Students in a semester-long introductory calculus course at a research university attended four 50-minute class periods each week. Phase I (409 students) took place in the fall, while Phase II (336 students) took place in the subsequent spring semester. There were a total of ten parallel sections each semester (taught by 8-9 different instructors) with a common curriculum. PAR was implemented in a single experimental section each semester; this paper focuses on only these two sections (not the comparison sections). Student PAR assignments were collected and scanned, and 4-7 student dyads were randomly chosen each week to be audio recorded during their peer conferences. A total of 155 conferences were recorded (66 during Phase I, 89 during Phase II).

Analysis

A total of 44 conferences were transcribed and de-identified. The transcripts were coded randomly to avoid systematic bias across tasks or phases of study. Each conversation was coded by assigning each sentence of talk to one of seven dimensions. Using a single sentence as a unit of analysis, it was possible to assign each sentence uniquely to a single category.

The categories were: (1) communication (focused on how mathematical ideas were expressed), (2) comparison (of different solutions or multiple parts of the same solution), (3) concepts (the underlying mathematics of the problem), (4) procedures (computational fluency), (5) task (clarifying the parameters of the task), (6) other (mathematical talk in none of the above categories), and (7) unrelated (talk not related to the problem). These categories were drawn from the framing of PAR (asking students to talk about communication and correctness), the nature of the tasks (focused on multiple solutions, allowing for comparison), and an iterative process of working with transcripts to develop a minimal set of codes. Because students often introduced themselves to start a conversation and said "thank you" to end the conversation, "unrelated" talk from the beginning and end of conversations was not analyzed. This also meant that off-topic talk that took place after students finished their discussion was not analyzed.

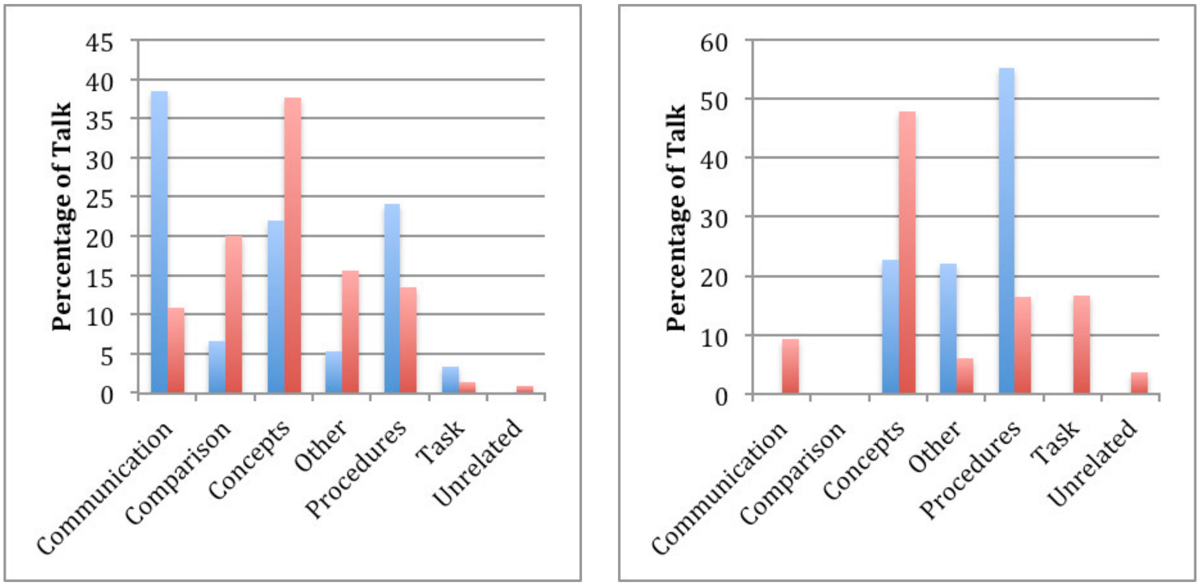
Results

Student conferences during Phase II were more than twice as long as those during Phase I (see Table 1). Conversations were also analyzed for percentage of on-topic talk (categories 1-6); overall, 98% of talk during Phase I and 97.8% of talk during Phase II was categorized as on-topic. This indicates that students during Phase II spent more than twice as much time as the Phase I students discussing the mathematics of the PAR problems.

Table 1. Length of Conversations (Number of Sentences)

	Phase I	Phase II
PAR06	18.8	31.9
PAR10	12.8	43.7
PAR14	17.0	44.8

Figure 1 gives the breakdown of talk for PAR06 and PAR14, averaged over all student conversations (PAR10 omitted due to space). During Phase II, students focused more on concepts, while Phase I students focused more on procedural computations. Nevertheless, students during both phases used peer conferences to deepen their understanding in a variety of productive ways,



PAR 06 PAR 14

Figure 1. Breakdown of Talk (Phase I in Blue, Phase II in Red)

connecting their solutions, improving their explanations, and discussing mathematical procedures and concepts.

Typical Phase I and Phase II discussions for PAR14 are given in Figure 2. Most of the Phase I discussions focused on computations involving solids of revolution (4 of 5 conversations):

> Ben: This is where I screwed up. You're going to want to substitute in 1/2 h, that quantity squared…like 1/2 h square root equals that. So when I kept subbing it kept screwing up. I kept on putting in 1/2 h to the 3/2, but it's gotta be this quantity squared in that.
>
> Sam: Gotcha.

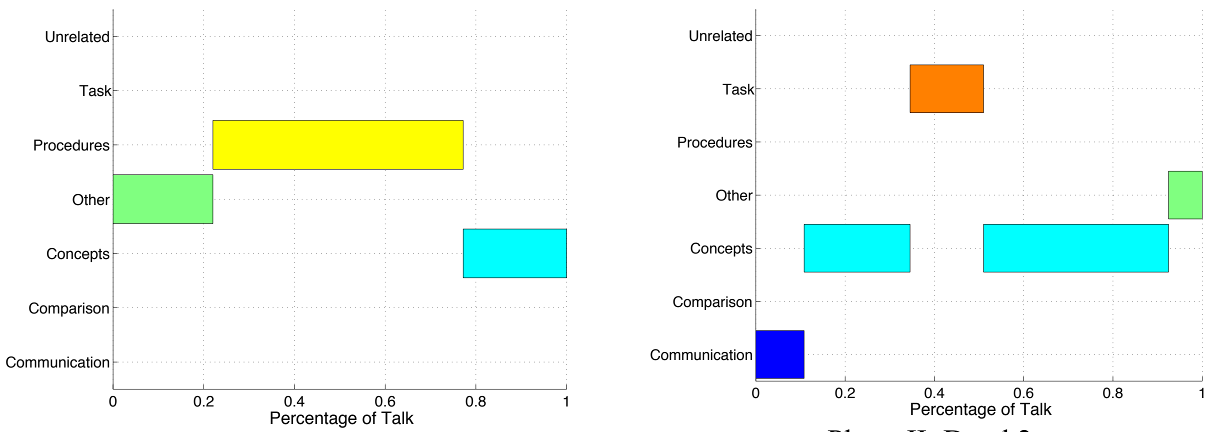
In contrast, Phase II students focused more on concepts. Moreover, while discussing concepts in the problem, Dyad 2 realized that they were confused and needed to clarify the nature of the task. While Tim was discussing the bounds for their integral, Bethany realized that she was not sure how to read the diagram in the problem:

> Tim: So your *x* bounds are *r* and big *R*. Uh, integral of that and then just the 2 times pi…
>
> Bethany: Wait, I'm confused; can I ask you about this thing? Is this saying that *h* is this whole thing?

The discussion continued on and the students resolved the confusion, and returned to discussing concepts. Returning to the task in this way mirrors how skilled problem solvers may return to a problem statement and reevaluate their approaches in the middle of problem solving (Schoenfeld, 1985). During Phase II, only 2 of 6 conversations were mostly procedural.

Discussion

This paper illustrates an approach to analyzing peer conferences and reports preliminary findings about the nature of student conversations. Students discussed a variety of aspects of the problems, such as communication, the nature of the task, procedures, and concepts. Moreover, the results suggest that the systematic training activities had a considerable impact on student discussions. Phase II students discussed more than twice as much mathematics as the Phase I students, and the nature of the conversations was qualitatively different; the students focused more on concepts than procedures.



Phase I: Dyad 1 Phase II: Dyad 2

Figure 2. Comparison of Pairs (PAR14)

This shift is consistent with the nature of the training exercises that focused on discussing concepts. This shift may also be due in part to the deeper understanding that the Phase II students developed (Reinholz, in press-a), which allowed them to move beyond the surface aspects of the problems. Future work will focus on establishing reliability with multiple coders and analyzing all of the PAR problems in more depth.

QUALITY INSTRUCTION, TEACHERS' SELF-EFFICAY, AND STUDENT MATH ACHIEVEMENT IN KOREA AND THE UNITED STATES

Ji-Won Son
University at Buffalo-SUNY
jiwonson@buffalo.edu

This study compares and contrasts student, teacher, and school factors associated with student mathematics achievement in Korea and the United States, using data from the Trends in International Mathematics and Science Study (TIMSS) 2011. We examine factors linked to teachers who deliver quality instruction with high self-efficacy the association between teachers with high-quality instruction and high self-efficacy and 8th graders' math achievement. Years of teaching experience and several student background characteristics such as parent's level of education and the number of books at home were associated with achievement in both countries. In addition, teacher's perceived academic emphasis was associated with teachers who claimed to provide high-quality math instruction with high self-efficacy. However, the two countries' results differed in the effect of teacher's opportunities to learn in professional development programs on teachers.

Keywords: Teacher Knowledge; Affect and Beliefs

Introduction

Students' mathematics achievement is often associated with the future economic power and competitiveness of a country. Accordingly understanding and identifying factors that may have meaningful and consistent relationship with mathematics achievement has been of great interest to policy makers and educators in the United States but also all around the world including Korea. Researchers have identified multiple variables that have an impact on student learning, including family background and socio-economic status (e.g., Bress & Mirazchiyski, 2010), peer influence (e.g., Guiso et al., 2008), gender differences (e.g., Else-Quest et al., 2010), and personal characteristics (e.g., Chiu & Klassen, 2010). However, growing evidence shows that teacher quality is a crucial contributor to student learning which in turn can lead to the development of highly knowledgeable and skilled workers. Effective teachers have the intersection of three important components including teacher knowledge, pedagogical skills, and dispositions resulting in a strong sense of self-efficacy.

In this study, we hypothesize that teacher's self-efficacy is a basis for creating quality instruction where teachers promote students' higher order thinking in mathematics. Based on the data collected in TIMSS 2011 (eighth-graders), we examine the factors that are associated with mathematics achievement of secondary students in Korea and the United States. In doing so, we first examine the factors that distinguish teachers who provide quality instruction with high self-efficacy. According to Cochran-Smith and Zeichner (2005), effective teachers need to provide not only cognitively demanding instruction but also possess high self-efficacy. Thus we first examine whether such teacher characteristics is a significant factor associated with student achievement. The factors that distinguish teachers who provide quality instruction with higher self-efficacy from other teachers are explored. Then, we examine the association between other teacher, school, and student factors that are related to students' mathematics achievement. In particular, by comparing and contrasting student, teacher, and school factors that are associated with student mathematics achievement in Korea and the United States, we intend to provide suggestions to mathematics education in both Korea and the United States. Research questions that guide this study are: (1) What factors are associated with teachers who provide quality instruction with high self-efficacy (i.e., teacher math instruction and self-efficacy typology) in the United States and Korea? and (2) To what extent teacher mathematics instruction and self-efficacy typology is associated with students' math scores, after controlling for student backgrounds, other teacher factors, and school contexts in the United States and Korea?

Method

This study used data from TIMSS 2011. Conducted on a regular 4-year cycle, TIMSS has assessed mathematics and science at the fourth and eighth grades since 1995. This study focused eighth graders, their mathematics teachers, classrooms, and schools in the United States and Korea. Note that total sample sizes are, 10,445 students, and 537 teachers in the US, 5,170 students, and 375 teachers in Korea, respectively. Figure 2 shows our conceptual framework for the study.

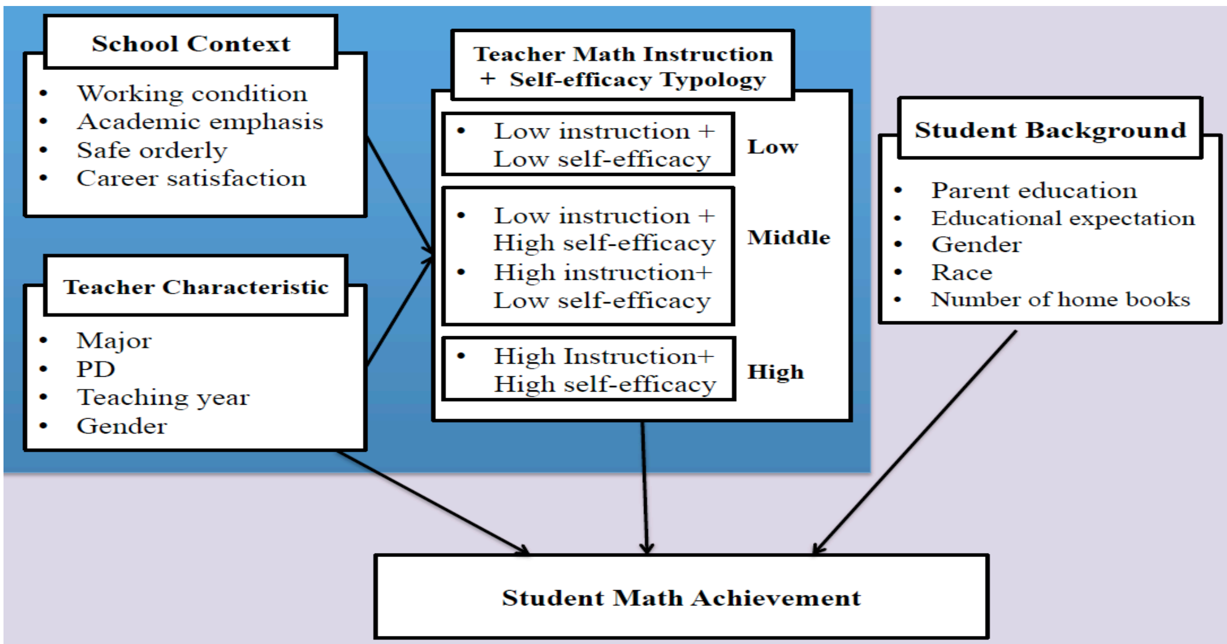

Fig 2. Conceptual basis for the study

The outcome measure for this study is students' math achievement scores. Teacher mathematics instruction and self-efficacy typology is selected as an independent variable for the study. Teacher background variables such as a teacher's major, gender, years of experience; student background variable including gender, race, number of books at home, and educational expectations; and school factors based on teachers' perceived collaboration and their perceived academic emphasis are selected as control variables for the study. We tried to input same background variables into both of two county models, however, two variables, race and teacher major, were considered differently. First, in the analysis of Korea, race variable was excluded because Korea is well-known as ethnically homogenous society (Kang, 2010). Second, when it comes to teacher major, four categories are used to represent US teachers whereas two categories are used for Korean mathematics teachers. For example, in the United States model, teacher major was classified into four categories including (1) no major in education and math; reference group, (2) major in education but math, (3) major in math but education, and (4) major in both education and math. In contrast, Korean teachers were classified into two categories—(1) Mathematics major or non-mathematics major. Because there are only few sample in "no major in education", and "major in both education and math" in Korea, we combined the cases. This study employed multiple imputations (MI) due to missing data on teacher and student background variables.

Analytic strategy

To answer the first research question, we first created three different types of math teacher typology; (1) a teacher with high-quality instruction and high self-efficacy (High group), (2) a teacher with high-quality instruction but low self-efficacy or low-quality instruction but high self-efficacy (Middle group), and (3) a teacher with low-quality instruction and low self-efficacy (Low group). The measure of math instruction is derived from items asking "*in teaching mathematics.* Next, we classified teachers into two groups: (1) above the median as teachers with high-quality instruction and (2) below the median as teachers with low-quality instruction. 49.6% and 50.4% of teachers are categorized as "low instruction teacher" and "high instruction teacher", respectively. The measure of teacher self-efficacy is derived from items asking *in teaching mathematics to this class, how confident do you feel to do the following;* (1) *show students a variety of problem solving strategies* (2) *provide challenging tasks for capable students* (3) *adapt my teaching to engage students` interest* (4) *help students appreciate the value of learning mathematics*." We summed teachers' responses on these 4 items and then classified teachers into two groups: (1) a teacher who reports the highest value for all 4 questions as a teacher with high self-efficacy and (2) a teacher reports all other values as a teacher with low self-efficacy. Next, multinomial logistic regressions were used to examine the factors that are associated with teachers who provide the quality instruction with high self-efficacy (i.e., teacher math instruction and self-efficacy typology). To the second research question concerning the degree to which teacher math instruction and self-efficacy is associated with students' math scores, after controlling for student backgrounds and other teacher factors and school contexts, we conducted OLS regression analyses. According to the findings from research question 2, the third research question was interpreted to provide implications to mathematics education in United States and Korea.

Summary of Results

Factors associated with teacher math instruction and self-efficacy typology

We found that several factors are associated with teachers' mathematics instruction and self-efficacy typology. In Korea, teachers' educational backgrounds are not significantly associated with teachers who deliver high-quality math instruction with high self-efficacy (high group), whereas in the United States data, teachers who majored in "education and mathematics" are about 2.4 times likely to be classified into the "high group" compared to teachers who did not major in education or mathematics. We also found that several school contexts including perceived academic emphasis and perceived safe orderly are positively associated with teacher math instruction and self-efficacy typology in the US data. One unit increase in the perceived academic emphasis index (e.g., from medium to high emphasis or from high to very high emphasis) is associated with a 2 times likely to be teachers who deliver high-quality math instruction with high self-efficacy in the United States. In addition, PD opportunities are found to significantly distinguish teachers in the middle group (i.e., a teacher with high-quality instruction but low self-efficacy or low-quality instruction but high self-efficacy) from teachers in the low group. This finding suggest that teachers in both high and middle groups tend to report that they participated in PD opportunities focusing on curriculum and inquiry methods more often that teachers in the low group who provide cognitively low demanding instruction with low self-efficacy.

Factors associated with 8th graders' mathematics achievement

There is the significant positive association between teacher math instruction and self-efficacy typology and student math achievement in the United States, even after controlling for other student, teacher, and school backgrounds. Nonetheless, we found no significant relationship between teacher math instruction and self-efficacy typology and student math achievement in Korea. Specifically, only US students who taught by high group teachers (i.e., teachers with high-quality math instruction and high self-efficacy) have 10.26 higher math achievements scores than students who are taught by teachers with low quality of math instruction and low self-efficacy. Interestingly, no significant difference in mathematics achievement was observed between students who taught by "high group teachers" and those with "low group teachers" in Korea. In addition to teacher's cognitively demanding instruction with high self-efficacy, teachers' year of teaching experience, their perceived academic emphasis, and their major were found to be significantly associated with students' mathematics achievement in the US context. Furthermore, we also found that several individual-level characteristics were associated with student math achievement.

Discussion and Implications

This study contributes to the current literature on student learning and teacher education. The current study expands the prior research by creating teacher math instruction and self-efficacy typology and finding the factors that are associated with teachers who deliver quality instruction with high self-efficacy. In the US context, teachers' major (i.e., education and mathematics), teachers' years of teaching experience, their perceived academic emphasis, and professional development opportunities are collectively associated with teachers who emphasized cognitively demanding instruction with high self-efficacy. The findings of this study highlight the importance of cognitively demanding instruction but also improvement of teachers' self-efficacy in the US context to improve students' mathematics achievement. Future research is needed to examine the degree to which professional development and teacher evaluation are associated with student achievement because current national and state policy in the US emphasize teacher evaluation to improve teacher quality.

Improving teachers' practice of using student mathematical thinking requires an understanding of why teachers respond to student thinking as they do; that is, an understanding of the goals, orientations and resources (Schoenfeld, 2011) that underlie their enactment of this practice. We describe a scenario-based interview tool developed to prompt teachers to discuss their decisions and rationales related to using student thinking. We examine cases of two individual teachers to illustrate how the tool contributes to (1) inferring individual teachers' goals, orientations and resources and (2) differentiating among teachers' uses of student thinking.

Keywords: Classroom Discourse; Research Methods; Teacher Beliefs; Teacher Education-Inservice

Researchers and teacher educators need to better understand teachers' reasoning about the practice of using student mathematical thinking in order to support teachers in enhancing that practice. In previous work (e.g., Peterson & Leatham, 2009; Stockero & Van Zoest, 2013), we have used classroom observations and recordings of instruction to understand teachers' responses to student ideas; however, these methodologies have been insufficient in two important ways. First, we have found that using video of instruction to analyze teachers' responses to student thinking does not provide sufficient data to make certain inferences, particularly when teachers do not respond to students' ideas—we have no way of knowing whether the lack of response was deliberate, or whether the teacher did not notice the importance of an idea. Second, we have found it difficult to make comparisons among the practices of teachers who are teaching different content, in different contexts, with different student responses, and thus, have different opportunities to use student ideas. To provide a mechanism for better understanding how different teachers respond to student mathematical thinking in similar contexts, we developed a scenario-based interview (Scenario Interview) as a tool to further understand teachers' use of student thinking. Here, we describe the interview tool and illustrate the type of information it avails us in regard to teachers' goals, orientations, and resources (GOR) in the context of using student thinking.

The Instrument

Schoenfeld's (2011) theory of goal-oriented decision making describes teachers' decisions as being shaped by their GOR. A goal is "something that an individual wants to achieve, even if simply in the service of other goals" (p. 20). Goals can be short- or long-term, and may relate to the learning of specific content, to broader outcomes for students or to teacher actions. Goals may or may not be conscious to the teacher, meaning that one cannot simply ask teachers to state all of their goals for their students and their classroom. Orientations are defined to include teachers' "dispositions, beliefs, values, tastes and preferences" (p. 29) of which, like goals and resources, teachers may not be explicitly aware (Leatham, 2006). Resources include everything a teacher could access to support instruction. They include not only physical materials, but also teachers' knowledge (of, for example, things such as mathematics content, teaching strategies, and typical student conceptions). Schoenfeld

(2011) stipulated that, together, teachers' GOR drive their behavior in the classroom. Understanding GOR in the context of using student thinking is critical to understanding why teachers engage with student mathematical thinking as they do and what might help them further develop this teaching practice. The Scenario Interview was created to provide insight into how a teacher thinks about attending to student thinking during instruction and to infer teachers' GOR in the context of using student thinking.

Throughout the Scenario Interview the teacher is presented with statements from eight individual students—four each from algebra and geometry contexts—that represent a range of thinking, including statements of answers, explanations of solution processes, a suggestion to modify a problem context, and unclear thinking. The interviewee is situated as a classroom teacher and asked to describe what they might do next were the student statement to occur in their mathematics classroom. Although normally a classroom teacher would know details of the context of the situation in which the student thinking occurred (e.g., the task that students are working on, what prompted the student statement, etc.), the Scenario Interview initially does not reveal to the interviewee any contextual information. Rather, after being presented with a student statement, the teacher is given an opportunity to ask questions about the context, which offers insight into possible GOR that the teacher relies on to make decisions. The interviewee is then given five more opportunities to reveal their GOR as they are asked to: (1) describe what they would do immediately after the student's statement was made, (2) explain why they would respond in that way, (3) articulate assumptions they were making that informed their decision, (4) explain their reason for wanting to know the contextual information they asked about, and (5) describe how their response may have been different had they known additional contextual information.

Usefulness of the Instrument

Here we describe two teachers who were chosen to highlight different GOR that might affect teachers' decision making with respect to using student thinking. Although the interviews revealed several GOR for each teacher, we limit our discussion to just one main goal for each (along with one related orientation and resource) to illustrate how the Scenario Interview allows us to infer the reasoning that underlies each teacher's use of student thinking. After discussing each teacher individually, we look across the teachers to highlight differences in their GOR that the interview revealed and discuss how this knowledge might inform the work of researchers and teacher educators.

Ms. Shaw

Ms. Shaw's main *goal* for having students share their thinking is to engage them in making sense of the mathematics behind the thinking. She wants to engage the sharing student in sense making through questions that highlight important mathematical ideas in the thinking, such as, "What are you assuming when you're giving me 4 pi? How did you come up with that band as 4 pi?" and "Why are you using [2] as your radius?" She also wants to engage the whole class in making sense of student ideas. For example, in a situation where a student modified a problem, she proposed turning that modification to the class and asking questions such as, "What would my table look like [in this new situation]? What would my graph look like? How does [this modification] change those two representations?"

One of Ms. Shaw's *orientations*—that an important part of student learning is providing students ample opportunity to think about mathematical ideas—helps her achieve her main goal by ensuring the presence of plenty of student thinking to ground the class discussion. She values providing students individual "think time" before hearing others' ideas about a problem, as well as time to individually "process" ideas that surface during whole-class discussion. Furthermore, Ms. Shaw believes in providing opportunities for students to collectively think about and, when appropriate, compare ideas during whole class discussion: "I want the class to look at the two methods… tell me what they're doing differently. What is similar?"

Consistent with the above goal and orientation, Ms. Shaw considers student mathematical thinking a *resource* for making instructional decisions and helping students make sense of the mathematics in a lesson. She thinks through what students might be able to contribute, and wonders "Can they talk through it?... Is someone going to bring that up for me?" For Ms. Shaw, having a student clarify their ideas provides a means to help all students make sense of the mathematics. For example, she sees student responses to her probing questions as opportunities for all students to "start to see" the compelling mathematics behind student thinking.

Mr. Mead

Mr. Mead's main *goal* for having students share their thinking is to position students as thinkers. He wants students to elaborate on their thinking, both "to see what they think about [a] situation" and to encourage that thinking by "grab[bing] onto that thinking". Although he sometimes has his own ideas about what students might be thinking, he still wants to "dig into" student ideas to "try to figure out what… the student [is] actually thinking," thus positioning students as mathematical thinkers.

Not surprisingly, Mr. Mead's *orientations* include the belief that students can learn mathematics through exploration—"developing their understanding through [a] problem." He is comfortable leaving ideas that surface early in a lesson unresolved, knowing that students will have opportunities to think about them further during the lesson: "If this was a launch of the lesson then… I would say, 'Ah, okay, that's interesting Chris. So how did you get that?'… and maybe get a couple others. If I didn't get any other ideas, then I would just go ahead with the lesson. I wouldn't even address the fact that Chris is wrong at this point."

Mr. Mead uses student thinking as a *resource* to develop the mathematical ideas in a lesson and to tie ideas together. For example, after two students shared different methods of solving a problem, he suggested that he would position the lesson as "more of a verification of what [they] did for us today, so… let's verify whether… the methods… are correct or not, and that would give me something to go back to at the end as well." In another instance, he positions a student idea as a resource for "helping me [and] the students with this context—understand this," because "it's… just a little bit ahead of where we wanted to go at that point, but it seems like it's great to take an idea like that and to run with it." Viewing the student's idea as an opportunity to help the class increase their mathematical understanding, even though it is "a little bit ahead" helps Mr. Mead meet his goal of positioning students as mathematical thinkers.

Discussion and Conclusion

The Scenario Interview helped us to infer subtle differences in teachers' GOR. For example, Ms. Shaw and Mr. Mead both viewed student thinking as a resource for helping students develop an understanding of the mathematics in the lesson. Their main goals for having students share their ideas, however, are slightly different. Ms. Shaw's primary goal is to engage students in making sense of the mathematics behind the thinking that is shared—a content related goal. By contrast, Mr. Mead's primary goal is to position students as mathematical thinkers—a goal more closely related to identity formation. Ms. Shaw's belief in the importance of providing students ample opportunity to think about mathematical ideas individually or as a group supports her goal of using student thinking as a vehicle for students to make sense of the content. Mr. Mead's orientation that students can learn through mathematical exploration positions them as the "doers" of mathematics, and thus supports the development of their mathematical identity. These two cases illuminate the value of the Scenario Interview for inferring GOR at a level that one can make distinctions among teachers—even those who use student thinking in similar ways. If we observed Ms. Shaw and Mr. Mead questioning students about their ideas, we might conclude that they had the same goals and orientations related to using student thinking as a resource.

However, the Scenario Interview revealed subtly different purposes for similar teacher actions. Because GOR are often implicitly held, they cannot be accessed merely through observation or direct questioning (Leatham, 2006). The Scenario Interview appears to be an effective mechanism for prompting teachers to discuss teaching practice in ways that contributes to revealing their GOR. For example, requiring teachers to ask for the contextual information they feel is relevant for deciding how to respond to an instance of student thinking provides information about what resources they draw on and what they value in making decisions.

Prompting teachers to talk about the same varied collection of instances of student thinking provides multiple opportunities to infer their GOR, allowing us to develop themes that characterize each teacher's GOR while also providing the similar context needed to identify important differences among teachers in terms of the GOR that underlie the practice of using student thinking. The Scenario Interview appears to be a valuable addition to our methods of collecting data that allow us to confidently infer teachers' GOR and thus better understand teachers' practice of using student mathematical thinking. Understanding the current state of this practice for particular teachers has the potential to support researchers and teacher educators in designing learning opportunities to enhance this teaching practice that are responsive to teachers' current thinking.

ats@email.arizona.edu

Recent scholarship in mathematics education has increasingly supported the power of connecting mathematics lessons to students' lived experiences. This case study, drawn from a larger multi-year study, traces the reflections and pedagogical practice of a middle school mathematics teacher who regularly connected her lessons to real-world contexts. We highlight how the teacher connected a fractions lesson to the context of making soup for her family to accomplish several goals including: (1) sharing stories to learn more about students, (2) moving beyond numbers to build understanding, (3) building students' mathematical confidence, and (4) making space for students to connect mathematical ideas. These findings provide insight into how making real-world mathematical connections may impact students' understanding.

Keywords: Instructional Activities and Practices; Teacher Knowledge

Mathematics educators increasingly agree that connecting school mathematics to experiences, situations and contexts outside of school, including students' own experiences and understandings of the world, is a critical element important to student learning (Ladson Billings, 2009; Turner, Aguirre, Bartell, Drake, Foote, Roth McDuffie, 2014; Turner & Strawhun, 2007). This argument is supported by studies that suggest that the knowledge and experiences that students bring from their everyday lives can serve as resources for learning mathematics (Civil 2002, 2007), as well as evidence that student learning is enhanced when concepts and skills are connected to realistic contexts and situations (Boaler, 2008). In this paper, we refer to teaching that includes connections to real-world contexts and situations, including students' own experiences outside of school, as *real world mathematics teaching*. While some prior research has documented examples of how mathematics teachers make real world connections, still needed are in-depth analyses of teachers' reasoning about these connections, and investigations of how these connections play out in teachers' instruction.

In one study of secondary teachers' understandings of real world mathematics teaching, Gainsburg (2008) found that although the teachers had a wide range of practices they classified as real world, the fleeting connections that teachers made did not often require students to actively engage or think deeply about the mathematics. Moreover, some teachers believed that real world mathematics learning should occur after students have mastered mathematical skills and concepts. Gainsburg also found that although some teachers saw great worth in rigorous tasks, others were apprehensive that challenging and poorly executed real world mathematics tasks might overwhelm students. Gainsburg's study illustrates the complexity and challenge that real world mathematics teaching poses for classroom teachers, and raises questions about what it might mean for teachers to connect their mathematics teaching, in meaningful and sustained ways, to students' experiences outside of school.

In this study we analyzed one early career 7th grade teacher's understandings and practices related to real world mathematics teaching, guided by the following research questions:

- What are the teacher's (Evelyn's) understandings about real-world mathematics teaching?
- How does Evelyn plan for, enact and reflect on connections to real-world contexts and situations, including students' own experiences outside of school?

Methods

Evelyn, an early career middle school mathematics teacher, is a participant in a larger ongoing research project, [TEACH MATH]that follows preservice teachers from their preparation programs and into early career classrooms. Across three years, we observed Evelyn teach 22 mathematics lessons; two observations occurred during student teaching and the remainder during her first two years as a classroom teacher. Evelyn was purposefully selected for this case study because she frequently made connections in her mathematics lessons to real world contexts, and her own and students' experiences in and out of school.

Data included transcripts of recorded pre and post observation interviews, field notes detailing the observed mathematics lessons, classroom handouts, and sample of student work. During the first round of analysis, the three authors reviewed all data for instances of real world connections during mathematics lessons, including Evelyn's planning or reflections on such connections. Then, through iterative analysis, secondary codes were developed that focused on specific instructional moves that Evelyn used to a) elicit and incorporate her students' knowledge and experiences, b) introduce a real world context for a lessons, or c) to share about her own experiences. Codes also attended to key ideas in Evelyn's reflections on connecting mathematics to real world contexts and/or students' home and community funds of knowledge. From this broader analysis, one specific lesson, "Making Tortilla Soup for my Family" was identified as a case of Evelyn building a mathematics lesson around her own experience. This lesson was then analyzed to build the following case study.

Findings

We first overview the "Tortilla Soup" lesson. We then use this lesson to highlight key features of Evelyn's understandings and practices related to real-world mathematics teaching.

Evelyn began her second year of teaching seventh grade mathematics at a different school and with a different curriculum. Although Evelyn saw merit in the curriculum she was expected to teach, she worried about the lack of real world examples and how/if her students would personally connect to, and see the relevance of the content they would be learning.

Evelyn recognized that her students had a limited understanding of multiplication of fractions. After teaching a "very numbers-based lesson," she realized students lacked conceptual understanding, leaving them apprehensive and unsure about following the procedure they had been taught. Although Evelyn felt pressure to "move" through the curriculum she was reluctant to do so, and opted instead to reteach the lesson. She considered presenting a "hands-on" activity from the textbook to support students' learning, but decided to veer from the text. She planned a lesson around cooking and scaling recipes that she believed might support understanding of multiplication of fractions in a "real way." Evelyn's choice of context was informed by a beginning of the year survey in which students reported using mathematics in family cooking and/or baking activities.

Evelyn began the reteach by presenting a handwritten version of her family's favorite tortilla soup recipe. She shared her experience of cooking soup and adjusting the recipe for groups of different sizes, hoping to link her experiences cooking to those of her students. Evelyn drew students' attention to the different ingredients, as well as how many people the recipe would serve (16). She then posed the task to students: Adjust the recipe for smaller and larger groups of family and friends. For example, how much of each ingredient is needed to serve 8, 32, 40, or 82 people? Evelyn's goal was for students to understand how to scale up or down the quantities in the soup recipe by multiplying each quantity by a fraction or mixed number.

As students worked on the task, Evelyn probed their thinking, asking questions such as, "What did you do to get this number?" or "What happened when you were feeding more people?" Students used multiple strategies to adjust the recipe, envisioning themselves cooking the soup, and questioning if their adjusted ingredients made sense. Some students made connections between multiplying ingredient quantities by a fraction and their prior understanding of operations with decimals and percents (i.e., multiplying by ½ is like taking 50% of a quantity). In summary, the lesson helped students connect the real world experience of adjusting a recipe to the mathematical concept of multiplying by a fraction.

Shared experiences leads to learning about students

A key feature of Evelyn's real world mathematics teaching was that she created spaces for students to share their experiences during her lessons. One way that Evelyn invited students to share about themselves was by telling stories from her own experience. She reported:

> I get [students] an hour each day, and it's been a lot more harder to make those connections. I say, "Hi" in the hall all the time and stuff like that to try and get them to feel comfortable with me. When I have something like [the recipe] that's sharing a part of me, they're willing to share a part of themselves. I just feel like everybody's a little bit more open to sharing and taking risks.

When Evelyn introduced her family's tortilla soup recipe, several other students shared food they made with their families and/or enjoyed eating (i.e. the making of enchiladas, the enjoyment of corn tortillas). Evelyn used this practice of sharing her out of school experiences as a means to discover more about her students' own experiences.

Moving from numbers to meaning

A key motivation underlying Evelyn's use of real world contexts in her mathematics lessons was that the connections would help students make sense of the mathematical tasks. Evelyn used gesturing to illustrate the concept of doubling the recipe of all the ingredients into two separate pots. When one student expressed confusion about how to adjust the recipe, and wondered whether he should add the quantities of all the ingredients together, Evelyn drew the student's attention to the activity of cooking soup to support his sense making. She noted:

> Yeah, but if we're cooking – I was like, "Sure we put it in the pot [the ingredient] but if you add them, what does that number mean?" He goes, "Oh! Okay!" Then it was like he thought about it in a real way.

This aspect of Evelyn's practice suggests she recognized that providing students with a familiar real world context (the making of soup) might help students move beyond seeing only numbers in mathematical tasks towards sense making and understanding.

Stepping up to do the mathematics

Additionally, Evelyn thought that real world connections in mathematics lessons would enhance students' engagement, particularly for students who tended to be less confident and more reluctant to share their thinking. In reflecting on the soup lesson, she explained:

> There was just this level of confidence from the start because they could connect to what we were doing. It wasn't just the digits and operations and think about it as math. It was, "This is an experience, and you guys know how to do it, so how do you do it?" Then it was more of them using the math to help them, but they had this huge experience that they could draw from to help them work with the numbers.

Evelyn reported that because students could relate to the context of cooking "A few people that are normally really quiet all of a sudden felt like they were experts, and they 'stepped up." Students' confidence appeared to flourish, as they used the experience of cooking (something they were familiar with) to make sense of the task of adjusting the recipe. Evelyn reflected that making these kinds of connections in her lessons seemed to support more equitable participation.

Making space to connect mathematical ideas

Finally, Evelyn saw the use of real world contexts in mathematics lessons as a means for students to create connections among mathematical ideas. For example, Evelyn found that when she invited students to share experiences and to make connections to lesson tasks, this opened a space for students to connect a range of mathematical ideas and understandings. In the soup lesson, as students were reasoning about multiplying fractions, they made connections to other mathematical operations. She explained:

> Then, one thing that I was impressed with [is that multiplying fractions] wasn't so much of a struggle. So many of them used a reference to money, or a reference to just decimals in general. One student changed, I think, all of his numbers to decimals, and then it was so easy for him to figure out what half of that was, and he just did it.

Evelyn felt that part of the value of real world mathematics teaching was that it encouraged students to make connections and to utilize multiple mathematics strategies to solve the tasks.

Discussion

This study provided a glimpse into one middle school teacher's understandings and practices related to real world mathematics teaching. More specifically, Evelyn's case highlights the importance of teachers sharing their own experiences with students as one entry point to connecting with students and eliciting students' experiences. Additionally, our findings suggest that teaching through familiar real-world experiences is important not only for student engagement and understanding, but also a way to address issues of confidence and status that may surround mathematics learning. Finally, our findings contribute understandings about the ways that teachers might plan, enact, and reflect on real-world connections in their teaching, which may inform mathematics teacher educators in their efforts to support other teachers in this complex and challenging practice.

The following case study details the analysis of a Lesson Study where middle grades teachers focused on the core teaching practices to teach and understand the different student generated models for a task on proportional reasoning. We analyzed the significant mathematics teaching practices that teachers engaged in during the planning, teaching and debriefing phases to depict ways in which teachers used students' representational models as a discursive tool to make mathematical thinking visible and instrumental in moving the mathematics agenda forward.

Keywords: Classroom Discourse; Teacher Knowledge; Rational Numbers; Instructional Activities and Practices

Theoretical Framework

In the *Principles to Actions*, NCTM (2014) calls for the mathematics education community to focus our attention on the essential core teaching practices that will yield the most effective mathematics teaching and learning for all students. Over the years, mathematics education scholars have challenged the profession of teaching to identify a common set of high-leverage practices that yield effective teaching. Ball and Forzani (2010) describe high-leverage practices as "those practices at the heart of the work of teaching that are most likely to affect student learning" (p. 45). Authors of the *Principles to Action* (NCTM, 2014) responded to this challenge by defining eight research-based core teaching practices that include: 1) Establishing mathematics goals to focus learning; 2) Implementing tasks that promote reasoning and problem solving 3) Using and connecting mathematical representations; 4) Facilitating meaningful mathematical discourse; 5) Posing purposeful questions; 6) Building procedural fluency from conceptual understanding; 7) Supporting productive struggle in learning mathematics; and 8) Eliciting and using evidence of student thinking. In the design of our professional development project, we used the eight listed Mathematics Teaching Practices outlined in the *Principles to Action*, through our content institute and our Lesson Study cycles. The intentional design of using a school-based Lesson Study as a follow up to the professional development institute was so that we could examine how teachers employed these eight teaching practices *in the enactment of the lesson*. Lesson Study (Lewis, 2002) allows for collective professional *"noticings"*(Mason, 2011)during Lesson Study that attends to children's strategies, interpretations and response to student learning. The focus of this research report is to share how professional development designed around these important teaching practices impacted teachers' knowledge, beliefs and practices for in-service teachers. By focusing on the research lesson we examine how these core teaching practices played a role in enhancing the teaching and learning of mathematics.

Method for Our Study

Research Questions

To explore how teachers engaged in the core teaching practices as they collaboratively planned and delivered a research lesson on proportional reasoning, we asked: 1) In what ways do teachers use the core teaching practices to make mathematical thinking visible through student-generated models? 2) What is the nature of teachers' reflection on a) their practice, and b) their beliefs as they engage in Lesson Study focused on the uses of students' representational models as a discursive tool?

Data and Procedures

Teachers' reflections, video clips and researchers' memos were collected of the preplanning, teaching and debrief sessions. This case study was part of a larger project involving forty elementary and middle grades teachers from grades 5 – 8 who met for eight weeks for a fall content institute and continued to meet as school teams over four face-to-face meetings before conducting Lesson Study by the end of the first semester. In order to sustain teachers' professional learning through the fall semester, the instructors met with teachers after the eight-week content institute in small vertical teams of five to six multi-grade teachers. In the following sections, we present the analysis of a Lesson Study focused on proportional reasoning called the "Candy Dilemma" problem as shown below.

> I bought a box of candy for myself last week. However, by the time I got home I had eaten ¼ of the candies. As I was putting the groceries away, I ate ½ of what was left. There are now 6 chocolates left in the box. How many chocolates were in the box to begin with? Be sure to show and explain all of your reasoning.

Data Analysis

To begin analyzing the themes, we used the document analysis technique using teachers' reflections from the Lesson Study, the group lesson plan and the researchers' memos. To display and organize the collected data, we systematically analyzed data by developing initial codes then used the method of axial coding to find categories in such a way that draws emerging themes (Miles & Huberman, 1994). To verify and compare recurring themes and categories, the research team worked individually on coding the documents before comparing preliminary codes in order to agree upon recurring themes from the reflections.

Results

I. Taking Stock of Student Generated Work to Make Mathematical Thinking Visible for Worthwhile Discussions

For the first research question, In what ways do teachers use the Core Teaching Practices to make mathematical thinking visible through student-generated strategies, we examined the videotaped lesson, debrief and reflections from teachers. While teachers focused on the core practices of using and connecting math representations to engage in math discourse, we found explicit attempts to use student thinking to adapt their instruction *in situ* to enhance and extend student learning. Teachers used student-generated models to take stock of what their student generated work revealed about their understanding while highlighting efficient strategies or novel approaches to build collective knowledge in the classroom; and question or incorporate manipulatives to repair misunderstandings.

We found that teachers planned very carefully so that they could take stock of student- generated work by creating the space for students to show their thinking. The host teacher in the Candy Dilemma Problem offered students a "work mat" to display student thinking. "I chose to give each student a "work mat" (large piece of construction paper). The teachers observing my lesson thought this was a great way to show all possible strategies with plenty of room to work and large enough to observe problem-solving abilities" (Kate's reflection). Initially, students hesitated to start the problem but then began by rereading the problem to themselves quietly before attempting to solve. All students attempted to solve the problem by using numbers and were not eager to try a different method and needed prompting. Additionally, students needed prompting to justify their answer, which in turn had them question their answer or pushed them to explain what the numbers meant in terms of this problem. The host teacher who adopted the *Five Practices for Orchestrating Math Discourse* (Smith & Stein, 2011) during the course referred to it in her reflection as she selected, sequenced and connected student strategies.

> "After looking at the student work around the room, I chose students to come up to the board to show their solution/s. I had ordered them for specific reasons according to what they had shown on their work mats. The second student asked up, documented their strategy and then talked about how theirs connected to the strategy of the person's before them. I have used this procedure a lot and find that it is a good way to further solidify student learning and understanding."

Teachers noticed that students were relying mostly on guess and check and although they had learned the multiplication of fractions, some did not use that operation. Students also did not know how to make sense of the whole number that was left over. This made teachers think about the next steps in their teaching, where they would introduce more related problems and see how the conceptual understanding in these work backward problems can connect to students working through some of the operations they are learning.

II. The Nature of Teachers' Reflection on the Core Teaching Practices

For the second research question, what is the nature of teachers reflection on the core teaching practices in terms of their a) their teaching and classroom norms, and b) their beliefs as they engage in Lesson study focused on students' generated models as a discursive tool, we found two important recurring themes of the importance of setting up mathematical norms and teachers experiencing their own unique productive struggles.

Teaching practices and learning expectations need to be set up as classroom norms.

Teachers focused on the new practice of connecting students' strategies but also recognized that engaging students in the "math talk" was not something that happens over night. The host teacher shared how she spent the beginning of the school year setting expectations for students to show their thinking in more ways than one. It was a mathematical norm/expectation set up in her classroom. She also was thoughtful in creating collaborative groups that would be able to share their thinking despite their diverse abilities. The mathematical norms set up in Kate's classroom was observable by the other teacher observers. Ashley, in her reflection noted how skillfully Kate sequenced the strategies.

> At the end, Kate asked several students to come up to the board and show/explain their strategy. Each subsequent student who came up was to do the same, and then explain how it connected to the previous ones. They saw that they did the same thing, but with a different representation, or working backwards from what someone else had (Ashley's reflection).

Nature of teachers' reflection on their beliefs-Teachers experienced their own productive struggles.

Implementing these core teaching practices were new to some of our teacher participants. Engaging in professional development that focused on these eight core practices provided our teacher participants with the opportunity to not only reflect on these essential practices but enact these practices during their research lesson. One teacher reflected on how watching the host teacher's use of these practices convinced her to try to incorporate problem solving and create productive struggle in her own classroom.

> I like seeing the process of problem solving and watching most of the kids struggle, get a little frustrated, and then have the moment where they figure it out. Rewarding! I am working to make my classroom a place with more of those opportunities and participating in this lesson study allowed me to see how I can make that work in my room (Jessica's reflection).

Conclusion

Implementing these eight Mathematics Teaching Practices outlined in the *Principles to Action* provided opportunities to engage teachers in high leverage practices during our professional development project. Our study addressed ways in which teachers enacted these core teaching practices during their research lesson. In many ways, teachers who engaged in enacting these teaching practices also experienced the "productive struggle" that we try to create for our students through the problem-solving task. In other words, teachers also "grappled" with their own unique "problem of practice". Although teachers voiced the challenges of the constraint of time and the pressures of standardized test as a hurdle in providing the time and space for students to engage in problem solving, they also shared how the productive struggle and reasoning created good mathematicians in their classroom. By analyzing student thinking through a problem-solving task such as the *Candy Dilemma* allowed teachers to learn more deeply about how students approach problem solving and some misconceptions that arise in understanding fraction concepts. Using student-generated models to engage in the core teaching practices made students' mathematical thinking visible and an important discursive tool in their mathematics classroom.

NATURE AND UTILITY OF TEACHER QUESTIONING: A CASE OF CONSTRUCTIVIST-ORIENTED INTERVENTION

This study examined question types utilized by a researcher-teacher to facilitate children's knowledge of unit fractions through a constructivist-oriented mathematics intervention. Data were derived from six tutoring sessions; analysis examined the nature and utility of employed questions. Preliminary analysis shows the teacher employed four main types and nine sub-types of questions. Future analysis will delineate the how questioning shifted to correspond with the evolution and solidification in children's conceptions.

Keywords: Rational Numbers; Learning Theory; Instructional Activities and Practices

This case study examined question types utilized by a researcher-teacher in a constructivist-oriented intervention as a means to foster conceptual understanding of students with learning disabilities (SLD). Development of conceptual understanding for SLD is critically important and presents an enduring challenge for researchers and practitioners. Current questioning methods used throughout much of the special education literature are rooted in Reductionist models (Poplin, 1988). Not surprisingly, interventions created for SLD use questioning based on student responses to teacher demonstration (e.g., Fuchs et al., 2014), as opposed to teacher's responses to student thinking. The issue we take with such interventions types is that although they are considered to yield procedural efficiency, they disallow SLD to cognitively reorganize and extend their informal thinking into abstracted, transferable conceptions (Hiebert & Grouws, 2007). Nonetheless, there is little research with respect to the nature of alternative questioning teachers might employ in interventions that have as their aim SLD's construction of conceptions. Initial depictions of questioning might support later studies that reveal how varying questions may be used to support thinking and, ultimately, how teachers may employ responsive interventions in the classroom. The research question was, What types of conceptually-driven questions were utilized by the researcher-teacher during a constructivist- oriented mathematics intervention used to promote unit fraction knowledge in one fifth grade SLD?

Conceptual Framework

One constructivist-oriented notion of knowing and learning that can guide teacher questioning is the Reflection on Activity-Effect Relationships (Ref*AER) framework (Simon, 2004). This framework defines the beginning of a mathematical conception as the assimilation of a situation into a child's existing conceptions. The perceived experience sets a goal for the child's learning that regulates his or her goal-directed, mental activity in a problem situation. In such activity, the child's mind makes two types of reflections. The first, within problem situation reflection (i.e., Type-I reflection), occurs when the child notices and reflects upon what they anticipated would occur as a result of their activity versus what actually occurred. The second, across problem situation reflection (i.e., Type-II reflection), occurs when the child reflects on and compares their effects of their activity across similar problems and begins to notice commonalities in the relationship between the mental activity and its effects. The child begins to anticipate that similar activity will result in similar effects as it did in past situations, and can thus use this anticipation to figure out effects in novel situations. Activity-based conceptions are participatory or anticipatory (Author, 2004). A learner who has participatory conceptions may know what activity leads toward an intended result, but he or she is relying on prompts in order to call upon the anticipation. Conversely, a learner who has anticipatory understanding of a concept has abstracted the anticipation resulting from their mental activity – learners can then apply abstracted conceptions to new situations.

The Ref*AER framework entails an adaptive, constructivist-oriented instructional approach comprised of facilitative activities (Author; Simon, 1995) that (a) identifies the child's goal- directed activities, mathematical objects they may operate on, contexts familiar to children, and effects they may notice and (b) focuses children's activity and reflection based on conjectures about how the child's activities and reflections may bring forth the intended learning. An essential part of focusing children's activity and indirectly influencing the child's advance or development from participatory to anticipatory conceptions involves "orienting students' noticing of differences between their anticipated and actual effects and interjecting prompts [questions] that orient reflection across the learners' mental record of activity-effect dyads" (p. 2). More explication is needed in the literature with respect to the types of questions teachers employ within constructivist-oriented interventions that utilize an Adaptive model.

Methods

Participants and Data Sources

Lia (11-year old, grade-5) attended elementary school in the Northwestern United States. She was purposively chosen to participate in the teaching experiment and subsequent tutoring sessions because she was identified by her school system as having a learning disability specific to mathematics performance. According to her Individualized Education Plan (IEP), Lia was 1.5 grade years behind her peers in terms of her mathematics performance, and had failed the district's state mandated testing in mathematics. Data collection was facilitated through a constructivist teaching experiment (Steffe & Thompson, 2000). We worked closely with Lia once a week for 60 minutes (fixed-time period) over six, non-consecutive weeks between February and April. Data collected for each teaching episode consisted of transcribed video-recordings and observation field notes taken independently by two observers during the episode.

Analysis

Constant comparison analysis (Glaser & Strauss, 1967) was used to delineate codes and themes from the data as to the main types of questions the researcher-teacher utilized in the tutoring sessions. The unit of analysis in this study was a speaking turn, that is, a tri-part interchange consisting of a) the child's utterance or action, b) the researcher-teacher's question in response to the child's utterance or action, and c) the child's responding utterance or action. Emergent coding was utilized within the constant comparison method across two dimensions: a) the overall type of each question asked by the researcher-teacher (e.g., to assess the child's understanding; to foster Type I reflection) and b) any varying utility or subtype (e.g., asking for more explanation; requesting clarification). To categorize the utility of varying questions found within each overall question type and the level of cognitive complexity the question was meant to elicit, a coding theme adapted from Webb's (1997) Depth of Knowledge (DOK) was used as a deductive framework (Leech & Onwuegbuzie, 2007). Additionally, researchers performed classical content analysis to obtain percentages of overall question types and subtypes across the six tutoring sessions. Additional analysis is currently underway to delineate how the utility of questioning changed across sessions to align with how the child's conceptions evolved.

Results

Preliminary analyses show the teacher employed four main types of questioning and nine utilities (or subtypes) of questions within and across overall question types (Table 1 illuminates themes and codes). Preliminary analysis shows that Assess the Child's Understanding questions were most used by the researcher-teacher across the tutoring sessions, followed in frequency by Focus Type-II Reflection, Focus Type-I Reflection, and Invite Application of Concept questions. In terms of question subtypes, Make a Prediction/Formulate a Plan (DOK Level 3), Explain and Defend (DOK Level 3), Explain (DOK Level 2), and Evaluate Cause and Effect (DOK Level 3) were the most often noted utilities across the tutoring sessions.

Table 1. Researcher-teacher's questions in constructivist mathematics intervention

Types of questions and their codes	Examples
1. Assess understanding	
Define/Recall	OK. I'm going to take one of your pieces and pull it out of there. Let's label that. What would we call that piece?
Clarify	Do you mean that it takes three of these, if I wanted to make the whole back up, that I would have to have three of these?
Explain	One of the whole? Say more.
Explain and Defend	One-third. Why do we call it one-third?
Defend reasoning	So we can call this one 11 elevenths, and we can call this one nine ninths, even though the numbers are different, it's still the same thing? How can that be?
Critique	Couldn't you just put that entire amount of the [shortage/overage] on your next estimate? Why would that not work?
2. Invite Type-I Reflection	
Cl: Clarify	Was your estimate too long or too short? Too long? The piece should have been shorter?
Ex: Explain	What happened with your second estimate?
CE: Cause/Effect	When you repeated your estimate, is that about where you thought it would stop?
DrC: Defend reasoning/conclusions	You said it wasn't big enough. Why wasn't that one [estimate] big enough?
3. Invite Type-II Reflection	
Cl: Clarify	What do mean when you say make the piece a little bit bigger?
Ex/DrC: Explain and Defend	How did you know how much longer to make it?
DrC: Defend reasoning/conclusions	Smaller than the one-fourth you made. Can you say how you knew it was going to be that much smaller?
FP: Make a Prediction/Formulate a plan	How much less will you have to put onto each to cover it all? Convince me of the amount before you do it.
4. Invite Application of Concept	
Ex: Explain	The more you're giving away, the smaller the size gets? Talk about that more. What's that mean?
Crt: Critique	There's an eleventh. And there's a ninth. You're right. But when I count, 11 is a bigger number than nine.
Ana: Analyze	Which one's bigger, a ninth or an eleventh? Say why.

Although analyses are preliminary, two discussion points can be offered. First, Assess the Child's Understanding questions seemed predominant, and consistent with a two-fold constructivist teacher's purpose—inferring the child's current conceptions and inviting the child to voice their reasoning (elaborate on and make public her ideas). This is an important departure from Reductionist models of teaching and learning often provided for SLD. Assess questions facilitate the teacher's inferences about an SLD's mental activity and subsequent instruction builds on these inferences to foster the child's conceptualization of the intended mathematics. Such an assessment is based on the teacher's response to the child and her present conceptions to guide subsequent questioning to support learning. In contrast, Reductionist-framed mathematics interventions focus on measuring the child's responsiveness to the teacher's thinking as a finite gauge of learning or knowledge (Author, 2004; Poplin, 1988).

Second, an associated utility of Assess questions involve an effort to reorient the child's disposition in her own mathematical learning toward taking ownership of and justifying her own mathematical reasoning. Utilizing questioning in this manner originates from teaching approaches consistent with constructivism (von Glasersfeld, 1995), and help situating the child's notion of "doing" mathematics. This valuing of children's reasoning stands in contrast with Reductionist questioning utilities that seem to render the child a passive, compliant participant in mathematics learning (Poplin, 1988), and submit SLDs to scripted instruction of rather minute skills through a series of targeted, teacher-directed questions and rapid child responses (Fuchs et al., 2014). We contend that, if the goal of mathematics intervention is the SLD's conceptual reorganization and growth, then questioning needs to shift so a teacher responds to the child's available and/or forming notions of mathematics, situating questioning as a formative, dynamic mechanism within and a basis for instruction.

This study concerns a discourse analysis of questioning and mathematical development in three middle level science classrooms. Teachers who received the same professional development on a mathematics and science integrated curricular unit adapted and assimilated the materials and content differently when implementation occurred. Each teacher's lesson enactment of measuring distances between objects in the sky was examined at length to determine the ways in which questioning and mathematical discourse were developed and how this impacted student responses. Two of the three teachers had high levels of questioning and highlighted mathematical content such as ratios, angles, measuring tools, and graphical representations. Higher level mathematical questioning led to higher occurrences of classroom interactions that promoted students' mathematical reasoning.

Keywords: Middle School Education; Measurement; Classroom Discourse

Objective and Theory

In this study, discourse analysis was conducted on three middle level teachers' science classrooms as they implemented a mathematics-science integrated curricular unit. All teachers received approximately 20 hours of professional development utilizing the curriculum and its materials. Teachers adapted and assimilated the unit within their individual classrooms differently when implementation occurred. We argue classroom discourse influences how well students learn mathematical content. Specifically, we examined the teacher's use of questioning and mathematical reasoning within their classrooms. Our research questions were: In what ways did classroom discourse drive the implementation of curricular materials by teachers? How did questioning promote productive mathematical discourse in STEM classrooms?

Duschl and Osborne (2002) emphasized that adequate instruction cannot occur within a STEM classroom without having students engaged and actively learning through means of questioning. They claimed that teaching is "a process of enquiry [*and*] without the opportunity to engage in argumentation, the construction of explanations and the evaluation of evidence is to fail to represent a core component of the nature of science or to establish a site for developing student understanding" (p. 41). Walshaw and Anthony (2008) similarly insisted that 'discourse' is not simply a one-way conversation, but entails the teacher and students actively engaged in back and forth questioning and evaluative discussion. In terms of mathematical discourse, White (2003) conducted a year-long study of an IMPACT (Increasing the Mathematical Power of All Children and Teachers) camp and found several key features to productive classroom interactions. These features include: (a) Valuing and highlighting students' ideas, (b) Exploring student answers, (c) Incorporating students' background knowledge, and (d) Encouraging student-to-student communications.

Enyedy and Goldberg (2004) argued that "social frameworks and microcultures established in the classroom have a direct impact on *what* students learn" (p. 928). So even when teachers receive the same professional development and materials, classroom culture, teacher beliefs, and teacher content knowledge will drive the instruction and classroom discourse that results in how and what students explore, connect with prior knowledge, and communicate to their peers.

Research Methods

Participants

Research subjects were three sixth-grade science teachers and their students from one south-central US middle school (ButternutMiddle School). Three student groups (*N* = 229) were taught by Mr. Land and Ms. Apple (both 2nd year teachers), and Ms. Roling with 16years teaching experience. Butternut middle school demographics showed 74% of the students as White, 10% Black, 8% Hispanic, 5% Asian, and 3% other races, with 26% of the students eligible for reduced lunch. *Pseudonyms were used for the school and teachers.*

Data Collection and Analysis

In order to determine how classroom discourse drove implementation and how teacher questioning promoted mathematical discussion, we implemented a qualitative research design. Three science teachers' implementation of one heavily integrated math/science lesson was videotaped and transcribed. We coded video clips using mathematical concepts and questioning as parent codes, then refined our questioning code into high and low level types of questions. The transcripts were analyzed separately by each researcher and then traded and reviewed. Finally, they were jointly coded in agreement. The inter-rater reliability was relatively high as most of the coded material agreed amongst the three researchers. The few instances of non-agreement initially were on the level of a question.

The lesson that was taught by all three teachers concerned measurement with a focus question of *How do I measure the distance between objects in the sky?* The intended lesson design goes as follows. The lesson begins with students using body parts such as their thumbs and fists to measure lengths of objects in the classroom (from their seats). Discussion ensues in terms of the requirement of consistency in their measurements (extended arms) and why each person would have similar numbers even when people's fists are different sizes. Constant body ratios are discovered as students plot data of arm lengths versus fist widths. Students then determine that one fist width per person is equivalent to 10 degrees as they utilize a protractor in their measuring. Finally students determine that a fist (with arm extended) can be used to measure the distance between objects in the sky as well as the altitude distance of the Moon from the horizon. Azimuth and altitude angles together can determine the location of an object in the sky. Students determine the number of fists required to go from horizon-to-horizon as well as full circle around their body. Students further confirm that each fist width equals approximately 10° after experiencing these activities utilizing body movements (arms extended while measuring). Students document altitude and azimuth angles of various objects in the classroom or outdoors.

Results

Although teachers received the same materials and professional development on the lesson enactment, each utilized their individual strengths, comfort levels with mathematics, and

Table 1. Number of Questioning (High and Low) and Mathematical Episodes

Teacher	Years of Teaching Experience	Total Questioning Instances	Low Level Questioning Instances	High Level Questioning Instances	Mathematics Instances
Ms. Apple	2	52	29	23	7
Mr. Land	2	34	18	16	12
Ms. Roling	16	6	4	2	4

instructional beliefs when implementation occurred. Instances of questioning (high and low) and mathematical episodes are illustrated in Table 1.

Two teachers (Apple and Land) tended to use more questioning and mathematics in their classrooms. Ms. Roling did not use as much of either category. If a question occurred that required only for the students to respond with a simple yes or no, we coded it as a low-level question. When a more substantial thoughtful response was required, we coded this as a high-level question. An example of a high-level question occurred with Ms. Apple's class when she asked students to consider how a scientist might determine the location of an object in the sky.

Apple: So raise your hand if you have an idea of how scientists measure and communicate the location of objects in the sky.
Student: Um, azimuth and the altitude?
Student: Satellites
Student: Knuckles? They used their knuckles to measure.
Student: Perhaps, like, stack their hands … one hand's equal to or equivalent to so many miles

This is a high-level question, since students drew from their real world background knowledge to speculate how scientists might determine the location of an object in the sky. The students who claimed that "knuckles" or "stack their hands" could be used as units of measurement were not far off since they were soon going to be learning how to use their fists as a measuring device.

A mathematical episode as well as high-level questioning was observed in Mr. Land's teaching. Students just finished plotting the class' arm lengths versus fist widths.

Land: All right let's look at the data now, so let me get…trend line. We'll add a linear trend line, so what's happening here? Somebody explain this slope. Is this positive or negative?
Class: Positive
Land: Positive, so what's happening, what does this slope mean? What can I extrapolate from this data? What can I take away from this data? Okay, what do you think?
Student: Okay, um, like the longer their arm to eyes are, um, wait never mind
Land: So the longer their arm is, what?
Student: Yeah, um, like the longer the arm is the or the, bigger their fist

Mr. Land requested that students explore the data set and determine a mathematical relationship between arm length and fist width. Students observed the linear relationship and were able to link the slope of the trend line to the body ratio of arm length to fist width.

Along with high-level questioning, teachers also asked a good deal of low-level questions. Ms. Roling tended to teach by telling for much of her class instruction. She explained to students the difference between an azimuth angle (cardinal direction where North means 0°, East means 90°, South means 180°, and West means 270°) and an altitude angle (angular measurement from the horizon). She followed each lecture with "Does this make sense to you?" Students responded by shaking their heads or saying "yes".

In contrast to Ms. Roling's azimuth explanation, Mr. Land had his students experience azimuth angles as they determined the number of fists that would go around one's body (360°) with arms extended.

Land: …360° in a circle, make sure you write down a little circle mark that represents degrees. Okay, because if you just write down 360, how the heck do I know what you're talking about? You could be talking about 360 pigmy elephants!
Student: But Mr. Land, it says how many degrees.

Land: It does, but generally speaking you always put the unit with the number. Okay, if there's 360 in a circle, and my 10, and my fists is how many degrees?
Class: 10
Land: 10 degrees, how many fists should I be able to do?...I want you to stand up and try it. Calculate how many fists it takes to go around your body. In one full circle.
Class: 36!!

Ms. Apple and Mr. Land emphasized mathematical terminology and concepts, such as degrees, ratios, data collection and graphing, slope, and angular measurements. They used these concepts embedded in science as a way of contextualizing the mathematics in order to make it more meaningful. Ms. Roling did not utilize much questioning or mathematics, and when it was used, it was at a low-level.

Discussion and Conclusion

Students' responses in the classroom corresponded with the level of discourse for which the teacher probed. The ways teachers used discourse as they enacted the measurement lesson influenced student learning as determined by their responses. In a related study, students of Land, Apple, and Roling were given a pre/post test that assessed both mathematical and scientific understandings. Figure 1 displays student gain scores by teacher with students of Land and Apple achieving higher gains than Roling's students from pre-instruction to post.

Within our qualitative study, we found that the teachers' approach to questioning and how they implemented the measurement lesson related to the amount of mathematical discussion in the classroom. Mathematical concepts tended to emerge when classrooms also had higher questioning episodes. Mr. Land and Ms. Apple incorporated White's (2003) discourse categories in terms of highlighting and exploring students' ideas and incorporating students' background knowledge. It is clear there was a discrepancy in how individual teachers enacted an identical curricular lesson. As described by Enyedy et al. (2004), these differences in implementation and ultimately in student learning can be explained by the microcultures each teacher established within their own instructional spaces. Even though all three teachers in our study were from the same school, Land and Apple appeared to have developed classroom cultures where students were encouraged to communicate their ideas and use language of the disciplines, rather than sitting at their seats being passive recipients of knowledge.

The NCTM (2000) suggests that students should be "actively building new knowledge from experience and prior knowledge" (p.11) and that teachers should be "listening carefully to students' ideas" (p. 19). The idea of teachers listening to students' thinking to help students build on prior knowledge is key within the enduring theme of teaching as responsive to various conceptions of mathematics. Our studies investigated how teachers support students to build on prior knowledge, paying particular attention to what teachers do as they listen to students' thinking. Here we explore these results, and make inferences regarding how the NCTM recommendations on students' prior knowledge and teachers' listening can be implemented widely and in tandem.

Through several recent projects, we have been considering the notion of 'setting aside' – that is, that teachers may guide or encourage students to 'set aside' some ideas and build on other ideas that have more potential in a current situation. Here, we explore the notion of setting aside as it relates to teachers' preferred approaches to a mathematics problem and expectations of students' thinking. Our data analysis draws upon Davis' (1996) three types of listening: hermeneutic, interpretative, and evaluative. Evaluative listening focuses on listening to student thinking to identify the correctness of a solution. Interpretative and hermeneutic listening focus on listening to make sense of students' thinking. Hermeneutic listening involves the teacher being "a participant in the exploration" (Davis, 1997, p. 369) and is often associated with a listener's learning.

We present classroom instances from a grade four lesson involving probability, and a post-secondary lesson for pre-service teachers that considered multiplication strategies. Analysis of our data suggests that teachers, while listening to students' thinking, 'set aside' some of their own preferences and build upon some of their students' preferences for ways of approaching/solving a mathematics problem. For example, to estimate 250x97, the teacher preferred (and also expected students) to compute 250x100. As she listened to a student explain that he divided 100 by 4 and then multiplied it by 1000, she set aside her own preference, learnt a new strategy for that question, and began to think about 250x36. The two classroom instances we share will include a description of the teachers' preferences that were set aside, the thinking that students and pre-service teachers shared, and the teachers' learning that took place. This poster adds to the literature on mathematics teacher listening and it is hoped that the notion of setting aside preferences for approaching/solving a mathematics problem will be helpful to teachers in enhancing their classroom practices to more fully engage with student thinking.

INVESTIGATING RELATIONSHIPS AMONG TEACHERS' MATHEMATICS BELIEFS, EFFICACY BELIEFS, AND QUALITY OF INSTRUCTIONAL PRACTICES

Fetiye Aydeniz
Indiana University
faydeniz@indiana.edu

Keywords: Teacher Beliefs; Instructional Activities and Practices

The relationship between teachers' beliefs and practices has been the focus of previous investigations because teachers' deeply held beliefs influence their decisions about what and how they teach, and how they design their learning environments (Fives & Buehl, 2008). To augment prior research on how teachers' beliefs shape their perceptions and practices, the main aim of this study is to gain a deeper understanding of teachers' beliefs about mathematics and the links between their beliefs and the mathematical quality of their classroom instruction. Accordingly, this investigation was guided by three main research questions: whether teachers' mathematics-related beliefs are reflected in their instructional practices, whether teachers' self-efficacy beliefs play a role in their practices, and whether the alignment between teachers' beliefs and practices brings about high-quality mathematics instruction.

My research, as part of a long-term project, was a collective case study involving data from six participants; six individual cases were compared and contrasted to explore the relationship between teachers' beliefs and practices, and then two selected cases were analyzed in terms of their quality of mathematics instruction. Interview transcripts, videos of classroom instruction, and responses to self-efficacy surveys were examined for evidence of the teachers' beliefs and practices in teaching mathematics. A priori codes (i.e.. productive beliefs, unproductive beliefs) were determined before examining the interview data in hand (NCTM, 2014). Also to examine teachers' classroom practices, I used an observational instrument, the Mathematical Quality of Instruction (MQI; Learning Mathematics for Teaching Project, 2011). Data from the teacher self-efficacy survey were analyzed by conducting descriptive analysis.

