service teachers (SMPSTs) we must continue to improve our understanding of SMPST knowledge and reasoning and respond critically by examining the way that we teach SMPSTs.

Research Problem and Question

This study seeks to explore the sources that influence the choices that SMPSTs make when planning lessons. Based on conversations with SMPSTs during the course of the author's responsibilities as a field placement supervisor, it has become obvious that SMPSTs at times struggle to exhibit strong curricular reasoning as defined by Breyfogle, Roth McDuffie, and Wohlhuter (2010). In an effort to understand the choices that demonstrate curricular reasoning, this research systematically examines what sources influence the curriculum choices of SMPSTs.

Description of Method and Timing

Data will be collected during the spring of 2015 using five SMPSTs who are currently student teaching using lesson plans, interviews with participants prior to implementing lessons, classroom observations, and interviews with participants after they implement the lesson. Sources of influence will be identified and grouped in ways that allow us as teacher educators to understand how we can help improve the curricular reasoning of SMPSTs.

Critical Use of Findings

By understanding the sources that influence the curriculum choices of SMPSTs we can respond in a way that improves the curricular reasoning of SMPSTs. Breyfogle, Roth McDuffie, and Wohlhuter (2010) explain that teachers need to be able to "adapt, supplement or omit portions of the [provided] curriculum materials" (p. 307). This study will shed light on the way that SMPSTs reason about curriculum in their field placement, and will allow those involved with teacher preparation, such as faculty members and field placement supervisors, to change the way they help SMPSTs learn to make decisions about curriculum.

DEVELOPING A FRAMEWORK FOR OPPORTUNITIES TO LEARN ABOUT EQUITY IN SECONDARY MATHEMATICS TEACHER EDUCATION PROGRAMS

Alexia Mintos
Purdue University
amintos@purdue.edu

Andrew Hoffman
Purdue University
hoffma45@purdue.edu

Jill Newton

Keywords: Equity and Diversity; Teacher Education-Preservice

In this poster presentation we will describe a framework developed to investigate the topics, themes, and types of emphases related to equity that preservice teachers (PSTs) experienced in five secondary mathematics teacher education programs. Our aim is to describe the motivation and development of this framework and its affordances and constraints.

The National Council of Teachers of Mathematics (2000) included “equity” as one of its six core principles in *Principles and Standards for School Mathematics*, but in teacher education programs PSTs often learn about equity issues independent of mathematics. Future mathematics teachers need an understanding of equity as it relates to mathematics in particular (Gutiérrez, 2009; Gutiérrez, 2012b). Thus, it is important to examine the required courses within secondary mathematics teacher education programs to investigate the topics, issues, and learning opportunities related to equity. We are also interested in the nuances of equity in teaching and learning algebra. This is motivated by descriptions of algebra as a civil right and a gatekeeper (Moses & Cobb, 2001).The framework we developed uses Gutiérrez’s (2012a) conception of equity and levels of specificity to algebra to answer the following: What is the nature of opportunities that secondary mathematics PSTs have to learn about issues of equity in their teacher education programs?

The data used in this is study is from a larger *National Science Foundation*–funded research project, *Preparing to Teach Algebra*. This project investigated how emphases on algebra were reflected in teacher preparation programs. Here we focus on the case studies of five teacher education programs. We examined all instructor interview transcripts and tagged any excerpts in which the participants mentioned issues related to equity; then we categorized tagged sections using Gutierrez’s equity constructs (access, achievement, identity, and power) and specificity to algebra (e.g., algebra, mathematics, general education). To promote reliability, we had two researchers code each transcript and discuss discrepancies to come to consensus; in the process, a coding book of examples was also developed. Preliminary coding experiences revealed successes and challenges when using the framework. In our presentation we will discuss results of analyses and the application of our two-dimensional framework.

DEVELOPING PRESERVICE ELEMENTARY TEACHERS' KNOWLEDGE OF THE CONNECTIONS BETWEEN FRACTIONS, DECIMALS, AND WHOLE NUMBERS

Christy Pettis
University of Minnesota
cpettis@umn.edu

Keywords: Mathematical Knowledge for Teaching; Number Concepts and Operations; Rational Numbers; Teacher Education-Preservice

Arithmetic involving whole numbers, fractions, and decimals is a significant component of the content of elementary mathematics. Prior research has found that preservice elementary teachers (PSTs) tend to rely on memorized rules and procedures for solving arithmetic problems and struggle to explain why the procedures work (Thanheiser, Browning, Edson, Kastberg, & Lo, 2013). Ensuring that prospective elementary teachers have the opportunity to develop a deep understanding of these areas is thus an important part of teacher education.

Participants in this study were 32 undergraduate, prospective elementary teachers enrolled in the first of two required mathematics content courses at a large, Midwestern university. This study aimed to examine the PSTs' understanding of the relationships between fractions, decimals, and whole numbers before, during, and after their participation in an eight-week instructional unit related to these topics. The goals of this study were to (a) document the ways in which individual PSTs understood the *connections* between fractions, decimals, and whole numbers, and (b) the ways that models such as stories, pictures, and number lines helped and/or hindered the PSTs in making these connections. Two theoretical frameworks guided this study. First is Gravemeijer's (1994) work on the ways models (i.e. situations, drawings, empty number lines, ways of notating) may be intentionally used to support student understanding of formal mathematical concepts. Second is the notion that the development of mathematical knowledge for teaching should entail helping PSTs develop "coherent and generative understandings of the big mathematical ideas that make up the curriculum" (Silverman & Thompson, 2008, p. 5).

Data sources included pre- and post-tests, classwork, and homework from participants as well as field notes taken by the researcher (who was also a co-instructor during the instructional unit). Using qualitative techniques, data were analyzed for patterns in student responses to tasks designed to support students in making connections between the number types, and for the types of models used by students in their work. Preliminary results suggest that the majority of the students developed a more connected understanding of the three number types during the unit, and that stories and pictures were particularly supportive models for many students. Number lines were found to be both supportive and problematic as a model, particularly for the connections between decimals and fractions.

ANALYSIS OF SINGULAR-PLURAL DIALOGUE OF MATHEMATICS TEACHERS

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

Keywords: Classroom Discourse; Teacher Beliefs

Introduction

The purpose of this paper is to describe the results of an empirical comparison of singular-plural usage during lessons by specially chosen mathematics teachers (whose classrooms demonstrated healthy student dialogue) with the usage seen in "typical" American mathematics lessons. Recent reform recommendations emphasize the importance of mathematics classrooms as learning communities where students have a chance to actively discuss their nascent understandings (e.g., NCTM, 2000). I hypothesized that in classrooms with such healthy student dialogue, teacher dialogue would manifest low singular (*me*, *I*, and *my*) as opposed to plural (*us*, *we*, and *our*) usage. Language often reflects the dominant paradigm guiding classroom activity: If teachers view themselves as the primary content deliverer, using singular terms more frequently than plural is expected; if, however, teachers view themselves as members of a developing mathematical community, shifts in descriptions of self should be manifested.

Methods and Results

The teachers demonstrating classrooms with healthy student dialogue participated in *The Mathematics Class as a Complex System* (MCCS) study, described in greater detail elsewhere (Ricks, 2007). For comparison, I chose the four American lessons highlighted in the 1999 Trends in International Mathematics and Science Study (TIMSS) video study as "typical" classes (National Center for Educational Statistics, 2003). Analysis of classroom dialogue (one lesson per MCCS teacher) demonstrated that the MCCS teachers had similar singular-plural usage with each other (average: .42), which varied substantially from the TIMSS mathematics teachers (average: 1.26). As a benchmark, a singular-plural ratio of 1.0 would indicate equal singular and plural use. Thus, all the MCCS teachers had low singular-plural usage (using singulars less than half as much)—as hypothesized, while the "typical" American teachers generally had a high singular-plural usage (using singulars more than plurals, some higher than twice as much).

Discussion and Conclusions

I interpret these findings as evidence that—compared with typical U.S. teachers—the MCCS teachers (with their classrooms manifesting healthy student dialogue) were more likely to use language that signaled their identification as part of a robust classroom community. This study contributes to the growing body of research on teacher dialogue by demonstrating a correlative relationship between classrooms manifesting healthy student dialogue and low teacher singular-plural usage. More research is needed to understand the observed statistical relationship; examining student singular-plural usage may also indicate their perceived participation, as well.

EXPLORING MENTORING CONVERSATIONS: WHAT MAKES THEM MORE OR LESS EDUCATIVE?

Sarah A. Roller
Michigan State University
rollersa@msu.edu

Keywords: Classroom Discourse; Teacher Education-Inservice; Teacher Beliefs

One way that mentors support prospective teachers' development within field placements is through conversations about classroom teaching. However, little is known about these conversations and the extent to which they are - or can be - educative. This study bridges the literature on educative mentoring (Feiman-Nemser, 2001) and teacher noticing (van Es and Sherin, 2002) by considering *educative conversations* as a product of both professional practices. For this study, I theorized a definition of what an educative conversation would include and used the definition's criteria as indicators to identify *potentially educative* mentoring episodes in a set of pre/post mentor-intern conversations about video teaching episodes. I report on the nature and quality of these conversations, and I consider the affordances of using noticing and wondering language in making mentoring conversations more educative.

This qualitative study examines three mentor-intern pairs' pre- and post-conversations about two publicly available video teaching episodes (BTSA, 2012). They did this before and after a short orientation session which introduced them to Smith's (2008) *noticing and wondering* model. The mentor-intern conversations were coded using the educative conversation criteria, defined as mentor-intern talk in which the purpose is to provide opportunities for novice teachers to: (a) learn in and from practice, (b) generalize from particular instances of their teaching practice; and/or, (c) focus their attention on student learning. The frequency of the terms "notice" and "wonder" was considered to evaluate the usefulness of this language. Out of the 86 educative mentoring episodes, 41% were identified as *potentially more educative* mentoring episodes, because they met all of the criteria, and 59% were identified as *potentially less educative* mentoring episodes, because they met only two of the three criteria. Further comparison of individual pairs' pre- and post-conversations demonstrated increases in the number of *potentially educative* mentoring episodes, improved quality of educative conversations, and increased usage of the words "notice" and "wonder."

Overall, understanding more about educative conversations is crucial both for prospective teachers to maximize field placement learning and for teacher educators and mentors to develop more intentional mentoring practices that support the development of mathematics teaching practices. This study acts as a starting point for this work by providing language, criteria, and examples for discussing conversation quality with teacher educators, mentors, and interns.

The Common Core State Standards for Mathematics (CCSSM) has provided the field of mathematics education with clear and consistent mathematics content foci, as well as practices for students to engage in (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). As mathematics teachers have begun to teach to these standards, they have been challenged to consider curricula that address the content foci and mathematical practices outlined in the CCSSM as well as, investigate research-informed teaching practices that allow their students to engage in mathematical reasoning and sense making. One particularly useful framework for addressing the standards and teaching practices is to embed technology into a progression of key learning activities through a curricular activity system (Vahey, Knudsen, Rafanan, Lara-Meloy, 2013).

The preliminary results of this study provide evidence that a curricular activity system in which teacher professional development is aligned with a technology-embedded curriculum impacts teaching of rate and proportionality. By having the participating teachers explore the mathematics in the learning module as learners prior to teaching it there was "an explicit focus on subject matter" by providing experiences that "engage teachers as learners" (Borko, 2004 p. 5). This allowed the teachers to leverage their mathematical knowledge as a way to explore their teaching practices, to provide insight into students' mathematical thinking, and as way to transform their teaching. Moreover, middle school students developed a deep understanding of crucial mathematics when their teachers engage in teacher professional development that is coherently aligned to a technology-embedded learning module.

STUDYING FRACTION CONTENT AND PEDAGOGICAL KNOWLEDGE GROWTH AFTER A VIDEO-BASED INTERVENTION

Robert Sigley
Rutgers University
robert.sigley@gse.rutgers.edu

Carolyn A. Maher
Rutgers University
carolyn.maher@gse.rutgers.edu

Keywords: Mathematical Knowledge for Teaching; Rational Numbers; Teacher Education-Preservice

Research has shown that there is much to be gained by teachers studying video episodes of children learning mathematics (e.g., Maher, 2008). Video provides learning opportunities for pre-service teachers to view certain teaching practices in action which may not be visible to them based on their field placement (Philipp et al., 2007) as long as the selected video clips align with the instructional goals of the teacher education context (Zhang et al., 2011).

This poster will describe a video-based intervention given to 137 pre-service teachers (89 experimental and 48 control). During the intervention, participants in the experimental group worked on open-ended problem solving tasks involving Cuisenaire rods and watched videos from a major video repository, the Video Mosaic Collaborative (http://www.videomosaic.org), of fourth grade children working on the same tasks as them. As a part of the tasks, the participants in the study and in the video were asked to construct arguments for their solutions and justify them to their classmates. Participants in the control group learned fractions in ways consistent with the NCTM standards, but did not engage with the tasks or videos.

Both groups were administered a pre- and post-test to measure growth in their fractional content knowledge after learning about fractions. Participants in the experimental and control both showed significant growth in their fractional content knowledge. Several questions on the assessment required the participants to explain how they would help students who held common misconceptions that arise during the teaching of fractions (e.g., adding 1/5 + 4/17 and getting 5/22). Pre-service teachers who underwent the video-based intervention showed significant growth in their ability to help the students who held the misconceptions by building conceptual understanding in the student (e.g., using benchmark numbers), whereas the control group members provided algorithmic explanations (e.g., teach about common denominators by multiplying) on both the pre- and post-assessment. This study underscores the value of using classroom video in teacher preparation and professional development interventions. Videos that focus on student reasoning, along with providing teachers time to work on the same problems as the students in the video, can be useful in preparing teachers to help their students understand mathematical concepts rather than teach them algorithmic approaches.

DEVELOPING A JOINT KNOWLEDGE BASE FOR NOTICING STUDENTS' PRIOR KNOWLEDGE WITH ANIMATED CLASSROOM VIGNETTES

Lisa Skultety
University of Illinois at Urbana-Champaign
Dobson2@illinois.edu

Gloriana González
University of Illinois at Urbana-Champaign
Ggonzlz@illinois.edu

Keywords: Teacher Education-Inservice; Geometry; Teacher Knowledge

The study aims to identify ways teachers related a set of animated vignettes to their classroom practice to develop a joint knowledge base amongst the participants (Hiebert, Gallimore, & Stigler, 2002). In order to investigate this question, video (and subsequent transcripts) from two teacher study group sessions were analyzed using the modified version of Toulmin's (1969) model of argumentation developed by Chazan, Sela and Herbst (2012).

The data comes from a professional development program for geometry teachers from high-needs schools to promote teacher noticing of students' prior knowledge. The research team created animated vignettes to provoke discussion of classroom practices (Herbst, Nachlieli, & Chazan, 2011). The study analyzes the discussion of vignettes illustrating possible launches for a problem-based lesson on dilations. The main question is, *what claims and justifications do the teachers provide in reaction to the vignettes, and how do the claims and justifications relate to their classroom practice and knowledge of students' prior knowledge, if at all?* This question addresses whether and how the teachers notice students' prior knowledge when viewing and discussing representations of teaching.

During the discussion of three launches, there were 33 claims, with 27 explicit justifications. In the discussion of the first launch, the teachers claimed that several aspects of the launch would resonate with their own students' prior knowledge, such as drawing 3D figures and playing video games. The teachers also provided rebuttals of others' claims when they were not representative of their own classroom experience. In the discussion of the second launch, one teacher shared her experience of using a similar problem to the one shown in the vignette, and how her own students used their prior knowledge of the buildings in their town to make sense of the problem. In the discussion of the third launch, the teachers provided several claims about their students' prior knowledge of vocabulary and experiences with video games and how that might affect their ability to relate to the launch. Findings show that the study group discussions provided the opportunity for the teachers to share their practitioner knowledge as they connected the vignettes to their classroom experiences, and their understanding of their own students' prior knowledge. This study is relevant in identifying resources for eliciting teachers' practical knowledge and promoting its transition towards professional knowledge. Understanding how professional development activities, such as discussions of representations of teaching, can provide opportunities for developing a joint knowledge base is fundamental in teacher education.

MATHEMATICAL KNOWLEDGE FOR TEACHING AND REASONING ENTAILED IN SELECTING EXAMPLES AND GIVING EXPLANATIONS

Rachel B. Snider
University of Michigan
rsnider@umich.edu

Keywords: Mathematical Knowledge for Teaching; Instructional Activities and Practices; High School Education; Teacher Knowledge

Recent attempts to improve mathematics teaching include two prominent lines, teachers' knowledge and teaching practices. Much of the research on mathematical knowledge for teaching has focused on understanding the knowledge entailed by the work of teaching (e.g., Ball, Thames, & Phelps, 2008; Baumert et al., 2010). This line of research has been fruitful, yet there is much left to understand about how teachers deploy their knowledge in doing the work of teaching. Likewise, research on teaching practices does not directly examine how teachers use content knowledge in the context of enacting these practices (Grossman, Hammerness, & McDonald, 2009). Despite this research disconnect, in the classroom, teachers' knowledge and teaching practices are intertwined. This poster describes a study asking: What knowledge and reasoning are entailed in the teaching practices of selecting examples and giving explanations? It draws on the theoretical framework of mathematical knowledge for teaching (Ball et al., 2008) and is part of a larger study, which also includes classroom observations.

Ten experienced Algebra II teachers participated in cognitive interviews, focused on the content of rational expressions and equations. They were presented with tasks where they were either asked to pick examples to teach a particular topic or to give an explanation they would use with students of a particular concept. For example, one task asked teachers to select example problems to teach simplifying rational expressions. Data were analyzed across two dimensions, components of each teaching practice and teachers' knowledge and reasoning, looking for patterns within each dimension and across the two practices.

The findings reveal that the knowledge and reasoning entailed by each task are unique to the task. In particular, they suggest that knowledge and reasoning cannot be separated from the particular tasks of teaching in which they are deployed. Although tied to particular tasks, teachers' knowledge and reasoning varied widely in selecting examples and in preparing and giving explanations. For example, on the item focused on selecting problems for teaching simplifying rational expressions, one teacher selected problems based on particular features of individual problems, such as a negative leading coefficient, or values that were less common for students or might evoke a common misconception. In contrast, another teacher described more broadly the types of problems he would want to use and then selected a problem that met each set of criteria. Full results will be displayed on the poster.

This study investigated the questions: (1) How do journals support students' learning to prove in an undergraduate elementary number theory course? (2) How do journals demonstrate the development of students' thinking about proof in an undergraduate elementary number theory course? Students' performance in proof writing has been investigated in recent years (Weber, 2001; Raman, 2003); however, research is still needed to investigate innovative pedagogical approaches to teaching proof and how students' thinking about proof develops. Journaling has been shown to be a valuable tool for supporting students' learning and providing insight into students' thinking in various mathematical domains (Borasi and Rose, 1989). This study seeks to gain a better understanding of the power of journals in developing student thinking, and suggests possible ways to connect journal writing more closely to proof writing as an integral part of learning mathematics.

Methods

The 17 undergraduate students in the course wrote weekly journal entries related to the elementary number theory course and submitted them online. The instructor of the course then read and responded to each student's submission. The journal assignments consisted of both structured and unstructured prompts. Our data collection included pre-post surveys asking the students' views about mathematical proof and their perceptions about journals; students' open-ended and structured journal responses and task-based interview transcripts with five of the students. The data were coded according to the framework provided in Borasi and Rose (1989) for the journaling component, and the students' proof attempts from the task-based interviews were coded using Raman's (2003) framework for students' proof ideas.

Results

Our findings suggest the students used the unstructured journal assignments primarily as a means to reflect on their feelings about the course material and their learning. However, in the structured journals, the students wrote specifically about the process of proving and their views about mathematics and proving. Implications of this study suggest that journaling creates an added dimension of communication for students and the instructor to support students learning the course material in a more responsive manner. Future studies will investigate the role of directed and more structured questions to focus student journals on specific mathematical ideas.

This study takes a socio-psychological approach (Wertsch, 1991) to examine how mathematics professional development facilitators and teachers enact a professional development program (PD) in the absence of strict fidelity expectations. In this view, how individuals make sense of their world is always mediated by their own socio-historical past knowledge as well as their own current and envisioned goals for the knowledge. Juxtaposed against this view of how adults make sense of new information is the construct in professional development of *fidelity*. Though often a major concern of educators and policy makers, ensuring fidelity of implementation can be an elusive goal if we are to understand knowledge construction as being culturally mediated and situated within local contexts. This mediation takes place on multiple levels: (a) as facilitators are trained by PD designers/developers, (b) as these facilitators then train teachers, and (c) as teachers instruct students.

If we are to understand the impact of PD, it is important to know more about these inevitable adaptations. We seek to shed light on this process by examining the way that a single PD is iterated across various regions in Texas and then how that PD is enacted across various schools and districts in each region as it is implemented in the classroom. Two research questions guided us: 1) What changes/adaptations are made each time the PD is implemented? 2) What reasons do participants give for making those changes? To investigate these questions, facilitators and teachers were administered parallel surveys after being trained and after implementing the PD in their own trainings (facilitators) or classrooms (teachers). Questions on these surveys mirrored one another so that comparisons could be made across the four surveys.

Open-ended responses were coded according to particular aspects of the original PD. Descriptive analyses of the data yielded a portrayal of the variations between sites at each level of implementation. Conditional probability analysis supplemented the description of what is implemented of the PD. Emergent themes from open-ended responses indicate distinct categories of interpreting and enacting PD that seems to be at least partially determined by contextual factors. These results have implications for the design and implementation of PD and how to support facilitators as decision-makers who are responsive to the contexts in which they teach.

Mathematics education researchers have long called for the use of rich tasks (Stein, Grover, & Henningsen, 1996). More recent work has identified challenges involved in launching such tasks (Jackson, Garrison, Wilson, Gibbons, & Shahan, 2013).

Cognitive science researchers have shown that experts and novices alike rely on *schema* to make sense of situations and inform decision-making (Carter, 1990). The long prevalence of initiation, response, evaluation (IRE) in American classrooms (Franke, Kazemi, & Battey, 2007) implies that teachers' schema for student thinking (right or wrong) and teacher responses (praise or correction) are relatively simplistic.

We sought to answer the following research questions:

- Would engaging in a multiple-choice activity involving diagnosing and responding to students' thinking enlarge participants' schema for student thinking and teacher response?
- Would this activity lead to participants adopting common language around student thinking and teacher responses in the context of a lesson launch?

The researchers created an experience on LessonSketch, an online computer environment that allows participants to view cartoon storyboards of teaching situations. In the experience participants encountered typical student responses to a proportional reasoning task. Then they chose among several diagnosis and response categories that we had chosen, based on research of teaching and student thinking. We hypothesized that having to think about the categories several times in the context of analyzing a lesson launch would support participants in developing more complex schema for diagnosis and teacher response.

Participant data indicate that the LessonSketch experience did help teachers and PST's develop richer, and more uniform schema of student reactions and teacher moves. This approach challenges teacher educators to continue to identify helpful schema for launching rich tasks.

Keywords: Standards; Teacher Education-Preservice

Studies of mathematics methods courses show substantial variation in activities intended to prepare teachers to teach mathematics (e.g., Kastberg, Sanchez, Edenfield, Tyminski, & Stump, 2012; Taylor & Ronau, 2006). However, the wide-spread adoption of the Common Core State Standards for Mathematics (CCSSM) (NGA & CCSSO, 2010) offers the possibility of more consistency across courses (e.g., Heck, Weiss, & Pasley, 2011) as mathematics teacher educators (MTEs) take up a common focus on teaching about the content standards and standards for mathematical practice in CCSSM. Our study sought to consider the variations in activities MTEs use in mathematics methods and content courses. This study is part of a larger project examining CCSSM in mathematics teacher preparation. We surveyed 370 MTEs who taught elementary, middle school, or secondary methods or content courses. This poster presents findings from analysis of 269 descriptions of activities used to teach PSTs about CCSSM.

Consistent with other studies, our findings show a wide variation in activities, including examining the standards documents (6.5%); watching videos or observing teaching to identify standards (6.5%), analyzing curriculum for alignment with CCSSM (2.3%), and engaging in a task consistent with the standards (8.8%). The activity with the most responses was preparing for or creating lessons or units using CCSSM (14.1%). In addition, many MTEs provided responses that described a mathematical or pedagogical activity, but did not elaborate how the activity was connected to CCSSM (8.6%). MTEs may have felt that the connection to CCSSM was implied or obvious and so needed no elaboration. Also interesting were the small but still not negligible number of MTEs (1.4%) who do not incorporate any CCSSM-related activities in their courses. Our findings suggest that MTEs see many ways in which PSTs should interact with CCSSM. As such, while CCSSM may provide a common area of focus of MTEs, it does not seem to narrow or restrict instructional activities nor result in more consistency across courses or institutions.

MATHEMATICS, LANGUAGE, AND DEGREES OF CERTAINTY: BILINGUAL STUDENTS' MATHEMATICAL COMMUNICATION AND PROBABILITY

Karla Culligan
University of New Brunswick
kculliga@unb.ca

David Wagner
University of New Brunswick
dwagner@unb.ca

While all mathematics is mediated by language, the role of language is especially complex in bi- and multilingual mathematics classrooms, and more so in bilingual education programs in which the explicit goals of both language and mathematics learning intersect. We explore bilingual French immersion students' linguistic and mathematical repertoires as they work through a series of probability problems. Focusing on the collaborative dialogue that occurred between students and researchers, our discourse analysis was informed by sociocultural theory and systemic functional linguistics. Findings indicate that students' linguistic and mathematical repertoires are intertwined, and that collaboration can offer opportunities for supporting bilingual learners' language and mathematics development. We conclude with implications and challenges for bilingual mathematics education.

Keywords: Classroom Discourse; Instructional Activities and Practices; Probability

One of the most novel characteristics of French immersion programs is that students whose first language is not French learn this target language not only through French language classes but also through content courses such as mathematics. Both mathematics learning and language learning are explicitly stated goals of the immersion program (Swain & Johnson, 1997). Around the world, students learn mathematics through languages other than their first or home language(s) in a variety of bi- and multilingual mathematics classroom contexts. Consequently, it is important for researchers and educators to examine how mathematics and language learning simultaneously take place in the classroom.

Theoretical framework

Work by Halliday (1978) and others has brought to the forefront issues related to language in mathematics and, more specifically, the mathematics classroom. Halliday described three aspects to consider with regard to any linguistic situation, including mathematical discussion: "first, what is actually taking place; secondly, who is taking part; and thirdly, what part the language is playing" (p. 31). Drawing on these ideas, we focus on mathematics as a meaning-making activity rooted in the social interactions of the learners. The notion of the mathematics register describes this in more detail: The mathematics register involves "the meanings that belong to the language of mathematics (the mathematical use of natural language, that is: not mathematics itself), and that a language must express if it is being used for mathematical purposes" (p. 195).

From a second language education standpoint, we adopt a theoretical framework that supports our view of mathematics and language. We draw on the work of Vygotsky (1962, 1978) and neo-Vygotskians (Cole, 1985; Donato, 1994; Lantolf, 2000; Lantolf & Appel, 1994; Swain, 2000; Swain, Kinnear, & Steinman, 2011; Wertsch, 1985, 1993), which has underscored the social element driving all individual cognitive functions. Moreover, this work has emphasized the key role language plays in all human interactions and learning. Language is viewed as a mediational means, in other words, language mediates thought and is not strictly a conveyor of thought. This approach, rooted in the exploration of language and learning through social interactions, guides our analysis of mathematical discourse.

Selected literature

Our review of selected literature has two main parts: first, a discussion of studies of mathematics and language from the mathematics education field, with particular focus on those based in bi- or multilingual contexts; and second, an exploration of some key sociocultural concepts related to second language education.

Mathematics and multilingual classrooms

Research based in a variety of multilingual mathematics classrooms has highlighted a number of important issues with regard to mathematics and language. In particular, scholars have pointed to a need to recognize that the mathematics register is enacted in unique ways within the mathematics classroom. The specialized language of the mathematics classroom is distinct from the specialized language of mathematicians (Barwell, 2005, 2007, 2009b; Barwell, Leung, Morgan, & Street, 2005; Morgan, Craig, Schüte, & Wagner, 2014; Moschkovich, 2003, 2007, 2010; Pimm, 2007; Setati & Adler, 2000). This work has underscored the importance of classroom context, and has viewed mathematics as a social, discursive activity. From this standpoint, "mathematical discourse includes not only ways of talking, acting, interacting, thinking, believing, reading, writing but also mathematical values, beliefs, and points of view" (Moschkovich, 2003, p. 326). Far from a homogeneous set of practices and norms, some general characteristics of mathematics classroom discourse can include "being precise and explicit, searching for certainty, abstracting, and generalizing,[… and] imagining" (Moschkovich, 2003, p. 327).

With regard to bilingual learners in particular, research has called for a refocusing on the resources these learners bring to the mathematics classroom rather than on their so-called problems or deficiencies (Barwell et al., 2005; Moschkovich, 2003, 2007). In this vein, studies have suggested that allowing for ambiguity, or the acceptance of multiple meanings, during mathematical collaboration can be a resource for mathematical understanding, particularly for bilingual students (Barwell, 2005). Moreover, hearing the mathematical in students' so-called everyday talk is also key to supporting bilingual learners, who may use this everyday talk to contextualize and understand the linguistic and mathematical aspects of problems (Barwell, 2009a; Moschkovich, 1999, 2003, 2005, 2009a, 2009b). This approach does not view mathematical and language learning as separate, but rather as intertwined and co-developing in a reflexive relationship (Barwell, 2005).

A further concept for consideration in bilingual mathematics classrooms is if, when, and how multiple languages are used and valued (or not). Often referred to as codeswitching, that is, the switching of languages "within the course of a single conversation, whether at word or sentence level or at the level of blocks of speech" (Baker, 2011, p. 107), this phenomenon has been explored in both mathematics and second language education contexts. As scholars in both fields have explained, historically codeswitching has been perceived as indicative of a deficiency with regard to bilingual students' mathematics and language proficiency. Recent work, however, has challenged this view. Researchers have argued for a positive, resource-oriented view of bilingual learners that recognizes the resources they bring to the mathematics classroom and, in line with sociocultural theory, this may include learners' first or home language(s). This approach challenges the monolingual norm and views codeswitching as socially and cognitively complex. However, codeswitching remains a contentious and controversial issue and the use of multiple languages in the mathematics classroom often conflicts with political agendas and language policy goals (Adler, 1999; Barwell, 2009b, 2014; Cummins, 2007; Moschkovich, 2005; Planas & Setati-Phakeng, 2014; Swain & Lapkin, 2000; Turnbull & Dailey-O'Cain, 2009; Setati & Adler, 2000).

Second language learning through content

With regard to second language learning in mathematics, two key sociocultural concepts emerge that are pertinent to our analysis. The first is the notion that as learners interact with a more capable other, who could be their teacher or their peers, they can achieve more than would have been possible on their own. In this scenario, the learner eventually gains control over the task, internalizes the skill, and is able to perform it independently. This movement from other- to self-regulation is described as what happens in the zone of proximal development (Vygotsky, 1978). It relates to a pedagogical notion called scaffolding, in which a temporary scaffold provided by an expert other is used to help learners with a particular learning task (Cole, 1985). The scaffolding is eventually dismantled as the learner becomes more capable and the responsibility for the task is gradually transferred from expert to learner.

The second pertinent concept is the notion that language learning occurs during collaborative dialogue. According to Swain (2000), collaborative dialogue "is where language use and language learning can co-occur. It is language use mediating language learning. It is cognitive activity and it is social activity" (p. 97). In this view, when language learners engage in problem-solving tasks they are able to notice and pay attention to linguistic elements and co-construct knowledge through producing output through collaborative dialogue. These language-related episodes mediate the learners' understanding of the problems and solutions (Donato, 1994; Swain, 2000; Swain & Lapkin, 1998).

The study

The current study is framed within a larger, 3-year longitudinal study entitled "Students' language repertoires for investigating mathematics" (supported by the Social Sciences and Humanities Research Council of Canada, Principal Investigator: David Wagner). In this paper, we focus on bilingual French immersion students' linguistic and mathematical repertoires during collaboration with an interviewer-researcher on probability-related problems and activities. (We have discussed different aspects of the larger study elsewhere. See, e.g., Culligan, Dicks, Kristmanson, & Wagner, 2014; Wagner, Dicks, & Kristmanson, 2015.)

Context and participants

The participants in the current study were Grade 3 French immersion mathematics students in their first year of the program. Students first engaged in a whole-class probability-based activity (Skunk die game, described in the next section) and then worked on related problem-solving tasks in small groups of two to three. As a follow-up, students interacted with an interviewer-researcher as an extension of the whole-class activity. During these interviews, students were introduced to a second probability-related activity (Skunk card game, described in the next section) and responded to questions related to the two games. The students were asked about their strategies for playing both games, about the differences between the two games, and about different words of interest (related to probability and degrees of certainty) they had used while responding to these questions and/or engaging in the problem solving.

The probability activities

In both the Skunk die game and the Skunk card game, students were introduced to the problem with a narrative: You are picking berries in the forest and trying to collect as many berries as possible before the skunk comes. Numbers 1 to 5 represent the berries you collect on each roll of the die. The number 6 represents the skunk and the end of the turn. If the skunk comes, you lose all of the berries you collected on that turn, unless you have "gone home" to avoid the skunk when you had enough berries. You do this for seven days (Monday to Sunday). The player with the most berries at the end wins the game.

In the Skunk card game, the interviewer-researcher laid playing cards (numbered 1 to 6, with 6 being the skunk) out on the table one by one, rather than rolling a die. The cards were not picked up once laid down. Rather, the interviewer-researcher continued laying down cards one by one as long as the student wished to continue. We moved on to the next day of the week once the students had decided to stop collecting berries for the current day, or once the skunk card was played. Cards were not picked up and reshuffled until all six cards had been laid down; this could happen in the middle of the current "day." Thus, the probability of getting the skunk on any given turn differs in the card game compared to the die game. In the card game, the events are mutually exclusive, and in the die game, the events are independent.

Data collection and analysis

Students were audio and video recorded during the whole-class activity and the follow-up interviews. Data were transcribed and written transcripts were the primary source for analysis. We analyzed the data using Swain and Lapkin's (1998) approach to discourse analysis, which entails describing and interpreting language-related episodes. Furthermore, we drew on the field of systemic functional linguistics (e.g., Halliday, 1994), which enabled us to describe and interpret specific instances of language use within our particular context.

Results

To discuss our results, we present selected excerpts of transcripts from the students' interviews with an interviewer-researcher and offer our interpretations.

Excerpt 1: Linguistic and mathematical uptake of "*absolument*"

The following is an excerpt from a Grade 3 interview. This is the first year of French medium learning for these children. English translations are provided on the right. The interviewer-researchers (R1 and R2) are asking the students (S1, S2, and S3) their predictions regarding the upcoming cards and their degree of certainty regarding these predictions. One researcher (R1) leads the interview and the other (R2) is behind the camera, taking note of students' language use and then participating in the interview later.

115	*R1:*	Est-ce que c'est absolument le quatre?	*Is it absolutely the four?*
116	*S3:*	Oui.	*Yes.*
117	*R1:*	Est-ce que tu es certain que c'est le quatre?	*Are you certain it's the four?*
118	*S3:*	Oui, non.	*Yes, no.*
119	*S3:*	Ça peut être une trois aussi.	*It could be a three too.*
120	*R2:*	Quelles sont les chances que ça soit un trois?	*What are the chances that it's a three?*
121	*S2:*	Beaucoup….	*A lot…*
…			
166	*R2:*	Alors ça doit être quoi ici?	*So it has to be what here?*
167	*S2:*	Il doit être, un, deux trois, quatre, cinq.	*It has to be one, two, three, four, five.*

168	*R2:*	Ça doit être des fraises (et non pas la moufette)?	*It has to be berries (and not the skunk)?*
169	*S1, S2, S3:*	Oui.	*Yes.*
170	*R2:*	Absolument des fraises?	*Absolutely berries?*
171	*S2, S3:*	Oui.	*Yes.*
172	*S1:*	Absolument.	*Absolutely.*

In this exchange, we see linguistic uptake of *absolument* (used by R1 line 115, R2 line 170;taken up by S1 line 172). Moreover, there is mathematical uptake of *absolument*, a concept related to probability. The students go from being very certain (line 116), to questioning/hedging (line 118), to using a modal expressing a greater degree of uncertainty (line 119). Throughout the exchange, the researcher-interviewer acts as a more knowledgeable other, providing scaffolding and pushing students to go farther than they may have done on their own. Notably, however, the questioning of the student's response did not lead the student to change her answer ultimately—she worked through the task and decided she was *absolument certaine*. Here, mathematics and language work together to solidify the students' understanding of the probability concept.

Excerpt 2: Explaining the meaning of "*çadoit*"

In this Grade 3 excerpt, the interviewer-researcher (R1) is asking the students (S1, S2, and S3) the difference between "it has to be a 6" (card game) and "you have to brush your teeth" which present different senses of the modal verb "have to"—one indicating logic and the other obligation. The students relate this distinction to the English expressions "it is going to be a 6" and "you are going to brush your teeth." (In the translation at right, the underlined text is not translated because it is English in the original.)

388	*S1:*	En anglais « doit » dans la première phrase, ça doit être une moufette.	*In English "has to" in the first sentence, it has to be a skunk.*
389	*S1:*	Et, dans l'anglais, ça veut dire « it's going » and, dans l'autre phrase, ça dire « you have to. »	*And, in English, it means "*it's going*"* and*, in the other sentence, it means "*you have to*".*
390	*R1:*	« You have to », comme tu doit te brosser les dents et « it's going. »	*"You have to", like you have to brush your teeth and "*it's going*."*
391	*S2:*	Tu n'as pas une choix.	*You don't have a choice.*

Here, the students use their first language, English, to clarify their ideas. The first language seems to provide them with resources to strengthen and confirm their explanation that there is a difference between the two uses of "have (has) to". Students use English to clarify or confirm their interpretation of the French expression "*çadoit*". Comparing "it has to be a six" in the card game, in which students knew the next card "had to" be the skunk (it was the only card left to be played), to the sentence "you have to brush your teeth" was a cognitively challenging activity both mathematically and linguistically. In the last line, S2 raises the question of choice, which is inherent in the “you have to brush your teeth” example, but not in the “it has to be the skunk” example. Students use their first language as a tool for discussing the multiple meanings of “*çadoit*” and, in so doing, construct both mathematical and linguistic understanding.