My findings indicated that, with the exception of two cases, the teachers expressed beliefs that could be considered as both productive and unproductive as the NCTM suggests. Their professed beliefs were in fairly close alignment with their instructional practices although they described varying productive and unproductive mathematics beliefs, which affected their instruction accordingly. I see that the alignment between teachers' beliefs and practices did not guarantee high quality mathematics instruction. Although there was a quite close alignment between teachers' beliefs and practices, no clear linear relationship between them could be established, and other factors, such as the nature of their beliefs, that influence how teachers perceive and enact their roles in the classroom might have affected the mathematical quality of their instruction.

RETHINKING MATHEMATICS TEACHING WITH PAPERT, BROWN AND OTHERS

Geneviève Barabé
Université du Québec à Montréal, Canada
gebarabe@gmail.com

Jérôme Proulx
Université du Québec à Montréal, Canada
proulx.jerome@uqam.ca

Keywords: Instructional Practices and Activities

This project aims at rethinking and exploring mathematics teaching theoretically and empirically. Papert's (1980) suggestions about what teaching mathematics should be diverge from usual views that center on attaining predetermined goals/objectives and keeping the attention of the class precisely on them while teaching. In Papert's view, mathematics teaching is about allowing students to *be* and *act* in mathematics (as mathematicians do and act), rather than focusing on teaching specific mathematical content. He proposes that students do mathematics by exploring them, asking new questions, developing new ideas, and so forth, which leads teachers to work and explore mathematical objects without having predetermined end points to reach. These ideas have also been explored by Brown & Walter (e.g. 2005), on issues of problem posing; they propose that mathematics teaching occurs through, and is grounded in, students' questioning on a given problem. Starting from a specific theme provided by the teacher, the intention is to make *mathematics* emerge in the classroom by working with students on/from their ideas and questions, which leads to mathematical explorations where students do mathematic; this acting thus as the central goal. Other like Kieren, Davis, Lampert, and Lockhart, to name a few, have also discussed similar ideas about mathematics teaching. However, these ideas have not been integrated into an encompassing framework that grounds theoretically and offers a coherent organization of these teaching ideas and their implications. This study aims to develop this grounding framework, which is to be developed by exploring Holton's (1988) three nested dimensions: the empirical (i.e. observations to develop meaning); the analytical (i.e. theories to explain the phenomena); and the thematic (i.e. reflections about the underlying assumptions, meanings, vocabularies, and methodologies). This poster presents preliminary results gathered from combining the analytical and empirical dimensions, taken from a case study of a teacher who adopts these views about teaching mathematics; the results in return lead to reflections on the third dimension, that is, the thematic. These preliminary analyses underline significant characteristics, three of which are: (a) *Author/ity* (e.g. Povey & Burton, 1999), where the teacher and students work together to develop a mathematics community in which all have a personal voice and are makers of knowledge; (b) *Openings* (e.g. Remillard & Geist, 2002), which refers to important unpredicted instances that emerge when doing mathematics, which expand and deepen the mathematics under study and demonstrate by their presence that learning happens and that mathematics evolves; (c) *Complicity* (e.g. Davis & Sumara, 1997) refers to the fact that the teacher becomes complicit in students' knowledge in shaping what is learned, from mathematics itself to their views/philosophies of mathematics. These characteristics and others will be presented/discussed in light of the thematic issues they underline about mathematics teaching.

MATHEMATICS TEACHERS' PERCEPTIONS OF FACTORS AFFECTING THE USE OF HIGH COGNITIVE DEMAND TASKS

Amber Candela
University of Missouri – St. Louis
candelaa@umsl.edu

Keywords: Teacher Education-Inservice

Mathematics teachers' difficulties implementing high cognitive demand tasks is well documented in the mathematics education literature, although teachers' perspectives on this issue are largely absent from such literature (e.g., Stein, Grover & Henningsen, 1996). In this study, I examined factors *teachers* discussed as inhibiting or promoting the use of high cognitive demand task. My intention was to give voice to middle school mathematics teachers who were trying to implement these tasks. This study can inform those providing professional development in relation to high cognitive demand tasks.

I conducted a multiple case study (Yin, 2003) with the seventh grade team of three teachers at Yellow Brick Middle School in the Southeastern United States, all of who had less than five years experience. The theoretical framework used in this study was the task implementation framework developed by Stein and colleagues (1996).I planned with the teachers for the specific implementation of two high cognitive demand tasks, observed the lesson, and interviewed each teacher after. The goal for data analysis was to gain teachers' perspectives of implementing high cognitive demand tasks. I realized the factors the teachers mentioned, not included in the task implementation framework, specifically related to events that happened before planning tasks. I used the new factors I identified, along with those in the task implementation framework to code the interviews accordingly making note of where the teachers had common barriers and supports, and then identified factors each teacher individually pointed to as being a barrier or a support.

During the course of this study, I looked at a more broad view of the task implementation process and gained teachers' perspectives on the entire process from planning, to implementing or not implementing a high cognitive demand task, and then into the classroom for the implementation of a high cognitive demand task. I found factors did not fit in with the task implementation framework (Stein et al.,1996) that included teachers' perceptions of students, time, district requirements and curriculum, and parental dispositions. I labeled these factors collectively as *factors influencing teachers' use of high cognitive demand tasks* and suggest these factors be attended to before the teachers implement high cognitive demand tasks. By knowing what factors teachers' perceive as affecting the decision to implement high cognitive demand tasks, researchers can help find ways to overcome perceived obstacles and support mathematics teachers. Teachers should realize how important and beneficial implementing high cognitive demand tasks is for their students and thus make the decision to find and implement high cognitive demand tasks. It is my intent this study will be a catalyst for further conversations about how to support mathematics teachers implementation of high cognitive demand tasks.

TEACHERS' PERCEPTIONS AND USES OF THE COMMON CORE STANDARDS FOR MATHEMATICAL PRACTICE

Cynthia D. Carson
University of Rochester
cynthia.carson@warner.rochester.edu

Keywords: Standards; Teacher Beliefs; Middle School Education

This study examined middle school math teachers' perceptions of the Standards for Mathematical Practices (SMP) in the Common Core State Standards for Mathematics (CCSSM), which are the de-facto intended U.S. national curriculum (Porter, McMaken, Hwang, & Yang, 2010). The SMP have their foundation in the NCTM process standards and strands of mathematical proficiency identified in the National Research Council's report, *Adding It Up* (Common Core State Standards Initiative, 2010). The authors of the CCSSM indicated that the SMP are intended for students to exhibit while engaging in mathematics. Therefore this analysis operated from the perspective that teachers' perceptions of the SMP will influence their enactment of the SMP in their planning and instruction. The background interview data were collected as part of a larger study with NSF funding (DRL-746573 & DRL-1222359) from 48 teachers from eight states. This analysis considered teacher responses that indicated the SMP represented a significant change from previous standards. These questions guided the analysis:

- What are the teacher's perceptions of the SMP their role in CCSSM and how should the SMP be enacted in the classroom?
- How are teacher's perceptions of the SMP evident their planning and daily instruction?

The primary finding is that teachers characterized the SMP as a measuring stick with regard to the level of rigor required by the CCSSM. One teacher expressed that the SMP showed the performance expectations associated with the CCSSM; "[SMP] gives us an opportunity to look at what we're expecting students to do and raise those expectations" (Granville, NY, all names are pseudonyms). Teachers stated that the SMP increased the rigor emphasizing a deeper level of engagement with mathematical content. For example, Ross (NY), stated that the SMP required "a lot more in-depth, a lot more deep thinking about math and explaining your reasoning and how you got to these conclusions, the number is no longer just enough." Teachers also indicated that the language of the SMP provided justification for their current instructional practices, which were not validated in their prior state standards. In addition, the SMP provided a mathematical authenticity to the content in CCSSM. For example, Tomar (NH) stated "that's probably a major innovation like we're defining what a math classroom looks like, what the practices of a mathematician look like." The implications of these findings provide a structure for further analysis of teachers' usage of SMP for instruction and formative assessment decisions, and for professional development designers providing learning opportunities.

SECONDARY TEACHERS' BELIEFS OF TEACHING MATHEMATICS IN DIVERSE SCHOOL SETTINGS

Mark Franzak
New Mexico State University
mfranzak@nmsu.edu

Keywords: Teacher Beliefs; Equity and Diversity; High School Education; Middle School Education

The body of research in teacher-held beliefs in mathematics education is wide and varied, with a legacy spanning more than four decades. Research topics in this literature base include teachers' beliefs regarding the use of manipulatives, incorporation of constructivist learning principles in instruction, and the degree of affiliation of beliefs and practice. It is not just important, but *critical*, to note that this body of research explores mathematics teachers' beliefs largely without consideration of race of the teacher or of the students. I problematize this in two ways. First, the absence of race of student and of teacher implies a generalizability of the research to all races, all ethnicities, all marginalizations. Second, the absence of race establishes a monolithic teacher and a monolithic student, each without color or culture

My study creates spaces for understanding conceptualizations of race in purportedly race-neutral mathematics, exposing uninterrogated aspects of secondary teachers' beliefs. In this session, I report on the preliminary results of my research focusing on secondary mathematics teachers' beliefs about race in conjunction with their beliefs about mathematics and mathematics education. In this qualitative multicase study of two white and two Hispanic secondary mathematics teachers in New Mexico, I explored two questions: (1) what are the intersections of teachers' beliefs of 3 areas: mathematics, teaching/learning mathematics, and race; (2) what are the origins of their beliefs? Participants engaged in four one hour-long interviews over a period of one month, and also provided three journals in which they responded to researcher-selected prompts on mathematics and mathematics education. Data from the interviews, journals, and researcher's field notes were coded and analyzed using the constant comparative method.

Preliminary results from the study indicate the complexity of teachers' beliefs in working with diverse student populations. Beliefs about the nature of mathematics and of methods of instruction varied substantially. Of the nature of mathematics, participants presented a wide range of thoughts from mathematics as independent of humans, and was discovered rather than invented, to mathematics as a purposeful tool to approach problems and find appropriate solutions. Beliefs of teaching methods also varied, from a traditional lecture model to constructivist only methods. Discussions of teaching methods were often in tandem with discussions of classroom management. Issues of performance in mathematics were often associated with student drive, work ethic, perseverance, determination, and grit. Success in mathematics was often presented as a binary construct of trying vs. quitting. Race and ethnicity were factors that white participants did not readily bring into the conversation, but were prevalent in discussions with one Hispanic participant, and evident to a lesser extent in the data from the second Hispanic participant. For white participants, student diversity was not a significant factor in planning for instruction. Survival mode as a teacher was a concern among participants that arose several times. Origins of beliefs were occasionally detailed, although probes into the sources of beliefs often returned vague replies, or the lack of specific episodes from which beliefs emerged.

CONSIDERING STUDENTS' RESPONSES IN DETERMINING THE QUALITY OF TEACHER'S QUESTIONS DURING MATHEMATICAL DISCUSSIONS

Previous researchers have analyzed the types of questions teachers ask during mathematics lessons and have generated frameworks for categorizing teachers' questions (Boaler& Humphreys, 2005). This body of research has identified specific types of questions as effective in eliciting students' mathematical thinking and reasoning and other types of questions as effective in eliciting rote, procedural, or factual mathematical knowledge. In this study, we aim to extend the literature to provide a better understanding of the close connection between teacher questioning and student engagement. Specifically, we investigate the extent to which question types identified as higher-order questions actually serve to generate high-level student responses during whole-group discussions in mathematics lessons. We hope to make a contribution to the field by providing empirical evidence to support previous theoretical frameworks for teachers' questioning.

Data have been collected from 6 mathematics teachers in a large urban school district. Eight mathematics lessons (two teachers recorded twice) were analyzed from video recordings of 90-minute block class periods for: 1) types and levels of questions the teacher asks, 2) types of responses students provide, and 3) the length of students' responses (number of words used). Teacher-student dialogues were transcribed from the whole-class discussion part of each lesson. Frameworks used in the analysis include Wimer's (2001) categories of higher order and lower order questioning, Boston's (2012) rubrics for high vs. low-level student responses, and Boaler and Humphreys' (2005) questioning types: Gathering information, checking for a method (G), Inserting terminology (IT), Exploring mathematical meanings and relationships (EMM), Probing (P), Generating discussion (GD), Linking and applying (LA), Extending thinking (ET), Orienting and focusing (OF), and Establishing context (EC).

Results from the study indicate that the level of teacher questioning significantly impacted the level of student response ($\chi^2 = 39.61$; $p < .0001$).Consistent with Boaler and Humphreys' (2005), we found: 1) the majority of questions were Gathering Information (G), and these questions almost always (94%) generated low-level student responses; 2) low frequencies of questions (38 of 120; 32%) considered to support students' mathematical thinking and reasoning (e.g., EMM, P, LA, ET); and 3) Probing (P) and Linking and Applying (LA) were likely to generate a high-level student response. Last, the mean number of words in students' responses is significantly higher for higher-order questions than for lower-order questions ($t\ (118) = 3.17$; $p < .0001$ [one-tailed]). Hence, the type and the level of teacher questions affect how much students engaged in providing responses.

TWO SECONDARY MATHEMATICS TEACHER CANDIDATES' ENACTMENT OF DISCOURSE MOVES AND QUESTIONING PRACTICES

Dana L. Grosser-Clarkson
University of Maryland
dgrosser@umd.edu

Keywords: Teacher Education-Preservice; Classroom Discourse; Middle School Education

Ambitious teaching practices provide opportunities for all students to engage with mathematics. Within the broader challenge of preparing future teachers to enact more ambitious teaching practices, teacher educators must specifically prepare future teachers to facilitate productive classroom discourse. Facilitating discourse-intensive situations is complex and requires practice and reflection. It is therefore important that teacher educators provide opportunities for teacher candidates (TCs) to enact more ambitious teaching practices through coursework and to provide them the opportunity to reflect and refine their practice. This case study research follows two teacher candidates enrolled in year-long, post-baccalaureate certification programs. Specifically, it addresses the following research question: what discourse moves and question types do two teacher candidates utilize during instruction?

To address this research question three video-recorded lesson enactments were analyzed. The first video recording took place in June 2014 at the completion of the TCs' first mathematics methods course. This recording was of an *approximation of practice* (Grossman, Compton, et al., 2009), during which TCs taught a 30-minute lesson to their peers. The second video was recorded in November 2014 at the completion of the TCs' second mathematics methods course. The third video was recorded in March 2015 as part of a performance-based assessment. The last two video enactments were recorded in the TCs' field placements with actual middle school students.

Transcriptions of video recordings were coded for specific discourse moves such as revoicing, restating someone else's reasoning, applying someone else's reasoning, or using wait time (Smith & Stein, 2011). The questions each TC posed during instruction were classified as one of nine-question types identified in Boaler and Brodie's (2004) study of secondary mathematics classroom instruction. The nine question types are as follows: (1) gathering information, leading students through a procedure, (2) inserting terminology, (3) exploring mathematical meanings and/or relationships, (4) probing, getting students to explain their thinking, (5) generating discussion, (6) linking and applying, (7) extending thinking, (8) orienting and focusing, and (9) establishing context. Initial findings show that both TCs' were successful in applying a variety of question types and using some discourse moves, even in the earliest video recording.

OBJECTIFICATION-SUBJECTIFICATION DIALECTIC IN MATH DISCOURSE

José Francisco Gutiérrez
University of California, Berkeley
josefrancisco@berkeley.edu

Keywords: Algebra and Algebraic Thinking; Classroom Discourse; Equity and Diversity; Learning Theories

Intro & Background. This study explores the dialectic between the semiotic resources (e.g., gesture and language, as well as conventional tools such as tables/graphs) to which students have recourse to make mathematical assertions, and the hierarchical subject positions that participants co-construct through these multimodal interactions. I focus on processes of objectification (Radford, 2003) and subjectification (Foucault, 1977) as a method of exploring this dialectic. I present a detailed analysis of a 35 min. span of data involving three high school students engaged in a collaborative generalization task. I observe that objectification and subjectification are co- constructed through mathematical discourse. Below is a sample transcript segment and analysis.

Ailani: [*counts on fingers*] Eleven, twelve, thirteen… Figure ten will be… nineteen. [*10 sec pause*] (Figure ten).. nineteen.
Thalia: [*gazes down at her sheet; indicates her table of values*] Figure ten will be fifteen.
Ailani: [*responds to Thalia*] Nineteen.
Thalia: [*gazes down; shakes head*] Figure ten will be fifteen.
Ailani: [*loudly*] Figure ten will be nineteen!
Thalia: [*gaze down; indicates entries with her finger as she talks*] It goes two-three-six, then it goes two-three- seven, then it goes two-three-eight, then it goes two- three-nine, then it goes two-three-ten, then it goes two- three-eleven, twelve, thirteen, fourteen, fifteen. [*keeps gaze down, continues working*]
Ailani: I say nineteen. [*4 sec pause*] I'm not even sure I counted that right, but who cares?

Results. Ailani's semiotic means of objectification consisted of a counting strategy and verbal speech (with a certain illocutionary force) to assertively express a partial solution, in the form of $f_3(10) = 19$. In contrast, Thalia too resorted to verbal speech, yet she also used rhythm, gesture, and repetition, and a mathematical table as semiotic resources. Entering a rhythmic cadence (Line 6) enabled Thalia to objectify a recursive *generalization*, in the form of $\{f_1(n), f_2(n), f_3(n)\} = \{2, 3, f_3(n-1)+1\}$ which, in this context, is more informative than Ailani's solution.

Whereas both students made statements that tacitly positioned themselves as having the correct answer, Thalia resorted to a broader arsenal of semiotic resources to make her point. Additionally, Thalia did not make eye contact with Ailani, instead keeping her gaze on her work. This social-mathematical power encounter resulted in differentiated status positions, and an opportunity was missed to engage in dialog and collaborate on the shared goal, to determine Figure 10. In this way, Thalia's and Ailani's respective semiotic means of objectification also functioned, simultaneously, as semiotic means of subjectification. Thus Thalia gained *mathematical ascendency* over Ailani, which is a construct that I claim is a version of Foucault's (1977) theory of power-knowledge, as a co-constructed, semiotic-based status hierarchy.

DIFFERENTIATING MATHEMATICS INSTRUCTION WITH MIDDLE SCHOOL STUDENTS

Amy J. Hackenberg Ayfer Eker Mark A. Creager
Indiana University-Bloomington
ahackenb@indiana.edu ayeker@indiana.edu macreage@indiana.edu

Keywords: Cognition, Design Experiments; Equity and Diversity; Middle School Education

Today's middle school mathematics classrooms are marked by increasing cognitive diversity—an enduring challenge in the field. Traditional responses to cognitive diversity are tracked classes that contribute to opportunity gaps (Flores, 2007) and result in achievement gaps. Differentiating instruction (DI) is a novel but untested response to cognitive diversity in which teachers proactively plan to adapt curricula, teaching methods, and student activities to address individual students' needs in an effort to maximize learning for all students (Tomlinson, 2005).

The purpose of this poster is to present preliminary findings about what characterizes differentiating mathematics instruction for cognitive diversity with middle school students. In the first two years of a 5-year project to study DI we conducted three 18-session design experiments, each with nine cognitively diverse 7th and 8th grade students. In keeping with design experiment methodology (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003), we made changes between experiments in order to foster the most possible progress while studying our interventions. For example, we knew that it was important to develop norms (Tomlinson, 2005) with students to help them learn to work autonomously and to honor differences among classmates. However, we found that we needed to help not just individuals but small groups work autonomously, and so we developed a focus on small group functioning.

Our preliminary findings include the following. When aiming to differentiate instruction:

(1) The teacher needs to use formative assessment to develop working models of students' ways of thinking and organize those ways of thinking into a network (Ulrich, Tillema, Hackenberg, & Norton, 2014). Planning for this network involves a "web-like" approach in which the teacher anticipates multiple (2-4) broad pathways for students. Implementing these plans requires a continual cycle of posing tasks, asking questions and listening, and making interpretations and adaptations for students moving along and/or across each of these pathways.

(2) The teacher needs to help structure students' exposure to different ways of thinking in order to help students navigate interaction with, and potential learning from, others. Doing so may help students make sense of and try out different ways of thinking without being overwhelmed by them. One aspect of this structure involves explicit conversations about how to respond to another's way of thinking. We view these findings to be components of a theory of differentiating mathematics instruction for middle school students.

Mathematics instruction that builds on children's mathematical thinking is advocated for within the larger mathematics education community (Carpenter et al., 1989; NCTM, 2014). This type of classroom instruction relies on what Pimm (1987) describes as genuine conversations in which students share the responsibility for determining the direction of lessons; however, established classroom routines in the U.S. favor IRE exchanges (Mehan, 1979). We describe instruction that incorporates children's thinking as *responsive* to children's mathematical thinking. Hiebert and Grouws(2007) claim that, "Documenting particular features of teaching that are consistently effective for students' learning has proven to be one of the great research challenges in education" (p. 371). In this session we propose a framework that documents a key feature of instruction that will allow researchers to specify relationships between responsiveness and other established constructs, to refine current theoretical models of teaching and learning, and to provide teachers with a tool to describe one aspect of their classrooms.

The framework is based on earlier research and has been revised based on recent data from over 160 lessons across 11 classrooms. *Responsiveness* reflects the extent to which student thinking is taken up and built on during mathematics instruction. Students' mathematical ideas must be expressed in order for teachers to be responsive. As such, a characterization of students' mathematical ideas is a necessary component of characterizing responsiveness. Thus, we holistically categorize segments of discourse in terms of two interrelated features of whole-class discussion in mathematics classrooms: (a) students' mathematical contributions, and (b) teacher responsiveness to these contributions. Categories of students' mathematical contributions express increasingly sophisticated contributions ranging from recalling facts and performing calculations (minimal); to sharing mathematical information without justification (limited); to participating in mathematical argumentation (substantial). Categories of teacher responsiveness reflect the extent to which students' mathematical ideas are made public, taken up, and the basis for instruction: low (ignoring, brushing-off, or evaluating student contributions), medium (revoicing student ideas, asking probing questions), and high (directing students to engage with others' mathematical ideas). Applications of this framework are presented on the poster.

THE INFLUENCE OF TEACHERS' BELIEFS, GOALS, AND RESOURCES ON INSTRUCTIONAL DECISIONS

Lindsey R. Haubert
University of Toledo
lindsey.haubert@utoledo.edu

Debra I. Johanning
University of Toledo
debra.johanning@utoledo.edu

Keywords: Teacher Beliefs; Number Concepts and Operations; Rational Numbers; Instructional Activities and Practices

The work of teaching is complex. There are numerous, not readily observable components involved in the decisions teachers make while carrying out a lesson that builds on students' mathematical thinking (Ball, 2008). One important decision involves deciding how to use evidence of student thinking during instruction. There are a number of factors that impact this decision. Developing goals for lessons is part of the work teachers do and help to drive the decisions they make during instruction (NCTM, 2014). Teachers' available resources also impact decisions. (Schoenfeld, 2011). Teachers come to a classroom with an already developed set of beliefs about how children learn mathematics (Vacc & Bright, 1999). These beliefs have an impact on the decisions teachers make in planning and implementing a lesson.

This research was part of a larger study in the domain of fraction operations when using a guided-reinvention approach to algorithm development. The purpose of this study was to examine the influence teachers' goals, resources, and beliefs about teaching mathematics have on the decisions they make during the planning and teaching in this domain. Data was gathered from three fifth-grade teachers and one sixth-grade teacher who were observed teaching an initial lesson in a unit on fraction multiplication. The lesson engaged students in solving contextualized problems where students bought fractional parts of partially full pans of brownies. All teachers, at some level, were observed eliciting student thinking in this lesson. However, how each teacher made use of students' reasoning in relation to supporting students' developing understanding of fraction multiplication differed. Through observation and post teaching interviews we also considered how beliefs, goals and resources impacted the mathematics developed as a result of the lesson. The portraits developed for each teacher revealed the importance of particular fraction multiplication questioning frameworks, how teachers interpreted and used students' reasoning in relation to their goals as revealed in these questioning frameworks, and how past teaching experiences, curricular and school-based resources were related to the mathematics developed in the lesson.

PROMOTING EFFECTIVE SMALL GROUP LEARNING IN THE MIDDLE GRADES

Daniel J. Heck
Horizon Research, Inc.
dheck@horizon-research.com

Jill V. Hamm
University of North Carolina at Chapel Hill
jhamm@email.unc.edu

Keywords: Classroom Discourse; Instructional Activities and Practices; Middle School Education

Background and conceptual framing. Peers Engaged as Resources for Learning (PEARL) integrates understandings of small group learning environments using three frameworks: Mathematics Task Framework (Stein et al., 1996), Math Talk Learning Communities (Hufferd-Ackles et al., 2004), and Peer Cultures of Effort and Achievement (Hamm et al., 2012). Small groups offer opportunities to address goals for all students in *Principles to Actions* (NCTM, 2014) and *Common Core State Standards for Mathematics* (NGA, 2010).

Research questions. The PEARL project's initial research questions are: "In current practice, what strategies do teachers use as they enact tasks, promote discourse and manage peer cultures of effort and achievement, and for what purposes? What challenges do teachers experience as they focus on tasks, discourse, and peer cultures?"

Research design and findings. The PEARL study combines examination of mathematics instruction for conceptual understanding and adolescent classroom peer processes through investigation, design experiment, teacher learning experiences, and experimental study. This presentation focuses on investigation using naturalistic field study. A preliminary study of existing data reinforced the importance of all three frameworks, leading to hypotheses about productive equilibrium, balancing areas such as exploration with sense-making; individual with group responsibility; and natural with guided peer interactions. These hypotheses informed the naturalistic field study of 11,6-9th grade teachers' classrooms, involving lesson observations, interviews with teachers, and focus groups with students. Findings illustrate productive equilibrium in small groups, pinpointing ways that teachers support productive equilibrium, and depict ways that small group learning environments can lack or lose productive equilibrium. The study indicated sparse explicit attention with students to establishing, supporting, and reflecting on small group functioning as an environment for learning mathematics.

Conclusion. PEARL aims to build stronger theoretical and practical framing of small group learning environments to inform teachers' professional practice in three domains: mathematics tasks, student discourse, and peer cultures. Situated authentically in classrooms, initial findings reveal opportunities and challenges for teachers to produce and maintain balance within and across these three domains to deliver on the promise of small group work.

EXPLORING BASE 10 COMPLEMENTS THROUGH MATHEMATICAL GAMES

Sabrina Héroux
Université du Québec à Montréal
sabrina.heroux@gmail.com

Keywords: Instructional Activities and Practices; Elementary School Education

This study about mathematical games concerns non-traditional way of teaching for improving and deepening students' experiences of mathematics. In addition to arguments in favor of using games to increase students' motivation as well as classroom interactions, researchers like Bragg (2003) or Peltier (2000), using pre- and post- tests and interviews, show students' improvement on mathematical content like arithmetic, geometry and probability through using mathematical games. However, few studies have analyzed in details what takes place *during* mathematical games in a classroom, that is, what are the actual learning opportunities and mathematical activity that students are immersed in while actually playing these mathematical games. This poster presentation presents such an analysis, taken in the context of an experimentation conducted in a Grade 1-2 elementary classroom.

There are many definitions in the literature about what a mathematical game is. For example, it can be described as a stage in the child development, as a social activity, as a fun teaching tool to develop knowledge, as an educational activity aimed at developing specific knowledge, and so forth. For this study, a mathematical game is defined as a teaching material explicitly designed to work on and explore a specific mathematical content. The game studied here is a memory game about base 10 complements in which two students, playing one against each other, have to match two cards picked from a stock of 30 face-down cards to make 10. Various representations are used (numeral, literal, box of ten, etc.) and numbers vary between 0 and 12 (11 and 12 are used for subtraction with 1 and 2). Figure 1 presents examples of possible combinations to make 10.

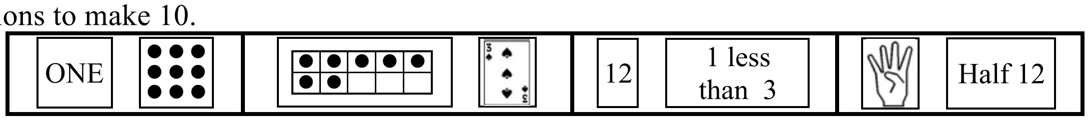

Figure 1: Examples of base 10 complement pairs

This poster presents a description and an analysis of how this game took place in a Grade 1-2 classroom, how the students interacted with it and what was the nature of the mathematical activity they were immersed in. For example, students engaged in a variety of strategies *to operate*, as some counted the numbers illustrated on the cards, either with dots or drawings, to get to 10, whereas others used their hands or even counted mentally without any physical support. Students also developed strong *associations* between a number and its complement. E.g., when kids picked 8, it was as if they also picked up a 2 "at the same time", where 8 was not considered alone but came with 2 as well. In that sense, when picking up a card, many knew what number to look for or anticipated the card to find (often by "cheating" through looking into the not-so-opaque cards!). Others students opted, at times, to decide for the value of the cards chosen (e.g. blank or joker cards, previously assigned the value of 0 in the game, were re-assigned the needed value to make 10 with the other chosen card). Students also demonstrated *fluency* and *flexibility* with the diverse representations: the various representations of numbers were not problematic at all to students, as they navigated through all of them and mixed them to make 10. These strategies (and others) will be shared and discussed in the poster presentation.

RESPONDING TO STUDENT THINKING: MAKING IN-THE-MOMENT TEACHING DECISIONS

Marc Husband
York University
husbandm@edu.yorku.ca

Parinaz Nikfarjam
York University
parinaz_nik@yahoo.ca

Tina Rapke
York University
Trapke@edu.yorku.ca

Keywords: Instructional Activities and Practices

The value that the mathematics education community places on student thinking is clear. What is less transparent in mathematics education research are the nuances of how a teacher can talk about, and enhance, the classroom practices by emphasizing and using student mathematical thinking in-the-moment. The NCTM principle, "students must learn mathematics with understanding, actively building new knowledge from experience and prior knowledge" (NCTM 2000, p.11) has inspired us to think about 'taking up' student thinking as a teaching practice. For us, taking up student thinking involves an emergent, cyclical, continuous process where students share what they think, teachers listen to student thinking, and then teachers make in-the-moment decisions about how to respond to student thinking. This research speaks to the enduring challenge of teaching as responsive to various conceptions of mathematics, and is grounded in the question: What kinds of in-the-moment decisions do teachers make in response to student thinking?

This study builds on research that examines teaching interventions from an enactive perspective (Towers & Proulx, 2013) and emerging research related to in-the-moment pedagogy (e.g., Mason & Davis, 2013). We specifically use notions of in-the-moment pedagogy and ideas from Towers and Proulx's (2013) work to identify, describe and characterize teachers' decisions that were made while taking up students' thinking. Similar to some of the research that this study builds upon, our ideas are framed by enactivism (a theory of cognition). Teaching and understanding, in this framework, have an in-the-moment quality. In-the-moment teaching decisions are neither easy nor predictable, as they stand in a reciprocal relationship with student thinking, perpetually influencing, and influenced by, one another.

We present findings from a project that occurred in the context of student-generated multiplication strategies and involved the authors co-teaching and co-planning with an in-service teacher. Students in a grade four classroom were asked to complete twenty multiplication questions, identify 'easy', 'easier' and 'harder' questions, and to explain their thinking/strategies. In our findings we will describe students' thinking and two types of teaching decisions that were made in response to what students shared. Drawing on Towers and Proulx's (2013) constructs, we will be investigating how these in-the-moment decisions *oriented students' attention* for a doubling strategy to emerge, and *coordinated the possible* for a strategy that was grounded in the associative property, but did not only involve doubling, to unfold. We hope to offer practical insight into, and generate interest around, the broad discourse of in-the-moment pedagogy.

USE OF EXAMPLES IN TEACHING CALCULUS: FOCUS ON CONTINUITY

Jihyun Hwang
University of Iowa
Jihyun-hwang@uiowa.edu

Dae S. Hong
University of Iowa
dae-hong@uiowa.edu

Keywords: Instructional Activities and Practices; Post-Secondary Education

Giving examples in mathematics instructions is a widespread instructional practice, but not a straightforward process. How mathematics teachers use examples can have significant effects on students' opportunities to learn because students can interact with abstract mathematics concepts through given examples in classrooms. Thus, it is necessary to observe instructors' use of examples to reveal its possible influences on students' learning in calculus classroom. The purpose of this study is to investigate mathematicians' use of examples in their calculus courses. In this case study, use of examples to teach the concept of continuity was observed.

In this research, the definition of an example is aligned with those suggested by a couple of previous studies; an example is referred as mathematical object serving a cultural mediating tool between a person and mathematical concepts or theorems (Goldenberg & Mason, 2008). An example in instructions should allow learners to mentally interact to mathematical objects with abstract mathematical ideas in educational settings (Zodik & Zaslavsky, 2008).

We observed two mathematicians teaching calculus 1 at a Midwest university. Data were collected by classroom observation, initial and reflective semi-structured interviews, and field notes. Video-recorded lessons were mainly analyzed with constant comparison to interviews and field notes. Based on the definition of example in this research, analysis units were identified in videotaped lessons. All data were analyzed using existing codes for examples in previous research (Goldenberg & Mason, 2008;Zodik& “ “ <Zaslavsky, 2008) and modified in a data analysis process. Member checking was conducted with participants in reflective interviews in order to ensure the accuracy of analysis.

Remarkably, both mathematicians used *incorrect* examples of target concepts and theorems in order to check understanding of concepts or show impossibility (Goldenberg & Mason, 2008). In introduction of the definition of continuity, both mathematicians similarly employed examples of discontinuous functions after presenting the definition of continuous functions. These incorrect examples for the continuity concept allowed the instructors to check whether students not only understood the definition but also could apply it to a certain function.

However, the participants showed different patterns to teach the intermediate value theorem (IVT).one mathematician asked students to build non-existing examples as an informal proof of IVT and assessment of students' previous knowledge; a continuous function satisfying following conditions of (a) $f(1) = -3$, (b) $f(2) = 4$, and (c) the function never crosses the x-axis. In the recall interview, the mathematician mentioned that asking students to create impossible examples can be an intuitive way to begin proving theorems like IVT. This use of incorrect examples could be students' preliminary opportunity for mathematical formal reasoning. Therefore, use of incorrect examples on instructional purpose can be an appropriate way for formative assessment as well as a bridge between informal and formal proofs in college mathematics.

ANALYZING DEVELOPMENT OF NORMS CONDUCIVE TO PRODUCTIVE DISCOURSE: PHASE ONE

Peter Klosterman
Washington State University
pklosterman@wsu.edu

Keywords: Classroom Discourse

For several decades, teachers and researchers alike have sought to create mathematically *productive discourse* in classrooms, that is, discourse focused on sense-making, creating coherency by relating mathematical concepts, and appealing to mathematical reasoning as the authority. Despite the widely-recognized importance of productive discourse, efforts to create it have not always been successful. Many examples exist of teachers who have successfully increased the *quantity* of discourse without achieving productivity. Furthermore, discourse may superficially appear productive while creating low press for conceptual thinking (Kazemi & Stipek, 2001). Social and sociomathematical norms are useful constructs for analyzing and explaining regularities in discourse. Research has indicated that certain social norms seem to be correlated with productive discourse, such as the expectations that students explain and justify their thinking, collaborative in problem-solving, listen actively, and find multiple solution paths. Certain sociomathematical norms also seem to be correlated with productive discourse, such as explaining the rationale behind computations, and using explicitly defined criteria to differentiate between *different* solutions (Kazemi & Stipek, 2001). Many studies investigating norm development have focused analysis on an episode-level. While offering insight, such analysis does not consider episodes in light of previous or subsequent episodes. A longitudinal study offers this broader perspective on norm development. However, comparatively few longitudinal studies of norm development exist.

My study intends to longitudinally investigate the development of norms conducive to productive discourse. Thus far, the first phase, a pilot study, has been performed in a case study 5^{th} grade classroom. Video recordings and observations notes have been made twice per week for most of the 2014-2015 school year, confirming that productive discourse frequently occurs in this classroom. I intend to observe the case study classroom daily for the first two months of the upcoming school year, since research indicates that the majority of norms are established during this period (Yackel, Cobb, & Wood, 1991). Using grounded theory principles such as the constant comparative method, video footage will then be analyzed to identify specific social and sociomathematical norms that emerged. A chronology of each norm's development will be created. I will then identify teacher strategies, methods, and key interactions that contributed to norm development.

Proportional Relationships and Geometric Similarity

One of the goals in mathematics teaching is to help students build connections among mathematical concepts/ideas and use them for future learning (NCTM, 2000). Geometric similarity and proportional relationships are two of these areas that students need to benefit from such connections. Studies reveal that students often struggle with recognizing the proportional relationships in similarity problems, and as a result, making inappropriate additive comparisons instead of multiplicative ones (Kaput & West, 1994; Lobato & Ellis, 2010). One possible reason for students' difficulties with recognizing proportional relationships is that they usually have trouble iterating or partitioning a composed unit (Lobato & Ellis, 2010). As a result, students often fail to consider coordinated changes of lengths in both dimensions.

Dilation is defined as "a transformation that moves each point along the ray through the point emanating from a fixed center, and multiplies distances from the center by a common scale factor" (CCSS; Common Core State Standards Initiative 2010, p.85). According to CCSS, eighth graders should use ideas about similarity to define and analyze two-dimensional figures and describe how these figures change under some geometric transformations (i.e., translations, rotations, reflections, and dilations). Beckmann and Izsák (2015) suggest using the Dilating Perspective Approach (or Fixed Numbers of Variable Parts Perspective of Ratios) for developing students' understanding of geometric similarity from a transformational approach. The Dilating Perspective Approach suggests that "two quantities are said to be in the ratio A to B if for some-sized part there are A parts of the first quantity and B parts of the second quantity" (Beckmann & Izsák 2015, p. 21).

In this paper, we have examined the effectiveness of the Traditional Approach (including the Cross-multiplication) and the Dilating Perspective Approach with embedded representations of similar rectangles. The Traditional Approach does not necessarily lead to the understanding of proportional relationships, because it does not enable students to be aware of uniform stretching and shrinking between the sides that need to be compared. On the contrary, the Dilating Perspective Approach with embedded figures enables students to realize uniform stretching or shrinking in both dimensions by providing an easier visual comparison of similar figures.

I-THINK: FRAMEWORK THAT IMPROVES PROBLEM SOLVING FOR ALL STUDENTS

Sararose Lynch
Westminster College
lynchsd@westminster.edu

Jeremy Lynch
Slippery Rock University
jeremy.lynch@sru.edu

Keywords: Classroom Discourse; Problem Solving; Equity and Diversity; Elementary School Education

There is a recent shift in the United States, driven by the National Council of Teachers of Mathematics (NCTM) and the Common Core State Standards (CCSS), from mathematics instruction in an inclusive classroom that traditionally used teacher initiation, student response, followed by teacher evaluation to an approach that is more student centered. According to NCTM (2014) and the CCSS for Mathematical Practice (CCSSI, 2011) kindergarten through high school mathematics instructional practices should promote mathematical discourse for all students, including students with disabilities. The I-THINK framework promotes reflective and conceptual instructional practices, such as student justification of solutions and mathematical discourse, which helps students to become aware of and learn to monitor and evaluate their mathematical thinking (Lynch, Lynch & Bolyard, 2013).

A quasi-experimental control group design was used to determine whether the I-THINK problem-solving framework leads to greater problem solving performance versus a structured Think-Pair-Share (TPS) framework (Kagan, 1994). Participants included 118 elementary students from six fully included classrooms. Two classes from each grade level, 2^{nd}, 3^{rd}, and 4^{th}, were selected based on voluntary participation by the classroom teacher in a professional development session on discourse and problem solving frameworks. For this study, we utilized a nonequivalent control group design consisting of a pre-assessment, a six-week instructional cycle, and a post-assessment. One class from each grade was randomly assigned to the intervention group that received problem-solving instruction using the I- THINK framework. The other class was assigned to the alternative intervention group that received problem-solving instruction using the TPS framework.

Within the combined groups, participants in the I-THINK groups scored statistically significantly higher on the post-test, as opposed to the pre-test. Participants in the TPS groups scored statistically significantly higher on the post-test, as opposed to the pre-test. Post-test scores for second grade were statistically significantly greater in the I-THINK vs. the TPS group (p = .037). There was also a statistically significant difference in post-test scores between the frameworks for third grade, with statistically significantly greater scores in the I-THINK vs. the TPS group (p = .016). There was no statistically significant difference in the post-test scores between the frameworks for fourth grade. When analyzing the scores from the two grades that had significant improvements in both groups (2^{nd} and 3^{rd}), there was a statistically significant difference in post-tests cores between the I-THINK and TPS groups, with statistically significantly greater scores in the I-THINK vs. the TPS groups (p = .008). Detailed results and implications will be discussed.

CALCULUS I TEACHING: WHAT CAN WE LEARN FROM SNAPSHOTS OF LESSONS FROM 18 SUCCESSFUL INSTITUTIONS?

Vilma Mesa	Nina White	Sarah Sobek
University of Michigan	University of Michigan	University of Michigan
vmesa@umich.edu	whitenj@umich.edu	srsobek@umich.edu

During classroom observations conducted as part of the Characteristics of Successful Programs in College Calculus (CSPCC) project we observed 73 lessons taught by 65 instructors at 18 institutions. In this poster we present an analysis of nearly 500 math problems enacted in those observed lessons, attending to how the tasks were enacted (lecture, group work, etc.), technology used, representations used, and other mathematical features of the problems.

Keywords: Post-Secondary Education; Instructional Activities and Practices; Curriculum Analysis

Relative to the literature in K-12 mathematics education, there is a dearth of information about what transpires in college classrooms. Although there are some exceptions (Laursen, Hassi, Kogan, & Weston, 2014; Mesa, Celis, & Lande, 2014), we know little about teaching or the nature of the tasks that instructors use in classrooms in lower division courses. One of the goals of the CSPCC project(NSF-DRL REESE #0910240, Bressoud, Rasmussen, Mesa, & Pearson) was to document such work for Calculus I. We observed 73 calculus lessons across18 institutions (including associate-, baccalaureate-, master-, and PhD-granting institutions) identified by the CSPCC project as having successful calculus programs. Our observation protocol included a *Problem Log* with which observers recorded the specific mathematical tasks seen in classes as well how the task was enacted (e.g., lecture or group work), what representations were called for (e.g., symbolic or graphical), what technology was used (e.g., graphing calculators or CAS) and other important features (e.g., presenting multiple solutions or doing a proof; see White & Mesa, 2012). By focusing on the content of the tasks and their enactment, we gain a disciplinary-rich perspective on the nature of Calculus I instruction at these institutions. In this poster we describe the pedagogical and mathematical features of the almost 500 observed tasks. We also report on similarities and differences within and across institutions and across institution types using various analytical techniques (e.g., ANOVAs, odd-ratio estimations, clustering), to account for the nature of the data.

In our analysis thus far we have found no significant difference in the method of task delivery across institutions types—that is, there is a uniform predominance of lecture across all institutions types. When we focus on the mathematical features of the tasks, however, PhD-granting institutions use fewer problems emphasizing symbolic representations than the other institutions and baccalaureate-granting institutions use more problems emphasizing skills and techniques than the other institutions. This analysis will allow us to better understand what teaching in successful institutions looks like and how that varies by institution type.

Keywords: Post-Secondary Education; Teacher Beliefs; Metacognition; Design Experiments

Graduate student instructors (GSIs) teaching introductory calculus participated in a semester-long working group to learn to use Peer-Assisted Reflection (PAR) in their recitation sections (Reinholz, in press), an activity which was developed through a three-phase design experiment (Cobb, Confrey, Disessa, Lehrer, & Schauble, 2003). PAR involves students analyzing one another's work and exchanging feedback before revising their solutions, which helps students improve their explanations, collaboration, and persistence (Reinholz, in press). The GSIs met six times during the semester, for one hour each time. This poster focuses on the learning of Beth, a second-year graduate student with two semesters of prior teaching experience.

All six of Beth's lessons were coded for teaching practices. Two lessons were double-coded, with 90% agreement. The two disagreements were on teacher probing for explanations. Teacher position was coded holistically, while all other practices were coded for frequency (see Table 1).

Table 1. Beth's Observed Classroom Practices

Week	Teacher Position	Teacher Probes for Explanations	Teacher Links Student Responses	Students Respond to Each Other	Students Present at the Board
2	Front of room	2	0	1	0
4	Front of room	2	0	0	0
6	Circulating	6	0	0	0
8	Circulating	7	4	9	1
10	Circulating	11	2	5	0
13	Circulating	0	0	21	2

Table 1 shows a dramatic shift in Beth's teaching. In a post-semester interview, Beth noted:

> I've definitely become a lot more reflective about my teaching, and I think about it a lot more than in the past. Just, I question, is this working. I feel like honestly when I first starting teaching, I would just do stuff, and think it's good, oh it's great, and I never really asked, is this working, do I think they are learning this way…compared to past semesters, I got students to come up to the board more and got them to explain their words more.

This poster highlights the potential of PAR to support GSIs to grow as teachers.

INVESTIGATING TEACHERS' BELIEFS AND TECHNOLOGY INTEGRATION

Lindsay Reiten
University of Wisconsin-Madison
reiten@wisc.edu

Keywords: Teacher Beliefs; Technology; Teacher Education-Inservice

Instructional technology (IT) offers a number of potential benefits toward enhancing student learning, yet many teachers do not effectively integrate IT in their instructional practices, a critical issue in mathematics education. By effective, I mean using IT to increase students' conceptual understanding of mathematics through reflection and communication (Hiebert et al., 1997), as well as through using and connecting mathematical representations (NCTM, 2014). Effective IT integration is *essential* to student learning and a necessary component of effective teaching (Ertmer & Ottenbreit-Leftwich, 2010). However, an important factor that influences teachers' use of IT is their beliefs about IT (Zbiek & Hollebrands, 2008).

This poster reports on the findings of a study that sought to investigate secondary mathematics teachers' beliefs and practices regarding instruction and IT integration, as well as how teachers describe effective IT integration. Rather than relying on Likert scale and multiple-choice questions to investigate beliefs, this study employed a new tool for investigating teachers' beliefs using an online survey implementing constructed-response questions (Philipp et al, 2003). The constructed-response questions provided situational context for investigating beliefs and how teachers described effective IT integration (Holstein & Gubrium, 2011).

Findings suggest that the constructed-response survey, designed to address shortcomings of previous tools used to investigate teacher beliefs, provided new insights into teachers' beliefs about "effective" IT integration, and highlighted that targeting beliefs is a necessary component of professional development aimed at increasing the effectiveness of IT integration. Teachers' responses indicate that there may not be a relationship between a teacher's preferred teaching style and how they use IT or what they believe is an effective use of IT. Survey questions, participants' responses and more detailed findings will be shared during the poster session.

MAINTAINING COGNITIVE DEMANDS OF ALGEBRAIC REASONING TASKS

Jessie C. Store
Alma College
storejc@alma.edu

Keywords: Instructional Activities and Practices; Algebra and Algebraic Thinking; Classroom Discourse"

Introduction

As recommended by Proulx and Bednarz (2009), the study's goal is to contribute to research on supporting mathematical thinking. It focuses on practices that maintain cognitive demands of rich tasks. This is a significant focus because meaningful experiences with rigorous curriculums depend on cognitive demands during enactment. This report is part of a grounded theory developed from analysis of classroom video data, artifacts, and interviews. Participating students were in grades 3-5 at six schools. Students worked on pattern finding activities.

Results and Conclusion

Launching with minimal instructions. The way the tasks were launched was critical in maintaining the cognitive demands of the tasks. The best launching practice, judged based on the variety and quality of student responses during instruction, involved giving only minimal instructions that were enough for students to understand what they are expected to do without funneling their thinking. Teachers described this approach as relaxed and a flexibly structured teaching style whereby you give students a task with an attitude of "here it is, see what you can do with it. And just ask them few questions and not trying to lead them, just seeing where they go." Teachers' view of the launching styles that maintained open-endedness of tasks of algebraic thinking had an emphasis on exploring mathematical relationships other than a focus on trying to find an existing specific algebraic generalization. As one teacher explained:

> My goal is to make learning discovery based, let the students work through it, not feel like there is an answer that they have to achieve as their goal, but help them to understand that there might be, and sometimes there is more than one answer.

Workspaces. Workspaces are "opportunities for students to use their own critical thinking." One of the critical practices for creating workspaces was moving from traditional worksheets that provide minimal spaces for exploring to 'work spaces' with minimal words and a lot of space. With 'work spaces,' students explored more, and the quality of their visible thinking improved greatly because they communicated the unspoken expectation of engaging with the mathematics more than the tradition worksheets did.

In conclusion, launching with minimal instructions and providing workspaces are critical in maintaining cognitive demands of rich tasks. This poster presentation will show a striking difference in students' visible thinking between classes with and without these practices.

ASSESSMENT OF EQUITY IN BELIEFS AND PRACTICES OF TEACHING MATHEMATICS TO AFRICAN-AMERICAN STUDENTS

Carmen Thomas-Browne
Duquesne University
thomas14@duq.edu

Melissa Boston
Duquesne University
bostonm@duq.edu

Joseph Frollo
Duquesne University
frolloj@duq.edu

Keywords: Equity and Diversity; Teacher Beliefs; Teacher Education-Inservice

Researchers who examine the experiences and opportunities of African-American children in learning mathematics identify certain mindsets and dispositions of teachers that can be productive or unproductive in supporting students' development (e.g., Ladson-Billings, 2009; Milner, 2010). Ladson-Billings (2009) describes teachers' *ways of being*, and the relationships teachers seek to form with African-American students, as critical in fostering students' learning.

The purpose of this study is to create and validate a survey to assess teachers' beliefs and practices in teaching mathematics to African-American students. Beyond our specific study and context, the survey can be used more broadly to raise awareness and analyze change over time of productive and unproductive mindsets at the personal, school, and district level.

The current version of the "Assessment of Equity in Beliefs and Practices of Teaching Mathematics to African-American Students" survey contains 80 questions spanning eight categories: Beliefs about Student Achievement and Motivation, Culturally Responsive Teaching, Perceptions of Challenges of African-American Students, Perceptions of Success of African-American Students, Mathematics as a Civil Right, Missionary Beliefs, Beliefs about Critical Thinking, and Student Behavior. The majority of the categories are derived from the components of culturally relevant pedagogy described by Ladson-Billings (2009) and the mindsets identified by Milner (2010), Martin (2007), and Jackson and Wilson's (2012) literature review. In addition to its emphasis on culturally relevant pedagogy, the instrument asks teachers to reflect on their schools' curriculum and course offerings for students of color.

We intend for the results of the survey to provide an indication of: 1) teachers' *mindsets* that may be more or less productive in supporting the mathematical learning of African-American students, 2) teachers' *awareness of and attribution for successes and barriers* in African-American students' learning of mathematics; and 3) teachers' *feelings of self-efficacy and/or support* (i.e., whether teachers feel equipped and supported) in enacting equitable teaching practices in mathematics. We hope to make a contribution to the field by providing a validated survey that could be used to foster critical reflection and awareness on a personal, school, or district level. By triangulating and correlating survey results with other data (e.g., teacher observations and interviews), we may be able to add specificity to Ladson-Billings' notion of teachers' "way of being" that supports mathematical achievement in African-American students.

THE IMPACT OF TEACHING EXPERIENCE ON MATHEMATICS GRADUATE TEACHING ASSISTANTS' EFFICACY

Patrice Parker Waller
Virginia State University
pparker@vsu.edu

Keywords: Post-Secondary Education

The urgency of improving teaching and learning in undergraduate mathematics education is deepening and graduate teaching assistants (GTAs) are becoming increasingly responsible for taking on this task. However, differences in GTAs training, and GTA actual teaching experience, makes it difficult to assess the GTAs' efficacy and ultimately their effectiveness in the undergraduate classroom. This study addressed the research question; do previous teaching experiences of graduate teaching assistant's impact teacher efficacy.

Graduate students often times enter school with little to no teaching experience. In fact, serving as a GTA may be the very first time these students have the opportunity to teach. Research has also shown that GTAs with more experience have reported higher levels of self-efficacy toward teaching (Prieto & Altmaier, 1994) and have been regarded as more effective by students (Ferris, 1991). More importantly, teaching assistants play vital roles in the mathematics education of undergraduates and may become mathematics professors one day.

Denham and Michael's (1981) Teacher Sense of Efficacy Model is used as a theoretical lens through which this study is framed. Denham and Michael "theorized that a teachers' sense of self efficacy is a strong mediating variable in teacher effectiveness and consequent to student achievement" (Prieto & Altmaier, 1994, p. 482). Denham and Michael's model suggests that a heightened sense of efficacy in teachers should affect their perceived and actual ability to teach more effectively" (Prietto and Altmaier, 1994, p. 483). This theoretical model is vital to the proposed study because it allows associations to be made between levels of efficacy among GTAs in the undergraduate mathematics classroom and increased student achievement.

Using the Teacher Sense of Efficacy Survey – long form (Tschannen-Moran& Woolfolk Hoy, 2001), this correlational study collected data regarding the demographics (i.e. previous teacher training/professional development, teaching experience and future career plans) and teaching beliefs of each the 184 voluntary GTA from the 32 participating mathematics departments classified by Carnegie as research extensive universities.

Based on the literature, it was hypothesized that positive relationships would be found between teaching experience and TE. A weak positive relationship was found among teacher efficacy and K-12 teaching experience. Implications for relationships among teaching experience and teacher efficacy call for more structured teaching assistantships (similar to those in the k-12 experience) during the graduate student phase in mathematics departments in order to enhance the effectiveness of GTA future teaching practices. This information moves the teaching experience forward in that it advocates for greater supervision and a larger amount of responsibility during the GTA phase.

TEACHING MATHEMATICS THROUGH SOCIAL JUSTICE: UNDERSTANDING TEACHERS' FIRST EXPERIENCES

Ashley P. Walther
The University of Tennessee
agrob@vols.utk.edu

Lynn Liao Hodge
The University of Tennessee
lhodge4@vols.utk.edu

Keywords: Instructional Activities and Practices

This study was designed to investigate the experiences of teachers implementing social justice themed lessons for the first time. Teaching mathematics through social justice activities has been proposed as a way to support students in building personal connections with and a sense of relevance when learning mathematics (Gutstein, 2003; 2006; Turner & Strawhun, 2007). Recent research has shown that supporting teachers in teaching math through a social justice lens is not a straightforward process (Bartell, 2013). Our central questions were:

- How do teachers view the role of math and context in social justice-themed activities?
- What are the challenges teachers experience as they implement social justice-themed activities?
- What are the supports that they find helpful as they implement these activities?

To address these questions, the authors designed a multiple-case study to examine teachers teaching mathematics through social justice contexts for the first time. Walther co-planned social justice themed lessons or units with the cooperating classroom teachers. All planning sessions were audio-recorded. After planning, the classroom teachers in each case implemented the lessons with students in their classroom. The lessons were video-recorded, with the authors present, taking field-notes throughout. After the lesson or unit concluded, interviews were conducted with teachers and students to gain further insights into their experiences during the events. Data were analyzed using open-coding in order to identify relevant themes and significant themes across cases.

The authors employed a situated perspective that theorizes one's learning as dependent upon social and cultural contexts, not solely on one's individual cognition that is tied to specific contexts (Lave & Wenger, 1991). Initial findings show that teachers experience tensions between math and context in implementing social justice activities, and they navigate these tensions in different ways. In addition, teachers view social justice in different ways that have implications for their implementation of this approach.

We compared classroom interactions during two episodes in a seventh grade virtual mathematics class. Both episodes were drawn from virtual live lessons utilizing different lesson layouts. We investigated how mathematical knowledge was negotiated in both episodes. The results show that the layout of live lessons had an effect on how students shared their thinking.

Keywords: Classroom Discourse; Technology

Technology is changing communication patterns as it introduces new forms of human interactions, asynchronously through emails, texts, blogs and discussion forums, and synchronously between large spatial distances. More remarkably, technology is altering how people experience education. In the U.S., the number of K-12 full-time virtual distant schools is growing exponentially (Barbour & Reeves, 2009). Mathematics too, is being encountered by K-16 students and teachers in virtual environments. Yet, research studies that carefully examine the content of interactions in such educational settings are rare. Such studies are necessary in order to unpack intricacies of mathematics learning and teaching specific to this type of environment. As Morgan and colleagues (2014) posited, there is an emergent need in the field to investigate online and mobile communication that are unique in mathematics contexts. Our goal of the case study we report here was to address this need. Our research aimed to unpack the nature of interactions taking place in one virtual mathematics classroom.

Background Literature

The utility of computer technology as a cultural tool for mediating knowledge construction has long been recognized (Saxe, 1991). The internet as a new form of technology-based learning medium, has also penetrated educational research in recent years. The range of reported research includes exploration of online teacher professional development, and online language programs (Bairral, 2009; Jonassen, 1986). Previously the main audience for online learning consisted of self-motivated adult professionals who clustered around a common interest. Asynchronous settings such as discussion forums and self-study online learning tools have provided the main context for learning among this population. Researchers and educators who explored the use of *hypermedia* or *hypertext* for online instruction have concluded that: (a) content representation in the web is not linear and can be hyper-linked; and that (b) it is beneficial for novices to access web automated knowledge representations that are pre-constructed by experts (Carlson, 1992). However, K-12 online or blended learning has entered the education arena and grown rapidly in the past five years. In comparison to the adult online learning format, synchronous lessons that are analogous to traditional brick-and-mortar classrooms represent a large part of online K-12 school curriculum. How mathematics is taught and learned in this environment has not been a subject of careful analysis. Arguably the most prominent and unique feature of a synchronous environment is how the teacher and students communicate about and with mathematics in the course of their interactions. As a starting point in developing a systematic research agenda surrounding online mathematics teaching and learning, a focus on unpacking synergistic interaction offers a productive scholarly venue.

Carlson (1992) provided a simple, but precise description of communication in a synchronous setting: "As a simple case example, participants are able to converse in dyads or triads with classmates not in close physical proximity; whereas, in the real classroom multiple, simultaneous discussions quickly degenerate into a cacophony of voices" (p.57). A systematic study of language usage and the internet was conducted within the linguistics discipline. For synchronous group chats in particular, linguists have identified the delaying feature (Crystal, 2001). Crystal posited that lags in conversations interrupt the conversational turn in traditional face-to-face interaction, because in the virtual synchronous environment, turn-taking as seen on the screen was dictated by the software rather than the intentions of the end-users. However, Crystal and other linguists' studies of synchronous group chats were drawn from social networks rather than educational settings. Other features absent from synchronous group chat that are critical to the educational environment, such as facial expressions and physical body language, provide challenges for teachers in receiving cues from learners. The constraints of online interactions can certainly impact the quality of discourse taking place. Yet, we know little about specific features of the environment that may motivate classroom interactions and mathematics learning. To address this topic, we planned to study a seventh grade virtual mathematics classroom as the teacher delivered live lessons over the course of one academic semester. In this report, we chose two different live lesson layouts to study mathematics classroom interactions. Two specific questions guided our data analysis: (a) What is the nature of interactions between the teacher and students, and among students in the virtual synchronous mathematics classroom? (b) How do different settings of synchronous virtual mathematics instruction promote productive interactions and discussions about mathematics?

Methodology

Data was collected from a seventh grade mathematics teacher's class at a full-time virtual school. At the time of data collection, two mathematics classes were combined, and the total number of students was around 70. The researchers observed the teacher on a regular basis. A number of live lesson recordings were collected for virtual classroom interaction research.

Since our plan was to examine how the use of various features of the online lessons impacted modes of communication among the students and the teacher, we selected two episodes from two virtual live lessons to complete a comparative analysis. Each live lesson was an hour long. Both lessons shared a similar structure, consisting of four parts: (a) greeting and pre-assessment of previous content (approximately 15 minutes); (b) teacher-led instruction of the main learning objectives for the day (15 minutes); (c) students solving problem(s) and whole-class discussions about the problem(s) (15-20 minutes); and (d) the teacher offering a whole-class summary or students completing exit questions (10 minutes). The selected episodes concerned the third part of the lessons as students worked on assigned problems and discussed their solutions. Episode 1 was 13 minutes and 32 seconds long. Episode 2 was 10 minutes and 7 seconds long. We selected these two episodes to ground our comparison of the two sessions since the teacher's live lessons relied on different layouts, giving rise to contrasting interactions both between the teacher and students, and between students. The teacher's oral communications were transcribed and textual records were downloaded. Both sets of transcripts were then organized in the order in which they appeared in the screen.

Adobe Connect virtual lesson setting

The software used during both virtual live lessons was Adobe Connect. The software connected the teacher and students in real time in various locations. The students were "participants", and chat pods were the only communication tool they were allowed to use. The teacher was the "host" with access to audio, chat pods, drawing tools, and other presentational features. The teacher communicated with the students using primarily audio, whiteboard drawing and the chat pods.

In Episode 1, the teacher intended for the students to write an algebraic expression representing a real-life situation. The layout of this episode is shown in Figure 1. The teacher utilized three functions of Adobe Connect: the poll question to gather student responses at the beginning, a chat pod labeled "EXPLAIN your thinking", and a "chalkboard" demonstration. In Episode 2, the content of the lesson concerned engaging students in solving two-step equations. In addition to the poll question and "chalkboard", two chat pods were utilized in the lesson: one labeled "QUESTIONS Only", and the other labeled "Responses to QUESTIONS" (Figure 2).

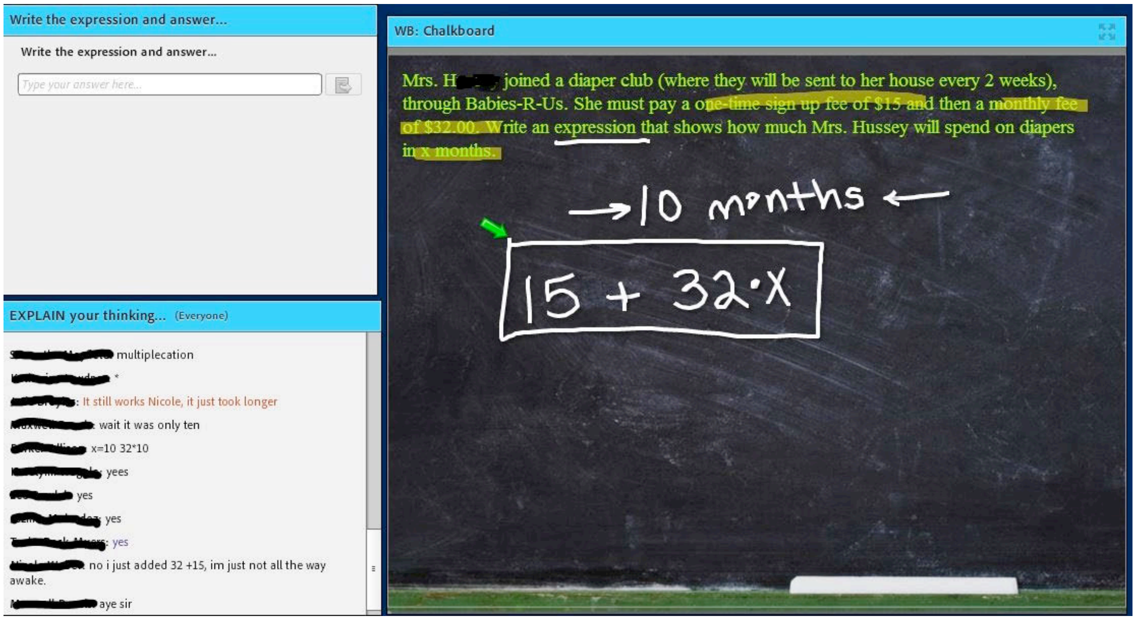

Figure 1:Layout of Episode 1

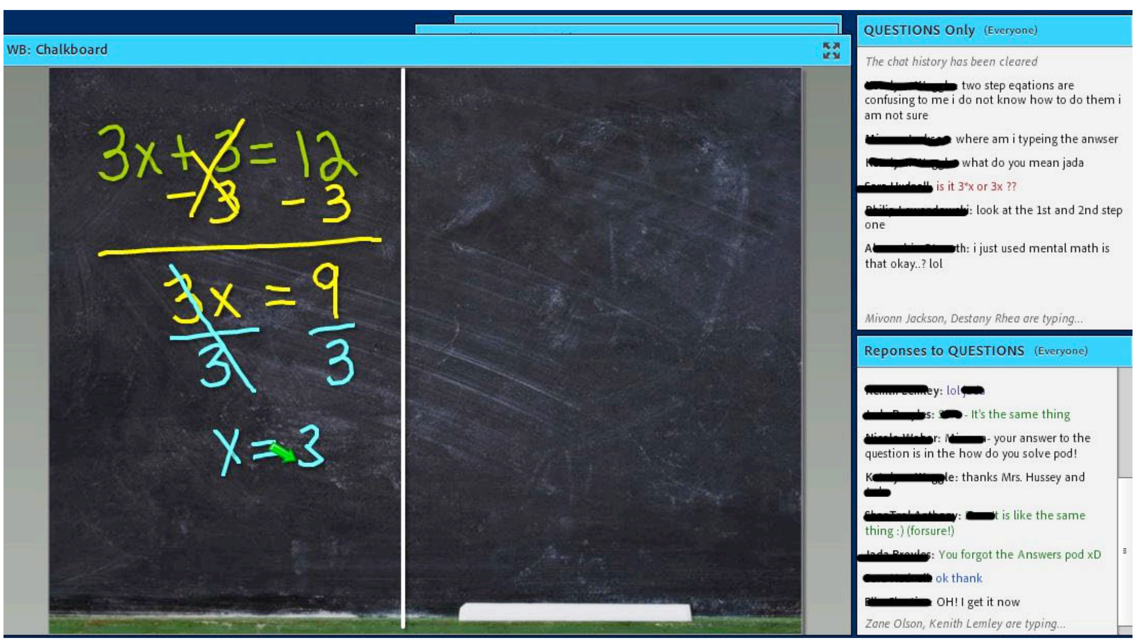

Figure 2:Layout of Episode 2.

Data Coding

The transcript was coded and analyzed in four phases by two researchers. First, we reorganized the individual exchanges by topics of conversation. Second, we segmented both episodes according to the questions that the teacher posed or the type of instructions that the teacher initiated. Then, in each segment, we coded each exchange in three dimensions: (a) whether it was a response or initiation; (b) potential subjects of the exchange (e.g., whether it was addressing the teacher, students or everyone); (c) language functions of each exchange using the Analytical Framework of Peer-Group Interaction (Kumpulainen & Wray, 2002), including experiential (sharing how students experienced the class or the problem), interrogative (asking questions), instructive (providing instructions), affective (sharing feelings and attitudes), judgmental (agreeing or disagreeing), and argumentative (providing arguments). We also added a few language function codes that existed in the data, but not in the Analytical Framework. These codes are observational (providing observations, often about the mathematics), encouraging (students encouraging students), receptive (responding neutrally to a command or idea) and the unclear category. In our last step of data analysis, we identified the mathematical knowledge that was shared and negotiated in both episodes. Relations were mapped out according to the classroom interactions taking place in both cases.

Results

In this section, we will first present findings related to the observed differences between the two episodes according to the number, the sequence, and the nature of exchanges that took place relying on analysis of language functions. We will then discuss how mathematics was shared and negotiated during each discussion session.

Modes of interactions

42 students actively contributed to the chat pods in Episode 1, and 29 in Episode 2. Based on the teacher's instructional initiations, Episode 1 was divided into s segments according to the instructional moves of the teacher. In this episode, only one problem was discussed. Students were given time to solve and comment on the problem in the first two segments. The teacher then raised a few questions for students to consider as they explored the problem. During this time she prepared the virtual whiteboard (segment 3). Once the whiteboard was prepared, the teacher redirected the class to think about the context of the problem, and then led them through solving it (segments 4-5). This part was followed by a Q&A session, which lasted less than one minute (segment 6). Among eleven segments, students contributed 146 exchanges in total, including 20 exchanges that were *initiative* (e.g. "would the first month be 47 because of the 15 dollar fee?"), and 122 exchanges that were *responsive* (e.g. "the one time fee is important"), 112 of which were replies to the teacher's questions. In summary, the mode of interactions in Episode 1was dominated by teacher-student interactions, with a typical pattern of teacher verbal questions, followed by student text responses. The teacher served as the primary initiator of the interactions.

In Episode 2, two group chat pods, the QUESTIONS pod and the EXPLAIN pod, were accessible to students, and two problems were discussed. This episode consisted of five segments. The teacher first reviewed and demonstrated one student's solution (segment 1), followed by a three-minute session (segment 2) devoted to addressing students' questions raised during segment 1. She then posed another similar problem to the class and students were given time to think and respond (segment 3). Then, the teacher again modeled how the problem could be solved on the virtual whiteboard (segment 4) and then devoted over three minutes to respond to students' discussions in the chats (segment 5). In comparison to Episode 1, more evidence of the teacher's facilitation of discussions and student thinking was present in Episode 2; the layout of the "QUESTION" and "Responses to QUESTIONS" pods provided a platform for students to raise questions and invite peer discussions, and for the teacher to facilitate student-student discussions. The teacher spent more than six minutes addressing students' discussions in Episode 2, whereas the teacher spent less than one minute in Q&A during Episode 1. In total, students contributed 65 exchanges with 34 of these exchanges contributed in response to peer comments. This evidenced a higher proportion of student-student interaction compared to the first episode.

Sequence of interaction

In the sessions that we have examined, the sequence of virtual interactions heavily depended on how the conversations were initiated by the teacher (e.g., yes/no questions, comments of the mathematics problem) and the opportunities for responding to the initiation (e.g., the availabilities of chat pods in the layout). When only one chat pod was available in Episode 1, the teacher modeled the solutions of the problem. She was able to maintain a sequential and focused teacher-student interaction by posing closed or dichotomous questions as exemplified in the excerpt below.

123. *T*: If I am paying something everything month, what operation is gonna help achieve that?
124. *Mel*:32*m
125. *Des*: multiplication
126. Mak: multiplication
... ...
140. *Pri*: Multiply
141. *Nic*: I added instead of multiplying OOPS

In the above exchange from lines 124 to 141, students were directly responding to the teacher's question in line 123, though the responses were presented in slightly different ways. Indeed, the interaction was highly sequential in the sense that exchanges could be traced naturally without disruptions. It was also highly spontaneous, since almost twenty exchanges appeared in the chat within a few seconds. Yet, this interaction mode took place only in Episode 1, when dichotomous or closed questions were posed, and responses required short-typed words.