Discussion

Our results highlight the mathematical and linguistic understanding that can occur during collaborative dialogue in the bilingual mathematics classroom. When viewed through a sociocultural theory lens, in the first excerpt, the learners, through the scaffolded guidance provided by the interviewer-researcher, are able to go farther, mathematically and linguistically, than they may have been able to individually. Through the interviewer-researcher’s introduction of the term “*absolument*”, students are able to pick up that language and use it to explore the mathematical concept of certainty. Similar to the reflexive relationship described by Barwell (2005), in this study students’ mathematical understanding of the probability-related concept of certainty develops in an interwoven fashion with their linguistic understanding.

In the second interaction, students engage in a phenomenon that is of particular interest to many working in bilingual mathematics classrooms—codeswitching. Despite some traditional, deficit-oriented views of codeswitching, recent research in the field of second language education has argued that in the classroom, judicious use of students’ first language can serve as a resource for second language learning (e.g., Cummins, 2007; Swain & Lapkin, 2000; Turnbull & Dailey-O’Cain, 2009). Moreover, research in mathematics education has argued that bi- and multilingual learners use their first language, home language(s), or shared language(s) as a resource for mathematical learning and that it plays an important social and political role (e.g., Adler, 1999; Barwell, 2014; Moschkovich, 2005; Planas & Setati-Phakeng, 2014). Barwell and Setati (2005), for example, have urged mathematics educators to find “ways of dealing with linguistic diversity that avoid reducing mathematics classroom interaction to a monolingual (English language) norm” (p. 23). Although the research contexts referred to here are varied and each is unique, codeswitching is a phenomenon that seems to occur throughout. A sociocultural theoretical framework that views language as a mediator of thought and as a cognitive tool, allows us to view students’ codeswitching in this study as a resource for mathematical and language learning, rather than a problem or deficit to be overcome.

Implications and challenges

The two excerpts featured here point toward implications, and corresponding challenges, for mathematics educators working in bi- and multilingual contexts. First, we suggest that providing opportunities for students to engage in collaborative dialogue with each other and with their teacher is important mathematically, linguistically, and socially. Taking the time to allow these interactions to unfold is challenging when faced with the demands associated with covering curriculum outcomes and assessment, but can result in learning that is mathematically and linguistically valuable. It will be imperative for mathematics educators to recognize, value, and build upon the mathematics present in students’ multiple meanings, and in their everyday talk. This is particularly true for bilingual learners. Viewing both mathematics and language as social, discursive activities may help foster collaborative exchanges.

Second, the ways in which multiple languages are used in any context, including the mathematics classroom, are complex. Interpretations of codeswitching practices must take into account contextual, political, and language policy factors. Nonetheless, researchers across contexts are increasingly viewing student codeswitching as a potentially resourceful way of understanding complex mathematical and linguistic content. In spite of this, local policy often dictates that one language only, the target language, be used as the language of teaching and learning in the classroom (and this is certainly the case in our study’s context, French immersion). The challenge will be for researchers and educators to continue to explore in more detail if and how students’ multiple languages can be used in the mathematics classroom, and how to do this in a way that results in effective and efficient language and content learning.

Conclusion

In sum, our results suggest that collaborative dialogue can be a meaningful activity in the bilingual mathematics classroom. In particular, interaction may provide opportunities for bi- and multilingual learners to learn not only mathematical content but also language. Learners can build on the scaffolding provided by teachers and even their peers to extend their understanding of linguistic and mathematical concepts.

We argue for a need to move beyond viewing strictly academic mathematics vocabulary as the only acceptable or valuable mathematical communication. While gaining control over mathematics terminology is without a doubt important, students also need to acquire the language necessary to talk about mathematics. Moreover, language use, language learning, and mathematics learning are largely, if not entirely, inseparable.

THE DISCOURSE OF ATTENDING TO PRECISION IN SECONDARY CLASSROOMS

Attending to precision (ATP) is essential in mathematics. This study examined ATP instances through the lens of univocal (functioning to convey information) and dialogic (functioning to generate new meaning) discourse. Analysis of data from five secondary mathematics classrooms focused on whole-class instances of ATP with coding based on the univocal or dialogic nature of the discourse. Although instances were predominantly univocal, there was variation in whether the teacher's or student's idea was being transmitted. We share examples of the rare dialogic instances where the co-construction of meaning through discourse involved ATP in qualitatively different ways than the univocal instances.

Keywords: Classroom Discourse; Problem Solving; Metacognition; High School Education

Within mathematics, precision is highly valued because imprecision can lead to holes in arguments or faulty conclusions and miscommunication can prevent the development of shared meaning. As a steward of the discipline, then, school mathematics must help students learn to attend to precision and recognize that standards of precision are different within mathematical communities than they are in other communities. In the United States, the importance of attending to precision (ATP) was affirmed by its inclusion within the *Common Core State Standards for Mathematics* (2010). Not only is ATP a worthwhile end in its own right but also has the potential to support student learning. For example, by paying careful attention to the precise meaning of algebraic symbols, students can successfully transition from arithmetic reasoning to algebraic reasoning and be prepared for higher levels of mathematics (Kieran, 2007). In general, students, by interacting with teachers and classmates, can express and refine mathematical ideas together, constructing shared meanings and becoming legitimate participants in mathematical discourse (Lave & Wenger, 1991) rather than passive recipients of knowledge.

This study focused on ATP in secondary mathematics classrooms. Our goal was to see a broad range of instances of ATP and analyze the nature of the discourse in those instances within the whole-class public discourse. This work adds to the literature on ATP, which is relatively thin compared to well-developed topics such as problem solving or reasoning-and-proving.

Theoretical Framework

For this study we took a sociocultural perspective wherein student learning is viewed as intertwined with social interactions (Vygotsky, 1978) and used tools from discourse analysis to examine the interactions. In particular, we drew on Herbel-Eisenmann and Otten (2011) who framed the learning of a subject as the process of coming to participate meaningfully in the discourse of that subject's community. We consider ATP to be one of the characteristic practices of the mathematics classroom community as well as the broader mathematics community.

Discourse serves two important functions—to transmit an existing meaning from one person to another and to generate new meanings through the process of interacting (Bakhtin, 1986). The term *univocal* refers to discourse that is primarily intended to fulfill the transmission function, whereas *dialogic* refers to discourse that is primarily intended to generate new meaning. Mathematics classrooms in the United States predominantly feature univocal discourse (National Council of Teachers of Mathematics, 2014), yet various scholars have provided evidence for the value of dialogic discourse (e.g., Lobato, Clarke, & Ellis, 2005; Otten & Soria, 2014) and called for more research on benefits of different forms of classroom discourse (Howe & Abedin, 2013).

Research Question

This study addresses the following question: What is the univocal or dialogic nature of the discourse within instances of ATP in secondary mathematics classrooms? Although the question draws a binary distinction between univocal and dialogic discourse, we recognize that the underlying characteristics form a continuum (Truxaw & DeFranco, 2008) and that all discourse involves both deciphering meaning (univocal) and generating meaning (dialogic). Nonetheless, like others (Peressini & Knuth, 1998), we see practical value in distinguishing between discourse that is more prevalent in one than the other. This distinction is especially appropriate with regard to a mathematical practice such as ATP because scholars (e.g., Barwell & Kaiser, 2005) have pointed out that dialogic discourse is a practice-oriented process within a community.

Method

Setting and Participants

This study is part of a larger project focused on the mathematical practices of reasoning-and-proving, generalizing, and ATP. The project has two interrelated goals: (1) to support mathematics teachers in understanding and implementing these practices, and (2) to better understand how practicing teachers and students at various grade levels engage in the practices (or not) during classroom instruction. We worked with a group of teachers during their summer break to achieve goal 1, and we conducted classroom observations throughout the following academic year to achieve goal 2. This particular study reports on an analysis of ATP within the classroom observation data of the secondary teachers.

The project took place in a rural school district in the central United States. The district is predominantly white in ethnicity but comprises substantial economic diversity and diversity in parental education levels. The district performed slightly above the state average on the secondary mathematics standardized assessment.

Eight mathematics teachers volunteered to participate in the larger project, spanning grades 5–12. The teachers' backgrounds, teaching experiences, and philosophies toward mathematics education varied. For this study, we focused on five teachers (grades 8–12) and one focal class per teacher. We observed the focal classes on typical instructional days in the fall and winter. We intended to conduct three observations per class to capture a range of mathematical topics and gain a sense of the variability of discourse per classroom. When the discourse was limited, two observations were sufficient. When the discourse involved a range of interactions, we made three or four observations. This does not threaten our analysis since we do not seek to compare classes. Instead, we focus on the ATP instances when they arise and the nature of the discourse therein.

Data and Analysis

Classroom observations involved a single video camera and four digital audio recorders. Analysis began by flagging instances of ATP in the whole-class public discourse using a coding scheme based on the Common Core State Standards (2010), Koestler and colleagues (2013), and Fennell, Kobett, and Wray (2013, January). In particular, we looked for the following indicators:

- Emphasis, clarification, questions, or discussion in regard to
    - Defining terms or using them appropriately
    - Defining symbols or using them appropriately
    - Labeling units, graphs, or diagrams
    - Precision of calculations
    - Precision of measurements
    - Rounding or estimating

- Making or refining claims
- Giving explanations or justifications
- Appropriate mathematical precision within a non-mathematical problem context

Note that a teacher or student merely *being* precise did not necessarily result in a flag for ATP. More important was whether explicit *attention* was given to the precision. Having flagged the instances of ATP, we marked their beginning and end based on when the focus of the discourse shifted to and from the issue of precision and then transcribed each instance. We compiled durations and descriptive statistics for each class and for the set of ATP instances overall.

Next, we coded each instance of ATP based on the distinction between *univocal* and *dialogic* discourse. Building on the definitions above, we operationalized these constructs using the following characteristics, adapted from Wegerif (2006) and Truxaw and DeFranco (2008):

- Univocal
  - transmission of meaning (giver and receiver(s))
  - closed discourse (answer or information concludes the exchange)
- Dialogic
  - shared development of meaning (give-and-take)
  - open discourse (information or ideas spur further discourse)

Note that having multiple speakers does not imply dialogic interaction. Multiple speakers can be involved in transmitting meaning rather than in opening up a discourse space for making new meaning. Also, a single turn, such as a teacher's question, cannot be coded on its own because the potential to spur dialogic discourse does not necessarily do so. Thus, we considered interactions overall when making coding decisions. In rare cases, there was difficulty coding but these were discussed until consensus was reached.

Our final phase of analysis was to look across the coding for patterns and themes both within and across the univocal and dialogic instances. These themes were used to structure the Findings, presented below with several examples used to illustrate the themes.

Findings

We found 140 instances of ATP in the classroom data, with an average duration of around 40 seconds per instance. Some were very brief and others lasted a few minutes. Overall, univocal instances (131) were more common than dialogic instances (9). Only two classes exhibited dialogic instances and univocal ATP was still predominant. Below we illustrate some themes that emerged from the univocal instances of ATP and give examples of the rare dialogic instances.

Univocal Instances of Attending to Precision

The 131 instances of univocal ATP comprised 93.6% of the total instances and ranged in duration from 3 seconds to 2 minutes, 48 seconds. The nature of the ATP in these instances varied. In some cases, teachers briefly pointed out a lack of precision, a need to be precise, or prompted students to use precise terminology. In other cases, teachers and students attended to precision of their communication to assure that the transmission of meaning was successful.

Many instances of univocal ATP were relatively brief, involving a teacher making an explicit remark about precision. For example, when working with graphs, Mr. Forrest said, "[The graph] doesn't have to be perfect, but I'm going to make sure I put the x-intercepts about where they are on this graph and the y-intercept about where it is on that graph." These instances were univocal because they simply involved a teacher transmitting an idea or warning with regard to ATP.

Other brief instances of univocal ATP involved teachers pressing for precise terminology. For example, Ms. Finley was working with students to prove that two triangles were congruent. One of the steps in the proof involved side NG being shared by both triangles.

Finley: OK, GN is equal to NG, which is true. My question to you is, why?
Students: Same line?
Finley: It is the same line, but we have a name for that… It's a property that we did back in Chapter 2, that seemed really silly at the time, but…
Students: Reflexive!
Finley: Reflexive. OK?
Male Student: I said it. I knew it.

Ms. Finley prompted the class to use the precise term in the written proof rather than simply saying that GN and NG are the "same line" segment. This interaction was univocal because the teacher knew the property and terminology she wanted and the interaction ended as soon as the term was supplied. It was not opened up into a discussion of the reflexive property itself or to other imprecisions such as the conflation of line and line segment. The student's final turn confirms that this interaction was univocal, directed toward supplying known information.

Longer instances of univocal ATP most often involved the teacher and students engaging in discourse to clarify or correct the communication of a mathematical idea. These instances were univocal because they were, in essence, a transmission of someone's idea and ATP played a role in assuring that the meaning was transmitted and received as intended. For instance, Ms. Finley drew a pair of triangles on the board (see Figure 1) and claimed they were congruent, but she purposefully wrote the congruence statement with the vertices listed in an incorrect order.

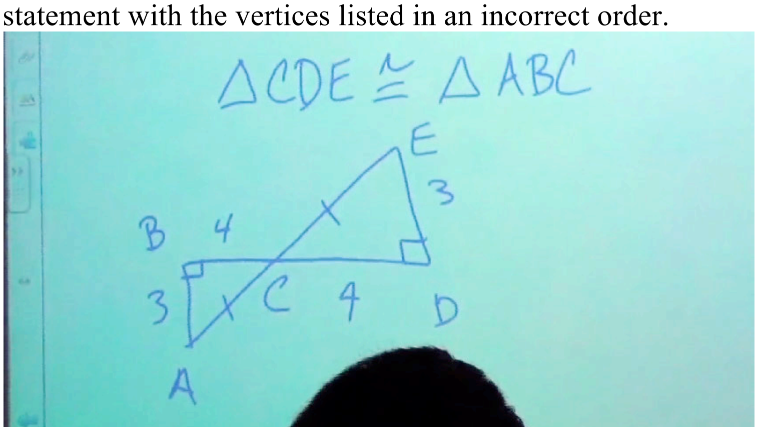

Figure 1: An incorrect statement about congruent triangles

Finley: OK, so, I'm telling you I'm wrong. Emily thinks I'm wrong because I can't draw. I get that. The question is, why am I really wrong?
Female Student: Does it have something to do with the right angle?
Male Student 1: You don't have congruent angles.
Students: Yeah.
Ms. Finley guided the students through a quick verification that, in fact, all the corresponding sides and angles were congruent to one another, so the triangles were truly congruent.
Finley: So there's something else that must be wrong with my thinking. Melissa?
Melissa: The numbers are wrong, or the letters.
Finley: The letters are in the wrong order. What did I not match up right?
Male Student 2: Ohhh, I see.
Finley: C should match with…
Students: C.

Finley: C [instead of A]. So, this [congruence statement] is not true, and don't make this mistake on your homework because if you do, we'll have a problem.

Note that there was not only ATP in this interaction but also a suggestion from Ms. Finley to be precise in the future. This interaction was univocal because Ms. Finley had a particular error she wanted to discuss and the exchange concluded when it was identified. Students made bids to open up a dialogic exchange when they questioned the angles instead of the labeling, but this did not lead to dialogic discourse as Ms. Finley led students through verifying the corresponding parts of the triangles were indeed congruent and then proceeded with the ATP of the labeling.

Less often, the long instances of univocal ATP focused on students' ideas. The following instance is from Mr. Forrest's lesson on graphs of polynomials. Mr. Forrest asked the class about "tangent to" and the interaction then focused on clarifying a student's idea about the phrase.

Forrest: Is the graph tangent to the x-axis, or does the graph continue through the x-axis at each x-intercept? … Does anybody know what "tangent to" is?
Dustin: Stops at it.
Forrest: How do you mean, "Stops at it"?
Dustin: Like, whenever it goes down (drawing in the air) and touches it [the x-axis], it immediately goes right back up and that's either the furthest point up or the furthest point down in that part.
Forrest: Alright, I like your explanation Dustin. Could you draw a picture on the board? [Dustin draws a curve on the board; see Figure 2]

Figure 2: Dustin's example of a curve tangent to the x-axis.

ATP occurred as Mr. Forrest asked Dustin to clarify his words, "Stops at it", and to represent his idea graphically. Although Mr. Forrest prompted the ATP, Dustin's idea was the focus. The interaction was univocal because it involved clarifying Dustin's transmission to the class.

Dialogic Instances of Attending to Precision

Although dialogic instances of ATP were rare, they are important to consider because they illustrate a different form of interaction and engagement with ATP. All 9 dialogic instances involved precision of language or communication, whether it be constructing definitions, refining student conjectures, or building upon (rather than merely transmitting) a student's idea.

The following excerpt is from Mr. Forrest's class as they discussed the graph of $y = \sqrt{-x}$. Mr. Forrest asked a small group how the calculator was able to display a graph even though the square root of a negative number is imaginary. He then engaged the whole class in this idea.

Forrest: Can anybody explain why you still got a graph there? What do you think, Matt?
Matt: Because all the x-values are negative, it's gonna make it positive.

Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

Forrest: So, "Because all the x-values are negative, it's gonna make them…"
Matt: Like, the x-values in the graph, whenever you plug them in it's gonna invert them into a positive number.
Forrest: Alright, so can you give me an example? Because we got [writes on board] y equals the square-root of negative x, right?
Matt: So x is negative three.
Forrest: So if we made an xy-table, plugged in negative three?
Matt: Yeah.
Forrest: We get the square root of…
Matt: Three.
Forrest: Three, right? Because, if you think of it another way, wouldn't that be the square root of negative negative three?
Female Student: Uh huh.
Forrest: Which is the square root of negative negative 3. This is why it's possible. Because even though it's the square root of negative x, what kind of values can we plug in for x? We can plug in negative values for x to give the square root of x. Does that make sense?

Matt offered an idea and the subsequent discourse involved attending to the precision of his language to facilitate communication while also building new meaning. For example, Mr. Forrest repeated Matt's original statement, which contained two vague referents ("it's" and "it"), then Matt added to his explanation. Mr. Forrest also requested an example and said, "So if we made an xy-table, plugged in negative three?" to push Matt to express his idea more clearly. Matt was able to give a specific example and Mr. Forrest then built on that idea to move toward a more general idea based on that shared meaning. It is important to note that Mr. Forrest was not the one doing all the reasoning. He did contribute, but he also pushed Matt to illustrate the reasoning behind his idea, which allowed Mr. Forrest to build upon and extend Matt's original reasoning.

This second example is also from Mr. Forrest's class because his class exhibited nearly all the dialogic instances of ATP. Here, Mr. Forrest was reviewing the definition of a polynomial in a univocal manner when dialogic discourse took place around the definition of whole number.

Forrest: Polynomial functions have only whole number exponents on the variables. What are whole numbers?
MS: Like, number one would be a whole number.
Forrest: That's true. Specifically, what is the set of whole numbers? … [pause] Because when we say whole numbers, it's actually a very specific mathematical set, right?
Zack: One, two, three, four.
Forrest: Say it again.
Zack: I just counted them.
Forrest: OK.
Ben: Like zero to infinity, positive.
Forrest: Zero to positive infinity?
Ben: Mm hmm.
Male Student: Wait, is there other kinds of infinity?
Henry: It could be fractions and decimals, and those aren't.
Forrest: Alright, so if we say zero to positive infinity, we're including too much? Is that what you're saying, Henry? [Henry nods] OK. So be specific.
Dustin: Starting at one and counting up by ones.
Forrest: Starting at one and counting up by ones. Is that the whole numbers?
Female Student: Sure.
Forrest: Sure.

Amy: It doesn't have zero.
Male Student: No, zero isn't.
Forrest: I don't really like pestering anyone, but I see lots of college algebra books right in front of people. You could find out, right?

The precision of language is apparent as Mr. Forrest repeatedly called on students to clarify how they describe whole numbers. In trying to precisely describe the set of whole numbers, several students contributed ideas in a dialogic manner. One student gave an example of a whole number ("one"), Zack then gave a pattern of whole numbers ("one, two, three, four"), and Ben attempted a definition ("zero to infinity, positive"). Then, Henry pointed out that Ben's definition included too many numbers. Mr. Forrest clarified this idea but then did not refine the definition. Instead, he left the discourse open and Dustin then provided a new definition ("starting with one and counting by ones"). Mr. Forrest and other students weighed in, unsure of whether this was an acceptable definition. At that point, Mr. Forrest directed attention toward the textbook definition, which ended the dialogic ATP. Although this interaction was dialogic, all shared ideas were not taken up in the discourse. In particular, one male student raised a question about "kinds of infinity" that was not addressed, and Amy's comment about zero possibly being a whole number was not discussed but was circumvented by appealing to the textbook definition. An exploration and determination with regard to zero would have been a further opportunity for ATP.

Discussion

We examined instances of ATP in the whole-class discourse in five secondary mathematics classrooms and focused on the univocal or dialogic nature of those instances. Some ATP instances were brief—for example, a teacher pointing out the need for labels in a graph or calling for the use of a specific term. Other instances were longer interactions focused on clarifying the transmission of someone's idea, many times the teacher's but sometimes a student's. Overall, the vast majority (93.6%) of ATP instances were univocal. Although past research (e.g., Stigler & Hiebert, 1999) led us to expect univocal discourse, its dominance was surprising for two reasons. First, due to grade level, topic, and teacher background variability, we expected at least some of the classrooms to exhibit more substantial dialogic discourse. As it turned out, even the class with the most dialogic instances (Mr. Forrest's) still had nearly 90% univocal. Second, many of the illustrations of the role that ATP can play in mathematics education (Koestler et al., 2013) involve dynamic, dialogic interactions wherein meaning is constructed through a collaborative process of critique, refinement, and extension. Such instances of ATP were rare in our data.

When dialogic ATP did occur, the meaning-making, by definition, was qualitatively different than in univocal interactions. A key question, then, is what spurred the dialogic discourse? The answer is certainly a multitude of factors and would require further analysis to parse out, but we can speculate that it was a confluence of the mathematical content or task available as a focus for the discourse, the teacher's discourse moves, and the students' contributions to the discourse. It is also important to consider ATP in particular, because it is possible that certain aspects of ATP—attention to labels, technical terms, etc.—lend themselves to univocal discourse because they are somewhat normative. Other aspects of ATP—the process of defining, clarifying reasoning—may naturally be better suited for dialogic discourse. This study provides preliminary evidence that such may be the case, but further research is needed.

Another important contribution from this study has to do with the role of students within ATP discourse. Many scholars have brought attention to the value of engaging students in dialogic discourse (e.g., Lobato et al., 2005; Otten & Soria, 2014). The present study highlights that involving students actively in the classroom discourse is not necessarily the same as engaging students in *dialogic* discourse. As we saw, even when students' ideas were the focus of ATP interactions, it often remained univocal because the purpose was to transmit or clarify those ideas to the rest of the class, which is distinct from engaging students in the collaborative meaning-making of dialogic discourse. Heeding Clarke's (2006) warning, we do not intend to set this as an unproductive dichotomy between univocal and dialogic discourse or of teacher-focused and student-focused discourse. Rather, this is meant to be a call to attend with precision to the different experiences provided to students in mathematics classrooms with regard to ATP.

FOSTERING CLASSROOM COMMUNICATION ON REPRESENTATIONS OF FUNCTIONS

Beste Güçler
University of Massachusetts Dartmouth
bgucler@umassd.edu

Teaching students how to use and interpret various representations of functions remains an enduring challenge for educators. Providing students access to such representations is a key feature of providing them access to mathematical participation and communication. This study is based on a teaching experiment, which aims to provide students access to the discourse on representations of functions by eliciting students' discourses and making them explicit topics of reflection in a post-secondary classroom. The results indicate that the pedagogical approach used in this study has the potential to foster mathematical communication in the classroom as evidenced by students' awareness of the tacit aspects of their discourses that shape their thinking about representations of functions.

Keywords: Advanced Mathematical Thinking; Classroom Discourse; Instructional Activities and Practices; Post-Secondary Education

Representations mediate thinking about mathematical concepts and play critical roles in mathematical communication. Kaput and Rochelle (1999) argue that the emergence of new representational forms can help learners engage in powerful mathematical ideas that can otherwise remain inaccessible to them—an affordance they refer to as *democratization of access*. Arcavi (2003) also notes that visual representations can help students think about concepts and meanings which can be bypassed by symbolic representations. The representational system of a concept carries the underlying structure of that concept and the possible irrelevancies within a representational system "are dismissed or unnoticed by experts" (Arcavi, 2003, p. 232). For students who cannot see the underlying structure of a concept within a representational system, those irrelevancies can be significant since experts of mathematical discourse can "lose the ability to see as different what children cannot see as the same" (Sfard, 2008, p. 59). These arguments indicate that mathematical representations have the potential to provide learners access to mathematical communication. However, if their roles and use remain invisible to the students, they can also lead to miscommunication in the classrooms. Teachers play critical roles in making mathematical ideas transparent for students to enhance mathematical communication. This work is based on a teaching experiment that aims to provide students access to the discourse on representations of functions and explores whether this pedagogical approach has the potential to foster classroom communication.

Function is a central concept in K-12 and undergraduate mathematics and it is a challenging topic to learn due to the various notions associated with the concept (Eisenberg, 1991). In particular, many researchers argue that students have difficulties moving flexibly across graphical, algebraic, tabular, and verbal representations of functions (Monk, 1994; Schoenfeld, Smith & Arcavi, 1993; Sierpinska, 1992; Tall, 1996). Teaching students how to use and interpret various representations of functions remains an enduring challenge for educators and mathematics education researchers. Given the role functional relationships and representations play in mathematics and science as well as everyday interpretations of data, students' lack of access to the discourse on representations of functions can hinder their access to mathematical participation and communication.

This study is based on a teaching experiment that used a discursive approach to elicit students' discourses about representations of functions and made them explicit topics of discussion and reflection in the classroom. The goal was to teach students how various representations of the function concept are similar to and different from each other to address particular aspects of functional representations that can remain implicit for the students. The study addresses the following questions: What are the features of a discursive teaching approach that aims to provide learners access to the discourse on representations of functions and how can this approach foster communication in the classroom about representations of functions?

Theoretical Framework

This work aligns with the theoretical approaches that view learning as becoming a more fluent participant in mathematical communities of practice. Each community of practice leaves a historical trace of physical, linguistic, and symbolic artifacts as well as social structures that define the characteristics of participation (Lave & Wenger, 1991). From this perspective, learning to become a fluent participant in mathematical communities of practice involves learning to speak mathematically and learning to use the artifacts of the practice in the manner of full participants by engaging in mathematical activities. Lave and Wenger (1991) refer to the artifacts employed in any practice as *technology of practice* and argue that transparency of the technologies of practice with respect to their meaning and use is a critical condition for access. The visual representations that mediate mathematical communication (e.g., graphs, symbols, words) are among the technologies of mathematical practice. When the meaning and use of these representations are commonly agreed upon, they enhance mathematical communication. If their use and purposes remain invisible for the learners, then they may also hinder communication in the classrooms. For example, Güçler's (2014) earlier work demonstrates that merely presenting a mathematical representation to students is not sufficient for transparent communication in the classroom.

This study views mathematics as a discourse, where discourse refers to "different types of communication set apart by their objects, the kinds of mediators used, and the rules followed by participants and thus defining different communities of communicating actors" (Sfard, 2008, p.93). From this lens, providing access to the technologies of mathematical practice is tantamount to providing access to the *discourse* on those technologies. Sfard (2008) uses the term *meta-level rules* to refer to the elements of mathematical discourse that can remain implicit for learners and separates them from *object-level rules*. Object-level rules are about the behavior of the objects of mathematical discourse, whereas meta-level rules characterize the patterns in the activity of participants. Meta-level rules are "about the actions of the discursants, not about the behavior of mathematical objects" (Sfard, 2008, p. 201). For example, "the graph of the function $y = x^2$ is a parabola" is an object-level rule of mathematical discourse whereas the patterns in learners' actions when drawing that graph (e.g., using the assumption of continuity consistently when thinking about functions and their representations) constitute the meta-level rules in the learners' discourses. The meta-level rules of mathematical discourse are often tacit and, if not made explicit, learners can talk about the same mathematical object (e.g., a graph) in different ways, leading to possible miscommunication (Güçler, 2013).

Providing learners access to the technologies of mathematical practice requires the teacher to attend to the tacit aspects of their meaning and use in the context of the classroom. For this study, the tacit aspects of the technologies of practice refer to the meta-level rules in participants' discourses that shape their thinking about representations of functions.

Methodology

This work is part of a larger study that explored student thinking on functions, limits, derivatives, and integrals over the course of 13 weeks. The focus here is on the classroom discussions about representations of functions that took place during the first 3 weeks. The study followed a teaching experiment methodology as outlined by Steffe and Thompson (2000), which involves experimentation with the methods that can influence student thinking. This paper is on the features of the teaching experiment and the nature of discourse it elicited in the classroom regarding representations of functions. The participants were one pre-service and seven in-service high school teachers, hereon referred to as *the students*, taking a mathematics content course on calculus for their teaching licensure programs. The researcher was the instructor of the course and all of the students taking the course volunteered to participate in the study. The classroom sessions about functions were video-taped. The sections during which the instructor and students talked about representations of functions were transcribed. The transcripts included the utterances and actions of the participants.

Consistent with the theoretical assumptions of the study, a specific goal of the teaching experiment was to make the tacit meta-level rules in learners' discourses about representations of functions explicit topics of discussion and reflection in the classroom. In order to do that, it was important to bring forward the various ways in which learners used and talked about representations of functions. The activities on representations of functions were designed so that the students had the potential to act according to different meta-level rules, leading to different realizations of those representations and the function concept. Those instances were considered critical interms of eliciting students' existing discourses on representations of functions and examining which aspects of them were visible or invisible for the learners.There were also specific discussions about the similarities and differences among various representations of functions with respect to the different meta-level rules on which they are based. At the end of each activity, after eliciting the students' discourses, the instructor explicated the meta-level rules in their discourses. This was an intentional part of the teaching experiment with the goal of making transparent the different meanings and uses of representations of functions andproviding students access to these technologies of mathematical practice. Throughout the three lessons on functions, students worked on various activities on representations of functions, two of which will be presented in the next section.

While the visuals students used constituted the representations in their discourses on functions, *how* they used those representations (their discursive acts when visualizing functions) revealed the meta-level rules in their discourses. For the analysis of the meta-level rules in students' discourses, particular attention was given to the types of assumptions students used when thinking about representations of functions (e.g., assumption of continuity, regularity, discreteness). In the next section, the discussions on some of the classroom activities about representations of functions are presented with a particular focus on the meta-level rules in students' discourses. Students' awareness of the tacit meta-level rules shaping their discourses about the function concept and its representations were considered as indicators of enhanced classroom communication. All the student names used in the study are pseudonyms.

Results

The first classroom discussion about representations of functions took place during the first lesson on functions when students were asked to provide a definition of the concept in their own words. When multiple students mentioned *graph* as a definition of function, the instructor hypothesized that they may be using the assumption that a function is the same thing as its representation. She posed the following question to initiate a discussion: "If a function *is* a graph, then is a graph a function?" The students mentioned that "a graph is not always a function" but did not realize that they were using *function* and *graph* as equivalent words in their initial definitions. The instructor then asked "If a function *is* a graph, then can we also define a function as a table or algebraic expression?" The responses indicated that the students were comfortable with defining a function "as a graph or equation" but "not as a table". When asked to elaborate, they said that "a table is only a representation". The teacher asked whether, and how, a graph or algebraic expression was different than a table. The students quickly realized that all of those visuals were representations of functions. They were confused with their acceptance of some of those representations as a definition of function and rejection of others as signifying a definition. To help students resolve this conflict, the instructor asked if a function is the same thing as its representation. The students said they "always assumed continuity", which made it "natural [for them] to think about graphs and equations as functions". They also mentioned using tables to draw graphs of functions but they did not consider a table as a function because it was "just a set of values".

Although this discussion was about definitions of functions, it revealed some meta-level rules that shaped students' discourses about representations of functions as well. The students were using the assumption of continuity as a meta-level rule when thinking about a function as a graph or equation. The discussion revealed that they were also thinking about that equation as a single rule through the assumption of regularity. The students used the assumption of discreteness when talking about a table as a set of values and they considered a table as a tool to generate a graph. However, they did not realize that the meta-level rule in their discourses when talking about the tabular representations of functions (using the assumption of discreteness) was not compatible with the meta-level rule in their discourses when talking about graphs and algebraic equations (using the assumption of continuity). At that point, using the ideas students generated during the discussion, the instructor explicated the tacit meta-level rules shaping their thinking about functions and their representations (e.g., students' referral to a function as the same thing as one of its representations; their incompatible assumptions when transitioning from one representation to another).

The students worked on another activity on representations of functions during the second lesson on functions. They were given a tabular representation as shown in Table 1 and were asked "what can you say about *F(x)* based on this representation?"

Table 1: Tabular representation of *F(x)*

x	*F(x)*
-3	3
-2	2
-1	1
0	0
1	1
2	2
3	3

Carrie initially mentioned that it should be the absolute value function, which she represented algebraically as $y = |x|$. Realizing that Carrie was thinking about *F(x)* through the assumption of regularity, the teacher asked students how they would translate this tabular representation to a graphical one. Fred said the prior class discussions made him think that he needed to know the domain on which the function was restricted. He argued that the algebraic representation of the function should also include $x \in \{-3,-2,-1,0,1,2,3\}$ and said the graph should consist of "a set of points" as shown in Figure 1(a). All of the students agreed that "the function" should be represented discretely as a set of points on the Cartesian plane. Since the students automatically assumed that *F(x)*is a function, the teacher then asked what would happen if the domain of *F(x)* in Table 1was $[-3,3]$. Figure 1(b) shows the graph students generated for the question.

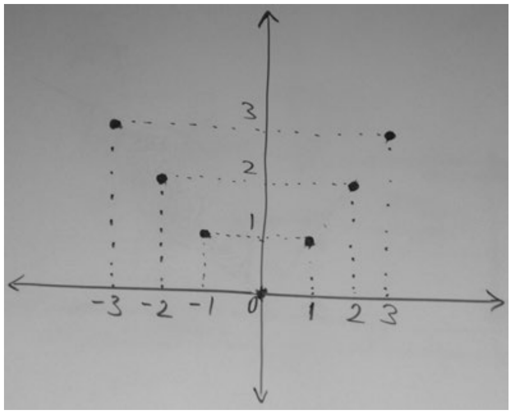

Figure 1(a): The first graph students generated during the activity

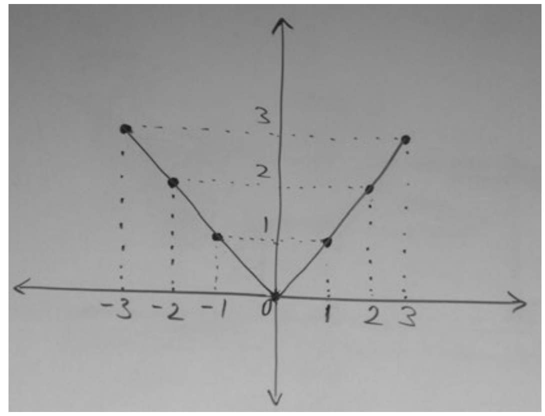

Figure 1(b): The second graph students generated during the activity

Note that, despite their realizations of the importance of the domain of a function based on previous classroom discussions, the students were still using the assumptionsof continuity and regularity as meta-level rules in their discourses when they generated the graph in Figure 1(b). They were thinking about *F(x)* as the continuous absolute value function over the interval $[-3,3]$, possibly due to the pattern they saw in the tabular representation in Table 1. Although the students recognized the tabular representation as consisting of static set of points using the assumption of discreteness when they generated Figure 1(a), they were using the assumption of continuity when they generated the graph in Figure 1(b). This clash in the utilization of different meta-level rules students used prompted the teacher to ask "how do you know that *F(x)* is a function?" In response to the students' puzzled looks, she drew two graphs as shown in Figure 2(a,b), which satisfied the conditions in Table 1 and asked students to elaborate on those graphs.

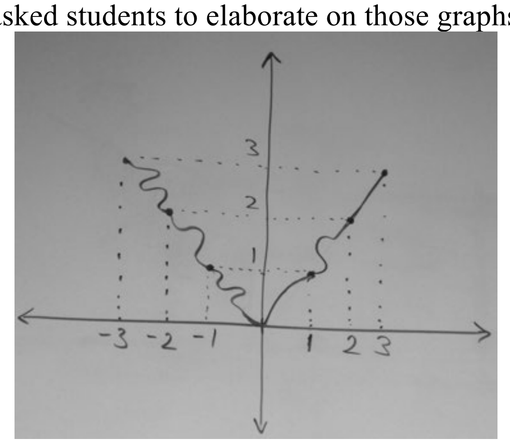

Figure 2(a): The first graph the teacher generated during the activity

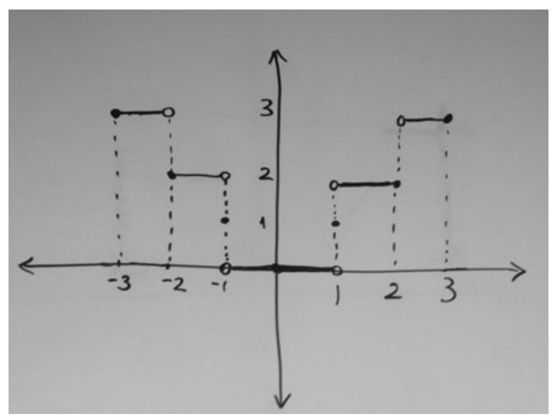

Figure 2(b): The second graph the teacher generated during the activity

The students quickly realized that the graph in Figure 2(a) did *not* represent a function on $[-3,3]$ and the one in Figure 2(b) was not continuous although both graphical representations were consistent with the set of values in Table 1. In addition, the students realized that Figure 2 (b) "does not represent a regular function that has a single rule". Sally mentioned that these challenges were occurring because they "only worked with continuous functions" in their education. Steve then mentioned that he used tabular representations every time he modeled continuous real-life phenomena. This led to discussions about how using different assumptions shape thinking about functions and their representations. During those discussions, the students explicitly mentioned that they were using two different assumptions—continuity and discreteness—which indicated that they became aware of those meta-level rules. At the end of the classroom discussion, the teacher explicated the connections and differences between a definition of function and the visual mediators that represent the concept. While doing so, she used students' considerations of function as a graph and rejection of any graph as a function to encourage them to think about how definitions of functions are formulated to avoid ambiguity.

The features of the teaching approach used during all the activities about representations of functions were consistent with those demonstrated in the aforementioned activities. Those features included (a) eliciting how students talk about functions and their representations, (b) listening to their responses carefully to capitalize on the instances in which students reveal the meta-level rules in their discourses by asking probing questions, (c) creating opportunities so that students act according to different meta-level rules, leading to communicational conflicts, (d) giving students opportunities to reflect on their discourses to resolve those conflicts, and (e) explicating the emerging meta-level rules in their discourses at the end of the discussions for further reflection.

The results of the study provide some evidence how a discursive approach to teaching has the potential to foster classroom communication, particularly with respect to students' awareness of the meta-level and tacit aspects of their discourses on functions and their representations. Although the focus of this paper is mainly on the classroom discussions due to space constraints, additional evidence regarding the affordances of the teaching experiment in fostering classroom communication is given in Table 2. Such evidence is based on students' weekly journal entries about functions in which they further reflected on any aspect of the classroom discussions that they found interesting.

Table 2: Examples from students' reflections on representations of functions

Sally: I didn't imagine that functions would be so complicated, there is much more to it than we are used to seeing…I'm on the mindset that the representation of the function doesn't define the function.
Martin: One theme that keeps coming up…is the notion of continuity. I feel I will need to develop strategies to address this issue. Students, just like us, have a tendency to assume continuity despite not being told or shown that a function is continuous.
Lea: The class activity highlighted the idea that both graphs and tables are merely representations of a function, and cannot always depict all the possible values in a function… However, even though the graph and table are limited, they are both still important in understanding functions as they offer students a unique visual representation of a function… This example, along with others, also demonstrated that functions are very often discontinuous, or piecewise and may also contain more than one rule to it.
Ron: In the some ways, it makes sense to gradually introduce different representation of a function over time as well as redefine a function as new concepts are presented. Through our class discussions, we talked about 8 different ways to represent a function... I think the big question is when we should introduce set notation and synthetic representations of a function.

Table 2 includes some representative examples of students' reflections on representations of functions. By the end of the lessons on functions, these students were aware of some of the assumptions they used (e.g., continuity and regularity) as meta-level rules in their discourses on function (Table 2, [2], [3]). They also talked about the difference between the abstract concept of function and its representations (Table 2, [1], [3]). Further, since these students were also teachers, the classroom discussions helped them think about how to teach these ideas to their students (Table 2, [2], [4]). These results suggest that the teaching approach used in the study helped students be aware of some of the meta-level rules shaping their discourses on representations of functions and the function concept. The study also confirms the tacit nature of meta-level rules and their role in mathematical communication since the students in the study mentioned that they never learned about those meta-level rules before this course.

Discussion

Representations of functions are among the technologies of mathematical practice and play important roles in classroom communication. However, if their meaning and roles are not shared by participants, they may also lead to miscommunication. This study demonstrated that some aspects of the discourse on such technologies of practice can remain invisible to learners—even to those who have been exposed to the technologies in their prior education. This finding is in accordance with Güçler's (2014) previous work and indicates that teachers should not take the communicative power of mathematical representations for granted; they need to make the discourse on those technologies of practice transparent for their students. The notion of transparency, which refers the visibility of the use and meaning of technologies of practice (Lave and Wenger, 1991), is a critical condition for providing learners access.

In this study, access to the technologies of practice was conceptualized as access to the discourse on those technologies through the use of Sfard's (2008) framework. This framework was useful in identifying and examining the features of classroom discourse that can remain tacit for the learners (e.g., meta-level rules) and served as a lens that helped shape the design of the teaching experiment used in this study. The results of the study indicate that a teaching approach that is responsive to the discourses of the students, which also elicits the meta-level aspects of participants' mathematical discourses, has the potential to foster classroom communication and transparency needed to make mathematical ideas clearer for the learners. Such a teaching approach elicits the various ways in which students think about technologies of mathematical practice to highlight which aspects of them remain invisible for the students in the context of the classroom.

This work may have some implications for teacher education. The participants of this study were pre-service and in-service high school teachers. Although they were considered as students in the content course they were taking, they were also the teachers of that content in high school classrooms. The results of the study indicate that these teachers' reflections on their discourses on functions and their representations also triggered their reflections on how to teach those ideas to their own students. Some of those teachers mentioned using the activities they worked on in the classroom with their own students. In this respect, this study offers educators some activities and ideas that may be useful in teacher education courses and professional development.

TEACHER NOTICING STUDENTS' MATHEMATICAL STRENGTHS

Lisa M. Jilk
University of Washington
jilklisa@uw.edu

Sandra Crespo
Michigan State University
crespo@msu.edu

Research about teacher noticing of students' mathematical thinking has been an important and ongoing strand of research and practice in mathematics education. Our work extends this agenda by working collaboratively with teachers to learn together how to notice students' mathematical strengths. The lens on strengths runs counter to the prevalent culture in U.S. schools to overemphasize gaps in students' understandings. In this paper we describe a video club focused on identifying and naming students' mathematical strengths and the protocols that support this focus. We illustrate and discuss the important shifts in teachers' ways of noticing and talking about students' mathematical activity. We also discuss implications for further research and professional development focused on teacher noticing of students' math strengths.

Keywords: Secondary Mathematics; Equity and Diversity; Teacher Knowledge

Researchers and professional developers focus on teacher noticing because noticing informs practice, and teachers' practices are consequential for students' learning. Current video technology has made it possible to study and facilitate teacher learning to notice students' mathematical thinking and understanding (Goldsmith & Seago, 2011; Jacobs et al., 2011; van Es, 2011; van Es & Sherin, 2008) and instructional features of classrooms (Star & Strickland, 2008). Video also supports teachers to practice attending to important features and critical events happening within the complex setting of classrooms before they are faced with them in real time.

As the knowledge base for equitable mathematics teaching continues to grow there is arguably more in classrooms now than ever before to which math teachers must attend, including knowledge of mathematics for teaching (Ball, Thames & Phelps, 2008), knowledge about communities (Civil, 2007), knowledge about math identities (Aguirre, Mayfield-Ingram & Martin, 2013), knowledge about social and academic status (Featherstone et al., 2011), and an understanding of the critical relationships between math learning, math learners and broader sociopolitical structures (Gutiérrez, 2013).

In addition, teaching for equity requires a focus on resources (what students have) and students' potential rather than deficits (what students are lacking). When teachers focus on strengths, they position young people as competent learners (Cohen, 1997), support students to create positive math identities (de Abreu & Cline, 2007; Jilk, 2014; Martin, 2000), help them recognize and value peers as intellectual resources (Cohen, 1997) and expand school mathematics to include a rich set of skills, practices and understandings in which students can find themselves (Boaler & Greeno, 2000; Featherstone, et al., 2011). Maybe even more important, a strength-based classroom culture disrupts the dominant educational discourse focused on gaps and deficits (Gutiérrez, 2008) and provides a new and more realistic narrative about learning for young people who have traditionally been marginalized by school math.

Believing that students have strengths from which to connect and build is challenging work. Recognizing (and naming) these strengths in real time is even more difficult. Research has shown that even very well intentioned teachers who profess a stance towards teaching for equity are challenged to enact these beliefs in their day-to-day teaching practice (Ladson-Billings, 1994; Walker, 2012). Our experiences working with math teachers confirm these results. Even teachers who desperately want their students to positively identify as "math people" often struggle to know what "counts" as a mathematical strength or how to talk with young people about the strengths they have. We believe that there are valid reasons for such challenges.

Teaching is a cultural activity filled with taken-for-granted assumptions and shared convictions and values (Stigler & Hiebert, 1999). As U.S. educators, we are immersed in a culture that focuses on students' deficits and perpetuates unexamined habits of teaching as fixing students' problems and misconceptions. These daily practices tend to get in the way of re-imagining and inventing instructional moves that instead focus on accessing and building on students' strengths and multiple ways of understanding (Ladson-Billings, 1994).

In addition, professional noticing is also a cultural practice. Hand (2012) argues that "dispositions relate to what teachers do or do not notice" (p. 234) in their classrooms and therefore drive instructional decisions. We attend to the classroom events that we have been taught to value. The cultures in which we have been immersed essentially train us to see and hear what is important to us. It therefore makes sense that if teachers are now expected to reshape their ways of noticing and their repertoire of teaching practices, then they need repeated opportunities to practice seeing and hearing students' strengths in action and practice articulating these strengths to students in ways that are convincing.

The video club we report on here sought to challenge and disrupt our collective tendency to look for students' mathematical shortcomings. The video club was designed to provide a shared, local experience from which a heterogeneous group of teachers could learn to notice (Sherin, Jacobs & Phillip, 2011; van Es & Sherin, 2002) students' math strengths in ways that could be useful and usable in their classrooms. A focus on drawing attention to students' intellectual strengths is a noteworthy feature of equity teaching practices in general and of *Complex Instruction* in particular, which is the instructional approach that the teachers in this video club had committed to learn and use in their classrooms. Next we share key features of the context and design of this video club in order to then share our analysis of shifts in teachers' noticing and their ways of talking about students' mathematical activity.

Context and Background of Video Club

The teachers who we describe in this paper are part of a professional development network that has six mutually informed learning spaces. The learning spaces include a weeklong course about Complex Instruction, In-Classroom Support, Common Planning Time with course teams, a monthly video club and Teacher-leader meetings. The learning spaces are connected in several ways for the goals of developing coherence with common themes and making connections across spaces. An important goal for this network is to re-culture math departments with empowering professional development experiences in ways that build and strengthen teachers' capacity to take up and sustain Complex Instruction as their equity pedagogy across the entire department.

Complex Instruction, at its core, requires a belief that all students come with intellectual, social, and cultural resources and are able to learn rigorous content (Cohen & Lotan, 2014; Cohen & Lotan, 1997). Complex Instruction (CI) creates a classroom "social system" that directly attends to and addresses problems of social inequality inside the classroom. Based on status generalization theory (Berger, Rosenholtz & Zelditch, 1980), CI methods are deliberately designed to "disrupt typical hierarchies of who is 'smart' and who is not" (Cohen, 1994; Sapon-Shevin, 2004, p. 3).

Multiple ability treatments and assigning competence are two specific CI strategies used to address status issues in classrooms (Cohen & Lotan, 1997, 2014; Tammivaara, 1982). A multiple ability treatment makes visible the array of intellectual abilities, skills and competencies that are required to be successful with a given task. Assigning competence is a teaching move that also disrupts students' perceptions of competence of self and peers by creating a mixed set of expectations for participation and success by publicly names the strengths students use when they are learning together. Hence, both of these practices rely heavily on teachers' abilities to notice and name students' mathematical strengths in real time. In short, successful implementation of Complex Instruction pedagogy requires an ability to look at students' mathematical activity and interactions with peers, listen to their sense making in real time in order to monitor their participation and understanding and find ways to further their learning.

It is important to clarify that we are not advocating for "feel good" teaching practices that emphasize compliments and empty praise to help students feel better about themselves. Nor are we suggesting that teachers lower their standards for academic rigor or cognitive demand by searching for anything a student does or says that is remotely mathematical. Not everything we see or hear in classrooms is worth attending to. In a strength-base video club we consider a rich and expanded view of mathematical understanding that is conceptually demanding and includes both content knowledge and learning practices.

The video club component of the professional development network was developed because program facilitators and math teachers needed an opportunity to observe the same classroom event simultaneously. The video club provided this experience along with a collective capacity to create a shared language about math strengths that could be used not only by individual teachers, but by *all* teachers, across grades and schools, thereby providing continuity and coherence to students' school math experiences.

The video club met monthly for two hours. Participants included all of the mathematics teachers who were members of the larger network, any student teachers who worked alongside these teachers, and the administrators and instructional coaches for math from participating schools and districts. A typical monthly video club meeting drew approximately twenty-five teachers from grades 6-12 from three different schools in two urban school districts. In the 2013-14 school year, there were 17 female and 9 male teachers who attended video club. Of these, 23 were White, 2 were Black and 2 were Asian. Table 1 reports the demographics for the public schools in which the teachers worked.

Table 1: School Demographic Data (U.S Department of Education).

	Male	Female	Multi-racial	White	Black	Latino	Asian Pacific Islander	American Indian	Free & Reduce Lunch	ELL
HS A	50.5%	49.5%	3.2%	4.4%	41.2%	11.8%	37.2%	2.2%	75.0%	12.2%
HS B	52.8%	47.2%	.9%	15.7%	34.8%	16.8%	30.8%	1.0%	56.9%	15.0%
Middle School	50.7%	49.3%	3.9%	12.1%	35.0%	20.0%	27.7%	1.3%	75.0%	15.0%

We share this data for several reasons. First, this particular information contributes to readers' understanding of the context in which we work and how it informs the examples we share about teachers' accomplishments in shifting any aspect of their teaching practice. Second, the meaning of "urban school" varies across the country depending on the local context in which schools and readers are situated. We want to be clear about the meaning of "urban" in this particular locale as it relates to teacher and student demographics. Finally, we provide this data, because culture matters. Skin color, gender, language, and SES, among other factors, shape our lived experiences, and these experiences act as lenses through which we notice and interpret classroom events. Since most of the teachers in this program are members of the dominant culture, and the young people with whom they work are poor students and students of color, it is reasonable to imagine these teachers might be additionally challenged to perceive and interpret moments of classroom activity as strengths and potential resources for learning (Chazan, 2000; Hand, 2012; Ladson-Billings, 1994).

The video clips we use come directly from the classrooms of teachers who participate in the network. For the purpose of supporting teachers to notice students' mathematical strengths, video clips show one group of 3-4 students working cooperatively for 8-10 minutes without interruption.

This kind of video clip makes several important things available for noticing students' strengths, including looking at students when working unassisted by the teacher, their resourcefulness and inventiveness, how they wrestle with ideas that they have not yet studied, and opportunities to watch and hear students get stuck and unstuck as they make progress on a group-worthy task (Lotan, 2003).

Supporting Teachers' Noticing of Students' Strengths

In addition to carefully selecting videos for video club, careful coordination of video club structures and attention to potential status issues from skilled facilitators is important. The norms, protocol and focus questions developed to guide the video club meetings include: learning requires participation, we all have something intellectually valuable to contribute, we all have something to learn, and we are smarter together. Unsurprisingly these norms were shaped by the pedagogical principles of Complex Instruction providing facilitators with opportunities to model, practice and reinforce strategies for promoting equal-status participation and learning.

Articulating strengths rather than deficits was initially challenging for teachers. The strengths teachers most often noticed at first were articulated in relation to state standards or learning objectives. For example, a 7th grade math teacher might state that her students could "use proportional relationships to solve multistep ratio and percent problems" (NGA, 2010). This grade-specific objective does not easily translate into language that makes visible *the actions* of students as they make sense of ratio and percent problems or what they did and said to figure out such problems. In other words, the shift towards noticing strengths in students' meeting particular learning objectives was a good start but not enough to make visible the important math thinking and actions the students had engaged with when working on those tasks.

In response to this challenge, program facilitators developed a structured evidence-based protocol to disrupt patterns of deficit talk about students' mathematical activity and to support teachers to generate descriptions and talk about students' strengths. In addition to a focus on strengths, the video club protocol aims to promote safety and intellectual risk taking and support teachers to make connections between the video footage and events in their own classrooms.

Unlike other projects that use small group discussions to support teachers' learning with video cases, this video club used a general Go-Round structure (McDonald et al, 2003), sometimes referred to as a Round Robin Protocol, to organize how the teachers shared ideas for each focus question. There are a few things to note about this protocol that are important for facilitating this kind of video club. First, this protocol is inclusive. It affords each person an opportunity to share ideas and it supports the expectation that each of us participates. The Go-Round structure also gives us access to an expansive set of ideas about student strengths that no one person would notice alone. Finally, the sentence frame we ask teachers to use in conjunction with the Go-Round Protocol offers explicit guidance for how to talk about students with a strength-based lens. Our assumption is that teachers are learning to speak and gain fluency with a new language (language of strengths) and this takes time and practice.

What Teachers Noticed about Students' Strengths

In order to appreciate students' mathematical activity and support the noticing of students' strengths, each video club starts with teachers doing math together. In this first phase of the meeting, teachers work cooperatively in groups of 3-4, most often with colleagues from different sites and grade levels to complete parts of the task that will be shown in the video. Doing math together affords a later conversation about learning objectives and provides teachers with the entire group-worthy task (Lotan, 2003), from which they might consider students' prior knowledge, potential common mistakes and misconceptions, the flow of mathematical ideas throughout a task, task development and the inclusion of Complex Instruction structures that support participation, autonomy and accountability (Cohen & Lotan, 2014).

The group then moves to phase two to consider students' math strengths in relation to the learning objectives for the lesson. They watch the video clip for the first time and attend to students' understanding of math content by pointing to and naming what students said and did that had mathematical potential and then provide a strength-based interpretation (Prompt #4 in the Protocol is reproduced in Figure 1 here).

> ***What did students do or say that was mathematically smart?***
>
> I think it was smart when <u>(name of student)</u> did/said <u>(evidence from the video),</u> and I think this because <u>(how does this strength support students' learning?)</u> .

Figure 1: Sentence Frame for Noticing Students' Strengths

The following are some examples of strengths teachers noticed using the sentence frame to name a student's strength and justify its connection to learning. These examples come from different video club sessions throughout a school year with teachers who work in grades 6-12.

- Damarius <u>**translated**</u> .40 into "4 tenths," and then he was able to write it as fractions, 4/10 and $\frac{2}{5}$, because three representations of the same number helped him figure out how to move between the different forms.
- Rashida <u>**created a system**</u> for organizing and making zeros and then keeping track of them in an algebraic expression, because it allowed Rashida and her group to keep track of their terms and combine them correctly.
- Lydia <u>**noticed a pattern**</u> for how to use parenthesis to group terms in an expression, because this pattern allowed her to see the like terms before she combined them.
- Tian <u>**hypothesized**</u> that the similar figure would be bigger and not smaller, because then her group decided to try multiplying the lengths of sides with the scale factor instead of dividing.

Many would consider it enough for teachers to notice that Damarius understood how to convert decimals to fractions or that Rashida correctly combined like terms. However, referencing topics, objectives or standards is not sufficient if teachers are to create classroom systems in which students choose to actively engage in learning, support each other in the learning process and create positive math identities. As we have noted earlier, equity-oriented teaching pedagogies such as Complex Instruction require an understanding of what students should come to know along with the processes, skills, and actions (verbs) they use as they come to know these things, so connections can be made to prior knowledge and leveraged for new learning. Damiarius and his team will soon believe in his strengths as a math learner and likely come to rely on these strengths much more often if Damarius's teacher notices and names his strategy for translating multiple representations of number and explains how this strength contributes to Damarius' learning. An orientation towards strengths and the specific strength-based language will support students' expectations for competence and produce more equal-status interactions between students when they are engaged in learning math.

In the third phase of video club the focus turns to the norms for participation that students enact that move their math understanding and groupwork forward. Norms for participation are "learning practices" (Cohen & Ball, 2001), ways in which we expect students "to go about the work of learning" (p. 75). Specific to Complex Instruction, norms are intended to promote autonomy and interdependence in groups and to foster mathematical learning (Cohen, 1994). Teachers must be transparent about participation norms, provide students with opportunities to practice them, and notice and assign competence to these practices to make them a more normal way of going about the business of learning math. To this end, we provide teachers with an opportunity to notice these behaviors in action (replayed back in the video clip) and practice talking about them as strengths. Below are some examples of the norms for participation that teachers noticed. Again, each teacher statement below used the sentence structure: *I think it was smart when_________________, because___________________.*

- Tamika **pressed for clarification** from her group about "what to go up by" when scaling the x-axis, so all of the group data could fit on the graph. I think it was smart, because then Dariana had to explain how she scaled the y-axis, and Jason talked about the range of their data set. It helped the whole group learn more about how to create an accurate graph.
- TJ **expressed confusion** about the different meanings of minus in both the geometric and algebraic representations, because knowing these different meanings will help her in other contexts that use minus.
- Asad **made sure that everyone in his group understood the directions** before they started the task, because then the whole group could get started together and consider more than one way to do the problem.
- Sierra **took a huge risk** by sharing her ideas about combining like terms with the entire class, because learning requires intellectual risk taking and people usually learn more when they are willing to try something new.

Implications for Research and Professional Development of Teacher Noticing

> "I just start talking this way. These sentences [from the video club protocol] help me focus my thinking on students and their strengths when I'm back in my classroom" (math teacher).

The small shifts we document here about the ways teachers are learning to notice and talk about students' strengths in the context of video clubs are hugely important because they carry into classrooms. Teachers who are participating in these video clubs *are* thinking and speaking differently about their students when they go back into their classrooms. We have evidence from working with teachers in the other learning spaces of this professional development network that they are seeing and hearing strengths more often in real time, and they are more willing to speak a language of strengths with their students. Perhaps more importantly teachers themselves are noticing their own transformation as the quote above suggests.

Collectively, the math teachers are often reminded of the power they have to help students notice their own mathematical strengths, change their participation and learn mathematics. The *Feature Teachers,* the teachers whose classroom videos are used, often reflect positively on video club after they have the rare experience of listening to their colleague's talk about the many ways in which their students are smart. Feature teachers usually return to their classrooms feeling rejuvenated by this feedback and convinced that teaching practices grounded in strengths are well worth investing in.

Changing how we frame students and their participation in math classes is not easy. It takes a concerted effort to shift perceptions about students and learning in which we have been immersed for many years. Even after one or two years of participating in this program, teachers still find it challenging to articulate math strengths in real time. The heterogeneity of the video club community addresses this challenge. Participants come with a range of experiences teaching different courses and grades. This means that they notice different things and contribute to a more expansive set of ideas about what counts as a strength, how different student behaviors might be interpreted as strengths, and how to name strengths in real time. Additionally, the diversity of teaching experiences affords articulation that is rare and powerful and often contributes to improved course design and program development in teachers' home-sites. High school teachers hear middle school students make sense of math in ways they rarely consider. Middle school teachers get glimpses of former students on film demonstrating math practices they never thought possible. Teachers often report feeling more hopeful about their ability to impact students' learning when they have opportunities to talk across grade levels.

Finally, and perhaps most importantly, we have also noticed shifts in the ways the teachers talk about themselves and their colleagues. They often assign competence to each other, sometimes playfully, but always with intent to bring attention to particular strengths. They might highlight something new they have learned from a peer and describe how it impacted their teaching. Sometimes they mention a particular way a colleague might draw out different strengths from others. These new ways of being professionals are not surprising. In addition to video club, these teachers are immersed in a culture of professional development in which the norm is to work from strengths rather than focus on deficits. We notice what we *can* do before addressing what we have yet to improve. We practice naming our resources so we know what we have to offer. We ask our colleagues to show up and speak up and share their many ways of being smart so we can be more successful together. This is the kind of transformative learning that all teachers deserve so as to support and sustain their equity work with students.

NOVICE ELEMENTARY TEACHERS' INSTRUCTIONAL PRACTICES: OPPORTUNITIES FOR PROBLEM-SOLVING AND DISCOURSE

Carrie W. Lee
North Carolina State University
cwlee5@ncsu.edu

Temple A. Walkowiak
North Carolina State University
twalkow@ncsu.edu

The purpose of this study was to examine the mathematics instructional practices of 75 second-year elementary teachers (K-5) in terms of the learning opportunities provided to their students. On average, each teacher completed instructional logs for 43 days across the school year. Select items were analyzed in order to better understand the elementary students' opportunities to engage in problem solving and discourse. Results indicated frequent opportunities for discussion but limited opportunities for engagement with more open-ended tasks and explanation. Implications for future research and mathematics teacher education are discussed.

Keywords: Classroom Discourse; Problem Solving; Instructional Activities and Practices; Elementary School Education

Purpose

Elementary teacher preparation programs strive to prepare high-quality teachers in the field of mathematics by increasing content and pedagogical knowledge through methods courses (Burton, Daane, & Giesen, 2008) and providing beneficial field experiences (Darling-Hammond, Chung & Frelow, 2002; O'Brian, 2007). However, all elementary teachers, including early-career teachers, continue to struggle to enact standards-based mathematics instruction due to variety of reasons including knowledge deficits (Mewborn, 2001), anxiety with mathematics (Bekdemir, 2010; Bush, 1989), and deep-rooted beliefs about the nature of the discipline (Raymond, 1997; Wilson & Cooney, 2002). Early-career teachers, whom we will call "novices" in this paper, also face challenges associated with induction into the profession such as learning to manage a classroom of students with varying needs and developing lessons on new topics (Feiman-Nemser, 2003).

All of these aforementioned factors affect instructional choices of novice elementary teachers; therefore, it is important to understand their enacted mathematics instructional practices in order to inform the work of elementary teacher preparation in mathematics. Little is known about the mathematics instructional practices of novices; existing research has looked at instruction generally rather than focusing on mathematics (e.g., Ingersoll & Strong, 2011). The current study aims to begin to fill this void in the literature by examining the mathematics instructional practices of elementary teachers during their second year of teaching. Specifically, the research questions guiding this study were:

1. What instructional practices, relative to problem solving and discourse, do novice elementary teachers utilize during mathematics lessons?
    a) What instructional practices are utilized in the primary grades (K-2)?
    b) What instructional practices are utilized in the upper elementary grades (3-5)?
2. How do instructional practices of novice teachers, specifically in problem solving and discourse, vary across their own mathematics lessons and in comparison to other novice teachers?

Theoretical Framework and Related Research

This study examines mathematical instructional practices using the *Opportunity to Learn* framework (OTL). That is, we are interested in the learning opportunities of elementary students during mathematics lessons. Initial research utilizing OTL emerged from evaluation work analyzing curriculum coverage as a measure of the opportunities students have to engage with certain topics (McDonnell, 1995; Wang, 1998). In more recent work, OTL has been applied to international comparison research (Floden, 2002), analysis of instructional strategies (Bell & Pape, 2012), and influences of diversity on opportunities for students (Tate, 2005). This study explores the opportunities given to students in novice teachers' classrooms to engage in particular mathematical practices or processes.

These mathematical processes were outlined in standards released by the National Council of Teachers of Mathematics (NCTM) in 2000. Then, the 2010 release of the Common Core State Standards for Mathematics (CCSSM) included a continued emphasis on students' mathematical practices as a critical component of K-12 mathematics instruction (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Two processes that are evident in these standards documents include students' opportunities to engage in *problem solving* and *discourse*, the foci of this study.

Problem solving refers to students' opportunities to grapple with mathematical problems to which they do not already have a solution method to use (NCTM, 2000). Furthermore, when students are given opportunities to demonstrate more than one method for solving a problem, they have the chance to demonstrate their ability to think flexibly. The nature of the tasks given to students translates to their opportunities to engage (or not engage) in problem solving (Stein, Smith, Henningsen, & Silver, 2009).

Past research in student discourse has shown that student interactions are a means of engaging as mathematicians (Nystrand, 2003; Herbel-Esienmann, 2009). Subsequent work by Bell & Pape (2012) analyzed the opportunities to learn that were created through social interactions, and this current study extends that line of research by exploring the opportunities students have to engage in discourse about their mathematical work.

Giving students opportunities for problem solving and discourse during mathematics has been proven to be challenging for elementary teachers (Walkowiak, 2010), but it can be particularly difficult for novice teachers. Research has shown that novice teachers are more likely to be concerned with management (Melnick & Meister, 2008), creating a different context for instructional decision making. However, research concerning enacted practice is limited when considering the novice teacher population. Much of the literature documenting novice teachers' practices are couched in induction and mentoring research and only looks at small samples of teachers. Also, this literature base examines teaching practices with broad strokes and not with a specific lens on mathematics education (Ingersoll & Strong, 2011).

Methods

Participants

The participants were 75 second-year elementary teachers, from a southeastern state in the United States. All teachers graduated from a public teacher preparation program within the state and were employed by a public elementary school. Propensity score matching was used to match teachers on aptitude scores (SAT, ACT) and other college-entry characteristics. Of the 75 participating teachers, 47 taught primary grades (K-2), and 28 taught upper elementary grades (3-5).

Measure

As part of a larger grant-funded project (Project ATOMS), the Instructional Practices Log in Mathematics (IPL-M) was created to measure the extent (as a proportion of time) to which certain instructional practices were present in a mathematics lesson. Within the log, teachers used a 4-point Likert scale (not today, little, moderate, and considerable) to respond to items beginning with the question stem, "During today's instruction, how much time did the students in the target class…"

Teachers used the scale response of "not today" to indicate when students did not engage in an instructional practice, and they used "little" to indicate when the practice was used for a brief amount of time. On the other hand, teachers chose "moderate" when the practice was used for a substantial amount of time but not the majority of the lesson, and teachers used the response "considerable"

Table 1: Percentage of Elementary Lessons Utilizing Instructional Practices

		Not Today	Little	Moderate	Considerable
Nature of the Task					
Work on exercises specifically for practice or review K-5		22.9	27.8	25.6	23.6
	K-2	27.1	26.7	22.8	23.5
	3-5	14.6	30.1	31.3	24.0
Listen to me explain the steps to a procedure K-5		42.1	42.0	14.0	1.9
	K-2	44.4	40.8	13.2	1.6
	3-5	37.6	44.4	15.5	2.5
Perform tasks requiring ideas or methods already introduced to the students K-5		11.0	23.7	28.4	36.9
	K-2	10.1	24.0	29.6	36.4
	3-5	13.1	23.1	25.9	37.9
Perform tasks focused on math procedures K-5		51.9	20.8	16.3	11.0
	K-2	59.2	20.0	13.8	7.0
	3-5	37.1	22.6	21.1	19.0
Perform tasks requiring ideas or methods NOT already introduced to the students K-5		55.1	23.2	14.3	7.4
	K-2	57.4	23.2	13.3	6.0
	3-5	50.4	23.2	16.4	10.2
Work on problem(s) that have multiple answers or multiple solution methods K-5		58.3	17.7	15.3	8.7
	K-2	59.9	17.1	14.8	8.2
	3-5	54.9	18.9	16.4	9.8
Demonstrate different ways to solve a problem K-5		53.9	23.8	15.2	7.1
	K-2	56.3	23.8	13.3	6.5
	3-5	49.1	23.6	19.0	8.3
Discourse					
Discuss ideas, problems, solutions, or methods with other students in small groups or pairs K-5		26.6	30.9	26.4	16.2
	K-2	32.1	30.0	22.9	15.0
	3-5	15.3	32.7	33.5	18.5
Discuss ideas, problems, solutions, or methods in large group K-5		20.6	35.3	28.4	15.6
	K-2	21.3	34.7	27.9	16.1
	3-5	19.2	36.6	29.4	14.7
Explain orally his/her thinking about mathematics problems K-5		31.9	36.7	26.1	5.4
	K-2	33.8	37.1	24.8	4.3
	3-5	28.1	35.7	28.7	7.5
Talk about similarities and differences among mathematical representations K-5		50.9	28.6	15.8	4.7
	K-2	54.2	28.1	14.2	3.6
	3-5	44.2	29.4	19.2	7.1
Talk about similarities and differences among various solution methods K-5		66.6	29.9	10.9	2.6
	K-2	70.3	18.9	8.8	2.0
	3-5	59.2	22.0	15.0	3.8

when a practice was used for more than half of the lesson. In addition to student activities, teachers also responded on items about the time and content focus of the lesson. As part of validation work on the log, a Kappa coefficient of .69 (Z=6.30, p<.001) was calculated between live observer and teachers' log responses to indicate there is evidence that teachers are reliably reporting the practices as stated in the items.

Instructional logs, like any measure of instruction, provide affordances for studying classroom instruction along with limitations (Rowan & Correnti, 2009). When compared to observational measures, which are often seen as the gold standard in the measurement of teaching practices, logs allow for sizable increases in number of lessons that can be examined. Additionally, in light of educational surveys that require teachers to reflect on instruction from previous weeks or months, daily logs reduce the error that comes with retrospection. Lastly, while logs are criticized due to self-report, past work has shown that with training and proximity of logging to time of instruction, teachers can reliably report on their instruction (Rowan, Jacob, & Correnti, 2009).

To support the reliability of log responses, each teacher attended a regional, two-hour training on the IPL-M. During this training teachers were provided with detailed explanations of items that were vulnerable to misinterpretation. In addition to item explanations, teachers practiced with scales and the online interface. Also, teachers were required to log as soon after instruction as possible and utilized a user's manual to support their understanding of the items.

Data Collection and Analysis

The teachers logged at three different time points throughout the 2013-2014 school year, with approximately 15 days per time point. Teachers logged for a range of 11 to 58 total days (M=42.83, SD=8.99) with each day corresponding to one mathematics lesson. A total of 2,741 mathematics lessons were logged with 1,837 being K-2 lessons and 904 being 3-5 lessons.

Descriptive statistics were analyzed using SPSS for items on the log. Lessons were analyzed to determine what percentage of lessons included opportunities for problem solving and discourse as demonstrated by the extent to which certain practices were or were not utilized in the lessons. Next, lessons were aggregated and analyzed based on primary (K-2) and upper elementary (3-5) grade bands.

Lastly, Intraclass correlations (ICCs) were calculated using a multi-level model approach within SAS to determine the amount of within- and between-teacher (Raudenbush & Bryk, 2002). That is, due to the nested nature of the data, a multi-level approach is necessary to account for how an individual teacher's instructional practices vary from lesson to lesson and how his/her practices vary from other teachers.

Results

Description of Instructional Practices for Full Sample of K-5 Teachers: RQ #1. Table 1 presents the percentage of all lessons in which students engaged in the instructional activity detailed in the item. The items are organized based on the *nature of task* and *discourse.* The items within these two constructs provide insight about students' opportunities (or the lack thereof) to engage in problem solving and talk about the mathematics. As we present the results, we focus on students' opportunities to engage in the instructional practices for a substantial amount of time by reporting the percentage of lessons in which the practice occurred for a moderate or considerable amount of time

Some of the log items within *the nature of the task* category describe instructional activities that more prescribed in nature such as "perform tasks focused on math procedures" and "work on exercises specifically for practice or review," while other items such as "Work on problem(s) that have multiple answers or multiple solution methods" are more indicative of tasks of higher cognitive demand with opportunities for problem solving. Two of the log items within the *discourse* category describe general opportunities for students to talk about the mathematics such as "discuss ideas, problems, solutions, or methods with other students in small groups or pairs." Other log items in this category such as "talk about similarities and differences among representations," provide more detail about the aspect of the mathematics in which the discussion is focused.

In 65.3% of K-5 lessons, students were engaging with tasks that they had already learned an idea or method to use to solve for a substantial amount of the lesson (moderate or considerable amount of time). In contrast, only 21.7% of lessons involved a longer span of time allocated for students to perform tasks without having a predetermined way to solve it (perform tasks requiring ideas or methods NOT already introduced to the students). Furthermore, 24% of lessons involved students working on problems with more than one answer or way to solve, and 23.2% of lessons included students demonstrating these different ways. These two items describe problems that were more open-ended in their solutions or solution methods. These types of problems are more amenable to elevating the cognitive demand based on the different ways students can approach the problem and possible comparison of solution methods (Stein, Lane & Silver, 1996); therefore, when utilized, the opportunity is present for higher levels of cognitive demand.

As shown under the discourse section of the Table 1, teachers reported 42.6% of lessons involved a substantial amount (moderate or considerable) of small group or pair discussion, and 44.0% of the lessons involved a moderate or considerable amount of whole group discussion. However, lower percentages of lessons are reported that utilized moderate to considerable amounts of time for student explanations (31.5%), talk about similarities and differences among representations (20.5%), and talk about similarities and differences in solution methods (13.5%).

Description of Instructional Practices of K-2 versus 3-5 Teachers: RQ #1a&b. Table 1 also presents the percentage of lessons by grade bands in regard to the use of instructional practices. For several of the practices, such as "perform tasks requiring ideas or methods already introduced to the students," primary and upper elementary lessons look similar in terms of the extent of the lesson utilizing this instructional practice. Other items show differences in the grade bands, such as "perform tasks focused on math procedures" and "discuss ideas, problems, solutions, or methods with other students in small groups or pairs." Upper elementary lessons have a higher percentage of lessons involving these practices, which can be expected due to content goals focused on mastery of algorithmic processes for addition, subtraction, and multiplication, and the increase in maturity and attention span to engage in small-group conversations with peers.

Also, as aforementioned, few lessons included the opportunity for students to discuss similarities and differences in representations and solution methods. When further aggregating the lesson percentages, K-2 lessons are limited (17.8% and 10.8% respectively) in the opportunities for these types of discussions.

Examining variance within and between teachers: RQ #2. Table 2 presents the Intraclass correlations (ICC) for the instructional practice items on the mathematics log. The ICCs represent the proportion of variability in how that item was reported between teachers. The higher the ICC, the more variability can be attributed to differences in teachers. The lower ICC indicates that more of the variability can be attributed to the differences an individual teacher's lessons across time. For example, the item, "Perform tasks requiring ideas or methods already introduced to the students," has an ICC of 0.12, which represents that 12% of the variance in that items response rate is attributed to differences between teachers (i.e., between-teacher variance) while 88% of the variance is attributed to the variation across lessons for individual teachers (i.e., within-teacher variance).

The items related to the opportunity for problem solving have a wider range of ICC values, .12-.48. Items "Perform tasks requiring ideas or methods already introduced to the students" and "Perform tasks requiring ideas or methods NOT already introduced to the students" have lower ICCs (.12 and .17 respectively), and therefore seem to vary between lessons rather than between teachers. The discourse items presented in Table 2 range in ICC values from .23-.33, with 33% of the variance

Table 2: Intraclass Correlations for Log Items

Log Item	Intraclass Correlation
Perform tasks requiring ideas or methods already introduced to the students	0.12
Perform tasks requiring ideas or methods NOT already introduced to the students	0.17
Work on exercises specifically for practice or review	0.20
Discuss ideas, problems, solutions, or methods in large groups	0.23
Work on problem(s) that have multiple answers or multiple solution methods	0.23
Discuss ideas, problems, solutions, or methods with other students in small groups or pairs	0.24
Demonstrate different ways to solve a problem	0.25
Listen to me explain the steps to a procedure	0.26
Talk about similarities and differences among mathematical representations	0.30
Talk about similarities and differences among various solution methods	0.31
Explain orally his/her thinking about mathematics problems	0.33
Perform tasks focused on math procedures	0.48

in the responses to the item "explain orally his/her thinking about mathematics problems" being between teachers.

Discussion

These analyses provide a glimpse into novice teachers' mathematics classrooms and the opportunities students have to engage in various practices. The instructional log used in the study shows promise in its ability to document the practices teachers are using, as seen by the distribution of responses and evidence of variability even with a relatively homogenous sample of teachers (novice, formally prepared teachers). Logs have been used in past research (Rowan, Harrison & Hayes, 2004; Stecher, 2006), but the IPL-M was carefully designed to align with mathematical practices and processes (CCSSM, 2010; NCTM, 2000). The ability to collect data on a large amount of lessons in a relatively efficient manner makes the log an advantageous tool for teacher educators and researchers to understand teachers' instructional practices during mathematics.