In Episode 2, such a sequential and simultaneous interaction mode was not evident. Instead, interactions between the teacher and students or among students were highly non-sequential and overlapping. Students now had two different chat pods for interaction instead of one, as illustrated in Figures 1 and 2. Because the two chat pods were designated for student questions and student responses to those questions, they promoted student-student interaction in comparison to promoting only teacher-student interaction as in Episode 1. The sequence of interaction became more complex as demonstrated in the excerpt below.

25. (Audio) *T*: Let's do another one I'm gonna throw at you and then we talk about it. Ok?
26. (QUESTION) *Al*: I just used mental math is that okay..?lol
27. (Audio) *T*: How about -2y-4
28. (QUESTION) *Des*: I am confused NO NEVER MIND
29. (QUESTION) *Miv*: what is it called when you put a line in the equal sign
30. (EXPLAIN) *Ken*: xD
31. (Audio) *T*: Try to specific, Des. We will try to help you.
... ...
35. (EXPLAIN) *Sha*: Al-That is fine! As long as you get the right answer. :)

Within these eight exchanges, several conversations were taking place: (a) the teacher was posing a new problem (#25, 27); (b) two students were asking separate questions (#26, 29), one of whom received a student response in #35; and (c) another student was expressing confusion (#28), which caught the teacher's attention in #31. Meanwhile, Ken (#30) may have been responding to either the teacher or the use of the caps lock by Des (#28). We use *linear* to describe the interaction in the Episode 1 excerpt, and *multi-directional*to describe this interaction in the excerpt from Episode 2. Students raised questions in Episode 1, but due to the large number of chat messages in a single chat pod, the questions became invisible; they did not become a source of contemplation or discussion, and never disrupted the lesson flow. In contrast to Episode 1, questions in Episode 2 had a designated place during the teacher's instruction, which made it easier for students and the teacher to notice questions thus providing an available space for group discourse.

Language Functions

Examining the language functions of the texts of student chats, two features distinguished the quality of interactions in the two episodes. First, the proportion of student-self initiated conversations was greater in Episode 2 than in Episode 1. Students openly shared their experiences of the problem (*experiential*), commented on characteristics of the problem (*informative*), and asked questions (*interrogative*). Second, students in Episode 2 engaged in each other's problem solving processes. Some students questioned and answered, commented, and judged each other's mathematics while other students took a lead on sharing information about the problem.(e.g. "*Don't forget, the 4 isn't negative*"). Texts were informative, interrogative, and judgmental inEpisode 2, while texts were mostlyreceptive (e.g., yes, ok), observational, and addressing the teacher in Episode 1.

Taken-and-shared mathematics

In the first half of Episode 1, the teacher asked students to discuss the problems. The teacher's questions provided ample opportunities for diverse student responses, though interactions were one-directional, short, and sequential as the teacher responded to the majority of students' questions or answers. Thus the primary source of knowledge was the teacher who verified answer and confirmed accuracy of responses. Some of the important mathematical information that the individual students provided during the discussion went un-noticed or un-acknowledged. Even more importantly, discussion around these different ideas was not pursued in places where conflicting views on the same question were expressed. Instead, the teacher directed the class, judged the answers, and moved on to a new problem or task. This was partly because student replies in the chat pod were quick, rich and non-uniform, which made it difficult for the teacher to closely follow each contribution. As shown in Figure 3, the content of mathematics discussed became rather linear.

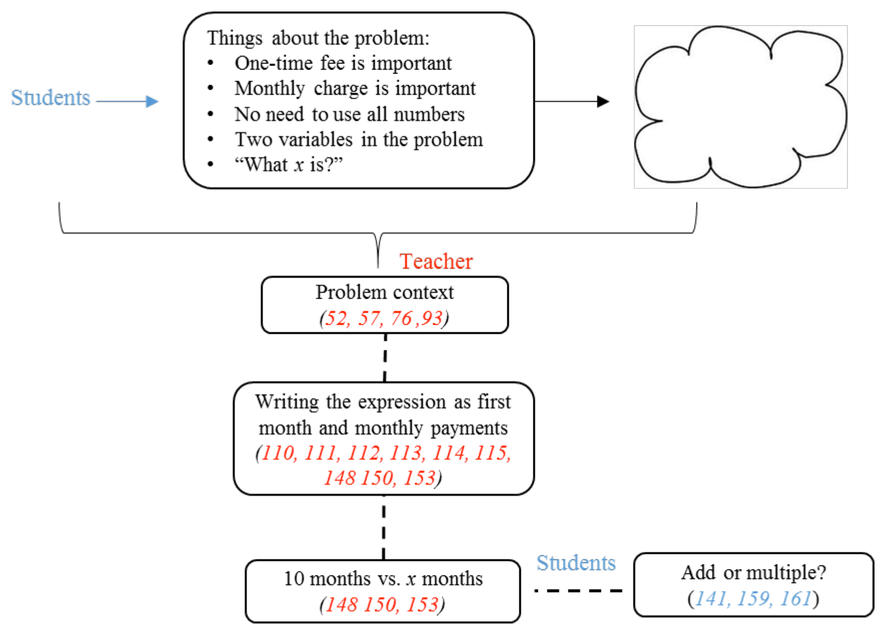

Figure 3: Map of knowledge shared in Episode 1. Blue indicates student contributions. Red indicates teacher contributions.

In Episode 2, mathematical knowledge shared was what we refer to as the "popcorn" style (Figure 4); which characterized features of open and simultaneous discourse. For instance, while the teacher was demonstrating the procedure for solving an equation on the "chalkboard", students'

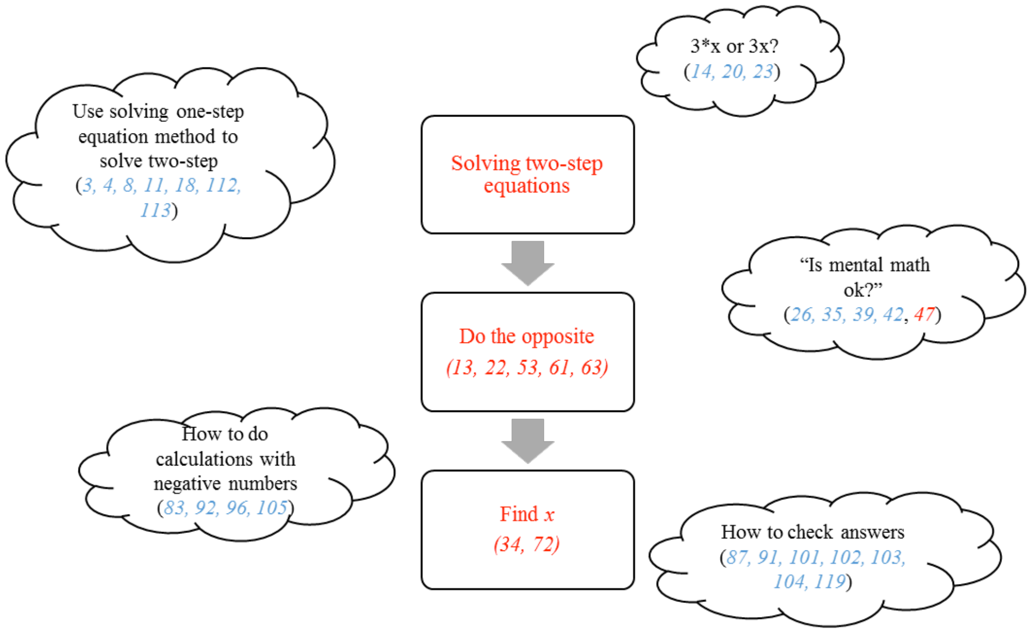

Figure 4: Knowledge shared and negotiated in Episode 2: popcorn style. Blue indicates student contributions. Red indicates teacher contributions.

discussion in the chat pods did not necessarily relate to each step of the teacher's demonstration. The students' comments often corresponded to other issues related to the problem, such as how and when mental arithmetic can be an effective approach to solve two-step equations, negative operations, and the conventions of algebraic expressions, which were separate from the teacher's original agenda of demonstrating the procedure. The content presented by the class was multidirectional. Students who were sitting in front of the computer could follow different "pops" of knowledge shared on the screen and could comment on those that they found interesting or useful. In this episode, students were sharing and negotiating different elements of solving two-step equations and the teacher was no longer the dominating source of knowledge. Instead of acting independently from the students by focusing on her own agenda of the problem's procedure as in Episode 1, the teacher depended on student responses to guide her facilitation of the discussion in Episode 2. The teacher's organization of the chat pods in Episode 2 allowed for greater opportunities for student thinking to be expressed, and for the teacher to have a greater role in facilitating the students' discussion.

Discussion

The purpose of this study was to explore the nature of interactions within online synchronous mathematics lessons resulting from different features of these lessons. By mapping out the transcripts of two episodes, it became evident that classroom interactions in a synchronous environment can be different when the layouts of the classroom were changed. These differences include changes from (1) teacher-students interactions to student-student interactions; (2) a linear conversation sequence to a multi-directional conversation sequence; and (3) students mainly responding to the teacher to interacting with each other. Consequently, these changes effected how students discussed and negotiated mathematics. The literature has documentedthe major feature of virtual interaction as non-sequential and overlapping (Crystal, 2001). Yet, our data showed that a synchronous lesson can be a highly structured lesson guided by the teacher, and communication quite spontaneous and sequenced as it would be in traditional brick-and-mortar classroom interactions. However, as soon as the layout of the lesson changed as in Episode 2, the interactions became non-sequential.

Our results indicate that the teacher's ability to closely monitor the students' interactions and mathematical discussions simultaneously in different chat pods helped effectively initiate and facilitate generative discourse among students. When opportunities were provided for students to negotiate their mathematical knowledge with one another, as seen in Episode 2, the dominating role of the teacher's mathematics was challenged. This issue raises several important questions that merit careful attention from the research community, some of which include: How could mathematics teachers synthesize multiple sources of students' mathematics to advance students' discussions towards building generalizations and identifying important mathematical structures? What type of knowledge might a mathematics teacher need to develop in order to do so? How might teachers manage social interactions using the chat pods or other functions in the environment so as to gear students towards mathematics learning and knowledge construction (Yackel & Cobb, 1996)? With a rapid increase in the desire to converge learning environments towards a virtual paradigm, it seems inevitable that our understanding of how such an educational setting might best be organized and moderated to allow for development of inquiry skills and conceptual understanding of mathematical ideas. The questions we raised here relate explicitly to this agenda.

This study investigated the impact of a dynamic geometry (DG)-centered teacher professional development program on high school geometry teachers' content knowledge and their students' geometry learning. 64 geometry teachers were randomly assigned to an experimental (DG) group and a control group. Both groups received appropriate and relevant professional development. Classroom observation data and the teachers' responses to the implementation questionnaires revealed that most teachers in the DG group were faithful to the DG instructional approach. Teachers in the DG group scored higher on a conjecturing-proving test than did teachers in the control group. The students of teachers in the DG group scored significantly higher than the students of teachers in the control group on a geometry achievement test.

Keywords: Teacher Education-Inservice (Professional Development); *Technology*

Introduction

Dynamic geometry (DG) refers to an active, exploratory study of geometry carried out with the aid of interactive computer software available since the early 1990's that allows for learner knowledge construction and exploration. The most widely used current DG software packages include the Geometers' Sketchpad (Jackiw, 2001), Cabri Geometry (Laborde & Bellmain, 2005) and Geogebra (Hohenwarter, 2001) as well as variations that are applications within handheld graphing calculators or applets on web sites. DG environments provide students with experimental and modeling tools that allow them to investigate geometric phenomena (CCSSI, 2010). With distinguishing features of dragging and measuring, DG software can be used to help students engage in both constructive and deductive geometry (Schoenfeld, 1983) as they build, test and verify conjectures using easily constructible models.

In a funded four-year research project, we conducted repeated randomized control trials to investigate the efficacy of an approach to teaching high school geometry that utilizes DG software as a supplement to regular instructional practices. Our basic hypothesis was that the use of DG software and DG teaching methods that engage students in constructing mathematical ideas through experimentation, observation, data recording, conjecturing, conjecture testing, and proving would result in improved geometry learning experiences for most students. The use of DG software and teaching methods was referred to as the DG approach in the project. The DG software used by the project was the Geometers' Sketchpad (GSP).

In this paper, we report the results from the second year of the project on teacher content knowledge and student achievement. We investigated the impact of the professional development of teachers and their students' geometry achievement in the DG group.The study built upon related research studies on mathematics teachers' professional development (e.g., Carpenter et al., 1989), including those concentrating on technology-centered (and especially DG-centered) professional development (e.g., Meng & Sam, 2011).

Theoretical Framework and Research Questions

An integrative framework (Olive & Makar, 2009) drawing from Constructivism, Instrumentation Theory and Semiotic Mediation was used to guide the study. Within this framework, as teachers and students interact in DG environments, their interactions with the DG technology tool influence the next act by each person, and continue in an interplay between the tool and user. As a user (teacher or student) "drags" an object and observes outcomes from that act, the user adjusts her or his thinking, which in turn influences the next interaction with the tool. Because DG technology allows users to adjust their geometry sketches and the relationships within them, users are transforming the tool, their use of the tool, and their thinking.

This study addresses the following research questions:

- Did teachers in the experimental (DG) group develop stronger conjecturing and proving abilities than did teachers in the control group?
- How well did the teachers implement the DG approach with fidelity in their classrooms?
- Did the students of teachers in the experimental group over a full school year achieve significantly higher scores on a geometry test than did the students of teachers in the control group?

Method

The participants in the study were sampled from the geometry teachers at high schools and some middle schools in Central Texas school districts. The study followed a randomized cluster design, randomly assigning 64 teachers to either an experimental group or a control group receiving relevant professional development, implementing the instructional approaches respectively assigned to them, helping the project staff in administering the pre- and post-tests of the participating students, and participating in other data collection activities of the project.

Professional Development and the DG Treatment

In order to effectively implement the DG approach in their classrooms, teachers must first master the approach. Without professional development, “teachers often fail to implement new approaches faithfully” (Clements et al., 2011, p. 133). So teachers’ professional development (PD) was a critical component of the project. For our PD to be effective, it had to be sustained, rigorous, and relevant to participating teachers, with substantial support from their school districts. Based on these guiding ideas, a weeklong summer institute was offered to the participating teachers in the DG group, followed by 6 half-day Saturday PD sessions during the school year. The PD was planned and implemented collaboratively by project staff that included mathematics and education university faculty members and school-based master teachers selected based on their success as mathematics teachers and their experience with DG software. The project team and master teachers served as partner facilitators for all PD sessions.

The teachers in the experimental (DG) group were actively involved in each PD session and focused on developing their conceptual understanding of mathematics using the DG software as a tool. They worked on challenging problems and developed important geometric concepts, processes, and relationships while building DG skills and teaching methods. They experienced how DG environments encourage mathematical investigations by allowing users to manipulate their geometric constructions to answer "why" and "what if" questions, by allowing them to backtrack easily to try different approaches, and by giving them visual feedback that encourages self-assessment.

Typically, each activity in a PD session consisted of the following instructional events: 1) Presenting a task (exploring concepts/relationships or solving a problem) to the teachers; 2) Requesting teachers to use DG tools to construct the related geometric object or problem situation (with help if necessary) or providing them with a prepared DG environment; 3) Asking teachers what conjecture(s) they can make based on their initial observation; 4) Requesting teachers to use dragging, measuring, and multiple, linked representations to experiment with the constructed or provided DG environment, and observe what characteristics change and what remain the same; 5) Asking teachers to further make and test conjecture(s); 6) Reminding teachers to redo events #4 and #5 in a new aspect or at a higher level, as appropriate; 7) Asking teachers to summarize and reflect on what they have conjectured; and 8) Helping teachers develop explanations to prove or disprove their conjecture(s).

In each PD session, teachers either worked individually at a computer or in small groups. In either case, PD facilitators encouraged teachers to share ideas and help each other. The facilitators circulated, observed (to monitor the progress) asked questions, and provided necessary assistance. They also initiated whole group discussions as needed.

In terms of content, the summer PD sessions concentrated on important and commonly taught topics of high school geometry: triangle congruence and similarity, properties of special quadrilaterals, properties of circles, and geometric transformations. School year follow-up PD aligned with the course scope and sequence determined by the participating school districts.

The PD facilitators modeled what teachers were expected to do with their students in geometry investigations. To help teachers change their instructional practices, their engagement of students, and how they facilitated student learning, mathematical explorations were always followed by discussions on questions such as “How will you teach this content using DG software?” and “How will you lead your students in conjecturing and proving using DG software?” The PD facilitators valued teachers learning from each other and sharing ideas and also sought to provide opportunities to apply new teaching skills. Therefore, teachers were encouraged to present their insights on and experiences with the DG approach and to describe problems they might have experienced or anticipated with other teachers offering suggestions to address the concern. Teachers also prepared lesson plans that they shared with the entire group.

The Control Group

The teachers in the control group taught geometry as they had done before. They also participated in a PD workshop that addressed the same mathematical content as the DG group but without the use of technology. The PD sessions for the control group utilized teaching methods with which teachers were already familiar. The PD facilitators lectured and involved teachers in activity-based instruction. Participants engaged in problem solving without using technology tools. They spent the same amount of time in PD training as the teachers in the DG group. The control group PD was included in the research design to control the variables tied to professional development and ensure both groups experienced sustained, rigorous, and relevant development in high school geometry teaching. Since all teachers participated in PD sessions and all were presented with the same mathematics content, any differences measured between the two groups would be attributed to the presence (or lack of) the interactive DG learning environment (since it was the only instructional difference between the two groups).

Measures and Data Analysis

Measures

A measure of teachers’ conjecturing-proving knowledge. A conjecturing-proving test was developed by the project team to measure teacher knowledge. As a result of a thorough literature review, geometry construct development, item construction, Advisory Board members’ review, and several pilot tests with resulting revisions, a test consisting of 26 multiple-choice items and 2 free-response proofs was produced. The test was administered to the teacher participants as both a pre- and post-test at the PD summer institute.

Teachers' implementation fidelity and classroom observations. The DG approach involves intensive use of dynamic software in classroom teaching to facilitate students' geometric learning. The critical features of the DG approach include using the dynamic visualization to foster students' conjecturing spirit, their habit of focusing on relationships and explaining what is observed, and their logical reasoning desire and abilities. To capture these critical features of the DG approach, two measures of implementation fidelity (the DG Implementation Questionnaire [DGIQ] and the Dynamic Geometry Observation Protocol [DGOP]) were developed. The DGIQ was adapted from a teacher questionnaire developed by the University of Chicago researchers (Dr. Jeanne Century and her colleagues) in an NSF-funded project, based on the critical features of the DG approach. The final version of the DGIQ consisting of six multiple-choice items and ten open-response questions was administered to the teachers in the experimental group six times across the school year. A different version of the questionnaire was administered to the control group teachers (also six times) to examine how they teach geometry without using dynamic technology.

The DGOP was developed to address the critical features of the DG approach. It was adapted from the *Reformed Teaching Observation Protocol* (Sawada et al., 2002). The final version of the DGOP consisted of 25 items with a 4-point Likert response scale from *Never Occurred* to*Very Descriptive* addressing four different aspects: (1) *Description of intended dynamic geometry lesson, (2) Description of implemented dynamic geometry lesson, (3) Assessment of quality of teaching, and (4) Assessment of engagement and discourse*. For the control group, an observation protocol (CGOP) was developed by removing from the DGOP items related to the implementation of DG software functions such as dragging and dynamic measuring. The DGOP or CGOP was administered in 16 Geometry classrooms (8 selected from each group). Each classroom was visited by two observers. Each selected teacher was observed four or five times across the school year.

Student level measures. Two instruments were used for measuring students' geometry knowledge and skills: (for the pre-test) Entering Geometry Test (ENT) used by Usiskin (1981) and his colleagues at University of Chicago; and (for the post-test) Exiting Geometry Test (XGT). The XGT was developed by selecting items from California Standards Tests – Geometry. The final version for XGT had 25 multiple-choice items. (See Jiang et al., 2011 for the details of the two tests.)

All research instruments mentioned above, except the student geometry pre-test, were developed by the project team. For all project-developed measures, the Cronbach's Alpha statistical values were within the acceptable ranges for reliability (e.g., reliability was calculated with Cronbach's alphas of 0.957 and 0.952 for the DGOP and CGOP, respectively.) Item Response Theory (IRT) scoring routines were applied to the DGIQ and students' post-test data providing evidence for the instruments' construct validity.

Data Analysis

Two-level hierarchical linear modeling (HLM), other statistical methods, and the constant comparison method (Glaser & Strauss, 1967) were employed to analyse the quantitative and qualitative data.

Results

Findings about Teacher Content Knowledge from the Conjecturing-Proving Test

The participating teachers completed the conjecturing-proving test at the beginning and end of the summer PD institute. A statistic for teacher content knowledge as measured by the instrument was calculated by adding the number of correct multiple-choice responses with points from free-response items. Average scores were 20.49 on the pre-test and 21.86 on the post-test with an average gain of 1.37. A paired-sample t-test showed that this gain was statistically significant ($p = .003$). These results show that the PD had a positive effect on teachers' conjecturing and proving capabilities. The teachers in the experimental group showed a greater average gain (1.56) than the teachers in the control group (1.18); however, this difference was not statistically significant ($p = .670$).

Findings about DG Approach Teaching from the Classroom Observations

Table 1 provides the results of the DGOP administration measuring the levels of fidelity of the dynamic approach implementation in the DG group. If we focus our attention to the mean scores (with a maximum score of 4) for the DG group, we observe that the three aspects with the highest scores were Good Lesson Design, Use of DG Features, and Teachers' Knowledge. The data provides evidence that the teachers in the DG group demonstrated an intention to implement the DG approach and to some extent they demonstrated knowledge about how to integrate the dynamic approach to teaching geometry. Overall, teachers in the DG group were implementing the DG approach at a moderate level (2.28). In part, this moderate level of implementation was explained by the challenges reported during the school year such as the inaccessibility of computer labs in the first several weeks and the pressure to spend time preparing for the state required tests. However, the majority of the classrooms observed can be described as being faithful to the DG teaching approach.

Table 1: Comparison between DG and Control Groups

Aspect	Sub-aspect	Mean DG	Mean Control	*p*-value
Intended Dynamic Lesson	Good lesson design	2.81	1.85	.032*
	Use of dynamic features	2.75	0.70	.000*
Implementation	Actions beyond use of software	2.06	1.33	.095
Quality of Teaching	Cognitive demand	2.30	1.78	.113
	Teachers' knowledge	2.89	2.84	.924
	Conjecture/Proof	1.93	1.40	.206
Engagement and Discourse		2.37	2.29	.735
Overall DGOP		2.28	1.68	.088

Comparing the two groups, Table 1 also shows the mean values of the CGOP and the *p*-values assessing the significance of the treatment effect computed using a mixed effect ANOVA. Results confirm the efficacy of the DG treatment by showing significant differences in the two aspects related to the intention to implement a dynamic lesson. As a whole, lessons in the DG group had a significantly better design aligned with the DG teaching approach, moving students from initial conjecture, to investigation, to more thoughtful conjecture, to verification and ultimately to proof. Further, lessons in the control group did not use dynamic features in teaching geometry. With respect to the other aspects of the DGOP (or CGOP), the two groups did not differ significantly, however all the DG ratings were higher than those of the control group. Note that most of those aspects assessed elements of the lesson that were not related to the use of dynamic features.

Findings about DG Approach Teaching from the Implementation Questionnaire

The purpose of the DGIQ was to assess the DG group teachers' effectiveness and comfort in using GSP in teaching geometry. Also, the questionnaire results provided the frequency of teacher and student use of GSP. Figure 1 shows how the teachers rated themselves on their effectiveness and comfort in using GSP. Out of 31 teachers who completed the questionnaire, 29% felt that they were at the high level of effectiveness, 61% at the middle level, and 10% at the low level. However, the majority of the teachers (97%) felt very comfortable or somewhat comfortable in using GSP in teaching. Overall, the teachers felt more comfortable than effective in using GSP with only one teacher not feeling comfortable in using GSP in teaching of geometry.

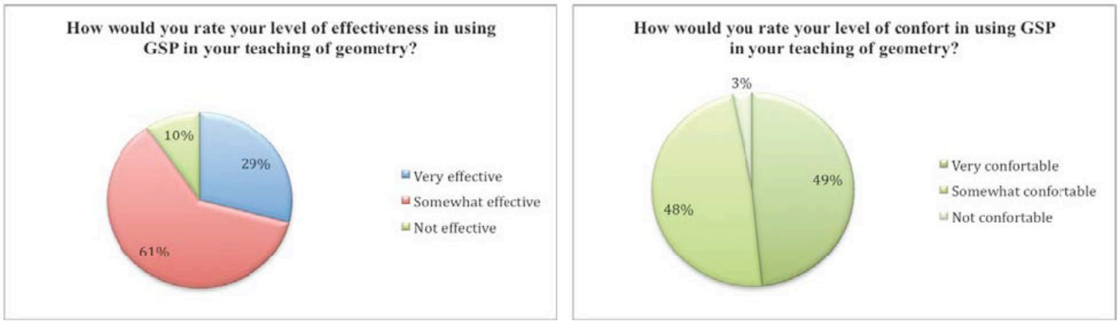

Figure 1: Effectiveness in Using GSP and Level of Comfort in Using GSP

Figure 2 shows average teacher and student use of GSP throughout the school year for those in the DG group. The "average teacher use of GSP" represents the average number of times per week the teacher used the demonstration computer in his/her classroom to do GSP presentations and demonstrations. The "average student use of GSP" represents the average number of times per week students worked in a computer lab doing hands-on explorations with GSP. Out of the 31 teachers who completed the questionnaire, 77% of them used GSP at least one time per week and 38% at least two times per week. However, the student use was lower, with 61% of them using GSP at least one time per week, and only 10% two times per week.

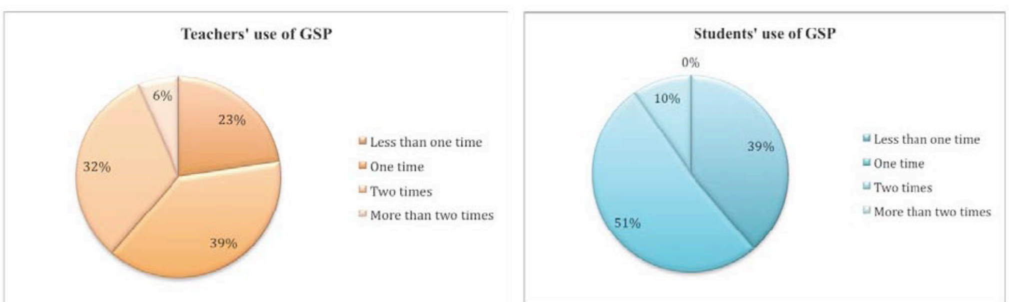

Figure 2: Average Teacher Use of GSP and Average Student Use of GSP per Week

Therefore, in terms of "taking students to the computer lab to do hands-on activities with GSP," the teachers' implementation of the DG approach was at the medium level of intensity. This finding is consistent with data from the classroom observations. However, almost all teachers were positive or enthusiastic in using GSP in geometry teaching. Again, considering the challenges that the teachers experienced during the school year, data supported the conclusion that most of the teachers implemented the DG approach faithfully.

Even though some teachers in the DG group might have not felt as effective in using GSP because of the students' limited use of GSP (one time or less than one time per week), some of them might still be considered very effective if we focus on the ways they used the DG approach. One teacher provided such an example. He felt "somewhat effective" and his students used GSP on average one time per week, but his classroom observations showed very effective use of GSP. During one of the observations, his students were exploring the midsegments of a triangle and their goal was to come up with as many conjectures as possible. Students completed the constructions on their own, made initial conjectures based on their observations, used measurements to confirm their conjectures, and wrote their final conjectures. The teacher circulated among students and provided guiding questions when needed. One student made many measurements but no conjectures. The teacher asked this student, "Do you notice any relationships? What conjectures can you make?" These questions helped the student focus on the objective of the lesson and form conjectures based on the measurements and observations. During the lesson, students also engaged in conversations with one another to discuss their observations and conjectures. Students were actively involved in their learning and the teacher took on the role of a guide by prompting his students through questioning. This lesson not only showed effective use of GSP, but also addressed higher-level thinking.

Findings about Student Achievement from the Geometry Test

Two-level hierarchical linear modeling (HLM) was employed to model the impact of the use of the DG approach on overall student geometry achievement measured by the student post-test (XGT). The model was analysed using student pre-test (ENT) scores as a covariate. The sample of classrooms studied included three different levels of Geometry: Regular, Pre-AP and Middle School (middle school students taking Pre-AP Geometry). Since the classroom expectation and quality of the students in each of these levels were very different, the factor *Class Level* was included in the model. Additionally, the covariate *Years Exp* (number of years of classroom experience) was included in the model. The results of the model indicated that the DG effect was strongly significant ($p = .002$). Comparing the means, the DG group was higher than the control group in each level of Geometry and the effect size (.45) was substantially larger at the Regular Geometry level. (See Jiang et al., 2011 for the details of the HLM analysis results.)

Using the integrative framework (Olive & Makar, 2009) as a lens, further quantitative and qualitative data analysis on the impact of the DG professional development is ongoing.

Discussion

The HLM model taking pretest, class level, and teaching experience into account provided evidence that the students of DG group teachers scored significantly higher than the students of control group teachers on the Exiting Geometry Test. Given that teachers were randomly assigned to the two groups and both groups received comparable sustained, rigorous, and relevant professional development on the same geometry topics, the results of this study provide evidence to support the finding that the DG professional development positively impacted the students' geometry achievement. Both DG and control group teachers demonstrated significant gains on the Conjecturing-Proving Test through the one-week summer PD institute. This result suggests that both the PD sessions designed for the DG group and those designed for the control group had an effect on teachers' conjecturing and proving ability. Although the DG and control teachers did not differ significantly on their mean gain scores, the DG teachers' mean gain score was 32% higher than that of the control teachers. Classroom observation data revealed that lesson plans that the DG group teachers prepared were designed significantly better than the control group teachers' lessons by facilitating students' conjecturing and proving abilities. The teachers' DGOP ratings (overall and in each sub-scale) were consistently higher for the DG group although most of the differences were not statistically significant. In summary, the results of this study suggest that the DG professional development offered to the participating teachers had a significant positive effect on the teachers' mathematics conjecturing-proving content knowledge and their ability to implement a dynamic geometry approach to teaching. The teachers, in turn, helped their students achieve better geometry learning.

cmartinez7@ucol.mx

Ricardo Ulloa Azpeitia
Universidad de Guadalajara
ricardo.ulloa@cucei.udg.mx

In this paper we analyze and discuss the postgraduate students' performance related to the tracing of tangent lines to the curve of a quadratic function within Dynamic Geometry Software in the context of Mean Value Theorem. The purpose is to show the possibility of using Dynamic Geometry in promoting learning of such Theorem, based on its geometric interpretation. The theoretical elements adopted in this study are based on the instrumental approach to tool use. The results illustrate the epistemic role of the Dynamic Geometry Technique, as well as the difficulties associated with their paper-and-pencil Techniques.

Keywords: Technology; Advanced Mathematical Thinking; Teacher Education-Inservice

Background

In literature, there is evidence about the influence of using Dynamic Geometry Software (DGS) to encourage students' mathematical thinking (e.g., Guven, 2008; Leung, Chan & Lopez-Real, 2006; Reyes & Santos, 2009). In these studies the possibility of using dynamic geometry is raised to discuss mathematical relationships exploring different cases. In particular, Guven (2008) and Reyes and Santos (2009) show how the dragging and the locus, that emerge in the explorations that let the DGS, promotes the development of conjectures about the mathematical relationships of the objects embedded in the mathematical dynamic model, in the sense of Reyes and Santos. From these studies, and the interest of the community in analyzing the influence of the technological environments in teaching and learning calculus (Ferrara, Pratt & Robutti, 2006), we propose the possibility of using DGS to analyze its potential in promoting the learning of Mean Value Theorem (MVT), based on its geometric interpretation.

In Ferrara, Pratt and Robutti (2006) a study compilation is included about central concepts of calculus such as function, limit, derivative and integral in technological environments; from these backgrounds, we consider that it is important to research the role of technology in the learning of calculus in which the concept of derivate is embedded. Therefore, this paper focuses on studying the use of DGS in learning the MVT through its dynamic modeling.

The understanding of MVT is important because it is the base of contents like the criteria for maximums and minimums. Taking into account the use of DGS allows us to approach the MVT and the mathematical concepts associated, through mathematical dynamic models, and not just in analytic ways, as it is usually presented in textbooks. In this sense, in the dynamic geometry environments, the approach to MVT can be done by tracing tangent lines to the curve of a function in the context of its geometrical interpretation. Thus, the aim of this study is to answer the question: how does the use of dynamic geometry influence the tracing of tangents to the curve of a particular function in the context of the MVT, based on its geometric interpretation?

Theoretical Framework

The theoretical framework adopted in our study is *the instrumental approach to tool use* (Artigue, 2002; Lagrange, 2003, 2005). The use of this approach in dynamic geometry environments is feasible (Leung, Chan & Lopez-Real, 2006). According to Artigue (2002) the instrumental approach encompasses elements from both cognitive ergonomics (Vérillon & Rabardel, 1995) and the anthropological theory of didactics (Chevallard, 1999). In this sense, there are two possible directions within the instrumental approach: one in line with the cognitive ergonomics framework, and the other in line with the anthropological theory of didactics (Monaghan, 2007). In the former, the focus is the development of mental schemes within the process of instrumental genesis (Drijvers & Trouche, 2008). Within this direction, an essential point is the distinction between artifact and instrument.

In line with Chevallard's theory, researchers such as Artigue (2002) and Lagrange (2003, 2005) focus on the techniques that students develop while using technology. According to Chevallard (1999), mathematical objects emerge in a system of practices (*praxeologies*) that are characterized by four components: *task*, in which the object is embedded (and expressed in terms of verbs); *technique*, used to solve the task; *technology*, the discourse that explains and justifies the technique; and *theory*, the discourse that provides the structural basis for the technology.

Artigue (2002) and her colleagues have reduced Chevallard's four components to three: *Task*, *Technique* and *Theory*. The term *Theory* combines Chevallards's technology and theory components. The *Technique* is a complex assembly of reasoning and routine work and has both pragmatic and epistemic values; techniques are most often perceived and evaluated in terms of its pragmatic value, but their epistemic value contribute to the understanding of the objects they involve, that is to say, they are a source of questions about mathematical knowledge (Artigue, 2002, p. 248). According to Lagrange (2003), *Technique* is a way of doing a *Task* and it plays a pragmatic role (in the sense of accomplishing the task) and an epistemic role in that it contributes to an understanding of the mathematical object that it handles during its elaboration; it also promotes conceptual reflection when the technique is compared with other techniques and when discussed with regard to consistency. The consistency and effectiveness of a *Technique*, according to Lagrange (2005) are discussed in a theoretical level; mathematical concepts and properties and a specific language appear.

Our study is in line with the anthropological theory of didactics; thus the focus of this research is the epistemic value of technique. That is, we are interested in studying the students' Techniques they develop within the dynamic geometry environment.

The Study

In the present paper, we discuss and report the results of the designed Activity. Its rationale, the population and the data collection, is detailed bellow.

The Design of the Activity

The design took into consideration the Anthropological line of the instrumental approach. Thus, the three elements *Task, Technique and Theory* were used. The Activity, as Kiernan and Saldanha (2008) note, is a set of questions related to a central Task. In our case, the *Task* is "Drawing a tangent line to the curve of the quadratic function $f(x) = -(x - 3)^2 + 4$ and parallel to a secant line to the curve. The Activity consisted of two phases; the first one involves just working with paper-and-pencil, in order to know the techniques used by the participants in this environment. The second one includes working with the DGS, in order to know how the use of DGS influences and modifies the initial participants' techniques and what other emerges; both phases include technical and theoretical questions. The DGS used was GeoGebra.

The Task consists in given the function $f(x) = -(x - 3)^2 + 4$, participants are asked to plot the curve and draw a secant line to the curve and determine its equation (blue line, Figure 1). Once this part of the Task is completed, participants are asked a Theoretical question related to whether or not a tangent line (red line) to the curve and parallel to the secant line could be traced (i.e., the geometrical interpretation of MVT). If the answer is affirmative, they are asked to trace and determine its equation, first in a paper-and-pencil environment; then, using DGS (with the restriction that differential calculus techniques are not allowed in this environment). The Figure 1 shows a graphic representation of the proposed Task.

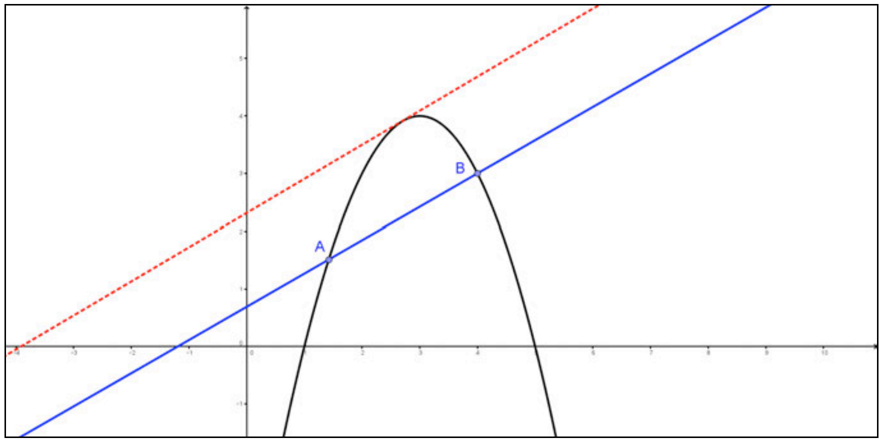

Figure 1: Graphic representation of the Task (graphic interpretation of MVT)

Population

The participants were 16 postgraduate students enrolled in a master program in the teaching of mathematics in Mexico. At the time of collecting data, they were in the 4th semester of the Master's degree. All participants knew GeoGebra and were familiar, at least a year and a half, with this software. All participants, except one, have teaching experience, some of them in university-level, others in senior-secondary-level and just a few in secondary-level. The professional degrees of the participants were among graduates in mathematics, engineers in different areas and one economist.

Implementation of the study

The data collection was carried out in three sessions, during one of the Master's degree courses conducted by one the researchers; each session lasted around 2 hours, which were recorded. The students worked in self-created pairs, in order to promote the dialogue among them and consequently make an audio recording about their own reflections in the use of GeoGebra according to the Task. Each team had a printed Activity, the GeoGebra software installed in their laptops, besides the SCREEN2EXE software which captures the computer screen in order to view the sequence of the students' work with the DGS. In this way, the research data sources include worksheets (printed Activity), the GeoGebra files, SCREEN2EXE files, video recorded files and the researcher's field notes.

Analysis and Discussion of Data

In this report we analyze and discuss the work of four pairs (Teams I, II, III and IV, henceforth), which exemplify the work done by all participants. The analysis conducted is of a qualitative nature inasmuch as we are interested in providing a detailed account of the kinds of Techniques that the participants used to solve the Task in both environments and the Theory they sustain. The analysis makes emphasis in the dynamic geometry techniques which were used by the students; that is to say, we are interested in research the kind of mathematical relations which they identified in the dynamic model of the Task that lead them to solve it.

On the paper-and-pencil work

The paper-and-pencil techniques and the Theory are based on the differential calculus. That is to say, on the usual procedure to determine a tangent line associating the function derivative with the slop of the tangents' family lines to the curve, although the kind of proposed function influenced in their reflections too. About the theory that sustains whether the possibility or not of drawing a tangent line with the required conditions, the participants refer the continuity of the function. Some of them describe it in an explicit way; others in the opposite way. The following Figures show the work of two Teams, that proves what is expressed, once they construct the graphic of the proposed function and pose the secant line equation to the referred function.

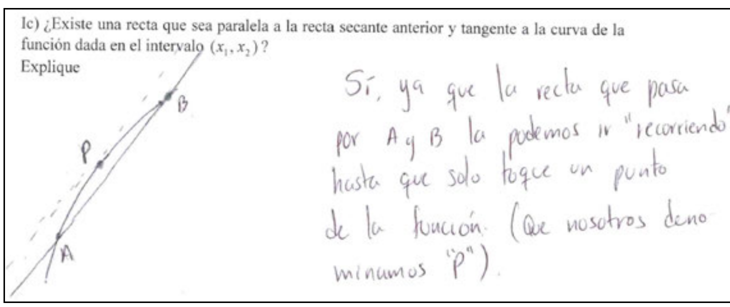
Ic) ¿Existe una recta que sea paralela a la recta secante anterior y tangente a la curva de la función dada en el intervalo (x_1, x_2)?
Explique

1. Si, porque la función es continua en el intervalo.

Ic) Is there a parallel line to the secant and tangent to the curve of the given function in the interval (x_1, x_2)
Explain it
Yes, because the function is a continuous one in the interval.

Figure 2: Theory from Team I

To the question Ic) whether it will be possible to trace a line that it is parallel to the secant and tangent to the curve in a certain interval by the abscissas of the points where the secant line cuts the function of the graphic, the Team I sustains its Technique in the continuity concept of the function (Figure 2). Other Teams do not express their answers in an explicit way, for example, the Team II (see Figure 3). Note that when the students describe that it is possible dragging the secant line, based on a dynamic model of the Task, they demonstrate and idea of continuity of the function.

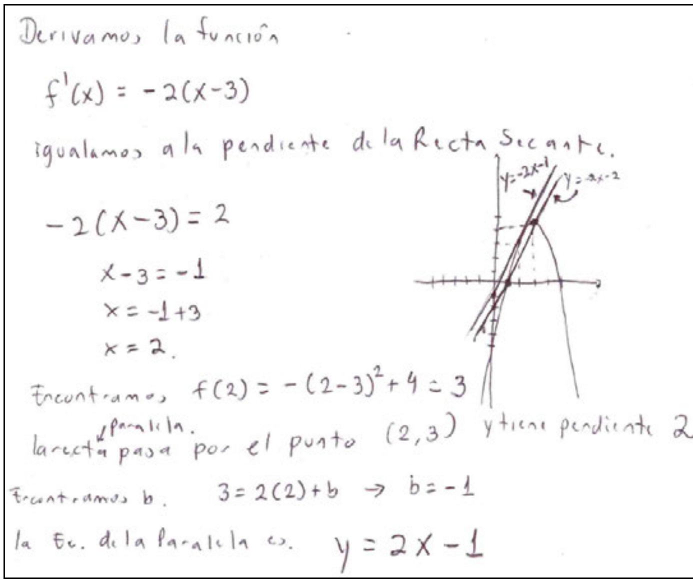


Yes, because we can dragg the line that passes through points A and B until it touches a single point of the function (which we denote by P).

Figure 3: Theory from Team II

Other teams justify their Techniques from their knowledge about the parabola; in particular about one of its specific points, the vertex. The Teams, which worked in this way, propose a parallel secant line to the axis of the abscissas, noticing the vertex of the parabola as the tangent point. However, they also showed ideas about the continuity of the function when they work in the dynamic geometry environment, as later discussed.

Because the participants' previous knowledge (Technique and Theory), it was expected that they would use differential calculus techniques to find and trace the tangent line equation. The analysis of the answers confirms this idea. Once the function is charted and the secant line equation to the curve is determined, those Teams that propose a secant non parallel to the axis of the abscissas use the derivate of the function to find the tangent point from solving the equation $f'(x) = m$, (where m is the slope of the secant line). The Figure 4 shows this Technique (*Derivate Technique*) from Team I.



We derived the [given] function
$f'(x) = -2(x-3)$
We equate to the slope of the secant line
$-2(x-3) = 2$
.
.
.
$x = 2$
We calculate $f(2) = \ldots = 3$

The parallel line passes through the point (2,3) and has slope 2

We find b $3 = 2(2) + b \rightarrow b = -1$

The equation of the parallel line is $y = 2x - 1$

Figure 4: Technique from Team I

In other hand, the Teams that traced the parallel secant line to the axis of the abscissas used an Analytic Geometry Technique taking the maximum of the function like the tangent point. That is to say, they solve the Task using the equation $y = k$, where they identify k like the ordinate to the vertex with coordinates (h,k) of the parabola $y = a(x-h)^2 + k$.

On the Dynamic Geometry work

The work from the Teams in the GeoGebra environment, which was asked not to use differential calculus techniques, shows three characteristics. Some of them use *Algebraic Techniques* provoked by the dynamic model of the Task, and they use the DGS to trace their answers. Other Teams used the geometry dynamic characteristics and specific GeoGebra commands, which we called *Dynamic Geometry Techniques*, to model the Task and look for the mathematical relations that it involves. Others did not consider the use of DGS to explore mathematical relations, because it is taken as obvious. Next, we present examples from each one of these cases.

The Team III was one of those which traced the parallel secant line to the abscissas axis (as it is shown in Figure 5). On the offered explanations by one of the Team members (Student A) it is found that, for them, the answer to the Task is obvious, based on their work that they developed with paper-and-pencil. The following extract illustrates this case.

> Student A: What we did was tracing this [shows a point that was traced on the function of the graphic], and then, traced the parallel [to the secant] […] we moved it, moved it, moved it, move it [they dragged it] until the tangent point was found, which it is easy for us because it is the parabola vertex.

As it is shown in the transcription, the students used parallel and dragging commands as Technique. This let them trace a parallel to the secant line and that passes through a point (traced by them) over the graphic of the function. The mathematical relationship which is shown in their dynamic model is that the parallel line that passes through the parabola vertex fits with the given conditions of the Task. Nevertheless, the tangent point is known in advance, it is not a result from the explorations in the DGS. This is to say, their paper-and-pencil Technique and Theory (their knowledge about the parabola) let them solve the Task in the dynamic environment. The answer that

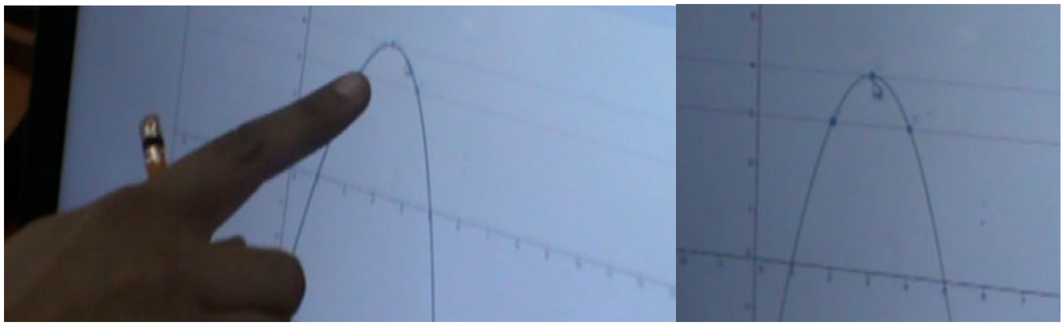


Figure 5: Dragging Technique from Team III

they give is particular, because if the secant line conditions are changed, the line which is proposed by them as the solution will not be the tangent, it just will keep the parallelism condition.

Meanwhile, for the Team I, the dynamic model leads them to try different paper-and-pencil techniques that differ from the calculus. They observed a mathematical relationship in the dynamic model of the Task which led them to the solution; it consisted of a system of equations with the parabola equation *($y = -(x - 3)^2 + 4$)* and the equation of the tangent line *($y = mx + b$)* so that the solution has multiplicity 2 (to fit with the tangent condition), where m is the value of the slope of the secant (in order to fulfill with the parallelism condition). In this way, they calculate the value of the parameter b (of the tangent line). Figure 6 shows this algebraic Technique.

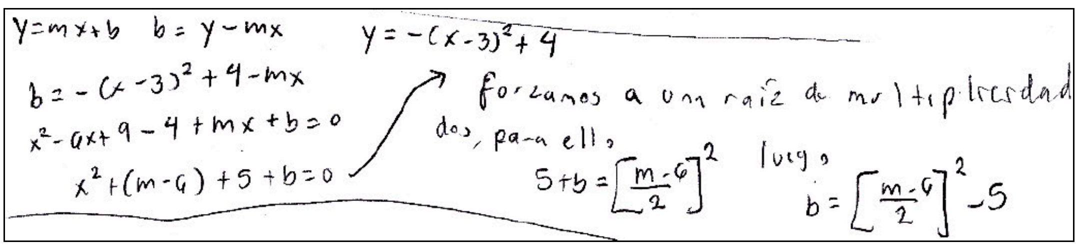

Figure 6: Algebraic Technique from the Team I

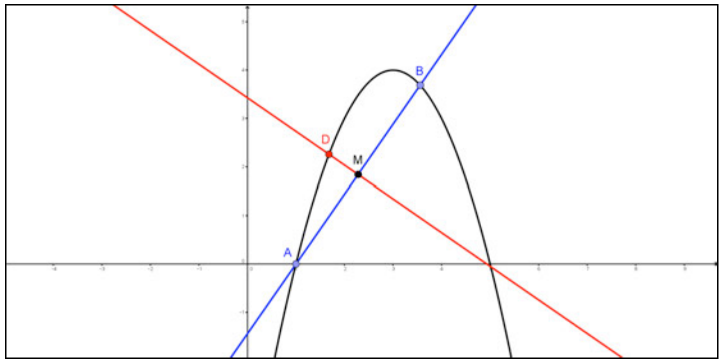
The given solution from the Team I is general; however, their answer is not supported by any Dynamic Geometry Technique, but it is an algebraic process. GeoGebra encouraged them to reflect in other alternative paper-with-pencil Technique. Once they found an expression for b in terms of m, they use GeoGebra to graph the equation with these parameters.

The Team II explored in the dynamic model by dragging through a slider as a possible Technique to solve the Task. Nevertheless, this technique lets them an approximation to the solution of the Task. This Team introduced in GeoGebra the requested equation $y = mx + b$ of the line, where m is the same as the value of the secant slope (with this, the condition of parallelism is completed) and associated the parameter b, the ordinate to the origin, with a slider; in order that they manipulate the slider (dragging the line) and propose a solution when, by trial and error, they observe in the graphic representation that the line fulfills the tangent conditions. However, they are aware, using the zoom Technique that their answer is just an approximation.

Finally, the Team IV tried to solve the Task, in the GeoGebra environment, based on the possibilities that the DGS offers. It is interesting how this Team, using the dynamic model, observes mathematical relations in the dynamic construction that they propose in GeoGebra (Figure 7). For this Team, the explorations they did in the DGS let them to conjecture that the middle point M from the segment AB (see Figure 7), the points where the secant (blue line of the Figure) crosses the curve; in particular, the perpendicular bisector (red line) of this segment, lead them to the find the tangent point.



1. A, B en la función 2. Recta que pasa por AB 3. Punto medio entre AB → Perpendicular en este punto. 4. Punto de Intersección entre f(x) y la perpendicular. Sin embargo al comprobar con la ecuación original no es el mismo punto de tangencia calculado analíticamente.	*1. A, B on the function.* *2. Line that passes through AB.* *3. Midpoint point of AB segment, perpendicular [to the AB segment] in this point.* *4. Intersection point between f(x) and the perpendicular.* *However, when comparing with the original equation, we found out that it is not the same tangent point calculated analytically.*

Figure 7: Dynamic Geometry Technique from Team IV

In this case, the students established the tangent point as the intersection of the perpendicular bisector and the function of the curve (Point D in Figure 7). Nevertheless, they found out that this Technique do not lead them to the solution, making comparisons with their initial paper-and-pencil Technique. The most important thing about the work from Team IV is to realize that the dynamic model of the Task let them make conjectures about the midpoint of the segment AB, which, actually, it is related to the solution of the problem.

Conclusions

The offered examples shown in the previous section let us know the influence of the dynamic geometry software, from the participants' Technique and Theory, in the tangent traces. In the paper-and-pencil environment, two types of Techniques are identified, one based on the differential calculus knowledge; the other one, based on the analytic geometry knowledge. Regarding the Theory, it is related to the concept of continuity of the function.

The influence of dynamic geometry is shown in those Teams which use a dynamic model that do not use a parallel secant line to the abscissas axis. Therefore, in one side, the DGS encourages the emergence of paper-and-pencil Techniques based on the explorations in the dynamic model. In other hand, DGS lets them work with their own Techniques and commands from the dynamic geometry and establish relationships between the mathematical objects involved and the emergence of others (for example the perpendicular bisector). It also let them contrast paper-and-pencil Techniques with the software Techniques. According to the instrumental approach, this contrast of Techniques encourages to a reflection in a theoretical level.

In this way, the emergence of new paper-and-pencil Techniques and the reflections about the mathematical relationships provoked by the dynamic models in the use of the DGS show the epistemic role of the dynamic geometry Technique in the trace of tangent lines in the TVM context.

In addition, the results show difficulties associated with their paper-and-pencil Techniques in the sense of holding to this environment, and not exploring the software potentials.

We examine relationships between prospective teachers' (PTs') beliefs about the nature of mathematics, learning and teaching mathematics, and the use of technology, and their knowledge of how to use technology to teach and learn mathematics. We interviewed 4 PTs and used Ernest's (1989) classification of beliefs and Goos, Galbraith, Renshaw, and Geiger's (2003) perspectives of technology to uncover PTs' beliefs. We examined PTs' knowledge of using technology by conducting a task-based interview based on the TPACK framework (Mishra & Koehler, 2006). We found there appeared to be relationships between PTs' beliefs about the nature of mathematics, learning and teaching mathematics, and the use of technology and their content knowledge, pedagogical content knowledge, and technological pedagogical content knowledge respectively.

Keywords: Teacher Beliefs; Teacher Education-Preservice; Teacher Knowledge; Technology

One of the guiding principles in the National Council of Teachers of Mathematics' (NCTM, 2014) *Principles to Actions: Ensuring Mathematics Success for All*is the use of tools and technology to explore and make sense of mathematics, reason mathematically, and communicate mathematical thinking. NCTM suggests when tools and technology are used appropriately they support effective teaching and promote meaningful learning. However, some teachers are reluctant to use technology to teach mathematics or do not use it in meaningful ways (Ertmer, 2005). Ertmer (1999) describes two types of barriers to teachers' integration of technology. First-order barriers are obstacles that can be eliminated if money is allocated. These barriers include resources such as access to digital tools, software, Internet, and time to plan and teach technology-based lessons. First-order barriers also include technology training and support, which contribute to teachers' knowledge of technology and how to integrate it into their practice. Second-order barriers are "typically rooted in teachers' underlying beliefs about teaching and learning and may not be immediately apparent to others or even to the teachers themselves" (Ertmer, 1999, p. 51). Second-order barriers are less tangible, more personal, and more deeply ingrained than first-order barriers (Ertmer, 1999). Moreover, research indicates second-order barriers are prevalent among teachers (e.g., Hermans, Tondeur, Valcke, & van Braak, 2008). In order to assist teachers to better overcome both types of barriers, we must understand the relationships that exist among them. In this paper, we share the results of our study in which we examined relationships between prospective teachers' (PTs') knowledge of how to use technology in the teaching and learning of geometry (first-order barriers) and their beliefs about the nature of mathematics, teaching, learning, and the use of technology (second-order barriers).

Related Literature Review and Theoretical Framework

Researchers (e.g., Cooney & Wilson, 1993; Pajares, 1992; Wilkins, 2008) have examined the relationships between beliefs and knowledge and found that one seems to influence the other. Pajares (1992) stated "beliefs influence knowledge acquisition and interpretation, task definition and selection, interpretation of course content, and comprehension monitoring" (p. 328). In other words, teachers' beliefs will influence the ways in which their knowledge is created and their instructional decisions. Conversely, Cooney and Wilson (1993) stated, "beliefs may be dependent on the existence or, perhaps, the absence of knowledge"(p. 150). Therefore, teachers' mathematical knowledge may lead to particular beliefs about the way that mathematical knowledge is best taught (Wilkins, 2008).

Thus, it seems there is a bi-directional relationship between teachers' beliefs and knowledge such that they influence each other. And, both beliefs and knowledge seem to influence teachers' decisions in planning and practice.

Ernest (1989) noted that teachers' approaches to mathematics teaching related profoundly to their system of beliefs. Ernest (1989) provided a model for conceptualizing teachers' beliefs. Ernest's (1989) classifications are organized by the possible ways that teachers may view (1) the nature of mathematics, (2) teaching and (3) learning mathematics. Goos, Galbraith, Renshaw, and Geiger(2003) developed categories, Servant, Master, Partner, and Extension of Self, to describe the different ways that teachers may use technology. We use Goos et al.'s(2003) categories as ways that prospective teachers may view the use of technology for teaching and learning mathematics (see Table 1).

Table 1: Beliefs Classifications

Beliefs about	Classification of beliefs	Description
Nature of Mathematics Ernest (1989)	**Instrumentalist**	Mathematics is a set of facts and rules
	Platonist	Mathematics as a unified body of knowledge that does not change
	Problem Solving	Mathematics as a human creation that is continually changing
Teacher's Role Ernest (1989)	**Instructor**	Goal of instruction is for students to master skills
	Explainer	Goal of instruction is for students to develop conceptual understanding of a unified body of knowledge
	Facilitator	Goal of instruction is for students to become confident problem solvers
Learning Ernest (1989)	**Passive Reception of Knowledge**	Child exhibits compliant behavior and masters skills. Child passively receives knowledge from the teacher
	Active Construction of Knowledge	Child actively constructs understanding. Child autonomously explores self interests
Learning and Teaching Mathematics with Technology Goos, et al. (2003)	**Master**	Dependence on technology, not capable of evaluating the accuracy of the output generated by technology
	Servant	Fast, reliable replacement for mental or pen and paper calculations
	Partner	Cognitive reorganization, use technology to facilitate understanding, to explore different perspectives
	Extension of Self	Incorporate technological expertise as a natural part of mathematical and/or pedagogical repertoire

One framework that has become popular in recent years to describe and examine teachers' knowledge is Mishra and Koehler's (2006) Technology, Pedagogy, and Content Knowledge Framework, known as TPACK. The TPACK framework consists of three main components: Content, Pedagogical, and Technological Knowledge (CK, PK, and TK), and the intersections between and among them, represented as Pedagogical Content Knowledge (PCK), Technological Content Knowledge (TCK), Technological Pedagogical Knowledge (TPK), and Technological, Pedagogical, Content Knowledge (TPCK).

Findings from research on the relationship between teachers' beliefs and their TPACK or integration of technology indicate that there are varying degrees of consistency between the two. Kim, Kim, Lee, Spector, and DeMeester (2013) showed that teachers' beliefs about the nature of content knowledge and learning and about effective ways of teaching influenced their technology integration practices. On the other hand, Chai, Chin, Koh, and Tan (2013) revealed discrepancies between participants' pedagogical beliefs and their TPACK. Chai and colleagues found teachers used a more traditional teaching practice aimed at knowledge acquisition when using technology even though many teachers held constructivist-oriented pedagogical beliefs. The use of a traditional teaching practice is likely due to teachers' lack of knowledge of how to effectively integrate technology into their classroom. Given the mixed results of research studies on the relationships that may exist between teachers' beliefs and their TPACK, additional research is needed to examine whether relationships, in fact, do exist and to describe those relationships. The purpose of this study is to investigate and describe ways in which prospective middle grades mathematics teachers' beliefs relate to their knowledge of technology, pedagogy and content. The research question that guided our study is: What are the relationships among middle grades prospective mathematics teachers' beliefs about the nature of mathematics, teaching, learning, and the use of technology in the mathematics classroom and their level of knowledge of the TPACK components in the context of geometry?

Methods

Our participants were four undergraduate PTs enrolled in a middle grades teacher education program at a university in the southeast United States. We collected data from two semi-structured interviews. In the first interview, we asked participants questions to uncover their beliefs about the nature of mathematics, teaching and learning mathematics, and the use of technology to learn and teach mathematics. In the second interview, we examined participants' TPACK by conducting a task-based interview (Hollebrands & Smith, 2010). The PTs completed four separate tasks in which they analyzed students' work in a Dynamic Geometry Environment (DGE) and created an activity using the DGE to assist students to develop a deeper understanding of the concept or to remedy students' misconceptions (see Figure 1). We analyzed the first interview using Ernest's (1989) classifications of beliefs and Goos et al.'s (2003) perspectives of technology (see Table 1). Independently, each member of the research team read the transcripts and classified each participant's beliefs according to Ernest's (1989) and Goos et al.'s (2003) categories. We shared and discussed our classifications for each belief category and came to an agreement. Next, one member of the research team wrote a brief narrative that described the participant's beliefs and justified our classification of his or her beliefs. The lead researcher performed a member check (Creswell, 2013) by sharing the narrative with each participant. Each participant agreed that we accurately captured his or her beliefs. For the second interview, we used rubrics designed by Hollebrands & Smith (2010) to score the PTs' work on each of the four tasks. The tasks and rubrics were designed to assess the PTs' levels of CK, PCK, TCK, and TPCK (see Table 2). Based on the participants' work on each of the tasks, one of four levels

TASK 1

Suppose students in your middle or high school mathematics class are studying rectangles and squares. They open a dynamic geometry sketch that contains a rectangle and a square, each of which have been constructed. Students are asked to consider properties of rectangles and squares, based on their exploration of the sketch. One pair of students has measured the diagonals and they have noticed they are always congruent. They claim, "quadrilaterals have congruent diagonals."

a. Is this claim always true, sometimes true, or never true? Explain.
b. How would you characterize their current level of geometric understanding?
c. Create a sketch using a dynamic geometry environment that you would like students to use to explore diagonals of quadrilaterals. Be sure to include directions and/or questions you would provide to students as they use this sketch.

Figure 1.Example Task for Examining Participants' TPACK (Hollebrands & Smith, 2010)

Table 2: Rubric Used to Analyze TPACK Interview Task 1

Content Knowledge	Pedagogical Content Knowledge	Technological Content Knowledge	Technological Pedagogical Content Knowledge
A. Responds that the claim is sometimes true. B. Knowledge that there exists at least one quadrilateral for which the diagonals are not always congruent. C. States that for at least the rectangle and square the diagonals are always congruent. D. Provides a correct mathematical justification for why the statement is sometimes true using proofs that involve triangles or other properties.	A. Identifies that the student is able to notice that for a square and a rectangle that the diagonals are always congruent based on their measures. B. Identifies that the student is at level 2 (descriptive) but probably not at level 3. C. Has students consider at least one counterexample of a quadrilateral that has congruent diagonals. D. Asks students to consider at least one example of a quadrilateral that has congruent diagonals.	A. Accurately constructs or draws a quad using a DGE that is a counter-example. B. Uses measures to find the lengths of the diagonals. C. Drags to create multiple examples in a DGE. D. Accurate constructions of the 2 of the following quads: • Square • Rectangle • Parallelogram • Rhombus	A. Uses the DGE technology to focus students on properties of different quadrilaterals and their relationships to the diagonals in the task. B. Creates more than a single example using DGE technology to show the student that they are incorrect in the task. C. Designs an exploration for students by creating accurate constructions and utilizing the measurement and dragging features
Emergent: 0 or no response. Beginner: 1 of A – D Intermediate: 2 of A – D Advanced: 3 of A – D	Emergent: 0 or no response. Beginner: 1 of A – D Intermediate: 2 of A – D Advanced: 3 of A – D	Emergent: 0-1 of A – D or no response. Beginner: 2 of A – D Intermediate: 3 of A – D Advanced: All of A – D	Emergent: 0 of A – C or no response. Beginner: 1 of A – C Intermediate: 2 of A – C Advanced: All of A – C

(Beginner, Emergent, Intermediate, Advanced) was assigned for each of the four TPACK categories. We coded each participant's beliefs and TPACK levels individually, then compared codes and reconciled differences.

Findings

Content

We found that participants' level of CK aligned with their views of the nature of mathematics. Ken viewed mathematics as a set of facts, rules, and procedures that are to be utilized to solve problems. He said, "I guess personally I would define it as being able to, again using numbers in a formula to solve problem." Thus, we classified his beliefs about the nature of mathematics as Instrumentalist. In the task interview, he was able to name various shapes but could not consistently identify properties, develop counter-examples, or justify the relationships among properties. We coded Ken's CK as Beginner. In the beliefs interview, Kim, May, and Sue held, in part, a Problem Solving view of mathematics. May said, "I also think math can seem like really rigid and like there is one right answer and this is how you do it. So I would also see the role as a mathematics teacher is kind of dispelling some of those myths about math." Sue initially stated she viewed mathematics as a unified body of knowledge. However, her college courses have influenced her view of mathematics such that she also viewed it as a process of inquiry in which the student creates the mathematics. Thus, Sue seemed to have both Platonist and Problem Solving views. The three PTs viewed mathematics to be, in part, created by the human mind and, thus, is constantly evolving for the learner. The three PTs also displayed high levels of CK. Kim, May, and Sue were able to identify properties of different figures, relationships between figures, and determine whether a figure was rotated or reflected by examining the orientation of the figure. While May and Sue were able to justify why certain conjectures were true, Kim, at times, struggled in this area. Thus, we classified May and Sue having an Advanced level of CK and Kim having an Intermediate level of CK. Thus, the PTs who held a Problem Solving view of mathematics displayed a high level of CK, while the PT who held an Instrumentalist view displayed a low level of CK.

Pedagogy

We found two potential relationships between the PTs' beliefs about teaching and learning and their level of PCK even though their beliefs were not the same. Ken believed students learn mathematics best when the teacher is in control of distributing the content, that is, he believed students learn mathematics through a Passive Reception. During the Task interview, Ken proposed activities that could help students see their mistakes, but would not allow students to determine why they were mistaken. Rather, his activities consisted of telling them what to do. Thus, we coded Ken at a Beginner level of PCK. The three other PTs held, in part, an Active view of learning mathematics. Kim thought students should be given the opportunity to pursue their own solution paths, to solve the puzzle in their own way. May also emphasized students should have ownership of their solutions to problems. She said, "[Students] can figure it out on their own and so I feel like they'd be more likely to understand it because they made that discovery themselves, instead of me just giving it to them." Thus, Kim and May viewed learning as an Active Construction of Knowledge. Sue believed students learn mathematics best through repetition, but she learns best through discovery. Sue seemed to hold both Passive and Active views of learning depending who is doing the learning. On the task interview, Kim displayed an Intermediate level of PCK. She analyzed students' thinking and made reasonable claims about students' understanding and how they came to that understanding. However, she did not consistently create activities that would help students fully understand why a certain conjecture was true or false. Both May and Sue demonstrated advanced levels of PCK. They identified students' levels of understanding and their misconceptions. The examples, counterexamples, and exploration tasks May and Sue developed would help students recognize whether their conjectures were true and allow them to deepen their understanding of the content. Therefore, the PT who held a Passive view about learning mathematics displayed a low level of PCK, whereas the PTs who held more of an Active view of learning displayed high levels of PCK.

There also seems to be a relationship between the PTs' beliefs about teaching and their levels of PCK. Ken believed that good teachers are those who explain mathematical concepts well. He said, "I think in order to be a good math teacher you need to be able to show those students different ways of solving a problem. I think you also need to be able to show them the longer ways of why formulas work." Thus, we coded Ken's view of teaching as an Explainer. Kim and May believed students should be given the opportunity to pursue their own solution paths to become better problem solvers. Thus, they wanted to engage their future students in learning mathematics using exploratory activities. Sue said teachers should facilitate discovery, encourage problem solving, and differentiate learning in the classroom. Therefore, Kim, May, and Sue believed that teachers should be Facilitators. As we mentioned above, Kim's level of PCK was at the Intermediate level, and May's and Sue's were at the Advanced level, all higher than Ken’s. Thus, the PT who viewed the role of a teacher as an Explainer displayed a low level of PCK, whereas the PTs who viewed a teacher as a Facilitator displayed a high level of PCK.

Technology

Comparing the participants’ beliefs about the use of technology in the teaching and learning of mathematics with their levels of TCK and TPCK, two relationships emerge. First, there appears to be a relationship between teachers’ beliefs about the use of technology in the mathematics classroom and their knowledge of how to use it to teach students mathematics (TPCK). Ken, Kim, and Sue’s beliefs about the use of technology in the learning and teaching of mathematics aligned, in part, with the Servant role; technology is to be used to amplify cognitive process, but not change the nature of the activities (Goos et al., 2003). In the task interview, the three PTs struggled to develop technology-based activities to help students overcome a misconception and the activities they created were limited to a certain number of examples or they did not use some of the basic features of the tool. We classified their TPCK at the Beginner level. May viewed technology as a Partner; technology should be used to explore and deepen students understanding of mathematics. In the task interview, May’s activities focused on correcting students' misconceptions and having students understand and consider fundamental properties and relationships that would deepen their understanding of mathematics. We coded May’s level of TPCK as Advanced. Thus, it appears that the PT who viewed technology as a Partner displayed a high level of TPCK while the PTs who viewed technology as a Servant displayed low levels of TPCK.

Second, there does not seem to be a relationship between their beliefs about the use of technology in the teaching and learning of mathematics and their level of TCK. Ken and Kim held very similar views that technology could be used as both a Servant and a Partner. We coded both Ken and Kim at a Beginner level of TCK because they could use multiple tools and features of the DGE (e.g., perform constructions of figures, measure different components of the figures, use the drag feature, and label points), but they did not use them consistently across all four tasks and struggled to accurately construct some figures. May viewed technology as a Partner. During the Task interview, May displayed an Intermediate level of TCK, but she may hold a more advanced level of knowledge because she was unable to use the technology on the final task due to time constraints. Sue’s beliefs about the use of technology aligned with the Servant view. During the task interview, Sue used multiple features of the DGE for the majority of the tasks but struggled performing transformations. Thus, Sue had an intermediate level of TCK. Ken, Kim, and May’s views of technology seemed to correspond with their level of knowledge of how to use technology; the greater the PT’s TCK, the stronger the belief in using it as a way to engage students in learning mathematics. However, Sue’s view of technology and her knowledge of how to use it did not follow this relationship. Thus, we cannot state with any degree of certainty that a relationship exists between teachers’ TCK and their beliefs about technology.