In looking at the descriptive log data, three themes emerged. First, it seems that majority of lessons are focused on tasks that more prescribed in nature. These lessons utilized methods that have already been taught or focused on review and practice. This aligns with findings from Rowan, Harrison, & Hayes (2004) that approximately 70% of elementary lessons from a more experienced teacher sample involved direct teaching with known ideas. Although international comparisons imply that U.S. teachers need to engage students in more opportunities to grapple with mathematics, it seems there is still a tendency to over structure our students' learning opportunities by presenting the mathematical procedures that they then need to practice. While it is important not to detract from the value of practice and the need to review, we need to be simultaneously critical of the proportion of lessons devoted to these goals. For a novice teacher, this might be especially difficult due to the newness of navigating pressures of curriculum pacing and student assessment.

The second theme that emerged from analysis of descriptive information is the presence of student talk in novice teachers' lessons. Teachers reported that majority of lessons included small group or whole group discussion for a substantial amount time in the lesson. This paints the picture of interactive classrooms, in contrast to the lecture-style environment with which traditional mathematics is often associated. Also, ICCs of the items indicating whole group and small group discussion were .23 and .24, respectively, meaning that over 20% of the variance in utilizing these modes of discourse is between teachers. Future steps will be employed to try to account for the contextual factors or teacher characteristics that explain this variance. Understanding why some novice teachers implement more discussion than others would provide important implications for elementary mathematics teacher educators.

The third theme emerges from a closer look at the opportunities for student discourse. Although a majority of the lessons involved some level of whole or small group discussion, other items provide supplemental information about the nature of the discourse in these discussions. Approximately 30% of lessons involved student explanation for a substantial amount of time, and an even smaller proportion of lessons had students discussing similarities and differences among representations and/or solution methods. It seems that students have the opportunity for classroom discussions, but they may be limited in their opportunities to engage in discourse specific to mathematical representations and ways of solving problems. This seems supported by the lower percentage of lessons involving open-ended tasks or multiple solution methods. Furthermore, the ICCs of items detailing the nature of the discussion (explain, discuss similarities in representations and/or solution methods) were each approximately .30 indicating that about 30% of the variation in these items can be attributed to the teacher. So while lessons vary in the opportunities for students to engage in specific discourse practices, overall some teachers are engaging in these practices more than others.

As preservice and inservice teacher educators strive to equip teachers to implement high-quality mathematic instruction, this work provides valuable insight into the instructional practices that novice teachers are utilizing. While it is encouraging that teachers are engaging students in opportunities for discussion, methods courses might further strengthen teachers' instruction by making more explicit how teachers can specifically prompt students to discuss aspects of mathematical ideas such as explaining or comparing solution strategies. Our next steps with this data and ongoing data collection are to begin to analyze the contextual factors that might account for teacher variance on the use of certain practices. This will provide teacher educators with important information to help support novice teachers and help break the detrimental cycle of reverting back to practices based on past experiences and anxiety.

Supporting students' mathematical reasoning is an important goal of mathematics instruction, but can be challenging for many teachers .We report the results of a study aimed at better understanding and identifying the ways in which teachers support student reasoning when provided with conceptually rich tasks. This study resulted in the Teacher Moves for Supporting Student Reasoning (TMSSR) framework, which organizes moves vis-à-vis their function and their potential for fostering student thinking. We describe the TMSSR framework, illustrate its affordances for studying teacher practices, and highlight its utility for teachers, teacher educators, and researchers.

Keywords: Instructional Activities and Practices; Algebra and Algebraic Thinking

Introduction

An important goal of mathematics instruction is to support meaningful and productive student reasoning; however, this is a goal that many teachers can find challenging (e.g., Rasmussen & Marrongelle, 2006). Two essential means for achieving this goal are the implementation of conceptually rich tasks and teachers' abilities to support and foster student engagement in such tasks. We report the results of a study aimed at better understanding and identifying the ways in which teachers can support student reasoning. This study is part of a larger project (http://tinyurl.com/badgerellis) that aims to a) help students develop deductive reasoning competencies in algebra through quantitative reasoning opportunities, and b) support teachers in achieving this goal. To scale up the findings from small-scale teaching experiments to whole-class settings, we partnered with practicing mathematics teachers to implement research-based curricular units in their classrooms. Analysis of a middle school classroom yielded the Teacher Moves for Supporting Student Reasoning (TMSSR) framework. Below we present the TMSSR framework, illustrate its affordances for studying teacher practices aimed at supporting student reasoning, and highlight its utility for teachers, teacher educators, and researchers.

Theoretical Background

Frameworks Investigating Teacher Moves

Various frameworks exist for investigating teacher moves during classroom instruction. While some frameworks focus on the questions teachers ask (e.g., Driscoll, 1999; Frey & Fisher, 2011), others focus on discursive moves (e.g., Herbel-Eisenmann, Steele, & Cirillo, 2013; Hufferd-Ackles, Fuson, & Sherin, 2004; Krussel, Edwards, & Springer, 2004). Yet others take a broader approach to include teacher questioning as well as other moves that teachers make in the course of instruction (e.g., Lampert et al., 2013; Staples, 2007). Taken together, these frameworks outline the general teacher moves and questions that occur in classrooms while teachers are eliciting, encouraging, and responding to students during instruction.

Additionally, there are frameworks that focus on student thinking. For example, Stockero et al.'s (2014) MOST framework for analyzing productive mathematical student thinking seeks to identify the most productive student thinking instances that warrant further teacher response. We build on these frameworks by investigating the moves teachers employ in quantitatively-rich contexts and the potential these moves have for supporting student reasoning. Like others have noted (e.g., Franke et al., 2009), teacher questioning is often used to help students make their thinking more explicit. However, in contrast to a focus exclusively on the questions teachers ask, a framework that includes additional practices that appear to support student thinking can provide a more complete picture of how teachers can foster student reasoning when engaged in conceptually rich tasks.

Quantitative Reasoning

Quantities are individuals' conceptions of measurable attributes of objects or events, such as length, area, volume, or speed. Relying on situations that involve quantities that students can make sense of, manipulate, and investigate can foster their abilities to reason flexibly about dynamically changing events (Carlson & Oehrtman, 2005). Reasoning with relationships between quantities has been found to support students' understanding of algebraic relationships and to encourage deductive argumentation (Ellis, 2007; Smith & Thompson, 2007). We therefore designed quantitatively rich tasks in a series of small teaching experiments, which we then provided to the teachers for implementation in their classrooms.

Methods

The study we report here occurred in an 8th grade mathematics classroom at a public middle school and consisted of ten days of instruction on linear relationships grounded in a context of gear ratios. We provided the teacher with a set of research-based tasks for exploring and identifying relationships between gears rotations; the teacher also had the liberty to make modifications to the tasks as she saw fit. All sessions were videotaped and transcribed. Additionally, field notes, student work, and an interview with the teacher provided supplementary data.

We began analyzing the transcripts (which also included the images of student work and written work on board) of the observed lessons via open coding, without any particular framework in mind. As we progressed into the data analysis using the constant comparison method (Glaser & Strauss, 1967), our attention focused on the teacher moves that supported student reasoning, and we eventually developed an emergent coding scheme through multiple passes of open coding. After the initial development of the coding scheme, we also analyzed the literature base to identify the ways in which our codes for teacher moves intersected with existing descriptions reported in the literature. After reaching a fairly stable coding scheme, we proceeded with focused coding (Saldaña, 2009) and two researchers independently re-coded the entire data set. Through constant comparison and discussion of each researcher's coding, the coding scheme was further refined by way of revising some definitions as well as delineating the functions the teacher moves served to support student reasoning.

Findings and Discussion

The TMSSR framework identifies and organizes teacher moves into four categories based on the function they serve in supporting student reasoning (i.e., eliciting, responding to, facilitating, and extending). In addition, teacher moves within the same category differ in their potential to support student reasoning. For instance, although *correcting a student error* and *prompting a student error correction* are both moves teachers make in response to student reasoning, prompting a student to correct her error has the potential to lead to a greater learning opportunity for the student than if the teacher had merely corrected the error (Speer, 2008). Drawing both from Speer's discussion about teacher moves offering different potential for supporting student learning and an analysis of how the teacher's moves affected student reasoning (as inferred from students' responses), we place teacher moves along a continuum for the potential each move has for supporting reasoning. More specifically, moves that offer greater potential are located towards the right hand side of each category. These moves occur during whole class discussions as well as when the teacher is working with students in small groups or individually. We begin by describing each category of the framework and then present an analysis of one teacher's classroom with the TMSSR framework, who we call Ms. L.

Focusing in on the TMSSR Framework

Tables 1-4 present the categories of the TMSSR framework. Although related teacher moves are organized along a continuum (signified by rows in the table), it is important to note that the continuum represents the *potential* each teacher move has for supporting student thinking. How the teacher enacts a move and the students' responses determine the *actual* affordance for supporting student reasoning. In some cases (e.g., re-voicing, encouraging student re-voicing, and re-representing) more than two teacher moves are organized within the same row to signify their related nature. Due to page constraints we are not able to demonstrate how all of the moves are placed along a continuum in the framework. We focus on a row from tables 1 and 4 since the moves in Tables 1 and 4 encourage students to take a more active role in the discussion (as opposed to Tables 2 and 3 where the teacher has a more prominent role).

Table 1: Teacher Moves for Eliciting Student Reasoning

<table>
<tr><td>Eliciting Answer: Teacher asks a question geared at eliciting the answer to a given task or problem.</td><td>Eliciting Ideas: Teacher asks a question geared at eliciting students' ideas for a solution strategy.</td></tr>
<tr><td>Eliciting Facts or Procedures: Teacher asks questions geared at eliciting students' recitation of facts or procedures.</td><td>Eliciting Understanding: Teacher asks questions geared toward assessing what students understand and how they are reasoning.</td></tr>
<tr><td>Asking for Clarification: Teacher asks a question to clarify the student's meaning because teacher genuinely does not know what the student meant.</td><td rowspan="2">Pressing for Explanation: Teacher asks student(s) to elaborate on their thinking, explain their reasoning, or reflect on and share their reasoning.</td></tr>
<tr><td>Figuring Out Student Reasoning: Teacher is trying to figure out a student's solution, or understand a student's explanation or reasoning.</td></tr>
<tr><td>Checking for Understanding: Teacher asks a question to assess students' understanding of the mathematical ideas that are currently under discussion.</td><td></td></tr>
</table>

The moves presented in Table 1 enabled Ms. L to elicit students' reasoning while implementing the quantities based tasks. These moves served to engage students in sharing their thinking and often occurred at the beginning of a discussion about a particular problem. These teacher moves commonly occurred when Ms. L worked with students in small groups as well as when she facilitated whole class discussions. The excerpts below demonstrate the potential difference that two related teacher moves, *Asking for Clarificatio*n and *Pressing for Explanation,* have for supporting student reasoning. As seen in the following excerpt, when Ms. L asks for clarification, the student's response (i.e., Leigh) is often minimal, with little or no elaboration:

Leigh: You could just plug in numbers so the middle gears teeth equals, the middle gears teeth is 12 and the big gears teeth are 16. So you need 3/4 times 12 and if it equals 16, if it equals 16, then…

Ms. L: So you are wondering this[*writes* $\frac{3}{4}(12)\overset{?}{=}16$ *on board*]?

Leigh: Yes.

Asking Leigh what she was wondering about may have clarified for Ms. L Leigh's current thinking about the task. However, if Ms. L had instead pressed Leigh for an explanation, as she did with Hope in the following episode, Leigh would have had more potential to think through and articulate her own strategy. For example, when Ms. L pressed Hope for an explanation (i.e., asking where the ratio 2/3 exists in Hope's work), this move encouraged Hope to think more about why her strategy made sense. Thus, Hope was able to start moving from a procedural explanation towards a more conceptual explanation:

Hope: I made the table again. So like, so this is the first one, so Lewis' formula yesterday was to divide the smaller number which is the bigger gear by two. So I wrote, so it's 2.5 *(points to 5 on table)(writes 5: 2= 2.5)* and then instead of writing a whole new one I worked by like continuing, so I added 5 even though it isn't proper and it said 7.5 and then it equaled this one (*points to 7.5 on table*) so you know it works because of the 2/3.
Ms. L: Okay, so can you maybe elaborate a little bit more? Which thing is the 2/3?
Hope: Okay, so like this is like you're reducing it down a different way.What I did is I would say, like this, you're just making 'cause, I don't know how to say this, okay so like 7 and a half like you're trying to find 2/3 of 7.5.*(points to 5)*

Table 2: Teacher Moves for Responding to Student Reasoning

***Validating a Correct Answer**:* Teacher actively confirms the student's idea by re-voicing, or re-wording in her own words, or adding a bit to the student's idea or response.	
***Re-voicing**:* Teacher repeats student ideas (verbally or written) in order to make those ideas public.	***Re-representing**:* A form of re-voicing in which a teacher provides her own representation as a way to publicly share a student's idea, work, or strategy. The teacher may organize, re-frame, or formalize the student's statement or work.
***Encouraging Student Re-voicing**:* Teacher asks students to re-voice other student ideas or solutions.	
***Correcting Student Error**:* Teacher corrects a student error or supplies the correct answer more generally.	***Prompting Error Correction**:* Rather than correcting the student, the teacher prompts the student to address an error herself.

Due to space constraints, we primarily focus on the organizational structure of Tables 2 and 3, which present the teacher moves for responding to and facilitating student reasoning, respectively. The moves in Table 2 often occur after a teacher has already elicited student reasoning and s/he is trying to make students' reasoning more public or amend a student's statement. Teacher moves in Table 3 also generally occur after the teacher has elicited student reasoning and is now trying to assist students in developing their reasoning through various forms of guidance and explanations. These moves may help students engage with a task or summarize students' contributions before moving on to a new task. Although the teacher moves described in Table 3 are common, the *Topaze Effect* is worth noting. Stein, Grover, and Henningsen (1996) describe this move as reducing, however, we build from Brousseau's (1997) description of how a teacher breaks a task into smaller parts and thus significantly alters how a student conceptually engages in the task. In the following excerpt Ms. L asks Laura a question about the relationship between the two gears. However, before Laura has a chance to respond, she immediately asks an easier question. The second question reduces the original question (in which Laura would have to determine a fractional amount of a rotation) down to a yes/no response (whereby Laura merely has to identify whether the gear made an entire rotation).

Ms. L: (*To Laura*) So if you turned the small gear once, how far around would the big gear go? (*Brief pause*) Would it make it all the way?
Laura: No.

Table 3: Teacher Moves for Facilitating Student Reasoning

<table>
<tr><td colspan="2">Cueing: Teacher cues students' attention by indicating that they should focus on a particular aspect of a problem, task, idea, solution, etc.</td><td colspan="2">Providing Guidance: Teacher provides hints, ideas, a potential strategy, or another type of conceptual scaffolding of the problem without outlining the solution structure or otherwise shutting down students' opportunities to reason on their own.</td></tr>
<tr><td colspan="2">Topaze Effect: Teacher breaks a task into smaller parts, reducing the complexity of the task by asking easier and easier questions, thereby reducing students' opportunity to engage in authentic problem solving.</td><td colspan="2" rowspan="2">Building: Teacher builds on students' earlier contributions to support new understanding, or encourages students to build on one another's contributions.</td></tr>
<tr><td colspan="2">Funneling: Teacher asks questions that move students down a specific path (e.g., through leading questions).</td></tr>
<tr><td rowspan="2">Providing Procedural Explanation: Teacher provides a procedural explanation for how to solve a problem. This move includes telling students a priori how to solve the problem by outlining the solution structure (or some other way).</td><td colspan="2">Providing Summary Explanation: Teacher summarizes for the class final thoughts about a task or problem, or a summary of information or discussion about the task.</td><td rowspan="2">Providing Conceptual Explanation: Teacher provides an explanation that has a conceptual basis, often focused on explaining why something works. This move can also be thought of as demonstrating logic.</td></tr>
<tr><td colspan="2">Providing Information: The teacher provides new information relevant to doing mathematics generally rather than information about a specific problem or task.</td></tr>
<tr><td></td><td colspan="2">Encouraging Multiple Solution Strategies: Teacher encourages a proliferation of solution strategies, including pressing students to come up with a different way to solve a problem.</td><td></td></tr>
<tr><td></td><td colspan="2">Providing Alternative Strategy: Teacher initiates a new or different way of solving a problem after students have shared their solution strategies or solutions.</td><td></td></tr>
</table>

Table 4 presents the teacher moves that were used to extend student reasoning. These moves usually occur after students have worked through a task for some time and have made some progress into the solution. To further extend students' initial reasoning, the teacher pushed students to provide complete answers rather than vague responses, to make connections to the context, to think about the underlying concepts involved in the task, and to justify their ideas. The excerpts below demonstrate the potential difference that two related teacher moves, *Topaze for Justification* and *Pressing for Justification,* have for supporting student reasoning. In both situations, Ms. L asked students to explain why an idea, solution, or strategy works; however, in the case of *Topaze for Justification*, Ms. L did not allow students enough time to grapple with the initial prompt to justify their ideas. Instead, she reduced the complexity of the question by following up with an easier question or by narrowing the question's focus. As an example, in the following excerpt Ms. L asked Gert to show why there was not a relationship between the gears, but she then immediately suggested testing with numbers. By doing so, Ms. L unwittingly prevented Gert from devising her own way to justify her claim:

Ms. L: What'd you come up with for a reason for part a?
Gert: I said because there's no relationship.
Ms. L: Good. Can you show why not? Can you show like with numbers?

Without the space to think of her own justification, Gert agreed to use Ms. L's suggestion, but the emphasis on numbers shifted the conversation to a calculational explanation. In contrast, Ms. L was able to better advance students' reasoning when she persistently pushed students to justify their ideas, allowing students enough time to think and solidify their reasoning. The following excerpt exemplifies the *Pressing for Justification* move:

Ms. L: Okay. So nine goes here is what we are saying (*writes 9 to "B" column*). So does that seem correct that if the medium gear spun twelve, the big gear would spin nine?
Students: Yes.
Ms. L: Okay. Yes, you are saying yes. (*spinning gears*) Anyone see a proof of why that works? Something you can use for evidence. Laura?
Laura: Okay. Well the ratio was three fourths
Ms. L: Uh-hum.
Laura: So then if you, um if you... Yeah, so the ratio is three fourths and now it's like, you could say it is nine twelfths. And then if you divide nine by three its three and if you divide twelve by three it is four.

Table 4: Teacher Moves for Extending Student Reasoning

Pressing for Precision*:* Teacher encourages student(s) to provide an exact rather than vague answer, to check his or her work for accuracy, or to quantify a qualitative statement.	***Encouraging Reasoning :***Teacher encourages students to think about the task conceptually, for instance by thinking about why a strategy makes sense, by thinking about where the numbers connect to the quantitative situation, etc.
	Encouraging Reflection: Teacher asks students to reflect on provided answers or explanations (either from the teacher or from another student).
Topaze for Justification: Teacher initially pushes for justification, but then immediately downgrades her question to a less-sophisticated why question by heavily leading students into justification via easier questions.	***Pressing for Justification****:* Teacher asks students to explain why something works or to justify (logically, conceptually) their idea, strategy, or solution.
	Pushing for Generalization: Teacher encourages students to generalize their reasoning, either through formulating a rule, describing a process in general terms, or making connections across problems, numbers, cases, or events.

Analysis of Ms. L's Classroom Using the TMSSR Framework

Table 5 illustrates Ms. L's moves for supporting student reasoning while implementing the quantities-based unit. Frequency counts for each move are listed in parentheses. It is important to note that more than one teacher move may occur at the same time (e.g., a teacher often elicits facts or procedures while she is funneling). Shading corresponds to the proportion of a specific move compared to all moves in the table, with the darker cells representing the moves that occurred more frequently. When comparing the four functional categories in the TMSSR framework, the table suggests that Ms. L spent more instructional time eliciting student reasoning compared to any one other category. Eliciting moves occurred most frequently because the other three categories represent moves that generally occur after student reasoning had been elicited. Given that the data come from Ms. L's first implementation of the research-based unit, it is not surprising that her moves for supporting student reasoning were on the left hand side,with less potential for supporting student reasoning. As a teacher becomes more familiar with the tasks and the moves that have greater potential for supporting student reasoning, we would expect to see more moves located on the right hand side of the continuum. Although the TMSSR framework focuses on teacher moves, it is important to note that such moves are also related to the classroom environment (for instance, it had already been established that students were routinely encouraged to share their reasoning and were viewed as responsible learners by themselves and the teacher) and students' ability to engage with the tasks. Because the TMSSR framework focuses on the potential support teacher moves have for fostering student reasoning, two teachers could have similar illustrations (e.g., both could look similar to Table 1) but their students' development of reasoning could be different.

Table 5: Illustrating Ms. L's Moves with the TMSSR Framework

Eliciting Student Reasoning		Responding to Student Reasoning	
Eliciting Answer (53)	Eliciting Ideas (13)	Validating a Correct Answer (85)	
Eliciting Facts or Procedures (144)	Eliciting Understanding (37)	Re-voicing (27)	Re-representing (26)
Asking for Clarification (25)	Pressing for Explanation (46)	Encouraging Student Re-voicing (4)	
Figuring Out Student Reasoning (46)		Correcting Student Error (26)	Prompting Error Correction (38)
Checking for Understanding (10)			

Facilitating Student Reasoning			Extending Student Reasoning	
Cueing (47)	Providing Guidance (40)		Pressing for Precision (17)	Encouraging Reasoning (20)
Topaze Effect (60)	Building (11)			Encouraging Reflection (25)
Funneling (73)			Topaze for Justification (12)	Pressing for Justification (13)
Providing Procedural Explanation (74)	Providing Summary Explanation (28)	Providing Conceptual Explanation (21)		Pushing for Generalization (5)
	Providing Information (14)			
	Encouraging Multiple Solution Strategies (26)			
	Providing Alternative Solution Strategy (9)			

Conclusion

We propose a framework for teacher moves that support student reasoning by organizing moves vis-à-vis their function and their potential for fostering student thinking. Although the teacher moves were made while implementing quantities-based algebra units, many of the moves(e.g., building, eliciting, re-voicing) are similar to those that have been presented in other frameworks(e.g., Herbel-Eisenmann, Steele, & Cirillo, 2013; Lampert et al., 2013; and Staples, 2007). Therefore, we posit that these moves are not unique to these classrooms and can serve others working with teachers and investigating the moves that they make to support student reasoning.

By examining teacher moves holistically, we can better understand the various ways teachers support student reasoning. The TMSSR framework classifies teacher moves into functional categories and locates these moves along a continuum based on the potential support that a move has for supporting students' reasoning. Ideally, we would like to see teachers more frequently employ moves for extending student reasoning. However, we also caution that only attending to the frequency of teacher moves across categories may lead to incorrect conclusions about a teacher's practices. Our analysis revealed that some teacher moves have more potential for supporting student reasoning than others within the same category (e.g. *Topaze for Justification* and *Pressing for Justification)*;thus, placing moves along a continuum is helpful for better assessing teacher practices for their potential for supporting student reasoning. Teachers who are interested in informally assessing their teaching may benefit from thinking about both the four categories of moves and the ways in which teaching actions are organized within each category. Similarly, researchers and teacher educators studying teachers' practices could use the TMSSR framework to identify specific areas in which teachers may benefit from additional support.

THE TELLING DILEMMA: TYPES OF MATHEMATICAL TELLING IN INQUIRY

Brandon K. Singleton
University of Wisconsin-Madison
bksingleton@wisc.edu

Teacher telling continues to be poorly understood within inquiry. In this paper I extend prior efforts to reimagine telling within contemporary pedagogical thought. Using a case study, I investigated a well-regarded teacher's use of mathematical telling while supporting groups and individuals working on tasks. The teacher used seven unique types of mathematical telling: assess, interpret, qualify, clarify task, guide, disclose, and validate. This mathematical telling framework aids in the identification of subtle telling, the recognition of implicit telling, and the acknowledgment of explicit telling. Telling practices should be conceptualized and evaluated contextually.

Keywords: Classroom Discourse; Instructional Activities and Practices

Introduction

At the heart of mathematics teaching lies an enduring dilemma of how and when to tell. This dilemma surfaces within a broader struggle to privilege the spontaneous thought and activity of the child while simultaneously cultivating and enculturating the child into a scientific and socialized society. Contemporary pedagogical practice is driven by progressive reforms advocating student-driven inquiry, on the one hand, and increased standardization and accountability to prescribed conventional knowledge of mathematics, on the other. These demands require a give-and-take approach since students cannot just independently discover everything they are expected to know, nor do they simply absorb foreign ideas that are explained to them. To teach, then, is to skillfully manage the intersection of the child and the curriculum. The telling dilemma repeatedly surfaces in that work. Teachers grapple with how to manage learning through tasks (Henningsen & Stein, 1997; Simon, 1995), how and when to steer class discussions (Ball, 1993; Chazan & Ball, 1999), how to reorient student inquiry that is misguided or trivial (Ball, 1993), and how to help diverse students access and benefit from implicit forms of knowing and learning in classroom discourse practices (Lubienski, 2002).

The issue is not whether always to tell or never to tell, but rather when and how to tell (Baxter & Williams, 2010; Chazan & Ball, 1999; Lobato, Clarke, & Ellis, 2005). Nevertheless, explicit teacher telling of mathematical *content* remains taboo as teacher practice is framed through less mathematically obtrusive constructs. Teaching has been framed in terms of orchestrating discourse (Lampert, 1990; Rittenhouse, 1998; Staples, 2007; Stein, Engle, Smith, & Hughes, 2008; Wood, 1998), facilitating collaboration and interaction (Clarke, 1997; Cohen, 1994; Dekker & Elshout-Mohr, 2004; Webb, 2009; Webb et al., 2009), and posing high-quality tasks (Henningsen & Stein, 1997; Simon & Tzur, 2004). When research does acknowledge and discuss teacher moves related to telling, either these telling moves are believed to compromise the quality of learning (Chiu, 2004; Dekker & Elshout-Mohr, 2004; Tyminski, 2010), or the mathematical substance originating from the teacher is absent or downplayed (e.g., Chazan & Ball, 1999; Smith, 1996; Staples, 2007).

Arguably, such treatment of teacher telling is overly conservative given that the teacher's mathematical discourse can be a tool for promoting student sense making (Baxter & Williams, 2010; Ding, Li, Piccolo, & Kulm, 2007; Lobato et al., 2005). Further understanding is needed of how teachers tell or speak assertively with students about mathematics, especially while they grapple with the major challenges of teaching within inquiry.

Although teacher telling might occur in various instructional formats, this study focused on telling during teacher interventions with collaborative groups. In the whole class setting, teachers can rely on student contributions of content to advance class discussions (e.g., Stein et al., 2008) whereas beforehand in the collaborative group setting, teachers must prepare students so they are able to make those contributions and access the contributions of others. During students' struggles with tasks, teachers may encounter opportunities to engage mathematically with particular students in response to specific needs. The research question of this study was, "What types of mathematical telling does a well-regarded inquiry-based teacher use to support students while intervening with small groups and individuals working on mathematical tasks?"

Framework

To address my research question I briefly discuss inquiry before framing telling more rigorously. The term "inquiry" in this study is meant as a broad descriptor of instruction that aspires to privilege student thinking and activity during the cultivation of curricular standards. Without claiming that inquiry is a well-defined and homogenous mode of instruction, I argue that the teacher in this case study upheld the basic aspiration of inquiry as she enacted various practices. The teacher varied her instructional format between whole-class discussion, small-group work, and individual work. She introduced non-routine mathematical tasks and monitored student progress. She facilitated students in sharing and critiquing one another's reasoning. The teacher helped students form complete and correct justifications of their ideas. She gave detailed feedback on their work in and out of class. These practices are believed to support student inquiry into mathematics (see Clarke, 1997; Staples, 2007; Stein et al., 2008; Webb et al., 2009).

To study mathematical telling, I followed Lobato et al. (2005) in framing telling as a phenomenon of verbal discourse with three main attributes: form, content, and function. These three attributes are discussed below.

The form of discourse refers to its organization and grammatical structure. Discourse is produced into questions, statements, requests, commands, and so on, by selecting from a complex variety of verb tenses and grammatical syntax. Although an utterance derives meaning in part from its grammatical form, the form does not uniquely determine whether that utterance is telling. Questions can tell and statements can question (Lobato et al., 2005, p. 9).

The content of discourse refers to the objects and ideas denoted by particular words and phrases. Although language does not literally transmit fixed meanings from speaker to listener (von Glasersfeld, 1995), the references of an utterance are important indexical markers for objects and their negotiated meanings. A mathematical reference is an indicator of telling even if the internal mental referent of the speaker's utterance is inaccessible to the listener.

The function of discourse refers to its purpose in a situated activity. Function is simultaneously determined by a speaker's intentions, a listener's interpretations, and the nature of the activity itself that is enacted through the discourse (Lobato et al., 2005). Although these three elements may or may not align with one another and are often difficult to infer, I managed this complexity by limiting my research focus to the verbalized discourse of the lesson. My inferences were therefore centered on the observable function of the discourse during an unraveling event rather than on the layers of meanings for the participants.

In coordinating these three attributes of discourse, I did not use form directly, but I was sensitive to form while making sense of content and function to overcome unwarranted prejudices about telling based on form (e.g., "questions don't tell"). I defined mathematical telling, then, as discourse that contained mathematical *content* (indexical references) and served the *function* of inserting something new mathematically into the conversation. During later analysis the "something new" came to mean the insertion of mathematical ideas, structure, constraints, or acts that were not in play before the utterance.

Method

I conducted a case study of a well-regarded teacher educator teaching one class at a large four-year private university. The course was a mathematics content course (the second of a two-course series) designed for pre-service elementary teachers and included topics such as fractional reasoning, probability, and statistics. The class met twice weekly for 110 minutes per class. I observed and analyzed two full curricular units of instruction, each with seven lessons. I typed field notes to index the events of each class and recorded conversations in abbreviated form. All classroom activities were filmed, and subsequently all interactions between the teacher and students during task-work were transcribed. These transcriptions formed the core data for analysis, supplemented by my field notes and the task-sheets and handouts from the course.

I first coded for mathematical telling using the definition articulated earlier. The unit size for a mathematical telling act was generally a teacher turn. I then started differentiating mathematical telling acts from one another by attending to their mathematical content and the relationship of that content to the students' inquiry. I analyzed small subsets of data and generated provisional categories of telling. I then analyzed my set of categories, working to find general overlaps, inconsistencies, ambiguities, and so on. Changes to the categories were then taken back into the data. I continued this process until a provisional set of codes had surfaced. I briefly explained the codes to an informed peer who coded a small portion of data. The questions and discrepancies from this exercise helped me to modify, invent, dissolve, and reorganize codes and improve their written theoretical definitions. I also picked two fresh lesson transcripts to code twice, with a one-week interval between coding. After comparing my first and second reading of each transcript, I identified potential technical overlaps at the boundaries of codes and updated code definitions to set precedents for how to handle similar cases. I had used about half of my data to solidify this coding scheme, and I coded the remaining half comfortably.

Results

There were seven telling types in the eventual framework. As I interpreted the results, two telling types (*guide* and *disclose*) contained significant internal variation that I sorted into four purposes each in order to understand them better. For presentation, I ordered the seven types roughly from the least obtrusive to the most obtrusive.

Assess

The first type of mathematical telling is to assess. Not every assessment is telling (such as "How did you solve the problem?"), so a telling assessment is a mathematically structured or constrained request beyond just an open elicitation of student thinking. Even though a telling assessment does not reveal the answer or solution, it imposes a new idea or constraint and is therefore a form of telling. A responding student shares not only his or her own thinking but shapes it in order to either conform or object to the constraint embedded in the assessment.

A typical example occurred frequently during a particular lesson. The teacher would assess students' understanding of two fraction images (i.e. conceptual representations) by asking of their reasoning, "Is that partitioning or iterating?" Despite seeming innocuous, there is considerable mathematical structure embedded in such discourse. The assessment restricted students to those two images despite there being reasonable alternatives that at least one student was observed to use. Furthermore, it created a forced choice between the images even though many students at times believed they were appealing to both images within a single justification. Other assessments were even more complex when they implied potential connections (e.g., between fractions and the operation of division) that students had not yet considered.

Interpret

The second type of mathematical telling is to interpret students' mathematical formulations. The teacher clarified or characterized a student utterance by rephrasing, summarizing, generalizing, condensing, or inferring unspoken pieces of a student thought. Even though the teacher attributed such interpretations to students, they were nevertheless filtered through the teacher's own conceptual grid of meanings and brought something new into play.

Qualify

The third type of mathematical telling is to qualify the mathematics. The teacher qualified a mathematical part of the conversation according to human experience such as student feelings, motivation, or common sense. Because some students saw mathematics as threatening, irrelevant, contrived, difficult, or tedious, the teacher attended to these issues. For example, the teacher downplayed student errors to minimize embarrassment, attached value to the activity or task, acknowledged interesting contributions, and characterized (valid) justifications as awkward or natural. The discourse in these telling acts mediated the students' relationships with the mathematics and consequentially communicated something new about mathematics. This telling type was a surprising result and suggests that how individuals think and feel *about* mathematics is inextricably related to what mathematics *is* to them.

As a brief example, a student worked on a probability question about drawing colored balls repeatedly from a bag. The students had not yet developed a formula or procedure and were calculating the probabilities by making lists of possible outcomes and determining the fractional part of the outcomes that answered the question. One student began to find the activity tedious:

Student: So like, what's the point of listing all the combinations? What's it teaching us?
Teacher: What's this teaching you? Well for a lot of— *(not coded mathematical telling)*
Student: Like to be patient.
Teacher: No, no, no [laughs]. It's not teaching you to be patient. It's first of all helping us think about the situation, like what's really involved here in the situation. We have these shortcuts. We can't make meaning of the shortcuts if we don't know what's actually going on. And so I know you have these nice shortcuts like multiplication, but if the shortcuts don't make sense in terms of the situation then they are meaningless. But writing out the combinations can help us see where the shortcuts are going to come in. *(qualify)*

Here the teacher qualified the value of the task by affirming that doing mathematics is about making meaning of situations rather than executing shortcuts.

Clarify Task

The fourth type of mathematical telling is to clarify the task. The teacher clarified the mathematics of the task, question, or activity without addressing the actual solution. Two main purposes for clarifying the task were to provide basic instructions for student engagement and to clarify the mathematical meanings prerequisite to engaging in the task.

Guide

The fifth type of mathematical telling is to guide. The teacher guided students while they developed solutions, constructed justifications, discussed concepts and addressed errors. The key characteristic of teacher guidance was that the mathematical substance it contributed remained partially incomplete or unresolved, requiring the student to act on, complete, or incorporate it into his or her work. The teacher guided students for four main purposes (see Table 1): focus toward or away from an idea, lead students into productive ways of thinking, address reasoning errors, and give helpful hints and suggestions.

Table 1: Purposes of Guidance

Focus	Direct student attention, encourage or discourage student approaches, point to parallel examples or previous experiences
Lead	Pose questions or next steps, structure student justifications or explanations, ask rhetorical questions, help students draw a conclusion or inference
Address reasoning errors	Identify a student contradiction, invalid assumption, or deficiency; give counter-arguments; workshop a student justification; locate or correct an error
Give hints, suggestions	Suggest a method, bound or estimate the solution, interpret the problem, state principles or guidelines, explicate the criteria for an acceptable solution

In the example that follows, a student was solving the following question with Cuisenaire rods: “If purple is 2, what is the value of black?” She had placed a purple rod adjacent to a black rod, and then lined up seven small white rods alongside them as shown in Figure 1. The student first expressed confusion with the problem, using language such as, “The purple is four out of seven, the black is seven out of seven.” The teacher guided the student by first *focusing* her attention toward the given information in the problem (that the purple rod has length 2), but the student could not reconcile this given information with her propensity to think of the little white blocks as units or ones (she continually referred to purple as “four”). The teacher *addressed the reasoning error* by explicitly inviting the student to reconcile her naming of purple as four and the problem’s given assumption that purple is two. When the student was unable to do so, the teacher followed up with a series of crucial *leading* moves (presented below) that marked the climax of the interaction and enabled the student to subsequently reason her way to the solution:

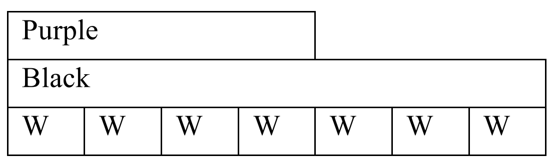

Figure 1. Student’s arrangement of purple, black and white Cuisenaire rods.

Teacher: So if this [purple] is, if this is two, what’s this? [picks up one white block] *(Guide-Lead)*
Student: A half.
Teacher: Okay what, how did you get that? Why do you know it’s a half? *(Not mathematical telling)*
Student: Because one half multiplied by four is two.
Teacher: Okay, so what would one be? *(Guide-Lead)*
Student: One would be, [shows the amount of two whites with fingers]
Teacher: Yeah. Okay, so now use this to figure out what black is. So you know that these [whites] are not one. *(Guide-Lead)*

Soon after this, the student correctly identified black as three and a half. The teacher’s leading questions were not just non-mathematical process help (see Dekker & Elshout-Mohr, 2004), nor were they “funneling” questions that trivialized the mathematical concept for the student (Wood, 1998). The first leading question firmly established the given assumption that purple is two as the premise from which to make a new deduction about the quantity that one white represents. This information helped the student to stop thinking of purple as four and white as one, and was the pivotal turning point after which the student began to reason appropriately about the situation. Guidance such as this was a frequent tool for this teacher and is a powerful form of telling whose mathematical substance should not be downplayed.

Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

Disclose

The sixth type of mathematical telling is to disclose. A disclosure, unlike guidance, was more mathematically complete and resolved and usually revealed a solution component, an alternative solution, an explanation, a justification, a norm, or a convention. The teacher disclosed this information while discussing complex concepts, answering student questions, helping students construct solutions and justifications, and refining student work. Four main purposes of disclosure emerged (see Table 2): amplify student input, explain mathematical concepts, model appropriate reasoning, and provide norms and expectations.

Table 2: Purposes of Disclosure

Amplify student input	Elaborate on a student answer, finish a student's thought, rephrase and modify mathematical language, validate a response, synthesize input from multiple students
Explain	Explain idea or concept, distinguish concepts, clarify method, illustrate with an example, contrast problem structures
Model reasoning	Justify a solution or algorithm, correct flawed student work, provide solution component, provide alternate solution
Norms & expectations	Explicate norms such as mathematical conventions, notation, terminology, expectations for justifications, or the intended form of an answer

An example illustrates two of these purposes. During one group discussion students were trying to understand the range of a set of shoe sizes (that varied from size 6 to 12) in a shoe store by counting the available sizes. They had some trouble deciding whether the range was six or seven (by whether they counted the smallest size), as well as whether one would need to count half sizes. To avoid this quandary one student joked that her store just wouldn't offer half sizes! The teacher decided to disclose the following explanation to help clarify range:

Teacher: You don't offer half sizes!? So, okay, so it's like—So, it sounds like, okay, it sounds like these are two different numbers. When you're talking about the range, um, that's saying I go—I, like, I encompass this amount. Whereas, if I say I offer fourteen sizes, that's a count of the number of sizes you offer. And I think those are two different numbers. *(Disclose-Explain)*

In something of a tentative follow-up, one student ventured her own definition of range, included below. The teacher amplified this student's input:

Student: Is the range the one number that's how many numbers are in between the smallest and the greatest?
Teacher: Yeah, it's the distance between the smallest and the greatest. So, that's a six. *(Disclose-Amplify)*

The teacher amplified the student's input by strategically modifying the mathematical imagery and accompanying language. Instead of the problematic phrase "how many numbers" (there are actually infinitely many numbers between any two real numbers), she used the more precise term "distance." In addition, she modeled appropriate usage of her definition to provide the answer to this particular example—the range of shoe sizes varying between 6 and 12 is six.

Validate

The seventh and final type of mathematical telling is to validate a student expression of mathematics as correct or incorrect. Validation was unique in that it could occur as the only function of a telling utterance or in combination with one of the other six telling functions (for example, many disclose–amplify utterances also validated student input). Validation was the least reliable code to discern in the data. At times it was ambiguous due to words such as "yeah, okay, uh-huh" and "alright" that were also social conversational markers. Other times validation occurred in the discourse simply by repeating student language with positive emphasis or negative skepticism. Other implicit interactional norms or gestures may have served as validation and gone unnoticed. I conservatively marked discourse as validate only when the speech before and after the incident in question showed evidence that the teacher and students treated it as validation. Even so, validation was a frequent type of telling, occurring in well over half of the mathematical conversations the teacher held with groups and individuals.

Discussion

Three important findings across the seven telling types distinguish this study from prior work in inquiry. First was to recognize the frequently overlooked mathematical contributions in subtle acts such as assessing and interpreting student thought. Second was to make mathematical contributions of indirect mathematical aid, such as guidance, more transparent. Third was to acknowledge that overt forms of telling, such as disclosing items and validating student work, were pervasive and integrated components of the teacher's inquiry-based instruction.

Conclusion

The primary contribution of this study is to empirically expand the construct of telling as it occurs in contemporary pedagogical spaces such as inquiry. Telling is more than "simply telling students whether their answers are right or wrong or giving students correct answers" (Chazan & Ball, 1999, p. 2). Mathematical telling comprises a rich vocabulary for talking about some of the mathematical content and pedagogical functions of teacher discourse. Telling as a conceptual space was enriched to include less conspicuous forms of telling whose embedded mathematical structures have frequently been eclipsed by the glaring omission of more conspicuous mathematical information.

Inquiry has informally been set apart from more direct modes of teaching by its pervasive lack of "telling." The descriptive case study presented here suggests that this need not be the case. The examples of mathematical telling presented in the framework were a consistent and integrated component of the teacher's inquiry-based practice. Naturally, not every instance of mathematical telling was ideal, and the study should not be taken to justify the indiscriminate use of telling. However, mathematical telling as a practice is not automatically harmful, unwarranted, or inferior to less mathematically saturated discourse simply by virtue of initiating mathematical ideas (see Lobato et al., 2005).

The main implication of these considerations is the need to take a more nuanced and contextual orientation to telling. Mathematical telling practices should be viewed as one set of many available instructional tools for creating structure and managing student activity, along with mathematical tasks, tools, physical environments, and collaborative interactional norms.

Further research should investigate teacher awareness of and intentional use of telling practices, the influence of mathematical telling on student thinking, the use of telling practices in whole-class discussions and other instructional settings, and the situated relationship of mathematical telling to the other parts of the teaching environment as a whole.

A MIXED METHODS STUDY OF ELEMENTARY TEACHERS' EXPERIENCES WITH AND PERSPECTIVES ON THE CCSS-MATHEMATICS

Susan Lee Swars
Georgia State University
sswars@gsu.edu

Cliff Chestnutt
Georgia State University
cchestnutt2@student.gsu.edu

This mixed methods study explored elementary teachers' (n=73) experiences with and perspectives on the newly implemented CCSS-Mathematics at a high-needs, urban Professional Development School in a state where roll-out of the standards has been fraught with opposition. Analysis of the survey, questionnaire, and interview data reveals the findings cluster around: familiarity with and preparation to use the standards; implementation of the standards, including incorporation and teacher change; and tensions associated with enactment of the standards. Notably, the teachers believed in the merit of the standards but were constrained by their inadequate content knowledge, limited aligned curricular resources, lack of student readiness, and a perceived mismatch with ELLs. The results illuminate the professional needs of teachers during this critical time of transition and also add to the scant research in this area.

Keywords: Elementary School Education; Instructional Activities and Practices; Policy Matters; Teacher Knowledge

Purpose

As a means of improving the mathematics education of students in the U.S., teachers in 43 states are now expected to utilize the academic standards of the Common Core State Standards for Mathematics (CCSS-Mathematics) in their daily classroom instruction (CCSS, 2015). The CCSS-Mathematics is intended to provide more rigor and depth of the mathematics for students, while potentially requiring increased specialized content knowledge and fundamental changes in instructional practices of teachers (Schmidt, 2012). Ultimately, the difficulty of transitioning to the CCSS-Mathematics lies in putting the standards into classroom practice, with teachers having control over how this will play out (Dacey & Polly, 2012).

For the state in which this study was conducted, the roll out of the CCSS-Mathematics was and continues to be fraught with uncertainty and opposition, contributing to a general climate of anxiety and unrest for teachers. Given this challenging context, coupled with the widespread acceptance of the CCSS-Mathematics across the U.S., careful scrutiny of these new standards is warranted. As teachers are the ultimate force on how these standards are implemented in classrooms, a close study of their perspectives is needed, particularly in light of the scant research in this area. Accordingly, this mixed methods study explored teachers' experiences with and views on the newly implemented CCSS-Mathematics, including awareness of and preparation to use the standards, integration of the standards into classroom teaching practice, and tensions associated with the standards, including affordances and constraints linked with enactment. This study adds to the much needed research base and also provides insights into the professional needs of teachers during this critical time of transition to the CCSS-Mathematics.

Related Perspectives

The CCSS-Mathematics represents a major overhaul of the standards previously used in most states adopting these new standards. The standards include 11 critical areas of mathematics for grades K-8 in order to provide a coherent and focused curriculum built around big ideas (CCSS-Mathematics, 2010). The standards go beyond specifying mathematical content and also include eight Standards for Mathematical Practice, with an emphasis on applying mathematical concepts and skills in the context of authentic problems and understanding concepts rather than merely follow a sequence of procedures. The standards were created with strong consideration for the research base about the development of students' understandings of mathematics over time (Cobb & Jackson, 2011). As such, the topics at particular grade levels are different, with this re-sequencing reflecting current research on learning trajectories (Sztajn, Confrey, Wilson, & Edgington, 2012). In addition, summative assessments have been created that align with the more rigorous and in-depth expectations. Given these significant shifts proposed by the CCSS-Mathematics, its introduction will require a significant revamping of mathematics education in many schools (Schmidt & Houang, 2012).

Whether or not K-12 students learn the CCSS-Mathematics depends upon teachers' instructional expertise (Schmidt & Houang, 2012). The introduction of the CCSS-Mathematics requires many teachers to change what and how they teach and therefore calls into question their readiness for implementing these standards. Phillips and Wong (2012) suggest ". . . that moving from the standards on paper to the deep changes required in practice will be a significant challenge" (p. 31). For example, many standards designated for a particular grade may be reintroduced unnecessarily over the course of several years and spanning different grade levels (e.g., 4th grade standards may be taught in classrooms from 2nd through 6th grades) if teachers continue to rely on past standards' implementation schedules (Gewertz, 2012). In addition, Schmidt and Houang (2012) suggest that many teachers view the CCSS as predominantly the same content as their state's previous standards and this lack of awareness poses significant difficulties. Further, the CCSS-Mathematics proposes that teachers focus on fewer "big" mathematical ideas so students will: build conceptual understanding, achieve procedural skill and fluency, and learn how to transfer what they know to solve problems in and out of the mathematics classroom (Phillips & Wong, 2012). In order to develop these student understandings, Ewing (2010) contends, "Teachers must have deep and appropriate content knowledge to reach that understanding; they must be adaptable, with enough mastery to teach students with a range of abilities; and they must have the ability to inspire at least some of their students to the highest levels of mathematical achievement" (para. 6), highlighting some of the necessary teacher competencies for teaching the CCSS-Mathematics.

Method

This descriptive study used a mixed methods research design, with data collection occurring via a survey, open-ended questionnaire, and individual interviews. Specifically, a "concurrent triangulation" (Creswell, Clark, Gutmann, & Hanson, 2003, p. 223) approach to mixed methods was used, which implies: (a) concurrent collection of quantitative and qualitative data, (b) equal prioritization of quantitative and qualitative data, and (c) integration during the analysis and interpretation phases. Both types of data were collected in an attempt to cross-validate findings within a single study.

Participants and Context

This study involved 73 teachers at a large, urban elementary school in the southeastern U.S. The school had partnered as a Professional Development School (PDS) with the researchers' University since 2005. During data collection, teachers reported demographic information, which reveals years of teaching experience ranged from 40% with 5 years or less, 25% with 6 to 10 years, and 35% with more than 10 years. The educational background of the teachers includes 68% with at least a Master's degree. The PDS perpetually faces challenges associated with a high rate of teacher turnover and also student mobility. With regard to student demographic information, the PDS is a Title I school with 95% of the students eligible for free or reduced lunch at the time of the study. The student population was highly diverse, including 69% Hispanic, 22% African American, 5% Asian, and 4% Caucasian. Seventy-two percent of the students were non-native English speakers, and the English as a Second Language (ESL) program served 55% of the student population. In

2002, this school was removed from the state's failing schools list and has achieved adequate yearly progress (AYP) goals for the subsequent years.

The PDS relationship included a close partnership between the University and elementary school focused on: improving the preparation of new teachers, enhancing faculty development, inquiry directed at improved practice, and increasing student achievement; one of the researchers had done significant work at the PDS across the past 8 years supporting these goals. Given this sustained, collaborative partnership, there was ready entry for this research project, as well as established rapport and trust between the researchers and PDS teachers.

At the time of data collection, the teachers were mid-way into their second year of implementation of the CCSS-Mathematics. The department of education for the state in which the PDS is located adopted the standards in 2010, and the roll-out included communication and administrator training during 2010-2011 and teacher training during 2011-2012. Initial classroom implementation of the standards was expected in fall 2012, with full implementation in fall 2014 (doe.k12.ga.us, 2014).

Data Collection

Quantitative data were collected via a survey, and qualitative data were collected via an open-ended questionnaire and individual interviews. Participants completed the survey and open-ended questionnaire on the same day during their grade level Common Planning Time. All interviews were conducted within two weeks of this initial data collection at the convenience of the interviewees and at the PDS site.

All teachers completed a survey focused on their experiences with and perspectives on the CCSS-Mathematics, as well as an open-ended questionnaire designed to provide insights into the survey items. At the time of this study, there were no published surveys or questionnaires addressing teachers' perspectives on the CCSS that emphasized mathematics. The survey includes 22 items, some of which are multi-part. Some of the items were written by the researchers, and some were modified items from EPE Research Center's (2013) national survey of teacher perspectives on the Common Core. The domains of the survey items cluster around: teachers' reported experiences with the standards, including familiarity with, preparation for, and implementation of them. Additional items focus on teachers' perspectives on the standards, including the potential of the standards to influence or change their instructional practices and students' learning, as well as mathematics education in general.

After completing the survey, all participants completed the open-ended questionnaire intended to illuminate the survey items; the questionnaire contains eight multi-part questions. Six randomly selected teachers participated in individual, semi-structured interviews, and the interview protocol was identical to the open-ended questionnaire. The interviews ranged from 30 minutes to 1 hour in duration.

Data Analysis

Data from the surveys were analyzed using individual response analysis by examining the scores for each item; data from the interviews and open-ended questionnaires were analyzed using constant comparative methodology (Lincoln & Guba, 1985). Specifically, the researchers individually analyzed the qualitative data through line-by-line open coding which generated numerous categories. Categories represented observed phenomenon found in the data (Strauss & Corbin, 1998). Researchers met and discussed the categories to reach consensus on meanings related to the categories. This discussion and analysis of all interview and questionnaire data resulted in a coding manual representing the relationships within codes. The researchers then engaged in data reduction by recoding interviews and questionnaires using the coding manual for guidance in comparing and refining codes. Coded categories were collapsed and renamed until themes were identified. The analysis of the survey data was triangulated with the themes from the qualitative data sources, resulting in final themes on teachers' experiences with and perspectives on the CCSS-Mathematics.

Results

Familiarity with and Preparation to Use the Standards

Teachers reported relative familiarity with the CCSS-Mathematics. On the item, "Please rate your overall level of familiarity with the CCSS-Mathematics," only 22% reported they were very familiar, while 67% indicated they were somewhat familiar. And, though mid-way thru the second year of implementation of the CCSS-Mathematics, 25% reported no professional development on the standards. Of the 75% indicating professional development experiences, 56% reported three days or less, while 29% indicated over five days. When asked to describe the format, teachers indicated the most frequent as "collaborative planning time with colleagues", with the next two frequent as "structured, formal setting (seminars, workshops, conferences)" and "Professional Learning Communities". Given these accounts, on the item, "To what extent do you agree with the following statement? Overall, my professional development and training on the CCSS-Mathematics have prepared me to teach the CCSS-Mathematics," only 7% strongly agreed, with 65% agreeing and 20% disagreeing. The qualitative data illuminated these data, and notably there was an emphatic call for more professional development:

> It's particularly challenging because there's been no support or staff development. . . I know myself and many teachers who are doing everything we can to reach our students. But, we don't necessarily feel that we really know what we are preparing them for and how to be prepare them. . . The most important thing I would say that I need or would like to have is some preparation and some support, which I don't and am not getting from my school and school system. And, I don't know if that's because it's not available or they're in the same boat that we are because they don't know either. But, this is an area that's going to have to be addressed if the implementation of this program is going to be successful.

Teachers proffered professional development should involve: "modeling of lessons", "unpacking the standards", and understanding differences between "same lesson taught using CCSS-Mathematics and not CCSS-Mathematics".

In addition, when considering preparation, teachers had varied responses based on different groups of students. Mean scores reveal teachers felt least prepared to teach students with disabilities and most prepared to teach low-income students. The qualitative data show preparation for teaching varying groups of students as a concern: "I don't necessarily feel that I am prepared to successfully reach all of my students and prepare them for math understandings."

Implementation of the Standards: Incorporation and Teacher Change

When considering implementation of the standards, the data reveal two subthemes: incorporation into teaching practices and changes in teaching practices. On the item, "To what extent have you incorporated the CCSS-Mathematics into your classroom teaching practice," 39% indicated incorporation into some areas of teaching but not other areas, while 57% reported full incorporation into teaching. Teachers were also asked about their incorporation of the eight Standards for Mathematical Practice into their classroom instruction. The data show the two most included as: "Make sense of problems and persevere in solving them" and "Use appropriate tools strategically". The least incorporated were: "Construct viable arguments and critique the reasoning of others" and "Look for and make sure of structure".

In regard to implementation, teachers reported the new standards necessitate a change in their instruction. For example, 73% strongly agreed or agreed the standards require them "to do things differently as a teacher of mathematics". On a similar item, 68% strongly agreed or agreed the standards necessitate them "to change their classroom teaching practices". Threaded across statements about changing teaching practice is the placement of students at the center—valuing and emphasizing students' thinking, reasoning, representation, and explanation, with less teacher direction. Reported changes include: "moving away from teaching a standard algorithm to having the students explain their work, and they're working more with manipulatives and coming up with models"; "It's so much more in-depth. And, it's definitely trying to get them to do, not just like know, for instance, the formula for area, but all the different ways to get area". A teacher described her changes in instruction as: "We didn't have discussions. It was more so, it's wrong. . . Where now, I'm like, how they did get that, and they can explain it." Similarly, another teacher described her shift in teacher practice as:

> More student-centered than teacher-related. . . I've had to back up a little bit because the students are kind of exploring and finding different strategies to use. So, that's a different practice for me. I kinda want to give them something but have to back off and say well, if that strategy worked for them or they're finding strategies that maybe I didn't know, then I give them the freedom to explain or teach it to the class.

This shift away from teacher as central during instruction is also described as, "Now they're the owner of what is being said. . . I enjoy it more because I have given more responsibility to the child." Interestingly, teachers reported more inclusion of student explanation, but of the eight Standards for Mathematical Practice, the one focusing on students constructing arguments was reported on the survey as the least incorporated.

Tensions Associated with the New Standards

The teachers identified tensions with their perceptions of the new standards and enactment. The teachers overwhelmingly believed the standards would improve their instruction and benefit student learning. But, they identified several challenges for implementation, and these competing affordances and constraints generated tensions for teachers.

Tension #1: Affordances for Teachers and Constraints. The teachers believed the new standards would make them better teachers of mathematics. On the item, "To what extent do you agree or disagree with the following statement? The CCSS-Mathematics will help me improve my classroom teaching practice", 83% strongly agreed or agreed. A teacher stated, "I feels like to me that the new standards are just good teaching." However, the teachers identified several constraints with incorporating them into classroom teaching practices. These tensions can be linked to: lack of *mathematics knowledge for teaching* (MKT) and inadequate curriculum materials.

Mathematical knowledge for teaching (MKT) is multi-faceted and includes in part common content knowledge and SCK for teaching mathematics (Hill & Ball, 2009). The teachers identified a struggle with the mathematical content in the new standards. Sample interview comments include: "One area I struggled with was math. . . now with the CCSS-Mathematics standards I have to go deeper, and I do not feel comfortable;" and "I am having to relearn math to be able help my students." The teachers also reported a struggled with what has been defined as SCK for teaching mathematics, which includes in part, teachers' abilities to analyze and interpret students' mathematical thinking and ideas. Teachers' struggling to understand children's invented solutions strategies was commonplace, as a teacher stated, "And half the time, I've seen something, I'm like how did you do that? And, then I have to look at it, and I'm like, oh, okay," and with another reporting, "I had a hard time conceptualizing how different thinkers think different ways. In the hardest part of my lesson I was trying to connect all those different ways of learning and the way that different thinkers think. As I think about math in a very different way than Johnny or Billy Bob might."

Another constraint identified by the teachers was a lack of curricular resources aligned with the new standards. The teachers recognized the need for changes in their curriculum, as 88% strongly agreed or agreed that the CCSS-Mathematics requires "new or substantially revised curriculum materials and lesson plans". In addition, of the options that would help teachers to be better prepared to teach the new standards, one of the top choices (44%) was "access to curricular materials aligned to the standards". The qualitative data supported this: "Teachers have not been given any curriculum materials, anything that aligns with the standards, and there really isn't much out there that is aligned… So, the challenge here is that teachers like myself are doing the best we can to learn these new standards. Not only are we having to learn new standards, but we are having to create everything we are doing and hoping that we are understanding."

Tension #2: Affordances for Students and Constraints. The teachers largely held a positive view of the new standards, with notable beliefs about the benefits for students and their learning. They believed the CCSS-Mathematics provides a positive direction for mathematics education, as on the item "The CCSS-Mathematics will improve mathematics education in the U.S.", 73% strongly agreed or agreed, with 19% reporting "I Don't Know". On a similar item, "The CCSS-Mathematics is more of a positive step than a negative step in mathematics education in the U.S.", 80% strongly agreed or agreed, with 19% indicating "I Don't Know". Further, the teachers perceived the new standards to be of benefit to their own students, as on the item, "The CCSS-Mathematics will improve my students' learning", 34% strongly agreed and 44% of agreed, though 16% reported "I Don't Know".

The interview and survey data offer insights into benefits for students. The teachers appreciated the emphasis in the new standards on mathematics as a sense-making activity, including a focus on conceptual understanding, explanation and justification, and connections. For example, a teacher asserted, "I think that it's preparing them to be better thinkers when it comes to math," with another stating, "I call them [students] microwaves because they want the answer now, but Common Core forces them to work it out and really just dig into it. . . It will have a great impact on deepening their knowledge and really getting them to understand why math is math." Another teacher stated:

> It will help students' learning because instead of just telling them to do it, they know why they're doing it. Why it's important. When things become more meaningful, it seems more real to them and their brains can connect the concepts better than when they are just memorizing. . . This is why the area formula is what it is. And, wondering things like perimeter or area and how they can connect and see how it all works together. It's not all isolated incidents that have no meaning in relation to each other. . . Students have to be able to explain why math is the way that it is. Students have to explain why formulas are the way they are. Students can explain why we do math the way that we do and not just use rote memorization to solve problems. I really like how it's supposed to make students think more critically.

Though teachers believed in the value and emphasis of the new standards for students, there were associated constraints related to enactment that generated tensions for teachers, including lack of student readiness and a perceived mismatch of the standards with ELLs. The teachers believed students were not ready for the new standards, with gaps in content and skills linked with past ways of learning mathematics. Interestingly, when considering student preparation to learn the standards, on a scale of 5 as "very prepared" and 1 as "not prepared", the findings reveal a mean score of 3.2, thus the perception that students had mediocre preparation. One teacher aptly stated, "It's almost like we're going back, undoing and unteaching what they have been taught." Another declared, "A lot of my students have been working with algorithms for the most part since they have been in school. It's difficult to try to go back and teach them really why the algorithm works, just understanding why they're doing it." Another teacher stated, "Students have a hard time explaining how they got the answer. They just say things like I know that 3+3 =6. . . It's hard for them to grasp the words to communicate what they understand. They have been so used to just memorizing facts it's very confusing for them. . . Students have to able to do it and explain their thinking as opposed to just answering or recalling facts." One teacher identified particular challenges with students in the upper grades, as she noted that with younger children, ". . . it's easier because you're teaching them what we would consider the proper way and they can go from there. . . The higher the grade level the harder it will be because they've learned a certain way and now they have to learn a new way. . . Because they have to go backwards, it tends to frustrate them." This teacher went on to propose a phasing in of the CCSS-Mathematics, starting with the primary grades: "A line should have been drawn to like, okay, phase one, implement K-2 and then phase two, 3-5, instead of everybody getting it at the same time. Instead of boom, you're in 5th grade but you need to learn how to do this."

In addition, the teachers had salient concerns about the misfit of the CCSS-Mathematics with ELLs. When asked about their preparation to teach the new standards to different groups of students, ELLs had the second to lowest mean score. In particular, this school has a large ELL population, and teachers voiced concerns with the emphasis on communication and explanation as posing difficulties: "Out of my 29 students, I have 26 ELLs and it's very challenging for them. . . Definitely with the Common Core, across the board it is always explaining why." Teachers also lamented multi-step tasks or word problems involving several parts that require higher levels of reading comprehension from ELLs, with one teacher asserting she has "learned to break the tasks or the activities down for them, and I find that works."

Conclusion and Discussion

Though the state adoption and implementation of the CCSS-Mathematics has been highly contentious, becoming a political issue and encountering parental opposition, notably, the teachers held decidedly positive views on the standards. They believed the standards improve their teaching of mathematics and benefit their students' learning, with this perspective linked in part with the emphasis on mathematics as a sense-making activity. This optimism is remarkable, considering this is the third set of academic standards for K-12 education in this state across the past 10 years, as one teacher lamented, "We have had three or four sets of standards and each time we are told these will be around for a long time only to see them changed every few years. This can be very frustrating for teachers… teachers are just so tired of change". Despite this revolving door of standards, such a hopeful view can go a long way with adequate teacher preparation and aligned curricular resources—of which, in general, teachers in this study seemed to need more. Allowing time for teacher change is crucial, particularly with the uncertainty about forthcoming assessments, and the rapidly approaching third year for when assessment scores are consequential seems premature.

Several constraints were identified. As indicated by others (Schmidt, 2012), content knowledge, particularly SCK, was a barrier for enactment. Teachers struggled to understand, interpret, and respond to children's thinking and invented solution strategies. The importance of well-developed mathematical knowledge for teaching is undisputable. Professional development for teachers should provide ways of concurrently building SCK while studying children's thinking, with one such option being the professional development materials from the Cognitively Guided Instruction (CGI) Project (Carpenter, Fennema, Franke, Levi, & Empson, 1999; 2014). CGI is an approach to teaching and learning mathematics that focuses on teachers using knowledge of children's mathematical thinking to make instructional decisions, which can simultaneously develop SCK. In addition, concerns about using the new standards with specific groups of students should be noted and in this particular study, teachers did not feel prepared to do so with students with disabilities and also ELLs, which are prevalent at this PDS site. The implications for the new standards differentiated for the learning needs of different groups of students must be considered and addressed. In addition, lack of student readiness was of concern, linked with their past experiences as learners of mathematics. Student explanation was one such challenge, with teachers needing ways to develop classroom norms for engaging in discourse and social mathematical norms that help students understand what constitutes a good mathematical solution and explanation. Guidelines such as these could help students to persevere when solving problems and forming mathematical arguments. In sum, the findings of this study illuminate both the tremendous potential for positive change provided by the CCSS-Mathematics and accompanying barriers. As teachers are ultimately the deciding factors on how the standards play-out in classrooms, this close study of their perspectives can hopefully provide insights into ways of better quipping them for teaching the standards and in turn benefiting students' learning.

This study investigated the attributes of 297 instances of student mathematical thinking during whole-class interactions that were identified as having the potential to foster learners' understanding of important mathematical ideas (MOSTs). Attributes included the form of the thinking (e.g., question vs. declarative statement), whether the thinking was based on earlier work or generated in-the-moment, the accuracy of the thinking, and the type of the thinking (e.g., sense making). Findings both illuminate the complexity of identifying student thinking worth building on during whole-class discussion and provide insight into important attributes of MOSTs that teachers can use to better recognize them. For example, 96% of MOSTs were of three types, making these three particularly salient types of student mathematical thinking for teachers to develop skills in recognizing.

Keywords: Classroom Discourse; Cognition; Instructional Activities and Practices

An enduring challenge in mathematics education is figuring out how to best support teachers' effective use of student mathematical thinking in their classrooms. For several decades reform documents (e.g., National Council of Teachers of Mathematics [NCTM], 1989, 2000, 2014) have consistently called for teaching that focuses on developing students' abilities to reason mathematically. For mathematical reasoning to happen, the NCTM recommends that students engage in exploration of complex tasks, state and test conjectures, and build arguments to justify their conjectures. In response to this recommendation, many researchers have investigated issues around student thinking, such as students' abilities to think mathematically using tasks with high cognitive demand (Stein, Grover, & Henningsen, 1996), obstacles to students' learning (Bishop, Lamb, Phillip, Whitacre, Schappelle, & Lewis, 2014), challenges beginning teachers face when trying to use student thinking (Peterson & Leatham, 2009), important teachable moments created by student thinking made public during classroom instruction (Stockero & Van Zoest, 2013), and classroom instances that have potential for building students' mathematical understanding (Leatham, Peterson, Stockero, & Van Zoest, 2015). However, little is known about the nature of student thinking that becomes publicly available for teachers to use during instruction.

Our ongoing work investigates student mathematical thinking made public during whole-class interactions that, if made the object of discussion, has the potential to foster learners' understanding of important mathematical ideas—instances of student thinking that we call **M**athematically Significant Pedagogical **O**pportunities to Build on **S**tudent **T**hinking [MOSTs] (Leatham et al., 2015). The work reported here analyzes instances of student thinking that have been identified as MOSTs in order to investigate attributes of this high-leverage subset of student thinking. A better understanding of the attributes of MOSTs has the potential to support research on mathematics teaching in at least four ways.

First, using student mathematical thinking productively requires that the thinking be noticed (van Es & Sherin, 2002). Stein, Engle, Smith, and Hughes (2008) suggested that teachers might be able to orchestrate classroom discussion effectively when student work with potential to enhance learning is identified, attended to, and sequenced in a developmentally appropriate way. Understanding attributes of MOSTs may help teachers develop their skills for noticing student thinking worth building on and thus improve their ability to orchestrate classroom discussion that fosters student learning. Second, Ball, Lewis, and Thames (2008) described students' mathematical thinking as "both underdeveloped and under development" (p. 15) and identified students' mathematical thinking as "the raw materials for building justified mathematical knowledge" (p. 25), but did not characterize the nature of the raw materials in student responses. Using students' mathematical thinking as a cornerstone for subsequent construction of student mathematical understanding requires an understanding of the nature of that thinking. Understanding attributes of MOSTs, a critical subset of student thinking, has the potential to provide insight into Ball et al.'s (2008) "raw materials" and contribute to the development of "justified mathematical knowledge" (p. 25). Third, Carpenter, Fennema, Peterson, Chiang, and Loef (1989) found that giving teachers access to different strategies students employ to solve problems positively affected teachers' beliefs about learning and instruction, their practices, their knowledge about students, and students' achievement. Giving teachers access to attributes of MOSTs may have similar positive effects on teachers because it would give them information about the nature of student mathematical thinking available to them in their classrooms and better equip them to use that thinking productively. Finally, Hiebert, Morris, Berk and Jansen (2007) argued that teaching should be assessed based on how teachers make use of student responses in classrooms to foster understanding of mathematical ideas rather than on the presence of recommended instructional features. Identifying attributes of student responses that are MOSTs might enhance the development of ways to assess teaching in this manner.

Theoretical Framework

Leatham et al. (2015) defined MOSTs as occurring in the intersection of three critical characteristics of classroom instances: student mathematical thinking, significant mathematics, and pedagogical opportunities. For each characteristic, these authors provided two criteria that can be used to determine whether an instance of student thinking embodies that characteristic. For student mathematical thinking the criteria are: "(a) one can observe student action that provides sufficient evidence to make reasonable inferences about student mathematics and (b) one can articulate a mathematical idea that is closely related to the student mathematics of the instance—what we call a mathematical point" (pp. 93-94). The criteria for significant mathematics are: "(a) the mathematical point is appropriate for the mathematical development level of the students and (b) the mathematical point is central to mathematical goals for their learning" (p. 97). Finally, "an instance embodies the pedagogical opportunity characteristic when (a) the expression of a students' mathematics creates an opening to build on student thinking to help develop an understanding of the mathematically significant point of the instance and (b) the timing is right to take advantage of the opening" (p. 103). When an instance satisfies all six criteria, it embodies the three requisite characteristics and is a MOST. We see analysis of MOSTs as a means toward identifying important attributes of high leverage student mathematical thinking that might be used to help support teachers in developing their skill at productively using such thinking.

Stockero and Van Zoest (2013) investigated and categorized "instances in a classroom lesson in which an interruption in the flow of the lesson provides the teacher an opportunity to modify instruction in order to extend or change the nature of students' mathematical understanding" (p. 127)—what they called pivotal teaching moments (PTMs). We see PTMs as a subset of MOSTs, and thus we used the PTM categories to inform our thinking about attributes of MOSTs. In particular, these researchers identified five categories of PTMs: (1) *extending*—students make connections to create a much deeper lesson from what was planned; (2) *incorrect mathematics*—student incorrect mathematical thinking becomes public; (3) *sense making*—students are trying to make sense of the mathematics under consideration; (4) *contradiction*—student responses have competing interpretations; and (5) *mathematical confusion*—students clearly state mathematically what they are confused about. These categories and the work related to the development of them provided a starting point for our exploration into attributes of MOSTs.

Methodology

This study is part of a larger project focused on understanding what it means for teachers to build on students' mathematical thinking (see LeveragingMOSTs.org). We selected 11 videotaped mathematics lessons from the MOST project that reflected teacher diversity (race/ethnicity, gender, experience, teaching style), mathematics diversity (6-12th grade, topic, textbook), and classroom diversity (region of the US, community type, race/ethnicity). The unit of analysis for identifying MOSTs was an instance of student thinking—an "observable student action or small collection of connected actions" (Leatham et al., 2015, p. 92) that had the potential to be mathematical. StudioCode (Sportstec, 1997-2015) was used for three passes of coding. In the first pass, classroom context and other relevant information were noted on the Studiocode timeline and instances of student thinking were identified and transcribed. During the second pass, the MOST Analytic Framework (see Leatham et al., 2015) was used to determine which instances were MOSTs. We identified 297 MOSTs in the 11 lessons; these MOSTs served as the data for the current study. The third pass of coding, completed for the current study, focused on identifying attributes of these MOSTs.

We coded the 297 MOSTs for seven attributes that fall into two groups: Locus and Cognition (Figure 1). The Locus group encompasses attributes that locate a MOST within the mathematical and lesson terrain and includes what immediately preceded the MOST (Prompt), whether the MOST was based on earlier work (Basis), and the distance of the mathematical idea of the MOST from the day's lesson (Math Goal). The Cognition group focuses on the expression of the student's thinking and includes whether the MOST was a question or statement (Form), whether the student thinking was correct (Accuracy), the extent to which the intellectual need is obvious (Intellectual Need), and the nature of the MOST (Type). To illustrate our coding and the nature of our results, we discuss four of the attributes (Basis, Form, Accuracy, and Type—bolded in Figure 1), as well as interactions between them.

Basis refers to whether the student mathematics (SM) in the MOST is based on earlier work (*Pre-thought*) or on in-the-moment thinking (*In-the-moment*). A MOST is coded *Pre-thought* when the student appears to be sharing thinking from previous work. Although this previous work could be from homework or another class, typically it is from small group or individual work completed during the lesson. A MOST is coded *In-the-moment* when the SM stems from students' in-the-moment thinking. This thinking might be in response to a follow-up request from the teacher or to another students' thinking or question, or it might be seemingly spontaneous.

Locus	Cognition
Prompt (Spontaneous, Open Invitation Spontaneous, Open Invitation Selected, Targeted Invitation) **Basis (In-the-Moment, Pre-Thought)** Math Goal (Lesson, Unit, Course, Math)	**Form (Question, Declarative, Tentative)** **Accuracy (Correct, Incorrect, Incomplete, Combination, N/A)** Intellectual Need (Obvious, Translucent, Hidden) **Type (Incorrect or Incomplete, Sense Making, Multiple Ideas or Solutions, Other)**

Figure 1: MOST Attribute Codes and their Categories by Groups

Form refers to the way in which the student thinking is expressed (*Question, Tentative Statement* or *Declarative Statement)*, regardless of its correctness or completeness. A MOST is coded *Question* if the student thinking is shared as a question or with the intent to question. *Declarative Statement* is used when students appear to be confident in what they are saying and *Tentative Statement* is used when the student appears to be making a conjecture or is wondering about something. Tentativeness is typically indicated by the student's voice inflection when making the statement, but it can also be indicated by their use of hedge words such as "maybe" or "I'm not sure."

Accuracy is used to categorize a MOST based on the validity of its SM. A MOST is *Correct* if its SM is a correct mathematical statement; *Incorrect* if its SM is an inaccurate statement; *Incomplete* if the SM is not incorrect, but it has gaps or ambiguities that keep it from being completely correct; *Combination* if it involves a complete statement(s) that falls in multiple *Accuracy* categories; or *N/A* if it is not possible to determine its correctness (e.g., if it is a question).

Type is used to categorize what about the SM made the instance a MOST. There are four *Type* categories: *Incorrect or Incomplete*, *Sense Making*, *Multiple Ideas or Solutions*, and *Other*. A MOST is coded *Incorrect or Incomplete* if it was compelling because its SM is inaccurate or missing critical components of the mathematical idea being expressed. A MOST is coded *Sense Making* if it was compelling because the SM implies that the student was trying to make sense of the mathematics, or they had comprehended an idea with which the class had been struggling. A MOST is coded *Multiple Ideas or Solutions* if it was compelling because the SM created an opportunity for comparison of multiple ideas or solutions.

To illustrate the attribute codes, consider the SMs from four MOSTs (see Figure 2). All four MOSTs came from class discussions based on tasks students had solved beforehand in small groups. SM1, SM2, and SM4 were in response to what was currently being shared rather than something they had done earlier, thus were coded *In-the-Moment (Basis)*. In contrast, SM3 was a reporting out of a student's earlier work, thus received the code *Pre-Thought (Basis)*. The first two MOSTs involved statements, rather than questions, thus received the code *Declarative Statement* (*Form)*. The third was also a statement, but the student preceded it by expressing a lack of confidence in her answer, thus it was coded *Tentative Statement.* The fourth was a question and was coded *Question*. In the *Accuracy* category, the first MOST received the code *Combination* because although it includes the correct idea that the rate of change is a constant $2.50, the language suggests that the slope is increasing at that rate rather than that the slope is that constant rate. The second MOST was coded *Incorrect* because it is possible to divide by a fraction. In SM3, also coded as *Incorrect*, the class had already agreed to the convention of putting the independent variable on the x-axis and the dependent variable on the y-axis and the problem the students were exploring implied that "money" was the dependent variable and "weeks" the independent variable. The fourth MOST was coded *N/A* for *Accuracy* because questions, by their very nature, do not have a truth-value. The compelling aspect of the first and fourth MOSTs was a student grappling with a mathematical idea—the difference

Student Mathematics of four MOSTs	**Coding (*Basis*, *Form*, *Accuracy*, *Type*)**
SM1: The slope is increasing at a constant rate. The slope is not going any faster. The slope is always going up $2.50.	*In-the-Moment, Declarative Statement, Combination, Sense Making*
SM2: You can't divide by a fraction.	*In-the-Moment, Declarative Statement, Incorrect, Incorrect or Incomplete*
SM3: I put the money on the x-axis and weeks on the y-axis.	*Pre-Thought, Tentative Statement, Incorrect, Incorrect or Incomplete*
SM4: Doesn't solving sometimes include simplifying?	*In-the-Moment, Question, N/A, Sense Making*

Figure 2: Coding Examples

between an increasing graph and a graph with an increasing slope in SM1 and the difference between solving and simplifying in SM4—thus they were both coded *Sense Making (Type).* The compelling aspect of the second and third MOSTs was that the students had introduced incorrect ideas, thus these MOSTs were coded *Incorrect or Incomplete.*

Three research assistants individually coded the 297 MOSTs and then reconciled them as a group. If they were not able to reach agreement, the issue was brought to the attention of the principal investigators and either the codes or the code definitions were modified to resolve the issue. We then determined the frequencies of the codes and interactions between them for each of the 11 lessons and compiled all the results into a spreadsheet that allowed for within and across lesson comparisons. We used that information to search for patterns among the results that would lead to a better understanding of the attributes of MOSTs.