Discussion, Limitations, & Implications

The goal of this study was to investigate the relationships among prospective middle grades mathematics teachers' TPACK in the context of geometry (first-order barriers) and their beliefs about the nature of mathematics, learning and teaching mathematics, and the use of technology (second-order barriers). We found that PTs' beliefs about the nature of mathematics relates to their CK, their beliefs about learning and teaching mathematics relates to their PCK, and the use of technology to teach mathematics is related to their TPCK. May was the only PT who displayed high levels in all of the TPACK components. Sue displayed the same levels as May for CK, PCK, and TCK. However, she displayed a low level of TPCK. May and Sue's beliefs were not the same either. May displayed student-centered views of learning and teaching while Sue seemed to have both teacher-centered and student-centered views. In addition, Sue had a servant view of technology. Sue's low level of TPCK is likely related to her beliefs. Sue struggled in developing appropriate technology based activities for students because she had not developed appropriate views of effectively teaching with technology. Kim et al. (2013) found teachers' integration practices differed even though the teachers had access to the same technologies, support, and training. Teachers who held more student-centered views were able to integrate technology more seamlessly into their practices than those with more teacher-centered views. Even though the teachers had a similar knowledge base, the researchers found their integration practices differed and their beliefs seemed to influence the integration. Based on the findings from both our study and Kim et al. (2013), developing a strong knowledge of content, pedagogy, and technology will not ensure that teachers will use technology effectively in the classroom.

Unlike May, Ken's views about the nature of mathematics, learning, and teaching mathematics were teacher-centered and he displayed low levels of TCK and TPCK. This leads us to believe that in order for teachers to use technology effectively, they must develop student-centered views of learning and teaching. However, Kim has student-centered beliefs about teaching and learning, yet she displayed low levels of TPACK. This finding is consistent with Chai et al. (2013) who indicated that while their prospective teachers had developed student-centered perspectives of learning and recognized the advantages of using technology, they struggled designing appropriate technology-based activities. Thus, having student-centered beliefs will not ensure teachers will be able to use technology effectively.

There are two limitations to our study. The first limitation is the number of participants. Perhaps if we had interviewed additional or different participants, we may have found different relationships. The second limitation relates to the underpinnings of the rubric used to determine the level of TPACK knowledge displayed by our participants. Hollebrands & Smith, (2010) developed the rubric based, in part, on what research considers the best practices to teach mathematics with technology, in particular a DGE (e.g. Laborde, Kynigos, Hollebrands, & Staesser, 2006). These practices are based on constructivist principles. Thus, the rubric is likely biased towards participants with student-centered beliefs such that participants who held these beliefs would perform at high level compared to those who held teacher-centered beliefs. In fact, Ken, who held teacher-centered beliefs, did not achieve high levels while May, who holds student-centered beliefs, displayed high levels of TPACK. However, Kim and Sue held, in part, student-centered beliefs and did not display high levels for all TPACK components. Thus, the relationships between the participants' beliefs and TPACK were not predetermined. Even though there are limitations to this study, we believe there are implications for researchers and educators.

As technology becomes more ubiquitous in the classroom, first-order barriers will persist; software developers and curriculum designers are constantly adding new features and creating new tools for the classroom each year. Teachers will need training and support to integrate these updated and new tools into their classroom. However, our findings indicate that just providing knowledge on how to use these tools will not be enough. In order for teachers to use technology effectively, mathematics teacher educators should also focus on developing teachers' beliefs.

In this study, we examined the relationships that may exist between prospective middle grades teachers' beliefs and their TPACK, although we only analyzed their work with a particular tool, a DGE. Future work should examine whether the relationships we found would be the same for other technological tools. In addition, we wondered if the same relationships would appear for prospective secondary mathematics teachers and practicing teachers. We believe further research is needed in this area to provide a clearer picture of the relationships between teachers' beliefs and their TPACK.

PRESERVICE TEACHERS' LEARNING MATHEMATICS FROM THE INTERNET

Aaron Brakoniecki
Boston University
brak@bu.edu

This paper presents the results of a study that examined how preservice teachers used the Internet to find information that would help them better understand one of the Common Core Standards around the Pythagorean Theorem. A brief review of the research around the participants' search strategies, and content understanding is presented first. The connections between the searching strategies used, and the form and quality of the mathematical connections made is the focus of this paper.

Keywords: Technology; Teacher Knowledge; Teacher Education-Preservice

Mathematics teacher educators can not prepare preservice teachers for every piece of mathematics content they will encounter during their career. This means that these future teachers will need to learn mathematics on their own, outside of their teacher preparation programs. Many of these teachers will turn to the Internet to learn about unfamiliar mathematics. This paper presents results from a study that investigated how preservice teachers learned mathematics online, connecting their information seeking strategies and their understanding of the content.

Information Seeking in Digital Environments

Several studies have attempted to describe the behaviors of information seekers as they use digital tools to locate information. These studies have focused on describing two aspects of the searching process; the behavior of the user while seeking resources, and attention to how the user interacted with the resources. (An analogy to a non-digital scenario would be looking at participant behavior while searching for a book in a library, and how the participant interacted with the book once it was located.) Patterns of behavior emerged when looking at how searchers located resources within hyperlinked environments and how searchers located information within particular resources.

Representing and Analyzing Mathematical Connections

Concept maps are visual tools that can be used to illustrate connections between ideas. Consisting of nodes, connecting phrases, and lines, the creator of a concept map can represent their own understanding of a topic, and how they are connecting and relating ideas. Concept maps have been shown to be an effective way to capture student understanding of content in mathematics (Baroody & Bartels, 2000). Concept maps have also been used to track changes in the content understanding of mathematics teachers (Hough, O'Rode, Terman, & Weissglass, 2007).

There have been many attempts in this history of mathematics education to describe ways that learners come to know mathematics. Many frameworks attempt to describe deeper and more richly connected understandings of mathematics and Jon Star (2005) recently contributed a clarification to these approaches, clearly distinguishing between the form of mathematical understanding (i.e. conceptual and procedural) and the quality of that understanding (i.e. rich or superficial). He noted that both forms of mathematical understanding could be understood richly as well as superficially.

Preservice Teachers' Learning of the Pythagorean Theorem from the Internet

This work is part of a project that investigated how seven preservice elementary teachers learned unfamiliar mathematics online. These preservice teachers were enrolled at a large Mid-Western university earning a degree and certification toward teaching at the elementary level. Additionally, these participants were also earning a minor in mathematics and had been taking additional mathematics courses as part of their coursework. In individual sessions, the participants were presented with one of the Common Core State Standards for mathematics (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) that they may be responsible for teaching later in their careers (Standard 8.G.B.6 – Explain a proof of the Pythagorean Theorem and its converse). They were asked, via two tasks, to search online for resources that helped them better understand the mathematical content related to this standard. Before, between, and after these tasks, the participants created concept maps representing how they were thinking about content related to the Pythagorean Theorem. The information-seeking behavior of these preservice teachers during their Internet searching was examined as well as the series of concept maps created over the course of these sessions.

Information-Seeking Online

A previous report from Brakoniecki (2014b) looked at the information seeking strategies employed by the seven preservice teachers when searching for information online. All the participants at some point during their searching exhibited a focus on content of the sites they were finding (showing that no person only skimmed the information). Additionally, all participants utilized a timid navigation strategy, sticking close to their search results, and not venturing far from their search results. However, some of the participants focused predominantly on one format of resource, either preferring to spend the majority of their time looking at static resources (e.g. text, pictures, etc.) or dynamic resources (e.g. movies, web applets, etc.). This is in contrast to a different group who split their time locating information with both of these types of resources, focusing both on static and dynamic content. Additionally, there was a distinction in how much time the participants spent attempting to locate information on sites. The three participants who spent the longest time exploring sites were also the participants who exhibited both a focus on static content and a focus on dynamic content, exploring resources with both forms of content. The four participants who spent the least time exploring content in sites, showed a preference for one format of resource over another. This varied by participant where some preferred static resources and others preferred dynamic. Further details on this analysis can be located in Brakoniecki (2014b).

Mathematical Connections

A second paper from this same data set analyzed the concept maps the participants made before, during and after the two Internet searching tasks. These concept maps were analyzed for the structure of the concept maps, the content that was included in the concept maps, and the connections between the content in the maps (Brakoniecki, 2014a). The preservice teachers organized their concept maps in either a hierarchal or radial design in their first map, and almost always chose the same representation for their later iterations where they were asked to redraw their concept maps. When looking at the content the preservice teachers included in their concept maps, overall, the most content appeared in the final concept maps, constructed after participants had performed both searches. A distinction emerged among participants when looking at the connections they included among their content. These connections were analyzed for their form (procedural or conceptual) and quality (rich or superficial). One group of participants included an overwhelming majority of conceptual kinds of connections in their maps, and only toward their final mappings did they include procedural connections. This group also had an absence of richly described links in their concept maps. In contrast to this group, a second group among the participants was found to have more of a balance of between conceptual and procedural links throughout their concept maps. Additionally, every one of their iterations of concept maps contained at least one richly described connection. Further details regarding this study can be located in Brakoniecki (2014a).

Connections Between Information Seeking and Mathematical Connections

The two previous studies found two patterns of behavior when looking at the preservice teachers' information seeking strategies, and two patterns of behavior when looking at the mathematics connections they included in their concept maps. What was surprising was that there was an exact correlation between the groupings of these preservice teachers. The participants who showed a preference for one form of content and spent less time examining content were also the participants who included almost all conceptual links among their content and had a lack of richly described connections. This group of participants seemed to have more of a big idea approach, or a zoomed out orientation, to the content. The participants who preferred a balance of forms of content and spent longer exploring the resource sites were the same preservice teachers who had more of a balance between procedural and conceptual links in their concept maps, as well as always including at least one richly described link in their concept maps. This second group seemed to have more of a detail approach, or a zoomed in orientation, to the content.

Preservice Teacher Understanding of the Standard

Prior to the beginning of these information-seeking tasks, preservice teachers were prompted to imagine that they were teachers in their own classrooms and they were asked what their goals would be for their classes as they worked toward achieving this standard. All of the participants in their responses to this question mentioned goals of having students be able to understand proof or be able to reason through a mathematical argument. Some of the participants also described classroom goals that were unique to the Pythagorean Theorem including details like the Pythagorean Theorem having multiple proofs or multiple representations. Additionally they may have mentioned mathematics that was specific to the Pythagorean Theorem. The division in the preservice teacher behavior to this question mirrored the split in their behavior to the previous tasks. The participants who responded to this preinterview question in the general way were the same participants as the big idea orientation from the prior grouping. The participants who responded to this preinterview question in the specific way were the same participants as the detail orientation in the prior grouping.

It wasn't until the preservice teachers were asked to think about what they wanted to do in their classroom, a pedagogical question that details emerged. This is an interesting point that, looking at content related questions of the preinterview did not show any distinctions among the preservice teachers in this study. Examining the pedagogical content question did show a distinction in the responses. This is important as it helps suggest that the "same" understanding of content does not imply that enacted lessons would also look the same. Teachers' pedagogical goals shape their classrooms just as much as their understanding of the content does.

Future Directions

We do not want preservice teachers to have only a zoomed in orientation or only a detail orientation. Being able to focus on details is an important process for teachers, but so too is the ability to zoom out and look at where the content of a lesson fits with other content. This is sometimes referred to as horizon content knowledge (Ball, Thames, & Phelps, 2008), the knowledge of how the content of a lesson fits in with the content from the day before, or the content of the next unit.

This study raises several questions that point to future directions for research. This study contributes to the conversation that examination of teachers' content knowledge must also be accompanied by an examination of their pedagogical approaches in order to understand their classroom practice. There appears to be a strong connection between the behaviors of participants when searching online for mathematical information, and how they chose to represent their understanding of content, of which classroom goals may influence this behavior (though other influences may yet be discovered). Additional study might also include how preservice teachers might be learning pedagogical content knowledge online. As the internet becomes a more prevalent location for teachers to learn about mathematics and ways to teach mathematics, it's important to better understand the ways in which this resource is being used and how it can be better leveraged for teacher learning.

MATHEMATICS TEACHING AS LEAN THINKING: A SOFTWARE DEVELOPMENT METAPHOR WHERE TEACHERS LISTEN AND NOTICE

Theodore Chao
The Ohio State University
chao.160@osu.edu

Eileen Murray
Montclair State University
murrayei@mail.montclair.edu

In this theoretical presentation, we connect research-based mathematics teaching practices with the software development movement known as Lean Thinking. By linking these two worlds, we hope to create educational technology products better aligned with research-based mathematics teaching practices, such as listening to and noticing children's mathematical thinking. The Lean Thinking movement focuses on minimal features, constant listening, and short response cycles as opposed to building out massive features with subsequent rounds of testing. Successful mathematics teachers position themselves the same way: listening to, noticing, and responding to their students' mathematical thinking in small increments with rapid feedback, as opposed to teaching massive units with little opportunity for student voice or formative assessment.

Keywords: Policy Matters; Teaching Beliefs; Teacher Knowledge; Technology

Objective

Current mathematics education research has shown that effective mathematics teaching requires teachers positioning themselves as listeners and noticers of mathematical thinking (Empson & Jacobs, 2008; Jacobs, Lamb, & Philipp, 2010). This focus on listening and noticing appears in multiple forms, from one-on-one clinical interviews (Ginsburg, 1997), orchestrated whole group discussions (Smith & Stein, 2011), or targeted strategy sharing techniques (Kazemi & Hintz, 2014). This shift from positioning teachers as authorities of mathematical knowledge to listeners of children's thinking is a drastic change within modern mathematics pedagogy (National Research Council, 2001). In a similar fashion, the rapidly changing software industry has also undergone massive paradigm shifts. Most notable, the Lean Thinking movement, which positions developers as listeners and responders to end users, has revolutionized not just the software industry, but our increasingly technology-based lives.

In this presentation, we lay a theoretical foundation connecting reform-oriented mathematics education and Lean Thinking. As mathematics educators wary of the over abundance of mathematics education technology, we use language from software development to connect to important ideas within mathematics educators in order to align paradigms in software development with research-based mathematics teaching practices. We hope to help technology developers and mathematics teachers find common ground and language in order to build technology that connects to teachers' practices and attends to teachers' and students' actual needs.

Theoretical Framework

Lean Thinking

The term Lean Thinking comes from Womack and Jones' (1996) profile of Toyota's constantly evolving car production techniques, which created an aura of dependability and quality around the brand. When applied to software development, Lean Thinking focuses on quick response to change, collaboration with end users, and short, frequent timescales for delivery (Highsmith, 2001; Poppendieck & Poppendieck, 2003). Many of us have benefited from Lean Thinking through software products that quickly evolve to meet the needs of its users, such as Facebook and Dropbox (Ries, 2011).

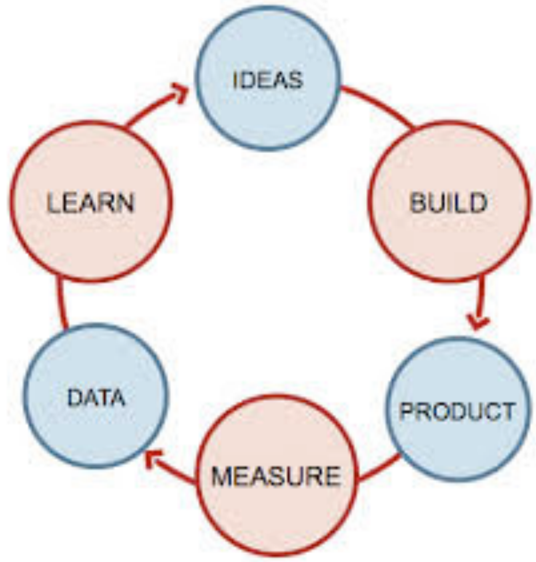

Figure 1. The quick Build-Measure-Learn feedback loop (Ries, 2011).

At the heart of Lean Thinking is a quick Build-Measure-Learn (BML) feedback loop (Figure 1), an ongoing collection of user data. Using the BML loop, developers start with an idea about how a feature might work and then quickly test it with users to see what happens. What sets Lean Thinking apart from traditional software development is the speed of this BML cycle. While a traditional software company rolls out a new version, beta tests, and then collects feedback data, Lean Thinking blasts through dozens of BML loops using a Minimal Viable Product (MVP), a product with only the features developers need to test (Ries, 2011). Often, MVP's are no more than screenshots, with users mimicking the pushing of buttons and telling an interviewer what they would be doing. No time is wasted in developing or building additional features. Through this mindset, developers are able to stay *lean* by focusing their energy on listening and responding to users as opposed to building what they predict a user will want to use.

Mathematics Teaching as Lean Thinking

A close reading of the research in mathematics education shows connections between Lean Thinking and current mathematics teacher education research. First, the research in how children learn mathematics emphasizes a three-step process: 1) Before, in which a teacher connects to a child's prior knowledge; 2) During, in which a student engages in a mathematical tasks; and 3) After, in which a teacher orchestrates a discussion of the strategies that students used to solve a task (Van de Walle, Lovin, Karp, & Bay-Williams, 2014). These three steps align with the Build-Measure-Learn loop. Just as Lean Thinking developers frame themselves as *building services for users* as opposed to *creating finished products*, mathematics education research frames teachers as *building mathematical thinkers* as opposed to *creating standardized memorizers*.

The Before/Build phase acknowledges what a child already knows mathematically in order to build mathematical tasks that connect to this prior knowledge. The During/Measure phase involves a child attempting their own strategies to solve these tasks while the teacher pays careful attention to listen to and notice how a child thinks. Finally, the After/Learn phase involves a teacher taking up children's thinking in order to respond to and orchestrate discussions for students to learn from one another. By being flexible to the many strategies and ideas that students bring up, a teacher can facilitate productive mathematical discussions and position him/herself as learning from the students.

Often, outsiders to education assume mathematics teachers facilitate classes using a dated "I do, we do, you do" approach (Hunter, 1982). But research in mathematics teaching has time and time again shown that an inquiry-based focus on eliciting and unpacking student thinking leads to greater mathematical understanding (Carpenter, Fennema, Franke, Levi, & Empson, 1999; Hiebert et al., 1997; National Research Council, 2001). Like Lean Thinking developers, teachers should not default to a single "right way" to solve a mathematical task, but listen to and extend students' created strategies in order to extend their own thinking. And just as traditional development techniques leads to a lot of wasted effort as developers build features that users will never actually use, research-based teaching practices asks teachers *not* to spend their energy creating lessons that "tell" students how to solve a task (which might be different than how a student conceptualizes the task), but to be flexible of the many ways children solve a task and to respond to this thinking appropriately (Carpenter et al., 1999; Jacobs et al., 2010; Smith & Stein, 2011). Therefore, Lean Thinking is not necessarily a new way of conceptualizing of mathematics teaching practice, but a way to connect research-based mathematics teacher practices with the vernacular of technology and development.

Discussion

We are aware of the challenges of such a marriage of fields, as well as reasons why this merging has been avoided in the past. First, educational technology is often purchased at a district level, a result of the top-down approach used in our nation's school systems. While the primary users of any educational tools are children and teachers, the decisions makers are often administrators. By using language that situates teachers as developers, our hope is for technology developers to see that educational technology must allow for teachers to experiment and learn from their students, something very similar to what they are doing as they build software. Additionally, by positioning teachers as developers, we hope to empower teachers to develop technology solutions for their own practice. We want development to start with the teacher, not the administrator.

Second, forcing children to serve as "beta testers" of an educational intervention traverses ethical boundaries, essentially experimenting unfinished products on real children. However, in our current educational system in which large scale assessments (e.g., PARCC and Smarter Balance) and federal-level standards (e.g., CCSS) are routinely implemented without prior testing, a Lean Thinking approach that focuses on small, quick interventions rather than large scale implementation causes much less harm for children's intellectual development.

In conclusion, we hope that by adapting language from software and technology development into our field, we can (1) help educational technology developers create products that align with research-based mathematics teaching practices and (2) empower mathematics teachers to see themselves as capable of developing and sharing their own technology products. The use of a Lean Thinking paradigm within mathematics education technology is not new, we are just connecting language from two field in the hopes that we can try to make something better together.

SCIENCE AND MATHEMATICS TEACHERS' PERCEPTIONS OF ONLINE COURSES

Kimberly A. Hicks
University of Houston
kahicks@uh.edu

Jennifer B. Chauvot
University of Houston
jchauvot@uh.edu

Historically, science and mathematics teacher educators' model best practices in face-to-face settings as a way to teach about learner-centered instruction. This presents a challenge for instructors of online settings. In order to move what is typically considered effective in face-to-face practices to an online model, it is essential for teacher educators to push their thinking about how they can model best practices in new and different ways and to study how teachers make sense of and translate what they learn to the K-12 face to face setting. This study examined science and mathematics teachers' perceptions of their learning in four online courses of an online graduate program that focused on the integration of science and mathematics in the middle grades. Findings validated the teaching practices that were in place or being developed in the teachers' own classrooms as well as the teachers' utilization of various teaching activities.

Keywords: Instructional Activities and Practices; Teacher Beliefs; Teacher Education-Inservice; Technology

Introduction

In the past decade, online education has quickly become a leading force in higher education due to the expanding role of technology and the increased access to the Internet (Bourne & Moore, 2004). With this increased growth, higher education faculty have found that building an effective course in an online environment is much more than just replicating their materials of a face-to-face course to an online setting. Providing effective course content online parallels face-to-face instruction in that considerations must include learner characteristics, course organization, and the preparation of the instructor. Also, moving to an online environment does not exempt the instructor from what is commonly accepted as effective teaching, such as understanding the learners' needs (Dick, Carey, & Carey, 2001).

A strategy for considering how to design effective online instruction is to be informed about learner perceptions in online environments. Existing research about learner's perceptions in online environments is on a myriad of topics that focuses mainly on how the learner understands theory about the online environment and/or how the learner interacts with various aspects of the online environment (Eom, Wen, & Ashill, 2006). What is missing from the literature are learners' perceptions in online environments *when the learner is a teacher*. Teachers as learners in online environments are unique because of the complexity of teaching teachers *about* teaching children, which is typically done in face-to-face environments. Adding to the complexity of teaching teachers in online environments is the specificity when the teachers are teachers of science or mathematics.

Purpose of the Study

The purpose of this study is to gain understanding of science and mathematics teachers' perceptions of online learning experiences over one year in an online graduate program that focused on the integration of science and mathematics in the middle grades. In this particular case, the teachers had taken four different courses over two semesters. Two courses were specific to mathematics education while the other two were specific to science education. Understanding and describing teachers' perceptions of their learning in various coursework is the first step to designing effective courses and creating meaningful learning environments for teachers of science and mathematics. Accordingly, there are two research questions for this study. First, how do science and mathematics teachers perceive online course experiences? Secondly, do science and mathematics teachers perceive their online learning experiences as transferrable to the face-to-face classroom?

Literature Review

There is a body of research (Moore & Kearsley, 2005) that focuses on how the learner interacts with their online environment. However, that research alone is not enough to understand the ultimate success of a learner because it is necessary to consider how the learner perceives their interaction within an online environment. Research studies in online learning have looked at various ways of producing effective and beneficial online class settings through: multiple types of assignments, asynchronous reflection and discussion boards, synchronous conversation, and the use of a variety of media tools (Lebaron & Miller, 2005). Armstrong (2011) & Lin (2011) looked at effective online class settings by studying the role of communication in online learning and found that students perceived their connection in an online class greater than a face-to-face class because they had to take ownership for their learning. Research is now beginning to emerge in the area of online professional development (OPD) programs for teachers (Carey, Kleiman, Russell, Venable, & Louie, 2008; Dash, de Kramer, O'Dwyer, Masters, & Russell, 2012; Dede, Breit, Ketelhut, McCloskey, & Whitehouse, 2006). In two particular studies focusing on mathematics teachers' education, results showed that teacher's perceived their learning as effective as traditional methods of professional development (Groth & Burgess, 2009; Groth, 2007).

Methodology and Context

This study took place within an online Master's of Education program called Integration of Science, Mathematics, and Reflective Teaching (iSMART) which is a two-year program for middle school science and mathematics teachers. [This program is generously funded through the Greater Texas Foundation (http://greatertexasfoundation.org/). The opinions expressed here are those of the author and do not necessarily reflect the views of the Greater Texas Foundation.] The program focuses on the integration of science and mathematics as a means of developing teachers' content knowledge, as well as developing the teachers' technological and leadership skills. The program emphasizes inquiry and reasoning, developing students' skills in becoming effective problem solvers and communicators of mathematical and scientific ideas, and creating learning environments in which the teacher is a facilitator of learning rather than a dispenser of knowledge (Graham & Fennell, 2001). Using reflective collaboration with on-line classmates, the iSMART program seeks to develop in-depth teacher content and pedagogical knowledge through activities of the program including: analyzing theories and models of integration of science and mathematics, analyzing and writing curriculum, studying children's thinking of content, and reflecting on video of own practices. Both asynchronous and synchronous formats are utilized in the program where the teachers meet online for three hours for class one week and then the next week has an asynchronous assignment that builds from the synchronous meeting or sets the stage for the next synchronous meeting.

To obtain the data a researcher-developed survey that combined information from published literature on both online learning and online professional development was given. The survey was constructed of Likert scale items where space for each item was provided for additional comments. The questions were addressing the teachers' perceptions of their online learning in various ways: comparing a methods versus a seminar course, how they viewed their participation within each course, collaboration with their colleagues in each of the four courses, each of the four course structures, the instructors' facilitation and presence, and the perceptions about the ability to transfer the course content. The survey was administered during a week-long face-to-face conference during the summer between the two academic years.

Once the surveys were completed, the surveys were collected and photocopied. The following day the surveys were then re-distributed to participants and they discussed their responses in small groups and were allowed to add to their responses accordingly. In order to best analyze both the Likert and free response data obtained, qualitative data analysis measures were employed. The open-ended responses of each question were coded using a constant comparative method, according to the categories of research significance, as supported by the literature (Merriam, 1998).

Results

A necessary component to understanding the complexity of teaching online graduate courses for middle grades science and mathematics teachers is to analyze the perceptions of the teachers that currently engaging in the coursework. During the coding process the following themes emerged: (a) the instructors' instructional practices, (b) community development within the courses (c) development of content & pedagogical knowledge & (d) ability to transfer knowledge to their own teaching practice.

The teachers emphasized that the format of the class impacted the learning process. Specifically when the structure was more direct instruction (or lecture format), as described by the teachers, less time in conversation occurred, and thus less community was developed which in turn impacted the learning process. In the other courses where the structure was focused on discussion-based, student-led activities, the teachers "enjoyed collaborating because the nature of the courses dealt with how to become stronger teachers/coaches." The teachers' also felt that they could share with colleagues who were in similar teaching situations that they may not otherwise have the opportunity to engage in because the instructors made the online environment a 'safe place' to discuss and aided in the understanding of curriculum they were currently teaching.

Several teachers felt that the coursework was challenging and that the design of the courses offered enough time to process the material in order to understand it as well as to make changes to their teaching practices. The teachers felt that the questioning strategies used by the instructors were highly beneficial to their own pedagogy in their classrooms. Additionally, there were teachers that felt that the way the instruction was structured and modeled assisted them in planning for instruction in their own classrooms.

Implications

Online learning has quickly become a means of delivering graduate education to teachers (Allen & Seaman, 2014). As this study shows, teachers perceive learning in an online setting as effective as a face-to-face class. Teachers are required to continue their professional learning even after they finish their graduate education. Many times this professional learning is place-based (off of the teacher's campus) and does not meet the content criteria they need. However, given the results of this study, that teachers' perceive their learning in an online setting as beneficial, then online professional development (OPD) could be an avenue for future research with teachers' of mathematics and science in the middle grades. Teachers could be in a community of practice while engaging in OPD at their home campus or district location. This type of OPD option for professional development as a venue for research is a new, barely explored, territory, particularly in the areas of science and mathematics education. The overall goal of any educational program, whether it is a graduate program or an OPD program, is to help teachers gain the technology skills and knowledge needed to improve their teaching practice. It is through these future studies that the refinement of teaching teachers about teaching mathematics and science in an online setting can occur.

This paper investigates middle school students' interactions while participating in learning activities in which they explored the connections between an arithmetic expression and the motion of a robot along a number line. Results indicate students utilized the technology to form conjectures, justify, and reflect on their experiments as they worked to interpret multiple meanings of the minus sign in the context of the robot's motion.

Keywords: Algebra and Algebraic Thinking; Number Concepts and Operations; Technology

Introduction

Technology-based learning environments can provide novel opportunities for students to build conceptual bridges between real-world phenomena and mathematical formalism. Often, these environments emphasize graphical representations of phenomena. Calculator Based Lab devices, for example, allow students to collect data about phenomena such as breathing patterns and to graph a function that fits that data (Doerr & Zangor, 2000). Motion detectors invite learners to directly experience the translation of physical motion into a graphical representation, and simulation environments can build the same bridge in reverse, allowing students to explore the ways that manipulating the graph of a position-versus-time function affects the motion of an animation (Roschelle, Kaput & Stroup, 2000).

In this paper, we explore a different approach, using the movement of physical robots as a context for students to explore the meaning of arithmetic expressions. We present results from a study in which the research team developed an iPod interface that allowed students to manipulate robot movement along a number line by inputting numbers and operations. Students' interactions with these tools and one another were examined through the framework of cycles of mathematical reasoning (Lehrer & Chazan, 1998) in order to investigate the ways enacting robot motion through mathematical expressions can support student learning.

Why Arithmetic Expressions: Importance and Challenges of Learning Signed Numbers

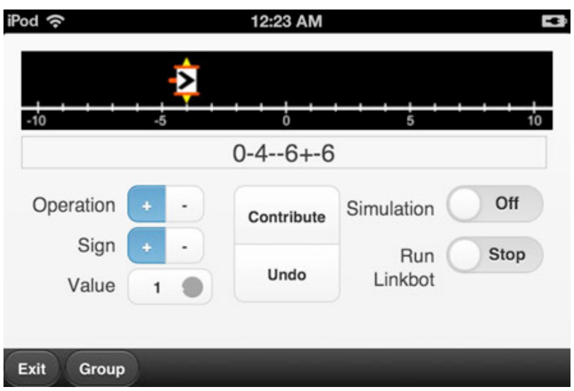
Signed numbers and operations are fundamental algebraic concepts, as the transition from arithmetic to algebra contributes to students' subsequent learning of more advanced mathematics (Vlassis, 2004; Lamb et al., 2012). However, the transition from arithmetic to algebra presents learners with complex cognitive challenges (Herscovics & Linchevski, 1994). Researchers suggest that the challenge of comprehending minus signs may reflect students' attempts to assimilate negative numbers with the characteristics of natural numbers (Vlassis, 2004). The minus sign can represent the *binary* operation of subtraction, as in the expression 5-3 = 2. The same minus sign, however, can also represent the *unary* operation of negation, as in the case of the integer -5 (Lamb et al., 2012). These varied uses of the same symbol may contribute to students' difficulty in grasping its mathematical meaning (Vlassis, 2004). However, understanding the multiple meanings of the minus sign, and developing the ability to flexibly shift among these different interpretations, are critical underpinnings of algebra learning.

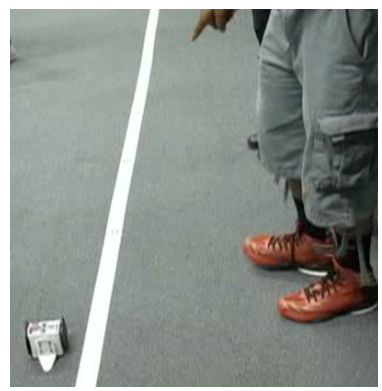
Research Design

We developed a graphical user interface for this study in order to enable students to interact more directly with mathematical representations. The robot moves along a number line in order to enact an arithmetic expression entered by one or more students through handheld devices. The robot behaviors and position are intended to model the mathematical expression in order to provide an accessible medium for students to explore its meaning.

In this activity, students in pairs used handheld devices (iPod touches) to jointly construct integer expressions by entering a series of operations and values into the devices through the graphical user interface (Figure 1). A number line was placed on the floor using velcro tape (Figure 2). After both students constructed and agreed on the inputted expression, the robot moved forward or backward depending upon the sign of the value, and turned around in place when it encountered a negative number. For example, 3+-4-2 indicates that the robot would move from position 3 backward for 4 units, then spin around and move forward towards a negative direction for 2 additional units. The backward motion enacted the *unary* interpretation of the minus sign, and the turning motion enacted the *binary* format of the minus sign. In situations where the previous experiment resulted in the robot facing the negative direction, the software made an adjustment accordingly.

The study took place in two semi-urban K-8 schools in northern California with approximately 130 7th and 8th grade students in six Algebra classes taught by two mathematics teachers. The activity was implemented for one week. Video and audio were recorded with cameras, and additional audio data was recorded from all participating students through the iPods. All student inputs from the iPod devices were captured through the computer server.





Figures 1 and 2: iPod interface and Robot with Number Line

Data Analysis

Analysis of these data was oriented toward three main research questions: 1) How do students understand arithmetic procedures in the context of robot motion? 2) How does using robot enactment of arithmetic expressions support students' understanding of integer and operation though motion metaphor? 3) How does the related robot behavior influence students' understanding of the minus sign's multiple meanings? The research team collected around 50 hours of video and 300 hours of audio of students' interactions with the handheld and robot tools. Next, we present an episode in which one pair of students demonstrated the potential opportunities for reasoning about signed numbers afforded by this learning environment.

Results: Reasoning about Binary and Unary Interpretations of the Negative Sign

In an early cycle of classroom activity with these tools, students were prompted by the teacher to freely explore the robot motions resulting from different expressions. After a few initial attempts to get familiar with the iPod interface and the robots, these two students jointly decided to search for a mathematics expression that would change the direction in which the robot faced by making it spin around 180 degrees. Table 1 provides the log record of the students' inputs in the iPod interface while completing this task.

Table 1. Record of students' inputs "make the robot spin"

Stage	Robot initial position	Student input		Expression
		Operation	Signed Number	
1	1	+	-6	1 + -6
2	-5	+	-7	-5 + -7 + 6
		+	6	
3	-6	-	6	-6 – 6 + 6
		+	6	
	-6	-	8	-6 – 8 + 4
		+	4	
4	-10	+	9	-10 + 9 + -9
		+	-9	
5	-10	-	5	-10 – 5 + 3
		+	3	
	-12	-	3	-12 – 3 + 2
		+	2	
	-13	-	4	-13 – 4 + 2
		+	2	

The episode started with the robot positioned at 1 and facing the positive direction. Student 1 suggested that they "Subtract. Make it a negative 6," then a moment later revised to "subtract 6." However, Student 2 followed the original suggestion, entering plus negative 6. At this stage the students were failing to distinguish between binary and unary meanings of the minus sign. In Stage 2, Student 2 reflected on the previous result and said "just add another, just add a positive, then it might spin." They entered the next expression, -5 + -7 + 6, and voiced optimism that they would "see if this works". The students' long sighs illustrated their disappointment at the unexpected resulting movement. In stage 3, the students then decided to attempt a subtraction with an addition, asserting "maybe we should do a negative and a positive" because "last time we used two positive." The students were now acknowledging that the minus sign has multiple meanings: after inputting -6 + -6, Student 1 asked "Plus a negative sign or is that the opposite? Should be minus a positive?" The two students decided to submit -6 – 6 + 6, and the robot spun. However, Student 1 voiced lingering confusion, stating "But I don't know why it spun." Students then experimented with the expression -6 – 8 + 4 to confirm their prediction. Next, in stage 4, despite Student 1's proposal to "put random stuff in," the fact that the signs and operations of the inputted expression -10 + 9 + -9 were all reversed from the previous attempt suggests this student may in fact have been testing the impact of these variations on the robot's behavior. The robot moved and failed to spin in this experiment. Stage 5 began with the students returning to their previous assumption from stage 3. While seeking ways to trigger the robot behavior of spinning, Student 2 concluded after attempted few more experiments that "so all it is is the negative, the operation" and "so it will have to be the operation instead of the sign".

Discussion

The episode offers evidence of examples where students identified the unique behavior of the robot changing direction as representing the binary meaning of the minus sign, which reveals her discovery that different meanings of the same symbol produced distinctive robot movements. Although this student demonstrated her acknowledgement of the relationship between robot movement and various meanings of the minus sign, the group also drew incorrect inferences. For example, these students had mostly chosen to submit two additional terms, when in fact users only need to input one mathematical term for the robot to spin. We suspect that this may be an artifact of students working in pairs, as each felt the need to each contribute a term.

The environment offered the opportunity to observe the robot motion as a direct enactment of the mathematical expression constructed by students. The activity and technology design provided the appropriate context for students to develop understanding through the cycle of mathematical reasoning (Lehrer & Chazan, 1998), offering learners a tool with which to form conjectures, justify, and reflect on the experiment result, and develop new experimentation to refine their conjectures. Frequent comments such as "Let's try it. Let's see what happens" suggest that students saw their mistakes not as errors, but as necessary elements of their process of exploration. Furthermore, students often justified and reflected on the result of each experiment, as illustrated through student statements such as "What did we do last time?" This experimental cycle repeatedly occurred within a single episode, resulting in students voicing comments such as, "this was actually easy, all it took was experimenting."

Conclusion

The analysis of this episode has enabled the authors to describe students' interactions when offered the opportunity to manipulate robot movement by inputting symbolic expressions. Students used these tools to experiment with signed numbers, using feedback from the technology to confirm or deny their hypothesis, and build up empirical evidence for interpreting the result of their conjecture. Our data demonstrate directly exploring the relationships between arithmetic expressions and robot motion allowed students to treat the environment as an exploratory setting to develop their mathematical reasoning through investigation.

This study examines how prospective teachers in Korea and the U.S. demonstrate Technological Pedagogical Content Knowledge (TPACK) and respond to new technology in mathematics learning. Overall, preliminary findings show that U.S. prospective teachers scored higher in most domains of TPACK than Korean participants. Korean participants demonstrated lower self-efficacy in Pedagogy Knowledge (PK) and Pedagogical Content Knowledge (PCK) when compared to U.S. participants. There were noticeable differences in the ways they evaluated technology and the ways in which they use new technology in instruction.

Keywords: Technology; Teacher Education-Preservice; Teacher Knowledge; Teacher Beliefs

A variety of approaches helpful in guiding teachers in implementing technology in mathematics classrooms have been developed (Kinuthia, Brantley-Dias, & Junor-Clarke, 2010; Polly, 2011). However, the ever-changing nature of technology demands a continued examination of the ways teachers develop successful technology-integrated practices. Researchers have considered a number of areas including teacher knowledge of technology, related pedagogical strategies, and the level of support available for teachers to implement technology in classrooms – we still need more detailed work that describes specific ways that teachers in different cultural and education settings *respond* to new technology and provides insight into effectively guiding teachers to implement appropriate use of technology in classrooms.

Purpose of the Study

The purpose of this study is to examine the ways teachers respond to new technology (e.g. equation solving apps) and how their perceptions of the technology may impact instruction.

While exploring various teacher responses toward new technology, we looked at two groups of prospective teachers in Korea and the U.S. Research questions guiding our study included (1) How do prospective teachers orient their instruction in response to the perceived benefits or hindrances of technology in mathematics instruction? (2) To what degree were prospective teachers in Korea and U.S. similar or dissimilar with regard to ways to respond to new technology?

Perspectives

Research on barriers and challenges affecting technology integration as well as strategies to overcome them have long been studied (Hew & Brush, 2007). Our frameworks include TPACK (Mishra & Koehler, 2006), the role of technology in the learning of mathematics (Goos, Galbraith, Renshaw, & Geiger, 2003), and psychological perspectives associated with teacher knowledge and beliefs, including its impact on teacher change (Ertmer & Ottenbreit-Leftwich, 2010). TPACK and other literature regarding the process of using technology in mathematics classrooms enabled us to conceptualize how teachers perceive the affordances and constraints of technology. Teacher knowledge, as well as attitudes and beliefs (Howard, Chan, & Caputi, 2014) are key attributes that influence teachers' decisions in the classroom. Therefore, understanding these attributes in light of educational technology may provide better insight into how teachers are likely to use technology in their classrooms in the future (Wachira & Keengwe, 2011). With this perspective, we are better able to understand technology integration as participants describe their belief systems about the learning of mathematics and teacher change after experiencing new technology.

Methods

The study setting included two teacher preparation programs in Korea and the U.S. Both programs offer middle grade mathematics education coursework. The program in the U.S. was at a large state university in a southeastern state in the U.S., while the other program was at a mid- sized, private university in a southern city of Korea. The participants included 18 U.S. prospective middle school mathematics teachers (15 female and 3 male) enrolled in a mathematics methods course prior to the semester of full-time student teaching experience in local school districts, and 22 Korean prospective middle school mathematics teachers (15 female and 7 male) enrolled in a mathematics education seminar course prior to student teaching.

The design of the study included three distinct stages: (1) collecting base-line data of belief, skills, and attitudes, (2) providing interventions to experience new technology, and (3) collecting data to document participant perceptions and changes. In the first stage, researchers conducted a survey titled "Survey of Preservice Teachers' Knowledge of Teaching and technology,"(Schmidt, et al. 2009). This survey included 28 Likert items with a scale from 1 (strongly disagree) to 5 (strongly agree), and provided data indicating the level of TPACK demonstrated by the participants. In the second stage, researchers introduced new technology in three separate 30- minute instructional sessions. Each session included a demonstration of PhotoMath, yHomework, and TI-83/84 linear regression demo. PhotoMath is a free app that solves math problems (mostly equations) through smartphone cameras; yHomework is a Math solver app that provides worked-out solutions when equations are entered. The TI-83/84 demo uses the linear regression equation to calculate the slope and the y-intercept of the line containing two points instead of multiple scattered points. Lastly, the third stage included conducting a survey with open response items (see Table 1).

Table 1: Six Open Questions in Our Response Survey

1. Describe perceived benefits of each technology.
2. Describe perceived hindrance of each technology.
3. Describe ways you would use each technology in instruction.
4. Describe situations when students should or shouldn't use each technology.
5. Describe your ideal practice of teaching with technology and how your students engage in the learning of mathematics with technology.
6. Describe ways you want to integrate technology in your instruction (e.g., learning tasks, collaborative projects, homework, assignments) in response to the emerging technology.

The analysis included calculating the mean scores for each student in the TPACK domains. Then we used open-coding on the response survey data to identify patterns related to benefits and hindrance, describing how participants' knowledge, beliefs, and attitudes impact their instruction by comparing the level of TPACK and participants' perceptions of new technology. We first conducted the analysis for the U.S. and Korean participants. Then we looked for any emerging patterns with regard to the participants' beliefs and attitudes, as well as the interaction between TPACK and responses to new technology.

Results

Our preliminary findings include the mean scores for TPACK by group. The response survey also yielded some findings about participants' perceptions of the three technology's affordances and constraints (see Table 2). The table below shows representative comments after the participants experienced each app.

Table 2: Most Common Responses about New Technology

	PhotoMath	yHomework	TI-83/84 "Linear Regression"
Perceived benefits of each technology	• Effective tool for autonomous learning (Korea; 82%) • Easy access to solutions (US; 61%)	• Effective tool for autonomous learning (Korea; 86%) • Display of detailed steps (US; 83%)	• No benefits (Korea; 59%) • Experiencing technology in mathematics (US; 56%)
Perceived hindrance of each technology	• Limitations including errors in producing correct answers (Korea; 64%) • Student cheating (US; 83%)	• Not available for free (Korea; 59%) • Decrease student motivation (US; 61%)	• Prevents opportunity to reason (Korea; 86%) • Too many steps before finding the solution (US; 50%)
How to use each technology in instruction	• Checking answers for practice problems (Korea; 68%) • Not to be used (US; 66%)	• Checking answers for practice problems (Korea; 86%) • Not to be used (US; 61%)	• Illustrating a case of linear regression (Korea; 55%) • Use it for writing linear equations (US; 77%)
Situations when students should or shouldn't use each technology	• Use it for getting help with procedural homework problems (Korea; 45%) • Do not use it at all (US; 72%)	• Use it for identifying mistakes in test corrections (Korea; 45%) • Use it during homework w/ adult supervision (US; 33%)	• Do not use if possible (Korea; 82%) • Use it for prepping standardized tests (US; 72%)

With regard to the degree of which the level of TPACK relates to (1) the ways participants describe an ideal integration of technology in instruction and (2) the ways the new technology influences their instruction, Table 3 shows the themes found among those with high TPACK scores and those with a low TPACK scores.

Table 3: Descriptions of Integration of Technology in Instruction

	Korean Participants	U.S. Participants
Those with higher TPACK score (4 points or above)	• Use technology to enhance mathematical understanding • Use the new technology selectively for those who struggle with procedural problems. • Design assignments which the technology cannot solve	• Use technology to improve problem solving skills • Use the new technology to check answers and find mistakes. • Avoid using the technology in class.
Those with lower TPACK score (2 points or below)	• Use technology to produce accurate solutions • Use the new technology to finish homework assignment	• Use technology to engage students in learning • Not to use the new technology

Discussion

The new technology in the study focused on solving equations and providing worked-out solutions for students. Since the apps solve mostly procedural problems—especially single variable equations—those valuing the teaching of procedures may have felt "threatened" by the emerging technology. It is not surprising that most prospective teachers whose school mathematics experiences were predominantly procedural mathematics would express concerns about students using the new technology mentioned in the study. However, participants expressed conflicting levels of resistance towards the technology depending upon the apps' mathematical capacities. For example, 72% of U.S. participants reported they would not allow students to use PhotoMath, but the same participants said they would encourage students to use yHomework at home if adults are present – we note that yHomework has more capabilities in detailing procedural steps. Also interesting is how most Korean participants considered the apps as similar to calculators and indicated that such apps are limited in their capacity to solve complex mathematics problems.

There was a variety of differences in how the two groups responded to the surveys and evaluated the technologies. First, Korean participants demonstrated lower self-efficacy scores for TPACK than U.S. participants. The cultural differences in expressing self-efficacy may explain this phenomenon (Ertmer & Ottenbreit-Leftwich, 2010). Most Korean participants felt negatively about abusing the linear regression feature of TI calculators; however, U.S. participants were more positive in their view of how such a function of the calculator may improve performance

on standardized tests. Those who had higher TPACK scores also differed between the two countries. Korean participants supported the use of technology to enhance mathematical understanding, while U.S. participants emphasized the potential of technology in serving as a tool for problem solving.

A further analysis of the data including a future study with a large group of participants is in order. We need more detailed work about the persistent patterns underlying prospective teachers' beliefs and skills related to technology integration, and developing ways to increase their abilities in successfully integrating technology in the classroom.

PROMOTING PRODUCTIVE MATHEMATICAL DISCOURSE: TASKS IN COLLABORATIVE DIGITAL ENVIRONMENTS

Arthur B. Powell
Rutgers University-Newark
powellab@andromeda.rutgers.edu

Muteb M. Alqahtani
Rutgers University-New Brunswick
muteb.alqahtani@gse.rutgers.edu

Tasks can be vehicles for productive mathematical discussions. How to support such discourse in collaborative digital environments is the focus of our theorization and empirical examination of task design that emerges from a larger research project. We present our task design principles that developed through an iterative research design for a project that involves secondary teachers in online courses to learn discursively dynamic geometry by collaborating on construction and problem-solving tasks in a cyber learning environment. In this study, we discuss a task and the collaborative work of a team of teachers to illustrate relationships between the task design and productive mathematical discourse. Implications suggest further investigations into interactions between characteristics of task design and learners mathematical activity.

Keywords: Technology; Geometry; Teacher Education-Inservice; Classroom Discourse

Mathematical tasks are central as they convey what mathematics is and what it means to do mathematics. Sierpinska's (2004) considers that "the design, analysis, and empirical testing of mathematical tasks, whether for purposes of research or teaching, is one of the most important responsibilities of mathematics education" (p. 10).Mathematical tasks shape significantly what learners learn and structure their classroom discourse (Hiebert & Wearne, 1993).Such discussions when productive involve essential mathematical actions and ideas such as representations, procedures, relations, patterns, invariants, conjectures, counterexamples, and justifications and proofs about objects and relations among them. Nowadays, these mathematical objects and relations can be conveniently and powerfully represented in digital environments, and many contain functionality for collaboration. However, for such collaborative, digital environments, the design of tasks that promote productive mathematical discussions is an enduring challenge and requires continued theorization and empirical examination (Margolinas, 2013). In this brief research report, guided by the question—What features of tasks support productive mathematical discourse in collaborative, digital environments?—we articulate theoretical and practical principles for designing such tasks for small teams of individuals working in online, collaborative environments.

Our work employs a specific online environment that supports synchronous collaboration and discussions and provides tools for creating graphical and semiotic objects for doing mathematics. The environment, Virtual Math Teams (VMTwG), has a multiuser version of a dynamic geometry environment, GeoGebra. Here, we first indicate our task design to promote potentially productive mathematical discourse among small groups of learners working in VMTwG. Afterward, we present an example of a task along with the mathematical insights a small team of teachers developed discursively as they engaged with it. We conclude with implications and suggestions areas for further research.

Task-Design Principles

Our principles of task design embody particular intentionalities for a virtual synchronous, collaborative environment that has representation infrastructures (GeoGebra) and communication infrastructures (social network and chat features). The intentions are for mathematical tasks to be vehicles "to stimulate creativity, to encourage collaboration and to study learners' untutored, emergent ideas" (Powell et al., 2009, p. 167) and to be sequenced so as to influence the co-emergence of learners instrumentation and building of mathematical ideas. To these ends, sensitive to the infrastructural features of VMTwG, we developed and tested the following seven design principles for digital tasks that are intended to promote productive mathematical discourse by encouraging collaboration in such environments:

- Provide a pre-constructed figure, instructions for constructing a figure, or invitation to construct a figure with particular properties.
- Invite participants to interact with a figure by looking at and dragging objects to notice how the objects behave, relations among objects, and relations among relations.
- Invite participants to reflect on the mathematical meaning of what they notice.
- Invite participants to wonder or raise questions about their noticings and meanings.
- Pose suggestions as hints or new challenges that prompt participants to notice particular objects, attributes, or relationships.
- Provide formal mathematical language that corresponds to awarenesses that they are likely to have explored and discussed or otherwise realized (Hewitt, 1999, 2001).
- Respond with feedback based on participants' work that pose new situations as challenges that extend what participants noticed, wondered, or constructed; invite participants to revisit a task, to generalize noted relationships and to construct justifications and proofs of conjectures; suggest that participants consider the attributes of a situation (theorem, figure, actions such as drag) in order to generate a "what if?" question and explore it.

The hints aim to maintain learners' engagement with a task and the challenges to encourage them to extend what they know. The hints support participants' discourse by eliciting from them statements that reveal what they observe and what mathematical sense or meanings they make of their observations. The challenges provide new, related situations to investigate. Hidden initially, the hints and challenges can be revealed by learners clicking a check box.

These design principals guided how we developed tasks in our research project, a collaboration among investigators at Rutgers University and Drexel University. VMTwG records users' chat postings and GeoGebra actions. The project participants are middle and high school teachers in New Jersey who have little to no experience with dynamic geometry environments and no experience collaborating in a virtual environment to discuss and resolve mathematics problems. The teachers took part in a semester-long professional development course. They met for 28 two-hour synchronous sessions in VMTwG and worked collaboratively on 55 tasks. In the next section, we provide examples of two tasks to illustrate the actualization of our task design.

Task Example and Analysis

Based on our design principles, we developed dynamic-geometry tasks that encourage interlocutors of a team to discuss and collaboratively manipulate and construct dynamic-geometry objects, notice dependencies and other relations among the objects, discuss meanings and wonderings associated to their noticings.

During a collaborative session, a team of three teachers worked on identifying the dependencies involved in the constructions of different triangles (see Figure 1). The team dragged the triangles vigorously to explore dependencies among objects in the task. The vertices of first triangle, ABC, were constructed as independent objects, so the team did not belabor discussing it. The second figure is an isosceles triangle DEF. The lengths of DE and DF are equal. Point F is constrained to a hidden circle with radius DE. Points D and E are independent objects. In the following excerpt, concerning the second figure the Team discusses their noticings and the meaning they derive from them:

Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

386 ceder: so in the second one, f is dependent on g
387 ceder: I mean d

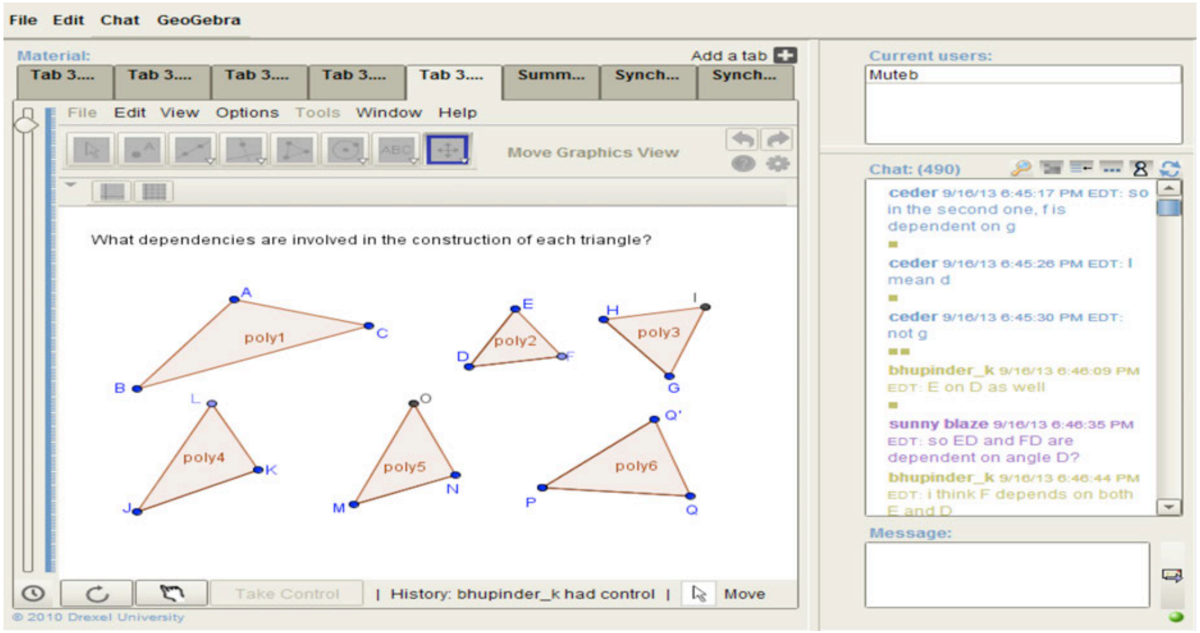

Figure 1: Dynamically examining dependences among different triangles

388 ceder: not g
389 bhupinder_k: E on D as well
390 sunny blaze: so ED and FD are dependent on angle D?
391 bhupinder_k: i think F depends on both E and D
392 ceder: f doesnt look dependent on anything now...am I imissing something?
393 ceder: ok, what am I missing? F can move independently, but when E is moved, F moves, so that makes which one dependent?
394 bhupinder_k: when you move F, ED stays fixed
395 ceder: right, so F is free to move anywhere
396 ceder: but not when E is moved
397 ceder so F is sometimes dependent?

The team discusses dependencies among points, segments and angles. In lines 386 to 388, ceder states that F is dependent on D then dismisses her assertion in line 392. In line 390, sunny blaze asks whether the two line segments are dependent on angle D. Though, week before, the team had already seen and constructed dependent objects, they struggled with this new, more complex situation. The idea of dependency is key and permits interlocutors to identify and build relationships in dynamic constructions. In a latter task, the team uses the concept of dependency to identify relations among objects. The task presents two circles constructed using the same radius, AB, where each endpoint is a center of a circle. Their points of intersections, C and D, were connected to create a perpendicular bisector to radius AB that intersects it at point E. In the session, one teacher states that points C, D, and E are dependent on A and B. Another teacher states that the two circles share the same radius and that dragging the center of one circle affects the size of the other, which makes the circles dependent on the centers. The teachers appropriate the idea of dependency and use it to understand components of the task's constructions.

In these two tasks, the teachers attended to the co-active feedback of the environment to their actions, which enabled them to appropriate the concept of dependency. For the team of teachers, engaging with tasks where dependencies are key relations among geometrical objects was an important step. These tasks triggered a discussion about how to use dependency to create valid geometric constructions.

Discussion and Conclusion

Our focus was to describe how we address task design challenges to promote productive mathematical discourse in an online synchronous environment. In the virtual environment, a teacher or facilitator is present largely as an artifact of the environment's digital tools and most specifically in the structure and content of tasks. An important feature of our task design are principles 2 to 4 since when collaborating interlocutors respond to those prompts they generate propositional statements that can become the focus of their discussions. Their discussions are mathematically productive as their noticings, statements of meaning, and wonderings involve interpretations, procedures, patterns, invariants, conjectures, counterexamples, and justifications about objects, relations among objects, and dynamics linking relations.

Our task-design principles aim to engage interlocutors in productive mathematical activity by inviting them to explore figures, notice properties, reflect on relations and meanings, and wonder about related mathematical ideas. The design provides support through hints and feedback to help learners with certain parts of the tasks. The tasks also include challenges that ask the participants to investigate certain ideas and extend their knowledge. Further investigation is needed to understand how the task-design elements, the affordances of collaborative digital environments, and learners' mathematical discourse interact to shape the development of learners' mathematical activity and understanding.

EXPLORING THE ENDURING GAP BETWEEN UNDERGRADUATE MATH AND PROFESSIONAL PRACTICE: THE CASE OF COMPUTER PROGRAMMING

Laura Broley
Université de Montréal
broleyl@dms.umontreal.ca

Keywords: Instructional Activities and Practices; Technology; Post-Secondary Education

Several mathematicians and researchers in math education have reported on the disconnection between post-secondary math education and the practices of professional mathematicians. A recent quantitative survey of 302 Canadian mathematicians points to one possible aspect of the gap: while 43% of the participants reported using computer programming in their research, only 18% indicated that they use such technology in their teaching (Buteau et al., 2014). The first statistic highlights the potential that programming may have for doing and learning math. The second inspires the need for further research: why would such a gap exist?

In response to this question, we put forth a qualitative study aimed at exploring the place, role, potential, and constraints of programming in both mathematics research and undergraduate mathematics education. Semi-directed interviews were carried out with 14 mathematicians working within various different mathematical subfields at universities across Canada. The participants were chosen in such a way that they had all used programming in their research or their teaching (or both). They were asked to speak about their own experiences with computer programming, as well as the programming experiences (if any) they provide for their students.

A qualitative analysis of our interviews allowed us to unveil some of the powerful ways in which both applied and pure mathematicians employ programming to accomplish a variety of tasks (e.g., modelling complex phenomena to solve real-world problems, performing calculations and simulations not possible by hand, doing so-called "experimental" mathematics, constructing proofs, developing powerful technological tools). Consequently, it also enabled us to describe the extent of the qualitative gap between how these mathematicians use programming and how this activity is experienced by their students. In the end, the interviewees draw attention to some crucial issues regarding the time required to develop and implement enriching programming activities, the resources available to professors and students in Canadian universities, and the structure and content of undergraduate mathematics programs. Our participants also shared their perceptions of the goals of undergraduate mathematics education, the nature and culture of mathematics departments, and the traditions in the research, teaching, and learning of mathematics. We suggest that some of these visions, traditions, and constraints, which limit the mathematical experience of an undergraduate student, could warrant re-examination.

POSING PURPOSEFUL QUESTIONS: AN APPROXIMATION OF PRACTICE USING LESSONSKETCH

Elizabeth Fleming
University of Maryland

Keywords: Technology, Teacher Education-Preservice, Classroom Discourse

An enduring challenge facing teacher educators is creating opportunities to support teacher candidates in enacting mathematics teaching practices, while attempting to manage the complexities of teaching (Darling-Hammond, Hammerness, Grossman, Rust, & Shulman, 2005). One response to this challenge has been to introduce technology as a tool for incorporating representations of classroom instruction. Teacher candidates can then engage with these representations in meaningful ways that serve as *approximations of practice* (Grossman, Compton, Igra, Ronfeldt, Shahan, & Williamson, 2009).

This research explored 12 teacher candidates' (TCs') responses to a representation of student work in a LessonSketch experience. LessonSketch is an online platform that allows users to explore cartoon teaching scenarios. The goal of this LessonSketch experience was to provide TCs with an opportunity to practice posing purposeful questions that both assess and advance students' mathematical thinking. Using the LessonSketch environment to represent practice allowed the teacher educator to manage some of the complexities of teaching, while still providing the TCs with an opportunity to practice responding in the moment (Herbst, Chazan, Chen, Chieu, & Weiss, 2011).

This poster presents the results from an experience called the Pizza Dough Problem. TCs were first asked to solve the following problem: If pizza dough doubles every five minutes and reaches its maximum volume in thirty minutes, how many minutes does it take for the pizza to reach half its maximum volume? After working on this problem individually and then sharing in small groups, TCs were asked to anticipate potential student solutions and errors. TCs then participated in the LessonSketch experience, in which they were shown three comics depicting both correct and incorrect work from student groups and asked to respond to each group with a question that would further assess students' thinking or develop students' understanding. TCs first wrote questions on their own, and then discussed with a partner and revised their questions.

Preliminary findings show that TCs' questions tended to focus on *assessing* student thinking in response to the first depiction of an incorrect use of proportions and on *advancing* mathematical thinking (e.g., changing parameters) in response to the second depiction where students correctly worked backwards. Further analysis will explore the form, content, and purpose of the questions posed.

HIGH SCHOOL STUDENTS' USES OF DRAGGING FOR EXAMINING GEOMETRIC REPRESENTATIONS OF FUNCTIONS

Karen F. Hollebrands
North Carolina State University
kfholleb@ncsu.edu

Allison McCulloch
North Carolina State University
awmccull@ncsu.edu

Kayla Chandler
North Carolina State University
kcchand2@ncsu.edu

Keywords: Technology; Geometry; Algebra and Algebraic Thinking

The goal of this study was to investigate seven students' uses of dragging in GSP as they engaged in a sequence of technological activities that utilized a geometric approach to function. Students were paired or grouped so that students with similar backgrounds worked together using paper and pencil and a shared laptop computer. Data collected from the first activity, "Identify Functions," developed by Steketee and Scher (2011) were analyzed. The ways different types of dragging were related to students' thinking about particular aspects of function such as, domain, range, covariation, multiple representations, function notation, invariances, and families of functions, were examined (e.g., Carlson, 1998).

Analysis of students' work revealed two new dragging modalities: dragging a non-draggable point and variable speed dragging. Dragging a non-draggable point is specific to the way in which the activity was created. The instructor made a choice to design the activity with the non-selectable feature to emphasize and connect the action of not being able to select with the idea of independent and dependent variables. It was clear from the work of the students that their use of trying to drag a non-draggable point assisted them in making the association between this dragging type and independent/dependent variables.

Students also used other types of dragging to focus on particular aspects of function. For example, a new type of dragging, variable speed dragging, was used by students to focus on rates of change and co-variation. It was also used, often in conjunction with other representations, when students wanted to provide a more detailed explanation of the relationship between two points. The drag test was also used by some of the students to describe relationship between two points and when students wanted to investigate invariants.

The mathematical backgrounds of the students influenced how students discussed function behavior. In particular a pair of Algebra I students focused on different behaviors, but did not draw on their knowledge of function families or geometric transformations to describe those behaviors. Honors Geometry and Algebra 2 students used the language of geometric transformations and linear functions to describe the behaviors they noticed. Honors Pre-Calculus students drew upon a large repertoire of functions families and function language to notice and describe the behaviors they noticed. These understandings likely influenced the methods of dragging students used and the aspects of function to which they attended. Understanding how students use features of dynamic geometry activities and relationships of these uses to their understandings and aspects of mathematics to which they attend can be useful to designers of instructional materials.

GETTING FROM HERE TO THERE: EFFECTS OF AN ALGEBRA READINESS INTERVENTION

Erin Ottmar
Worcester Polytechnic Institute
erottmar@wpi.edu

David Landy
Indiana University
dlandy@indiana.edu

Erik Weitnauer
Indiana University
eweitnau@indiana.edu

Keywords: Algebra and Algebraic Thinking; Technology; Number Concepts and Operations; Middle School Education

Mastering basic algebraic concepts is extremely challenging, and many students never achieve adequate levels of proficiency. Although math instruction often emphasizes memorization of abstract rules, being able to fluently construct, interpret, and manipulate algebraic symbols involves the use of appropriate perceptual processes to *see* expressions and equations as structured objects (Kirshner, 1989; Goldstone, Landy, & Son, 2010). Learning technologies that focus on perceptual-motor training have shown substantial promise (Ottmar, Landy, & Goldstone, 2012), but are underexplored relative to other math interventions.

In this study, we present preliminary findings from a classroom study using *From Here to There (FH2T),* a dynamic computer-based visualization method designed to enhance students' understanding of algebraic notation through building appropriate perceptual strategies. *FH2T* uses discovery-based puzzles to learn mathematical patterns and think more flexibly about numbers and operations. The students' goal is to transform an expression from the starting form (*here*) to the ending form (*there*). Students perform a series of dynamic interactions, including decomposing numbers, combining terms, applying operations to both sides of an equation, and rearranging terms through commutative, associative, and distributive properties.

85 7th grade students participated in a 3-hour study over 6 class periods. This study compares learning gains from 2 dynamic versions of *FH2T* (fluid verses retrieval practice) compared to a control group and explores plausible mechanisms of this learning. Students in the fluid visualizations condition performed 0.20 SD higher than students in both the retrieval practice and control conditions. Next, a significant main effect was found for exposure: for every additional world completed, posttest accuracy scores increased by 0.76 problems (effect size=0.48). Third, a significant interaction between exposure and pre-test scores was found.

Only students who used the more fluid version of *FH2T* demonstrated strong learning gains. These gains seem to be primarily due to practice; however, we cannot tease apart whether this is due to a difference between retrieving explicit rules and perceptual training afforded by the fluid instantiation, or the increased exposure to content that the fluid group received. Future studies should be designed to address these concerns. Overall, these results suggest promise for tablet-based technologies for teaching algebraic content and support that algebra literacy encompasses strong visual-motor routines. Interventions involving the movement of symbolic forms for algebra learning have been receiving widespread attention in recent years; however, this work represents some of the first published outcomes from such perceptual interventions.

LATTICE LAND: A MATH MICROWORLD FOR CLASSROOM INQUIRY

Yu (Christina) Pei
Northwestern University
cpei@u.northwestern.edu

Keywords: Advanced Mathematical Thinking; Technology; Geometry; Problem Solving

Based on the constructionist principles of Seymour Papert (1980) and the largely unexplored universe of lattice geometry (Sally & Sally, 2011), *Lattice Land* was designed to be a "restructuration" of the geometry curriculum (Wilensky & Papert, 2010). *Lattice Land* is a colorful, interactive, and mathematically rigorous computer environment for students to discover advanced mathematical thinking through play, conjecture, and experimentation. Unlike most mathematics software, there are no built-in solutions to any set of problems, or any linear pathways a student must take. Together with an inquiry-based curriculum, students at any level of fluency with mathematics will uncover many interesting and mathematically profound results.

This poster introduces some potential explorations in *Lattice Land*: "taxicab" geometry, area optimization, dissection and triangulation, Pick's Theorem, and extensions such as polyomino packing. It is a low threshold, high ceiling exploratory software, a "microworld" (Edwards, 1995) that encourages mathematical discovery and developing *powerful ideas* (Papert, 1980). Even seemingly trivial exercises quickly gain complexity.

For children, *Lattice Land* provides an escape from procedural mathematics. The software backgrounds much of the calculation requirements that often prolong the discovery of more powerful ideas. For more experienced students, the study of lattice geometry shows how familiar mathematic concepts can be constructed and derived in unexpected ways. While users will find that polygon constructions and their properties—distance, perimeter, area—are the same, the derivation of these formulas is tangential to the greater learning goal of being able to reconceptualize mathematics. Additionally, because lattice geometry is unfamiliar to both young mathematicians-to-be and adults trained in traditional school mathematics, *Lattice Land* is an interesting microworld for families to visit together.

Coded in NetLogo (Wilensky, 1999), each model within the *Lattice Land* software suite emphasizes a facet of lattice mathematics. The virtual environment is particularly conducive to exploring abstract mathematics, as it is easy to manipulate and change on the fly. *Lattice Land* is purposely unlike canonical mathematics. As "restructurations" go, *Lattice Land* maintains the cognitive properties of Euclidean geometries, but uses a more approachable platform, backgrounds procedural calculations, and provides a low threshold and playful environment (Wilensky & Papert, 2010). Citizens of *Lattice Land* should also traverse microworlds, and learn how each is deeply connected with the others. I hope this leads the citizens of *Lattice Land* to recognize that mathematics is imbedded in other worlds, as well. Perhaps, even in our own.

SECONDARY MATHEMATICS TEACHERS' CRITERIA FOR EVALUATING TECHNOLOGICAL TOOLS

Ryan C. Smith
University of Georgia
smithryc@uga.edu

Dongjo Shin
University of Georgia
dongjo@uga.edu

Somin Kim
University of Georgia
somin84@uga.edu

Keywords: Technology; Teacher Education-Preservice

As technology is an essential tool for learning mathematics in the 21st century (NCTM, 2014) and is becoming more ubiquitous in the classroom, mathematics teachers need to be able to select quality technological tools to use with their students. The question that guided our study: What criteria do secondary prospective and in-service teachers use and value most when evaluating technological tools to teach geometry, specifically the triangle inequality theorem?