Results and Discussion

Figure 3 provides the percentages of MOSTs in each category of the four attributes *Basis*, *Form*, *Accuracy,* and *Type*. Roughly 20% of the 297 MOSTs in our data were based on work that students had completed earlier in the class, thus were available for the teachers to identify by monitoring students as they worked. This percentage speaks to the benefit of teachers developing skills such as the five practices for orchestrating classroom discussion identified by Smith and colleagues (e.g., Smith & Stein, 2011). The finding that 80% of the MOSTs were based on student thinking that occurred during whole-class interaction speaks to the importance of teachers also developing skills for carefully listening and responding to evolving thinking.

BASIS		**FORM**		**ACCURACY**		**TYPE**	
In-the-Moment	80	Question	16	Correct	40	Incorrect or Incomplete	31
Pre-Thought	20	Tentative	7	Incomplete	8	Sense making	50
		Declarative	77	Incorrect	24	Multiple Ideas or Solutions	15
				Combination	9	Others	4
				Not Applicable	19		

Figure 3: Percentages of MOSTs in Attribute Categories

The vast majority of the MOSTs were declarative statements (77%) as opposed to questions (16%) or tentative statements (7%). This means that it is insufficient to focus only on expressions of student mathematical thinking that are intuitively suggestive of thinking worth building on (such as questioning or wondering).Instead, teachers must develop more sophisticated ways of recognizing which student thinking has this potential.

Knowing the accuracy of an instance of student mathematical thinking is also insufficient to determine whether it is a MOST, as there was no predominate *Accuracy* category. There were, however, more correct (40%) than incorrect (24%)MOSTs. This is particularly interesting given that the project team had initially hypothesized that it would be difficult for correct student mathematical thinking to meet the MOST criteria.

Half of the MOSTs (50%) occurred when students were grappling to make sense of a mathematical idea. The next highest *Type* category involved instances of student thinking that were incorrect or incomplete (31%). Student thinking that led to multiple ideas or solutions being available for students to consider occurred in 15% of the MOSTs and 4% did not fit in the three main categories of *Type*. Although *Incorrect or Incomplete* and *Multiple Ideas or Solutions* had lower frequencies than *Sense Making*, they may be easier for teachers to recognize. Thus, it seems important for teachers to attend to all three main categories of *Type*. The fact that 96% of the MOSTs were captured by these three categories is encouraging as it suggests some parameters for developing teachers' abilities to recognize MOSTs.

Figure 4 considers interactions between the attributes. All but one of the MOSTs in the form of questions (see the Q column in Figure 4) were compelling because the student was grappling to make sense of a mathematical idea (see, for example, SM4 in Figure2). The fact that all questions in this data that qualified as MOSTs involved sense making suggests the need for teachers to consider the potential of a question to determine the nature of their response. If the question is a MOST, the most effective teacher response might be to provide an opportunity for the class to join the student who asked the question in making sense of the idea.

	FORM			BASIS		ACCURACY*				
	Q	T	D	ITM	PT	CR	ICR	INC	COM	N/A
TYPE										
Incorrect or Incomplete	1	12	87	80	20	0	66	22	11	1
Sense making	32	5	63	83	17	58	1	3	3	35
Multiple Ideas or Solutions	0	2	98	71	29	58	16	0	24	2
Others	0	18	82	91	9	55	9	0	9	27
FORM										
Question (Q)				98	2	0	0	0	0	100
Tentative (T)				91	9	27	45	5	23	0
Declarative (D)				76	24	49	27	10	10	4
BASIS										
In-the-Moment (ITM)	20	8	72			36	25	9	7	23
Pre-Thought (PRE)	2	4	94			55	19	5	17	4

*Accuracy Abbreviations: Correct (CR); Incorrect (ICR); Incomplete (INC); Combination (COM); Not Applicable (N/A)

Figure 4: Percentages of MOSTs in Interactions between Attribute Categories

The MOSTs that were compelling because they provided an opportunity for students to consider multiple ideas or solutions were predominantly declarative statements (98%). As might be expected, MOSTs in which students shared thinking from previous work were also typically declarative statements (94%). Still, 76% of the declarative statements resulted from in-the-moment thinking, as did 98% of the questions and 91% of the tentative statements. There were also no extreme differences among which *Types* result from in-the-moment thinking, with *Sense Making* having the highest frequency (83%) of in-the-moment thinking of the three main *Type* categories and *Multiple Ideas or Solutions* having the lowest (71%). Thus the earlier stated need for teachers to skillfully respond to evolving thinking stands, regardless of the form in which that thinking is expressed or what made it compelling.

Figure 4 also shows a much higher percentage of the tentatively stated MOSTs were incorrect as were correct (45% vs. 27%); nearly the reverse was true of the MOSTs that were declarative statements (27% vs. 49%). This finding suggests that although there was some correlation between students' confidence in their thinking and the accuracy of it, the relationship was not strong enough to be counted on. That is, in the context of MOSTs, relying on tentative thinking to be incorrect and confident thinking to be correct would cause one to be wrong much of the time. Likewise, although pre-thought SM was more likely to be correct than SM that was generated in the moment (55% to 36%), both types of SM were also often incorrect (19% and 25%, respectively).

Finally, with the exception of MOSTs that were compelling because they involved incorrect or incomplete thinking (e.g., SM2 and SM3 of Figure 2), there did not seem to be a strong relationship between *Accuracy* and *Type*. For example, although 58% of MOSTs that provided the opportunity for students to consider multiple ideas or solutions were based on correct SM, 24% were based on SM that had both correct and incorrect elements, and 16% were based on SM that was incorrect. Again, it seems that accuracy of student mathematical thinking is not a useful predictor of MOSTs.

Conclusion

This study set out to contribute to our developing understanding of how to best support teachers' effective use of student mathematical thinking in their classrooms by investigating attributes of MOSTs—a high leverage subset of student thinking. The results provide insight into claims about the complexity of responding to students' mathematical thinking on the spot (e.g., Choppin, 2007; Jacobs, Lamb, & Philipp, 2010). We now know that surface features of thinking, such as how it occurs, the form in which it is expressed, and how accurate it is, are not sufficient to determine whether the thinking should be pursued. Rather, responding effectively to student mathematical thinking requires careful attention to the content of the thinking to discern the underlying mathematical idea and what it might offer as the object of a class discussion. For example, some student questions may be best answered directly, but those that reflect a student's grappling with important mathematical ideas provide rich opportunities to engage the class in the type of mathematical activity advocated by current reforms (e.g. NCTM, 2014). Calculation and other surface mistakes may be dispensed with quickly, but errors in students' thinking are often worth building on. Similarly, correct answers may be an indication to continue, or they may provide an opportunity to stop and engage the class in consolidating important mathematical understandings.

Despite the lack of easy answers about which thinking is worth building on in whole-class discussion, this work does provide some parameters that may make the process more manageable. For example, correct student thinking that does not involve sense making or multiple ideas or solutions is not likely to be worth pursing in a whole-class discussion. Being aware of this pattern can help teachers avoid initiating unproductive discussions.

In general, this work supports the need for teachers to have criteria they can use for evaluating which student thinking is worth building on. The MOST Analytical Framework (Leatham, et al., 2015) is one such set of criteria. Such criteria, in conjunction with the parameters contributed by this study, provide a starting place for designing teacher education and professional development to support teachers in developing the teaching practice of productive use of student thinking.

DO YOU NOTICE WHAT I NOTICE? PRODUCTIVE MEDIUMS FOR TEACHER NOTICING

Megan H. Wickstrom
Montana State University
megan.wickstrom@montana.edu

This article is a report on the findings of three case studies that focused on elementary teachers' in-the-moment noticing across a month of instruction. Extending Jacobs and her colleagues' framework (Jacobs, Lamb, and Philipp, 2010), this articles categorizes the mediums (i.e., written accounts, verbal interactions, physical strategies) by which the teachers attended to their students' mathematical reasoning. Even though the teachers taught similar lessons, they attended to students' actions through different mediums. These mediums reflected and often aligned with individual teaching practices and routines. More interestingly, the teachers' preferred medium was also the most productive for them in terms of discussing students' understanding and informing instructional decisions.

Keywords: Teacher Knowledge; Teacher Beliefs; Mathematical Knowledge for Teaching

Background

In our everyday lives, we each attend to and notice different things. When walking down a city street, some of us might be drawn to the items displayed in a storefront window, others to the aroma of a local restaurant, and some may be drawn to something that they have seen before or perhaps something that has changed. We each make sense of our world in different ways and may not notice the same details. As Schoenfeld (2011) states, "noticing is consequential-what you see and don't see shapes what you do and don't do" (p.228). What we notice and make sense of shapes our daily decision-making processes.

In a similar sense, what teachers notice and make sense of in the classroom is often different depending on the teacher. Erickson (2011) found that teacher noticing is selective (attending to some events, but not to others), multi-dimensional, and influenced by prior experience. He also noted that teachers most often noticed events in the classroom that required immediate attention or action on the part of the teacher. Even though teachers notice many things during instruction, how to respond to what they notice is sometimes difficult. Multiple researchers (Berliner, 2001; Jacobs, Lamb, & Philipp, 2010; Mason, 1998) have documented that teachers often have difficulty devising instructional responses based on what they notice.

Even though noticing and responding to students' thinking is a difficult task, researchers have shown, with professional development, it is a learnable skill (Jacobs et al., 2011; Santagata, Zannoni, & Stigler, 2007). Using mediums such as classroom artifacts (Goldsmith and Seago, 2011), student video cases (Jacobs et al., 2010;), and videos of teachers' in-the-moment noticing, researchers noted growth in teachers' abilities to attend to students' mathematical thinking and form instructional responses.

With regard to in-the-moment noticing, researchers have devised ways for teachers to capture moments as they occur using a Déjà Vu camera and then later reflect and respond to these moments. This camera attaches to the teacher's body and she can press a button to capture 30 seconds of video at any time. Sherin, Russ, and Colestock (2011) discussed that teachers often use these cameras in multiple and unexpected ways (i.e., using it as a still life camera). Star, Lynch, and Perova (2011) took this idea a step further and categorized what pre-service teachers noticed during practice (i.e., classroom environment, classroom management, tasks, mathematical content, and communication).

When using the Déjà Vu camera and analyzing their own teaching, teachers have the freedom to choose what is significant to them. By using this camera, researchers can gain insight into how teachers attend to and make sense of their students' mathematical reasoning. There is little to no research examining the types of events teachers choose in their daily practices and why these events are significant. It important to investigate the ways in which teachers naturally attend to students' actions and reasoning.

Within this paper, I categorize the mediums used by three teachers to attend to their students' mathematical thinking across a month-long unit of instruction. In art, a medium is the substance the artist uses to create his or her artwork. Within this paper, medium refers to the way in which what was noticed was conveyed to the teacher (i.e., drawing a picture, counting using fingers). The paper describes a framework for categorizing mediums as well as the significance of specific mediums for individual teachers. Within the paper, I address the following research questions:

- By what mediums do teachers attend to students' mathematical thinking in the classroom?
- In what ways, if any, do these mediums aide in teachers' instructional decision-making?

Theoretical Framework

This study is grounded in the theory of teacher research. Cochran-Smith and Lytle (1993) defined teacher research as "systematic, intentional inquiry by teachers about their school and classroom work" (p.24). Teacher research usually stems from issues and questions that arise within the practice of teaching. It is grounded in the epistemological belief that teachers should have a voice and a presence in the research community and acknowledges that the teachers' perspectives are critical when implementing and evaluating research.

This paper embraces this theory by examining teacher noticing from the teachers' perspectives. When we, as researchers, investigate teacher noticing, we often have an end goal in mind or something we hope teachers notice and respond to. By allowing teachers to choose important events, we gain insight into their natural practices and how they use these practices to guide decision-making.

Methods

Participants

Three teachers participated in the study: Mrs. Grey, Mrs. Purl, and Mrs. Brownstein. Mrs. Grey and Mrs. Purl were both fourth-grade teachers while Mrs. Brownstein taught fifth grade. The teachers had 10-18 years of teaching experience and were second-year participants in a two-year professional development (PD) focused on measurement topics. Throughout the PD, each of the teachers had experiences watching and writing about videos of their teaching in terms of students' thinking and instructional implications. These teachers were chosen as case studies from the PD because they taught similar grade levels at the same school, Terrace Elementary.

Terrace Elementary

The study took place at Terrace Elementary, located in an urban city in the Midwestern United States. At the time of the study, 554 students attended Terrace and of these students 54% were boys, 46% were girls. They identified according to the following ethnicities: 54.7% Black, 23.3% White, 10.3% Multiracial, 9.6% Hispanic, 1.6% Asian, 0.4% Native American, and 0.2% Native Hawaiian. The average class size of the school was 18 students and the student to teacher ratio was 12 to 1. At the time of this study, 80% of the students came from low-income households and were eligible for free or reduced-price school meals.

Data Collection

During a month-long unit on measurement topics, each teacher was asked to wear a Déjà Vu camera to record events that she noted as important. This camera was a small device pinned to the teacher's shirt that connected to a collection box clipped to the teacher's pants. When the teacher pressed a button on the collection box, the camera collected and saved a 30-second video clip of the events prior to her pressing the button. Each teacher was asked to press the button on the camera when she felt that she noticed something important about students' thinking or when she made an important decision based on student thinking. All of the lessons were videotaped with a secondary camera, as well.

At the end of each day, I watched the videos and marked time stamps on the main video for each of the events that the teachers found important. These clips were then used as the main focus of a one-on-one interview. On a daily basis, each teacher and I would sit down for an interview in which we discussed the clips that she noted. For each clip, the teacher was asked to describe what the student(s) was doing, why she chose the clip, what she thought the student was thinking or understood, and in what ways this clip might inform her instruction going forward.

Following each teacher-researcher interview, I transcribed each conversation verbatim. This resulted in over 300 pages of written transcripts (100 pages per teacher).

Data Analysis

To examine what and how the teachers noticed, I began with the teacher noticing framework (Jacobs, Lamb, & Philipp, 2010) as my primarily analytical tool. However, the construct of teacher noticing has been primarily used in clinical interview settings and I experienced limitations in analyzing the data I had collected for this study. Using qualitative methods (Miles, Huberman, & Saldana, 2014), I instead envisioned the three tenets of teacher noticing as broader analytical categories to be explored. I incorporated provisional coding (Miles, Huberman, & Saldana, 2014) to expand and elaborate codes to better fit the aims of this study.

I decided to call each episode that the teacher noticed an event. The event was composed of four components: what the teacher noticed, interpreted understanding, implications for teaching, and significance to the teacher. It is important to note that an event could be composed of multiple student actions because a child could be doing two things simultaneously (e.g., drawing and counting area units).

I began the analysis by first reading the transcripts and taking descriptive, qualitative notes about each of the events. I recorded where an event began and ended and notes related to each of the constructs. I repeated this process for each of the teachers. Following the note-taking phase, I used an event-listing matrix (Miles, Huberman, & Saldana, 2014) to record the events the teacher noted in a chronological manner. I devised a matrix for each teacher in which the columns were the analytical categories of the event (what the teacher noticed, interpreted understanding, implications for teaching, and significance to the teacher) and the rows represented a description of each event in terms of those categories.

Because of the brevity of this piece and the focus on mediums of teacher noticing, I will only describe how what the teacher noticed was coded. For each event, I began by coding what the teacher noticed within the event and what task the action centered around. After each event was coded, I scanned the events again to see if codes were similar in nature or could be collapsed. I repeated this process for each lesson and each teacher. For this piece of analysis, the codes usually centered on specific tasks or routines within the classroom. As new codes emerged in the analysis, I reanalyzed each event for each teacher looking to see if the code had been missed.

For each teacher, I created codes that described what the event pertained to. In the results section, each of these codes are described in detail in the mediums framework (See Fig 1).

Results

What the Teacher Noticed		Description
Written Accounts	**Drawing Strategy**	The event involved a student's drawing a picture to represent or help find their answer.
	Written Answer	A solution or student's work recorded during instruction.
	Journal Account	Written reflections, definitions, and homework recorded by students in their journal.
Verbal Interactions	**Statement**	The student makes a claim or states a response in class.
	Question	The student poses a question to the teacher.
	Student to Student Interactions	Interactions, discussions, conversations made by students to each other within groups or pairs.
	Language Comprehension/Usage	The way in which students use and interpret language. Example: The teacher notices the student is confusing the words area and perimeter.
Physical Strategies	**Length/Area/Volume Counting Strategy**	The way in which the child counts length, area, or volume. Example: For area, students may count individual units, skip count by rows, or use the algorithm.
	Length/Area/Volume Measurement Strategy	The student uses tools to find length, area, or volume. Example: laying tiles down and counting them to find the area of a rectangle.
	Building Strategy	Students using tools to construct something. Example: Building a rectangle with a certain area or a prism with a certain volume.
Visualization Strategies	**Visualization Strategy**	A statement, the student makes, involving how they see volume or area. Example: Students states that the volume of a prism is like an elevator visiting multiple floors.
Non-Mathematical Behaviors	**Behavior**	Mainly non-mathematical events such as students rushing to complete a problem or not attempting a task.

Figure 1: Mediums by which the teachers attended to students' actions

When using the Déjà vu camera to indicate important events, the teachers noticed different types of student actions related to length, area, and volume measurement. These actions centered around five themes: written accounts, verbal interactions, physical strategies, visualization strategies, and non-mathematical behaviors (as shown in Fig 1). The types of actions the teachers attended to varied by teacher (as shown in Figure 2). Mrs. Purl primarily attended to verbal interactions, Mrs. Grey to written accounts, and Mrs. Brownstein to physical strategies. The teachers' classroom norms and practices often aligned with the ways in which they attended to students.

Written Accounts. Written accounts included when teachers noticed students' written strategies, drawings, or journal accounts. Of the three teachers, Mrs. Grey most often noted students' written accounts. Mrs. Grey reflected that she found it difficult, at times, to manage her classroom and implemented the concept of a math journal. On a daily basis, Mrs. Grey asked students to write down thoughts, explanations, and definitions in a personal journal. The math journal allowed her to maintain control while also allowing students to write and reflect on their mathematical understanding. Mrs. Grey viewed the journal as a window into her students' mathematical reasoning.

When asked to use the Déjà Vu camera, Mrs. Grey often used it as a still life camera to take photos of students' work or drawings. In the transcript below, Mrs. Grey had asked students to write their own definition of area, prior to instruction. She noticed one student's definition changed over time and speculated what the student might be thinking.

> **Researcher:** What stood out to you at this moment?
>
> **Mrs. Grey:** I think it was in her definition that she wrote down. When I looked at it, her definition was "area is the inside of a triangle, rectangle, or square". So that was when I asked her about the inside of a circle. Then, when we talked about changing our definition today, as a class, and I noticed she wrote "area is the inside of every shape and every shape has area".
>
> **Researcher:** So what do you think she was thinking, initially?
>
> **Mrs. Grey:** Um, it looks like maybe, from her drawing, that the units we use to fill in a shape don't fit the right way into a circle or oval because she is drawing square-ish shapes.

For Mrs. Grey, students' drawings and written explanations were powerful in helping her to see the ways in which students were reasoning about mathematics.

Verbal Interactions. Verbal interactions included statements, questions, language comprehension, and student-to-student interactions. Of the three teachers, Mrs. Purl primarily attended to students' verbal interactions. Mrs. Purl's classroom was designed as ELL (English Language Learners). During interviews, she described the need to help students explain their thinking aloud as well as explore the meaning of different words. She listened carefully to students' discussions, purposefully arranged students in groups or pairs, and encouraged them to share ideas aloud. During instruction, Mrs. Purl circulated the classroom and listened to different groups as they worked. For example, when measuring the area of a rectangle using tiles, Mrs. Purl noticed that two girls were using rulers as place markers to help structure rows and columns. The place markers took up space and Mrs. Purl noted the conversation that unfolded between the girls. She stated,

> I loved the interaction between Stephanie and Marlaysia. Stephanie thought using the rulers to mark rows and columns was a great idea, but she was missing the space under the ruler where she used them. Marlaysia realized and explained to Stephanie that the ruler took up space so their measurement was off.

Mrs. Purl often noted the questions students posed as well as the wording they used. She thought that this could tell her more about the ways in which students were thinking mathematically and what remained unclear to the class.

Physical Strategies. All of the teachers used square tiles, cubes, and measurement tools to help students study length, area, and volume. They attended to students' physical strategies as they measured, counted, and built areas and volumes. Mrs. Brownstein, a math and science teacher, frequently used physical materials as a starting point in the lesson. She noted how students counted volume units and the strategies they used. For example, when asked to find the volume of a rectangular prism that was 10 units high, 10 units wide, and 5 units long, Mrs. Brownstein noticed Promise's counting strategy.

> She was able to count 50 in a layer by then she ended up focusing on rods (vertical sections) of 10 and skip counting by 10. I think she is moving from seeing rods to seeing layers, but she isn't using the layers to find the total volume. Last class period she was able to count 50 (cubic units) in a layer but when I asked her to find the total volume she focused in on the rods of 10.

Beyond counting strategies, physical strategies also involved the ways in which students used a ruler, how they used tools like tiles to measure area, and how they built different figures with specified areas or volumes.

Visualization Strategies. Teachers also noted visualization strategies during instruction. These strategies were statements that included how students imagined area or volume or metaphors for area and volume. During a hands-on volume task, Mrs. Brownstein noticed students discussing the idea of volume as an elevator, a hamburger, and a waterfall. She stated:

> When I heard him say elevator, he was describing this kind of motion (moving her hand up and down). From what he said, I think that he is imagining a cart or an elevator going up and going down the prism.

It is important to note that visualization strategies were always coded with another strategy. Students had to speak or write down how they imagined the concept for the teacher to notice it.

Non-Mathematical Strategy. Lastly, teachers sometimes noticed students' non-mathematical behaviors in relation to the task. This included teachers describing that students had worked too quickly through the task, or they did not put enough thought into it. Since teachers were asked to focus on what they noticed mathematically, these events did not arise often.

Mediums by which the teacher attended to students' strategies.		Teachers: Mrs. Purl 37 Events 48 Student Actions	Teachers: Mrs. Grey 24 Events 31 Student Actions	Teachers: Mrs. Brownstein 27 Events 29 Student Actions
Written Accounts	**Drawing**	4	6	0
	Written Strategy (in class)	0	1	2
	Journal Account	0	6	0

1 Implication Arose	2 Implications Arose	3 Implications Arose

Figure 2: Mediums that led to instructional implications

Significance of the Mediums. Each of the teachers attended to students' actions through different mediums, as shown in Figure 2, even though they enacted similar lessons. Mrs. Purl primarily attended to students' physical strategies (46%) and verbal interactions (29%), while Mrs. Grey attended to students' written accounts (42%) and physical strategies (26%). Mrs. Brownstein noticed students primarily through physical strategies (41%) and verbal interactions (28%). It is important to consider these mediums because they can act as pathways into how the teachers see and understand their students.

As prior researchers have noted (Jacobs et al., 2010), it is difficult for teachers to enact the cycle of noticing students' actions, reasoning about the students' thinking, and describing implications for instruction. Teachers often see students doing something but are unsure of what the student is thinking and how the students' thinking can be addressed in instruction. For example, the teachers within this study were only able to complete this cycle for 22% to 25% of events noticed (Mrs. Grey, 25% of events, Mrs. Purl, 25% of events, Mrs. Brownstein, 22% of events).

In figure 2, the cells that are shaded show student events in which the teacher was able to describe students' thinking as well as implications for instruction. Cells that are darker indicate a greater number of events led to instructional implications. The darkest cell indicates that three of the events led to instructional implications while the lighter cells indicate two events and one event. For example, in the table, we can see that Mrs. Grey noticed six events that involved students drawing. Of these six events, three of them resulted in an implication for instruction.

As shown in Fig 2, the student actions that teachers attended to most frequently were the most productive for describing students' thinking and instructional implications. For example, Mrs. Purl, who primarily attended to students verbal interactions, had five incidences where she was able to describe students' understanding and instructional implications related to verbal interactions. This was the highest of any of the categories. The same is true for Mrs. Grey in terms of written accounts and Mrs. Brownstein in terms of physical strategies.

Discussion and Concluding Remarks

In considering the cases of Mrs. Brownstein, Mrs. Purl, and Mrs. Grey several themes emerge. The data highlights that teachers notice in different ways when teaching. The mediums by which teachers notice are often dependent on the tasks they pose, classroom norms and practices, and beliefs. Strategies that teachers use on a daily basis (i.e., math journals, encouraging discussions) can be productive mediums and pathways for teachers to glimpse students' mathematical thinking.

Secondly, the types of actions more frequently noticed were also most productive in reasoning about students' thinking and instructional decisions. Each of the teachers had 10 or more years of teaching experience and noticed in ways that aligned with their teaching. This result seems logical because the teachers had many years to think and reflect on their teaching and its ramifications. For example, Mrs. Grey used mathematics journals for several years and had practice reading and reviewing students' journals. It made sense that she could see things about her students through these journals that perhaps she had witnessed before.

This article highlights that teachers learn about their students through multiple and varied mediums. As researchers, it is important to consider this phenomenon when working with teachers and choosing professional development tasks. Examining teachers' current practices can aide in determining how best to help teachers understand students' thinking and reasoning. It is also important to expose teachers to multiple and varied mediums by encouraging multiple forms of expression in the classroom.

scannon5@student.gsu.edu

Utilizing narrative inquiry, this study documents the experiences of one middle level mathematics teacher (Andrew) as he works to design mathematics lessons focused on student empowerment and power-sharing. We share snapshots of Andrew's three-year story—a story focused on engagement, push-back, collaboration, and Andrew's decision leave his school after three years. Implications for teacher education and support programs are shared.

Background Information and Relevance to PMENA Audience

Andrew and I are sitting together over drinks and cheese fritters on a Tuesday in February; he came directly from school so it is relatively quiet in the bar. Andrew is in his second year of full-time teaching at a local middle school and in his third year of participating in interviews with me—we have met regularly from the beginning of his university student teaching experience until now. We engage in casual conversation first and then he updates me a bit on his new position at Parkview as a 6th and 7th grade teacher teaching all four content areas; he's still overwhelmed at times but managing. I probe a bit more and ask about his recent mathematics lessons—he prides himself on creating "outside the box" projects—and he hesitates; "I'm leaving," he says. "I got my contract for next year…I didn't sign it."

Andrew was a part of a larger study focused on mathematics pre-service teachers' experiences throughout university coursework, but we were struck by his case in particular. In his words, Andrew taught lessons with one goal in mind: "to produce informed, driven, fulfilled individuals capable of making an impact on the world." From the beginning of student teaching he talked frequently about his desire to engage in "authentic power sharing" with students. Intrigued by Andrew's curriculum design process and also the struggles he faced as he engaged in this sort of teaching, we decided to follow him throughout his first few years of teaching. Using data from interviews, observations, and coursework artifacts, our study centered on one main research question: *What are the experiences of a new middle level mathematics teacher engaged in "against the grain" (Simon, 1992) teaching practices?*

Brief Literature Review

Research on new teacher induction concludes that nearly half of all new teachers in the U.S. exit the classroom within their first five years (AACTE, 2010). In urban schools, it only takes about 3 years for half of all new teachers to leave. This high rate of attrition often results from challenging working conditions and the absence of a supportive professional culture. For mathematics teachers in particular, this attrition may also be related to curricular issues as teachers are increasingly placed in schools where a predetermined curriculum dictates what mathematics is covered and how it is taught. Through the adoption of specific mathematics textbooks, pacing charts, or state and national frameworks, districts are mandating curriculum materials and curricular frameworks as a strategy for improving student achievement (Corcoran, 2003). As mathematics teacher educators, we need to understand how these mandates position new teachers as they engage in teaching while still learning how to teach.

Inquiry and Analysis

We utilized narrative inquiry throughout this study; we “began with the experiences as expressed in lived and told stories” by Andrew (Creswell, 2007). Closely following Creswell’s (2007) process for implementing narrative inquiry, we gathered data through the collection of Andrew’s stories and reporting of his individual classroom experiences and “chronologically ordered the meaning of those experiences” (p. 54). Drawing on Clandinin and Connelly’s (2000) procedural guidelines for narrative inquiry, we spent considerable time gathering Andrew’s story through multiple types of information: interviews (eight formal recorded interviews and multiple informal conversations each year); written artifacts from Andrew including lesson plans, reflections on teaching, and statements of teaching philosophy; and stories about Andrew from others close to him. All formal interviews with Andrew and veteran educators who worked with him were audio-recorded and transcribed for inclusion in the data set, along with all written reflections and philosophies. We also created research memos after informal conversations or meetings with Andrew and others when audio-recordings were not used. As described by Creswell (2007), our narrative inquiry describes the story of Andrew “unfolding in a chronology of [his] experiences, set within [his] personal, social, and historical context, and including the important themes in those lived experiences” (p. 57).

Andrew’s Story

When he entered his teacher education program, Andrew was several years older than most students in his cohort. He talked about his path to education and his road to finding passion:

> It took me ten years to get through a degree. I was out doing other things. Looking back on it was trying to discover what a passion for me would be. Then I decided to give education a shot. I walked in my first class and my professors came in and gave this impassioned rant about oppression and training and—I mean, really, he gave a step-by-step account of my life in education thus far. I was convicted and inspired and thought, “Okay, something feels different.” I’d finally found that one thing that I have to do.

During student teaching, Andrew continued to talk about his passion:

> What drives my passion is that I feel like I was failed by my education. It wasn’t that I wasn’t good at it; I graduated top of my class. I was able to do what they wanted me to do. I figured out pretty early that I could give back what was asked of me and do it well. It doesn’t sit right with me to know that millions of others are coming up the same way.

Andrew’s curriculum appeared to come out of a space of frustration with what he encountered as a student, and also his desire for his students to develop a passion for and reason to engage in mathematics. During student teaching, when Andrew was required to create and teach a 4-week unit around several standards related to ratios and proportions within the 7th grade mathematics curriculum, he talked about wanting his students to encounter life and math “more naturally” and decided to design a math unit around fear:

> Okay, we’re taking the next four weeks of math to study proportions, but more so talk about our fears, and how we can decide whether or not our fears are rational. Are we okay with our fears being a little unreasonable if it means it keeps us out of danger? We can explore how fear might be mongered purposefully by media in order to get something. Through all that, we encounter proportions; we encounter ratios; we encounter a mathematical thing that yes, is going to be tested on the [end of grade test], but encountering it that way, it’s more meaningful, and I think there’s room for that.

After teaching this unit, Andrew and others (his mentor teacher and many students) reported success. Andrew discussed his students’ initial apprehension when he positioned himself as a facilitator, someone off to the side allowing student voice and choice to dictate the classroom environment and activities. Andrew wrote the following reflection at the end of student teaching:

> I am convinced that if the purpose of education is to produce informed, driven, fulfilled individuals capable of making an impact on the world, then authentic power sharing is absolutely necessary in our schools, and this sharing must be prominent in relationships, in what content is taught, and in how content is taught.

Andrew received an offer to come on as a lead teacher the following year, and he frequently cited his fear unit as the reason he got the job. Like most new teachers, Andrew found himself struggling at the beginning of his first year of full-time teaching, explaining that "I don't feel like I belong in my classroom right now." However, different from most new teachers, Andrew cited collaboration as one of his biggest frustrations and felt like there are "all these demands and all these emphases on collaboration that force me to be on a particular pace." Andrew related this to Paul Simon and Nickelback:

> I went to see Paul Simon speak earlier this year and the topic was "The solo artist in an increasingly collaborative culture." What I took away from it was that you've got people who are gifted. He is a gifted guy. And you wouldn't ask Paul Simon to do a duet with the guy from Nickelback, right? …. You wouldn't ask Mozart to collaborate with Beethoven. They are both fantastic—but they have their own way of doing things and it would likely be disastrous. That's kind of the way I feel about collaboration right now.

When talking about collaboration with other teachers, Andrew also talked about "having had more freedom as a student teacher." He explained further:

> I'm not playing into my strengths, you know. That's where the not having a sense of belonging comes from. My strengths of sitting and going through this organic process of taking math content and figuring out, okay, what can we learn from this? What is the big idea that may not even be content related, but we'll use the content to get there. That's where I'm at my best and I'm not—I just can't do that right now.

As Andrew moved into his third year of teaching at Parkview, he interviewed for and accepted a position as a 7th grade teacher tasked with teaching all content areas. When we met in October, he continued to talk about a lack of opportunity to create math lessons "my way" and about how hard it was to teach lessons that he did not design: "When I design a lesson or unit, I know the purpose of each piece of the lesson, and I can more easily modify in the moment. It's much harder to do that when using someone else's plan." Despite this frustration, he thought it might get better as thought about how to integrate the subjects. He will not, however, have the chance to find out. When we met in February he told us he had resigned. When asked what his plans were next he responded: "I do not know what I'll be doing next year, but I will not be at Parkview. I haven't been able to talk about it yet and it's hard to say out loud, but I'm done."

Findings and Discussion

Andrew talked a lot about the overall purpose of schooling during the three years we worked with him. He talked about the importance of developing close relationships with students. He spoke frequently about his desire to design math lessons that would empower students to take control of their own learning. Considering carefully the role of mathematics in this quest, Andrew spoke of the importance of designing lessons around "bigger" questions about culture, society, and topics of particular interest to middle schoolers. He felt quite certain that it was then, as students engaged in projects around these topics, that they would learn the math.

Despite this belief, Andrew found himself quite often using daily lessons designed by other teachers—lessons that (1) did not align with his belief that there should be some larger goal in mind when teaching math and (2) lessons that Andrew felt would not position him to be "at his best" in the classroom. In short, Andrew's recognition of this inconsistency between actions (his use of other teachers' lesson plans) and beliefs (that the lesson plans he designed himself designed to empower students were better) caused cognitive dissonance (Festinger, 1957).

Cognitive dissonance theory (CDT) posits that dissonance is resolved in three basic ways: change beliefs, change actions, or change perceptions of actions (Festinger, 1957). When analyzing Andrew's narrative through the lens of CDT, it is interesting to consider the choices he had as he tried to resolve dissonance and move towards internal consistency. First, Andrew could have *changed his belief*—he could have concluded that designing empowering lessons around larger questions was no longer important. This happens to many new teachers in the field; they believe in the power of new curricular innovations learned during university coursework but then their beliefs about what could happen in a mathematics classroom change when they are in the field. This move to alleviate cognitive dissonance was unlikely for Andrew. He felt strongly that math should be taught differently and did not waiver in that during his three years teaching.

Alternatively, Andrew could have *changed his actions.* This was also unlikely for Andrew and for most teachers faced with competing responsibilities and assignments in their first few years in the field. Changing his actions to align with his original beliefs and cognition would mean that Andrew would have had to design all lessons on his own. In order to teach in the way he wanted to teach, Andrew would have likely had to work nights and weekends designing these new curricular units; there was simply no time in the day to do that work.

Finally, Andrew's third choice was to *change his perception of action*. Andrew's narrative made it clear that he tried to justify his actions in his first and second years as a lead classroom teacher, at least for a short period of time. He found himself reconceptualizing his decision to utilize other teachers' lessons because he wanted a life outside of work. He rationalized his decision to collaborate and use others' lessons because his administration asked him to work with other teachers and share lessons. For Andrew and other new teachers, policies (and politics) in place in his school—like a severe lack of planning time, additional responsibilities often placed upon teachers at charter schools, etc.—could be seen as levers that push teachers towards changing their perceptions of actions designed to relieve dissonance—actions made in their classrooms that do not align with their beliefs. Even worse, like in Andrew's case, teachers leave teaching all together. For Andrew, who no longer felt that his passion—the thing he "could not *not do"*—was teaching, leaving was the only option.

EXPLORING TEACHERS' EXPERIMENTATION AROUND RESPONSIVE TEACHING IN SECONDARY MATHEMATICS

Elizabeth B. Dyer
Northwestern University
elizabethdyer@u.northwestern.edu

Experimentation has been proposed as a key mechanism by which teachers learn through experience. However, few studies have illustrated what experimentation looks like or how teachers think while experimenting during instruction. This paper investigates the experimentation used by two secondary mathematics teachers that exhibit responsive teaching practices using point-of-view observations to gain access into teachers' in-the-moment thinking. Both teachers engaged in deliberate experimentation around how to influence student thinking. Similar to qualitative methods of inquiry, this experimentation is focused on developing contextually-relevant models of the way that student thinking is influenced by instruction.

Keywords: Teacher Knowledge; Teacher Education-Inservice; Metacognition; High School Education

Supporting teacher learning and growth is essential for improving student outcomes. However, the processes by which teachers are able to improve their teaching, particularly from a cognitive perspective, have been overlooked in empirical studies of teacher change. Researchers have suggested that experimentation with teaching practice may be an important process by which teachers improve their teaching (Hiebert, Morris, & Glass, 2003; Little, 1993). This paper takes a first step at investigating the role that experimentation plays in changing teaching practice and the teacher thinking involved during this experimentation.

Experimentation and Teacher Growth

While there is an intuitive idea that teachers improve through experience, research about the impact of teacher experience on student learning has been inconsistent. Additionally, this work largely ignores *how* teaching experience influences teaching and the different ways that teachers may learn through experience (Sullivan, 2002). The framework of teacher noticing suggests that the experiences teachers attend to and the way they make sense of them should have a profound impact on the way that teachers grow through experience (Sherin, Jacobs, & Philipp, 2011).

One proposed way that teachers are thought to learn through experience is using experimentation (Hiebert et al., 2003; Little, 1993). While research has documented that teachers report experimenting with their practice (Grosemans, Boon, Verclairen, Dochy, & Kyndt, 2015; van den Bergh, Ros, & Beijaard, 2015), and examined hypotheses developed by pre-service teachers from classroom video (Yeh & Santagata, 2015), there has not been a focus on understanding how the process of experimentation unfolds in practice. This study investigates the experimentation that teachers engage and examines the teacher thinking that is at play for teachers that exhibit consistent responsive teaching practices. In other words, these teachers typically attend and base instruction off of the substance of student thinking (Hammer, Goldberg, & Fargason, 2012; Pierson, 2008). This selection of teachers allows this work to examine whether experimentation could support the development or refinement of responsive teaching practices, which are complex, difficult for teachers to enact, and take time to fully develop (Hammer et al., 2012).

Methods

Participants

This paper focuses on two secondary mathematics teachers, Rachel and Mary, who have consistently used responsive teaching practices. Both teachers were videotaped several times since the 2003-2004 school year, and most recently during the 2013-2014 school year. Examining two videotaped lessons from each teacher, one from the beginning and one from the most recent data collection, both teachers were found to have stable responsive teaching practices (Dyer & Sherin, in press). Specifically, the majority of their turns of talk during whole class discussions included substantive probes of student ideas (Pierson, 2008), invitations for students to comment on each other's ideas or "student uptake" (Lineback, in press), and substantive comments on students' ideas or "teacher uptake" (Lineback, in press; Pierson, 2008).

Data

The data used include interviews with the two teachers from the 2013-2014 school year. The interviews come from a series of point-of-view (POV) observations (Sherin, Russ, & Colestock, 2011) with the teachers. During these observations, the teacher captures video from their perspective using a small wearable camera. The camera records the previous minute of action when the teacher presses a button on a remote. Teachers were asked to save moments they "wanted to reflect on or think about later", After the lesson, the teachers were interviewed about each of the saved clips (referred to as moments) in order to access what the teacher was thinking. The discussions focused on (a) the reason the moment was saved, (b) what the teacher noticed in the moment, (c) the teachers' interpretation of the moment, and (d) what implications the teacher drew from moment. Fifteen POV observations were completed with the teachers, 10 with Rachel and seven with Mary. These observations provided a total of 91 discussed moments.

Analysis

The discussion with a teacher around a saved clip or moment was the unit of analysis. The first phase of analysis identified discussions where the teacher implemented or proposed a change to their teaching. In the second phase, the process of using an experience as feedback in each discussion was characterized through open coding. Deliberate experimentation was one of several processes identified. In deliberate experimentation, the teacher purposefully tried or proposed to try multiple ways of achieving an instructional goal. This process was defined by meeting two criteria: (1) the teacher describes or references experiences that use different methods of achieving an instructional goal, and (2) the effectiveness of the methods are compared. These methods or tests could happen during the same lesson or across different lessons, as well as with similar students or across different groups of students.

Findings

The analysis found that both teachers engaged in deliberate experimentation, both during the same lesson and across different lessons (see Table 1). The results also indicate a difference in the frequency by which the two teachers experimented. Across Mary's discussed moments, most of the changes she proposed or implemented were a part of experimentation. Rachel, by contrast, seemed to use her experiences in a variety of ways to inform changes to her teaching.

The following example from Mary is used to illustrate an instance of deliberate experimentation. In this example, Mary considers what questions she could ask different groups to help them accurately model the snow shoveling situation students were working on in her AB Calculus class. The students were developing an equation that modeled the total amount of snow that had been shoveled from 6AM to 7AM when they were given the rate of snow shoveling was 0 ft^3/hour from 12AM to 6AM and 125 ft^3/hour from 6AM to 7AM.

Table 4: Distribution of Deliberate Experimentation Across Lessons

	Mary							Rachel								
Observation Number	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**Total**
Moments Discussed	15	17	13	5	8	4	2	7	3	2	3	4	1	4	3	91
Deliberate Experimentation	2	2	3	2	1	0	0	0	0	0	0	0	1	0	1	12
During one lesson	0	1	3	0	0	0	0	0	0	0	0	0	1	0	0	5
Across multiple lessons	2	1	0	2	1	0	0	0	0	0	0	0	0	0	1	7

Mary explains the experimentation that was at play when discussing the moment, "[I knew] that this is where they were going to screw this up. This group had the 125*t* and the 108*t*…and initially, some of them aren't doing subtraction, [they] divide by 6 first. So they know that there's something that you do with 6…So, and, I think I just experimented with different ways, like, how I interact with the groups, like, sort of, the best way to get them to understand that it was t minus 6 as opposed to just t [which was asking students how much snow had been shoveled as specific times between 6 and 7]." In this example that Mary explicitly mentions experimentation in the ways that she interacted differently with multiple groups in the same lesson. Additionally, she mentions her goal in this experimentation of trying to find the best way to help students understand the equation. Mary also considered how asking students to respond to the idea that the time term in the equation is *(t-6)*, but decided that method was less "cognitively demanding".

One striking feature of all of the experimentation identified was that both teachers were experimenting around how to influence student thinking. This experimentation involved complex teacher reasoning. First, the teachers interpreted how students are thinking during the multiple tests as well as before and after each test. In addition to these interpretations, the teachers make hypotheses about how that student thinking was changed or influenced. In the discussions, teachers mentioned a variety of aspects of the classroom environment that influenced student thinking, including the design of mathematical tasks, the wording of questions, or the representations used in diagrams or graphs. Overwhelmingly, the teachers created hypotheses that were contextualized in the specific thinking, specific students, or environment of the classroom. This thinking is well aligned with responsive teaching in that these hypotheses identify the different ways that student thinking can be influenced, which is the basis for responsive teaching.

This was apparent in Mary's example described above when she went on to describe the way the questioning helped students understand the equation:

> What I think right now is the best way to approach it is [a round of questioning about] "how much snow has she shoveled at 6?" And you know, they say "0." "How much snow has she shoveled at 6:30?" And they say, "125 divided by 2, 125 times one half". "How much snow has she shoveled at 6:45?" Asking them those questions for them to get to the *t-6*, um, but then still kind of affirming that "yeah, 125*t* is good, like, you're thinking antiderivative, and like, it's a constant rate, therefore like, *G(t)* would be, you know, 125*t*," but then a nuance is the *t-6*, and then the *t-7*, and so on for the next part.

In this quote, Mary explains how this line of questioning relates to what students are initially thinking about the equation, namely that students start with 125*t* for the equation. Throughout this quote and the previous excerpts, she makes three different interpretations of student thinking, (1) the initial idea that the situation is modeled by 125t, (2) the idea that the time variable in the equation should be divided by 6, and (3) the idea that time variable should be shifted by 6. Mary also develops a model of how the questioning influenced students to think in a different way. In particular, she recalls how students are able to determine how much snow has been shoveled at discrete points in time, and how that progression can be leveraged to off of the initial thinking that $125t$ is an accurate way to model the snow shoveled at 6AM.

Discussion

In many ways, the findings reflect much of the theory that has been proposed about the existence of experimentation. However, these findings suggest that making conclusions about an experiment and developing hypotheses for future experiments, seen in the findings as models that teachers created for the ways that student thinking is influenced by teaching, are in many ways intertwined. These models may represent a key part of the teacher thinking that is involved in experimentation. This type of contextually-valid mental model is similar to how Hiebert et al. (2003) describes experimentation as a test of “a teacher’s local theory of how students learn and how instruction facilitates learning” (p. 208). The contextual nature of these models suggest that video-based studies of experimentation or learning through experience may not accurately reflect the process that happens in real classrooms.

Additionally, the findings show that experimentation happens on a moment-to-moment basis, suggesting that this micro-level time scale may be important level for looking at experimentation, and more generally mechanisms for teacher growth. Thinking about experimentation in small moments during a lesson also stands in contrast to many of the ways that experimentation is supported in current teacher education contexts, which often focus on more long-term experimentation and study of teaching practice. The findings suggest a more balanced approach where teachers are also supported in engaging in experimentation at a more micro-level that could be easily incorporated into everyday instruction.

WHAT INFLUENCES A TEACHER'S WILLINGNESS TO CREATE OPPORTUNITIES FOR DISCUSSION IN A GEOMETRY CLASSROOM?

Ander Erickson
University of Michigan, Ann Arbor
aweric@umich.edu

Patricio Herbst
University of Michigan, Ann Arbor
pgherbst@umich.edu

This study presents an analysis of geometry teachers' willingness to create opportunities for student discussion in the classroom as revealed through the use of a multimedia survey instrument. We presented 42 geometry teachers with 8 multimedia narratives and asked them to choose between a normative instructional action which closed off discussion and a less typical action that encouraged student discussion. Our analysis provides insight into the professional obligations that teachers use to justify their departure from the norm in order to encourage student talk as well as the background variables that are associated with such decisions. We found that while experienced geometry teachers are more likely to make a normative decision than those who are less experienced, there are some cases in which experienced geometry teachers will justify their departure from the norm with their obligation to the discipline.

Keywords: Geometry; Teacher Knowledge; Classroom Discourse; Teacher Beliefs

The importance of discussion in the mathematics classroom has been argued by a number of researchers (O'Connor, 2001; Stein & Smith, 2011) whether it takes place in the context of whole class interactions or within small groups. However, the positive benefits of discussion can only be realized if a mathematics teacher creates opportunities for such interactions in the classroom. The persistence of lecture and recitation format in mathematics classes, however, suggests the importance of understanding the conditions under which a mathematics teacher is willing to choose discussion as an appropriate thing to do. This paper presents initial results from the use of a scenario-based instrument that probes the decision-making of secondary mathematics teachers and, in particular, explores if and when teachers are willing to depart from customary instruction in order to give their students opportunities to discuss problems in small groups or as a whole class.

Theoretical Framework

Researchers have catalogued many benefits of small group and whole class discussions. These interactions provide unique opportunities for thinking and learning (Yackel, Cobb, & Wood, 1991; O'Connor, 2001; Ge & Land, 2003; Stein & Smith, 2011). These studies do not, however, look at what influences mathematics teachers' willingness to depart from customary instruction in order to encourage discussion in their classroom. Researchers who examine intact secondary instruction have documented the presence of customary ways in which teachers carry out their work, both at the large grain size of cultural teaching scripts (Stigler & Hiebert, 1999) and at smaller grain size in instructional situations customarily used to teach particular mathematical ideas (Herbst et al., 2009; Chazan & Lueke, 2009). This literature suggests that opening the classroom discourse to include more classroom discussion might require departing from some of the norms that characterize instructional practice. How can we gauge teachers' disposition to do so?

Most of the research on teachers' decision making is qualitative and is difficult to replicate at a larger scale. Outside the field of educational research, researchers have examined decision making in professional settings (Chan & Schmitt, 1997; Lievens, Peeters, & Schollaert, 2007) using written vignettes and video-based representations as a stimulus for a particular context-based decision. In mathematics education Herbst, Aaron, and Erickson (2013) have shown that animations of cartoon characters work just as well as live-action video clips for provoking teachers' thinking about content and pedagogy; and Herbst and Chazan (2015) have shown how storyboards realized with cartoon characters can be used to study decision making. Thus, we argue that a scenario-based instrument where the scenarios are realized with cartoon characters may provide a means of conducting larger-scale studies of teacher decision-making.

These instruments are grounded in the theory of practical rationality which posits that instructional norms, obligations to the profession, and individual teacher resources (such as beliefs, knowledge, and skills; Herbst & Chazan, 2012) come into play in teachers' in-the-moment instructional moves. We argue that teachers' decision-making can be understood as part of an instructional system wherein the teachers' role is to manage the terms under which students interact with the mathematical content to be learned. Further, we theorize that a practical rationality of instruction enables teachers to call on their professional obligations as sources for justification to support deviations from customary practice (Herbst & Chazan, 2012). In earlier work we gathered evidence that we can use scenario-based assessments to help determine whether teachers recognize departures from a norm in the situation of doing proofs, where those departures might increase students' opportunities to participate in mathematical discussions (Herbst et al., 2013); the data gathered in that pilot study supported the contention that these departures might be justified on account of professional obligations to individual students, the class as a whole, the discipline of mathematics, and the institution. From that work the question remained—if an individual teacher was given the opportunity to depart from a norm of doing proofs in ways that might increase chances for students' discussions, would they choose to do so? What could explain the variance of these responses?

Methodology

The Decision instrument was designed as a means of assessing teacher decisions in the context of an instructional situation. The participant is presented with a storyboard depicting a teaching scenario set in a geometry classroom where the teacher is about to assign a proof problem to their students. For each item, there is a choice between four actions where one action is consistent with a norm (e.g., the teacher provides the givens and prove statement) and the other three are breaches of that norm in favor of a participation structure that may or may not incorporate greater student talk: discuss the problem as a class, work on the problem in small groups, or work individually. After choosing one of those options participants are asked to choose justifications for their choice from a collection of ten statements which contained pairs tied to each of the four obligations respectively and another pair which served as distracters. The distracters are statements that make the decision a personal matter for the teacher (e.g., "This action best aligns with my beliefs about mathematics teaching"). The participant may choose as many of these statements as they wished which meant that we could give them a composite score between 0 and 8 across the four items corresponding to a norm for each obligation. In the following section, we describe some of the significant differences between items with respect to opportunities for student talk and with respect to the obligations chosen to justify teaching decisions. We also looked for relationships between these choices and whether a participant had more than 4 years experience teaching geometry (EGT; N = 22) or not (non-EGT; N = 20).

Results

While the modal choice for each of the eight decision items was either small group or whole class discussion, thus showing that teachers tended to prefer increasing opportunities for discussion, there were some items that evoked more responses encouraging discussion than others. For example, in item 61001, the teacher writes a proof problem without an accompanying diagram and a student asks for clarification. The participant can choose between rewriting the problem with a diagram or encouraging the students to work through the problem themselves, as a whole class, or in groups. Similarly, in item 61003, the teacher draws a figure and tells the students what they are going to prove. The participant can choose to clarify the givens and prove statement on the board or make moves to encourage student discussion. There were significantly more EGTs who chose the small group discussion option for the first item while there were significantly more non-EGTs who chose the small group option for the second item. Why were EGTs more supportive of discussion in one case than the other? Looking across the open responses to 61001 reveals that many of the EGTs who chose the small group option wanted students to draw the diagram while the non-EGTs either did not address the diagram or suggested that the teacher provide one. A review of the teachers who did *not* choose the small group option for 61003 suggests that the EGTs may have been more concerned with maintaining control of the conversation in order to clarify the problem for their students whereas the non-EGTs focused more on encouraging student contributions.

In order to learn more about how teachers justify departures from the norm, we looked for connections between the professional obligations that participants used to justify their decision and their personal characteristics as well as their responses to the decision items. We ran a two-tailed t-test and found that there was a significant difference in favor of EGTs for justifying decisions on account of the disciplinary obligation ($p < .0001$) and that there was a significant difference in favor of non-EGTs for doing so on account of the institutional obligation ($p < .05$). By way of contrast, there was no significant difference with respect to experience for the individual or interpersonal obligations. We conjecture that more experienced geometry teachers have a better conception of the demands of the discipline while teachers with less experience may feel more bound by the school curriculum. We also found that use of the interpersonal obligation to justify a decision was negatively correlated with the normative option and positively correlated with the whole class discussion option. These results have face validity since the choice of a whole class discussion suggests concern for the manner in which students communicate with one another.

Conclusion

We have demonstrated how scenario-based assessment of teachers' decision-making can be used to find out when mathematics teachers are willing to depart from an instructional norm in order to encourage student talk. Taking as a case the situation of doing proofs in high school geometry and looking in particular at the setting of a task that might encourage student discussion, our results suggest that a majority of high school teachers approve of actions that encourage discussion (either in small groups or whole class form) even if these actions may depart from common practice. We have further evidence about the nature of the professional obligations that these teachers see either justifying the encouragement of talk or else justifying a normative action. In particular, we found that appeals to the disciplinary obligation featured more often as justifications for those teachers who have more experience teaching geometry while the institutional obligation did so for teachers with less experience teaching geometry.

WHAT IS HAPPENING IN CALCULUS 1 CLASSES? THE STORY OF TWO MATHEMATICIANS

Dae S. Hong
University of Iowa
dae-hong@uiowa.edu

Kyong Mi Choi
University of Iowa
kyonngmi-choi@iowa.edu

This study examined class practices of two Calculus 1 classes to understand what really happens in the class. The mathematicians' and students' questions as well as tasks used in class were analyzed to examine students' opportunities to engage in cognitively demanding tasks and discussions. The findings of this study indicate that students in these particular calculus classes did not seem to have enough learning opportunities to explore high-level cognitively demanding questions, to experience multiple representations and alternative solutions, and to engage in meaningful discussions.

Keywords: Classroom Discourse; Instructional Activities and Practices; Post-Secondary Education

Introduction

Recent studies show that work–force demands for students with science, mathematics, and engineering backgrounds have increased in the last few decades, but the number of students pursuing these majors in the U.S. and other countries either remains constant or is declining (Hurtado, Eagan, & Chang, 2010). One influencing factor of pursing a degree in these areas is students' experiences in undergraduate mathematics, especially calculus classes (Ellis, Kelton & Rasmussen, 2014). Since the nature of classroom teaching significantly influences how students learn mathematics (Hiebert & Grouws, 2007), it is important to know what transpires in calculus classrooms. Here are the research questions that we attempt to answer.

- What types of questions, in terms of cognitive demand and mathematical content, are asked by both the calculus instructor and students?
- What types of representations are presented in Calculus 1 class?
- What discourse patterns are found when various calculus concepts are introduced to students?

Related Literature

Studies on calculus teaching and learning

The overall consensus among calculus studies is that students do not have full conceptual understanding of various calculus concepts (Bezuidenhout, 2001). There has been criticism that calculus students' understanding is heavily procedural and algebraic without conceptual depth (Swinyard, 2011). In a recent calculus study by Ellis and her colleagues (2014) showed that "Good and progressive teaching" includes listening to students, presenting more than one method of solving problems, and more actively engaging students.

Theoretical Framework

It is very complex to understand classroom practices because it is both an individual and social process (Sfard, 2001). Mathematical tasks and questions should also be examined to understand class practices (Franke et al., 2007). Providing worthwhile tasks is a critical part of class practices (Boston, 2012). Teachers can provide productive discourse when tasks enable students to connect various mathematical ideas with multiple representations and alternate solution strategies (Franke et al., 2007).

Methodology

Setting, Data Collection and Analysis

The setting for this study was a Midwestern research university in the United States. Two mathematicians, Jenny and Tom[1], have a PhD in mathematics. All calculus classes were videotaped in 2014. In total, we collected 59 video clips. In all, we analyzed 602 questions by the mathematicians, 370 tasks, 32 student questions, and 91 calculus concepts.

Categories of Analysis

The analytic framework used for this study was based on previous studies that examined class practices and class observation theory (Boston, 2012; Franke et al., 2007).

Analyzing Questions

A two-dimensional framework was used to analyze each question – cognitive demand and mathematical content. We carefully analyzed the cognitive demand of each question asked by both mathematicians and students. In addition to cognitive demand, we examined the mathematical content (algebra or calculus) of each question. Lacking understanding of algebra concepts is one difficulty for calculus students (White & Mitchelmore, 1996). Tables 1 illustrate each example.

Table 1Questions by Code

	Mathematical Content	
	Algebra	Calculus
Higher level Cognitive Demand		Task: Understanding the derivative of a function. Question: What does it mean to have slope of tangent is zero?
Lower Level Cognitive Demand	Task: Find the slope of the tangent to $f(x) = x^2$ at $x = 2$. Question: (after graph was sketched) What is the y – coordinate?	Task: understanding anti-derivative. Question: What function would be an anti-derivative of x?

Representations and Alternate Solution Methods of Implemented Mathematical Tasks

Providing multiple representations to students has been emphasized in calculus teaching (Haciomeroglu et al., 2010). Thus, we paid attention to types of representations used to solve implemented tasks. Whether alternate solution methods were presented to students or not was also examined.

Presenting Concepts, Theorems, and Properties in Calculus 1

One interesting finding from a very well–known classroom-based study, the **Trends in International Mathematics and Science Study (**TIMSS) video study, is the way mathematical concepts are presented to students. In U.S., compared to other countries, large number of concepts (78 %) were presented to students without being developed (Stigler & Hiebert, 1999). We also paid attention to how these concepts and rules were presented to students.

Coding Reliability

After the codes were set for analysis, we went over each code carefully to fully understand their meanings. The second author and the third rater, a doctoral student in mathematics education, were trained to code the questions, tasks, and segments. Both authors and the doctoral student in mathematics education viewedthe video clips several times to code each question and task. Next, the three raters coded each segment independently and discussed the discrepancies. When the two authors disagreed, those items were coded based on majority rule using the third rater's codes. There were no questions or tasks in which all three raters disagreed. The percent agreement of the three raters was between 93% and 96% for questions and tasks.

Results

In this section, we present results of our analysis.

Analysis of Questions

There is a large difference in the number of questions asked by the two mathematicians. Jenny asked 17.5 questions per lesson while Tom only asked 1 question per lesson. The way Tom taught his classes, which were mostly lecture based, could account for this. Over 80% of their questions required low cognitive demand, meaning that many questions asked by both mathematicians were about simple recall and/or procedures. A question such as "What is the derivative of x^1?" only requires procedural knowledge of finding the derivatives of simple function. On the other hand, to answer "Can anyone explain why the derivative of a constant function is zero?", students need to think about rate of change, slopes, and the derivative.

In Jenny's lessons, algebra and calculus related questions were asked a comparable number of times, where 269 (46.6%) were algebra related and 276 (47.8%) were calculus related. About half of Jenny's questions were algebraic nature, which suggests that algebraic skills are necessary to solve some of the tasks in her calculus class. On the other hand, 76% of Tom's questions were about calculus; however, there were only 25 questions, about one per class, so it is difficult to come to a definite conclusion about Tom's questioning. A total of 27 questions were asked by Jenny's students in contrast to only 3 questions from Tom's students. These numberssuggest that regardless of cognitive demand and content, students had few opportunities to pose any questions. Out of the 27 questions asked by Jenny's students, none required high level cognitive demand and 25 were related to algebra concepts. Here is one question asked by Jenny's students. When the task, "Find the tangent line of $f(x) = \frac{(2x)}{x^2+1}$ $at\ x = 1$," was given, one student asked (after the derivative $\frac{(x^2+1)2-2(x)(2x)}{(x^2-1)^2}$ was found) "Why don't we cancel $x^2 + 1$?" This question is about finding the common denominator for rational expressions, an algebra topic. This indicates that the implemented tasks in their calculus classeswere about algebraic procedures or that they still lacked understanding of these algebra concepts. While we can say a few things about Jenny's students, it is very difficult to say anything about Tom's students because they asked only three questions. In Tom's class, opportunities to create norms by asking questions were too limited.

Analysis of Representations and Solution Strategies

The first notable finding from this table is the difference in the total number of tasks solved in each instructor's classes. The main reason that contributes to this is that Tom spent large portions of instructional time lecturing. Also, we can see that many implemented tasks were solved algebraically in both classes. It appears that opportunities to synthesize different representations were not often provided to these calculus students (21.6 %) . Furthermore, in both mathematicians' lessons, there were only few times, one time in Jenny's classes and three times on Tom's classes, in the semester that alternate solution strategies were presented to students. In Jenny's lesson, the problem was to differentiate $\sqrt{x^2+1}$. She first stated that there were two functions, $f(x) = \sqrt{x}$ and $g(x) = x^2 + 1$, so that it can be solved by the chain rule, but in an alternate approach, she also noted that it can be written as $(x^2+1)^{\frac{1}{2}}$. Thus, it can be differentiated by the power rule. From these two ways, students not only saw how these two rules are related but they also reviewed the algebra topics of the law of exponents. However, such opportunities were very rare in this calculus class.

Concepts Presented without Development

In total, there were 46 calculus concepts, theorems, and rules presented to students during the semester in Jenny's class while 45 were presented to Tom's students. Among these, 29 (63%) were not developed and simply stated by Jenny while 30 (66.7 %) were developed in Tom's class

In all, there were differences in class discourse when various calculus concepts and rules were introduced. The fact that more than 60% of calculus concepts were not developed in Jenny's class and 98% of concepts were either developed *uni–directionally* or not developed (30 were developed *uni–directionally* and 14 were not developed) indicates that it is rare for students to express, reason, and evaluate their own or someone else's mathematical thinking when these concepts were presented in class.

Discussion and Conclusion

Results of this study reveal that calculus students may not have opportunities to answer high level cognitive demanding questions, experience multiple representations and alternate solutions, and engage in meaningful discussions. Moreover, many calculus concepts, theorems, and rules were introduced either not being developed in any way or developed *uni–directionally* by the mathematicians. Since opportunities to engage in meaningful discussions and tasks are limited, it may be difficult to establish norms − acceptable and adequate mathematical answers, interaction, and activities in classes. Finally, an important question we need to ask is, Can we find similar results from other calculus instructors' classes? More studies that examine other calculus instructors' classes will be needed to fully understand what needs to be done to improve calculus teaching.

SUPPORTING FRACTION OPERATION ALGORITHM DEVELOPMENT: NUMBER SENSE AND THE ENACTMENT OF ADDITION

Debra I. Johanning
University of Toledo
debra.johanning@utoledo.edu

Lindsey R. Haubert
University of Toledo
lindsey.haubert@utoledo.edu

Number sense is a key component in being able to make sense of problem situations that involve fraction addition. Positioning students to invent algorithms for adding fractions involves their ability to use number sense-based reasoning. This paper offers five forms of mathematical interaction that teachers engaged in during classroom discussions to support student engagement in number sense-based reasoning when estimating fraction sums.

Keywords: Rational Numbers; Classroom Discourse; Instructional Activities and Practices

This study of teacher practice is situated in the context of fraction operations with a specific focus on number sense-based estimation in preparation for fraction addition and subtraction algorithm development. It is founded upon arguments that practice should have more attention in an effort to unpack the professional work teachers do in classrooms (Grossman et al., 2009). In an effort to understand teacher practice and the orchestration of mathematical discourse in the domain of fraction operations the following question was studied: What were the key mathematical ideas teachers elicited or accepted from student reasoning that framed mathematical conversations about students' number sense-based work related to fraction operation algorithm development for addition?

Background and Theoretical Framework

The literature on fraction number sense and operation development has revealed the struggles students have had related to fraction addition and subtraction (Petit, Laird & Marsden, 2010). For example, when asked to estimate in computational settings, students often want to compute an exact solution and then round that to the nearest benchmark. Students may also view the numerator and denominator of a fraction as individual numbers that are unrelated. In turn, students struggle to engage in number sense-based reasoning with fractions. Gravemeijer and van Galen (2003) differentiate between engaging students in the learning of algorithms as a process of building number sense and the direct teaching of algorithms. Instructional activities that support the construction of a network of number relations are a key part of the process where algorithms emerge from the development of number sense. Engaging students in modeling and representation use are also important components in the development of fraction number and operation sense (Petit, Laird & Marsden, 2010).

The findings reported here draw from the initial days in a fraction operation unit that began with a three to five-day task sequence for approximating and estimating sums of fractions that preceded a task sequence to draw out algorithmic strategies for adding and subtracting fractions. During the estimation sequence, it was not uncommon for students to fail to fold back and use fraction number sense developed in prior instructional units. It is argued that these moments represent common scenarios that emerge in classrooms when asking students to engage in number sense-based reasoning related to fraction addition and subtraction. This research will share five forms of mathematical interaction that teachers routinely used to position and support students when they struggled to engage in number sense-based reasoning.

Methodology

The settings for this qualitative study were the classrooms of four experienced skillful sixth-grade teachers and their students. Each teacher used the Connected Mathematics Project (CMP) II instructional unit *Bits and Pieces II: Using Fraction Operations* (Lappan, Fey, Fitzgerald, Friel & Phillips, 2006). The instructional unit used a guided-reinvention approach (Gravemeijer & van Galen, 2003) allowing algorithms to arise through student engagement with both contextual and number-based situations. During the teaching of the *Bits and Pieces II* unit, classroom lessons were videotaped each day during the five to six weeks it took to cover the unit. In addition, the teachers wore an audio recorder during each lesson. When a teacher completed a lesson, they audio recorded a short five-minute reflection about their teaching and student development during the lesson. The first researcher visited each classroom approximately once every ten days. This timeline was repeated across two school years. Data analysis was guided by Erickson's (1986) interpretive methods and participant observational fieldwork, which addresses the need to understand the social actions that take place in a setting.

Findings

There were five forms of mathematical interaction (see Figure 1) that occurred routinely in teachers' mathematical conversations with students when they were working on the three to five-day estimation sequence. These five forms of interaction are in response to common ways that students struggle in this mathematical domain. They suggest fraction-specific ways that teachers can support and further students' ability to reason with fractions and to make sense of what fraction addition is an enactment of. Two classroom examples will be used to illustrate the forms of interaction.

- Prompting students to rename benchmarks (0, 1/2, 1) in terms of specific fractional denominators;
- Developing and eliciting levels of precision: closest to a benchmark, greater than or less than a benchmark, or how far from a benchmark;
- Drawing out explicit distinction between exact and estimated solutions;
- Pressing for consideration of how estimated sums and exact sums are related; and
- Highlighting when estimation is used as a reasoning tool.

Figure 1: Five Forms of Mathematical Interaction Framing Number Sense-Based Estimation Instructional Conversations

Example 1: Making Fraction Strips To Think About "How Large" and "How Far"

At the start of the fraction operation unit, most students were able to reason about the size of an individual fraction in relation to benchmarks and other nearby quantities. However, the main focus of the instructional sequence was to engage students with reasoning about the approximate size of the sum of two or more quantities. One teacher provided grid paper to students who needed support to visualize fractions in relation to benchmarks (see Figure 2). For example, when trying to estimate whether the sum of 7/10 + 2/5 would be closer to 0, 1, 2, or 3, a student was directed to make a tenths strip and then locate and mark 0, 1/2, and 1 on the strip. Next, they labeled 0/10, 5/10, 10/10 and 7/10 on the strip. The student then marked, and labeled a strip for 2/5. This allowed the student to visualize and count how far 7/10 and 2/5 were from neighboring fractions.

This teacher was working to support a student who had not yet developed a strong visual sense of where individual fractions were located in relation to nearby benchmarks. Without this reasoning a student would struggle to understand what estimating a sum would entail and to use location and magnitude when estimating. This discussion highlights the first form of mathematical interaction: prompting students to reinterpret benchmarks in terms of specific fractional units being used (i.e.; tenths or fifths). This episode also highlights the second form of mathematical interaction: determining how far a fraction is from a benchmark. In addition, this work supported conversations about what an estimate was and how reasoning with quantities as locations is important.

Teacher: How far is 7/10 away from one whole?
Student: Three tenths.
Teacher: How far is it away from the 1/2?
Student: Two tenths.
Teacher: So which is it closer to?
Student: 1/2.
Teacher: How far is 2/5 from 0?
Student: Two fifths.
Teacher: How far away from 1/2 is it?
Student: Half of a fifth.
Teacher: Is 2/5 closer to 0, 1/2, or 1 whole?
Student: To 1/2.
Teacher: So would 7/10 + 2/5 be closer to 0, 1, 2 or 3?
Student: 1/2 + 1/2 would be 1. Closer to 1.

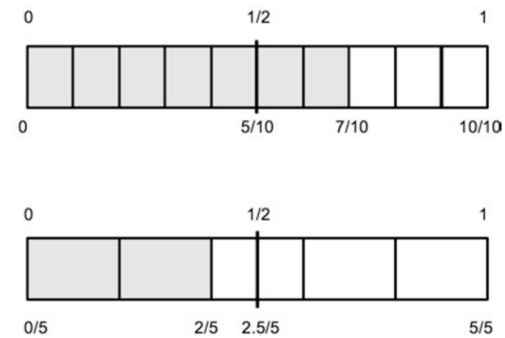

Figure 2. Discussion with Fraction Strips When Estimating Sum of 7/10 + 2/5.

Example 2: Plausibility of a Calculational Approach

This episode supports students to understand number sense-based estimation entails. In this episode students had been asked to think "about how big" the sum of 1/9 + 9/10 would be.

Teacher: Tell me where you would start. How big would the sum of 1/9 and 9/10 be?
Student: Well, first I would try to find a common denominator.
Teacher: I really don't want the exact answer. Can you tell me about how big it is?
Student: 10/20.
Teacher: Around 10/20 so about 1/2? Tell me how you did that.
Student: I thought 9 + 1 is 10.
Teacher: So you are doing 1+9 is 10.
Student: Yeah. Then I just thought on the bottom 9 + 10 was 19.
Teacher: Okay, about how big is 9/10?
Student: Almost a whole.
Teacher: And you think if I add something more to that [teacher points to 9/10] I am going to get around 1/2?
Student: Wait. No, that wouldn't [work].
Teacher: Yeah. It seems like it's going to be more than 1/2, doesn't it. So I think you were trying out a strategy like add these [numerators] and add these [denominators]. It didn't seem to work very well did it? Could you show this with some kind of model?

Another student then offered a strip model of 9/10. Pointing to the unmarked 1/10 of her fraction strip she said, "I knew that 1/9 is bigger than 1/10. So it would be over one. Maybe right here." She gestures to show how it would be a short distance beyond one whole.

At the beginning of the episode the first student showed awareness of how to calculate an exact sum using common denominators. He also correctly reasoned that 10/19 was about 1/2 and that 9/10 was about 1. In his struggle to understand what estimation involved, he tried adding numerators and adding denominators to calculate a sum. While he was able to think about magnitude and location for an individual fraction, he struggled to reason about the resulting location and magnitude of the fractional quantities when combined.

In this episode the teacher did multiple things to move the conversation forward and focus on using number sense-based reasoning. With the first student she utilized the third and fifth form of mathematical interaction. She made an explicit distinction between finding an exact sum and an estimate by stating, "I really don't want an exact answer". Second, she prompted the student to use number sense-based estimation as a reasoning tool to determine if his approach of adding numerators and adding denominators led to a reasonable result. When the second student offered reasoning that would allow one to consider how the estimated sum and the exact sum were related, the fourth form of mathematical interaction was utilized.

Discussion

The students highlighted in the cases represent learners a teacher might typically encounter. This includes students who are able to reason with individual fractions but not sums. The forms of interaction in Figure 1 offer ways teachers can support students to use number sense-based reasoning when adding fractions together. These interactions support the development of number relations. According to Gravemeijer and van Galen (2003), students' invented algorithms emerge from the development of a mathematical framework of number relations that they use as tools when solving problems. This focus on reasoning about the combining of fractions as quantities and as locations can help support reasoning needed if the goal is for students to develop valid computational strategies for adding fractions.

PRESERVICE TEACHERS' CRITIQUE OF TEACHER TALK

Ji-Eun Lee
Oakland University
lee2345@oakland.edu

Kyoung-Tae Kim
College of Central Florida
kimk@cf.edu

This study aimed to explore pre-service elementary teachers' (PSTs') conceptions of effective teacher talk in mathematics instruction through a two-phase task that involved analyzing and evaluating a sample teacher-student talk and developing alternative ways of communicating with students. Findings were interpreted in terms of PSTs' views of mathematics, their perceived roles in classroom discourse, and their conceptions of effective forms and functions of teacher talk. The outcome has implications for teacher education and future research in addressing this important aspect of mathematics teaching practice and opening up pedagogical possibilities for teacher educators.

Keywords: Teacher Education-Preservice; Classroom Discourse; Teacher Beliefs

Effective classroom communication calls for teachers to facilitate meaningful mathematical discourse and pose good questions. With this said, it is an important first step to identify teachers' conceptions of effective communication in a mathematics classroom. The purpose of this study is to explore PSTs' conceptions of effective communication in mathematics instruction through a series of tasks that involve analyzing and evaluating a sample teacher talk and developing alternative ways of communicating with students. Specifically, this study examines how the criteria PSTs used in analyzing, evaluating, and modifying a sample teacher-student talk reflect the following aspects: (1) PSTs' views of mathematics and teacher roles in classroom discourse and (2) PSTs' conceptions of effective forms and functions of teacher talk.

Theoretical Framework

Teachers' Views of Mathematics and Roles in Effective Classroom Discourse

Teachers' communications enacted in mathematics instruction are highly associated with their conceptions of teacher roles. Ernest (1989) categorized three different models of teaching mathematics by focusing on the teacher's role and intended outcome of instruction: (a) Teacher as an instructor: aims at skills mastery with correct performance, (b) Teacher as an explainer: aims at conceptual understanding with unified knowledge, and (c) Teacher as a facilitator: aims at confident problem posing and solving. Which of these roles the teacher adopts will have a great impact on the overall classroom communication and actions such as the teacher's questioning strategies or feedback patterns.

Forms and Functions of Teacher Talk

The analytical frameworks used in the previous research differ across various studies, and there is no prescribed equation for knowing what and when to say because teacher talk can be used for various purposes. In terms of cognitive level, higher-order versus lower-order thinking questions/prompts framework is frequently used. Whether the type of teacher question/prompt is open or closed is also frequently addressed in the prior studies. Generally, the more open questions/prompts, which are designed to ensure that multiple answers are valid and valued, the more they will identify the students' mathematical understanding and abilities (e.g., Blosser, 2000). However, studies also comment that posing open-ended questions alone is not a sufficient condition to initiate an explorative interaction for investigating the child's own understanding of mathematical knowledge. In this regard, researchers suggest that it is necessary to distinguish between form and function when analyzing and evaluating teacher-student interactions (Wells, 1999 cited in Mercer & Dawes, 2014).

Methods

Participants

Data from this study came from 46 PSTs who enrolled in a K-8 mathematics methods course at a Midwestern university in the United State. For most of PSTs, it was one of their last two semesters before student teaching.

Tasks and Data Collection

The following short transcription of the teacher-student talk was provided for PSTs to analyze and evaluate.

Given Question: The price of a video game is $60. You want to buy it using a 20 % off coupon. How much should you pay for the video game?

S_1: Do I have to worry about taxes?
T_1: No, we're just calculating the price.
S_2: Price is $60 and I have a 20 % off coupon…
T_2: So what are we supposed to do with that coupon? Multiply? Divide? Add? Subtract?
S_3: I have to find out what 20% of 60 is, right?
T_3: That's right! So how do we do that?
S_4: Multiply, I think. I need to do 60 times 20, right?
T_4: Well, sort of. If wanted to know what 20 times 60 was, yes...but what am I actually looking for? You just said it a few seconds ago.
S_5: I want to find what 20% OF 60 is.
T_5: Yes! So we need to do something other than just multiply them. Remember the rule, what way do we move the decimal?
S_6: To the left.
T_6: How far?
S_7: 2 places.
T_7: You got it!
S_8: But what if it is already a decimal, like .5%?
T_8: The rule never changes, still 2 spots to the left.
S_9: Ok, so I have to make 20% .20 and multiply it by 60. (When the student does the math, he sets it up correctly but gets 1200 and looks at it confused for a minute.)
T_9: So what's wrong with that?
S_{10}: It's way too big. How can it be bigger than the price of the game?
T_{10}: See now this is why I ask you guys all to show your work!! Let's look back at your math.
S_{11}: Ok. I multiplied zero by each number, then 2 by each number and I get one, two, zero, zero….wait, the decimal point! I forgot about it.
T_{11}: Yes! You got it, so where does it go?
S_{12}: Well there are two places to the right so I need to move it two places over, $12.00 is the discount then?
T_{12}: Yep! So how much would you be paying?
S_{13}: I need to subtract that now from the first price so it would be ….$48.00 for the game?

Using this sample teacher-student talk, PSTs were asked to engage in two tasks.