Our participants were 15 prospective and in-service teachers enrolled in a mathematics education course focused on technology. We placed our participants in 5 groups based on the amount and level of teaching experience and their technology background. During one class meeting, each trio developed a list of criteria, analyzed and evaluated four online applets designed to help students learn the triangle inequality theorem. Then, we conducted a stimulated-recall interview during which each group was asked to rank their list of criteria in order of importance. We video-recorded each group's working during the class activity and interview. After we created transcripts, we coded each group's criteria according to Dick's (2008) descriptions of Pedagogical, Mathematical, and Cognitive fidelities. Some of the groups' criteria did not fit Dick's descriptions and we created two additional codes: Scaffolding and Assistance.

All groups developed criteria coded as Mathematical fidelity, how the technology represents mathematics, and Pedagogical fidelity, how the students interact with the technology. But, none of their criteria was coded as Cognitive fidelity. That is, they do not seem to consider how students will think using the technology or how the technology will reflect how students are thinking about the mathematics. We did notice some difference between the criteria created by teachers with and without teaching experience. The groups of participants with no teaching experience created criteria coded as Assistance, whether the tool provides instructions on how to use it. The groups with teaching experience did not create Assistance criteria. Rather, they focused on whether technology could help students develop an understanding of the content. They created Scaffolding criteria and ranked it as the most important criteria. The groups with no teaching experience ranked criteria coded as Mathematical fidelity very high, whereas the groups with teaching experience ranked other types of criteria higher (i.e. Scaffolding) because they thought that mathematical ideas were innate in the higher ranked criteria.

Even though all groups considered whether mathematics is accurately represented and how students will interact with technology, they did not seem to consider how students think when using technology. By not taking this into account, teachers may not select the best tools for their students. Thus, mathematics teacher educators need to help teachers develop their abilities to examine technologies based on student thinking.

DIGITAL RESOURCES IN MATHEMATICS: TEACHERS' CONCEPTIONS AND NOTICING

Eryn M. Stehr
Michigan State University
stehrery@msu.edu

Keywords: Technology; Teacher Education-Inservice

Mathematics education researchers have explored ways in which teachers construct or supplement their mathematics curriculum (Darling-Hammond, 2006; Remillard, 1999; M. G. Sherin & Drake, 2009). As teachers construct or supplement their mathematics curricula they must find, choose, and decide how to use instructional resources. One available strategy is searching online (Ruthven, 2013) to find digital resources and digital tools. Access to digital tools and resources can be a powerful tool for K-12 teachers. In order to use digital tools and resources effectively, teachers must make decisions in choosing which to use and how to use them as they supplement or construct their curriculum. Decisions depend on the general, pedagogical, and mathematical features that teachers notice. In order to make sense of the features teachers notice and how to support teachers' professional development of their abilities to find, choose, and decide how to use digital tools and resources, this poster presentation presents preliminary frameworks and qualitative analysis results.

Brown (2009) discussed the differences in teachers' skills in "perceiving the affordance of the materials and making decisions about how to use them to craft instructional episodes that achieve her goals" (p. 29). Dietiker, Males, Amador, Earnest, and Stohlmann (2014) defined curricular noticing as "how teachers make sense of the complexity of content and pedagogical opportunities of written curriculum materials" (p. 4), which included attention to analyzing the materials for mathematical content and practices as well as pedagogical practices. To sum up, this type of noticing focuses on what aspects teachers think are important and what aspects teachers perceive in instructional resources.

In this poster presentation, I narrow the focus of these previous ideas on teachers' noticing of features of digital tools and resources designed for use in mathematics teaching and learning. That is, I explore the characteristics of digital tools and resources that teachers decide are important, whether the characteristics are general, pedagogical, or mathematical in nature. I also look to whether the characteristics are superficial or profound in nature.

INVESTIGATION OF PRE-SERVICE TEACHERS' TECHNOLOGICAL PEDAGOGICAL CONTENT KNOWLEDGE

Erol Uzan
Indiana University Bloomington
eroluzan@indiana.edu

Keywords: Technology; Teacher Education-Preservice; Teacher Knowledge

The impact of technology on education has increased; however, technology itself is not guaranteed to support students' mathematical thinking (Heid, 2005). The development of teachers' TPACK (technological pedagogical content knowledge) is critical. In order to help pre-service teachers (PSTs) to gain an understanding and experience about technology integration, case analysis has been adopted in many technology courses, which allows PSTs to enact and examine authentic, content and context specific scenarios.

Dick and Hollebrands (2011) categorized technologies as conveyance or mathematical action tools, based on their purposes within mathematics instruction. Conveyance technologies are used to convey information, whereas mathematical action tools enable students to interact and receive feedback during the performance of mathematical tasks. Many researchers consider mathematical action tools as "cognitive technologies" which Pea (1987) defined as those which help users "transcend the limitations of the mind…in thinking, learning, and problem-solving activities" (p. 91). Pea (1987) articulated cognitive technologies as amplifiers (accelerate processes) and as reorganizers (engage cognitive processes). While amplifiers enhance students' ability to solve problems in an efficient way, but does not change their thinking, reorganizers "modif[y] cognitive processes…which affect our modes of approaching the acquisition of knowledge" (Barrera-Mora & Ryes-Rodriguez, 2013, p. 112).

The purpose of this study is to explore PSTs' TPACK through case analysis completed in an introductory technology integration course in a large Midwest state university. In content specific case analysis, PSTs select technologies, provide descriptions and justifications for their selections and create a lesson plan. The research questions of the study are: What technologies do PSTs select in doing mathematic case analysis with technology integration focus? How do they justify that their technology selections address the case? In what ways do they integrate technology in the content specific case? How do the outcomes of their case analyses provide an understanding about their TPACK?

The data sources of this multi-case study are eight PSTs' case analysis documents. By using qualitative data analysis methods, the researcher identified what kinds of technologies PSTs used and in which purpose these technologies were used. The preliminary findings of the study suggest these PSTs use both kinds of technologies but they choose to integrate technologies as amplifier more than reorganizer. The findings of this study would help future researchers to understand PST's TPACK development at an early stage of their program through case analysis.

SPECIALIZED CONTENT KNOWLEDGE DEVELOPMENT WITH GSP: A CASE STUDY

Vecihi S. Zambak
Marquette University
vecihi.zambak@marquette.edu

Andrew M. Tyminski
Clemson University
amt23@clemson.edu

Keywords: Mathematical Knowledge for Teaching; Technology; Geometry

In response to the changes in what and how teachers should be teaching mathematics within K-12 schools, various organizations within the mathematics and mathematics education communities have proposed recommendations and guidelines for teacher education programs and for the mathematical preparation of teachers. The MET II report was the first report which explicitly underlined that prospective middle school teachers need to take mathematics content courses with an emphasis on deep understanding. Considering new insights about the theoretical structure of the mathematical knowledge, these courses were expected to support prospective teachers' subject-matter knowledge development special to their profession, which is called specialized content knowledge by Ball, Thames and Phelps (2008). One possible way to accelerate teachers' development of specialized content knowledge is the use of electronic technologies. In this paper, we present three PSTs' responses to a "square construction" and "inscribed circle of a triangle" tasks, in order to answer the following research question: "How does GSP influence middle grade mathematics PSTs' development of SCK?"

We employed a single case study research methodology with embedded units, as described by Yin (2008). PSTs enrolled in a graduate geometry course at a Southeastern research university in Fall/2013. The geometry course was the case of analysis, while three PSTs served as the embedded units who participated two clinical interviews outside the class. The clinical interviews each involved an open-ended task allowing the participants opportunity to demonstrate their SCK. During the first interview, the three PSTs were asked to complete a square construction task a middle school student started on GSP, and predict what the student was thinking with his/her procedure. During the second interview, two months after the first one, three participants were asked to find the relationship between the area and perimeter of a triangle, and the radius a circle inscribed in the triangle by watching animations built using GSP.

Data from two interviews underlined the necessity of CCK in SCK development. Three focal participants managed to demonstrate SCK as long as they had the required CCK for the event. Simultaneous development of CCK enabled PSTs to demonstrate SCK during interviews. Their ideas on the given tasks with or without the GSP initiated an opportunity for them to develop their SCK. One of the reason for this finding could come from the definition of SCK and its differentiation from CCK. Data also indicated that views about GSP seemed to determine whether GSP would be conducive for a PST's SCK development. If a PST views GSP as a tool for precise measurements and demonstration rather than a learning partner, then the role of GSP in SCK development might be limited. These initial findings provide a starting point for helping teacher educators understand in greater detail how technology should be used for SCK development.

A CALL TO ACTION: TOWARDS AN ECOLOGICAL-DYNAMICS THEORY OF MATHEMATICS LEARNING, TEACHING, AND DESIGN

Dor Abrahamson
University of California, Berkeley
dor@berkeley.edu

Raúl Sánchez–García
Universidad Europea de Madrid
raul.sanchez@uem.es

Whereas Natural User Interface technological devices, such as tablets, are bringing physical interaction back into mathematics learning activities, existing educational theory is not geared to inform or interpret such learning. In particular, educational researchers investigating instructional interactions still need intellectual and methodological frameworks for conceptualizing, designing, facilitating, and analyzing how students' immersive hands-on dynamical experiences become formulated within semiotic registers typical of mathematical discourse. We present paradigmatic empirical examples of tutor–student behaviors in an embodied-interaction learning environment, the Mathematical Imagery Trainer for Proportion. Drawing on ecological dynamics—a blend of dynamical-systems theory and ecological psychology—we describe the emergence of mathematical concepts from the guided discovery of sensorimotor schemes.

Introduction: In Search of Action-Oriented Theory of Mathematical Ontogenesis

Whereas commercial production of interactive math apps is booming, extant theory of learning is still a theory-of-learning-with-*paper*(Papert, 2004). In the short term, scarcity of bold research on interactive mathematics learning impedes the formulation of informed policies concerning the integration of technological environments into educational institutions. In the long term, this scarcity is accelerating misalignment between extant theory of learning and emerging practices to which it should apply. As children are learning to move in new ways, so, too, should theory of learning.

A motivation of this paper is that the pedagogical quality and institutional acceptance of action-based learning environments is largely pending on developing informed scholarly and public discourse concerning what it means to learn a mathematical concept and what an instructor's role might be in this process. As such, we are echoing Seymour Papert's consistent call to leverage the technological revolution as an opportunity for deep discussion of the potentially radical changes the educational system should undergo. Similar to Papert, we are optimistic that technological advances in educational media bear the potential of fostering students' deep understanding of mathematical concepts. Complementarily, we submit, these technological advances bear the potential of fostering researchers' deep understanding of learning processes.

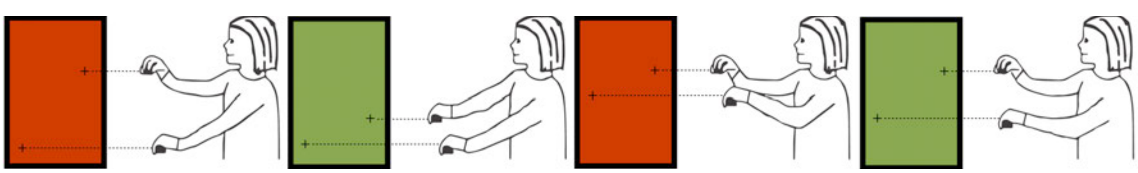
A pedagogical rationale to ground mathematics learning in physical interaction echoes centuries of educational scholarship. We now sketch its recent history. From his cultural–historical psychology perspective, Vygotsky believed that meanings are established through physical interaction. Moreover, he asserted that mature mathematical reasoning tacitly retains and evokes its originary enactive quality (Vygotsky, 1926/1997, pp. 161-163). From a cognitive-developmental psychological perspective, Piaget (1971, p. 6), too, viewed thought as truncated action, emphasizing that "mathematics uses operations and transformations…. which are still actions although they are carried out mentally." Piaget (1968, p. 18)later introduced the notion of *action coordination* as the root of reasoning (see also Nemirovsky et al., 2013).From a philosophy perspective, a resonant view of thought as truncated action has been elaborated by Melser (2004), who puts forth aphylogenetic embodied model of language and reasoning. From an educational-research perspective, Skemp (1976) critiqued math instruction as fostering disjointed "instrumental" knowledge. He promoted an alternative educational program that instead would foster deep "relational" knowledge that resides in non-symbolical dynamical interactions. Similar, Pirie and Kieren (1994) advanced an Enactivist view of knowledge to implicate mathematical reasoning as drawing on dynamical imagery (see Reid, 2014). Decades later, Nathan (2012) denounced mainstream educational practice as still implicitly subscribing to a "formalisms first" epistemology and called to ground mathematical meaning instead in "our direct physical and perceptual experiences" (p. 139). Thompson (2013), too, points to the fundamental problem of mathematics education as the absence of *meaning*, that is, webs of multimodal imagery actions. These inspirational fiats leave us with a set of questions: How do naïve goal-oriented actions give rise to reasoning about immaterial entities? How do students first accept cultural signs? In particular, how might this transpire in discovery-based instruction?

Granted, a number of theoretical frameworks from the learning sciences have been formative in modeling artifact-mediated guided learning of STEM content, such as instrumental genesis (Vérillon & Rabardel, 1995), professional perception (Stevens & Hall, 1998), cultural anthropology (Hutchins, 2014), and semiotic approaches (Radford, 2014). However, these frameworks are not optimally geared to treat the new forms of pedagogical, technological, epistemological, and interactional opportunities created by NUI embodied-interaction learning environments. In particular, extant theoretical frameworks lack analytical specificity for treating sensorimotor schemes—how they emerge, how they are steered, and how they give rise to conceptual knowledge—as the phenomenal core of mathematics learning. And so we present a call to *action* as our *Critical Response to Enduring Challenges in Mathematics Education* (PME-NA 37).

We hasten to note up front that our focus in this paper on fostering motor-action coordinations should not for a moment suggest that we are disregarding or mitigating the formative role of symbols in the development of mathematical knowledge or disavowing the rich theoretical and practical challenges that the symbolic register introduces (Duval, 2006). Rather, we believe that there has not been sufficient focus in the literature on the initial development of action schemes via direct or vicarious interaction with instructional media (but see de Freitas & Sinclair, 2012). And we view NUI technologies as powerful yet under-researched means of fostering those action schemes. Accordingly, this article treats the initial guided construction of mathematically oriented operatory schemes more so than the subsequent signification of these schemes in disciplinary semiotic systems.

Empirical Context: Design-Based Research of the Mathematical Imagery Trainer

The *Kinemathics* project (Reinholz et al., 2011) took on the design problem of students' enduring challenges with proportional relations. We assumed that students have scarce sense of what proportional equivalence is, feels, or looks like. We began by choreographing a bimanual motor-action scheme that enacts proportional equivalence, and then we envisioned, designed, and engineered conditions in which students could learn to move in a new way that emulates this scheme. Our two-step activity plan was for students to: (1) develop a target motor-action scheme as a dynamical solution to a situated problem bearing no mathematical symbolism; and (2) describe these schemes mathematically, using semiotic means we then interpolate into the action problem space.



a.

Figure 1. The Mathematical Imagery Trainer for Proportion (MIT-P)

Figure 1 shows the MIT-P set at a 1:2 ratio, so that the favorable sensory feedback (a green background) is activated only when the right hand is twice as high along the monitor as the left hand. This figure sketches out our Grade 4 – 6 study participants' paradigmatic interaction sequence

Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

toward discovering an effective operatory scheme: (a) while exploring, the student first positions the hands incorrectly (red feedback); (b) stumbles upon a correct position (green); (c) raises hands maintaining a fixed interval between them (red); and (d) corrects position (green). Compare 1b and 1d to note the different vertical intervals between the virtual objects.

Our design solution was the Mathematical Imagery Trainer for Proportion (MIT-P, Fig. 1). We seat a student at a desk in front of a large, red-colored screen and ask the student to "make the screen green." The screen will be green only if the cursors' heights along the screen relate by the correct ratio (e.g., 1:2). Participants are tasked first to make the screen green and then to maintain a green screen while they move their hands.

The activity advances along a sequence of stages, each launched when the instructor introduces a new display overlay immediately after the student has satisfied a protocol criterion (Fig. 2). The full design includes a ratio table for students to control the cursors indirectly via inserting numbers. (For an iPad version, seewww.tinyurl.com/FreeMITP).

Figure 2. MIT-P display schematics, beginning with (a) a blank screen, and then featuring the virtual objects (symbolic artifacts) that the facilitator incrementally overlays onto the display: (b) cursors; (c) a grid; and (d) numerals along the *y*-axis of the grid. For the purposes of this figure, the schematics are simplified and not drawn to scale.

We implemented the MIT-P design in the form of a tutorial task-based clinical interview with 22 Grade 4 – 6 students, who participated either individually or in pairs, and these sessions were audio–video recorded for subsequent analysis (Reinholz et al., 2011). Our primary methodological approach is for the laboratory's researchers to engage in collaborative ethnographic micro-analysis of selected brief episodes from the entire data corpus (Siegler, 2006), where we focus on the study participants' range of physical actions and multimodal utterance around the available media (Ferrara, 2014). The process is iterative and in dialogue with the learning-sciences literature, leading to the progressive identification, labeling, and refinement of emergent categories (Strauss & Corbin, 1990). New constructs might constitute ontological innovations extending beyond the study context (diSessa & Cobb, 2004). Here we re-analyze our empirical data via a new lens.

Ecological Dynamics

Constructivist pedagogy champions the principle of fostering opportunities for individuals to re-invent cultural–historical knowledge (Kamii & DeClark, 1985). Yet how does this principle play out in learning environments where students are first to re-invent sensorimotor schemes prior to signifying the schemes in a discipline's semiotic register? We sought a theory of learning focused explicitly on the development of physical skill.

Ecological dynamics (Vilar et al., 2012) is a theoretical approach used in sports sciences to study skill acquisition in representative designs of real-game conditions. The framework blends *dynamical systems theory* (Thelen & Smith, 1994)and *ecological psychology* theory of affordances(Gibson, 1977).Applying dynamical systems theory to ecological psychology enables sports scientists to explain the learning of physical skills as the complex and adaptive self-organizing of subject–environment dynamical systems.

Dynamical systems theory is a branch of physics that provides a formal representation of any system evolving over time. The behavior of any living system can be plotted as a trajectory into a state space. In a dynamical systems approach, decision-making and learning processes are modeled not as generating a sequence of disembodied symbolical propositions, such as abstracted inferences and decisions, but as emerging from the agent's goal-oriented, situated, adaptive interactions in the environment (Araújo et al., 2009). The emergent quality of self-organizing complex adaptive systems implies also that learning processes are not linear but stochastic, and the non-linear dynamics of systemic behavior increases with the number of agents, variables, and interactions.

The self-organizing behavior of dynamical systems consisting of human agents (e.g., students) engaged in goal-oriented activity can be affected or "channeled" (Araújo & Davids, 2004, p. 50) by different types of constraints. Newell(1996) identified three sources of constraints affecting the behavior of the system either on a short time scale (i.e., decision making while performing a skill) or a longer time scale (i.e., the process of learning a skill): organism, environment, and task.

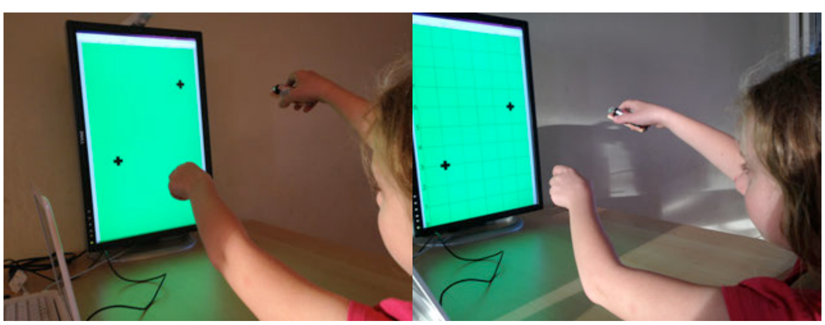
In terms of methodology, ecological dynamics may offer STEM educational research interpretive analytical schemes for modeling the role of instructors' multimodal utterance and actions in shaping students' construction of dynamical enactments. From its systemic view, ecological dynamics regards all forms of intervention, such as physical guidance or metaphoric framing, as productive constraints on the solution of motor-action problems.

The Ecological Dynamics of the Mathematical Imagery Trainer

We now present three ecological-dynamics accounts of children's guided work with an embodied-interaction design for mathematics content, the MIT-P. These concise narratives were selected as appropriate exemplars for showcasing numerous analyses of manipulation, discovery, and coaching in the context of math learning. For continuity, we will treat aspects of student behavior only around the numerical item of a 1:2 ratio.

The Emergence of an Attentional Anchor Mediating System Dynamics

Students typically begin the activity by lifting the controls and, in an attempt to make the screen green, waving them up and down in several different patterns. Eventually, the students discover that their hands "have to be a certain distance" from each other, and yet they attempt to keep this distance fixed. But as they further explore the screen regions, they figure out that "the higher you go, the bigger the distance" (Fig. 3a)Students thus discover, articulate, and empirically validate a systemic interaction principle governing a phenomenon under inquiry: a proposed correlation between two



a. *b.*

Figure 3. (a) A child discovers the vertical interval between the markers as an attentional anchor for making green while moving the hands: the higher it is, the bigger it should be (and vice versa). (b) Once the grid is overlaid, she shifts spontaneously to a new routine.

qualitative properties of *a new object*—the height and size of a linear interval subtended between their hands.

We have been intrigued by students' initial discovery of the interval between their hands as a means of controlling the screen color as well as by the subsequent smooth shift from keeping this interval fixed as they elevate their hands along the screen to varying the interval size in proportion with its elevation. Crafted spontaneously out of thin air, the interval articulates into being, foregrounded from negative space as a new auxiliary stimulus wedged between agent and artifact. The interval coalesces as a ready-to-hand tool for engaging latent correlations in the perceptual field, thus mediating the situated implementation of motor intentionality. It served the students as a spontaneous self-constraint—an order parameter, "steering wheel" (Kelso & Engstrøm, 2006; Newell et al., 2010), or *attentional anchor* facilitating enactment (Hutto & Sánchez-García, 2014).

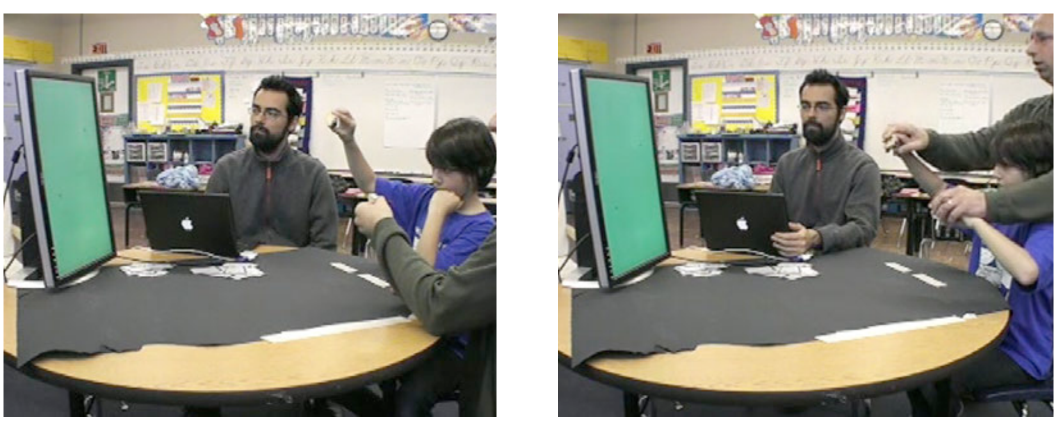
Decomposing and Recomposing an Attentional Anchor in a Reference Field

Once a student discovers the "the higher, the bigger" control strategy oriented on the interval between their hands as a new attentional anchor, the interview protocol proceeds to the next item, the introduction of the grid onto the screen (Fig. 3b). The appearance of the virtual horizontal gridlines materialized the imaginary attentional anchor. The grid's figural qualities immediately relieved students from having to hold the interval between their hands: The attentional anchor was thus electronically reified in the public domain in the form of a perceptually stable, externally present, deictically referable, bounded entity. Yet this frame of reference shifted students abruptly into a new interaction routine: raise the left hand 1 unit, then raise the right hand 2 units, iteratively, to make green. Now the old attentional anchor no longer mediated a goal, so it receded back into negative space.

The theory of ecological dynamics thus offers a view of conceptual development as spontaneous, situated adoption of symbolic artifacts *as action tools*. Symbolic artifacts bear hybrid ontology, in the sense that they are both perceptual and semiotic entities (Uttal, Scudder, & DeLoache, 1997). They are "transitional objects" (Papert, 1980)—both sensory and abstract. We might grab a symbol for its perceptuomotor affordance for action yet only subsequently—as personal and interpersonal situations evolve—leverage its semiotic potential for planning and communicating prospective actions, elaborating reasoning, and supporting argumentation. We kindle then obey new constraints.

Instructor's Multimodal Intervention as Environmental Constraints on Action

Learning is the education of perceptuomotor attention, and teachers can play pivotal roles in this educational process. One expert–novice co-enactment method is to distribute the operation of the



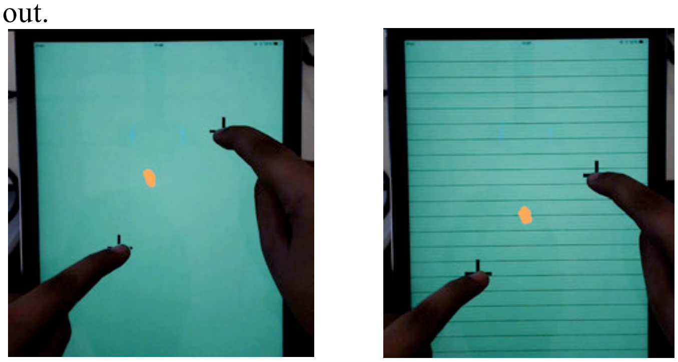
a. *b.*

Figure 4. Hands-on learning may need hands-on teaching:(a) co-manipulating virtual objects as distributed co-enactment; and (b) molding as joint co-enactment.

Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

control devices, one person per device. Another method is to co-operate both of the control devices, that is, with both people each handling both devices.

Similar to a pair of athletes in a two-person sport, such as rowing or luge, the tutor and student optimize for effective joint production by continuously and dynamically adjusting each to the other's spatiotemporal actions (Fig. 4). They reach an intimate level of intersubjective sensorimotor coordination by anticipating and closely tracking their mutual actions. Yet as in the martial-arts practice of push-hands, these two participants silently negotiate leadership. The tutor progressively hands over agency to the student, who eventually solo-enacts the new strategy. The tutor-as-dynamical-scaffold fades out.



a. *b.*

Figure 5.Spontaneous evolution of an attentional anchor. The eye gaze (orange spot) hovers over a location on the screen that contains no information in-and-of-itself but only with respect to the dynamical motor-action coordination. A grid then offers a frame of reference for bringing forth the attentional anchor into mathematical consciousness.

Recent results from eye-tracking studies (Fig. 5) confirm our qualitative analyses of the interview data: Just before students articulate a new manipulation strategy, their visual attention tears away from figural constituents on the screen to anchor onto a new location, a higher-order invented "handle" on a structural constellation, that facilitates operable interaction with a dynamical yet invariant conservation (Shayan et al., 2015).

Conclusion

We have introduced an ecological-dynamics view on mathematics teaching and learning. We further presented and interpreted empirical data from implementations of embodied-interaction activities so as to contextualize the ecological-dynamics view and argue for its purchase on enduring research problems germane to the learning sciences in general and to scholarship and application of mathematics education in particular. Based on our findings, we contend that the theory of ecological dynamics offers a useful framework for designing, implementing, and analyzing pedagogical interactions in which students develop fundamental understandings of mathematical notions via solving and reflecting on motor-action inquiry problems. We also explained how an ecological-dynamics view of mathematics learning coheres with, integrates, and extends seminal constructivist and socio-cultural historical perspectives on human learning. From this view, mathematical meanings are cultural constructs that individual agents build by developing and then signifying appropriate motor-action coordinations oriented on discovered attentional anchors. These dynamical coordinations are embodied solutions to physical problems that students encounter when engaging in carefully designed activities.

We wish to position this article as attempting to rekindle essential themes of situated cognition (Greeno, 1998). To our reading, ecological dynamics should offer an effective and comprehensive framework for analyzing socially guided ontogenesis of intelligent participation in cultural practices. In particular, ecological dynamics, with its view of learning as coordinating motor actions in perceptual fields, may replace the cognitive semantics theory of conceptual metaphor (Lakoff & Núñez, 2000) as a more viable means of tracking the subjective and intersubjective emergence of mathematical concepts from situated solving of sensorimotor interaction problems (Gibbs, 2014). Ecological dynamics offers new tools for minding the epistemic gap between action and symbol and thus stands to fill a critical, enduring lacuna in mathematics-education research literature.

Given appropriate cultural mediation, children can learn quite rapidly to move and therefore think in new ways that become signified, elaborated, refined, and reformulated as disciplinary discourse. This thesis suggests *all* children's universal capacity to deeply understand mathematical concepts, regardless of prior academic accomplishment, because it shifts the site of critical mathematical learning away from the symbolic semiotic register toward situated sensorimotor engagement with manipulation problems.

Embodied-interaction activities offer solutions for researchers and teachers alike who wish both to observe mathematical thinking as it is occurring and offer students opportunities to reflect on their actions. Technology-enabled embodied-interaction learning environments transform the practice of mathematical teaching, rendering it similar to coaching in disciplines more readily associated with physical action, such as music, dance, or carpentry. Yet for these instructional devices and methodologies to enter educational institutions, we would all have to rethink multiple aspects of mathematics teachers' professional practice, beginning from epistemology and through to assessment.

EXPLORING ROLES OF COGNITIVE STUDIES IN EQUITY: A CASE FOR KNOWLEDGE IN PIECES

Aditya P. Adiredja
Oregon State University
adiredja@math.oregonstate.edu

Underrepresentation of people of color in mathematics at the postsecondary level warrants more focus on equity issues. The prevalence of cognitive studies at the undergraduate level is met with the call for critical analysis about the kinds of knowledge that get privileged in mathematics education. Connecting to the Funds of Knowledge work, this paper discusses the utility of diSessa's Knowledge in Pieces cognitive framework to uncover productive informal knowledge in learning formal mathematics. Seeing the valorization of knowledge as related to issues of power, a case of a Chicana student's productive sense making about the formal definition of a limit illustrates the way diSessa's framework can help challenge what counts as productive mathematical knowledge and reasoning.

Keywords: Learning Theory; Advanced Mathematical Thinking; Equity and Diversity; Cognition

> Whether parents, teachers, students, or researchers, we all bring valorization of knowledge to our views of what counts as "proper" or "better" approaches to doing mathematics.
>
> –Marta Civil (2014, p. 12)

The President's Council of Advisors on Science and Technology (PCAST) called for 1 million additional college graduates in science, technology, engineering, and mathematics (STEM) fields based on economic forecasts (Executive Office of the President, PCAST, 2012). Within STEM, the number of mathematics degrees being conferred continues to be generally low. People of color, in particular, continue to be severely underrepresented in mathematics. A recent National Science Foundation report shows that historically marginalized population accounts for 20% of the mathematics degrees conferred (NSB, 2014).

Gutiérrez (2002) characterizes equity research as one that explicitly focuses on efforts to understand and mitigate systematic differences in how people experience educational opportunities, particularly differences that privilege one group over another. In the broader area of undergraduate STEM education, some studies have begun to explore issues of marginalization of women and students of color and ways that students manage it in their everyday lives (e.g., McGee & Martin, 2011). However, there has not been a sustained and concerted effort to focus on equity considerations in undergraduate mathematics education research (Adiredja, Alexander & Andrews-Larson, 2015), like there has been in K-12 mathematics education research in recent years (Gutiérrez, 2013).

The need to understand how students make sense of challenging topics in undergraduate mathematics contributed to the prevalence of studies about students' and teachers' individual cognition and practices (Adiredja et al., 2015). Several scholars have argued for critical analysis of the kinds of knowledge and practices that we privilege in teaching and learning of mathematics (Civil, 2014; Gutiérrez, 2013). Considering the socio-political nature of education, Gutiérrez (2013) emphasized the interconnectedness of knowledge and power:

> Knowledge and power are inextricably linked. That is, because the production of knowledge reflects the society in which it is created, it brings with it the power relations that are part of society. What counts as knowledge, how we come to "know" things, and who is privileged in the process are all part and parcel of issues of power.

For example, children of immigrant parents at times would discount their parents' mathematical knowledge as a result of the way things are taught in US schools (Civil and Planas, 2010). This example illustrates one explicit implication of power vis-à-vis the kinds of knowledge students learn to be valued in the classroom. The question then becomes how can we begin to unpack issues of power behind our valorization of mathematical knowledge and approaches, particularly at the undergraduate level?

At the K-12 level, some researchers have responded to this question by trying to leverage and build on cultural aspects of the students' communities in designing curriculum (Moll, Amanti, Neff & Gonzalez, 1992). The goal with the Funds of Knowledge project (Moll et al., 1992) is to help teachers explore and document the often invisible but productive knowledge of non-dominant students. While it is tempting to assert that the nature of mathematics at the undergraduate level is different from that of K-12 mathematics, I posit that the spirit of the Funds of Knowledge work can also be productive at the post-secondary level.

The kind of mathematics that is being learned at the postsecondary level does become increasingly abstract and are often built on prior formal mathematical knowledge. Moreover, the Euro-centricity of mathematics (Joseph, 2010) becomes even more privileged at the post-secondary level. As such one might argue that these realities of mathematics at the post-secondary level limit opportunities for teachers to connect to students' informal knowledge and experiences. For example, in the context of limit in calculus, some researchers have argued that students' intuitive knowledge is an obstacle in learning (Davis & Vinner, 1986), despite the prevalence of such knowledge student thinking about the concept (Monaghan, 1991).

While the Euro-centricity of advance mathematics is a reality, students' intuitive knowledge about mathematics, and more importantly ways that such knowledge might be productive in learning formal mathematics, are largely underexplored in undergraduate mathematics education. Wawro et al. (2012) have shown a case where incorporating students' intuition about using different modes of transportation in traveling is productive to explore concepts in linear algebra. This study suggests that there is room for intuitive knowledge in learning mathematics at the undergraduate level. Recognizing the potential utility of students' informal knowledge, and its potential in disturbing power distribution in the classroom, where can we find such knowledge? What might be able to assist us in uncovering many of the invisible productive knowledge students bring with them to learn formal mathematics?

This paper attempts to offer a response to those questions, particularly in the context of undergraduate mathematics education. This paper argues that the theoretical perspective on epistemology and learning in cognitive studies plays an important role in uncovering knowledge resources students bring into learning formal mathematics. In particular, this paper argues for the utility of the Knowledge in Pieces cognitive framework (diSessa, 1993) to recognize productive knowledge resources students might use in learning formal mathematics, particularly in the face of non-normative language. The analysis shows how this framework has a potential of challenging the existing distribution of power vis-à-vis what counts as productive knowledge.

Theoretical Framework for Cognition

The Knowledge in Pieces (KiP) theoretical framework (diSessa, 1993; Smith, diSessa and Roschelle, 1993) models knowledge as a system of diverse elements and complex connections. The nature of the elements, their diversity, and connections are typical interests for studies using this framework. Characterizing knowledge using generic ideas like "concept" or the commonly used idea of "misconceptions" is viewed as uninformative and unproductive (Smith et al., 1993). Instead, KiP focuses on the context specificity of knowledge to maintain the *productivity* of the particular piece of knowledge. KiP also pays particular attention to the continuity of knowledge, i.e., ways that knowledge gets used or built upon in new contexts. It is common for studies using this framework to uncover productive sense making behind students' use of non-normative language to describe their reasoning (e.g., Campbell, 2011; diSessa, 2014).

One of the main principles of KiP is that knowledge is context specific (Smith et al., 1993). This means that the productivity of a piece of knowledge is highly dependent on the context in which it is used. Context variation can happen as a result of change in the literal problem context, the passage of time, or simply as knowledge is assessed more or less carefully. For example, the knowledge that "multiplication makes a number bigger" is productive in the context of multiplication with numbers larger than one. The knowledge is not productive in the context of multiplication with all real numbers. In contrast to studies that focus on identifying students' misconceptions, KiP focuses on building new knowledge on students' prior knowledge, instead of focusing on efforts to "replace" students' misconceptions (Smith et al., 1993). Adopting this theoretical framework implies that the analysis in this paper will focus on ways that students build on their prior ideas while suspending judgment about their correctness. KiP also posits that students have a lot of intuitive ideas that can be leveraged in instruction. KiP was developed in the context of physics where students have a diversity of intuitive ideas about physics originating from their everyday experience. Some studies have shown that intuitive ideas can also be found in mathematical reasoning as well (e.g., Campbell, 2011).

Mathematical Context and Literature

The formal definition of a limit of a function at a point, also known as the epsilon-delta (ε-δ) definition, is an essential topic in mathematics majors' development that is introduced in calculus. The limit of a function $f(x)$ as x approaches a is L and is written as $\lim_{x\to a} f(x) = L$ if and only if, for every positive number ε, there exists a positive number δ, such that all numbers x that are within δ of a (but not equal to a) yield $f(x)$ values that are within ε of the limit L. This defining property is often written as "for every number $\varepsilon > 0$, there exists a number $\delta > 0$ such that if $0 < |x - a| < \delta$ then $|f(x) - L| < \varepsilon$". Informally, one might say, "If L is the limit, then for however close one wants $f(x)$ to be to L, one can constrain the x-values so that $f(x)$ would satisfy the given constraint." We return to this intuitive idea shortly.

The formal definition provides the technical tools for demonstrating how a limit works and introduces students to the rigor of calculus. Yet even thoughtful efforts at instruction leave students, including intending and continuing mathematics majors, confused or with at most a procedural understanding about the formal definition (Cottrill, Dubinksy, Nichols, Schwingendorf, and Vidakovic, 1996; Oehrtman, 2008). Many studies assert that students' dynamic conception (the limit is the number that $f(x)$ approaches as x approaches a) is an obstacle in learning the formal definition (Parameswaran, 2006; Williams, 2001). These studies largely focused on the unproductivity of students' prior conception and their sense making.

In the meantime, a small number of studies that focuses on students' sense making of the formal definition (Knapp & Oehrtman, 2005; Roh, 2009; Swinyard, 2011) suggest that students' understanding of a crucial relationship between two quantities featured in the formal definition, epsilon (ε) and delta (δ), warrants further investigation. Davis and Vinner (1986) used the term *temporal order* to describe their relationship. While studies have shown the existence and prevalence of this particular difficulty, its nature is largely underexplored.

The relationship between the quantities δ and ε in the definition can be described using the idea of quality control in manufacturing an item. The conceptual structure at issue can be described as follows: given a permissible error in the measurement of the output (ε), one determines a way to control the input to achieve that result. One does so by determining the permissible error in the measurement of the input (δ) based on the given parameter for the output (ε). In this way, the error bounds follow the following sequential order, error bound for the output, then the error bound for the input. This is because the error bound for the output is given. In some ways, the error bound for the input could be seen as being dependent on the given error bound for the output. Epsilon can be seen as the error bound of the output whereas delta is the error bound for the input. Therefore, δ and

εfollow the order of ε first, and then δ, or δdepends on ε. In this paper, the student discussed this idea of quality control in the context of working at a pancake house that is known to make 5-inch diameter pancakes. Students are given a permissible error for the size of the pancakes, and they were responsible to control the error in the amount of batter.

Data Collection and Analysis Methods

The data presented in this report is a case study from a larger interview study investigating the role of prior (and intuitive) knowledge in student understanding of the temporal order of epsilon and delta within the formal definition (Adiredja, 2014). Participants of the study were calculus students at a large Western public research university. Students were interviewed about their understanding about the temporal order. They were asked a series of questions about the temporal order before and after engaging with the instructional intervention. The instructional intervention, the Pancake Story uses the context of working at a pancake house to leverage the idea of quality control in discussing the formal definition, as explained in the previous section. A video recording of the interview was transcribed following Ochs' (1979) guidelines. Transcripts were organized by turns, marked changes in the speaker. They included non-verbal behaviors, including relevant gazes, laughter and gestures. Turns that discus one mathematical argument make up an episode. The transcript was modified to facilitate reading. Many hedges, and uh-huh's and um-hm's from the interviewer were removed.

Adriana, the focus of the analysis of this paper, was a mathematics and Chicano studies major. She ethnically identified as Chicana. Adriana received an A in her first semester calculus course in high school and in college. She was selected because despite her strong academic background, even after engaging with the Pancake Story, she still initially (and incorrectly) argued that ε depended on δ. Ultimately, Adriana adopted many of the productive resources from the story and used them to reorganize her knowledge and modify her claim. The analysis was interested in understanding how and why she did so. The analysis did not explore ways that Adriana's identity as a Chicana influenced her reasoning about the topic. Her ethnicity and gender were included to better represent her as a student and challenge the common unintended assumption with cognitive studies that the student is a White male student (Nasir, 2013).

The analysis focused on identifying a knowledge entity called *knowledge resources* (Adiredja, 2014), which is defined as a single or a collection of knowledge elements that might be involved in making a single claim from larger ideas that the student used to make her claim. Knowledge resources were assumed to be neutral; they are not correct or incorrect. This theoretical assumption distinguished knowledge resources from larger ideas that were combinations of several knowledge resources. To identify knowledge resources, the analysis exploit any relevant data (e.g., gestures, other parts of transcripts) that might inform the aim to optimally understand the activation of knowledge resources in various contexts. The analysis then generated multiple models (interpretations) of the student's argument in each episode. The analysis then put these models of student thinking in competition with one another. This process of *competitive argumentation* (VanLehn, Brown, & Greeno, 1984) was used to refine interpretations of student thinking. In this paper I only present the final model of each episode that was the result of the process of competitive argumentation.

Results

This paper only presents two of the four episodes of Adriana's sense making: the first and final episode. These episodes illustrate the changes in Adriana's thinking and salient ideas from the Pancake Story. They also show the initial conflict that Adriana faced in aligning the ideas from the story with her prior knowledge. The four episodes occurred on the span of 14 minutes.

The first episode started with the interviewer's asking Adriana about the dependence between$\delta$and ε after they discussed the Pancake Story. Adriana responded with the same [incorrect] claim she made before she engaged with the story. She argued that ε depended on δ because epsilon was with $f(x)$and delta was with x and $f(x)$ depended on x. The bolded texts marked the ideas that from which knowledge resources were identified.

Adriana: [They kinda depend on each other], yeah in a sense because, but more whatever you're getting, like $f(x)$ is always gonna depend on what x you're inputting it. But then, if you want to get something that's within delta [*marks a small interval on the x axis with two fingers*] you need to see if /.../ for example here [*points to the pancake story*] our epsilon here was already set, then that [*points back and forth between* 4.5 *and* 5.5 *in the inequality* $4.5<f(x)-L<5.5$] kind of depended on what we were putting in for x [*points at the same interval around x on the graph*] but..but mostly whatever you're putting in to your x is gonna determine what you get for $f(x)$ [*pause*]. So I'm still saying the same thing like delta depends on epsilon but=

Interviewer: =Delta depends on epsilon? Or epsilon depends..

Adriana: No, yeah, epsilon depends on delta. But, /…/ if epsilon's already set then you'll manipulate your /…/ delta so it's within an error bound and /…/ then continue to manipu- wait [*long pause*] wait, so you're… hm.

Final model of episode 1: Adriana focuses on her prior claim that epsilon depends on delta. She justifies the claim using *functional dependence* and *function slots* resources. She simultaneously brings up many of the productive resources from the story: *domain constraint for a limit, the givenness* of epsilon and *quality control.* However, these resources are in conflict with her prior conception. Adriana's use of the knowledge resource of *functional dependence* can be seen in her statement, "whatever you're putting in to your x is gonna determine what you get for $f(x)$." Analysis of the final episode revealed that in this episode, Adriana thought about epsilon and delta as a range of errors, i.e., x and y values, instead of error bounds for those values. This suggests that along with *functional dependence,* Adriana uses the knowledge resource *function slots*, i.e., the assumption that when two quantities share a functional relationship, one quantity is the x and the other is the $f(x)$ or the y.

Separate from her previous argument, Adriana also mentioned the idea that the epsilon (the error bound for the pancake) was given (*givenness* knowledge resource) in the story, and that she wanted to get "something" that was within delta. That statement reveals Adriana's preference of only considering x values that are close to a in discussing limit problems. She would control that closeness by choosing x values that were within a small delta. This suggests her use of the knowledge resource *domain constraint for a limit*. The last line of the episode suggests that Adriana might have also taken up the idea of *quality control*: for a given specification on the output, one would manipulate the input so the output would be within the specified error bound. The sentence also reveals her use of the *dynamic conception of a limit* when she talked about continuing to manipulate the delta to get x closer and closer to a. She also erroneously talked about wanting delta to be within an error bound, which is consistent with the interpretation that delta in this episode as a range of x values.

In the final episode, Adriana repurposed the *functional dependence* resource to describe the relationship between the errors but not the error bounds. This productive move helped Adriana to align productive resources from the story with Adriana's prior knowledge. She then prioritized the idea of *givenness* of epsilon and *quality control*, which she already knew since episode 1,to conclude that delta depended on epsilon. She also adopted the story's language.

Interviewer: So, do they depend on each other, is it just one way now?

Adriana: Um, see cus I was looking at it like /…/ **the f of x [$f(x)$] depends on the x** and that's how I was like saying that epsilon depends on delta because **epsilon is related to the f of x** [*f*(*x*)]/…/. But that's just saying **the error of the *L* and the f of x [*f* (*x*)] depends on the *a* and *x*** but that's not to say that epsilon depends on delta.

Interviewer: Ok, so?

Adriana: So, I think that delta depends on epsilon now [*laughs*]. Just cus if it's given like this [*reference unclear*] and **you're trying to aim at getting /…/ within a certain error bound**, then you're gonna **try to manipulate your entries /…/ to be within a certain error bound** [*gestures a small horizontal interval with her palms*]

Interviewer: Ok. Alright, so and so you changed your mind it seems? Um, so how did that happen? Why did you change your mind?

Adriana: Because I was **given an epsilon** [*points at the inequality* $4.5<f(x)–L<5.5$] and that's kinda like the main goal. **The main goal is to get the pancake, /…/ and they gave me a constraint** /…/ and /…/ they **didn't give me an error bound for the batter** or for like the *a* or *x*, they didn't give me an error bound. But I know I **want to make it small so that it's within the error bound, the epsilon**. So then **I would kinda base my delta on what was epsilon**.

Final model of episode 4: Adriana uses *functional dependence* to describe the relationship between the errors ("But that's just saying the error of the *L* and the $f(x)$ depends on the *a* and *x,* but that's not to say that ε depends on δ."). To determine the dependence relationship between ε and δ, she prioritizes the resource *givenness* of epsilon and *quality control*, as seen in her statement, "you're trying to aim at getting within a certain error bound, then you're gonna try to manipulate your entries to be within a certain error bound." Adriana also made the productive observation that delta was not given, showing her use of the *givenness* resource with delta as well. More importantly, not only did Adriana treat delta as an error bound, she also stated that she wanted delta to be *small*. By making delta small, Adriana was no longer using the idea of smaller and smaller or "continuing to manipulate" the input errors that suggests the use of *dynamic conception of a limit* in the first episode.

Discussion

In summary, the analysis revealed that Adriana took up many of the productive resources from the story despite its initially looking as if her understanding seemed unchanged. It took effort for Adriana to align the new productive resources from the story with her prior knowledge. After she repurposed the *functional dependence* resource to describe a relationship between the errors, she prioritized the productive resources from the story. Adriana also used the story to make a novel observation about the temporal order (delta was not given). That move and the adoption of the language of the Pancake Story suggest that the story was a rich learning context for Adriana. The story was able to leverage Adriana's prior knowledge about *functional dependence* and *quality control* while reasoning about the temporal order.

The Knowledge in Pieces framework guided the analysis in revealing knowledge resources from the story that were salient to Adriana, as well as those that existed as part of her prior knowledge. Adriana's language in describing her conception in the first episode was not clear. However, analysis of the structure of her knowledge revealed these productive resources. The analysis was also able to recognize the productivity of Adriana's moves because KiP takes seriously the process of reorganization of knowledge. The theoretical assumptions about epistemology and learning make KiP particularly sensitivity to subtle changes in sense making and potential productive roles that students' prior knowledge can play in learning. It challenges the deficit perspective of student thinking and challenges what counts as productive mathematical knowledge and reasoning. More broadly, researchers studying student thinking wield a great deal of power in deciding what kind of knowledge is valuable, and particularly in suggesting implications to practice from the findings of the analysis. For example, cognitive studies that focus on pathologizing students' thinking might have simply characterized Adriana's return to her prior argument about the temporal order as a result of a persistent misconception. Moreover, a lot of the subtle changes and her adoption of many of the productive resources might have been easily overlooked. Thus, not only would it position her and her thinking in a deficit way, it would also fail to recognize her contribution.

The findings also show the utility of intuitive knowledge in building a conceptual understanding of formal mathematics. The spirit of the Funds of Knowledge work can be seen in the way that the Pancake Story leveraged the intuitive notion of quality control to learn about the temporal order within formal definition of a limit. At the same time, the story was designed with the KiP framework's assumptions about the potential productivity of prior knowledge and ways that knowledge is reorganized. In addition to Wawro and colleagues' (2012) work, we see another case where intuitive knowledge can be productive in learning formal mathematics.

In sum, I argue that cognitive studies can contribute to equity issues more directly by addressing issues of power vis-à-vis valorization of knowledge. In this paper, I made a case for the KiP framework, and recognize that there might be other frameworks that can help uncover non-normative but potentially productive ways of thinking with formal mathematics. This type of work would benefit all students, but would particularly benefit non-dominant students whose knowledge are often devalued or unrecognized at the post-secondary level. In the face of underrepresentation and marginalization of non-dominant students more broadly, cognitive research can play an important role in challenging issues of power in mathematics education.

PROBLEM POSING: A REVIEW OF SORTS

Geneviève Barabé
Université du Québec à Montréal
barabe.genevieve@courrier.uqam.ca

Jérôme Proulx
Université du Québec à Montréal
proulx.jerome@uqam.ca

In this paper we offer a review of sorts of the studies conducted around issues of problem posing in mathematics education research. We first ground the work on problem posing in the seminal work of Polya and of Brown and Walter, which influenced most studies on this subject. We then propose two perspectives taken on problem posing: the implicit and the explicit. These illustrate the varying emphasis concerning the conception of what is meant by problem posing, one being about actual requests for creating a problem and the other about defining the nature of problem solving processes. We conclude by discussing the significance of this categorization for making theoretical advances in problem posing research.

Keywords: Cognition; Problem Solving

Context

Issues about problem posing have been around for a number of years in mathematics education research. This being so, recently there has been a resurgence of studies on the topic, illustrated through Working Groups (e.g. PME 2009, 2011), Special Issues (e.g. ESM, *83*(1)), and books (e.g. Singer, Ellerton, & Cai, 2015). Through this spread of studies on problem posing, however, numerous orientations have been developed, and often one is at a loss in making differences or even finding similarities between the perspectives taken. Far from being a negative aspect of the field, as it shows its richness and enlargement, there is however a need to distinguish and categorize the kind of work being conducted in order to develop clearer views on what problem posing means and how to study it. Other researchers have also attempted classifications in the past (e.g. Voica et al., 2013; Christou et al., 2005). We re-use and deepen these classifications, combining them with the work of Polya (e.g. 1957) and of Brown and Walter (e.g. 2005), who are seen as pioneers on the theme. In addition, we outline another line of studies to which little attention has been paid to, that is, studies focusing on the activity of problem solving defined as an activity of problem posing. Thus, in this paper we extend the current categorization of studies on problem posing, leading us to varied views of what is meant by problem posing in the community of mathematics education researchers.

To do this, we first situate the field on problem posing through an overview of the work of Polya and of Brown and Walter. We then offer a first category of studies, termed the *explicit perspective*, which focuses on explicit requests to students to participate in an activity of composing problems. We then offer a second category of studies called the *implicit perspective*, which focuses on studies that define the activity of problem solving as one of problem posing.

This being said, as expected, we do not claim to offer an exhaustive list of all work ever conducted on problem posing. In this sense, we do not offer a review, but mainly a review *of sorts*. The intention with this review of sorts is to offer fruitful distinctions related to the underpinnings of what is considered an activity of problem posing. Through these distinctions, we aim to take a step forward in the direction of Silver's (2013) suggestion for more developed theoretical frameworks to support studies in problem posing.

Pioneers of Problem Posing: The Work of Polya and of Brown and Walter

Numerous researchers have mentioned being influenced, directly or indirectly, by the work of Polya or Brown and Walter, making them important sources in the problem posing literature. We thus refer to their work as a way of grounding and contextualizing this review of sorts.

George Polya's Problem Posing

Polya's (e.g. 1957) work on problem solving focuses on helping and pushing students to analyse the problems they solve and to think of other interesting problems in relation to them. In so doing, for Polya, teachers help students to consolidate their knowledge, develop their ability to solve problems and improve their solution or their understanding of it. Polya did not used the expression *problem posing* in his work, referring mostly to what he called the *Looking back* technique, which enables students to generate new ideas and investigate possible connections between mathematical problems. Having solved a problem, students are asked to look at what they have done and then to formulate new problems out of it. Polya argues that through this activity, students gain a better understanding of their solutions and increase their solving abilities. To formulate new problems, Polya suggests various heuristics of *Looking back*, four of which are discussed here. For example, consider this problem for students to solve (Figure 1):

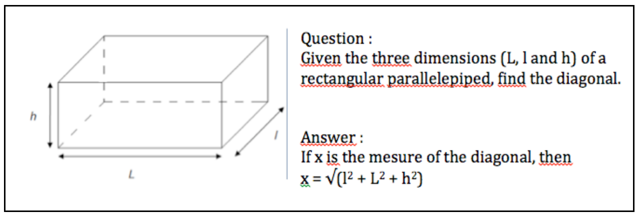

Figure 1: Polya's parallepiped problem (Polya, 1957, p. 7)

A first heuristic consists, once one knows the solution to this problem, of *generating analogous problems*, i.e. similar problems to this one. Polya gives examples of possible formulations: "a) Given the three dimensions of a parallelepiped, find the radius of the circumscribed sphere; b) The base of a pyramid is a rectangle of which the center is the foot of altitude and the sides of its base, find the lateral edges; c) Given the rectangular coordinates (x_1, y_2, z_3), (x_1, y_2, z_3) of two points in space, find the distance of these points." (1957, p. 66) These problems allow students to go back to the initial solution, but for other contexts, which requires them to rethink the solution and not only apply the formula. A second heuristic consists of applying the formula found by *modifying* the problem and its data. For example, the initial problem requires looking for the diagonal of the parallelepiped in relation to its width, length, and height. Another problem can be formulated by asking to find the height of the parallelepiped depending on the diagonal, the length, and the width. This heuristic requires interchanging the role of the various givens of the problem. Polya's third heuristic is *generalizing/specifying*. Generalizing consists in solving the same problem, but for an entire category of numbers or givens. For the above problem, one possible generalization could be: "Find the diagonal of a parallelepiped, being given the three edges issued from an end-point of the diagonal, and the three angles between these three edges." (1957, p. 67), which requires e.g. aiming for algebraic letters to represent the needed values of the problem. Also, a way of specializing the problem would be to look for specific cases, like finding the diagonal of a cube knowing one of its edges. A fourth heuristic is *studying variations*, that is, studying the effect of varying some of the data in the problem. For example, in the analogous problem of the circumscribed sphere, one can vary the radius of the sphere and study its effect on the problem and solution, leading to three possible cases: the sphere is entirely contained in the cube, the sphere is circumscribed in the cube; and finally the sphere encompasses the cube. Polya's heuristics are illustrations of his *Looking back* approach. For him, binding problem posing to problem solving allows students to see the possible mathematical connexions between various problems. By looking back at their solution, by reconsidering and examining the solution and the path they have followed, he argues that students consolidate their knowledge and develop their problem solving skills.

Brown and Walter's Problem Posing

The main goal of Brown and Walter's (e.g. 2005) problem posing is to study mathematics by working on students' questions and reflections on a given topic. For Brown and Walter, questions that arise in the classroom must not only be instrumental (i.e. posed to ensure understanding and performance of what the teacher asks students to do), but rather should help student to develop their mathematical skills, understanding and autonomy. In *The Art of Problem Posing*, Brown and Walter present two perspectives of problem posing: *Accepting* and *What-if-not?* (WIN). These perspectives are to help teachers to develop strategies for using problem posing in class with their students. The *Accepting* perspective refers to students accepting a concept suggested by the teacher (e.g. the concept of prime numbers defined as natural numbers that have exactly two natural divisors), and then finding interesting problems/questions about it. In the case of prime numbers, it could be questions like: *How many prime numbers are there? How to find the next prime number?* They argue that this leads students to explore and work mathematically on a concept, in order to develop an understanding of it.

The WIN perspective consists, on the other hand, in seeing what happens when instead of "accepting" the concept, one contests its characteristics. Brown and Walter suggest various levels of WIN, which they illustrate with the example of the Pythagorean theorem. A first level is for students to list the attributes of the Pythagorean theorem. For example, it may be noted that all number are squared or that the variables are connected by an equal sign. A second level consists of asking a WIN question for each of the attributes listed. For example, *What-if* the variables were *not* connected by an equal sign, but by an inequality? This question opens and becomes a new route to be explored for both students and teacher. A third level, called the *What-if-Not-ing* level, requires combining the negation of two of the attributes listed. In this case, it could be by looking at what happens when the variables are not linked by an equal symbol *and* all numbers are not squared. This also opens a new route to explore. For Brown and Walter, these mathematical explorations allow students to understand the Pythagorean theorem through the importance of its mathematical attributes, as well as developing their ability to formulate questions, explore mathematics, and solve problems. In this sense, the authors argue that after solving a problem, a person does not fully understand the meaning of what he/she has done unless new interconnected problems are formulated and analyzed, which affords a better grasp of the concept worked on. Thus Brown and Walter's problem posing is related to an inquiry process that leads to the exploration of concepts for understanding them better, arguing also for openness toward mathematical questions and thoughts that occur in classrooms.

Conceptualizing Problem Posing: Explicit and Implicit Perspectives

Grounded or not in Polya or in Brown and Walter's ideas, various meanings about problem posing are found in the literature. We distinguish these meanings by suggesting two perspectives. The explicit perspective refers to an explicit request for students to compose problems, whereas the implicit perspective refers to something that occurs implicitly in the activity of problem solving, i.e. every act of problem solving is seen as an activity of problem posing in itself.

The Explicit Perspective: A Pragmatic View of Problem Posing

In the explicit perspective, we distinguish three categories of studies being conducted, highlighting their diverse but complementary nature. We discuss these and give examples for each of them. In our description, we use the word *learners* to refer whether to students or (prospective) teachers who are doing the various kinds of problem posing.

Category 1: To compose a problem without any context or constraint. This first category refers to asking learners to compose a problem without imposing any context or constraints. In short, they need to compose from scratch. This category of problem posing can be linked to what Stoyanova and Ellerton (1996) call a free problem posing situation where students have to formulate new problems in an open situation. For their part, Christou et al. (2005) refer to this kind of problem posing as tasks that require students to pose a problem in general, in free situations. In this category, we find, for example, the work of Ellerton (1986) and of Crespo (2003). In her work, Ellerton asks students to compose a problem that would be difficult, a challenge, for a friend to solve. The students then have a blank card to compose mathematical problems of any kind related to the concepts that they wish. In Crespo's study, elementary students are paired with prospective teachers and correspond one-on-one by sending each other letters. Through this, Crespo aims at placing prospective teachers in an authentic experience of generating problems by asking them to write mathematical problems in their letters for their elementary student. The prospective teachers have no constraints on the type of problem to compose or the mathematical concepts to use.

Category 2: To generate problems from specific constraints. Another category refers to asking learners to generate problems on the basis of specific constraints. Many, if not most, studies conducted on problem posing can be placed in this category. In fact, this category can even be subdivided into three subcategories covering the constraints given to learners for generating problems: (a) generate from a general context; (b) generate from specific constraints; (c) generate from a previously solved problem.

The *generate from a general context* subcategory contains studies that ask learners to generate a problem in a general context. Brown and Walter's (e.g. 2005) *Accepting* perspective of problem posing is an example of this. In the example given above about *Accepting*, the context is the prime numbers, which are introduced to students who then have to generate problems about this mathematical concept without other indications. Work conducted by English (1998) is also of this type, where students have to compose problems in an informal mathematical context free of symbolic representation. For example, she asks students to make up a story problem about what they see in a large photograph of children playing with a set of brightly coloured items. A general mathematical context is then given to learners who have to generate problems from it. The subcategory *generate from specific constraints* refers to studies that ask learners to generate problems within or in relation to specific constraints. Silver (1994) refers to this subcategory as *problem generation*, where the goal is the creation of new problems from a situation prior to any problem solving. This subcategory can also be linked to what Christou and *al.* (2005) call a task that requires students to pose a problem with a given answer, a problem that contains certain information, a question for a problem situation, or a problem that fits a given calculation. Brown and Walter's (e.g. 2005) WIN perspective, as discussed above, takes place in this subcategory as it asks students to generate problems based on a initial mathematical situation using the WIN technique. The WIN technique is seen here as a constraint because it gives insight into the kind of problem students have to generate. Lavy's works (Lavy and Bershadsky, 2003; Lavy and Shriki, 2007), using the WIN technique in class with prospective teachers in a geometry context, is another example of this subcategory. We can also refer to studies of Silver and Cai (1996) and Silver, Mamona-Downs, Leung and Kenney (1996), in which before solving a mathematical task, students are asked to compose three problems that can be solved from the information/data given in an initial problem. When they have composed a new problem based on this one, students are asked to solve eight related problems. The researchers then studied the nature of the composed problems and the relationship between their ability to compose and to solve problems. This kind of problem posing contrasts with the other subcategories because the specific constraints (the technique or the problem) guide the kind of problem that learners would be more likely to compose. The last subcategory, *generate from a previously solved problem*, contains studies asking learners, *after* having solved a specific problem, to create other problems based on this solved problem. The problems then created are modifications of the goals or the conditions of the previously solved problem. Silver et al. (1996) above mentioned study is also in this subcategory, where in another part of their study students have to generate a problem from previously solved ones. Polya's (e.g. 1957) heuristics of the *Looking back* technique (*analogies*, *modifying*, *generalizing-specifying* and *studying variations*) are also examples of this.

Category 3: To transform an initial problem. The third category of problem posing is intricately linked to problem solving strategies, as it contains studies that ask learners to transform an initial problem in order to solve it. This kind of problem posing occurs during the problem solving process, when students are invited, as an efficient solving strategy, to reformulate for themselves the given problem. For example, strategies given to students are to decompose the problem into sub-problems, to simplify or modify the original problem or to solve a related problem. Students use these strategies to achieve one goal: to be able to solve the original problem. The problem posing is then seen as a *means* of solving the given problem. Silver (1994) refers to this category of problem posing as occurring during the process of solving when students must ask themselves "How can I formulate this problem so that it can be solved?" (p. 20). Kilpatrick (1987) mentions that problem posing consists of reformulating an existing problem in order to make it one's own; seeing problem posing (what he calls problem formulating) as an important companion to problem solving. Mason, Burton and Stacey's (1982) *Thinking Mathematically* book explains this approach in detail to help learners solve a problem. In a similar vein, Polya's (1966) video on *Guessing* amply illustrates this category of problem posing. In the video, Polya tells his students that if a problem is too difficult to solve, they should pose easier sub-problems, which could prepare them to solve the bigger problem; examples explored are to consider the problem in 2D instead of 3D, reducing the number of constraints/givens in the problem, and so forth. The aim is that, as they solve these sub-problems, learners gain a better sense of the original problem and prepare themselves for solving it.

The Implicit Perspective: An Epistemological View of Problem Posing

Studies under what we term the *implicit perspective* are less frequently, if ever, accounted for in reviews on problem posing. In this perspective, we integrate studies that conceptualize the problem solving process as events of problem posing. Thus whereas in the first perspective the notion of problem posing was related to *explicit* requests for creating problems through varied contexts, in this second perspective the notion of problem posing happens *implicitly*, without any request, as it defines the activity of problem solving itself. In various ways, work conducted under this lens makes the argument that when students solve problems, they are in fact posing their own problems, as we show below.

Category 1: Problem posing that influences the problem solving path. This category comprises studies that focus on the link between problem posing and problem solving, emphasizing the influence of the posed problems on the solving process. The work of Sevim and Cifarelli (2013) illustrates this. They argue that when solving a problem, a solver creates his/her own goals and purposes. These change as the solver progresses in the solution and also indicate the path of solving that the solver chooses. Armstrong's (2013) work is another example of this, as she records and studies students' questions that arise while they are solving a problem, and which influences the course of the solving. In her work, she looks at the questions that a group of students working together ask themselves when solving a task. For example, students would ask questions like "What is meant by an interval?" "Is it a square root?" or "What if there are x people?" (p. 67), in order to think about the task and arrive at a solution. Each group of students asks different or similar questions, and some groups also ask questions more than once during the same problem solving process. Armstrong made a "tapestry" schema out of this that shows the problem posing path followed by each group when solving their problem. She illustrates that the process used by learners directly influences their problem solving process. Stoyanova and Ellerton (1996) definition of problem posing, "the process by which, on the basis of mathematical experience, students construct personal interpretations of concrete situations and formulate them as meaningful mathematical problems" (p. 518), can be linked to this implicit problem posing. In order to solve a problem, learners formulate for themselves meaningful problems on the basis of their mathematical experience; this is not done as a request or as a strategy for solving, but mainly reflects what they do, their solving processes.

Category 2: Gaps between teachers' and students' task. Researchers like Perrin-Glorian, Robert and Rogalski (see e.g. Perrin-Glorian & Robert, 2005; Robert & Rogalski, 2002; Rogalski, 2003) have also worked along those lines to develop meaning about students' problem solving processes. Like Polya, they have not used the expression *problem posing*, but have focused on students' interpretations of the problems given to them, where they formulate for themselves, they pose, what the problem to be solved is. Rogalski (2003) identified various natures that tasks can assume when presented by teachers in the classroom, all of this happening implicitly during the activity of problem solving. First, the teacher prescribes a task to students, which consists essentially in the formulation of the problem. This *prescribed task* may be directly observed, as it consists of the instructions presented by the teacher to the students. The teacher has expectations about the task that the students have to work on: this is the *expected task*. On the other hand, students do not necessarily work on the teachers' prescribed task, but on one that has been redefined from that prescribed task. The *redefined task*, therefore, represents the student's personal representation of the task; somehow his/her *implicit* posing of the task in his/her own terms. Finally, the *effective task* is the actual one to which the student responds, which is not necessarily identical to the one he/she thinks he/she is responding to; this leads to a dynamical interrelation between the *redefined* and *effective* task. These redefined and effective tasks illustrate the problem that the student actually asks/poses him/herself and intends to solve (again, all of this happening implicitly in the solving process). The studies conducted within this framework focus on the gaps between teachers' expectations and students' mathematical activity in solving problems, their problem posing process.

Category 3: Problem posing versus problem solving. Work in this third category is related to Varela's (1996) epistemological definition of problem posing, which he contrasts with problem solving. For Varela, problem solving implies that problems are already in the world, independent of us, waiting to be solved. Varela explains, on the contrary, that we specify the problems that we encounter through the meanings we make of the world in which we live, leading us to recognize things in specific ways. We do not choose problems that are out there in the world independent of our actions. Rather, we bring problems forth, we pose them: "The most important ability of all living cognition is precisely, to a large extent, to pose the relevant questions that emerge at each moment of our life. They are not predefined but enacted, we bring them forth against a background." (p. 91). The problems that we encounter, the questions that we ask, are thus as much a part of us as they are a part of our environment: they emerge from our interaction with/in it. The problems that we solve are relevant for us as we allow them to be problems. Working in this perspective, René de Cotret (1999) notes that one cannot assert that instructional properties are present in the tasks presented and that these *causally determine* solvers' reactions. As Simmt (2000) explains, it is not tasks that are given to students, but mainly prompts that are taken up by students who themselves create tasks with. Prompts become tasks when students engage with them, when, as Varela would say, they pose them as problems. This posing, as we show in Proulx (2013) about mental mathematics contexts, determines the task solved, hence the strategy developed for it. Students *make* the "wording" or the "prompt" a multiplication task, a ratio task, a function task, an algebra task, and so forth, and solve accordingly, which leads to varied strategies and answers because they often start from "different" posed problems.

In this implicit perspective, students play an important role in what the problem to solve is: not because they have created it, but because a student is always solving his/her own problem, from a given prompt. In this sense it is implicit, that is, it is not an explicitly requested task by someone external to the student (as in the first explicit perspective), but something implicit in the solving process when students engage with the(ir) problem to be solved. In sum, they *implicitly* create a problem in the action of solving the problem; whereas in the first explicit perspective they were explicitly asked to create a problem from various context and data given. Both perspectives and their categories are summarized in Table 1.

Table 1. Summary of Implicit and Explicit Perspectives

Explicit perspective on problem posing (as an explicit request to learners)	**Implicit perspective on problem posing (as defining the problem solving process)**
To compose a problem without any context or constraint	Problem posing that influences the problem solving path
To generate problems from specific constraints	Gaps between teachers' and students' tasks
To transform an initial problem in order to solve it	Problem posing versus problem solving

Final Remarks on these Categorizations of Problem Posing

What do we learn from this? This categorization of work conducted on problem posing is more than a review: it is an extension of the field. By integrating the work under the implicit perspective, which we have seldom encountered in reviews and activities about problem posing (Working Groups, books, Special Issues), we extend what are normally considered as studies in problem posing by opening the way to epistemological considerations about students' mathematical activities. Whereas problem posing as a field is widely known in terms of an activity to plunge students into, as a teaching device or as a strategy for solving problems (see e.g. Voica et al, 2013; Christou et al., 2005), what we have grouped under the implicit perspective is much less known and tackles epistemological issues related to students mathematical activity in itself. Epistemological questions/issues are not new in problem posing work, as some of them can be seen and felt through the work of Stoyanova and Ellerton (1996) and of Kilpatrick (1987), however they oscillate between a view of problem posing as a request on students and as representing students' mathematical activity. The distinction offered here between explicit requests for problem posing and the implicit problem posing activity happening in students' mathematical activity appears fruitful for developing a sharper understanding of what is meant by problem posing and clarifying where one's focus is. As mentioned, this can be felt as a step forward in the direction of Silver's (2013) suggestion for developing finer theoretical frameworks to support studies in problem posing.

REFRAMING URBAN MATHEMATICS EDUCATION: THE SPATIAL POLITICS OF OPPORTUNITY

Erika C. Bullock
University of Memphis
erika.bullock@memphis.edu

Gregory V. Larnell
University of Illinois at Chicago
glarnell@uic.edu

Although equity-oriented discourse is working to move the mathematics education community from achievement-gap rhetoric toward a focus on opportunity gaps, it does not currently recognize the role of space and the politics of space in creating and maintaining opportunity gaps as it relates to mathematics education in urban settings. The purpose of this paper is to engage the task of re-conceptualizing urban mathematics education by proposing a framework for scholarship, policy, and practice. The authors engage scholarship in mathematics education, urban education, critical geography, and urban sociology to substantiate a socio-spatial framework for urban mathematics education, which features a visual schematic that locates mathematics teaching and learning—vis-à-vis a mathematics-instructional triad—within a system of socio-spatial considerations relevant to U.S. urban contexts.

Keywords: Equity and Diversity; Research Methods

An enduring challenge within mathematics education (and in education more broadly) has been to recognize the role that mathematics plays in societal stratification and to address systemic inequities that marginalize populations. “Equity” has been positioned as the key principle for responding to this challenge (National Council of Teachers of Mathematics [NCTM], 2000), and over the last few decades, equity-oriented discourse in mathematics education has developed alongside the emergence of urban mathematics education scholarship. The boundaries between the two domains are difficult to distinguish, thus the two are often conflated or interchanged based on common components related to issues of race, class, power, and status. We argue, however, that contemporary equity discourse has not adequately responded to the particular relationship between the “urban” as a socio-spatial construct and mathematics education. Until these discourses are more clearly framed, neither can fulfill its potential to contribute to the enduring challenge above.

Although we argue that equity and urban mathematics education are separable discourses, we acknowledge that the two are related. Particularly, equity discourse is helping the mathematics education community to move from an achievement gap orientation toward an opportunity gap orientation (Flores, 2007). Considering gaps in opportunity makes room for new analyses of mathematics education related to the ways in which opportunity is constructed within education discourses. In the inaugural issue of the *Journal of Urban Mathematics Education* (*JUME*), Tate (2008) issued a challenge related to conceptualizing urban mathematics education in relation to opportunity:

> The challenge is to build theories and models that realistically reflect how geography and opportunity in mathematics education interact. If this challenge is addressed, the field will be one step closer to making scholarship in urban mathematics education visible. (p. 7)

In a later *JUME* commentary, Rousseau Anderson (2014) returned to the need to consider space in urban mathematics education as “‘place matters’ in the study of urban mathematics education (p. 10). Our aim in this paper is to move further toward recognizing the role of space and the politics of space in creating and maintaining opportunity gaps.

Background

The roots of urban mathematics education as a subdomain of mathematics education extend back at least to efforts during the 1980s (see Tate, 1996), concurrent with the development and publication of the NCTM standards for mathematics curriculum and evaluation (1989) and for mathematics teaching (1991). These developments also coincided with commensurable shifts in research as mathematics education scholarship around the world entered its much-discussed social turn (e.g., Meyer & Secada, 1989; also see Lerman, 2000; Martin & Larnell, 2013; Stinson & Bullock, 2012). For researchers, teachers, policymakers, and education-interested foundations in the United States (e.g., Ford Foundation, National Science Foundation), a crucial new question emerged: How would the then-new vision for school mathematics reform extend to and take shape in urban districts and classrooms (Tate, 2008)? This question remains central in the latest shift to the Common Core State Standards for School Mathematics.

Our aim in this paper is to broaden the discourse in urban mathematics education in ways indicated by Tate's (2008) challenge in the inaugural issue of *JUME*. According to Lou Matthews (2008), *JUME* founding editor-in-chief, the journal was founded "to open up a space in mathematics education that would honor and enrich the work in this domain [i.e., urban mathematics education]" (p. 1). The young journal's growing popularity signals that urban mathematics education has advanced to the point at which we may now begin to evaluate the production of knowledge in this subdomain—and, particularly, the building of "theories and models that realistically reflect how geography and opportunity in mathematics education interact" (p. 7). What has the study of urban mathematics education entailed? What can it become? The purpose of this paper is to take "one step closer" toward addressing these questions and toward new directions for urban mathematics education scholarship and practice.

Overview of the Socio-spatial Framework for Urban Mathematics Education

In the spirit of addressing Tate's challenge (also see Rousseau Anderson, 2014), our objective is to posit a new theoretical framing for scholarship in urban mathematics education—the first of its kind (Figure 1). In this section, we detail the theoretical concepts undergirding the framework. We

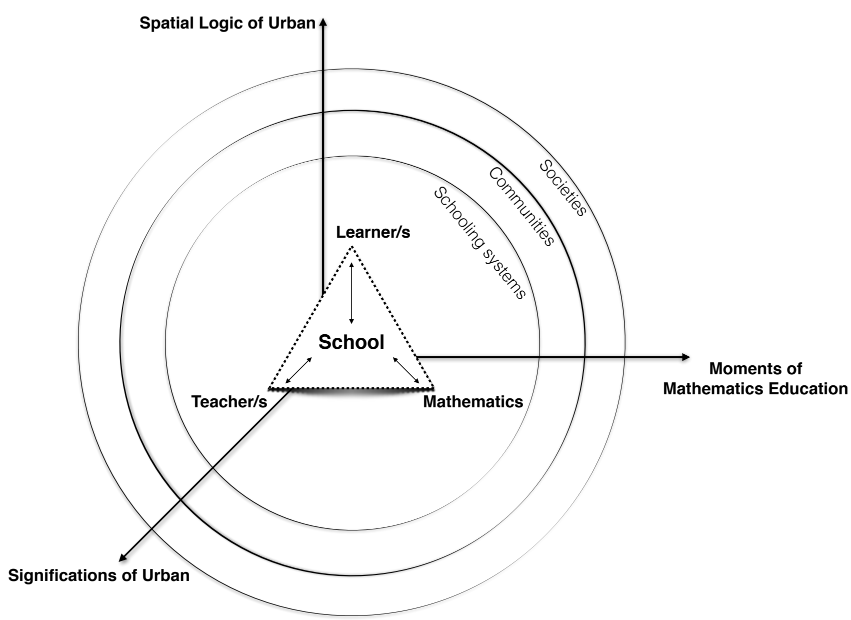

Figure 1. Socio-Spatial Framework for Urban Mathematics Education Scholarship

Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

situate this framing squarely (but not entirely) in mathematics education—using as our central unit of analysis the mathematics-instructional triad of teacher(s), learner(s), and mathematics (Cohen, Raudenbush, & Ball, 2003; NCTM, 1991; Stein, Smith, Henningsen, & Silver, 2009). We also incorporate the various theoretical orientations—e.g., cognitivism/behaviorism, constructivism, sociocultural perspectives—that have emerged amid "moments" of mathematics education during the past century (Stinson & Bullock, 2012). We represent these theory-driven moments of mathematics education scholarship as a dimensional axis that intersects with the socio-spatial elements of the framework.

The NCTM Research Committee (Gutstein et al., 2005) argued that, in order for researchers to advance equity in mathematics education, we must "break with tradition, expand boundaries, and cross into fields outside of mathematics education *and* outside education" (p. 96; emphasis original). In this spirit, we extend beyond mathematics education, looking toward the interdisciplinary areas of urban sociology, critical geography, and urban education scholarship to consider the various forces that influence mathematics teaching and learning in urban spaces as well as the social significations that shape interactions in urban settings. We recognize, however, that the task of defining urban has been an overwhelming challenge across disciplines, and our attempt here is to incorporate what is known inasmuch as we can given what is available to us contemporarily (Milner & Lomotey, 2013).

In recent decades, there has been considerable momentum in the humanities and the social sciences to consider space as a social construction that is integral to social analysis (Arias, 2010). This *spatial turn* renders geographic considerations equal to—and mutually constructed with—temporal and social considerations in the analysis of social phenomena (Warf & Arias, 2009). In many ways, this framework represents a spatial turn within mathematics education research in which temporal (i.e., the Moment of Mathematics Education axis), social (i.e., the Significations of Urban axis), and geographic (i.e., the Spatial Logic of Urban axis) elements are taken together as mutually constitutive of urban mathematics education.

To inform the framework with respect to the social meanings that shape urban mathematics education, we draw on Leonardo and Hunter's (2007) typology of significations that circumscribe urban education (also see Martin & Larnell, 2013). We represent that typology as an axis of the framework that intersects with spatial considerations of urban, drawn from scholarship in critical geography (e.g., Soja, 1980; Thrift, 2003). The coordinate representation is intended to signal a socio-spatial dialectic regarding the urban—that is, that social significations and spatial considerations necessarily intersect "to realistically reflect how [spatial] geography and [social] opportunity in mathematics education interact" (Tate, 2008, p. 7). We then add a third axis to situate the socio-spatial elements in relation to the evolution of mathematics education and the theoretical orientations association with these evolutionary "moments" (Stinson & Bullock, 2012).

Mathematics-instructional triad as the central element of the framework

At the center of our framework are interactions among learners, teachers, and mathematics curriculum (see Figure 2). Not only does this center the processes of formal and informal mathematics teaching and learning, but in terms of the diagrammatic representation of the framework, the triad represents a kind of coordinate point with respect to the social, spatial, and mathematics-education "theory-moment" axes. As such, the framing allows for questions that relate mathematics teaching and learning, social contexts, spatial logic, and the evolution of the mathematics education enterprise (also see Weissglass, 2002).

Spatial logic axis of the framework

Most often, discussions of urban space are connected to population density and physical geography (see Milner, 2012). While these elements contribute to our understanding of urban as a means of geographical classification, they are insufficient in that they do not allow for a nuanced

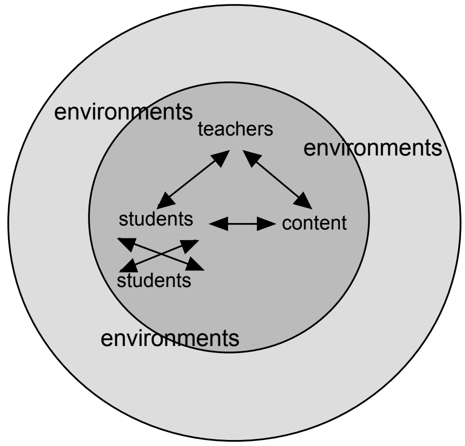

Figure 2. Mathematics-instructional Triad, with Cohen & Ball's (2000) focus on interaction

understanding of space and the non-geographic (i.e., affective) meanings associated therein. To substantiate the spatial aspect of this framing, we draw primarily on human geography and Thrift's (2003) four conceptions of space: (a) empirical-constructing space, or the ways in which space is rendered measurable or objective; (b) interactive-connective space, or the pathways and networks that constitute space; (c) image space, the visual artifacts that we readily associate with space; and (d) place space, or our everyday notion of spaces in which human beings reside (p. 102). These conceptions of space form a spatial logic that is not limited to a geographical sense of urban space and that takes into account meanings associated with space. The strength of articulating four distinctive conceptions of urban allows one to look across their various permutations in ways that provide a nuanced perspective on space.

Social-signification axis of the framework

"Urban" is not simply a geospatial concept; it also carries social and political meanings. Accordingly, urban mathematics education scholarship must engage its social and political dimensions—i.e., relating mathematics teaching and learning to the many ways in which urban can be experienced, influenced, shaped, and contested. Toward offering some conceptual framings, the social-signification axis of our framework includes Leonardo and Hunter's (2007) three significations of urban: urban-as-sophistication (or cosmopolitan space), urban-as-pathological (or urban as "dirty, criminal, and dangerous;" p. 789), and urban-as-authenticity (or the politics of authenticity). This view of urban as more than just physical space also challenges the prevalent use of urban as a proxy descriptor for poor, Black, and Brown populations who inhabit these spaces and disproportionately fall victim to the segregation and concentrated poverty (Darling-Hammond, 2013). Such employment of "urban" ignores the heterogeneity of urban space, its politics, its people, and their experiences (Fischer, 2013).

Theory-Moment Axis of the Framework

Stinson and Bullock (2012) outlined four moments of mathematics education research since its emergence as a research domain. These moments—the process-product moment, interpretivist-constructivist moment, social-turn moment, and socio-political-turn moment—are characterized by particular theoretical orientations—cognitivism, interpretivism/constructivism, sociocultural theories, and theories of power, respectively. These moments are overlapping categorical periods of research, practice, and policy (also see Gutierrez, 2013). These periods have often been indexed by a crisis metaphor (Washington, Torres, Gholson & Martin, 2012).The third axis incorporates these moments and the associated theoretical orientations.

With a third axis in the framing, we attempt to construct what could be called a mathematical-socio-spatial dialectic. That is, we situate the mathematics-instructional triad within the dimensional space of not only the socio-spatial dialectic but also with respect to the ongoing "moments" of mathematics education theory and practice (Stinson & Bullock, 2012; also see Martin & Larnell, 2013). Put differently, the axes represent the intersectionality of geography (or spatiality), social opportunity, and the development of mathematics education, which is what Tate (2008) originally outlined.

Implications: Urban Mathematics Education and Equity

Central to this framework is the understanding that urban mathematics education is a complex domain in its own right. It is *more than just* mathematics education performed with—or on—people who are labeled "urban" based on race and/or class signifiers. Additionally, it is more than just a descriptor for situating traditional or reform-oriented mathematics teaching and learning in certain locales (i.e., the "inner city"). Thus, it is important that we address explicitly the need for a consideration of urban mathematics education that is separate from—yet connected to—prevailing equity discourse in mathematics education. Examining mathematics education in urban spaces through an equity-oriented lens appropriately centers conversations on children of color and their mathematical identities and experiences. However, engagement with the urban in such work is often limited either to contextual descriptors connected to racial demographic and free-and-reduced-lunch data or to situated applications of mathematics curricula or pedagogies in spaces inhabited by people who are largely Black and/or Brown and poor.

As a descriptor in research, "urban" functions as a sort of veil. This veiling allows the researcher to acknowledge race and class in superficial ways that obscure weightier systemic issues related to race and class. This urban-as-veil perspective also frames our collective understanding of urban populations in ways that—perhaps ironically—obscure populations that do not align with notions of urban educational contexts as Black, Brown, and/or poor. The challenge with this veiling is that it allows equity discourse to disengage from the substantive issues in urban education, racism, and classism that inhabit mathematics classrooms and other aspects of the "network of mathematics education practices" (Valero, 2012, p. 374). We propose that this framework for urban mathematics education encourages a more complex understanding of "urban" that attends to the role of place in mathematics education and, additionally, unveils race and class as distinct categories that each warrant significant analysis in their own right.

These examples represent common ways in which equity discourse interacts with the urban in mathematics education. However, these approaches miss possibilities for understanding the implications of place on mathematics teaching-and-learning environments. We propose that engaging the elements of this framework allows equity-oriented mathematics education researchers to remove the urban veil in a way that acknowledges the roles of place, race, and class as distinct and mutually constitutive. Specifically, it aims to position urban mathematics education as a system of connections among mathematics, race, class, power, and the politics of space. This positioning allows mathematics education researchers to explore the interactions between geography and opportunity within a multidimensional framework that acknowledges the political underpinnings of opportunity gaps that equity discourses reveal.

We present findings from an analysis of the Calculus Concept Inventory. Analysis of data from over 1500 students across four institutions indicates that there are deficiencies in the instrument. The analysis showed the data is consistent with a unidimensional model and does not have strong enough reliability for its intended use. This finding emphasizes the need for creating and validating a criterion-referenced concept inventory on differential calculus. We conclude with ideas for such an instrument and its uses.

Introduction and Literature Review

As educators and educational researchers, we seek to develop calculus courses effective in building conceptual understanding in addition to procedural fluency, and continually investigate promising new pedagogical strategies. The Mathematical Association of America recommends that all math courses should build conceptual understanding, "mental connections among mathematical facts, procedures, and ideas" (Hiebert & Grouws, 2007, p. 380) by helping "all students progress in developing analytical, critical reasoning, problem-solving, and communication skills and acquiring mathematical habits of mind" (Barker et al., 2004, p. 13).

Concept inventories have emerged over the past two decades as one way to measure conceptual understanding in STEM education. These inventories intend to assess student understanding of concepts before entering a course addressing those concepts. Thus, students are required to use common sense and prior knowledge to respond to assessment items. After completing a course, the concept inventory can measure gains in conceptual understanding. Therefore, items should avoid using terminology taught in the course to which students have no prior exposure.

The first concept inventory to make a significant impact in the undergraduate education community was the Force Concept Inventory (FCI), written by Hestenes, Wells, & Swackhamer (1992). Despite the fact that most physics professors considered the Inventory questions "too trivial to be informative" (Hestenes et al., 1992, p. 2) at first glance, students did poorly on the test, and comparisons of high-school students with university students showed modest gains between the two. Of the 1,500 high-school students and over 500 university students who took the test, high school students were learning 20%-23% of the previously unknown concepts, and college students at most 32% (Hestenes et al., 1992, p. 6). Through a well-documented process of development and refinement, the test has become an accepted and widely used tool in the physics community, and has led to changes in the methods of instruction for introductory physics.

The FCI paved the way for the broad application of analyzing student conceptual understanding of the basic ideas in a STEM subject area (Hake, 1998, 2007; Hestenes et al., 1992). Concept inventories exist in a variety of scientific disciplines; including physics, chemistry, astronomy, biology, and geoscience (Libarkin, 2008).

More recently, Epstein (2007, 2013) developed the Calculus Concept Inventory (CCI) for introductory calculus. However, there is a lack of peer-reviewed literature on its development or psychometric analysis. Additionally, several recent analyses call into question the ability of the CCI to measure conceptual understanding. One study showed that the current CCI measured no difference in conceptual understanding between students in a conceptually focused class with frequent student group work and those in a traditional lecture based class, even though other measures indicated that a difference existed (Bagley, 2014). While this result may reflect shortcomings of the conceptually focused class, it may also suggest the inadequacy of the CCI.

The concerns with the CCI motivated us to take a deeper look at how it performs for its original purpose. Specifically, we wanted to determine if the CCI measured gains in conceptual knowledge and to investigate its reliability. In this study, we analyze the results on the CCI from over 1500 students at four institutions to determine whether there is evidence that the CCI, in its current form, exhibits the psychometric properties originally suggested by the author, and to suggest appropriate potential modifications or revisions.

Calculus Concept Inventory

Content Validity

The Calculus Concept Inventory (CCI) was developed by a group of seven individuals to measure topics from differential calculus that they believed were basic constructs (Epstein, 2013). The main purpose of the instrument is to measure classroom normalized gains (change in the class average divided by the possible change in the class average) for the purpose of evaluating the impact of teaching techniques on conceptual learning. The developers of the instrument intended the instrument to measure above random chance at the pre-test setting and to avoid “confusing wording” (Epstein, 2013, p. 7). However, a released CCI item uses terminology, including “derivative” and “f’(x)” (Epstein, n.d.), which is not part of the vocabulary of a first-time calculus student. Such items would be confusing to the student and generate responses around random chance for those items. We seek to determine the extent of the use of such terminology to verify that vocabulary issues do not confound results from the CCI.

Internal Structure Validity

The dimensionality of the CCI is unknown. Epstein (2013) states that the instrument has two primary components, related to functions and derivatives, with a third dimension related to limits, ratios, and the continuum. However, the use of a total percent correct to determine normalized gains implies that the instrument measures a single construct evenly distributed over the 22 items. These two proposed structures of the instrument are contradictory and no details regarding the analysis conducted to support the three-component structure exist. A comprehensive analysis of the internal structure of the instrument is thus necessary to determine whether a unidimensional model is appropriate.

Reliability

Epstein (2013) reports that the CCI has an internal consistency reliability 0.7 for Cronbach’s alpha. This level of internal consistency is at the low end of an acceptable range for an instrument designed to measure differences in means between groups of at least 25-50 individuals. However, there is no such standard for internal consistency necessary for comparing the normalized gains of two different groups. In fact, the use of the normalized gain as a measurement parameter is questionable (Wallace & Bailey, 2010). Instead, the similar types of gains can be measured using ability estimates obtained through item response theory models. Therefore, there is a need to use such models to determine the internal consistency reliability of the CCI.

Methods

Content Validity

Since the CCI was designed to measure normalized gains in conceptual knowledge of calculus, it is given as both a pre-test and a post-test. As such, at both of the sittings, the test should measure conceptual understanding, and not include items requiring vocabulary and notation specific to calculus. Otherwise, students who are repeating calculus would likely have higher pretest scores, regardless of their conceptual understanding of calculus, and would thus likely have lower normalized gains, as seen in previous studies (Epstein, 2013). Therefore, we conducted an analysis of the items to determine which items may contain vocabulary and/or notation not included in any of the Common Core State Standards for Mathematics (NGACBP & CCSSO, 2010) that have become accepted as preparation for calculus throughout most of the United States.

Internal Structure Validity

We collected data from approximately 2000 students at four universities at the beginning and the end of a first semester calculus class. We cleaned the data by eliminating subjects with missing data and randomly selecting either a pre-test or post-test for all remaining subjects to avoid dependent samples. This left a sample size of 1792 students with an even distribution of pre-tests and post-tests.

We then used the eigenvalues of the inter-item correlation matrix to determine the expected number of factors related to the instrument, followed by a confirmatory factor analysis based on the predicted number of factors, with a bent toward a unidimensional model. In the eigenvalue analysis, we compared the results from the actual data to results from randomly generated data with the same sample size and with a 20% probability of correct answers, as nearly all of the items on the CCI had five choices.

Reliability

Using the results of the factor analysis, we used an appropriate unidimensional or multidimensional item response theory model to analyze the internal reliability of the instrument and to measure the test information and standard errors for the instrument.

Results

Content Validity

Out of the 22 items on the CCI, nine contained language or notation not included in any standards for courses that are considered prerequisite for calculus. These included the words derivative and concavity, and notation such as f'(x), f''(x), and dy/dx. An additional two items contained language closely related to some precalculus topics; for instance, some students may have exposure to the relationship between velocity and acceleration and the concept of linear approximations. However, these topics are not necessarily included in the courses prior to calculus.

Therefore, the CCI does not satisfy the conditions necessary to measure conceptual understanding for students as they enter a calculus course. However, since all of these language and notation conventions are part of the normal language during the first semester of calculus, including such language on a test at the end of a semester of calculus may measure conceptual understanding. This issue needs to justification by anyone using the standard normalized gains when researching or evaluating first semester calculus courses.

Internal Structure Validity

From the analysis of the eigenvalues from the factor analysis, the CCI has at most two components. Both the first and the second eigenvalue are above the 95% confidence interval for the randomly generated data. However, since the second eigenvalue (1.24) is extremely close to the 95%

confidence interval of the eigenvalue generated by random data 1.1765 +/- 0.04, this second component may or may not actually be present (since a large first eigenvalue will pull up the second eigenvalue).

Question 13	4.228	0.985	0.735	0.060
Question 14	3.386	0.803	0.587	0.055
Question 15	3.735	0.880	0.650	0.058
Question 16	2.928	0.704	0.504	0.052
Question 17	5.619	1.282	0.975	0.065
Question 18	1.535	0.412		
Question 19	3.322	0.790	0.570	0.055
Question 20	3.575	0.849	0.617	0.058
Question 21	3.857	0.917	0.661	0.064
Question 22	3.885	0.913	0.678	0.059

Since the scree plot and eigenvalue analysis favors a unidimensional structure, and since the intended use of the instrument is as a one-dimensional inventory, a one-dimensional confirmatory factor analysis model was used to determine model-data fit. The model had 231 degrees of freedom, $p<0.001$, with the item estimates given below. The fit indices were excellent with a Comparative Fit Index (CFI) of 0.936 and a Root Mean Square Error of Approximation (RMSEA) of 0.024 (Hu & Bentler, 1999). Therefore, a unidimensional model is assumed to fit the data well. One notices that three of the items (1, 11, and 18) have significantly lower estimates that the remaining items. If one removes these items, we maintain the unidimensionality of the instrument (CFI: 0.939 and RMSEA: 0.028) and all estimates are approximately equal values. This enables a more appropriate use of number correct to estimate an individual's ability without having to scale the values of certain items.

Reliability

Since the instrument satisfies the unidimensionality assumption, one, two, or three-parameter models can be used to analyze the data. Since the different items are believed to have different discrimination, only the two and three parameter models were used. The three-parameter model did not have good model-data fit on several of the items loading heavily on the construct with the c parameters for the majority of the items significantly below random chance. Therefore, a two-parameter model was determined to be the best fit of the data and the theoretical construct of the inventory. In the analysis of the two-parameter model, three items demonstrated a weak fit, items 1, 11, and 18. These three items also had low loadings in the factor analysis and so were removed from the analysis to determine if the remaining items have an improved fit. The remaining 19 items had a good fit (-2LL of 37258, $p<0.0001$) with the two parameter model. The standard error for the ability estimate of individuals is extremely high with the lowest value of 0.4128 logits and an average error of 0.7307 logits (see Figure 2). For example, if an individual is at the mean in terms of actual conceptual understanding of calculus, as measured by the CCI, the measured score of the person by the inventory has a 68% chance of being within 0.42 logits of the mean. Therefore, the inventory would only be able to differentiate between samples of means if there is a substantial difference between the samples or the sample size approaches 100 students each. Furthermore, in order to use the logit scores one must first transform the percent correct score into logit scores using the results in Table 2.

Figure 2: Test Information Function and Standard Error

Table 2: Transformation of Scores to Logits

Number Correct	Ability Estimate		Number Correct	Ability Estimate		Number Correct	Ability Estimate
0	-3.05		7	-0.13		14	1.47
1	-2.52		8	0.10		15	1.77
2	-1.75		9	0.31		16	2.13
3	-1.28		10	0.53		17	2.60
4	-0.93		11	0.74		18	3.36
5	-0.63		12	0.97		19	4.00
6	-0.37		13	1.21			

Discussion and Conclusion

The purpose of this study was to assess the degree to which the CCI conforms to certain standards for psychometric properties, including content validity, internal structure validity, and reliability. We conclude that the existing CCI does not conform to accepted standards for educational testing (American Educational Research Association, 2014; DeVellis, 2012). We thus argue that there is a need to create and validate a criterion-referenced concept inventory on differential calculus. Such a concept inventory would significantly impact teaching and learning during the first two years of undergraduate STEM students by providing a resource to measure students' conceptual understanding of differential calculus. The work of Carlson, Madison, and West (2010) in developing the Calculus Concept Readiness instrument could serve as a model and foundation for a differential calculus concept inventory. Such an instrument would be useful for instructors for formative and summative assessment during their calculus courses to improve student learning. Researchers and evaluators to measure growth of student conceptual understanding could also use such an instrument during a first semester calculus course to compare gains of students in classrooms implementing differing instructional techniques.

TOWARD A FRAMEWORK FOR ATTENDING TO REFLEXIVITY IN THE CONTEXT OF CONDUCTING TEACHING EXPERIMENTS

Michael A. Tallman
Oklahoma State University
michael.tallman@okstate.edu

Eric Weber
Oregon State University
weber@onid.orst.edu

In this paper, we present an analytical framework for attending to reflexivity in the context of conducting teaching experiments and rationalize its components by appealing to the constructivist foundations on which the methodology is based. To illustrate the importance and utility of this framework, we discuss our analysis of recent mathematics education literature that has employed the teaching experiment methodology. In so doing, we reveal the extent to which researchers' presentations of their models of students' mathematical thinking and learning reflect these researchers' attention to reflexivity. We conclude by reflecting on the implications of researchers attending to reflexivity in the context of conducting teaching experiments.

Keywords: Research Methods; Design Experiments; Learning Theory; Cognition

Steffe and Thompson's (2000) elaboration of the teaching experiment methodology has gained traction in recent years as a scientific methodology for constructing models of students' mathematical thinking and learning. The teaching experiment methodology is grounded in radical constructivist epistemology, and the methods and procedures that comprise it reveal its constructivist roots. However, the constructivist foundations of both the experimental and analytical aspects of the methodology are often overlooked or, at a minimum, are not explicitly addressed in reports of studies that employ teaching experiments. We have especially noticed that while researchers may strictly adhere to the experimental practices of teaching experiments, the analytical practices essential to the methodology are less rigorously observed. We conjecture that researchers' inattention to particular analytical procedures of teaching experiments derive, at least in part, from their lack of attention to, or understanding of, the constructivist foundation on which these analytical procedures are based. A particularly common analytical practice of teaching experiments that researchers often overlook is the necessity of attending to *reflexivity*, a critical discernment and communication of the researcher's role in the constitution of his or her model of students' mathematical thinking and learning. Accordingly, the aim of the present paper is to present a framework for what it means to attend to reflexivity in the context of conducting teaching experiments. We take the position that justifying the need for attending to reflexivity, and conceptualizing what is involved in doing so, results from an understanding of specific constructivist premises that underlie the teaching experiment methodology.

Teaching Experiment Methodology

The principal aim of a teaching experiment is to construct a model of another's mathematical thinking and learning. It is important to note that such a model is not a direct representation of another's mathematics, but is rather a characterization of plausible conceptual operations from which his or her observable actions may have derived. It is thus the goal of a teaching experiment for a researcher to construct a model of another's mathematics that is viable with the researcher's interpretation of his or her observable behaviors. To achieve this goal, Steffe and Thompson (2000) designed the teaching experiment methodology to provide researchers with opportunities to experience and make sense of students' mathematical learning and reasoning, both in real time and retrospectively.

A teaching experiment, Steffe and Thompson explain, is "primarily an exploratory tool, derived from Piaget's clinical interview and aimed at exploring students' mathematics" (2000, p. 273). While the intent of a clinical interview is to understand students' current knowledge, teaching experiments,

Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

in contrast, are aimed at investigating students' progress over multiple teaching episodes. Teaching experiments, therefore, allow researchers to investigate student learning, which involves the modification of students' current cognitive schemes, as they engage in mathematical activity. In the context of a teaching experiment, the schemes that students construct through spontaneous development are brought forth through exploratory teaching, and the interest of the researcher is to discern how students modify their cognitive schemes as they encounter specific teaching actions.

In a teaching experiment, the researcher generates a major hypothesis at its outset and returns to this major hypothesis retrospectively at the conclusion of the teaching episodes. In addition to testing a main research hypothesis, the researcher continually generates and tests sub-hypotheses within and among teaching episodes. These sub-hypotheses are tentative models of students' mathematical realities that seek to explain the specific actions or utterances the researcher observes. Accordingly, the researcher develops these sub-hypotheses by attending to students' language and actions, and abductively postulating meanings that may lie behind them.

"Teaching" in the context of the teaching experiment methodology is a dynamic interaction informed by an evolving model of students' mathematics. Accordingly, learning how to productively interact with the participant is an instrumental component of conducting a teaching experiment. There are two complimentary types of interaction between the teacher-researcher and the student in a teaching experiment: (1) *responsive and intuitive interaction*, and (2) *analytical interaction*.

In responsive and intuitive interactions, the teacher-researcher is usually not explicitly aware of how or why she acts as she does and the action appears without forethought; the researcher acts without planning the action in advance of the action (Steffe & Thompson, 2000, p. 278).Steffe and Thompson define analytical interaction as "an interaction with students initiated for the purpose of comparing their actions in specific contexts with actions consonant with the hypothesis" (2000, p. 281). Between teaching episodes, the teacher-researcher develops a hypothetical model of student thinking and defines initial goals. The teacher-researcher interacts responsively and intuitively prior to constructing this hypothetical model of student thinking. In the teaching episode that follows the teacher-researcher's development of the hypothetical model of student thinking and the initial goals, he or she interacts in an analytical manner, extending and articulating the initial goals and revising the hypothetical model of student thinking. This process repeats itself until a mature living model of students' mathematics emerges.

Framework for Attending to Reflexivity

Constructing models of students' mathematical thinking and learning in the context of conducting a teaching experiment requires the researcher to construct a model of the mathematical knowledge students bring to the instructional context and to design and/or select mathematical tasks that will allow students to construct the understandings the researcher envisions. Both of these aspects of constructing models of students' mathematical thinking and learning are fashioned by the researcher's theory of learning as well as his or her mathematical knowledge. It is therefore important that the researcher explicate these two aspects of his or her cognition. While conducting a teaching experiment, the researcher engages in responsive and intuitive interaction with students as they engage in the mathematical experiences in order to elicit observable products of their reasoning. Effectively eliciting observable products of students' reasoning requires that the researcher's actions be informed by a model of students' emerging ways of understanding and ways of thinking. The researcher constructs this provisional model through analytical interaction. The researcher's interaction with students plays a significant role in students' behaviors from which the researcher constructs his or her model of the students' mathematical thinking and learning. Explicating the demands of the researcher on constructing models of students' thinking and learning reveals the various ways that attention to reflexivity is warranted in the context of conducting teaching experiments. We illustrate these four areas of attending to reflexivity in Figure 1 and offer concrete recommendations for how a researcher may attend to reflexivity in each of these areas. These recommendations derive principally from the constructivist assertion that researchers do not explain phenomena, rather researchers explain their *interpretation* of phenomena.

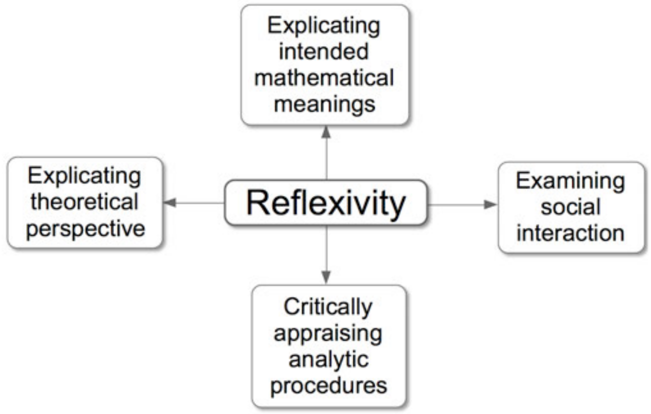

Figure 1. Four Areas of Attending to Reflexivity

Explicating One's Theoretical Perspective

von Glasersfeld (1995) developed the psychological learning theory of radical constructivism as an elaboration of Piaget's genetic epistemology (1971, 1977). The "radical" qualifier emphasizes von Glasersfeld's position that cognitive processing is the foundation of the only reality an organism may come to know. Accordingly, researchers do not have unfettered access to the phenomena they observe and thus must make sense of such phenomena through a variety of interpretative lenses. The purpose of defining and adhering to a theoretical perspective is to attempt to view the world in a systematic and disciplined way that can be communicated. It is important to note that researchers who do not conduct their work by adhering to a particular theoretical orientation have no more direct access to the phenomena they observe than those who do. Not adhering to a particular epistemological stance does not liberate one from perceiving phenomena through a number of subjective interpretative lenses; these lenses are simply not explicit and are thus unavailable to the researcher's conscious awareness. The utility of adhering to an explicit theoretical orientation, then, is that it allows one to become aware of at least some of the interpretative lenses through which he or she views the phenomenon under investigation, thereby giving one agency over these interpretative lenses.

Generally speaking, the role of theory in educational research is to orient and constrain the researcher's attention to those causal variables assumed to be most fundamental to explaining a particular phenomenon, thereby making the complex phenomenon under investigation accessible to empirical study. The theoretical perspective one assumes serves as a lens through which one is able to "control" specific aspects of the phenomenon he or she investigates so as to permit the construction of a viable characterization of a system in a particular state, or of a system undergoing transformation. In other words, researchers adopt theoretical perspectives in an effort to isolate what their theoretical perspective prescribes as the causal variables with the most explanatory power. In this way, our theoretical perspectives impose a set of assumptions and expectations about the phenomena we study that serve "to constrain the types of explanations we give, to frame our conceptions of what needs explaining, and to filter what may be taken as a legitimate problem" (Thompson, 2002, p. 192).

In order for others to ascertain the conceptual origins of a researcher's model of students' mathematical thinking and learning, the researcher must explicate the theoretical suppositions on which her or his work is based. Doing so allows others to discern the interpretive lenses through which the researcher views the phenomenon she studies and to evaluate the researcher's theoretical justification for what she is studying and how she studies it.

Our proposal is for researchers to make explicit their understanding of the background theoretical orientations (e.g., constructivism, sociocultural theory, situated cognition, cognitive information processing theory, embodied cognition) that orients them to framing their work in particular ways, and which conditions how researchers interpret the phenomena they study. It seems to us that, at a minimum, researchers constructing models of students' thinking and learning should address questions like, "What is knowledge? What is learning? What is the process by which one learns? What constitutes evidence of learning? How can one engender learning?" Making explicit one's answers to questions like these allows others to infer aspects of the researcher's role in the constitution of his or her model of students' mathematical thinking and learning.

Explicating Mathematical Meanings

As previously emphasized, a core consideration of conducting a teaching experiment is constructing models of students' initial and emerging mathematical knowledge. In a teaching experiment the researcher interprets what students say and do through the lens of his or her mathematical understandings and creates inferences about students' knowledge through those interpretations. It is in this way that one's own mathematical knowledge very much constitutes an interpretative framework. It is therefore important that a researcher specify what it means to understand the mathematical concept for which he or she is attempting to model students' understandings and to anticipate a multiplicity of ways of understanding this idea. Doing so allows the researcher to expand his or her mathematical interpretative lens so as to accommodate for a variety of students' observable actions in order to construct a viable model of students' mathematical thinking and learning.

Steffe and Thompson (2000) note that the goal of teaching experiments is not that students will come to see an idea as the researcher or teacher does. Instead, it is important that a researcher's model of students' learning represent a reasonable development of a student's thinking given his or her initial mathematical knowledge. At this stage, the researcher might consider a number of questions to explore these issues:

- What is my understanding of the idea that is the focus of the teaching experiment?
- In what way do I intend students understand this idea?
- What understandings do I assume students have at the onset of the teaching experiment? In what ways do I expect these initial understandings to support or inhibit the students' learning the idea that is the focus of the teaching experiment?
- What are the principles on which my design of the activities within the teaching experiment is based?
- How do I anticipate the activities I have developed will support students in constructing the meanings I intend?

Consideration of these questions allows the researcher to expand the interpretative lens through which he or she views the students' mathematics as well as recognize important mathematical understandings that might be surprising or different from his or her own. Addressing these questions also pushes the researcher to articulate the understandings he or she assumes students have at the beginning of the teaching experiment. By documenting these issues during the design of a teaching experiment (often prior to working with students) the researcher creates a record of his or her initial hypotheses. These hypotheses later serve as a means to consider how the researcher's ways of thinking changed in tandem throughout the teaching experiment with the students' mathematical thinking.

Critical Examination of Social Interaction

To suggest that researchers' examination of the social interaction between themselves and the students is an important aspect of attending to reflexivity in the context of conducting a teaching experiment is to suppose that developments in students' knowledge, and thus the models of students' learning that researchers construct to account for such developments, are conditioned by social interaction. We must therefore explain how a researcher's construction of a model of students' mathematical thinking and learning is fashioned by the social interaction that occurs between a researcher and students during the teaching experiment episodes.

From a constructivist perspective, an individual's enacted knowledge is fashioned by his or her understanding of the stimuli inherent to a particular environmental context—stimuli that are often mediated by social interaction. Accordingly, the model of students' mathematical thinking and learning a researcher constructs in the context of a teaching experiment is very much influenced by the social interaction that conditions the evocation of students' mathematical knowledge. Consistent with our recommendation for researchers to explicate their theoretical orientation, we now turn to providing a justification, grounded in constructivist epistemology, for the claim that students' knowledge, and thus the model a researcher constructs to account for its development, is fashioned by the social interaction that occurs in the context of a teaching experiment.

The evocation of specific knowledge is contingent upon an individual interpreting stimuli that activate particular cognitive schemes. In other words, certain knowledge is not made manifest until an individual interprets a certain stimulus in such a way that his or her construction of the stimulus serves as a cue for the enactment of a particular cognitive scheme or a network of related schemes. Therefore, while many believe knowledge is invariantly accessible across time and space, we consider knowledge to be the set of one's cognitive schemes that may become operational in the space of stimuli in which the individual is situated that may enact these schemes. Accordingly, one's ways of perceiving his or her environmental context constitutes a space of stimuli that maintain the potential to make a subset of one's knowledge operational. An individual's knowledge, then, can be thought of as the set of cognitive schemes that *may* become enacted as a consequence of the individual's interpretation of the stimuli inherent to a given environmental context. It is therefore appropriate to say that enacted knowledge is conditioned by the individual's interpretation of his or her environmental context. This is not to suggest that knowledge resides external to the knower since individuals *interpret* and *appraise* their environmental context—interpretations and appraisals that inform the knowledge one employs. To speak of enacted knowledge, then, is to speak of the cognitive schemes that become operational upon one's interpretation of stimuli in a given environmental context that serve to activate such cognitive schemes.

Given our view that knowledge is conditioned by an individual's interpretation of his or her environmental context, we contend that the observable actions students demonstrate in the context of a teaching experiment derive from enacted knowledge that is influenced by their interpretation of their interaction with the researcher. What students make of the researcher's language and actions constitute environmental stimuli that may support or inhibit specific cognitive schemes from being activated. For example, if a student interprets a researcher's questioning as suggesting that the researcher simply wants the student to recite the correct answer, the student may be disinclined to engage in sustained reasoning and sense making. We have ourselves observed students demonstrating very different mathematical knowledge after simply switching the interviewer in a teaching experiment session or task-based clinical interview (cf. Thompson & Thompson 1994). For this reason, it is important for a researcher to discern how students perceive his or her language and actions.

To this end, there are a couple of specific practices to consider. Regularly asking students to verbalize their interpretation of the researcher's questions and statements allows one to obtain artifacts of students' image of their social interaction with the researcher. For instance, asking students questions such as, "What is your understanding of what I just said?" and "Can you tell me in your own words what am I asking you to do?" allows the researcher to gain insight into how students are interpreting their interaction with the researcher. Discerning how a researcher's instructional actions support students in attaining the understandings that the researcher seeks to promote is an essential to constructing viable models of students' mathematical thinking and learning. It is important at this point to reiterate that a researcher's instructional actions do not influence students' thinking. Rather, students' *interpretation* of a researcher's instructional actions influence students' thinking. It is for this reason that, in addition to attempting to elicit observable products of students' reasoning, researchers should consistently attempt to provide occasions for the students to convey their interpretation of the researcher's language and actions.

Critical Examination of Data Analysis

While conducting a teaching experiment, the model a researcher constructs of students' emerging mathematical knowledge is fashioned by his or her ways of perceiving and conceiving students' observable behaviors. Mason's (2002) observation eloquently summarizes this point: "what we learn from an observation is something about the researcher, as well as, perhaps, something about the phenomenon" (p. 181). It is therefore imperative for researchers to document and explicate the decisions and interpretations they make throughout their construction of a model of student's mathematical thinking and learning, and to detail the evolution of this model throughout the research process.

While conducting a teaching experiment, data analysis proceeds in a cyclic fashion whereby the researcher continually generates and refines hypotheses until a stable and viable inductively-derived theory regarding the process by which students construct a desirable understanding of some mathematical idea emerges. Refining provisional hypotheses requires purposeful data collection informed by ongoing analysis. Thus, a hallmark of the teaching experiment methodology is the reciprocal relationship between data collection and analysis; that is, while constructing models of students' mathematical thinking and learning, the data a researcher collects influences the hypotheses he or she constructs, and the hypotheses a researcher constructs informs subsequent data collection. Hence, the boundary between data collection and analysis is necessarily blurred when one conducts a teaching experiment. For this reason it is important for researchers to critically examine how they interpret data during ongoing analysis so that they may ascertain their role on subsequent data collection and, ultimately, on the model of students' mathematical thinking and learning they construct.

Researchers' attention to the role of their interpretation of data on the construction of their model of the process by which students may understand a particular mathematics concept not only clarifies the phenomenon under investigation but also details researchers interaction with the phenomenon. Researchers' documenting their decisions and interpretations during ongoing analysis is important because it produces a form of data about their interaction with students that they can then use in subsequent analyses to bring into conscious awareness the ways in which their interaction with the subject informed their interpretation of students' language and actions.

To discern the role of one's interpretation of data on the model one constructs to account for students' mathematical thinking and learning, a researcher may consider creating artifacts of his or her thinking during ongoing analysis in the form of audio recordings or written memos that focus on the following:

1. Explicating hypothetical conceptual operations that may explain the researcher's interpretation of the students' language and actions throughout testing the viability of an emerging model of students' thinking and learning;

2. Identifying students' specific utterances and actions that contributed to the researcher's construction of these hypothetical conceptual operations;
3. Explaining how the researcher interpreted these utterances and actions so as to make their contribution to his or her model of the students' conceptual operations explicit;
4. Justifying the researcher's instructional actions throughout implementing the instructional sequence and describing his or her interpretation of students' responses to these instructional actions.

It is clear that a researcher's responses to foci (2), (3), and (4) constitute a data set that he or she may retrospectively analyze for purpose of providing insight into the conceptual origins of his or her model of students' mathematical thinking and learning. This data set comprises a record of a researcher's interpretation of the primary data, and the inferences the researcher drew from this data, throughout ongoing and post analysis. One's retrospective analysis of these analytical artifacts is in the service of elaborating a chronology, presented in narrative form, of the development of his or her model of students' thinking and learning by explicating the interactional, institutional, emotional, discursive, theoretical, epistemological, and ontological influences that contributed to its construction (Mauthner & Doucet, 2003). This chronology allows a researcher to present his or her model of student's thinking and learning not just as a product but also as a process, and not by an impersonal machine but by a researcher abounding with subjective interpretative lenses.

Teaching Experiment Literature Analysis

To examine the utility of the analytical framework presented earlier, we examined nineteen of the most highly cited studies in mathematics education that employed a teaching experiment methodology, beginning two years after Steffe & Thompson's (2000) work was published. These articles came from all of the top journals in mathematics education, and covered a wide variety of mathematical topics. We constructed a coding scheme, the components of which corresponded to the four domains of our framework for attending to reflexivity. In our initial coding, we found that less than half (8/19) of these studies met the "explicating mathematical meanings" criterion; just over half (11/19) clearly identified a theoretical perspective; most (18/19) examined social interaction in some way; and roughly half critically examined the data analysis procedures (11/19). While this analysis is in its initial stages, it clearly illustrates important role these components of our framework play in the highest quality studies in our field, yet suggests that there are ways in which the analytical practices of the teaching experiment studies could be expanded. We also recognize that in some cases, the limitations of a journal space and the review process shape the focus of each paper. Yet we think it is important that the field begin to critically appraise what elements must be present in the presentation of results based on a teaching experiment and to include the four components we have presented in this paper.

Conclusion

In this paper, we have proposed four ways in which researchers may attend to reflexivity in the process of conducting teaching experiments in mathematics education. A reviewer of a previous version of this manuscript suggested that each of the four domains of reflexivity we discuss appear as analytical recommendations elsewhere. We respond by noting that such recommendations have not been rationalized with an appeal to the foundational theoretical premises on which specific qualitative methodologies are based. Such rationalizations are essential to supporting researchers in observing the analytical practices that comprise attention to reflexivity in non-superficial ways. It is for this reason that we consider the present paper a contribution, and encourage other researchers to explicate what it means to attend to reflexivity in the context of other qualitative methodologies informed by other theoretical orientations.

Attending to reflexivity is an essential component of the teaching experiment methodology and involves researchers in a systematic and disciplined investigation of how their interpretations and actions influence the models and theories they construct to explain students' mathematical thinking and learning. The recommendations we outlined in this paper assist researchers in becoming consciously aware of at least some of the subjective interpretative lenses through which they perceive the phenomena they study, thereby affording researchers agency over these interpretative lenses. When researchers bring into conscious awareness the lenses through which they make sense of data, they are positioned to communicate the products of their research in way that reveals that their results and conclusions are not about a particular phenomenon, but are instead about their *interpretation* of the phenomenon. Communicating the products of one's research in this way lends a transparency to the research process, thereby inviting others to scrutinize the origins of the models and theories presented in the literature, thereby fulfilling one of the necessary conditions for a scientific enterprise.

Although lecture is the traditional method of university mathematics instruction, there has been little empirical research that describes the structure of lectures. In this paper, we apply ideas from narrative analysis to an upper-level mathematics lecture. We develop a framework that enables us to conceptualize the lecture as consisting of collections of narratives, to identify connections between the narratives, and to use the narrative structure to identify key features of the lecture. By looking at repetitions of the mathematical concepts across the narratives, graph theory tools provide a means of examining the structure of the lecture. The analysis highlights the demands that students may face to understand the connections between the various mathematical ideas that the instructor introduces.

Keywords: Post-Secondary Education; Research Methods

Lecture is the traditional method of university mathematics instruction. Although there have been a few attempts to describe these lectures (e.g., Dreyfus, 1991), Speer, Smith, and Horvath (2010) noted that, due to the dearth of empirical studies, most of our beliefs about the structure of lectures are based on popular opinion or personal experience.

In general, we view mathematics lectures as consisting of instantiations of mathematical entities (i.e., objects, concepts, and symbols) in service of enacting and modeling broader mathematical processes (such as conjecturing, representing, and justifying) and habits of mind (e.g., looking for patterns). The goal of the current study is to create and use a framework based on narrative analysis to analyze a lecture, identify and describe the various processes and habits of mind that are modeled by the instructor, illustrate the ways the mathematical entities evolve and transform over the course of the lecture, and describe the ways in which the entities and processes are connected to each other.

Theoretical Framework

Narrative analysis, a common analytical technique in literary theory (e.g., Bal, 2009; Holley & Coylar, 2012), considers the sequencing of the elements of the text and how initial elements influence and shape later events (Holley & Coylar, 2012) and focuses on the evolving relationship between characters. Several researchers have described the close relationship between mathematics texts and narratives (e.g., Netz, 2005), and others have directly applied concepts from narrative analysis to analyze aspects of mathematical texts (e.g., de Freitas, 2012; Dietiker, 2012; Andrà, 2013).

Although there are numerous definitions of what a narrative is, they commonly attend to the temporal ordering of events, the way in which these events are connected, and the meaning that is ascribed to the sequence of events by a particular audience(see, e.g., Czarniawska, 2004; Reissman, 2005). We adopt the perspective of Holley and Colyar (2009), who identify narratives as texts in which a reader or observer can identify events, characters, and a plot—and sees connections between the events of the narrative.

Event structure

Bal (2009) describes the interrelated ideas of event, story, and fabula: The narrative text conveys events—"transition[s] from one state to another state" (p. 6); the sequence of events in the text make up the story; and the fabula is the "series of logically and chronologically related events that are caused or experienced by actors" (p. 5). Dietiker (2012) adapted these ideas to apply to mathematical texts:

- A *mathematical event* is "a transition from one mathematical state to another" (p. 15), such as instantiating a mathematical object, creating a representation, or making a conjecture.
- A *mathematical story* is "the [temporal] sequence of events encountered and experienced by a reader throughout a mathematics text" (p. 15).
- The *mathematical fabula* is "a reader's reorganization of the logic around how certain mathematical ideas support or connect the meaning of other mathematical ideas" (p. 16).

Dietiker (2013) thus conceptualizes a mathematical text as a narrative through the lens of comparing the mathematical story and fabula. While the former describes the chronological sequence in which an instructor presents mathematical concepts, the latter describes the logical relationships between the concepts.

Mathematical Characters

In the previous research on mathematical narratives, there has not been a consensus on what constitutes a character (e.g., Dietiker, 2013; Andrà, 2013; de Freitas, 2012). We describe *characters* in a mathematics lecture as including (but not limited to) the mathematical objects and concepts that the instructor instantiates that play a role in the story; these objects can be either general (e.g., the concept of an equivalence class) or specific (e.g., "the equivalence class of 3"). A character is identified by both the underlying concept and its representation (e.g., "the integer a" and "the integer b" are different characters).

Mathematical plot

The plot of a narrative consists of the meaningful connections between the events and informs the construction of a fabula (Polkinghorne, 1988). We define the *plot* of a mathematics narrative to be a description of the way a mathematical process or habit of mind is applied to a collection of mathematical objects or concepts. For example, in the lecture described here, the instructor used integers to illustrate a property of a specific equivalence relation, and then used this example to explain properties of equivalence relations in general. We can describe this process using the habit of mind "articulating a generalization using mathematical language" (Mark, Cuoco, Goldenberg & Sword, 2010).

Identifying Narratives in Mathematics Lectures

Boundaries of narratives. According to Labov (1972), a narrative includes, at a minimum, a sequence of two temporally ordered clauses. The process of identifying the "boundaries" of narratives—where the story begins and ends—can be nontrivial. To address this for the case of mathematics lectures, we identify the initiation and conclusion of a narrative by a shift in the presented content or mode of operation of the class, the use of board space, or natural language speech cues (e.g., the instructor saying "Now…" or "Let's consider…").

Identifying plot and characters. The plot and characters are not found "neatly packaged as such by the narrator" (Emden, 1998, p. 35). Rather, plots and characters are identified through a "tacking procedure" (Polkinghorne, 1988, p. 19) or a process of abduction (Czarniawska, 2004). This begins with the proposal of a potential plot and characters, and then these are compared with the events of the story to see how well they provide a coherent theme.

Framing and embedded narratives. In some cases, narratives are contained within other narratives and function as events within the containing narrative. This can be described by the ideas of *framing narratives* and *embedded narratives*, which describe a hierarchical relationship between two narratives. Following Ryan (1991) and Palmer (2004), we describe the role of a framing narrative as providing a context for its embedded narratives. The plot of the framing narrative provides coherence and focus for the plots of the embedded narratives; thus, the framing narrative influences the way we might read (or observe) an embedded narrative. Conversely, an embedded narrative typically serves as an event in a framing narrative.

Logical connections between events. Although a fabula must be consistent with the plot of a narrative, as Dietiker (2012) notes, "there are many deductive lines of reasoning that can lead to the same conclusion" (p. 16). From a broad perspective, we view two narratives or events as connected when one mathematically builds upon the other. Typical plots of a mathematical narrative include defining and redefining, constructing patterns, and forming and verifying conjectures; such plots may intuitively establish mathematical connections with other narratives by applying these mathematical processes to characters shared between two narratives. Thus, we attempt to capture the idea of mathematical building from one narrative to another by saying that narrative A *connects* to narrative B if a character in narrative B is first formally defined or instantiated in narrative A. Using this definition, the two narratives are connected if the plot of B involves mathematical processes that are applied to the same mathematical objects and concepts that are introduced in the plot of A. These logical connections form the basis for identifying a fabula for a narrative.

Methods

Data Collection

The lectures were taken from a standard junior-level abstract algebra course at a large university in the northeastern United States. The instructor was a tenured professor with a research focus in algebra; he had previously taught the course numerous times. We selected four lectures from the beginning, middle, and near the end of the semester and included instances of presenting definitions, examples, theorems and proofs.

A member of the research team attended each of the lectures and took notes on the instructor's speech and writing. Each lecture was video-recorded; we transcribed the instructor's speech verbatim from the recorded video and used the video to check the accuracy of the researchers' notes. For the analysis presented here, we selected a 45-minute excerpt from one of the lectures; this portion of the lecture included instances of definitions, examples, theorems, and proofs, and the instructor's presentation style was similar to the other lectures. Thus, we view this portion of the lecture as representative of the entire corpus of data.

Identifying Narratives and Plots

To identify characters in the lecture, we began by looking for instances where the instructor instantiated a mathematical object or concept, using the instructor's gestures, speech, and writing to inform this identification.

In order to identify potential framing narratives, we employed a "top-down" approach by identifying a coherent, meaningful plot and its constituent characters. We read the transcript of the lecture holistically and identified broad themes along with the mathematical objects, characters, and representations that were the primary focus of these themes. To identify potential embedded narratives, we employed a "bottom-up" approach by identifying sequential clauses that, when taken together, appeared to describe or apply a mathematical process to a set of characters.

To identify potential plots from these themes and characters, we looked for mathematical processes and habits of mind that the instructor employed, as well as definitions, theorems, and processes that typically play an important role in an abstract algebra class and might serve as a focal point for processes and habits of mind. Then, we worked abductively by identifying the characters and events and then revising the proposed plots so that they provided coherence to the chronologically related elements.

Results and Analysis

Embedded Narratives

The primary focus of our analysis is the collection of framing narratives in the lecture. Consequently, we present here only a summary of the plots of the embedded narratives and other events of the framing narratives, as shown in Table 1.

Table 1: Embedded Narratives

Narrative Number	Description of Plot or Events
Framing Event 0	The instructor identifies the "goals" for the lecture and provides motivation for each goal: examining equivalence relations and introducing the idea of equivalence classes.
1	The instructor recalls and summarizes a narrative from a previous class: "R4" (i.e. for $a,b \in \mathbb{Z}$, $a \sim b$ if $\|a\|=\|b\|$) is an equivalence relation
2	The instructor starts to construct an alternative method for representing an equivalence relation and applies it to the R4 equivalence relation: The set of integers is represented by a large circle; each integer is represented by a labeled dot inside the circle; and a line is drawn between two dots when the corresponding integers are equivalent under ~.
3	The instructor poses the question: Can there be a triangle (i.e. three distinct dots that are all connected to each other) in the dot-and-line diagram?
4	The instructor poses and answers the question: Can there be line segments (i.e. three distinct dots where one dot is connected to the other two) in the dot-and-line diagram?
Framing Event1	The instructor describes R4 as relating pairs of numbers
Framing Event2	The instructor describes motivation for introducing the idea of an equivalence class.
5	The instructor elaborates the dot-and-line diagram by introducing "loops"
6	The instructor poses and answers the question: Does introducing "loops" violate the "no line segments" condition?
Framing Event3	The instructor describes additional motivation for introducing the idea of an equivalence class
7	The instructor generalizes from a "concrete" equivalence relation to an abstract one by translating the dot-and-line diagram for R4 into a dot-and-line diagram for an "abstract" equivalence relation

Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

Framing Event4	The instructor presents a general, formal definition of equivalence class
8	The instructor generalizes from the previous examples to create a precise mathematical description of equivalence classes for R4
9	The instructor challenges his previous work and works to make more precise his definition of equivalence classes. He poses and answers the question: Are equivalence classes well defined?
10	The instructor poses and answers the question: Are there any equivalence classes under R4 with a single element?
11	The instructor conjectures that [3]=[-3] under R4 (this example is subsequently generalized to all integers). He then tests this conjecture, setting up a proof by contradiction by asking whether [3]≠[-3].
12	The instructor conjectures and proves that [*a*]=[-*a*] for any integer *a* under the equivalence relation R4
13	The instructor conjectures and then sets up a proof that, for integers *a* and *b*, if *a*~*b* then [*a*]=[*b*] under the equivalence relation R4

Framing Narratives

At the beginning of the class, the instructor described the "goals" he had for the day and wrote them on the board: Identifying general properties of equivalence relations, introducing the idea of an equivalence class, and identifying general properties of equivalence classes. Based on this, as well as a holistic reading of the transcript, we identified the three framing narratives as shown in Table 2.

Table 2: Framing Narratives

Framing Narrative	Plot
A	Creating and refining an alternative representation: The instructor develops a diagram for representing a particular equivalence relation
B	The instructor generalizes from a "concrete" example to develop the concept of an equivalence class and construct a precise, abstract definition.
C	The instructor conjectures and then proves that two equivalence classes that share an element are equal

Connections Between Narratives

Figure 1 shows the connections between the various embedded narratives and other events in the lecture; the shape of each vertex indicates the framing narrative of which it was a part, as shown in

Figure 2. In the graph drawing, each vertex corresponds to an embedded narrative or a non-narrative event, labeled with the corresponding number from Table 1. The edges between the vertices

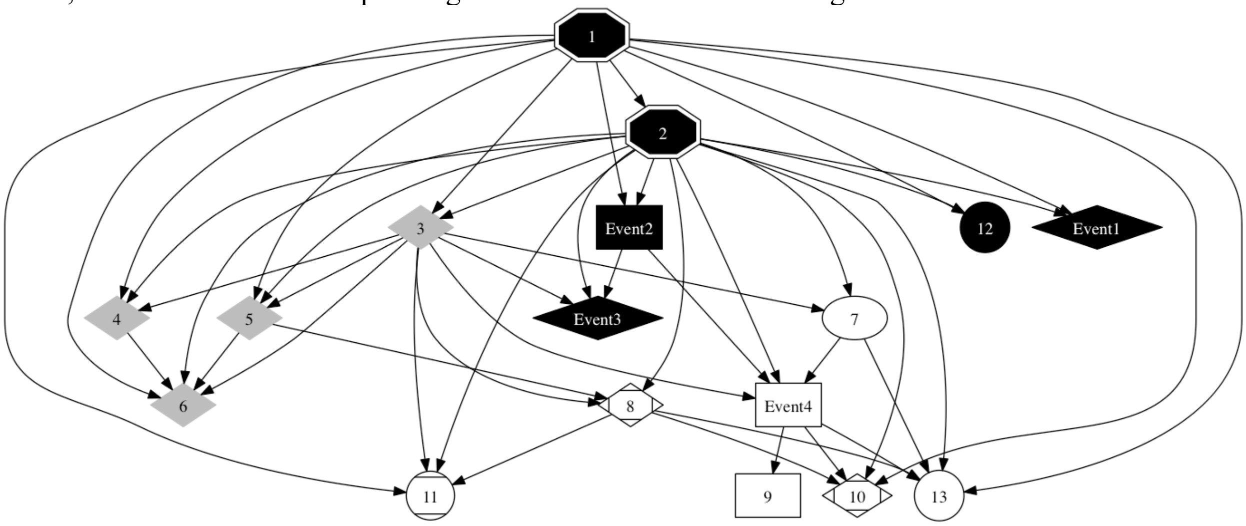

Figure 1: Diagram of Connections Between Embedded Narratives and Events

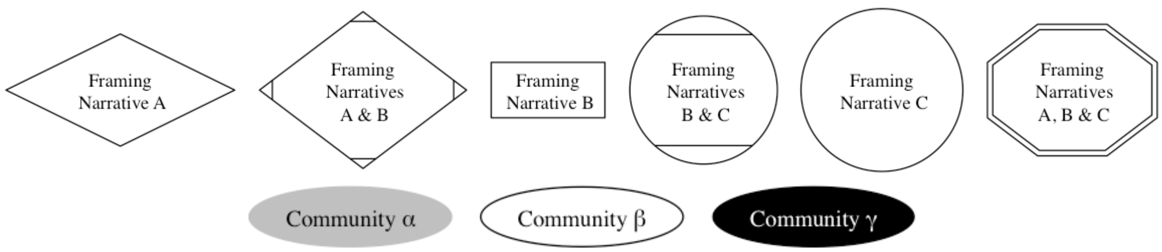

Figure 2: Legend For the Diagram of Connections

represent the connections, and the connection X ➔ Y indicates Y includes characters that were introduced in X.

Structure of the Graph

There are numerous methods for analyzing the graph to identify structural aspects of the lecture. One such method is to identify the *community structure* of the graph; this partitions the graph so that the collection of narratives in each subgraph is relatively densely connected but the connections between the subgraphs are relatively sparse. Using a modularity maximization algorithm, the graph in Figure 1 can be split into the three communities, which are indicated by the shading of the vertices as indicated in Figure 2. There is a close alignment between the communities and framing narratives, which suggests that each framing narrative has relatively dense internal connections and, consequently, relatively strong internal coherence

The graph also displays how "closely related" various pairs of embedded narratives are—i.e., how directly the characters introduced in one narrative are included in a subsequent narrative. This can by identified by analyzing the various paths between vertices. For example, fully understanding the plot of EN10 indirectly required an understanding the characters in embedded narratives 8, 5, 4, and 3 and the relationship between these characters. This "chaining" is reflected in the length of the directed path between embedded narratives 3 and 10.

Another aspect of the lecture highlighted by the graph-theoretic structure is the "centrality" of various embedded narratives, which reveals their narrative significance. There are numerous types of graph-theoretic centrality measures that can be used. For example, the *pagerank centrality* of a vertex measures the number of connections from other vertices and gives a higher weight to connections from other highly connected vertices (Brin & Page, 1998). A narrative with high pagerank centrality has numerous direct and indirect connections to previous narratives; it integrates characters from numerous other narratives and is likely to be culmination of many paths through the graph of embedded narratives. Embedded narratives 6 and 13 had the largest page rank centrality. Both of these narratives integrated the characters from numerous other narratives: EN6 combined R4, the dot-and-line diagram, and the idea of follow-on lines to refine the diagram; EN13 drew upon most of the mathematical objects in the lecture to prove a conjecture about the equality of equivalence classes.

Discussion

In contrast to the common notion of lectures as consisting of formal sequences of definitions, theorems, proofs, and applications (Dreyfus, 1991), the results described here suggest that mathematics lectures may have a significantly more complex structure.

We hypothesize that thinking about parts of a lecture in terms of plots and characters is useful for researchers to assist in identifying the main mathematical ideas of the lecture and the different ways that those ideas may be connected and built upon by the various mathematical objects and concepts. Identifying elements of embedded and framing narratives—including the characters, plots, complications, and resolutions—enables us to describe the temporal development of the important mathematical ideas in the lecture.

In addition to being useful for researchers, identifying the plots and connections between the narratives can help us better understand the challenges that might arise in learning from a lecture. In particular, the complexity of the narrative structure and the numerous habits of mind that are used in the plots suggest reasons why students—who might not possess these habits of mind or be able to quickly identify the structure—might struggle to make sense of a lecture.

Constructing meaning from a text by viewing it as a narrative is a different process than employing a logico-scientific mode of knowing. From a narrative perspective, events are given meaning through abduction; the only way to identify the plot or structural elements of a narrative is by "negotiating and renegotiating meanings by the mediation of narrative interpretation" (Bruner, 1990, p. 67). Consequently apprehending the plot of a framing narrative can involve a complex process in which students must identify the multiple roles that can be played by each embedded narrative, identify potential orderings of these roles, and understand how they fit together.

The analysis of the connections between the embedded narratives revealed several important aspects of the lecture. First, the community structure analysis showed that each framing narrative contained relatively dense connections. If these connections are not made explicit, it may be challenging for students to identify the ways in which the embedded narratives are related to each other. Conversely, these connections may also support sense-making: If students can understand aspects of one narrative, then they can use its connections to develop an understanding of the connected narratives or to identify the plot of a framing narrative. In addition to this structure analysis, the centrality analysis can reveal the ways narratives synthesize ideas, serve as key focal points, and incorporate characters that play significant roles in the narratives.

As long as lecture remains a common form of mathematics instruction, more research is needed to describe lectures themselves as well as the ways students interpret and learn from lectures. The data reported here come from a case study and may not necessarily be representative of all mathematics classes—or even all abstract algebra classes. In order to more completely describe mathematics lectures, it will be essential to gather a larger corpus of data—both more classes from a single instructor, and lectures from other instructors. It will also be essential to collect data on students' interpretations of lectures and to determine what students learn from each lecture and how the narrative structure—and their interpretation of the structure—relates to this learning.

This paper describes a tool developed by the researchers and used to evaluate preservice teachers' professional noticing responses to prompts posed after viewing a video interview of a child solving an arithmetic task. The tool, a series of flowcharts, was designed to increase scoring efficiency and reliability across a team of six raters. Inter-rater reliability increased from 60% to 83% after implementation of the flowchart-scoring tool. This measurement tool and process has the potential to inform assessment strategies in the context of professional noticing frameworks. Streamlining the tool and challenges to generalizability will be addressed.

Keywords: Teacher Education-Preservice; Teacher Knowledge; Assessment and Evaluation

Introduction

Preparing teachers to practice responsive teaching is an enduring challenge of teacher educators. Identifying, measuring, and evaluating responsive teaching practices add to the challenge. Professional noticing has been identified in the literature as a promising practice to provide a foundation for teachers to become responsive practitioners (Goldsmith & Seago, 2011; Santagata, 2011; van Es & Sherin, 2002). This paper describes an innovative tool developed by the researchers and used to evaluate preservice elementary teachers' (PSETs') responses to prompts posed after viewing a video-based measure of professional noticing.

The assessment measured PSETs' responses pre- and post- to a researcher developed instructional module based on professional noticing (Jacobs, Lamb, & Philipp, 2010) within the context of the Stages of Early Arithmetic Learning (SEAL) trajectory (Steffe, Cobb, & von Glasersfeld, 1988). The module decomposes professional noticing into its three interrelated skills, *attending, interpreting, and deciding*, that allows for the skills to be progressively nested and intentionally developed (Boerst, Sleep, Ball, & Bass, 2011). Our results indicate that preservice elementary teachers (PSETs) can grow significantly in the three skills of professional noticing (Schack, Fisher, Thomas, Eisenhardt, Tassell, & Yoder, 2013).

Theoretical Framework

Teacher Professional Noticing

Following Jacobs, Lamb, and Philipp's 2010 study, and the publication of Sherin, Jacobs, and Philipp's (2011) seminal book, *Mathematics Teacher Noticing*, the construct of teacher professional noticing has garnered the attention of researchers and practitioners alike. In earlier work, Carpenter, Fennema, Levi, and Empson (1999) provided evidence that teachers' *attention* to children's mathematical thinking can affect student learning. Jacobs et al. (2010) built upon the foundation of *attending* to children's thinking by offering a definition that includes three interrelated components, *attending, interpreting,* and *deciding*. Kaiser, Busse, Hoth, König, and Blömeke (2015) report on the challenges of creating valid and reliable instruments for feasibly measuring professional noticing. Determining what teacher competencies to measure and maintaining scoring quality on instruments that do not demand too much time from participants and scorers present the challenge. Kaiser et al. (2015) suggest that beginning with a well-defined theoretical framework is key.