Task 1: Critique of sample teacher-student talk. PSTs were asked to comment on/evaluate each of the teacher's statements (T_1 ~ T_{12}). PSTs first indicated whether they evaluated it positively or negatively and then provided their justifications to explain their evaluation. They were also asked to suggest alternative statements for the negatively evaluated statements.

Task 2: Small group discussions for revisions of the sample teacher-student talk. Small groups were formed for this task. Each group needed to reach a consensus if they wanted to replace the original teacher statement. If a group was unable to reach a consensus, they were asked to note why it could not be resolved. Each group's final revision was shared with the researcher in a small group discussion setting.

Data Analysis

PSTs' written responses from Task 1 were analyzed using an inductive content analysis approach (Grbich, 2007). Thus, throughout the data set, each sentence was coded for whether it referenced in some way the categories identified. At the completion of coding, frequencies of coded themes were identified. The data from Task 2 were analyzed descriptively, highlighting the features of teacher talk on which PSTs agreed or disagreed.

Results

Table 1 shows the major themes found in the PSTs' evaluations of the sample teacher talk in Task 1.

Table 1:Aspects considered in evaluating the sample teacher-student talk

A. Interpersonal skill	A. Offering encouragement, compliments, reassurance (to provide emotional support)
B. Follow-up questions/prompts	B1. Asking for content-specific explanation (to press students to restate/ explain the math content)
	B2. Asking for procedure-specific explanation (to press students to recall mathematical procedures)
C. Format of questions/prompts	C1. Asking open-ended questions (to probe student thinking and make it explicit)
	C2. Asking close-ended questions (to get or guide to predetermined answers)
D. Language/word choices	D1. Using appropriate words/ expressions; non-mathematical in nature (to improve clarity/politeness)
	D2. Using correct math terms and concepts (to be mathematically precise)
E. Response to student work/question	E1. Offering clear directions (to avoid confusion)
	E2. Offering straightforward/ neutral responses (to avoid confusion, but not to be directive)
F. Information provided by teacher	E3. Confirming correctness of student work (to immediately confirm)
	F1. Refraining from talking or providing direct solutions (to encourage student's own thinking)
	F2. Offering detailed explanations (to offer more instruction and guidance)

Figure 1(a) shows the distribution of number of positive/negative comments on each teacher statement. T_4 and T_5 received the most comments from the PSTs, and the negative comments were the majority in the evaluation of these two teacher statements. While most statements received more negative comments than positive ones, there are several statements that received more positive comments than negative ones (e.g., T_3, T_7, and T_{11} for emotional support). Figure 1(b) shows the distribution of positive/negative comments per each theme. Theme A was most frequently used in the evaluative comments of the teacher statements. PSTs used this theme more to address positive aspects than negative aspects. Other themes used in positive evaluations also included C2 and E3. Most of the themes were more frequently used to negatively evaluate teacher statements, especially themes D1 and D2.

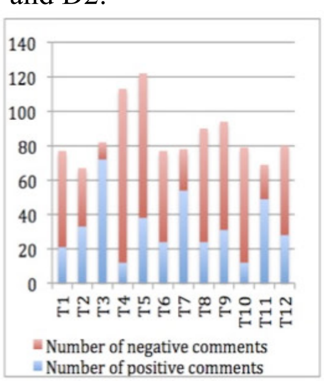

Figure 1: Frequencies per teacher statement

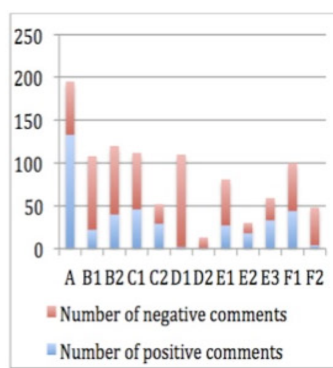

Figure 2: Frequencies per theme

There were several consenting improvements suggested in the group revision process (Results from Tasks 2). Those include the need to strengthen the following aspects: (a) checking for student prior knowledge, (b) increasing clarity/specifications, (c) asking for more explanations/justifications from the student, and (d) employing more positive tones. Several conflicts/disagreements noted in Task 2 were mainly focused on the following questions: (a) Who is responsible for learning? (b) What is the role of compliment? (c) When to stop probing questions in response to student struggles and confusions? (d) How to interpret students' mistakes?

Discussion and Implications

Teachers' Views of Mathematics and Roles in Effective Classroom Discourse

While the view of the teacher as a facilitator was a more supported view in Task 1, it was difficult to see the same pattern in Task 2. The small group discussion in Task 2 noted only minimal changes in the forms of teacher statement and also showed that even though PSTs shared similar views of mathematics and teacher role in mathematics communication, they revealed a wide range of differences on the quality and quantity of teacher talk and showed varied levels of struggles with deciding what should be the right amount of information or teacher assistance in specific contexts. One notable pattern in PSTs evaluations and modifications was that using vague languages were considered defects (e.g., $T_{4:}$ "Well sort of"). PSTs strongly revealed the 'teacher as a knower' view in this critique. The perception of "the traditional hierarchy of teacher as the autocratic knower and learner as the unknowing" (Fosnot, 2005, p. ix) seems to be still prevalent among the PSTs. Many PSTs noted that this kind of vague teacher statement would cause student confusion by implying confusion as a negative experience to be avoided.

Forms and Functions of Teacher Talk

Despite the acknowledgement of various forms/functions in Task 1, many PSTs did not fully demonstrate a deep understanding of the pedagogical moves, nor an ability to plan for effective alternative statements. Disagreements/conflicts within group discussions in Task 2 were usually raised by a small number of PSTs. This implies that although the PSTs have already been familiar with many features/forms of effective classroom talk and many have entertained the idea of facilitating effective classroom talk, they seemed to be unsure of what it actually looked like or how it functioned in context.

This study provides a window into the potential roadblocks for PSTs to shape the nature of their classroom talk. It is anticipated that the patterns identified in this study would provide teacher educators with insights into how they can better offer the opportunities to learn to teach. Reflection and critical discussion in the teacher education program that scaffold new understandings about the pedagogical knowledge teachers should have will eventually help PSTs develop the foundation for their professional career.

Using interactional analysis we examined the content of interactions during a whole group discussion in a 9th grade geometry classroom with the intent to identify the teachers' modes of intervention as he tried to engage students in criticizing two mathematical arguments raised in proving uniqueness of midpoint of a line segment. The teacher's multiple invitations for engaging students in identifying problems with the two arguments were not well received.

Keywords: Classroom Discourse; High School Education; Cognition; Reasoning and Proof

Introduction

It is widely agreed that peer interaction and group discussions can positively influence the growth of mathematical understanding among learners. A major interest in mathematics education community is describing modes of teacher intervention that allow for development of productive interactions leading to increased learning for all students. Analysis of teachers' practices according to the type of learning opportunities they attempt to create is far more useful than judging learning outcomes instantaneously, since time and space may be needed for learning to manifest.

In this work we examined the practices of a teacher and his attempts at structuring students' reflections on, and analysis of the validity of two arguments that were offered as proofs to a mathematical proposition. Two inter-related questions guided our analysis: What type of mathematical actions does the teacher try to enable in the course of his interventions during the large group interactions? What results from the teacher's interventions?

Literature Review and Theoretical Grounding

Kahveci and Imamoglu (2007) proposed that all instructional interactions have the purposes of increasing participation, developing communication, receiving feedback, enhancing elaboration and retention, supporting learner control and self-regulation, increasing motivation, team building, discovering, exploring, clarifying understanding, and/or closure (p.139). In synthesizing factors considered in studies concerning classroom interactions and mathematics learning the authors included: Structure of lessons, norms/context established and maintained for judging mathematical arguments, student motivation to learn, teacher goals and teacher knowledge, how the teacher interacts with students or leads discussion, and physical and social environment of the classroom. As it pertains to the activities of the teacher in the course of interactions, some studies have focused on unpacking teacher talk within the whole or small group settings (Cobb & Bausersfeld, 1995), while others have captured the strategies that teachers used (or did not use) or the knowledge bases from which they drew (or could draw) while doing so (Stein et al., 2008). Not all these reports though focus on the activity of teaching focused on supporting inquiry or conceptual development among learners. For instance, Sinclair (2005) reported on study conducted by Towers (1999) in which the investigator catalogued twelve intervention strategies used by teachers when interacting with students:(1) managing—carrying out administrative and disciplinary work, (2) checking—asking if the student understands, (3) enculturating—introducing students to terminology and processes used in the mathematics community, (4) reinforcing—stressing an idea, (5) clue-giving—deliberately pointing the student to the correct answer or path, (6) anticipating—trying to prevent the student from making a mistake, (7) blocking—stopping a student from following a particular path, (8) inviting—suggesting "a new and potentially fruitful avenue of exploration" (p. 201), (9) modeling—

providing an example of the teacher's own approach, (10) rug-pulling—deliberately introducing a puzzling idea, (11) retreating—walking away and allowing the student to think further, and (12) praising.(Sinclair 2005, page 90). According to Towers the strategies of "rug-pulling" and "inviting" were most effective in facilitating growth of understanding in mathematics (Sinclair, 2005, pg. 91). Nonetheless, Sinclair reported that the teachers in Towers' study were not particularly concerned about nurturing student centered learning.

Wagner (1994) defined identified two specific purposes associated with instructional interactions: to change learners and to move them toward an action state of goal attainment. (p.8). This spontaneous acting and reacting towards increasing understanding in mathematics classrooms is what Cobb and Bauersfeld (1995) characterized as co-learning, "a process of mutual adaptation wherein individuals negotiate meanings by continually modifying their interpretations" (p. 8). As such the teacher is recognized as a co-learner in the classroom enterprise. It is this perspective that guided our data analysis.

Methodology

The case on which we based our analysis for this report is grounded in data from one session in one 9th grade geometry classroom taught by Mr. Chris, a highly qualified teacher who stressed the importance of student-centered instruction and utilized it in his lessons daily. The session that became the focus of our analysis was a part of an instructional unit on logical reasoning and lasted approximately two weeks. During this session the students were asked to consider three propositions and to prove or disprove them (Diagonals of regular pentagons are of equal length; Angle bisectors of rectangles are concurrent, A line segment has only one midpoint). Approximately 20 minutes of the class time was devoted to small group work on the tasks. The whole group discussion of the first two propositions progressed quickly as all students had identified counter-examples to each of the two statements. The discussion of the third proposition however, became complicated due to the group's lack of willingness to conform to the teacher's goal of registering flaws in two arguments presented in class. The teacher's struggle to avoid direct instruction and the students' reluctance to comply to the teachers' requests provided a fruitful ground for careful analysis of interactions.

Data Analysis

Data Analysis consisted of three phases. First, an interactional diagram was constructed to capture the group's exchanges, depicting turns in discourse by the contributing members, highlighting episodes of "action-reaction" during the interactional event. Since the goal of our research was to catalogue the teacher's types of interventions during the whole group interactional episode as a starting point in our coding process we used Towers' (1995, cited in Sinclair) typology of interventional strategies. Particular Teacher's interventions that did not fit Towers' typology were identified accordingly. Lastly we considered the students' reactions to the comments that the teacher made so to trace how his comments influenced their thinking.

Results

The session included a total of 70 turns. Eleven of the 33 teacher utterances either *invited* students to *reflect on* arguments or aimed to *provok*e them to examine ideas more carefully. 8 of his comments challenged students' claims. 3 comments *reinforced* socio-mathematical norms of reasoning and thinking in his class. Two comments attempted to provide a structure for students' thinking as he asked them to recall specific events from previous class sessions. The remaining comments were either reflective of his own thinking or provided evidence of his reflecting on arguments raised in group. Here we also counted the teacher's prolonged silences as another interventional strategy since they were perceived as invitations for extended thinking.

Although the majority of the teacher's comments intended to gauge students towards identifying flaws in reasoning of peers his pleas were not well received. Throughout the whole group dialogues students reflected on each other's and their own ideas, provided additional explanations and refined their previously stated ideas. They referenced and verified knowledge and conventions by examining textbook definitions; they considered consequences of definitions and re-stated their ideas in presence of anomalous results from their search and yet throughout the episode students resisted the teacher's persistence that their peers' arguments be confronted.

Uniqueness of the midpoint

The whole group discussion began as one student (S1) presented her group's argument for why a line segment can have only one midpoint. Their method consisted of drawing 5 segments of varying lengths and then using a ruler they had marked the midpoint of each segment. The group then argued that since the midpoint moved with the segment then there was only one midpoint for each segment (S1). Although the teacher recognized that this mode of reasoning was not a proof he was unsure of how to respond to it during the group deliberations. During this segment the teacher's comments were primarily reflective (turns 2,3,4), disclosing his desire to learn more about how the students had resorted to this approach (turns 6), or his appreciation for the connections that the students had made to the work previously done in class (turns 8, 10). He also expressed his confusion about how to react to the argument and that he needed time to contemplate the idea (turn 13, 15). Indeed the first six minutes of the whole group discussion were devoted to the teacher seeking space to think about the proposed argument and in doing so he even appealed to the group for help (turn 10). Interestingly, despite the fact that the students did not object to the first group's argument they appeared to respect the teacher's need for thinking since a member of another group asked if they could present their method (turn 14). This delicate intervention resonated Towers' *retreating* strategy, though the strategy was enacted by the students, in reaction to their acknowledgement of the teacher's need for space to think.

During the second segment of the whole group discussion a second argument was offered: since in a triangle from each vertex only one median could be constructed and that since a median demanded a midpoint then it "proved" uniqueness of the midpoint. The teacher invited students to respond to the new argument while acknowledging that he was still thinking about the first group's reasoning (t 19, 21, 24) and yet the group defended the validity of their peers' arguments and expressed that they found both reasonable and convincing. The teacher was solitary in his quest to reveal flaws in reasoning and in doing so he attempted to provide learning opportunities for students to realize and share his mathematical goal. Indeed, among the 15 student utterances expressed during the second segment 9 were statement of peer approvals (t 18,20,21, 23, 26, 29). Rather than confronting the arguments of the two groups the teacher then resorted to a different strategy and asked if other students had used different approaches to proving the proposition (t 28). It was during the third segment of the episode that he became more explicit in his judgment of the arguments. He asked the students to consider specific assumptions that each group had made and in examining the assumptions he asked that they revisit definitions and conventions.

Refinement and Resistance

The third segment of the session marked the teacher's direct attempts at pointing out areas in at least one of the arguments that needed careful attention. He asked students to identify the specific assumptions that the second presenting group had made (turn 32). In response to this call, members of the first group offered further explanation for why their argument was true (turn 37). The additional explanations they provided indeed resembled proof by contradiction. Nonetheless, the discussion returned to whether uniqueness was a part of the definition of the median, as one student in defense of the second's group's argument stated (turn 38, 39). Pleading to the norms of practice in his classroom the teacher reminded students that in presence of even one disagreement then claims to definitions needed to be carefully verified and in doing so he reminded students that they must distinguish statements of definitions from consequences of those definitions (turn 51). Despite these efforts the group remains unsure of the teacher's expectation (turn 52, 53, 54, 56). Only one student responds to the teacher (turn 55) and yet his comment goes unnoticed by peers. During the last segment of the session, and as a final resort the teacher asked the students to recall what they had done in class the previous week and in doing so he appealed to their memory as a strategy for structuring their activities (turn 61, 64), which he ultimately used to engage the students in revisiting both arguments (turn 70). Students' responses to the teacher's comments indicated their awareness of what the teacher intended for them to consider as they stated specific memories they had attached to the mathematics discussed in class (turn 67, 67, 69).

Discussion

In the case we presented here, the teacher's desire to refrain from dictating what technique students may use to prove the proposition he had assigned certainly created an environment for students to think, reflect, and in some cases make connections and explore ideas they had not considered themselves. The learners were in tune with the arguments that their peers had raised and yet they were not responsive to the teacher's pleas for conforming to reason and convention; they were not alert to the mathematical performance they were expected to display. Their cognition was only shifted in presence of the teacher's plea to collective memory and remembering. Here, of course, we do not make a claim that the students came to identify theirs and their peers' arguments as less convincing or even flawed, only that the collective remembering provided them with a platform for understanding the teacher's expectations for their mathematical work. It remains unclear, considering the multitude of research on learners' difficulties with proofs and proving what modes of teacher interventions might be fruitful in advancing learning while supporting student autonomy. Studying classroom interactions using content as a lens for analysis of forms and types of interventions is highly needed.

We discuss findings from a study of 226 K-12 mathematics teachers who rated the appropriateness of instructional actions in a scenario-based assessment. The teaching actions shown in the scenarios were designed to represent mathematics teachers fulfilling their obligation to the discipline of mathematics. Our analysis of the participants' follow-up responses provides insight into how other professional obligations interact with teachers' obligation to the discipline. We describe our method for detecting what we call conditional construals—assumptions participants regarded as critical for rating the appropriateness of instructional actions. In addition, we report preliminary findings about how those assumptions can be accounted for in terms of the professional obligations of mathematics teaching.

Keywords: Instructional Activities and Practices; Teacher Knowledge; Teacher Beliefs; Research Methods

Introduction

Scenario-based assessments are widely used to assess judgment in professional fields, such as medicine, police work, army tactics, and human resources (Weekley & Polyhardt, 2006). In this study, we analyzed a set of open-ended responses to scenario-based assessment items of K-12 mathematics teaching. Open responses from participating teachers followed forced-choice ratings of instructional actions shown within scenarios of K-12 mathematics classrooms. There were two parts to the analysis. The first part of the analysis involved validating a procedure for identifying when a response contained linguistic markers that indicated that the appropriateness of an instructional action was dependent on an element of the scenario (e.g., traits of the students, the amount of available time, the content that had been previously covered) that was unspecified in the representation that they viewed. We call such markers *conditional construals.* For the first part of the analysis, we analyzed responses from 226 teachers to 15 items (*n*=3405) designed to probe teachers' professional obligation to the discipline of mathematics (Herbst & Chazan, 2012). The second part of the analysis was a qualitative examination of the kinds of additional information participants stated they would need to know about a scenario in order to rate the appropriateness of an instructional action. The qualitative analysis examined the responses to 2 of the 15 items that had the highest incidence of responses that contained a conditional construal. In this paper we report on the results of the preliminary qualitative analysis of the responses to these 2 high construal items.

We looked for additional aspects of the represented scenario that teachers considered critical in deciding whether an action was appropriate. The following research questions guided our inquiry: 1) What types of assumptions do teachers make in order to justify instructional decisions that respond to a professional obligation to the discipline? 2) How do the different professional obligations support or constrain teachers' departures from "business as usual" in favor of their obligation to the discipline of mathematics? Our purpose with this study is to investigate the types of assumptions teachers make when considering instructional actions that respond to the professional obligation to the discipline of mathematics.

Theoretical Framework for Research

Herbst and Chazan's (2012) account of the *practical rationality of mathematics teaching*attempts to synthesize rational actor theories of teacher decision making (e.g., Calderhead, 1996; Schoenfeld, 2010) with accounts of teaching as a sociocultural activity (Stigler & Hiebert, 1999). Herbst and Chazan (2012) propose that while teachers have personal resources such as knowledge and beliefs, teachers also play roles in activity systems (e.g., algebra instruction) that have customary norms (Much & Shweder, 1978). Within such activity systems, teachers are accountable to four professional obligations—to the discipline of mathematics, to individual students, to the classroom community, and to the institutions of schooling (Herbst & Chazan, 2012). While actions following customary norms may be enacted without reflection, a teacher's deviations from those norms, whether motivated by individual resources or in response to social demands, need justification (Buchmann, 1986). Herbst and Chazan (2012) argue that the four obligations provide a basis for the sources of professional justification. For example, while the obligation to the discipline of mathematics would require a teacher to limit the range of symbolic strings that she allows herself to call *equations* (e.g., $2x = 5$ is an equation but $3x -7$ is not an equation), this same obligation could also justify her calling *equation* a symbolic string like $2^x = x^2$ in spite of the fact that the beginner's algebra curriculum might not include it under the equations that algebra students learn to solve (Herbst & Chazan, 2012).

While much work has been carried out to establish links between teachers' beliefs and conceptions about mathematics and instructional practices (Skott, 2001; Stipek et al., 2001), the notion of *practical rationalit*y suggests that teachers' decision-making is not driven by individual resources alone. Rather, teachers' decisions are context-dependent and a fuller understanding of the resources that they can employ for departing from normative practice can be achieved through the use of instruments that represent the situated nature of practice. As such, we approach the work of understanding teachers' decision making by presenting them with scenarios of instruction in which the represented teacher departs from instructional norms in order to act on behalf of the professional obligation to the discipline.

Methodology

We conducted our study on data collected from K-12 inservice mathematics teachers with a 15 item scenario-based instrument designed to measure recognition of teachers' professional obligation to the discipline of mathematics. Within each item, participants examined a scenario in which a teacher departs from an instructional norm in order to attend to one of the professional obligations. Participants were asked to rate the extent of their agreement (using a 6-point Likert-like response format from strongly disagree to strongly agree) with the teacher's action. Participants were then prompted to comment on their ratings. In order to identify conditional construals in these responses, we located *circumstances of contingency* (Halliday & Matthiessen, 2004, p. 271) which are accompanied by linguistic markers such as "depending on", "as long as", and "assuming". In particular, we examined the nominal group introduced by the circumstances of contingency. These nominal groups are usually "a noun denoting an entity whose existence is conditional, a noun denoting an event that might eventuate, or a nominalization denoting a reified process or quality" (Halliday & Matthiessen, 2004, p. 272). We present an example with the following response, "This depends on timing. I think it can be valuable information for students to see common errors played out in a solution, but time will dictate whether or not that can happen in any given scenario." We argue that "timing" is marked here as a circumstance of contingency by the prepositional phrase "this depends on". We then categorized those circumstances by professional obligation. In this example, we placed the conditional construal in the *institutional* category because the participant indicates that the appropriateness of the action is contingent on the amount of time available, and time constraints are imposed by the institution.

Findings

We found that teachers consider the other obligations—to the students as individuals, to the classroom community, and to the institution—as they consider whether to respond to their professional obligation to the discipline of mathematics. We illustrate these categories of conditional construals by sharing teachers' responses from the two items with the highest number of responses that contained conditional construals. The analysis reported below qualitatively assesses the content of these conditional construals, with respect to the professional obligations.

In the first item, participants view a scenario in which the teacher announces that students seem to be on the right track and, rather than spend time on practice problems (which we hypothesize would be the normative action in such a situation), the teacher decides to discuss mathematical theory related to the topic at hand. Participants were asked to rate the statement: "The teacher should give students additional practice problems, rather than elaborate on mathematical theory." Of the 226 participant responses, 16% indicated that their decision depended on assumptions they had made about the scenario. In the second item, participants viewed a scenario in which a student makes a mistake while working a problem at the board; rather than point out the mistake directly (which we hypothesize would be the normative action in such a situation), the teacher allows the student to build on the mistake. Such an action could be justifiable on the disciplinary grounds that the teacher is creating an opportunity for a contradiction or anomaly to arise from mathematical reasoning that builds on the mistake. Participants were asked to rate the statement: "The teacher should correct the mistake observed, rather than ask students to build on mistaken work," and we found that 7% of the participants indicated that their decision depended on assumptions they made about the scenario.

These items highlight the variety of factors that teachers consider in order to make instructional decisions that respond to the disciplinary obligation and demonstrate how the role of the other professional obligations can vary depending on the scenario. For example, while there were 30 participants who referenced the individual obligation in their responses to the first item, the individual obligation was used in different ways. One perspective suggested that knowing the "level" of the class is essential for determining whether or not a particular instructional action is appropriate; another perspective suggested that it was of primary importance to determine whether students had been taught relevant information. While these are both manifestations of the obligation to the individual student, they have different implications for how the teacher perceives the agency of the students and the responsibility of the teacher. Such differences manifested themselves across items as well: In the case of the first item, there were 30 references to the individual obligation, but there were only 9 references to the individual obligation for the second item. Ongoing analysis is being to conducted to perceive patterns in the way each of the obligations are manifested within participants' construals.

Study's Significance

Mathematics instruction is beholden to the discipline of mathematics as the source of legitimacy of the knowledge at stake in the classroom as well as the practices that govern the development of that knowledge. Nonetheless, there is often a tension between the type of instruction advocated by mathematicians and mathematics educators and the everyday reality of K-12 education (Schoenfeld, 2004). We have demonstrated how we have been able to collect a corpus of data from K-12 teachers of mathematics describing the circumstances that dictate whether they approve of a fellow teacher departing from customary classroom practice in order to respond to their perceived professional obligation to the discipline of mathematics. Our analysis of that corpus suggests that, for these teachers, their professional obligation to the individual students (e.g. students' understanding), to the discipline of mathematics (e.g. mathematical value), to the classroom community (e.g. class norms), and to the institution of school (e.g. time) all have a bearing on their approval of such decisions. It remains an open question for us whether individual differences account for part of the variance in participants' conditional construals. To explore this, we could examine how proxies for such differences, such as mathematical knowledge for teaching and experience, are related to the ways that they see the professional obligations impinging on their practice.

While surveys of teachers' beliefs about mathematics provide one way of conceptualizing how the discipline of mathematics may influence instructional decisions, our work presents a different approach by suggesting that there are aspects of the professional position (for example, the need to teach a given curriculum, a limited allowance of time, the characteristics of the class being taught, the various characteristics and needs of individuals one is assigned to teach) that may mediate a teachers' willingness to respond to the discipline regardless of their beliefs about the subject. As a better model is developed of the way that the professional obligations interact both with one another and with personal resources of the mathematics teacher, and as the different aspects of the professional obligations themselves are further analyzed as we have begun to do here, we will be closer to being able to understand the hidden factors that obstruct or facilitate the take-up of instructional practices that depart from the norm in order to align with the discipline of mathematics.

TRACING STUDENTS' ACCOUNTABILITY AND EMPOWERMENT IN AN ONLINE SYNCHRONOUS ENVIRONMENT

Kate O'Hara
Cleveland State University
kateohara222@gmail.com

This study traced students' chat and whiteboard interactions in an online, synchronous environment as they collaborated to solve cognitively demanding, open-ended mathematical problems. The objective was to document the emergence of discourse that showed accountability to a community of practice when doing thoughtful mathematics. Findings also revealed that the students transitioned into empowering stances about their ability to think mathematically. The pedagogic conditions under which the students worked and how those influenced students' development as a learning community are also discussed.

Keywords: Classroom Discourse; Problem Solving; Technology

Purpose

As Ernest (2002) indicates, there is a need to research teaching practices that encourage student accountability and empowerment in mathematics education. With the increased demand for online learning, it is critical to understand how these attributes can be fostered in online synchronous environments (Stahl, 2009). The online learning environment can be designed for students to engage in the mathematics on their own terms. Yet issues and challenges may arise as students figure out how to collaborate and, ideally, form a learning community. The purpose of this study was to engage students from diverse backgrounds in doing thoughtful mathematics by working to solve open-ended problems and justify their approaches and solutions. Through capturing students' chat and whiteboard representations, researchers traced their discursive interactions and mathematical reasoning to seek evidence of empowerment and accountability.

Theoretical Perspective

This study is rooted in sociocultural theory that highlights the meditative role of social interaction in the development of individual knowledge (Vygotsky, 1978).This perspective acknowledges that learners actively construct knowledge and that their knowledge is constantly modified by their social interactions. It is further posited that (a) students need to be engaged to support the transfer of knowledge; (b) engagement is best accomplished through discourse and a sense of belonging to a community of learners; and (c) this can be an empowering experience for students. Through practicing mathematics collaboratively, students increase their own accountability, and that leads to a strengthened empowerment over the subject of mathematics.

Michaels, O'Connor and Resnick (2008) propose three forms of accountability in the classroom: accountability to the learning community, accountability to accepted standards of reasoning, and accountability to knowledge. Their research also draws on constructivist and sociocultural principles that emphasize the importance of learning through discussion. In accountability to the learning community, participants listen to each another, build on each another's ideas, and question each other to expand upon their own individual ideas. Accountability to accepted standards of reasoning emphasizes logical connections and the drawing of logical conclusions that occur during interactive reasoning and discussion. The third and most complex form, accountability to the knowledge, depends upon the accurate use of facts and knowledge in the discussion. One focus of this study was on the students' accountability to a learning community as they shifted away from individual, competitive work and more towards a collaborative group sharing of mathematical ideas.

The second focus, empowerment, can be divided into two domains: mathematical and epistemological. Mathematical empowerment is a social process of acquiring facility in talking about mathematics, using its specialized language, and gaining proficiency in using and applying mathematics (Ernest, 2002). Mathematical empowerment occurs over time as a result of social interactions and achievement in a mathematics classroom. Epistemological empowerment concerns the individual's growth in confidence: the development of a personal identity so as to become a more personally empowered person. As Ernest (2002) contends, students cannot be autonomous learners or think critically without first becoming empowered. To foster student empowerment, an environment must first allow them to overcome internal inhibitions and perceptions of inadequacy. Classroom practices can facilitate the process of encouraging students to assume responsibility for their learning (Stinson, 2004).

Methods

The data for this report is a subset of a larger data corpus. Total participants consisted of 17 seniors from two different high schools in New Jersey. Eight of the students were from an urban public high school, and the remaining nine students were from a suburban private high school. Twice a month, during their regular class time, they participated in the research project by solving mathematical tasks in the online environment, called Virtual Math Teams (VMT). The VMT project was a NSF-funded research program designed to investigate sustained collaborative problem solving in a computer-supported environment. Its two main interactive components are a shared drawing board, referred to as a workspace, and a chat window. All VMT sessions were observed while the students worked on tasks, as well as afterward, and chat discussions were downloaded for coding. Students worked on open-ended combinatorial tasks not seen in their traditional mathematics classroom.

Online chat discussions were coded for accountability to their learning community and mathematical and epistemological empowerment. Coding identified the nature of the chat in order to observe whether there were shifts in their behavior during the six sessions. Chat statements that built on the efforts of the group as they solved the mathematical task were coded as accountable to the learning community. Examples include (a) encouraging one another to join or continue efforts in the problem task; (b) agreeing with the current approach; and (c) asking clarifying questions that show positive participation towards the group effort of solving the mathematical task. Coding for epistemological and mathematical empowerment highlighted moments that displayed the individual's growth in confidence within the group as they solved the mathematical tasks. Instances of showing epistemological empowerment include: (d) taking the lead, (e) redirecting, and (f) posting an answer to the chat and/or workspace. Mathematical empowerment (g) was evidenced during the creation or validation of the knowledge.

Results

This study focused on analyzing data from Team Two, which consisted of four male students: Pedro, JohnC, John, and Jordan (not their actual names). The following narrative reports online interactions among Team Two and how they evolved over six sessions. During the opening 12 minutes of the first session, the students socialized and questioned their virtual teammates about gender, sports, and music. Pedro initiated the lead by encouraging his teammates to shift from their initial socializing and begin the task. There were statements of apprehension from each member of the team as they commented that they were unsure how to proceed with the mathematics. Jordan persuaded Pedro to enter his work onto the whiteboard, claiming they he and John had an idea but would like to see Pedro's solution strategy first. Pedro submitted the first solution onto the whiteboard and to that, John responded, "I had the same idea but was doing it on paper b/c I didn't know how to put it on the computer." John then immediately submitted his own solution, which contained an error, directly to the final solution tab and requested that Pedro write up the summary. Pedro complied with the directive. The team accepted John's final solution and did not question why it was different from Pedro's solution. JohnC's only contribution was several apprehensive comments in the beginning about how to proceed but he did not engage in any of the problem solving. Jordan was the last to log off, thanking Pedro for writing up the summary. At first it appeared that Pedro was the leader and everyone was extending him a turn to show his work. It quickly changed when John posted his work and positioned himself as the one who provided the solution. Jordan encouraged the team to produce solutions but did not submit any work of his own. For three teammates, the session ended on a positive note, however, for JohnC, the session might not have been as positive. Not only did he not engage in any of the problem solving, he drew pictures on the whiteboard that were erased by his teammates without discussion, and he logged off several minutes before the session ended.

As the sessions progressed, routines and rituals emerged that were similar to the first session. Pedro often began his chat statements with the words, "we," and "let's," as he encouraged the team to work together. He was tenacious in his desire to always contribute a solution; however, he rarely stated that he was sure of his strategy. Most of his statements began with, "I think this is it," or, "I am not sure." John initially did not consider his teammates' solutions or strategies. He would show his frustration by entering one word at a time into the chat log, commanding his teammates to agree with his solution to the task. However, as the sessions progressed, he began to display evidence of accountability by asking whether his teammates agreed with his solutions and, in the sixth session, he considered a solution other than his own. Jordan's chat entries were not frequent, yet the content of his contributions were pivotal to the community coming together. At first his accountability was exclusively slanted towards his co-located teammate John. Yet, as the sessions progressed, Jordan began to value solutions other than John's and expanded his notion of community to the four teammates. In contrast, JohnC generally entered negative comments and used the shared whiteboard to occasionally doodle. The other team members allowed him to stay adrift, and erased his doodle without mention. Yet in the fourth session, JohnC tried to work on the task and argue his point contrary to John's solution. However, JohnC's solution was never accepted and he appeared to harbor anger from this point forward.

A very interesting exchange occurred during the last session as John assigned tasks to Jordan and Pedro. Jordan's task was to tally John's listed items as he entered them into the chat and Pedro's task was to re-enter them into the workspace. The process was seamless as the three boys worked, however, two times John entered a duplicate into the chat, which was counted by Jordan, but not transferred to the workspace by Pedro. He intentionally left out the duplicates thus correcting John's mistakes. He did not at any time mention his corrections or his teammates error. Interpretation of these results is discussed below.

Discussion

Accountability to community means that group members listen to each other, build on each another's ideas, and question each other to expand on their own individual ideas (Michaels et al, 2008). Pedro displayed a strong sense of accountability to the community from the first session to the last. He continuously encouraged the team to work together and solve the tasks assigned to them. John and Jordan's accountability to community evolved during the study, in the sense that they expanded their definition of community. John displayed a modest shift in his accountability as he eventually considered solutions other than his own and Jordan expanded his view of the team from himself and John to a team of four. JohnC struggled with his accountability to community, notably supported by evidence of his involvement being oppressed by the other members. It appeared that lack of contribution was construed as inattentive by his teammates.

Sharing mathematical ideas is an empowering experience and from this empowerment, a student's mathematical identity is strengthened (Ernest, 2002). Pedro's and John's mathematical empowerment was evidenced in their submitted solutions. Initially each student created his own solution in the workspace and neither discussed nor justified their reasoning. However, in the last session, both used the heuristic of controlling for variable to create two similar lists that were better organized, and each were able to follow the others' work because of the organization.

Epistemological empowerment is the individual's growth in confidence in using, creating and validating mathematical knowledge (Ernest, 2002). Pedro's epistemological growth was evidenced when he was confident enough to fix John's solution without mention. John epistemological shift was most poignant as he developed a sense of himself in relation to the group as he began to value other members of the team. His epistemological growth is evidenced in how he managed and improved in his leadership skills. Team Two went from a group of four boys individually solving combinatorial tasks to a cohesive team under John's leadership.

In summary, the analysis revealed that the students displayed accountability to their learning community, as well as epistemological and mathematical empowerment, as they engaged in thoughtful mathematics in an online synchronous environment. As they worked in a small group to solve open-ended mathematics problems, they shifted away from individual, competitive work to more group cooperation and collaboration. They developed their own unique practice, expectations of one another, and most importantly, how to work together as a unique learning community. The data also indicated that this accountability was an empowering experience for the participants, one that may affect their relationship with the subject of mathematics. This study indicated that the environment provideda virtual and empowering forum for diverse students to construct mathematical ideas and reason collaboratively, even when remotely located.

SUPPORTING PEER CONFERENCES IN INTRODUCTORY CALCULUS

Daniel Reinholz
University of Colorado, Boulder
daniel.reinholz@colorado.edu

This paper focuses on the nature of student talk during peer conferences about calculus problems. Conversations were studied in the context of Peer-Assisted Reflection (PAR), an activity structure that supports communication and conceptual understanding through peer assessment. Despite a wealth of research on peer assessment, relatively little has been published on the specifics of students' conversations as they discuss each other's work. This paper introduces a coding scheme for analyzing such conversations, and applies it to illustrate the impact of a systematic training procedure on improving student conversations.

Keywords: Classroom Discourse; Design Experiments; Metacognition; PostSecondary Education

Calculus is an area of persistent challenge for students pursuing STEM careers (Bressoud, Carlson, Mesa, & Rasmussen, 2013). This paper focuses on student conferences in Peer-Assisted Reflection (PAR), a promising activity for improving student outcomes; PAR increased pass rates (completing the course with a C or higher) by 13% and 23% during two phases of study (Reinholz, in press-a, in press-b). PAR is built around peer assessment, a core part of formative assessment (Black & Wiliam, 2009). Broadly, formative assessment is focused on eliciting information about student thinking and using it to modify learning activities, which improves student outcomes (e.g., Black, Harrison, & Lee, 2003). In peer assessment, students collaborate and explain their reasoning to each other, developing self-assessment skills as otherwise invisible assessment processes become more explicit and transparent (Reinholz, in press-b).

Despite considerable work on peer assessment (e.g., Falchikov & Goldfinch, 2000), little is published on student talk during peer conferences. As a result, it is difficult to design to improve such discussions, because they are not well understood. This paper focuses on student talk during two phases of a design experiment (Cobb, Confrey, Disessa, Lehrer, & Schauble, 2003), exploring the impact of systematic training included in Phase II. It addresses two questions:

- What was the focus of student conferences on calculus problems?
- What was the impact of systematic training on student conferences?

Method

Design

Each week, students completed a challenging PAR problem as a part of their homework (14 problems total). After completing an initial solution, students came to class and exchanged their work with a peer. Students read each other's work silently for five minutes before discussing it together for five more minutes. After conferencing, students revised their work and turned in a final solution. This cycle of activities was implemented during both Phase I and Phase II.

During Phase II, a systematic training procedure was added. Each week, the instructor led a whole-class discussion in which students analyzed three sample solutions to a part of the PAR problem and discussed how to improve them; these discussions focused on how the solutions explained and communicated the mathematical concepts of the PAR problem.

This paper focuses on conferences from three PAR tasks: PAR06, PAR10, and PAR14. These tasks were chosen to span the duration of the semester. These tasks had: a low floor and high ceiling, multiple solution paths, and required explanation (cf. Schoenfeld, 1991); PAR6 explored the difference between radians and degrees with sine and cosine functions, PAR10 focused on the approximation of complex areas using simple shapes (as a precursor to Riemann sums), and PAR14 involved creating a bead as a solid of revolution (the napkin ring problem).

Participants and Data Collection