Trajectory-based Mathematics Teaching

Multiple researchers have explored learning trajectory based mathematics teaching (Clements & Sarama, 2009; Sztajn, Confrey, Wilson, & Edgington, 2012) resulting in trajectories of various mathematics concepts. We situated PSET professional noticing development specifically in one such trajectory, SEAL, developed by Steffe and his colleagues (Steffe et al., 1988). SEAL is an early numeracy progression exemplary of "learning trajectories built upon natural developmental progressions identified in empirically based models of children's thinking and learning" (Clements, 2007, p. 45). Video cases illustrating the nuanced behaviors of children's mathematical thinking along the early numeracy progression of SEAL provided a contextualized reflective setting for PSETs to develop the three component skills of professional noticing.

Methodology and Data Sources

To examine PSET growth across the interrelated skills of professional noticing, the authors developed a measure consisting of a brief video clip in which an interviewer poses a comparison, difference unknown task (Carpenter et al., 1999). This clip, while brief, is rich in details of the child's thinking that can be easily attended to, but also includes nuanced details that might be missed by novices thus allowing for a range of scores. The three prompts were drawn from the work of Jacobs et al. (2010) and each focused on one of the three interrelated components, attending, interpreting, and deciding. The prompts were: 1) Please describe in detail what this child did in response to this problem, 2) Please explain what you learned about this child's understanding of mathematics, and 3) Pretend that you are the teacher of this child. What problems or questions might you pose next? Provide a rationale for your answer.

We examined samples of PSET data for each of the professional noticing components for emergent themes (Glaser & Strauss, 1967). The emergent themes were assimilated with researcher-identified key features for each of the components. The themes and key features resulted in benchmarks that defined several ranked response types. The PSETs' professional noticing responses from all implementation and comparison sites were compiled into a spreadsheet and blinded. Scorers did not know if responses were from an implementation or comparison site, nor were they aware if it was pre- or post-assessment data. All data were randomly assigned to deter any biases that may possibly occur when scoring the response.

Initially, three teams of two scorers each rated data sets using the benchmarks determined through the emergent themes. Average inter-rater reliability using this process was 60%. This process was cumbersome, as it required a third scorer when the original scorers' ratings did not agree. Ultimately, more efficient and reliable processes were needed to evaluate the complex professional noticing responses. We drew upon the literature of flow processes (AMSE, 1947) to develop a series of flowcharts to guide the scoring process of each interrelated skill.

Results and Conclusion

The benchmarks developed from the emergent themes of PSETs' responses provided the foundation for the yes/no questions of the flowchart used to guide the raters' scorings. Figure 1 illustrates the flowchart for the interpreting component. The resulting inter-rater reliability averaged 83% for all components across six scorers, a marked improvement from the inter-rater reliability of 60% reached prior to the use of the flowchart scoring tools.

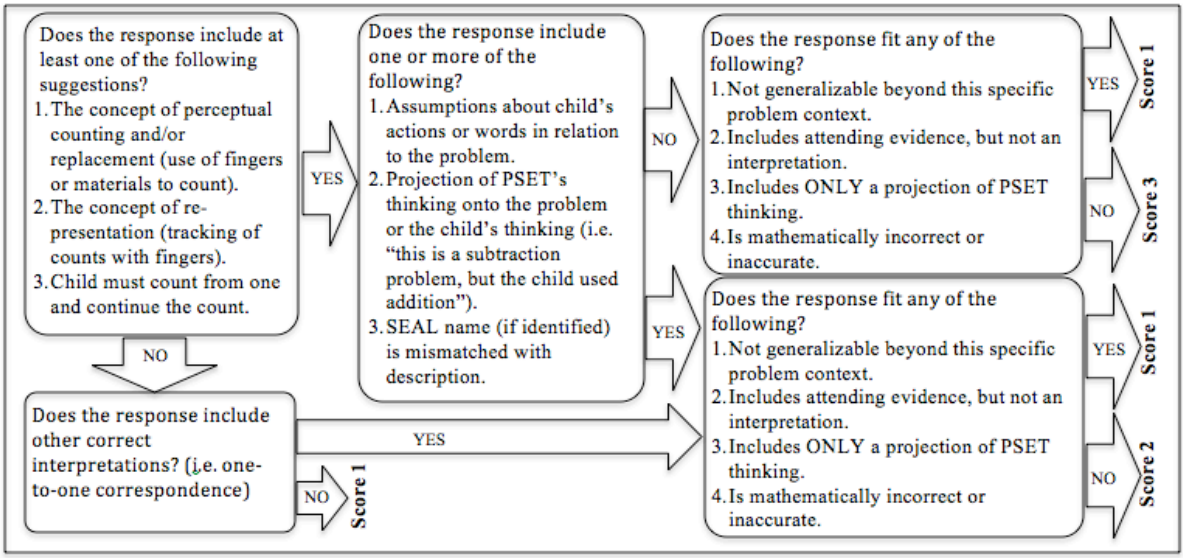

Figure 1: Interpreting Scoring Flowchart

To illustrate the use of the scoring flowchart, one PSET's response to the interpretation prompt is examined.

> "I learned that this student is still using manipulatives or his fingers to count items, but he can also use a counting on strategy to solve problems. I feel that if I was to place this student in one of the SEAL stages, I would have to say he is somewhere between stage 2 and 3. He is still using his senses such as touching (perceptual counting) to count the bears. However, he also counted up from seven to get to eleven."

The criteria for "yes" in response to the first rater question of the scoring flowchart in Figure 1, is satisfied because at least one of the three benchmarks is met. The PSET referenced the child's use of fingers. Following the "yes" route of the flowchart, the PSET response does not include any of the three limitations in the second question, resulting in a "no" response by the rater. The third question, "Does the response fit any of the following [four criteria listed]?" also rates a "no," resulting in a score of 3 for this response.

The scoring flowcharts proved valuable to the scoring process not only for ensuring inter-rater reliability, but also raters could track their responses through the chart with codes such as, "y1nn score 3" for the response above. If questions or discrepancies arose, the subsequent discussion could be focused quickly on the aspect of the response in dissension.

Qualitative data can provide insights on participants' understanding. However, qualitative data is often rich in text, which can pose a challenge to researchers to make meaning from the data (Creswell, 2013). While the open-ended professional noticing responses were concise, our sample included 224 PSETs, which meant 448 responses (due to the pre-post research design) required scoring. It was critical for our research team to establish a systematic process of scoring to make the data analysis process manageable and comprehensible across six scorers. The flowcharts allowed for such systematic processes and increased our inter-rater reliability to 83%. Kaplan and Maxwell (2005) argue that flowcharts can serve multiple purposes including: making data visible, reducing data, and presenting analysis in a holistic form.

The measurement processes developed in this research have the potential to refine the strategies for measurement of responsive teaching practices with respect to noticing frameworks and beyond. Thus, researchers and teacher educators may design or adopt tools to better ascertain individuals' development of key skills. There are limitations with this example, most notably the case specific nature of this assessment. Situational assessments such as this, however, do address the validity question in that what competencies were being measured were definable. Creating an assessment protocol beyond the case level is a challenge, but we argue that this flowchart process can inform similar processes to interpret and analyze future studies of this nature. Used in balance with other measures, this process might further contribute to understanding the complexities of teacher competencies that result in effective responsive teaching practices.

OBSERVING MATHEMATICS IN COLLECTIVE LEARNING SYSTEMS

Elaine Simmt
University of Alberta
esimmt@ualberta.ca

In the past decade there is growing interest in mathematics education research that has emerged from complexity sensibilities that focuses on the collective (group) as a learning system. With this growing emphasis there is a need for methodological tools to study those systems. I am concerned with ways in which we can observe for the emergence of mathematics and mathematical thinking in the collective (rather than the individual). The purpose of this paper is to explore means and methods that can be used to anticipate, describe and account for the mathematics that emerges in collective activity in its own right. What are the markers of collective learning and understanding? How can we observe those markers of collective learning and understanding?

Keywords: Cognition; Learning Theory; Research Methods

I have been struggling with a tension that has emerged for me since first thinking about the class as a complex learning system. How do I observe and account for the mathematics of the collective (the group) rather than the individual? Fifteen years ago I conducted a research study to explore the impact of high activity mathematics within a grade 7 mathematics class. In that class a number of norms were established: working cooperatively with peers; sharing and critiquing solutions with the class; an understanding that the knowledge needed for a task or problem is within the group; and the justification for an answer is in the mathematics rather than with the teacher. One day while the students were writing a quiz (which they were expected to complete independently) one boy got up from his desk, paper in hand and approached a very competent peer to ask a question. I immediately interrupted him to ask what he was doing out of his desk and talking during a test. He replied he was asking Todd what a hexagon was (a fact he needed to proceed with the problem posed in the quiz). When I asked why he would do that during a test, he responded very matter-of-factly, "Well *he* knows." Upon reflection it became clear to me that the student was simply acting within the well established class practice of using all the resources within the group to find out what you need to know in order to proceed with a task or work on a problem.

Reflecting on this event and many others as I worked with the class, my colleagues and I began to theorize the class as a collective learning system. This led me to wonder about the enduring challenges we face as mathematics educators in regards to assessment practices. Why do we have students work in groups on mathematics but then assess each individual's understanding with little or no recognition that their understanding is not only a product of highly interactive group processes but is supported and potentially contingent on the group processes and the knowing of others? Why is it that in spite of using the social group to facilitate understanding we continue to insist students display their understanding isolated from the support of others? Why is it that we do not assess the group's mathematics?

In this paper then, I am not focused on how knowledge is developed by the individual in groups or collectively; rather, I am trying to identify different forms of activity within a group that signal collective learning and understanding. If we can identify markers of the class acting as a single unit (collective activity), we can use those markers to observe that unit's (collective) understanding. As a result we will be better positioned to ask not only how might we assess mathematics learning in school settings differently but what is it that we should be assessing in school mathematics. The purpose my work is to explore the means and methods that can be used to anticipate, describe and account for the mathematics that emerges in collective activity in its own right. What are the markers of collective learning and understanding? How can we observe those markers of collective learning and understanding?

Theoretical Perspective

Learning and Cognition

Maturana and Varela (1992) assert that "knowing is effective action, that is, operating effectively in the domain of existence of living beings" (p. 29). Varela et al. (1991) take this one step further when they claim cognition is perceptually guided action that brings forth a world of significance. These two claims are not discussed in this short proposal but they have been explored by various authors (e.g. February 2015 issue of ZDM). With these definitions I seek to illustrate how a class of mathematics learners with their teacher constitute a cognitive system, which I will henceforth label as a learning system. Of particular relevance here is that the learning system brings forth a world of significance. Hence I am not speaking of the transmission of pre-established knowledge from an expert to the group (teacher to learners). Rather the focus is on the *knowing in action* of the learners and teacher *as a learning system* (or smaller groups with the class). For the purpose of this paper, learning is defined as any transformation that enables the system to maintain its coherence moment by moment in the circumstances in which it finds itself.

Group Learning

There has been a great deal of interest on the learning that emerges through the interaction of students in groups (citations go back at least 30 years). Such research focuses on (for example) the learning of individuals as it arises in mathematical discourse (Sfard, 2001), how it is scaffolded (Goos, et al., 2002) and how it demonstrates the development of socio-mathematical norms (Yackel and Cobb, 1996). More recently, that work is beginning to be theorized in terms of collective learning systems (Rasmussen and Stephan, 2008; Towers, et al., 2009; Stahl, 2009; Hershkovicks et al., 2014; Conner et al., 2014). With this work there is a deliberate shift to investigate the emergent understandings, patterns of interaction, and other phenomena that are not (can not be) attributed to the individual or the sum of the individuals.

Markers of Collective Learning

I would like to propose that there are (at least) two kinds of collective activity we might observe: cumulative and transformative. The former is a result of the combined effort of the group all contributing the same thing. Take for example the lifting of something very heavy like a beam. The capacity to lift is with each individual. However, a beam is far to heavy for a single person to lift. The way to lift the beam is to get enough people to participate in its lifting. Each individual's capacity to lift is added to the cumulative strength of the group to lift the beam. Notice that if an individual is strong enough to lift on her own then additional persons are not needed. The second kind of collective activity is different in that it happens only with a group (at least two people). This kind of activity involves a number of people whose contributions are transformed as they interact with the contributions of others. It is an activity that is not additive or cumulative but transformative. A new form or process emerges from the intersection of the contributions. It is this second kind of collective activity that I am interested in because I believe it is this kind of activity that defines a collective learning system. I ask, what in the mathematics class can only happen when more than one person is present? This suggests a different way to think about collective understanding.

A sports team analogy might be useful to point us in the direction of what to observe for since I am not interested in what the individual learns but rather how the group functions when working on mathematics that enables further activity (maintenance of coherence) the group. Take for example a pass in hockey. One individual sends the puck and another receives the puck. This group activity involves the interaction of individual contributions to create something new. It is not more sending or more receiving, the "send" and the "receive" are transformed into a "pass." Note how without the receiver the "send" might be a shot on goal or it might be a clearing the puck from the zone but it is not a pass. The same act "sending the puck" is only understood as a pass with the interaction between the sender and the receiver. This example has led me to ask what are those individual actions that are transformed to create something new.

What are other examples of collective activity that emerge from the transformation of individual contributions? Rasmussen and Stephan (2008) offer the example of a "fun couple" where neither person would be considered fun on their own. Imagine an act like that of vaudeville comedians, Gracie Allen and George Burns. Their humor emerges from the interaction of Grace who delivers silly lines and George who delivers straight lines. The combination of the silly and straight are transformed into humorous jokes. Neither Grace's lines nor George's are funny on their own; only in the interaction of the lines is the joke created.

The pass in hockey and the joke in the comedy act are two exemplars that have led me to look for the interaction between the contributions of individuals from which something new emerges. I have identified a couple of examples of such transformations observed in clinical interviews. To illustrate, I offer an example from a parent-child dyad working together to understand how to predict the number of possibilities in a geometrical patterning activity. The child was arranging the materials, calling out and counting the patterns. The father was keeping records but at the same time watching his daughter making the tilings and checking for himself that all of the patterns were accounted for. As he recorded he would use words to denote each of his pencil strokes that was replicating the pattern (noted to the right of the transcript).

Kerry: Okay, you could do this one. | = | |
Dan: Okay, What is that one? Okay, one—
Kerry: One, going, going.
Dan: One going, going, going, going. Okay. | = =
Okay, you got your going, going. Yeah, that's the same as your other one, just turned around. Okay, so what do you have?
Kerry: One, one, one [gestures with her finger three times top to bottom over the vertical tiles, then gestures left to right over the two horizontal tiles]
Dan: [repeats as he sketches] One, one, one. | | | =
Kerry: Two sideways.
Dan: [As he draws the two horizontal tiles he utters] Blip blip.
Dan: Okay, what do you call the one sideways or something else?
Kerry: Blip blip.
Dan: Okay the blip-blips.
Kerry: [Calling out the next arrangement] Blip, blip, one, one, one.
Dan: Blip-blip, one, one, one. =| | |

In this case, "blip-blip" emerged from the interaction between the father and child. From their joint action of arranging, calling out the pattern, recording the pattern and calling it back again emerged the utterance "blip-blip." This transformation of their actions and utterances created a new object, the pair of horizontal parallel tiles that must be treated as a unit. From this point forward in the session the blip-blip was integrated with their knowing actions. The emergence and use of a new word out of their collective activity was quite different than the use of language for another pair in the room. At one point in the session the daughter in the other dyad overheard Dan and Kerry talk about looking for mirror images. She almost immediately said, "Oh, I know. Look for mirror images." I observe and interpret the first example (blip-blip) as a transformation of the individual contributions as collective knowing (and object). Whereas in the second example, I see the mimicking of “look for mirror images” as an accumulation within the group of more members doing the same thing.

A “pass” between team players or the creation of a new idea between people working on a mathematical task is but one form of a marker of collective learning. Rasmussen and Stephan (2008) have suggested that in collective activity the content of that activity is not as important as the practices that allow the group to function (p. 203). Hence, I speculate that a second form of marker is a practice within the group. In the vignette shared at the beginning of this paper, we might identify the student going to a classmate to seek information as a practice within that class. The pattern of a question posed to another student, the offering of a response and the listening for the response also may be a marker of collective activity.

The goal of my work in this project is to propose other markers. Once a set of such markers have been proposed, I will then ask what forms of data could be collected that will enable researchers to observe differences in collective learning systems. Is videotape adequate? Are transcripts necessary? Can we remove attributions to individuals (Towers, Martin and Heater, 2013)? What might we learn about the group processes by fast forwarding video-tape and not listening to voices? What value might there be in studying the sound intensity over the period of a class? These questions are the beginning of the second part of this work of trying to identify new methods for studying the collective learning systems known as math classes.

COGNITIVE NORMALIZATION: A FOUCAULDIAN VIEW OF MATH PEDAGOGY

José Francisco Gutiérrez
University of California, Berkeley
josefrancisco@berkeley.edu

Keywords: Classroom Discourse; Cognition; Equity and Diversity; Learning Theories

Background & Theoretical Perspective. This poster presents a theoretical literature review and describes an ongoing study being conducted with these theories. I focus on the text of Foucault (1977) and apply his notion of *normalization* as a meta-lens on mathematics pedagogy.

Previous research shows that normalizing occurs in a variety of educational settings (Gore, 1995; Hardy, 2004), and recent studies demonstrate that normalizing—among other techniques of power—can stymie the implementation of reform-oriented regimes in math and science education (e.g., Donnelly, McGarr, & O'Reilly, 2014). These studies highlight that the normalizing exercise of power impacts learning outcomes by mediating students' *opportunities* to engage the content. I conjecture that normalizing also affects the *quality* of this engagement, by implicitly reproducing non-agentive dispositions toward mathematics content and practices. Furthermore, I maintain that, through discourse, normalization is unfortunately liable to be recreated, and yet it also stands to be renegotiated, reconfigured, and thus ameliorated.

I conceptualize mathematics education as indeed part of a broader form of "disciplinary power" (Foucault, 1977). As such, the practice of mathematics pedagogy *cognitively normalizes* students when it: (a) *evaluates* student action in relation to a cognitive/conceptual norm; (b) *differentiates* among students according to their apparent progress toward this norm; (c) *hierarchizes* students in terms of their "level" of understanding/achievement in relation to this norm; (d) *homogenizes* students when it asserts or demands a group norm; and (e) *excludes* students whose behaviors fall below a minimum threshold and are therefore deemed "abnormal."

Drawing on data from a year-long ethnography of a diverse high-school classroom, this poster presents detailed examples of cognitive normalizing at work in a particular math lesson.

Ongoing Research. My methodology involves using the tools of the learning sciences such as microgenetic analysis of video data (Schoenfeld, Smith, & Arcavi, 1993) with an explicit focus on the classroom availability and individual appropriation of semiotic artifacts (Abrahamson, 2009), to examine the effects of normalizing on the quality of students' engagement and conceptual development. The data corpus consists of 60+ hours of classroom footage, fieldnotes, and student interviews gathered during the 2013-2014 school year. I am currently analyzing two aspects of the entire corpus: (a) teacher-facilitated class discussions; and (b) teacher interventions in group tasks. I am identifying and coding categories representing distinct forms of participation and learning surrounding students' encounters with normalizing power across these two settings. Early findings suggest that in this particular classroom community normalization differentially impacts mathematics learning for women, racial minority students, and students who are non-native English speakers. Findings also reveal teaching tactics that potentially minimize students' inter- and intrapersonal mathematical strife.

USING DIGITAL LEARNING MAPS TO IMPROVE COHERENCE WITH INTERNET MATERIALS

Keywords: Learning Trajectories; Assessment and Evaluation; Standards

Research suggests that teachers are creating their own curricula using web-based resources in order to address the Common Core State Standards for Mathematics (CCSS-M) (Davis, Choppin, Roth McDuffie, & Drake, 2013.) The challenge is that this blend of resources often lacks curricular coherence, does not meet the needs of a diverse student body and lacks an assessment method that is well aligned to instruction and curriculum content. Moreover, research on teachers' choices of digital materials states that when under time constraints, teachers can be influenced by superficial affordances rather than deep content concerns (Webel, Krupa, & McManus, in press).

Coherence can be improved by providing teachers with a digital learning map, which affords a visualization of the middle grades content, is aligned to the CCSS-M and linked to high quality materials. This is a critical response to the challenge of aligning curriculum and assessment to CCSS-M in a coherent manner. The map comprises of four fields, nine regions (big ideas), 24 related learning clusters (RLCs) and 65 constructs. It introduces the idea of a RLC (Confrey, Maloney, & Corley, 2014), which shows how closely related constructs can be grouped to create a coherent learning experience. For teachers, the map gives a description of the common expected student behaviors at the construct level and is a guide for them to promote active student exchange. Additionally the map links to free web-based resources aligned to the RLCs. The map also aims to promote personalization as described by Confrey (2014) that does not devolve into individualization.

The poster uses data from a recent design study covering middle school statistics. Teaching activities employed were informed by research on the learning trajectory for statistics. Data was collected over a week using lesson observation videos, pre and posttests, student artifacts and interviews. The data collected was used to elicit information about how students interpreted the concepts of natural and measurement variability, how students coped with the idea of uncertainty and their use of data displays to further their understanding of key ideas in statistics. The results describe observable behaviors of students participating in the study and thus confirm the structure at the construct and stack levels of the learning map. The design study has implications for the teaching of statistics at the middle school level.

As the title suggests, this Working Group has a dual focus on issues of mathematics teaching and learning and issues of equity and diversity. Following on the topics discussed at the Working Group in 2009, 2010, 2011, 2012 and 2013, this year we are going to focus on identity in relation to mathematics education, and the ways in which power, agency, and authority play out in classrooms. Session 1 will consist of a panel discussion with scholars around these issues. They will share their perspectives on the state of the field and elaborate next steps in attending to these and other equity issues in the learning of mathematics, particularly for historically marginalized student groups. During sessions 2 and 3 there will be round table discussions to provide attendees with the opportunity to network, plan potential collaborative work, and/or discuss issues raised by the panel.

Keywords: Equity and Diversity; Affect and Beliefs (and Emotion and Attitudes); Teacher Knowledge; Teacher Education-Inservice (Professional Development)

Brief History

This Working Group builds on and extends the work of the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME scholars graduated from one of three major universities (University of Wisconsin-Madison, University of California-Berkeley, and UCLA) that comprised the DiME Center. The Center was dedicated to creating a community of scholars poised to address some critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).

The DiME Group (as well as subsets of that group) has already engaged in important scholarly activities, including the publication of a chapter in the *Handbook of Research on Mathematics Teaching and Learning* which examined issues of culture, race, and power in mathematics education (DiME Group, 2007), a one-day AERA Professional Development session examining equity and diversity issues in mathematics education (2008), a book on research of professional development that attends to both equity and mathematics issues with chapters by many DiME members and other scholars (Foote, 2010), and a book on teaching mathematics for social justice (Wager & Stinson, 2012) that also included contributions from several DiME members. In addition, several DiME members have published manuscripts in a myriad of leading mathematics education journals on equity in mathematics education. This working group provides a space for continued collaboration among DiME members and other colleagues.

We continue DiME's tradition of discussing current work, hearing from leading scholars in the emerging field of equity and diversity in mathematics education, and opening up this space beyond DiME members in this Working Group. Specifically, the Center historically held DiME conferences each summer. These conferences provided a place for fellows and faculty to discuss their current work as well as to hear from leaders in the emerging field of equity and diversity issues in mathematics education. Beginning in the summer of 2008, the DiME Conference opened to non-DiME graduate students and new faculty with similar research interests from other CLTs such as the Center for the Mathematics Education of Latinos/as (CEMELA), as well as some not affiliated with an NSF CLT. This was initially an attempt to bring together a larger group of emerging scholars whose research focuses on issues of equity and diversity in mathematics education. In addition, DiME graduates, as they have moved to other universities, have begun to work with scholars and graduate students including those with connections to other NSF CLTs such as MetroMath and the Urban Case Studies Project in MAC-MTL whose projects also incorporate issues of equity and diversity in mathematics education. Funding for the DiME project has ceased and the PMENA Working Group has become a major way in which to keep the conversation going.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Theoretically we have been building on the work of such scholars as Marta Civil (Civil, 2007; Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Eric Gutstein (Gutstein, 2003, 2006; Gutstein & Peterson, 2013), Jacqueline Leonard (Leonard, 2007; Leonard & Martin, 2013), Danny Martin (Martin, 2000, 2009, 2013), Judit Moschkovitch (Moschkovich, 2002), Rochelle Gutierrez (2002, 2003, 2008, 2013a, 2013b) and Na'ilah Nasir (Nasir, 2002, 2011, 2013; Nasir, Hand & Taylor, 2008; Nasir & Shah, 2011). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), and Megan Franke (Kazemi& Franke, 2004), as well as many others outside of the field of mathematics education.

We were pleased for the opportunity offered by the first five years of being a Working Group at PMENA 2009 – 2013 to continue working together as well as to expand the group to include other interested scholars with similar research interests. We have learned through experience that collaboration is a critical component to our work. We were encouraged that our efforts were well received; more than 40 scholars from a wide variety of universities and other educational organizations took part in the Working Group each of the past five years.

Focal Issues

Under the umbrella of attending to equity and diversity issues in mathematics education, researchers are currently focusing on such issues as teaching and classroom interactions, professional development, prospective teacher education (primarily in mathematics methods classes), factors impacting student learning (including the learning of particular sub-groups of students such as African American students or English learners), and parent perspectives. Much of the work attempts to contextualize the teaching and learning of mathematics within the local contexts in which it happens, as well as to examine the structures within which this teaching and learning occurs (e.g. large urban, suburban, or rural districts; under-resourced or well-resourced schools; and high-stakes testing environments). How the greater contexts and policies at the national, state, and district level impact the teaching and learning of mathematics at specific local sites is an important issue, as is how issues of culture, race, and power intersect with issues of student achievement and learning in mathematics.

There is much existing research that either focuses on professional development in mathematics (e.g., Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Kazemi& Franke, 2004; Koellner, Jacobs & Borko, 2011; Lewis, 2000; Saxe, Gearhart, & Nasir, 2001; Schifter, 1998; Schifter & Fosnot, 1993; Sherin & van Es, 2003), or professional development for equity (e.g., Grant & Sleeter, 2011; Lawrence & Tatum, 1997; Payne & Smith, 2011; Sleeter, 1992, 1997;). Less research exists, however, which examines professional development or mathematics methods courses that integrate both (Aguirre et al, 2013; Battey & Franke, 2013; Turner et al., 2012). The effects of these separate bodies of work, one based on mathematics and one based on equity, limits both the impact that teachers can have in actual classrooms and students' opportunities to learn mathematics. The former can help us uncover the complexities of children's mathematical thinking as well as the ways in which curriculum can support mathematical understanding in a number of domains. The latter has produced a body of literature that has helped to reveal educational inequities as well as demonstrated ways in which inequities in the educational enterprise could be overcome.

To bridge these separate bodies of work, the Working Group has begun and will continue to focus on analyzing what counts as mathematics learning, in whose eyes, and how these culturally bound distinctions afford and constrain opportunities for traditionally marginalized students to have access to mathematical trajectories in school and beyond. Further, asking questions about systematic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This research begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Some of the research questions that the Working Group will continue to consider are:

- What are the characteristics, dispositions, etc. of successful mathematics teachers for *all* students across a variety of local contexts and schools? How do they convey a sense of purpose for learning mathematical content through their instruction?
- How do beginning mathematics teachers perceive and negotiate the multiple challenges of the school context? How do they talk about the challenges and supports for their work in achieving equitable mathematics pedagogy?
- What impediments do teachers face in teaching mathematics for understanding?
- How can mathematics teachers learn to teach mathematics with a culturally relevant approach?
- What does teaching mathematics for social justice look like in a variety of local contexts?
- What are the complexities inherent in teacher learning about equity pedagogy when students come from a variety of cultural and/or linguistic backgrounds all of which may differ from the teacher's background?
- What are dominant discourses of mathematics teachers?
- What ways do we have (or can we develop) of measuring equitable mathematics instruction?
- How do students' out-of-school experiences influence their learning of school mathematics?
- What is the role of perceived/historical opportunity on student participation in mathematics?

Specific to this year's Working Group focus, we will also consider these research questions:

- What is the role of both teachers' and students' academic and mathematics identity in achievement?
- What is the role of teachers' and students' ethnic and cultural identities in mathematics classrooms?
- How do teachers support students' agency in mathematics classrooms?
- How does agency influence students learning of mathematics?
- How do power and status play out in the mathematics classroom?

Plan for Working Group

The overarching goal of the group continues to be to facilitate collaboration within the growing community of scholars and practitioners concerned with understanding and addressing the challenges of attending to issues of equity and diversity in mathematics education. The PMENA Working Group provides an important forum for these scholars to come together with other interested researchers who identify their work as attending to equity and diversity issues within mathematics education in order to develop plans for future research. Some areas we have identified and intend to continue to examine include: incorporating out of school practices, explicitly examining race (including educator identity around race and teaching about race), analyzing broader social structures (teaching math for social justice; the role of privilege), integrating an equity focus into mathematics education reform efforts (equity and the Common Core) and, for this year, understanding identity, power, and agency. Our main goal for this year, then, is to continue a sustained discussion (theoretical and methodological) around these key issues related to research design and analysis in studies attending to issues of equity and diversity in mathematics education. We will do this by bringing together scholars to share their perspectives on the field, and then provide space and time for smaller groups to discuss, reflect on, and amplify ideas from the presentation.

Our plans for PMENA 2015 will proceed as follows.

SESSION 1:

- Review and discussion of goals of Working Group
- Introduction of participants
- Panel discussion on identity, power, and agency

SESSION 2:

- Round table discussions, networking, and collaboration

SESSION 3:

- Continued round table discussions, networking, and collaboration

Previous Work of the Group

The Working Group met for five productive sessions at PMENA 2009, PMENA 2010, PMENA 2011, PMENA 2012 and PMENA 2013. In 2009, we identified areas of interest to the participants within the broad area of equity and diversity issues in mathematics education. Much fruitful discussion was had as areas were identified and examined. Over the past five years subgroups met to consider potential collaborative efforts and provide support. Within these sub-groups, rich conversations ensued regarding theoretical and practical considerations of the topics. In addition, graduate students had the opportunity to share research plans and get feedback. The following were topics covered in the subgroups:

- Teacher Education that Frames Mathematics Education as a Social and Political Activity
- Culturally Relevant and Responsive Mathematics Education
- Creating Observation Protocols around Instructional Practices
- Language and Discourse Group: Issues around Supporting Mathematical Discourse in Linguistically Diverse Classrooms
- A Critical Examination of Student Experiences

As part of the work of these subgroups, scholars have been able to develop networks of colleagues with whom they have been able to collaborate on research, manuscripts and conference presentations.

As a result of our growing understanding of the interests of participants (with regard both to the time spent in the working group and to intersections with their research), we began to include focus topics for whole group discussion and consideration and we continued to provide space for people to share their own questions, concerns, and struggles. With respect to the latter, participants have continually expressed their need for a space to talk about these issues with others facing similar dilemmas, often because they do not have colleagues at their institutions doing such work or, worse yet, because they are oppressed or marginalized for the work they are doing. These concerns, in part, informed the focus topics for whole group discussion and consideration. For example, in 2009 research protocols (e.g., protocols for classroom observation, video analysis and interviewing) were shared to foster discussions of possible cross-site collaboration. In 2012, the Working Group explicitly took up marginalization in the field of mathematics education with a discussion about the negotiation of equity language often necessary for getting published; this was done in the context of the 'Where's the mathematics in mathematics education' debate (see Heid, 2010; Martin, Gholson, & Leonard, 2010). Dr. Amy Parks was invited to join Working Group organizers to share reflections on their experiences. Last year we offered our first panel in which scholars (Dr. Beatriz D'Ambrosio, Dr. Corey Drake, Dr. Danny Martin) shared their perspectives on the state of and new directions for mathematics education research with an equity focus. The success of the panel discussion and feedback from attendees led us to plan to continue this structure again this year, using the working group as a sight for discussion and planning of collaborative work as well as reflection on ideas of senior scholars. Given the focus on new directions for mathematics education research, one of the subgroups of the 2013 Working Group focused on equity and the Common Core. A commentary for the *Journal of Research in Mathematics Education* is currently under review (Bartell, et al., 2015).

Anticipated Follow-up Activities

As has happened following previous years of this working group, we anticipate that scholars who make connections at the working group sessions will maintain contact and at least in some cases, this will lead to collaboration on research questions, conference presentations, manuscripts or research projects.

The purpose of this working group is to open discussion and foster collaboration amongst researchers and educators on the theoretical and methodological concerns as well as practical implications related to collective learning. The two themes for the working group include: In what ways can we conceptualize classrooms as collective learning systems? And, in what ways can we analyze how the collective, as a coherent entity, learns? Through our work we intend to engage in discussion to further the concept of collective learning in relationship to mathematics teaching and learning, and to explore research methodologies that offer potential insight into classrooms as collectives. Shaping the discussion throughout the three sessions of the working group will be leading scholars in this field who share their current thinking as fodder for smaller groups to discuss, debate, and extend.

Keywords: Cognition; Research Methods

History of the Working Group

Over the past two decades, the working group leaders have individually and in subgroups, been theorizing about, as well as collecting, analyzing, and reporting on data relating to collective action in mathematics classrooms (e.g., Davis & Simmt, 2006; Martin, McGarvey & Towers, 2011; Martin & Towers, 2011; McGarvey & Thom, 2010; Proulx, Simmt & Towers, 2009). Recognizing our overlapping interests and similar theoretical framework in complexity science (e.g., Mitchell, 2009; Waldrop, 1992) and enactivism (e.g., Maturana & Varela, 1992; Varela, Thompson & Rosch, 1991), we came together several times in the past five years to establish points of intersection in our individual programs of research. A major impetus for the work is to more fully understand the ways in which mathematics learning occurs in classrooms viewed as collective systems. That is, how mathematics classrooms can be seen as complex systems in which agents spontaneously interact and adapt to each other, organizing and sustaining learning processes in collaborative ways. Through this working group we would like to expand our discussion to interested PME-NA members to open new opportunities for collaboration and avenues of research. In this working group, our general themes are to conceptualize collective learning and address methodological issues when the 'learning body' consists of a group or classroom as a whole.

Focus Issues

Within mathematics education research, there is an extensive body of literature pointing to group dynamics and discourse (see Francisco, 2013). Indeed, the 1990s and the following two decades were ripe with visions of cooperative learning, collaborative inquiry and communities of practice

(Balacheff, 1991; Bauersfeld, 1995; Cobb, Wood, & Yackel, 1993; Lampert & Cobb, 2003; Lampert, Rittenhouse & Crumbaugh, 1998; McCrone, 2005; Staples, 2007; Yackel & Cobb, 1996). This research helped transform mathematics classrooms: rows of desks where students worked in isolated silence were rearranged into groups where students interacted cooperatively together. Further, this research led to an emergence of efforts to understand, describe and define collective learning systems within the field of education generally, and was taken up specifically in mathematics education (e.g., Bowers & Nickerson, 2001; Cobb, 1999; Cobb, Boufi, McClain & Whitenack, 1997; Crawford, 1999; Goos, 2004; Lave, 1997; Rogoff, 1995; Roth, 2001; Roth & Lee, 2002; Saxe, 2002; Sfard & Kieran, 2001; Stahl, 2006). From this work came a growing realization that acts of cognition often arose from the classroom as a whole and could not be traced back to any one individual. While we do not discount the value of research that explores individual understanding, we recognize that teacher actions and decision making within classroom contexts are often not based on the multitude of individual actions, but on the teacher's sense of the class as a whole of which they are a part (Burton, 1999; Towers, Martin & Heater, 2013).

In order to have a shared framework for discussing collective learning systems, we situate this work within the view that classrooms are complex systems. Complex systems are a particular class of phenomena that include, for example, weather systems, world economies, human interaction, nervous systems and many others. Each complex system arises from the inextricable layering and entanglement of biological, social, societal and environmental sub-systems (Davis & Simmt, 2003; Davis & Sumara, 2006). Events within the systems may be unpredictable in foresight, but are potentially understandable in hindsight. Further, complex systems present possibilities that neither arise from nor are representative of individual agents (Davis & Simmt, 2003). These collective possibilities are established through a self-initiating, self-organizing and self-sustaining process. Another key aspect of complex systems is the dialectical entanglement of the system and its environment. Drawing on Maturana and Varela's (1992) view of an entity's cognition, the system both shapes and is shaped by its surroundings. In this sense, *a collective learning system can be defined as a complex system in which agents spontaneously interact and adapt to each other, organizing and sustaining the group's dynamical processes in a collaborative and collective way.* This description is how we view mathematics classrooms as collective learning systems and it provides the theoretical orientation to situate our discussion on conceptualizing collective learning. In this working group we offer some of our work on complex systems as starting points for discussion (described below), but we make space for alternative perspectives as well as extensions of the work. The first theme we address is: *In what ways can we conceptualize classrooms as collective learning systems?*

We recognize that even if we agree on the importance of viewing classrooms as collective learning systems, researchers describing and analyzing group interaction often report findings based on individual achievement results. Even when group work is considered as a whole, a lack of methodological tools leads to analyses that offer connected, but still individual actions, utterances and understandings. Hence, a second theme of our working group is to address the methodological considerations for viewing groups and classrooms as collectives. *In what ways can we analyze how the collective, as a coherent entity, learns?*

Research methodology for collective systems outside of school contexts is a burgeoning scientific field of study. To begin discussions, we offer studies that provide insight into the adaptive learning and self-organization of complex and collective systems such as insect colonies (e.g., Gordon, 2011; Johnson, 2002), underground webs of fungi and roots in forests (Simard, Martin, Vyse & Larson, 2013), small-world communication networks (Watts & Strogatz, 1998), workplace learning (Garavan & McCarthy, 2008), social movements (Kilgore, 1999), and stock market fluctuations (Ralph, n.d.). These studies and many others, make use of computer models of complex phenomena to create visual expressions and explanations of large volumes of data.

Within mathematics education some approaches to analyzing collective learning have been offered:

- preparing transcripts where all individual identifiers have been removed and the transcripts are analyzed as though there is only one voice (Glanfield, Martin, Murphy & Towers, 2009; Martin, Towers & Pirie, 2006);
- tracing the development of a mathematical idea through a group by attending not to individuals, but to collective utterances and discussion, drawings, working papers and whiteboard markings (Davis & Simmt, 2003; Gordon Calvert, 2001; Namukasa & Simmt, 2003; Proulx, 2003; Simmt, 2011; Thom & Roth, 2009);
- modelling classroom interactions using a dynamic visual network by electronically streaming the observations of conversations turns (Bender-deMoll& McFarland, 2006); and
- analyzing video to track the patterns of physical movement within a class and sound by measuring the overall intensity of amplitude over the period of the lesson.

While these techniques show promise, we seek new and different avenues to explore.

Through this working group we hope to extend the initial forays into conceptualizing, collecting, analyzing and interpreting data from collective learning systems. We seek to enlarge researchers' and educators' understandings of what counts as a 'learner' to include a group as a learning system. We also examine the potential for observational and assessment tools where a group stands as the unit of analysis.

This work has the potential to transform research and teaching practices that address the collective, rather than individualistic learning in schools, and challenge institutional norms that privilege a focus on the individual.

Plan for Engagement

The purpose of this working group is to open discussion and foster collaboration amongst researchers and educators on the theoretical and methodological concerns as well as practical implications related to collective learning. The two themes for the working group include:

In what ways can we conceptualize classrooms as collective learning systems?

In what ways can we analyze how the collective, as a coherent entity, learns?

Through our work we intend to engage in discussion to further the concept of collective learning in relationship to mathematics teaching and learning, and to explore research methodologies that offer potential insight into classrooms as collectives. Shaping the discussion throughout the three sessions of the working group will be leading scholars in this field who will share their current thinking as fodder for smaller groups to discuss, debate, and extend.

Session 1. Theoretical considerations for collective learning

Presentation A. Collective behaviours. What does a collective learning system mean? What might collective learning be? One of the ways to address these questions might be through studying/understanding similar collective phenomena exhibited by insect colonies, vertebrate schools, flocks or plants. Despite the differences, research shows that these systems appear to exhibit similar collective behaviours suggesting the possibility of common underlying mechanisms or patterns. The potential of common mechanisms underlying insect, animal, plant and human collective phenomena might help to conceptualize behaviour along with methodological tools for observing collective learning in mathematics classrooms. For example, studies on ants' foraging behaviour show that ants exhibit collective behaviours by obeying very simple rules: The ants pick up grains at a constant rate, approximately two grains per minute; they prefer to drop them near other grains, forming a pillar; and they tend to choose grains previously handled by other ants, probably because of marking by a chemical pheromone. This example is one of many that will be shared to help conceptualize collective learning in a mathematics classroom.

Focusing questions for small group discussion:

- What interactions might we observe in a mathematics classroom that characterize collective learning phenomenon (e.g., decentralized control)?
- In what ways can foraging, flocking or other simple rules be observed in mathematics classrooms?
- What aspects of interaction signify collective behaviour: students' mathematics productions, mathematical ideas, emergent use of words or expressions, and/or other markers?

Presentation B. Ideas as species. It is not uncommon to encounter suggestions that mathematics "is a living, breathing, changing organism …" (Burger & Starbird, 2005, p. xi) or that it "emerges as an autopoietic [i.e., self-creating and self-maintaining] system" (Sfard, 2008, p. 129). More pointedly, Foote (2007) has argued that mathematics is an adaptive, complex system that is approaching the limits of human verifiability.

Picking up on such notions, this presentation develops the suggestion that *ideas* are *species* – and, more fundamentally, that *thinking* and *evolution* are self-similar processes. It begins with the observation that the words ***idea*** (> Greek *idein*, "to see") and ***species*** (> Latin *specere* "to see") are, in a sense, synonymous, and offers a brief historical trace of how the notions were historically connected.

From there the discussion draws on the following literatures:

- memetics (e.g., Dawkins, 1989; Blackmore, 1999)
- complexity science (e.g., Mitchell, 2009)
- embodiment/biological cognition (e.g., Maturana & Varela, 1979; Varela, Thompson & Rosch, 1991)

This literature serves to support the development of the dynamical similarities of cognition on the level of the knower, knowledge production on the level of society, and evolution on the level of a species. These elements are knitted together in the assertion that mathematical concepts are complex coherences that arise in but transcend the co-entangled activities of a collective of mathematical knowers – that is, an account of the emergence and evolution of mathematical ideas/species is offered.

Focusing questions for small group discussion:

- What mathematics ideas/species might we observe in a school mathematics classroom?
- What are the conditions for a collective learning system from which mathematics transcend?
- What implications arise when mathematical ideas are theorized as species?
- What new possibilities, theoretical and pedagogical, are occasioned when mathematical ideas are conceived as species?

Session 2. Classrooms as Collectives

Presentation C. Mathematical meme ecosystem. In this discussion we bring together *Collective Behaviours* from Presentation A and *Ideas as Species* from Presentation B to bridge our understanding of and consideration for the potential utility for the construct of a mathematical meme ecosystem (MME) in the classroom. Memes as introduced by Dawkins (1989) are ideas (and behaviours) that persist in a social group as individual agents mimic the ideas (and behaviours) of others. We acknowledge the individual and social literature on understanding, and we want to go beyond to focus on the memes, the threads and traces of ideas.

The collective behaviours previously discussed, such as the rules for foraging ants and flocking, allow us now to consider the ways in which teachers are implicated in the collective system as they contribute ideas/species and intentional memes. Moving to the level of an ideational system that rides above the agents in the system and in order to develop the idea of a meme ecosystem, we explore how ideas are picked up and have currency in a classroom setting.

Focusing questions for small group discussion:

- What are some of the memes we can identify in a mathematics classroom?
- How do we observe the emergence of the memes in a mathematic classroom?
- What are the dynamics of the movement and persistence of memes?
- What insights into student learning are gained through conceptualizing mathematics classrooms as mathematical meme ecosystems?
- In what practical ways do memes offer a different sensibility for what it means to teach and learn mathematics in the classroom?

Presentation D. Improvisational coaction. In this presentation we begin by offering the beginnings of a theoretical framework focusing on the collective mathematical activity of learners collaborating in small groups (Martin, Towers, & Pirie, 2006; Martin & Towers, 2009). Influenced by the literature that focuses on improvisational action in the fields of jazz and theatre (e.g., Sawyer, 2003), we demonstrated that it was possible to observe, explain, and account for acts of mathematical understanding that could not simply be located in the minds or actions of any one individual, but instead emerged from the interplay of the ideas of individuals, as these became woven together in shared action. This early theorizing prompted us to develop the theoretical construct of "improvisational coaction" in mathematics learning (Martin & Towers, 2009). Improvisational coaction is a process through which mathematical ideas and actions, initially stemming from an individual learner, become taken up, built upon, developed, reworked, and elaborated by others, and thus emerge as shared understandings for and across the group, rather than remaining located within any one individual. We have applied these ideas to a breadth of educational contexts from elementary school to workplace learning and in small group and whole-class settings (e.g., Martin & Towers, 2011, 2012; Towers & Martin, 2009, 2014) and most recently have turned our attention to developing methodological advances for studying such mathematical collectivity (Towers & Martin, 2015). In this presentation, we position the structures of improvisational coaction as one potential organizing mechanism that might underlie a mathematical meme ecosystem.

Focusing questions for small group discussion:

- Can improvisational coactions provide a conceptual structure for understanding the organizing mechanisms underlying mathematical meme ecosystems?
- What insights into mathematical meme ecosystems might be gained by analyzing students' improvisational coactions?
- What are some of the indicators/markers of coaction?
- What are the dynamics of mathematical meaning making of a group of agents and how can we observe them?

Session 3. Methodological considerations for studying collective learning in mathematics classrooms

Presentation E. Observing processes of collective learning. In the past two decades the use of group work in schools has become pervasive. Justification for this move range from "that's how people learn" to "that is how people get on in the *real* world." Yet, when it comes to assessment (accountability) the emphasis is always placed on the individual. What does the individual know (stripped of any opportunity to know with others in a group)? We are troubled by educational systems that emphasize group work and students' ability to work together on shared projects, but continue to point back to the individual in accountability and assessment. In spite of decades of research done with pairs, small groups and class-sized groups of students/learners, we as educational researchers have made little progress on understanding *learning* as anything beyond what an individual does. Regardless of our beliefs about the purpose of education, we (collectively) live with the unexamined assumption that at the end of the day we must assess what the individual learned from his or her time in school. As educational researchers we are aware that we have not examined/researched observational practices that could focus on the group as a learning system; hence, our (collective) underlying assumptions face few challenges.

Gharajedaghi (2011) writing about systems in a business context states:

> The obstructions that prevent a system from facing its current reality are self-imposed. Hidden and out of reach, they reside at the core of our perceptions and find expression in mental models, assumptions and images. These obstructions essentially set us up, shape our world and chart our future. They are responsible for preserving the system as it is and frustrate its efforts to become what it can be. (p.159)

With the growing understanding of complexity thinking and the awareness that it offers us a way to consider learning systems at many levels of organization, we are at a point where the methodological obstructions we have faced may be excavated and examined. It is important to study the methods by which we can observe the group as a learning system. From there we can propose methods by which teachers can assess the group's, as well as the individual's learning.

In this work we reflect on identifying some of the processes involved in the collective learning and ask how they might be observed. Initial processes are likely related to the presence of feedback loops and binding processes, the emergence of ideas and practices, the collection/selection of new information, as well as the transformation of the contributions of individuals. So, how do we observe these phenomena when we do not and likely cannot know exactly what they are or what they look like?

Focus questions for small group discussion:

- How might thinking about ecosystems and the means by which these are studied enable deeper examination and critique of methods used in mathematics education to observe collective learning?
- In what ways does such examination and critique present the possibility for the generation of radically different methods of observations to study collective mathematics learning in the classroom?
- What are some of the obstructions that have prevented educators from recognizing the paradox of students learning with a group and being assessed individually?
- What methodological tools do we have or might we imagine for assessing the learning and understanding of a group?
- How might we imagine, develop and study alternative assessments, attending to group learning and knowledge creation?

Final Forum. In this final forum of open discussion we return to each of the previous presentations and insights arising from the small/large group discussions to consider moving the theoretical and methodological issues of collective learning forward. We also return to the two themes posed: *In what ways can we conceptualize classrooms as collective learning systems?* And, *In what ways can we analyze how the collective, as a coherent entity, learns?*

We offer a cycle of inquiry to help frame our discussion that allows us to consider existing/new tools for analysis as well as existing/new data collection (see Figure 1).

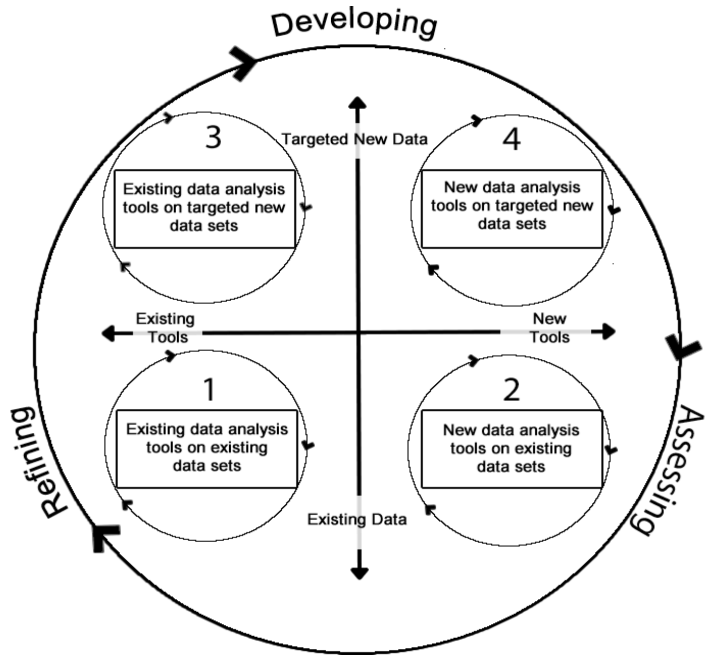

Figure 5: Cycle of inquiry for developing, assessing and refining data collection techniques and data analysis tools.

Anticipated Follow-Up/Future Work

We anticipate that this initial working group discussion at a PME-NA will bring together interested researchers who have wondered about collective learning within a mathematics classroom, what it might look like, and how it might be observed and described. Our hope is to extend this work from the conceptual and methodological to the pedagogical. That is, how might we use insights gained through research to consider how teachers might 'notice' or 'observe' collective learning in their practice.

Acknowledgment

Argumentation, justification, and proof are conceptualized in many ways in extant mathematics education literature. At times, the descriptions of these objects and processes are compatible or complementary; at other times, they are inconsistent and even contradictory. The inconsistencies in definitions and use of the terms argumentation, justification, and proof highlight the need for scholarly conversations addressing these (and other related) constructs. Collaboration is needed to move toward, not one-size-fits-all definitions, but rather a framework that highlights connections among them and exploits ways in which they may be used in tandem to address overarching research questions. Working group leaders aim to facilitate discussions and collaborations among researchers and to advance our collective understanding of argumentation, justification and proof, particularly the relationships among these important mathematical constructs. Working group sessions will provide opportunities to engage with a panel of researchers and other participants who approach these aspects of reasoning from different perspectives, as well as to: hear findings from a recent analysis of these constructs in research; reflect on one's own work and position it with respect to the field; and contribute to moving the field forward in this area.

Keywords: Reasoning and Proof; Advanced Mathematical Thinking

Brief History of the Working Group

This is a new working group intended to advance the field's collective understanding of the interrelated objects and processes of argumentation, justification, and proof. We reviewed the prior 20 years of PME-NA proceedings (1995 – 2014) and prior 10 years of PME proceedings (2005 – 2014) to determine whether any previous working groups have focused on these topics. We found one related working group and two related discussion groups; however no group focused on the connections among these three constructs.

A working group on "Learning and Teaching with Proof" was facilitated by Stylianou and Blanton (2004) at PME-NA 26. That working group focused specifically on the development of proof across K-16, whereas the proposed working group focuses on the field's understanding and study of not only proof, but also argumentation and justification, as well as the interrelationships among them. A discussion group on argumentation in mathematics education convened at PME 30 that focused partly on defining and discussing the role of argumentation in mathematics education and research (Schwarz & Boero, 2006). While informative to the current efforts, the focus of that discussion group was distinct from the present working group. Most recently, a discussion group at PME 33 focused on the value of "generic proofs," a particular type of proof presentation (Leron & Zaslavsky, 2009), a topic which is much more specific than this proposed working group. Thus, we classify the present working group as new, while recognizing the contributions of earlier efforts in prior PME-NA and PME meetings. Additionally, none of the leaders of the proposed working group have participated in the aforementioned working groups, providing a further distinction between prior work and the present group. The leaders of this working group are researchers working in different areas of argumentation, justification and proof. Recent collaborations and conversations have led us to consider a need for the field at-large to converse about these interrelated objects and processes, which subsequently led to this newly proposed working group.

Focal Issues

There is a large and growing body of research in mathematics education focused on argumentation, justification, and proof. The research on proof, for example, includes studies on: the role of proof in the discipline; proof in school mathematics and at the undergraduate level; what counts as a proof; proof schemes and categories; teachers' conceptions of proof; students' abilities to write valid proofs; and what teaching proof looks like in classrooms at various levels (e.g., Boero, 2007; Harel & Sowder, 2007; Reid & Knipping, 2010; Stylianou, Blanton, & Knuth, 2009). At the same time, researchers and policy documents have issued calls to engage school children with disciplinary practices such as constructing viable arguments, justifying conclusions, critiquing the reasoning of others, and constructing proof for mathematical assertions (National Council of Teachers of Mathematics [NCTM], 2000; National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010).

Yet, as the field moves forward to strive for maximizing students' learning opportunities for engaging in these disciplinary practices, mathematics educators need to refine their notions of these terms in scholarly activities and in policy documents (Cai & Cirillo, 2014). How, when, and why decisions related to word choices are made (e.g., 'argument' versus 'proof') in curriculum materials, policy documents, and research is an open question. In fact, some researchers have hinted that these choices are not always purposeful. For example, Lynn Steen, a member of the 1989 NCTM Standards Committee, claimed that uncertainty about the role of proof in school mathematics caused NCTM in its first *Standards* (1989) document to resort to, what he called, "euphemisms" such as "'justify,' 'validate,' 'test conjectures,' [and] 'follow logical arguments'" (Steen, 1999, p. 274). Rarely, he stated, did the document use the term 'proof.' Although Steen's comments were published over 15 years ago, we would argue that his proposition, that the role of proof (as well as argumentation and justification) in school mathematics is uncertain, continues to be true today.

Building on NCTM's (2000) document, which recommended that students' experiences with reasoning and proof include making and testing conjectures, judging the validity of arguments, and constructing proofs, the *Common Core State Standards for Mathematics* (*CCSSM*; NGA & CCSSO, 2010) continued this emphasis. Although proof is no longer included as an explicit standard, the authors added attention to argumentation through the third Standard for Mathematical Practice. Proof and justification (or proving, justifying, etc.) are also included, with proof appearing most often in the high school standards. As the field continues to grapple with the meanings and interconnections of argumentation, justification, and proof, the usage of these varying terms could point to potential challenges of implementing and studying this aspect of CCSSM.

One challenge of reading extant research or developing a research agenda related to these disciplinary practices is that the classifications offered differ according to the perspective of the researcher, the focus of the research, and the particular data being analyzed (Reid & Knipping, 2010). Only recently have we begun to see mathematics educators offering explicit definitions of these constructs in their work. This is ironic given the importance of definitions in the field of mathematics itself. A review of the literature reveals much more specific attention to proof than to justification and argumentation in mathematics. Table 1 provides some definitions of the three constructs.

When considering the definitions provided in Table 1, one might notice various things. For example, two of the authors describe proof as an argument. This is interesting given that Cabassut and colleagues (2012) claimed that opposing views exist in the field: On the one hand, it has become customary in mathematics education to use the term 'argumentation' for reasoning which is not yet a

Table 1. Definitions of Proof/Proving, Argumentation, and Justification.

Proof/Proving	Argumentation	Justification/Justify
"the process employed by an individual to remove or create doubts about the truth of an observation" (Harel & Sowder, 1998, p. 241)	"mathematical explanation intended to convince oneself or others about the truth of a mathematical idea" (Mueller, Yankelewitz, & Maher, 2012, p. 376)	"to provide sufficient reason for" (National Research Council, 2001, p. 130)
"arguments consisting of logically rigorous deductions of conclusions from hypotheses" (NCTM, 2000, p. 55)	"discursive exchange among participants for the purpose of convincing others through the use of certain modes of thought" (Wood, 1999, p. 172)	"an argument that demonstrates (or refutes) the truth of a claim that uses accepted statements and mathematical forms of reasoning" (Staples, Bartlo, & Thanheiser, 2012, p. 448)
"a mathematical argument, a connected sequence of assertions for or against a mathematical claim, with the following characteristics: (1) It uses statements accepted by the classroom community (*set of accepted statements*) that are true and available without further justification; (2) It employs forms of reasoning (*modes of argumentation*) that are valid and known to, or within the conceptual reach of, the classroom community; and (3) It is communicated with forms of expression (*modes of argument representation*) that are appropriate and known to, or within the conceptual reach of, the classroom community." (Stylianides, 2007, p. 291)	"the process of making an argument, that is, drawing conclusions based on a chain of reasoning" (Umland & Sriraman, 2014, p. 44)	

proof, on the other hand, other researchers, such as Balacheff (1988) and Duval (2007), believe that argumentation and proof are fundamentally different.

Reid and Knipping argued that while ignoring multiple uses of 'proof' can lead to communicative challenges, the answer is not to insist on one "correct" usage (Reid & Knipping, 2010; Herbst & Balacheff, 2009). In particular, Herbst and Balacheff (2009) stated:

> If the field is in a deadlock as regards to what we mean by "proof," we contend this is so partly because of the insistence on a comprehensive notion of proof that can serve as referent for every use of the word…. We have argued that to make it operational for understanding and appraising the mathematics of classrooms we need at least three meanings of the word. (p. 62)

Awareness of the different uses of proof is an important step in deciphering and making progress in mathematics education research (Reid & Knipping, 2010). In fact, Balacheff (2002) claimed that "research speaks in a very confusing way about the topic" (p. 39).

Conflicting Constructs, Methodologies, and Findings from the Research Literature

In a forthcoming review of the literature, Stylianides, Stylianides, and Weber (forthcoming) asserted that the field has made substantial progress in tackling these issues. Researchers have developed powerful conceptual constructs and methodologies, and our collective understanding of how students perceive proof and how justification, argumentation, and proof are taught in K-12 and university classrooms has very much improved. Nonetheless, there are several places where different researchers have generated conclusions that conflict with one another. Here, we present a few such contradictions.

First, in the debate on how proof should be introduced to students, Marty (1991) proposed teaching students the rules of logic and standard proof techniques while deliberately keeping the content shallow, suggesting that the notion of proof as a justification to prove mathematically meaningful statements should come later. Alibert and Thomas (1991) suggested the opposite; students should initially be engaged in argumentation about the veracity of interesting mathematical statements. In socially negotiating what counts as an acceptable argument, the instructor can lead students to produce the standard norms of proof. Both researchers presented research results that supported their point of view.

Second, as mentioned above, there is a debate as to whether argumentation and proof are activities that are deeply intertwined or fundamentally separate. For instance, numerous authors have proposed that students will be more successful at proof writing if they base their proofs on informal arguments, often involving the inspection of examples and graphical reasoning (e.g., Garuti, Boero, & Lemut, 1998; Raman, 2003; Sandefur, Mason, Stylianides & Watson, 2013; Weber & Alcock, 2004). However, Duval (2007) contended that argumentation and proof occur in different semiotic registers. Due to the different goals and demands of each activity, they must occur separately.

Third, several researchers have presented classroom studies that demonstrate that even young children are capable of writing proofs (e.g., Maher & Martino, 1996). Yet there are numerous studies that suggest that high school geometry students and even advanced mathematics majors struggle to write relatively simple proofs (e.g., Moore, 1994; Senk, 1989). Is it possible that young children have greater competency at proving than most geometry students or mathematics majors? Or are their proofs being evaluated according to different standards?

Fourth, a number of researchers have defined proof to be a convincing justification (cf., Balacheff, 2008). Yet there are other mathematics educators who emphasize that some proofs do not always provide full justification to mathematicians, and mathematicians sometimes are convinced by justifications that they would not call proofs (e.g., de Villiers, 1990; Tall, 1989; Rodd, 2002; Weber, Inglis, & Mejía-Ramos, 2014).

What we contend is that these, and other, inconsistent claims are based on researchers holding different conceptions of argumentation, justification, and proof. What we hope to accomplish in this working group is to develop a better understanding of these differences, an appreciation for what different perspectives of proof can accomplish, and a framework that describes how different perspectives can complement each other, rather than oppose each other and lead to inconsistent findings.

Frameworks for conducting research: The case of proof

In the forthcoming review, Stylianides et al. (forthcoming) described three broad research traditions with respect to proof. One theoretical frame is to view *proving as problem solving*. In these studies, little emphasis is given to the issues of what constitutes a proof, why students engage in this activity, and how they interpret the proofs that they produce. Issues of argumentation and justification are typically ignored. Instead, these studies focus on what competencies are needed to successfully write a proof and design instruction that helps students develop these competencies (e.g., Selden & Selden, 2013; Weber, 2001).

Another school of thought views *proving as convincing* (e.g., Harel & Sowder, 1998). Researchers in this perspective seek to determine what types of justifications students find convincing and attempt to develop instruction that leads students to transform their standards of conviction to those held by mathematicians (e.g., Harel, 2002; Recio & Godino, 2001). Careful attention is paid between arguments that are complete convincing justifications and those that merely increase one's belief in the likelihood of a statement.

A third framework treats *proof as socially embedded activity*. In this perspective, researchers focus on what it is students, from their perspective, are *actually* doing when they engage in proving (e.g., Herbst & Brach, 2006) and how students' and teachers' activities are shaped by social and institutional constraints (e.g., Herbst & Chazan, 2003). Researchers often focus on the cognitive, social, and pedagogical goals that proof can and should play in the classroom beyond being a skill to acquire or a means of conviction (Staples, Bartlo, & Thanheiser, 2012).

In the review, Stylianides and colleagues found that each perspective (a) used different conceptions of argumentation, justification, and/or proof, (b) addressed different questions, (b) developed different theoretical constructs to understand and investigate these questions, and (d) measured the success of instructional interventions in different ways. They also found that considerable progress has been made within each of these perspectives that has enhanced the field's understanding of proof and related constructs. As one can see, many varying conceptions of argumentation, justification, and proof exist in our field. It would be an unrealistic and inappropriate goal of the working group to try to reach a consensus on what argumentation, justification, and proof are. Indeed, in mathematical practice, mathematicians adopt different standards and perspectives on these objects and corresponding processes depending upon their aims and context (Weber, 2014). Rather what we seek to explore is the different ways that researchers conceptualize these constructs (including, but not necessarily limited to, the perspectives above), the consequences of such conceptualizations, and how they might work in tandem to address overarching research questions.

Balacheff (2002) put forth a set of recommendations to help address what he called a research "deadlock" (p. 1). Heeding his recommendations, we will consider the following during the working group: (a) looking for a common lexicon to improve available definitions; (b) engaging with different research programs and their possible contrasts and relationships; (c) considering the theoretical commonalities and divergences, and possibly turning them into research questions; (d) discussing different methodologies, their benefits, and possibly limitations; and (e) acknowledging accepted results or turning objections and differences into research problems.

Plan for the Working Group

The overarching goal of the working group is to facilitate discussion and collaboration among researchers in the field doing work in this area – at various stages of their careers – and to advance our collective understanding of argumentation, justification and proof, and relationships among these important mathematical constructs. Aligned with these goals to advance our collective understanding, we anticipate organizing our time together in the following manner.

Session 1: *Where are we now? Where is the field? Where are you?*

In Session 1, we begin with introductions and discerning interests in the working group, and then provide an overview of the goals for group. We then engage participants in two activities in order to establish some common ground for our collective work and to provide a reflective opportunity for participants to position their own thinking and work with respect to the field. The key activities in Session 1 are as follows:

- We will facilitate Introductions, Define the Problem, and outline Working Group Goals.
- Keith Weber, a co-author of the proof chapter in the forthcoming NCTM handbook, will offer an historical view of the use of these constructs in mathematics and educational research. The talk will highlight convergence in the literature as well as contradictions in definitions and research results. The purpose of the talk will not be to call for convergence, but rather to highlight different traditions and where points of disagreement may lie, and to propose ways in which different traditions may inform each other to advance the field collectively.
- All working group participants produce a diagram or concept map with the terms *argumentation, justification,* and *proof* to elicit personal conceptions and uses of these terms and how they are interrelated. Small groups will then compare and discuss these representations.

Session 2: *How have individual researchers used these constructs to support their work? What choices have they made?*

Session 2 features an interactive panel discussion by three invited math educators who focus on one or more notions of argumentation, justification and proof in their research. The panel of experienced researchers will share their expertise through a facilitated format, beginning with set questions and then evolving into a question-and-answer period and group discussion. Potential guiding questions include the following:

- *What process(es) and object(s) (justifying-justification, argumentation-arguments, and proving-proof) are central to your work? Why did you choose these? How have you conceptualized or defined them for your work?*
- *How do you see these conceptualizations mattering for the work you (we) do with teachers, with students, and/or as researchers as members of the mathematics and/or mathematics education community?*
- *From your perspective, where is the field now with its understanding of these processes and objects, how to foster them in classrooms, and how to support teacher learning of pedagogies to organize student participation in these critical processes?*

Three researchers, whose work is prominent in this area, will serve on the panel:

- Kristen Bieda, Michigan State University, has investigated the interaction between opportunities in curriculum to engage in justification and proof and how teachers enact those opportunities with students in middle school classrooms. Bieda is particularly interested in teachers' goals for justification in their classroom and how they modify and deploy curricular tasks to achieve those goals.
- Anna Conner, University of Georgia, studies the role of the teacher in collective argumentation, specifically how teachers learn to support their students in making mathematical arguments. Within this, Conner also studies teachers' beliefs about proof and how this may influence the argumentation in their classes.
- Pablo Mejía-Ramos, Rutgers University, focuses on the reasoning processes involved in the three main argumentative activities related to the notion of proof in university mathematics: constructing a new proof, reading a given proof, and presenting a known proof. Two of the main goals of Mejía-Ramos's research are (1) to better understand the ways in which different types of students and mathematicians engage in these argumentative activities, and (2) to identify effective strategies for performing such activities.

Samuel Otten, University of Missouri, will moderate the panel discussion.

Session 3: ***Where are you now? What are next steps?***

We anticipate pursuing three general goals in Session 3 and recognize that the particulars of this session will be in response to the first two days. The three goals are:

- Gaining clarity in situating oneself and one's own work within the broader field. Toward this end, we revisit the set of individual diagrams generated in Session 1. Participants will have opportunities to revise their diagrams. We anticipate discussing two or three representations that emerge regarding the relationships among argumentation, justification and proof as "prototypical" views. We will discuss their similarities and differences, consequences for the field, and whether they are complementary or contradictory.
- Generating key questions or suggestions for the field to better leverage the work it is doing. First in small group discussion, and then with the full group, we will develop a handful of key questions that the collective identifies as important to furthering individuals' and the field's work with respect to argumentation, justification and proof. Subgroups may organize around these questions.
- Organizing work on a white paper and identifying next steps. We will share an outline for a white paper, and elicit input for the focus of Year 2 work at the next PME-NA conference. Given the group's interest and the key questions they develop, subgroups can contribute specific sections to the white paper. Subgroups may also organize around a focal process. Finally, a subgroup may plan to take up particular key questions or activities during the year.

Anticipated Follow-up Activities

We anticipate two follow-up activities and products for the first iteration of this working group. First, we have inquired with editors of some of the leading mathematics education journals in the field regarding the potential for publishing a summary of a panel discussion (similar to Sfard, Nesher, Streefland, Cobb, & Mason, 1998), or, alternatively, a research commentary. The commentary might provide recommendations for how mathematics education researchers report what they mean by argumentation, justification and/or proof in their work. Such a commentary may also document key questions for the field as well as share core ideas from discussions and differences in perspectives from organizers, panel members, as well as working group participants.

We also anticipate the development of a white paper from participants of the working group. The paper will have multiple sections documenting ideas from our generative work together, as well as solidifying and extending some of those ideas. A white paper format affords flexibility in how the document is organized and how authorship is assigned (e.g., authorship of sub-sections within the larger white paper). While not suggesting a definitive structure *a priori*, one potential format would include perspectives from developing sub-groups within the working group based on participants' diagrams and particular conceptions of argumentation, justification and proof. This activity will allow for further engagement within and beyond this meeting of the working group. The white paper would be developed over the months following PME-NA 37 with the goal of sharing the document widely (e.g., through our institutions' open-access digital repositories). Thus, such products fulfill our purpose of creating a working group at PME-NA: to engage colleagues in discussion of the different understandings and operations of argumentation, justification and proof. While consensus on these points is not anticipated, and not necessarily a goal, efforts towards consensus regarding how mathematics educators convey their conceptions of these objects and processes is.

Embodied cognition is growing in theoretical importance and as a driving set of design principles for curriculum activities and technology innovations for mathematics education. The central aim of the EMIC (Embodied Mathematical Imagination and Cognition) Working Group is to attract engaged and inspired colleagues into a growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education .A thriving, informed, and interconnected community of scholars organized around embodied mathematical cognition will broaden the range of activities, practices, and emerging technologies that count as mathematical. EMIC builds upon earlier investigations in professional workplaces, formal K-12 math and science classrooms, mathematics centers, museums, marching bands, bike paths and city streets.

Keywords: Classroom Discourse; Cognition; Informal Education; Learning Theory

Motivations for a New Working Group

Recent empirical, theoretical and methodological developments in embodied cognition and gesture studies provide a solid and generative foundation for the establishment of **an Embodied Mathematical Imagination and Cognition (EMIC) Working Group** for PME-NA 2015 and future meetings. The central aim of EMIC is to attract engaged and inspired colleagues into a growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education, including, but not limited to studies of mathematical reasoning, instruction, the design and use of technological innovations, and learning in and outside of formal educational settings and across the lifespan.

The interplay of multiple perspectives and intellectual trajectories is vital for the flourishing of embodied mathematical cognition. Partial confluences and differences have to be kept throughout the conversations; this is because instead of being oriented towards a single and unified theory of mathematical cognition, we are aiming towards a philosophical/educational "playground" in which entrenched dualisms, such as mind/body, language/materiality, or signifier/signified are subject to an ongoing and stirring criticism. A thriving, informed, and interconnected community of scholars organized around embodied mathematical cognition will broaden the range of activities and emerging technologies that count as mathematical and to envision alternative forms of engagement with mathematical ideas and practices (e.g., De Freitas & Sinclair, 2014). This broadening is particularly important at a time when schools and communities in North America face persistent achievement gaps between groups of students from many ethnic backgrounds, geographic regions, and socioeconomic circumstances (Ladson-Billings, 1995; Moses & Cobb, 2001; Rosebery, Warren, Ballenger & Ogonowski, 2005). There is also need to articulate evidence based findings and principles of embodied cognition to the research and development communities that are starting to generate and disseminate programs for promoting mathematics learning through movement (e.g., Petrick Smith, King, & Hoyte, 2014). Generating, evaluating, and curating empirically validated methods for promoting mathematical development through embodied activities that have engaging social bearing and curricular relevance is an urgent societal objective.

A Brief History

The submitters are proposing a new working group to PME-NA. They draw, however, on earlier interest in this topic from the International PME community (ESM, 2009), and several years of collaboration and intellectual exchange exploring the nature of EMIC from multiple methodological perspectives.

As early as 2003, several of the submitters proposed the idea of a Science of Learning Center to NSF organized around the nascent research on embodied cognition for mathematics education, and worked on a funded NSF "catalyst" grant to begin to curate and publicly share the scholarship distributed across multiple disciplines, such as linguistics, psychology, anthropology, philosophy, and neuroscience. This early work led to, among other things, a 2007 AERA symposium on mathematics learning and embodied cognition entitled, "Mathematics Learning and Embodied Cognition." This early experience led to a 6-year NSF-REESE grant, "Tangibility for the Teaching, Learning, and Communicating of Mathematics," starting in 2008, in which collaboration across three campuses (San Diego State University, University of Wisconsin-Madison, and Vanderbilt) instituted a multidisciplinary approach to the empirical investigation of embodied mathematical thinking, drawing equally on ethnomethodology, phenomenology, and experimental psychology. The three campus-based research teams ran a coordinated series of empirical and design studies that focused on learning the mathematics of space, scale, modality, and motion. The investigations took place in professional workplaces such as medical response teams, formal K-12 math and engineering classrooms, mathematics professors' offices, museums, football fields, bike paths and city streets -- places and contexts where people were learning, communicating, and doing mathematics.

Some of the research findings have been reported in a special issue of *The Journal of the Learning Sciences* (2012), "Modalities of Body Engagement in Mathematical Activity and Learning," and an NCTM 2013 research pre-session keynote panel, "Embodied cognition: What it means to know and do mathematics," as well as a series of academic presentations, book chapters, and journal articles, as well as several masters' theses and doctoral dissertations.

Along with this group, numerous other research efforts formed to investigate the embodied nature of mathematics (e.g., Abrahamson 2014; Arzarello et al., 2009; De Freitas & Sinclair, 2014; Edwards, Ferrara, & Moore-Russo, 2014; Lakoff & Núñez, 2000; Radford 2009). There is good reason at this point in time, to proclaim that there is a "critical mass" of projects, senior and junior investigators, research findings, and conceptual frameworks to support an on-going community of likeminded scholars within the mathematics education research community.

Focal Issues in the Psychology of Mathematics Education

Emerging, yet still influential, views of thinking and learning as embodied experiences have grown from several major intellectual developments in philosophy, psychology, anthropology, education, and the learning sciences that frame human communication as multi-modal interaction, and human thinking as multi-modal simulation of sensory-motor activity (Clark, 2008; Hostetter & Alibali, 2008; Lave, 1988; Nathan, 2014; Varela et al., 1992; Wilson, 2002). These views acknowledge the centrality of both unconscious and conscious motor and perceptual processes for influencing conscious awareness, and of embodied experience as following/producing pathways through social and cultural space. As Stevens (2012, p. 346) argues in his introduction to the *JLS* special issue on embodiment of mathematical reasoning, it will be hard to consign the body to the sidelines of mathematical cognition ever again if our goal is to make sense of how people make sense and take action with mathematical ideas, tools, and forms.

Three major ideas mesh with embodied cognition and serve as useful examples of the ways that embodied cognition perspectives are relevant for the study of mathematical understanding: (1) Grounding of abstraction in perceptuo-motor activity. This conception shifts the locus of "thinking" from a central processor to a distributed web of perceptuo-motor activity situated within a physical and social setting. It suggests that to make meaning people ground seemingly abstract concepts in modality-specific, sensory-motor systems, as an alternative to representing concepts as purely amodal, abstract, arbitrary, and self-referential symbol systems. (2) Cognition is for action. This tenet proposes that things, including mathematical symbols and representations, are understood by the actions and practices we can perform with them, and by mentally simulating the actions and practices that underlie or constitute them. (3) Mathematics learning is always affective: there are no purely procedural or "neutral" forms of reasoning to be learned in a manner detached from the circulation of bodily-based feelings and interpretations surrounding our encounters with them.

Alongside these theoretical developments have been technical advances in multi-modal and spatial analysis, which allow scholars to collect new sources of evidence and subject them to powerful analytic procedures, from which they may propose new theories of embodied mathematical cognition and learning. Just as the "linguistic turn" in the social sciences was largely made possible by the innovation that enabled scholars to collect audio recordings of human speech and conversation *in situ*, growth of interest in multi-modal aspects of communication have been enabled by high quality video recording of human activity (e.g., Alibali et al., 2014; Levine & Scollon, 2004), motion capture technology (Hall, Ma, & Nemirovsky, 2014; Sinclair, 2014), and developments in brain imaging (e.g., Barsalou, in press; Gallese & Lakoff, 2005). New and still largely under-explored advances in location-aware technologies and spatial analysis, such as wearable GPS devices that capture personal space-time paths, expand our opportunities to study human activity and learning in natural settings and at an increasing broader set of spatial and temporal scales (Christensen, 2003; Miller, 2007). A growing suite of *geographic information system* (*GIS*) software tools is now available and can be employed to analyze path structures in relation to other spatially anchored data (e.g., the accessibility of cultural resources that provide children with learning opportunities; Ma, Hall, & Leander, 2010).

Plan for Active Engagement of Participants

The formation of this new scholarly group requires some initial structure and the cultivation of distributed leadership. EMIC scholars will meet for 90 minutes each of three days during the PME-NA 2015 conference. We propose commencing the first gathering on Day 1 of the EMIC working group by engaging participants one or more embodied activities for promoting mathematical reasoning (a sample of the activities we propose is presented in Figure 1). Each of the activities has been used in formal and informal learning settings. The implementation and points of discussion and reflection for each activity will be informed by our prior experiences. One activity (Figure 1a) fosters deeper understanding of the Cartesian coordinate system through physically pushing and pulling handles that control coordinate displays by perceptuomotor integration of the physical and the semiotic. This has been used in interactive museum exhibits. A second activity (Figure 1b) engages participants in a projection activity using Alberti's Window. Participants look through the eyehole to draw projected images on the vertical drawing pane. A third activity uses a walking scale geometry activity (Figure 1c) to facilitate geometric reasoning in new ways by placing participants within the inscriptions (e.g., an isosceles triangle) rather than looking over them on paper from a bird's-eye-view, using everyday objects (string), and participating in large scale imagery that is necessarily collaborative. Finally, an activity engages one's body to experience spatial relations of geometric forms through body mechanics in order to influence their proof practices (e.g., for the Triangle Inequality Theorem).

Day 2 of the working group would invite participants to provide brief (5 to 10 mins) synopses of their research interests and goals for the group. The balance of Day 2 and a portion of Day 3 would be devoted to generating and discussing topics of interest. A partial list of seed topics is presented below. The final time on Day 3 would focus on practicalities, including assigning action items and roles for specific participants.

Sample Seed Topics

- Conceptual blending (Tunner & Fauconnier, 1995) & metaphor (Lakoff & Núñez, 2000)
- Development of spatial reasoning (Uttal et al., 2009)
- Gesture & multimodal instruction (Alibali & Nathan 2012; Alibali et al., 2014Cook et al.; Edwards, 2009)
- Gesture in mathematical imagination (Nemirovsky, Kelton, & Rhodehamel, 2012)
- Perceptuo-motor grounding of abstractions (Barsalou, 2008; Glenberg, 1997)
- Mathematical cognition through action. (Abrahamson, 2014; Nathan et al., 2014)
- Modal engagements (Hall & Nemirovsky, 2012; Nathan et al., 2013)
- Perceptual boundedness (Bieda & Nathan, 2009)
- Perceptuomotor integration (Nemirovsky, Kelton, & Rhodehamel, 2013).
- Progressive formalization (Nathan, 2012;Romberg, 2001) & concreteness fading (Fyfe, McNeil, Son, & Goldstone, 2014)
- Sensuous cognition (Radford, 2009)
- Simulation of sensory-motor activity (Hostetter & Alibali, 2008; Nemirovsky & Ferrara, 2009).
- Use of manipulatives (Martin & Schwartz, 2005)
- Bodily activity among professional mathematicians (Nemirovsky & Smith, 2013)
- Ways spaces are be mathematized by architects and urban designers
- Ways bodies are deployed (or suppressed) in the diversity of conceptual practices we call mathematics

Follow-up Activities

We envision an emergent process for the specific follow-up activities based on participant input. At a minimum, we will develop a list of interested participants and grant them all access to a common, closed discussion forum. We also offer these proposed activities as outcomes for extending the intellectual work of the group beyond the PME-NA meeting. The proposed activities include:

- Develop a multicampus course or MOOC
- Compile/curate literature, activities demonstrating principles of embodied cognition for promoting mathematical thinking, learning, and communicating
- Propose a sharable corpus of video data focused on gesture and action during math learning and instruction (e.g., hosted on Databrary.org)
- Exchange resources/interventions for embodied mathematical cognition for students or teachers, potentially conducting cross-institutional research studies on their use.

- Propose and edit a journal special issue.
- Sponsor the participation of colleagues from outside the community of research in mathematics education (e.g. philosophers, technologists)

EXAMINING SECONDARY MATHEMATICS TEACHERS' MATHEMATICAL MODELING CONTENT KNOWLEDGE

Kimberly Groshong	Monelle Gomez	Joo Young Park
The Ohio State University	The Ohio State University	Florida Institute of Technology
groshong.4@osu.edu	gomez.158@osu.edu	jpark@fit.edu

This is the initial formation of a working group with the purpose of addressing research questions that surfaced during the 38th International Group for the Psychology of Mathematics Education conference in Vancouver, Canada concerning the need to increase the mathematics education community's understanding of secondary teachers' knowledge of mathematical modeling content and pedagogy. In an attempt to develop this knowledge base, this working group will be driven by the following research question: What kinds of knowledge are required for secondary mathematics teachers to facilitate effective and meaningful mathematical modeling instruction? While this question can be dichotomized into subject matter and pedagogical knowledge, the working group will focus explicitly on identifying, distinguishing, and developing secondary teachers' content knowledge. Participants of working group sessions will propose a framework for identifying 1) mathematical modeling knowledge, 2) mathematical content knowledge required/important for modeling 3) modeling knowledge for implementation of mathematical modeling instruction in the secondary mathematics classroom. Efforts will be continued through digital meetings and discussion forums. Findings of the working group and subsequent discussions will be summarized and reported.

Keywords: Modeling; Mathematical Knowledge for Teaching; Teacher Knowledge; Teacher education-Inservice

The Common Core State Standards for Mathematics (CCSSM) regards mathematical modeling as both a content standard and a Mathematical Practice (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Mathematical modeling describes a problem-solving process associated with ill-posed, less structured tasks often set in real-world contexts (Lesh, Galbraith, Haines, & Hurford, 2013). The modeling process requires the modeler to interpret the task's situation, make assumptions, identify variables, build a mathematical model, manipulate and solve the model, and interpret the solution in the problem's context (Jensen, 2007). Modeling problems have multiple solution paths which are dependent upon the modeler's experiences (Confrey& Maloney, 2007). Teachers' limited experiences with mathematical modeling as learners of mathematics make implementation of this important standard and practice problematic (Goos, 2014).

Mathematics teacher educators are challenged with preparing teachers to understand the intricacies of mathematical modeling and to define effective strategies for classroom implementation. This challenge is greater at the secondary level because past research has focused on implementing mathematical modeling in elementary education (English & Sriraman, 2010) or on undergraduate modeling courses with a pure mathematics lens (Lesh et al., 2013). In addition, literature addressing secondary teachers' modeling cognition or ways to increase their pedagogical knowledge regarding modeling is scarce. The proposed working group will be devoted to describing the mathematical modeling content knowledge secondary mathematics teachers need to facilitate rich opportunities for students.

Formation of the Mathematical Modeling Working Group at PME-NA

We wish to assemble a working group comprised of mathematicians, mathematics educators, mathematics teacher educators, researchers, and psychologists. We encourage participation from scholars and graduate students who are interested in exploring the content knowledge secondary mathematics teachers need to enhance their own mathematical modeling knowledge and how this knowledge is used to develop, implement, and facilitate mathematical modeling as a standard and a practice in the classroom. We propose that members of the working group will divide into smaller groups to provide an intellectual support system, offer critique, and discuss scholarship focused around common research aims. The working group will be committed to the goals of PME-NA with an emphasis on collective reflection, collaborative inquiry, and addressing challenges.

To advance the question driving the working group "*what types of knowledge do secondary teachers need in order to implement mathematical modeling in their secondary classrooms?",* three research areas need to be reviewed: 1) definitions of teachers' knowledge, mathematical modeling, and types of mathematical modeling tasks form the foundation, 2) types of knowledge required for working on mathematical modeling tasks indicate mathematical understanding, and 3) levels of sophistication and mathematical modeling competencies suggest a path for noting progression.

Mathematical knowledge for teaching

Identifying what mathematics teachers need to know to be effective in the classroom has been the source of much debate. Shulman (1986)'s forms of teacher knowledge has provided a comprehensive consideration of the factors that influence teaching performance. Following the work of Shulman (1986), other researchers had examined the nature of teacher knowledge (Chazan& Ball, 1999; Ball, 2000). Ball, Thames, and Phelps (2008) outlined a domain-specific understanding of mathematical knowledge for teaching (MKT) distinguishing teachers' mathematical content knowledge from their pedagogical knowledge. Teachers' *knowledge of content* (CK) has three subcategories of interest: *common content knowledge* (CCK) and *specialized content knowledge (SCK)*, and *horizon content knowledge* (HCK). CCK refers to the mathematic knowledge that educated adults use in their daily lives. SCK refers to the mathematical knowledge teachers employ "in particular teaching tasks, including how to accurately represent mathematical ideas, provide mathematical explanations for common rules and procedures, and examine and understand unusual solution methods for problems" (Hill, Ball, & Schilling, 2008, pp.377-378). HCK refers to teachers' understanding of how mathematics is connected both internally and externally to other subjects, disciplines, and academic grade levels; and it the use of mathematics in everyday life and in the world of work.

What is mathematical modeling?

Mathematical models are mathematical constructs, often equations, intended to explain or predict real-world events or systems going beyond superficial physical attributes to explore structural features, e.g. patterns and relationships (English, 2007;Dossey et al., 2001). Applying mathematics to real world systems is a complex modeling process "of encountering an indeterminate situation, problematizing it, and bringing inquiry, reasoning, and mathematical structures to bear to transform the situation" (Confrey& Maloney, 2007, p. 60).

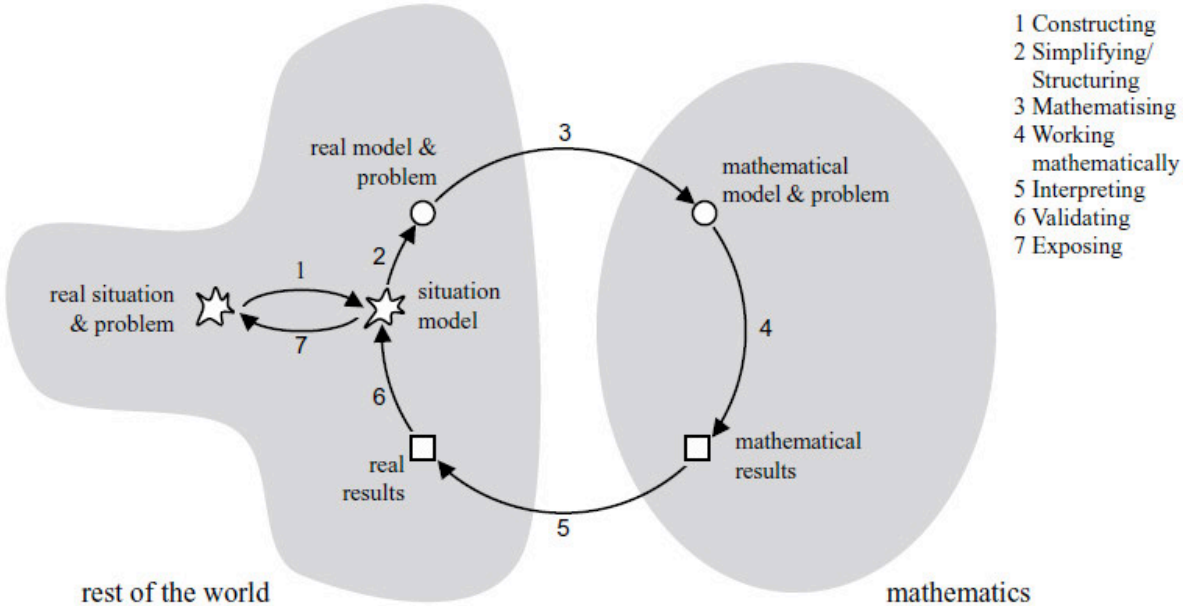

Figure 1: A visual representation of the mathematical modeling cycle (Blum, 2011)

There are many representations of the modeling process leading to the mathematical modeling product needed to solve problems in everyday life. Blum's (2002) description of the modeling process focuses on stages, as shown in Figure 1. In the first stage, the solver interprets the problem's context and *Constructs* a situation model, demonstrating understanding of the problem statement. Variables, assumptions, and relationships are detailed in the second stage, *Simplifying and Structuring,* moving the work from the real world to the mathematical world and leading to the third step, *Mathematization,* where the mathematical model is formed. Mathematizing demands that modelers select relevant information and translate it into an appropriate mathematical statement making it the most difficult step (Voskoglou, 1995). In stage 4, *Working Mathematically,* technical skills are needed to perform calculations and produce mathematical results to be *Interpreted* in the real world context in step 5. *Validating* the model, in stage 6, identifies model limitations, which may suggest the need for revisions and restarts the modeling cycle. When the modeler accepts the solution as reasonable, the last step publishes the results, *Exposing* the findings for others to consider.

Types of mathematical models

Mathematical models, as well as being a powerful tool in the field of applied mathematics, can be categorized by their general characteristics. Some researchers create two general groups: (1) normative models, which use mathematics to establish norms or optimized results such as interest problems, and (2) descriptive models, which use mathematics that describe data about business and physical phenomena (Blum & Niss, 1991). Other classification systems categorize models according to degrees of randomness distinguishing those that ignore random variation from those built upon probabilistic equations and according to levels of theoretical information distinguishing models that are deeply rooted in theoretical principles from those models that are empirically driven (Edwards & Hamson, 2001). The Common Core State Standards for Mathematics (CCSSM, 2010) add probabilistic and statistic models to predict outcomes of events.

Knowledge needed for mathematical modeling

Because mathematical modeling tasks often describe messy real-world situations found in science, engineering, business, art, and literature, modelers need both a broad knowledge of the world and extensive mathematical knowledge to successfully generate a model (Jensen, 2007). During the mathematical modeling process, modelers use organizational and communication skills to collect and make sense of information. Modelers also engage in discussions about the reality of the task situation and the assumptions they make about the situation (Verschaeffel, Greer, & De Corte, 2000; Galbraith & Stillman, 2001).

Understanding the problem context is essential for modelers to link mathematical knowledge to their real world knowledge (Imm & Lorber, 2013). When modelers are unfamiliar with the context of the task, they usually only make general statements about the situation but cannot mathematize the problem because the assumptions made and the variables defined are limited by their lack of knowledge about the problem context (McNair, 2000). Since it is important for the modeler to be familiar with the real world context referred to in the mathematical modeling task, more research is needed to understand how modeling students make connections between reality and mathematics as well as the degree of familiarity needed with the task context in order to mathematize the situation. Mathematical modeling tasks used in secondary mathematics classrooms vary widely in their degree of authenticity as close simulations of real life. More research is needed to determine the relationship between the task's authenticity and modeling performance.

Many types of mathematical knowledge are accessed in solving mathematical problems, and this knowledge can be increased through exposure to different types of modeling activities (Doerr, 2007). Tirosh (1999) detailed a list of mathematical knowledge areas that includes instrumental, formal, relational, conceptual, procedural, algorithmic, visual, intuitive, implicit versus explicit, and elementary versus advanced; suggested considerable overlap between these categories; and recommended that more research is needed. When looking at the mathematical modeling content knowledge needed to successfully generate a modeling solution, research should seek to answer the basic questions of *what* mathematical knowledge is demanded, *why* a particular type of mathematical knowledge is required, and *how* the mathematical knowledge may be applied when working with mathematical modeling situations.

Modeling sophistication and competency

Once a mathematical model is generated, the *level of sophistication* of the modeler can be examined by analyzing the model's degree of complexity, generalizability, effectiveness, and efficiency (Blum, 2002). The level of sophistication depends upon the breadth and depth of mathematics employed by the model as well as the use of constraints which expose deeper understanding of the modeling situation (Zawojewski, 2010). Along the thread of research monitoring modeling progress, mathematical modeling competence is defined as an "insightful readiness to carry through all parts of a mathematical modeling process in a given situation" and should be viewed from a holistic perspective, examining progress in the entire modeling process, as well as a piecemeal perspective, tracking progress through specific individual modeling stages (Blomhoj & Jensen, 2007).

Jensen (2007) defined three dimensions of mathematical modeling competence: the *Degree of Coverage* dimension, which indicates the ability to work independently and monitors the interpretation of the situation; the *Radius of Action* dimension, which tracks the real world and mathematical domains where modelers are able to work; and the *Technical Level* dimension, which monitors the scope and quality of mathematics used in modeling as well as the flexibility in revising models.

Mathematical Modeling Working Group at PME-NA

The framework for the working group is adapted from Jensen's (2007) *expanding box*, which represents growth in competencies while solving mathematical modeling tasks, to a three-dimensional depiction of the three areas of mathematical modeling knowledge for teaching (MMKT), shown in Figure 2. With the three dimensions of MMKT identified, the representation encourages research identifying, tracking, and analyzing mathematical modeling thinking including knowledge, skills, and competencies. It is important to note that difficulties in one dimension can impact performance in other dimensions.

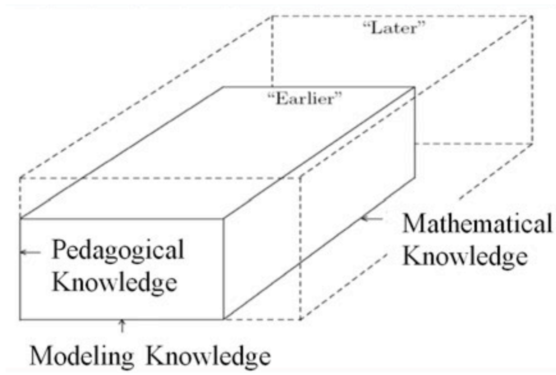

Figure 2: Framework for mathematical modeling knowledge for teaching (Authors, 2015)

Both the *Mathematical Knowledge* and *Modeling Knowledge* dimensions are features of mathematics teachers' content knowledge of mathematical modeling. The first dimension, *Mathematical Knowledge,* tracks growth in modelers' mathematical knowledge and skills as they work with a variety of mathematical modeling tasks. "This dimension represents the size and content of the 'mathematical toolbox.'" (Jensen, 2007) For example, some teachers may exhibit proficiency in algebraic situations but may struggle with probabilistic contexts. Working with real world questions is difficult for less sophisticated modelers who find mathematizing the situation to be challenging, and they often do not incorporate advanced mathematics into their models even though they have completed advanced mathematics coursework (Blomhoj & Jensen, 2007). Jensen's (2007) dimension of *radius of action* maps directly to horizon content knowledge while his technical dimension maps directly to mathematical content knowledge. This dimension provokes many possible discussion questions including the following:

1. What *mathematical content* knowledge is required for secondary mathematics teachers' mathematical modeling instruction?
2. How can progress in teachers' mathematical content knowledge for modeling instruction be monitored?
3. How does general domain-mathematical content knowledge influence mathematical modeling knowledge for teaching?

The second dimension, *Modeling Knowledge*, examines both a teacher's ability to work independently through the modeling process and the teacher's proficiency with different types of modeling problems and contexts. Teachers with a low level of modeling sophistication may struggle stating assumptions, defining variables, and identifying and incorporating key relationships when beginning new modeling tasks; and those with a high level of modeling sophistication may progress more efficiently from translating the real world situation to interpreting the solution. Jensen's (2007) dimension of the degree of coverage maps directly to modeling skills. This dimension provokes many possible discussion questions including the following:

1. What *modeling* knowledge do teachers need to possess to teach mathematical modeling?
   a. What knowledge is needed for working with different types of mathematical modeling tasks?
   b. What knowledge is needed to pose mathematical modeling tasks?
   c. What knowledge is needed to critique a mathematical model?
2. How can progression in modeling knowledge be followed?

The third dimension is *Pedagogical Knowledge*, which monitors teachers' classroom interactions and lesson planning for an increase in teachers' knowledge of students and curriculum with mathematical modeling. Due to the complexity of the main research question, the *Pedagogical Skills* dimension is not a primary focus for the initial working group sessions, but the participants may decide to expand their discussions to include this category.

Plan for Active Engagement of Participants

Members of the working group will actively participate in defining this research arena. The working group will meet three times during the conference and virtually during the course of one year.

Session 1: Foundation

The first session will outline the structure of the working session and lay the foundation for mathematical modeling knowledge for teaching by establishing common definitions and presenting the digital environment as an archive of forum discussions and research ideas that can be shared publicly or privately to promote involvement and collaboration. Sample mathematical modeling tasks will be provided as a vehicle to elicit discussion, establish definitions, and note points of distinction. Members are invited to bring mathematical modeling tasks to share with the group and suggest and generate research questions. The final part of the session will be allocated to introducing the framework that will guide the research focus of the working group and forming research groups based on the interests of the participants.

Session 2: Content Knowledge

The second session will focus on clearly defining mathematical content knowledge needed for mathematical modeling and outlining research goals and objectives to monitor progression in this area. Due to the interdisciplinary nature of mathematical modeling, as well as the various mathematical approaches taken by modelers, the meaning and implications of horizon content knowledge with regards to mathematical modeling will be included in group discussions. Sample tasks and student work samples will be shared to facilitate group discussions regarding mathematical modeling thinking in terms of mathematical knowledge and sophistication in the scope of each groups' research interests and discussion questions.

Session 3: Modeling Knowledge

Using discussion questions, the third session will focus on clearly defining modeling knowledge needed for mathematical modeling and outlining research goals and objectives to monitor progression in this area. Discussions will be focused on how to improve teachers' modeling knowledge holistically and individually.

Post-conference

To sustain the working group's efforts, results of all sessions and meetings will be documented and disseminated to all members. Following the conference, participants will be invited to continue discussing research interests in this area through a web-based discussion forum created, hosted, and monitored by the leaders of the working group and supported by The Ohio State University. The discussion forum will offer an environment for suggesting and reviewing research, posing and critiquing mathematical modeling tasks, posting and discussing teacher and student solutions, and developing an archive of useful and productive mathematical modeling tasks. Working group members will participate in digital meetings throughout the year to review progress on scholarship. Findings of the working group and subsequent discussions will be summarized and reported.

Conclusion

With the lack of literature on developing mathematical modeling content and pedagogy in secondary teachers and the ambiguity of the mathematical modeling strand and mathematical practice as defined by the Common Core State Standards for Mathematics, the mathematics education community is in need of a dedicated group of individuals who will investigate this field. Working group participants will be committed to increasing knowledge on mathematical modeling and sustaining the educational and research goals of PME-NA. A working group at PME-NA devoted to investigating mathematical modeling knowledge for teaching will provoke interesting and productive research questions and studies to expand the field.

The debate in understanding what content knowledge secondary teachers should have in order to provide effective instruction is the main theme of this new Working Group. Our goal is to explore connections between advanced and secondary mathematics as an entry point into this debate. In particular, we will gather interested individuals in an effort to deepen our understanding of existing connections between abstract algebra and secondary mathematics and which of these connections are important for secondary teachers to know and understand. Moreover, we aim to further research in this area by considering possible links between knowledge and understanding of connections and secondary instruction as well as how we might be able to assess teachers' knowledge about connections between advanced and secondary content. We hope to accomplish these goals by discussing important connections between abstract algebra and secondary mathematics, providing opportunities for participants to share their experiences with connections, and engaging in conversations about the impact and assessment of connections in secondary teaching.

Keywords: Advanced Mathematical Thinking; Teacher Education-Preservice; Teacher Education-Inservice; Teacher Knowledge

There has been a longstanding debate in the mathematics and mathematics education communities concerning the knowledge secondary mathematics teachers need to provide effective instruction. Central to this debate is what content knowledge secondary teachers should have in order to communicate mathematics to their students, assess student thinking, and make curricular and instructional decisions. This debate has already led to many fruitful projects (e.g., Connecting Middle School and College Mathematics [$(CM)^2$] (Papick, n.d.); Mathematics Education for Teachers I (2001) and II (2012); Mathematical Understanding for Secondary Teaching: A Framework and Classroom-Based Situations (Heid, Wilson, & Blume, in press)). A common thread in these projects is the belief that mathematics teachers should have a strong mathematical foundation along with the knowledge of how advanced mathematics is connected to secondary mathematics (Papick, 2011). But questions remain about what secondary content stems from advanced connections, which connections are important, and how might knowledge of such connections impact classroom practice. This new working group is being created to further explore these and other related questions.

More mathematics preparation does not necessarily improve instruction (Darling-Hammond, 2000; Monk, 1994). In fact, some research has shown that more mathematics preparation may hinder a person's ability to predict student difficulties with mathematics (Nathan & Petrosino, 2003; Nathan & Koedinger, 2000). Nevertheless, the requirements for traditional certification to teach secondary mathematics across the country continue to include an undergraduate major in the subject. Moreover, questions regarding mathematics teachers' content knowledge and preparation continue to be the topic of concern as evidence from the current conversations around national and international test result of student achievement in mathematics. Therefore, it is important that, as a field, we investigate the nature of the present mathematics content courses offered (and required) of prospective secondary mathematics teachers to gain a better understanding of which concepts and topics positively impact teachers' instructional practice. We hypothesize a valuable starting point would be to develop a better understanding of the nature of the mathematical connections between advanced content taken in undergraduate programs and secondary content taught in schools. Explicit attention to these connections could play a pivotal role in making the mathematics major more meaningful to prospective teachers and could positively impact future teachers' instructional practice.

Research focused on connections between advanced and secondary mathematics has begun to gain traction in the mathematics education community. Such research addresses (a) the connections that exist between particular advanced content courses (e.g., abstract algebra) and secondary mathematics (e.g., Baldinger, 2014; Cofer & Findell, 2007; Usiskin, 2001; Wasserman, 2014) and (b) the impact learning connections between advanced and secondary content has on teachers and their instruction (Baldinger, 2013; Wasserman, 2014).

This new working group will continue and expand on this research in order to explore the following questions:

1. What are the connections between advanced and secondary content?
    a) What connections between advanced and secondary content are important for teachers to know and understand?
2. What is the link to classroom practice?
    a) How does knowledge of connections between advanced and secondary content impact instruction in secondary classrooms?
    b) How can we better support teachers to understand connections between advanced and secondary content and to use pedagogy that employs these connections?
2. How do we assess teachers' knowledge about connections between advanced and secondary content?
    a) How do we determine the depth of teacher knowledge of advanced content and connections to secondary content?
    b) What are indicators that teachers have gained particular understandings?
    c) What do we want teachers to be able to do with this knowledge?

Background

We take the view that connections between advanced mathematics and secondary mathematics encompass both mathematical content and ways of thinking about and engaging with that content. We draw on research around mathematical knowledge for teaching (e.g., Ball, Thames, & Phelps, 2008), key developmental understandings (Simon, 2006), mathematical practices (e.g., Council of Chief State School Officers [CCSSO], 2010; RAND, 2003) and habits of mind (e.g., Cuoco, Goldenberg, & Mark, 1996) to define these connections.

Mathematical knowledge for teaching (MKT) (Ball et al., 2008) describes different domains for the mathematical knowledge teachers draw on in the practice of teaching. Broadly, it encompasses subject-matter knowledge and pedagogical content knowledge. More specifically, subject-matter knowledge entails three domains of mathematical knowledge used in teaching: common content knowledge, specialized content knowledge, and horizon content knowledge. Pedagogical content knowledge includes knowledge of how the content is related to students, to teaching, and to curriculum. These categories were developed based on the mathematical work of teaching at the elementary level, and many scholars have utilized them at the secondary level (e.g., Baumert et al., 2010; Tatto & Senk, 2011), although others have problematized this direct translation to secondary mathematics (e.g., Speer, King, & Howell, 2014). Although these categories may not perfectly capture all that secondary teachers need to learn, they represent a potentially useful framework for thinking about the scope of mathematical knowledge needed for teaching. In the context of connections between advanced mathematics and secondary mathematics, the MKT framework invites the following questions: What knowledge of mathematics does a secondary teacher need that goes beyond the mathematics of the school curriculum? How might advanced mathematics enable a teacher to unpack a secondary mathematics topic? How might an understanding of advanced mathematics influence instructional choices in presenting a secondary mathematics topic?

One useful strategy for exploring teacher learning of connections between advanced mathematics and secondary mathematics is through the construct of “key developmental understandings (KDUs)” (Simon, 2006). A KDU is a "conceptual advance that is important to the development of a concept" (Simon, 2006, p. 365). Silverman and Thompson (2008) use this construct in their framing of teachers’ mathematical knowledge, by proposing that teachers develop MKT of a topic if: (a) they have achieved a KDU that encompasses mathematical understanding of the topic; and (b) they have an understanding of how the topic may evolve instructionally in support of students' reasoning in the K-12 classroom. This highlights questions such as, what are the key developmental understandings around advanced mathematics that have connections to secondary mathematics? How might these particular KDUs support the development of MKT?

It is useful to expand our consideration of what secondary teachers need to know beyond content and concepts to encompass mathematical habits of mind (e.g., Cuoco et al., 1996) and engagement in mathematical practices (e.g., CCSS, 2010). Mathematical habits of mind include looking for patterns, giving precise descriptions, and utilizing visualizations. Mathematical practices include making conjectures, attending to precision, and connecting representations. These are habits and practices that cut across content areas and levels of mathematical study. Engagement in mathematical practices is an explicit feature of school mathematics through their inclusion in the Common Core State Standards. Attending explicitly to mathematical practices in our context invites asking: How is engagement in mathematical practices around advanced mathematics content similar to and different from engaging in those same practices around secondary content?

We draw on these ideas to develop a description of connections between advanced mathematics and secondary mathematics. Connections might be purely mathematical in nature; that is, they might relate directly to subject-matter knowledge. Connections might highlight a relationship between content and students or content and teaching; that is, they might relate to pedagogical content knowledge. Connections might be part of the key developmental understandings that support the development of mathematical knowledge for teaching. Further, connections might go beyond knowledge *of* mathematics and encompass engagement *in* mathematics through the lens of mathematical practices.

History and Goals for Working Group

The purpose of this new working group is to strengthen our collective understanding of connections between advanced and secondary content and their role in secondary mathematics teaching and learning. The members of this working group came into the idea of investigating connections and teacher preparation through various disparate individual and group pursuits. Recently, we began having informal conversations about these ideas based on our experiences. We realized we had common interests and that there were others pursuing similar research. As a result, we saw the opportunity to advance our collective ideas as well as the field’s understanding of connections. For example, one common interest for the working group is the experience of prospective or practicing secondary mathematics teachers as they take advanced mathematics courses, such as abstract algebra. In general, prospective teachers, similar to some math majors, struggle with understanding the material and applying their knowledge (Clark, Hemenway, St. John, Tolias, & Vakilet, 1999; Zazkis & Leikin, 2010). Additionally, many do not understand the purpose of taking advanced mathematics courses (e.g., Cuoco, 2001), especially the relevance to teaching secondary mathematics (e.g., Cuoco & Rotman, 2013a). For example, Broderick (2013) interviewed prospective secondary teachers about the usefulness of their college math courses. He found their comments were consistent with the literature (e.g., G. Hill, 2003), with one caveat. One participant had not passed abstract algebra the first time and went through it again. She found more relevance the second time through and was more satisfied with taking the course. Such findings have led to several efforts to make abstract algebra more accessible and applicable.

Abstract Algebra Textbooks

Based on the need to connect with prospective secondary mathematics teachers, mathematicians have written textbooks in abstract algebra for this specific audience (e.g., Cuoco & Rotman, 2013b; J. Hill, Thron, & Weathers, 2012; Nicodemi, Sutherland, & Towsley, 2007). The preface to Cuoco and Rotman (2013b) states that the textbook is designed for college students who want to teach mathematics in high school. The textbook authors also state that it can serve as a text for standard courses in abstract algebra as well. What distinguishes this text is the authors' assertion that they "have found that the first encounter with groups is not only inadequate for future teachers of high school mathematics, it is also unsatisfying for other mathematics students" (p. xiii). They also specifically "include sections in every chapter, called ***Connections***, in which we explicitly show how the material up to that point can help the reader understand and implement the mathematics that high school teachers use in their professions" (p. xiv, emphasis in original).

Similarly, Nicodemi et al. (2007)'s abstract algebra textbook is written for an audience of both preservice secondary teachers and mathematics majors. They also take the approach to introduce rings and polynomial rings before groups because of the "natural parallel of facts about integers to facts about polynomials" (p. ix), which connects to secondary mathematics. They acknowledge that

> All students appreciate links that connect the abstract mathematics encountered in upper-level courses to familiar, more concrete mathematics of their earlier experiences. Such links are crucial to the future teacher as a bridge between the mathematics they are learning and the mathematics they will teach. (p. ix)

Thus, in most of the sections the authors finish them with a short note to the teacher.

Other textbooks are designed specifically for secondary teachers (e.g., J. Hill et al., 2012). Hill's text focuses on group theory and homomorphisms, but does not consider rings and fields. It also adds references to school mathematics and discusses topics such as cryptography and algebraic coding theory. Thus, while there exists research-based textbook support for courses in connecting abstract algebra to secondary mathematics, J. Hill et al. (2012) show that some textbooks can make choices for which typical abstract algebra topics they cover and do not cover. These choices are also reflected in the research that exists chronicling various implementations of modified abstract algebra courses.

Modified Abstract Algebra Courses

In efforts to make abstract algebra more accessible to secondary teachers, and other majors, certain modifications have been made to the traditional lecture-based format. Courses have been developed with a focus on cooperative learning environments (Barbut, 1987; Cnop & Grandsard, 1998) and including a component of technology (Leron & Dubinsky, 1995; Clark, et al., 1999). For example, Freedman (1983) conducted an abstract algebra course where students were responsible for presentations of the material based on their work with original sources. In another example, Grassl and Mingus (2007) used a new pedagogical model where they conducted an abstract algebra course using team teaching and cooperative learning. They found that this approach provided deeper learning for students as a community of scholars.

Other courses in abstract algebra have been created specifically for prospective and practicing secondary mathematics teachers. These courses focused on connections to high school mathematics (Baldinger, 2013; Cuoco & Rotman, 2013a). The course in Baldinger's study was motivated by studying the concepts necessary to understand a certain proof of the fundamental theorem of algebra. Each concept they studied allowed for opportunities to make connections to secondary mathematics. These topics were studied from an advanced perspective and in non-standard settings. Examples included the natural numbers, polynomials, proofs by induction, and prime factorization. Other connections to the secondary curriculum involved drawing parallels between the integers and polynomial rings.

The tension of content coverage was highlighted in the studies of the implementation of abstract algebra courses as in textbooks. For example, Baldinger (2013) mentioned that the course in her study did not cover groups or rings and gave only a minimal treatment of field extensions. The course in Freedman (1983) took three years to complete. Cnop and Grandsard (1998) also stated they needed to take the class at a slower pace with their modifications. Cuoco and Rotman (2013a) affirmed that their modifications did not "dumb down" the course, which can be an issue when working with prospective teachers. With the potential for issues regarding content coverage, we are brought to the question of what connections can be made to secondary mathematics, while covering the content necessary for teachers and non-teachers alike.

Such research in undergraduate mathematics education has led to the types of questions this working group is interested in exploring, such as what content can best help prospective teachers see relevance to their future teaching and not wonder why they had to take a particular advanced course? If this content can be the focus of an advanced course, could this help people become more effective teachers and foster the development of higher order skills in their secondary students?

Abstract Algebra and Secondary Instruction

Beyond considering abstract algebra courses themselves, it is critical to consider how teachers' knowledge of advanced mathematics influences their teaching practices. G. Hill (2003) describes how a secondary teacher was able to build on the axiomatic approach to abstract algebra in a unit on complex numbers for her secondary students. Wasserman (2014) described some of the ways that prospective and in-service teachers were introduced to ideas of abstract algebra, which drew upon solving simple equations. Wasserman and Stockton (2013) used vignettes to capture some of the potential implications on teaching secondary mathematics in relation to their planned practices.

Wasserman (in press) looked at teachers' practices for teaching some specific elementary, middle, and secondary topics, before and after being learning about introductory concepts in abstract algebra. In identifying the specific topics, he developed a framework that considered the K-12 content areas for which teaching might be influenced by teachers' knowledge of abstract algebra. This provides a different perspective than the traditional listing of connections between abstract algebra and secondary mathematics (e.g., (Z, +) is a group).

Because work with prospective teachers' understanding and practice of the connections between abstract algebra and secondary mathematics is in the emerging stages (e.g., G. Hill, 2003; Wasserman, 2014; Wasserman, in press; Wasserman & Stockton, 2013), additional research is required to evolve and validate this area. A natural next step would also be to assess the prospective teachers' knowledge and practice.

Therefore, this new working group seeks to continue and extend the research described above and to consider the following questions: (a) What are connections between advanced and secondary content? (b) How are these connections linked to instructional practice in secondary classrooms? (c) How do we assess prospective teachers' knowledge about connections between advanced and secondary content?

Rationale and Relevance for PMENA

Drawing meaningful connections between secondary and advanced mathematics has been an enduring challenge for secondary mathematics teachers (e.g., CBMS, 2012). This new working group aims to capitalize on cooperation among mathematicians and mathematics educators to investigate critical issues in the mathematical preparation of prospective secondary mathematics teachers. The working group will promote the exchange of ideas around (a) identifying important connections between abstract algebra and secondary mathematics; (b) exploring the impact of such connections on secondary instruction; and (c) thinking about how teacher educators might be able to assess knowledge and understanding of such connections. For example, in exploring connections between abstract algebra and secondary mathematics, the group will identify key developmental understandings (KDUs) that can be targeted by and connected to specific tasks for prospective teachers.

The exploration of these topics connects directly to the conference theme of *developing critical responses to enduring challenges* by opening a dialogue around the nature of abstract algebra for secondary teachers and how connections to secondary mathematics can be used to enhance the learning of both prospective teachers and other majors. The work will be relevant to the PME-NA audience through the exploration of conceptual ideas such as extending notions of mathematical knowledge for teaching to this advanced level and through practical ideas such as strategies teacher educators might use to assess teacher understanding of connections between advanced mathematics and secondary mathematics.

Organization and Plan for Active Engagement

The overall goal for this new working group is to strengthen our collective understanding of connections between advanced and secondary content and their role in secondary mathematics teaching and learning. We focus on abstract algebra as an entry into this domain, particularly for its rich connection to secondary mathematics topics such as algebra and functions, while also anticipating that the impact of these conversations will prompt research into other content areas (e.g., calculus, linear algebra, and analysis).

Across the three sessions, participants will engage with facilitators about the current state of the research through brief presentations and guided discussions.

Session 1: Exploring connections between abstract algebra and secondary mathematics

In the first session, we will introduce the working group by sharing our definition of connections along with the background and goals of the working group. After this brief presentation, group members will share some of their own work about important connections between abstract algebra and secondary mathematics to allow participants to share and learn about different connections. The discussion will be among the entire group and will focus on the following question: What are the important connections between abstract algebra and secondary mathematics? At the end of this session, the facilitators will create a summary of important connections discussed to help organize and motivate the following sessions.

Session 2: Exploring the impact of connections on secondary instruction

In the second session, we will begin by sharing our summary of the previous session. We will then have a whole group discussion focused on the question: What do we mean by and how do we measure impact on instruction? The second part of this session will use the group's working definition and the important connections from Session 1 to address the following questions:

1. How does knowledge of connections between advanced and secondary content impact instruction in secondary classrooms?
2. How can we better support teachers to understand connections between advanced and secondary content and to use pedagogy that employs these connections?

Participants will be expected to think about important connections they have seen for the teaching of secondary mathematics and how these connections might be applied to secondary mathematics teaching. At the end of the session, the facilitators will create a summary of how important connections might influence teachers' practice to help organize and motivate the final session.

Session 3: Assessing teacher understanding of connections

In the final session, we will begin by sharing our summaries of the previous session. We will engage in a whole group discussion of how group members have assessed or might assess whether teachers have indeed acquired knowledge and understanding of the important connections between abstract algebra and secondary mathematics discussed. Through this conversation, we will collect ideas for assessment and focus on the following questions: (1) How do we determine the depth of teacher knowledge of the connections between abstract algebra and secondary mathematics? (2) What are indicators that teachers have gained particular understandings? (3) What do we want teachers to be able to do with this knowledge? We will conclude the working group by summarizing the ideas shared about important connections, impact on teachers' practice, and ideas for assessment. We will collect contact information from participants to continue the conversation and wrap up by establishing a set of next steps.

Anticipated Follow-up Activities

As a result of this working group, we anticipate three primary follow-up activities. First, we will submit an article to the Notices of the American Mathematical Society. The Notices is the most widely-read journal by professional mathematicians. Our article will provide an opportunity for us to engage mathematics professors in a conversation about the mathematical preparation of secondary teachers. In particular, we will share results from each of the three themes within our working group: (1) specifying mathematical connections between abstract algebra and secondary mathematics, as an opportunity to draw on such examples in abstract algebra courses; (2) recognition that mathematical connections are necessary but insufficient, and sharing ways that, for teachers, abstract algebra may have implications for their *teaching* of secondary mathematics, not just their knowledge of mathematics itself; and (3) discussing ideas about how assessments might inform whether teachers have acquired such desired understandings.

Second, we will prepare an entry for the American Mathematical Society's blog on the Teaching and Learning of Mathematics. We have been invited to contribute such an entry by one of the blog editors who is an author of this working group proposal. This will allow us to reach a wide online audience and provide an overview of connections between abstract algebra and teaching secondary mathematics.

The third anticipated follow-up activity has to do with longer-term work via continued meetings at other conferences and establishing a collective research agenda. The discussion group will provide, based on some of our previous work and interests individually, an opportunity for all of us to get a sense of a bigger picture about abstract algebra for secondary teachers. In the nearer future, this shared perspective will provide opportunities for the group to continue working together, studying and researching more rigorously some of the ideas related to abstract algebra and secondary teaching that arise from the working group. In the farther future, we anticipate branching off into other areas of advanced mathematics (e.g., real analysis). A long-term collective goal is to fundamentally reconsider the teaching of more advanced content courses for teachers in ways that are useful both generally for the teaching of all mathematics majors and also specifically for the unique considerations and professional practices of secondary teachers. With the discussion group as a starting point, building into more rigorous research about connections to secondary mathematics and its teaching, we imagine collectively developing materials for such courses.

LEVERAGING DIFFERENT PERSPECTIVES TO EXPLORE STUDENT THINKING ABOUT INTEGER ADDITION AND SUBTRACTION

Nicole M. Wessman-Enzinger
George Fox University
nmenzinger@gmail.com

Laura Bofferding
Purdue University
lbofferding@purdue.edu

This is the third meeting of a working group on student thinking about integers. The main goal of this working group includes utilizing different theoretical perspectives and methodologies in small groups to design complementary studies, where student thinking about integer addition and subtraction will be explored. This working group aims to provide a space for participants to capitalize on their differences in theoretical perspectives and methodologies to promote productive scholarly discussion about the same research topic, student thinking about integer addition and subtraction. Participants will actively engage in work that progresses towards these studies, with the intent to develop a monograph that highlights this research.

Keywords: Number Concepts and Operations; Cognition; Research Methods

A Brief History of the Working Group

The first working group on student thinking about integers convened during PME-NA 35 (Lamb et al., 2013). During this working group, facilitators shared perspectives of current research in the field on student thinking about integers. Discussion with these speakers and participants revolved around the presentations and what "Integer Sense" entails. The work initiated at PME-NA 35 continued at the joint PME 38 and PME-NA 36 meetings (Bofferding, Wessman-Enzinger, Gallardo, Salinas, & Peled, 2014). At this meeting, the organizers presented an extensive review of all of the integer articles from the PME and PME-NA proceedings. Further, they shared and discussed perspectives on integer research stemming from seminal work on integers. The group concluded with a discussion on next directions for collaborative research on the teaching and learning of integers. Responding to the need for collaborative research, this working group proposes a collaborative research project that welcomes all perspectives on student thinking about integer addition and subtraction and provides a platform that embraces these collective differences.

Relevance to Psychology of Mathematics Education

Compared to research on whole number addition and subtraction, research on student thinking about integer addition and subtraction is fairly limited. Perhaps for this reason, there is increased interest in student thinking about integer addition and subtraction in our field (e.g., Bishop et al., 2014a, 2014b; Author, 2014; Stephan & Akuyz, 2012). However, research on student thinking about integer addition and subtraction has been conducted, and even represented at PME and PME-NA, for over three decades (e.g., Bell, 1982; Gallardo, 2003; Marthe, 1979; Peled, Mukhodpadhyay, & Resnick, 1989). This points to a need for research on student thinking about integer addition and subtraction to begin building bridges to connect the research. One way to do this will be to discuss similarities and differences when using different theoretical lenses or analyses on similar topics (e.g., Lewis, 2008).

For guidance as a field interested in the growth of research on student thinking about integers, it is helpful to turn to well-established agendas, like the research on student thinking about whole number operations, and reflect on how these agendas have flourished and have became well-connected. Research on student thinking about whole number operations grew and became the most proliferated and well-connected area of research (Mathematics Learning Study Committee, 2001) with researchers taking different perspectives on similar topics. The 1970s involved investigations into how young children counted on or solved different types of word problems (e.g., Jermam, 1970; Steffe & Johnson, 1971). Research on student thinking was often focused on "basic skills," accuracy, and speed (Jermam, 1970; Bright, Harvey, & Wheeler, 1979).

By the 1980s and 1990s, research exploded on student thinking about whole number operations, where most of the scholarly discussion revolved around student-invented strategies and different problem types (e.g., Carpenter, Ansell, Franke, Fennema, & Weisbeck, 1993; Carpenter, & Moser, 1984; Fuson et al., 1997). As this influx in research on student thinking about whole numbers increased, researchers responded to the multiple perspectives on student thinking. For example, Cobb (1985) reacted to three different papers from Baroody (1984), Carpenter & Moser (1984), and Fuson (1984) that appeared in *The Journal for Research in Mathematics Education*. We can now look across these agendas and compare and contrast the findings and perspectives, and even categorize these perspectives by agenda (e.g., Cognitively Guided Instruction (CGI), Conceptually Based Instruction Project (CBI), Problem Centered Mathematics Project (PCMP), Stages of Early Arithmetical Learning (SEAL), Supporting Ten Structures (STST)).

By the 2000s, the similarities and differences of these different theoretical perspectives and research methodologies were embraced and projected the field forward, not only in the area of whole number arithmetic but in many other areas, such as early algebra (e.g., Carpenter, Franke, Levi, 2003; Carraher, Schliemann, Brizuela, & Earnest, 2006), understanding of the equal sign (e.g., Jone & Pratt, 2011), rational numbers (e.g., Empson & Levi, 2011; Steffe & Olive, 2010), and even preservice teacher education (e.g., Vacc & Bright, 1999).

If we compare the development of research and research agendas on student thinking about integers to the field of whole numbers, we can learn that embracing multiple perspectives is productive and insightful. Similar to the increased interest in student thinking about whole number arithmetic of the 80s and 90s, we are currently positioned to respond to this increased research interest on student thinking about integers. Drawing upon these productive comparisons and research, this working group aims to establish a space for those interested in researching student thinking about integer addition and subtraction. Based on past participation in the working group, we anticipate that participants will represent a variety of theoretical perspectives, which will fuel a set of complementary studies and continued discussion about similarities and differences in our investigations.

Theoretical Perspectives & Methodological Approaches

Across the PME and PME-NA proceedings and recent journal articles, researchers have presented work around negative integers from a variety of perspectives and using different methodological approaches. Some or all of these may play a role in the working group discussion, studies, and final products. We present a few examples:

Integer sense. Both Gallardo (2002) and Bishop et al. (2014a) point to ways that that we can think about and use negative integers (see Table 1). Gallardo based her framework for interpreting negative integers on historical analyses of the topic and clinical interviews with middle-schoolers. Bishop et al. based their interpretations from the literature and mathematical reflections.

Rather than focusing on the different ways of interpreting integers, Kilhamn (2009) theorized about what number sense is in relation to concepts involving integers. These components include "intuitions about numbers and arithmetic" (p. 331), the "ability to make numerical magnitude comparisons" (p. 332), the "ability to recognize benchmark numbers and number patterns" (p. 333), and "possessing knowledge of the effects of operations on numbers" (p. 334).

Table 1: Comparisons and Interpretations of Gallardo (2002) and Bishop et al. (2014a)

Gallardo (2002) interpretations of negative numbers (p. 179)	Bishop et al. (2014a) interpretations of -5 (p. 20)	Reflections
Subtrahend "where the notion of number is subordinate to the magnitude (for example, in a – b, a is always greater than b where a and b are natural numbers"	"An action of removing 5 from a set"	Removing five from a set matches closely to interpreting a negative number as subtracting a positive number.
Relative or Directed Number "where the idea or opposite quantities in relation to a quality arises in the discrete domain and the idea of symmetry appears in the continuous domains"	"The location on a number line (coordinate plane, etc.) 5 units to the left of, or below, 0" "An action of moving 5 units left or five units down" "A debt of $5 is also a directed number; it is the opposite of a credit of $5."	Placing a negative number on a number line allows one to interpret the negative number as a relative number or a directed number. Debt can be interpreted as direction. Or, -5 can be a relative number that represents a loss of five dollars.
Isolated Number the result "of an operation or as the solution to a problem or equation"	"The integer between -6 and -4"	The negative number may be treated as a symbolic number that has order.
Formal Negative Number "a mathematical notion of negative number, within an enlarged concept of number embracing both positive and negative numbers (today's integers)"	"Describing the equivalence class [(0,5)] in which we define (a, b) to mean a – b, and all other ordered pairs (a,b) such that a + 5 = 0 include (1, 6), (2, 7), (100, 105), and all other ordered pairs (a,b) such at a + 5 = 0 + b for a,b that $\in \mathbb{N}$. [More formally, we can write (0, 5) ~ (a, b).]"	The negative number can be thought of in more formalized ways. For example, -5 is compared to an equivalence class. We can also talk about the additive group of the integers or the ring of the integer and how integers are not a field because the multiplicative inverses are not all integers.

Integer number line and conceptual change. Using an experimental design involving pre- and post-test task-based interviews as well as instruction around different aspects of integer concepts, Bofferding (2014) identified different conceptions children have of integers. Aligned with a conceptual change paradigm (Vosniadou, 1994), the conceptions fall along a continuum where initial ideas about negative numbers arise from students' conceptions of whole numbers and progress to more formal understanding. Although the categories and concepts explored in the research support Kilhamn's (2009) ideas of number sense, Bofferding's interpretation of students' work focuses on how their conceptions arise and become differentiated from their whole number understanding and when planning for instruction focuses on how to effectively bridge learning of whole number and integer concepts. Further exploration of students' developing integer conceptions would benefit from the use of additional research methods, such as a teaching experiment (Steffe & Thompson, 2000) or microgenetic analysis (Siegler, 1996), which could further clarify what portions of the instruction or work with integers influenced students to change their thinking in Bofferding's study.

Conceptual models. Wessman-Enzinger & Mooney (2014) found that when children posed stories for integer addition and subtraction problem types the students' reasoning could be classified into the Conceptual Models for Integer Addition and Subtraction (CMIAS). The five CMIAS described are Bookkeeping, Counterbalance, Translation, Relativity, and Rule. With *Bookkeeping,* the integers are treated as gains and losses, and zero represents neither a gain nor a loss. For example, students posed stories that involved gains and losses of candy bars. And, other students used "needs" and "wants" of various other items, like baseball cards, to represent the negative integers. With *Counterbalance,* the integers are treated as neutralizing each other, and zero represents a status of neutralization. A distinguishing feature of Counterbalance from Bookkeeping is that the quantities always remain present with Counterbalance. For example, consider -2 + 3 = 1, which can be represented by two electrons and three protons, where there is an electrical charge of 1. Although there is an electrical charge of 1, the two electrons and three protons still remain present. With *Translation,* the integers are treated as a vector or with movement. Zero in Translation represents either the position or no movement. With *Relativity* the integers are treated as a comparison to an unknown referent. Zero represents the unknown referent. For example, for -5 + -10 = -15 a student posed the story, "Say you are down five runs in the first inning of a baseball game. And you end up losing by fifteen runs. You would have to have ten runs in the other innings to be down by fifteen runs" (Wessman-Enzinger & Mooney, 2014, p. 203). In this story, the actual score of the game is unknown. The integers are used as relative numbers to the unknown referent, the score of the tied game. Relativity is related to Translation, but both movement and the dual-role of the zero in the model distinguish Translation. Although related to Gallardo's (2002) interpretation of directed number and relative number, the CMIAS distinguishes the use of the integers here. With *Rule* the integers are treated with a procedural rule about signs. Wessman-Enzinger and Mooneys' interpretations of student thinking about integers is that hidden behind the use of contexts are implicit mathematical meanings. And, the utilization of these contexts is isomorphic to mathematical uses of integers. Further investigation into ways that students respond differently to contextualized problems, promoting different CMIAS, could be supported by both task-based interviews (Goldin, 2000) or teaching experiments (Steffe & Thompson, 2000).

Goals of Working Group

During this working group, one of the goals will be to establish small-groups that will work collaboratively together on a research project of their creation. Each of these groups will begin by analyzing similar video data provided by the organizers. This will initiate discussion on ways that using different theoretical perspectives and analysis highlight similarities and differences in student thinking about integer addition and subtraction. However, the main aim of this working group will be to begin formulating research questions and begin designing small studies that are each related to each other. It is the hope of this working group that each of these small studies would be conducted in 2016 and that participants will begin analysis in 2016 as well. Participants could share their initial results at a future meeting so that the group can begin to make comparisons and larger conclusions about student thinking. Additionally, the working group will select a journal to propose a monograph to that illustrates and embraces these different perspectives on making sense of student thinking about integer addition and subtraction.

Extending the Previous Work from Past Working Groups

Both of the previous working groups, PME-NA 35 and PME 38/PME-NA 36, were discussion-oriented. Drawing on colleagues' work and literature reviews, the focal point of each of these discussions was on student thinking about integers and integer addition and subtraction. Each of these working groups concluded with participants eager to work collaboratively on a project. This working group extends the work from these previous groups by presenting a collaborative project that supports connecting our multiple research agendas, inviting all, whether neophytes or experienced researchers, interested in student thinking about integer addition and subtraction to participate.

Plan of Working Group

Plan for Session 1

The first session will begin with a brief overview on the history of the working group for any new members attending. The facilitators will also give a brief update from the joint PME 38 and PME-NA 36 meetings. Then, the session will transition to introductions among participants. The participants will briefly share their interests in integer addition and subtraction research and the general theoretical perspectives and methods they employ. The facilitators will ask participants to break into small groups. The facilitators will show a short video clip of a student solving an integer open number sentence. Discussion will begin with the following question:

1. Using your preferred theoretical perspective on student thinking about integer addition and subtraction (e.g., Metaphorical Reasoning, Mental Models (MM), Ways of Reasoning (WoR), Conceptual Models for Integer Addition and Subtraction (CMIAS)), how would you make sense of or describe the student thinking in this video?

This question will be discussed extensively in small-groups first, and then we will transition to whole-group discussion together. In whole-groups we will discuss the following question:

2. What similarities and differences are present in our discussion about student thinking?

Plan for Session 2

The second session will begin with a brief summary of the previous day's discussion. The facilitators will then describe the proposed collective study where participants will work in small groups to design and implement small studies in the domain of integer addition and subtraction. Together, the group will brainstorm a central, overarching research question to drive the individual studies. The participants will then spend time in their small-groups deciding a topic and research question for their mini-study. At the end of the session the participants will submit their status and progress in a Google survey document so that the facilitators are aware of progress or issues within the group.

Plan for Session 3

The third session will begin with the facilitators engaging the participants in discussion about what was reported in the Google survey document. Discussion will also revolve around expectations for the studies and ways to keep active as a group throughout the year (e.g., scheduling virtual check-ins, meeting at other conferences throughout the year). Then, the remainder of the time will be spent in small groups actively working on the planning and the logistics of the implementation of their small studies.

Anticipated Follow-up Activities

The facilitators will promote active engagement throughout the year in at least two ways. First, the facilitators will provide a shared Google spreadsheet listing our groups' goals to participants. The shared Google spreadsheet will have the small-groups listed as the rows and the collectively-decided group goals (e.g., topic, research questions, theoretical lens, participants, data collection, data analysis) as the columns, which will be modified during the third session. The group will use this shared spreadsheet as a place to report dates when they complete a goal and as a way to see the progress of the other groups in comparison. Second, the small groups will be encouraged to plan at least one Skype session with the facilitators. That way, the facilitators will be aware of each of the group's progress. This will be important for coordinating both the next PME-NA working group session, as well as planning the monograph, where each of these studies become chapters.

This Working Group will consider multiple aspects of research and practice related to mathematics learning and teaching with English Learners. Our goals for the Working Group include: (1) developing a shared understanding of the research questions, issues, challenges, and contributions that research studies focusing on English learners can make to research in mathematics education and (2) developing a plan for supporting further connections among research projects in the future. We will examine the mathematics education of English learners from a variety of angles, including student, teacher, preservice teacher, school, and community perspectives. Further, we will examine current and future avenues of research around a variety of aspects of mathematics learning and teaching with English learners such as assessment, curriculum, resources, and instructional strategies. By sharing current work and focusing on particular methodologies, we hope to describe the current landscape and build structures to catalyze translational work in this area.

Brief History

This group of researchers started working collaboratively as part of the NSF-funded Center for the Mathematics Education of Latinas/os (CEMELA). CEMELA brought together researchers from across the country to collaborate on research focused specifically on critical issues related to Latinos/as in mathematics. Prior to CEMELA, researchers interested in such a focus worked mostly in isolation. In considering issues related to Latinos/as in US schools, the issues of language and English Learners (ELs) are closely related. While not all Latinos/as are English Learners, and not all ELs are Latinos/as, these two groups have significant overlap. For example about 80% of ELs speak Spanish as a first language, and Spanish-speaking ELs appear to struggle on measures of academic achievement (Goldenberg, 2008).

CEMELA expanded the field's knowledge of ELs in mathematics through conducting studies in interdisciplinary teams that helped increase the field's understanding of Latinas/os and mathematics education. CEMELA's research focused on teacher education, research with parents, and research on student learning, resulting in well over 50 publications and presentations. Several of these studies involved the investigation of questions related to the interplay of language, culture, and mathematics education.

Following the conclusion of CEMELA's funding, Zandra de Araujo, Sarah Roberts, Craig Willey, and Bill Zahner continued to meet regularly. These meetings focused on examining intersections among these early career scholars' work related to the mathematics education of ELs. To date these meetings have resulted in a number of national presentations at the annual meetings of the National Council of Teachers of Mathematics, the American Educational Research Association, and PME-NA. Currently, this group is working on several manuscripts and follow-up studies related to the preparation of teachers to work with ELs. This Working Group will provide a space for these scholars to continue their work and further their scholarship. It will also provide a forum to engage other scholars interested in this topic and foster meaningful collaborations among all the participants.

Focal Issues

ELs are the fastest growing group of U.S. students (Verplaeste & Migliacci, 2008). In fact, U.S. schools have seen an increase of 152% in EL students over the past 20 years (National Clearinghouse for English Language Acquisition, 2008). The growing number of ELs across the country provides the basis for all states, cities, schools, and teachers being prepared to attend to the needs of ELs in their mathematics classrooms. No longer is supporting ELs a concern for only those states, like Arizona, Texas and California, with traditionally high numbers of EL students. Instead, with all but ten states across the country seeing increases in their EL populations between 2002-03 and 2011-12 (National Center for Educational Statistics (NCES), 2014), there is increasing pressure for support in addressing the needs of these students.

Despite the rise in ELs, teacher preparation has not kept up with this trend. In 2002, the NCES reported that out of the 41% of teachers who worked with ELs in their classrooms, only 13% received EL-specific professional development. In 2008, Ballantyne, Sanderman, and Levy found that it was "likely that a majority of teachers have at least one English language learner in their classroom," although "only 29.5% of teachers with ELLs in their classes have the training to do so effectively" (p. 9). This misalignment of the realities of today's classrooms and teacher preparation has necessitated examination into effective means of supporting current teachers and preparing prospective teachers to meet the needs of linguistically diverse learners.

The implementation of the Common Core State Standards for Mathematics (National Governors Association Center for Best Practices (NGA Center) and the Council of Chief State School Officers (CCSSO), 2010) will put additional pressure on teachers of students who are still gaining proficiency in English. Teaching aligned with the CCSSM's content standards and the standards of mathematical practice will increase the language demands required to engage in mathematical discourse, which is typically in English. Providing ELs with quality educational experiences is no longer relegated to only language specialists; it is a "mainstream" issue for which all mathematics teachers must be prepared (Bunch, 2013).

Our Working Group aims to provide a response to the critical and enduring challenge of providing quality educational experience for linguistically diverse students in mathematics. This Working Group will bring together researchers from several universities to examine current and past research on ELs in mathematics education while also supporting new collaborations to establish future, imperative research directions. As part of these discussions, we aim to think through logistical and structural arrangements that will facilitate and support these collaborations going forward.

Aims of the Working Group

The Working Group will consider multiple aspects of research and practice related to mathematics learning and teaching with ELs. The aim of this Working Group is to present and discuss several research projects related to mathematics learning and teaching with ELs in order to develop new research questions, to refine data analyses, and to move these research agendas forward.

The larger Working Group will break into several subgroups: a) Student Learning; b) Preservice Teacher Education; c) Inservice Teacher Education; d) Family and Community Resources; e) Curriculum; and f) Language Perspectives. In the following sections, we provide a brief overview of key issues in each of these areas as well as the key research questions that will guide the work of these subgroups.

Student Learning

The subgroup focused on student learning will discuss our past and current research connected to investigating the mathematics learning of ELs. The goal of this discussion is to connect broader research on mathematics learning to our ongoing development of research on ELs, and vice versa. Building upon situated and sociocultural perspectives (Moschkovich, 2002), we start from the premise that ELs, like all students, learn mathematics through a process of appropriating discourse practices, tool use, and perspectives of mathematics. The area of researching student learning in classrooms with a high proportion of ELs is open for further development. In particular, we need better understanding of how research in mathematics education at large is connected with research on the learning of ELs. For example, there is a substantial body of research on student learning of particular mathematical concepts such as rate, ratio, and proportional reasoning (Lobato & Thanheiser, 2002). However, much of the content-focused work in mathematics education is isolated from research on how ELs develop specific mathematical understandings. This has resulted in a gap in the literature where we need to develop more linkages between mathematics education research on student learning of specific topics, and the mathematics education research on student learning of ELs. The following questions will help guide the student learning subgroup's activities during the Working Group's meetings.

- How should learning trajectories in specific content areas be adjusted (if at all) for the learning of ELs?
- What do we know from past and current research about how ELs learn particular key concepts in mathematics?
- How do the needs of ELs in mathematics classrooms vary depending on age, grade, English proficiency, and past educational experiences?
- How do students connect learning to read and use vocabulary to doing mathematics?

Preservice Teacher Education

Preservice teachers typically have few opportunities to think specifically about how they will work with ELs in their mathematics classrooms. Preparation programs often include coursework on teaching ELs that is not specific to the content areas in which preservice teachers will work. Meanwhile, the content courses that preservice teachers do take are often focused solely on content, devoid of exploring how to support ELs in mathematics classrooms. Recently researchers have shared strategies for engaging preservice teachers in working with ELs in mathematics classrooms. For example, Fernandes (2012) suggested a series of content interviews to engage preservice teachers in the process of noticing the linguistic challenges that ELs face and the resources these students bring to their mathematical communication. Additionally, the TEACH MATH (Drake et al., 2010) research team is using tasks in their content courses to support preservice teachers in drawing on students' funds of knowledge (Turner, Drake, Roth McDuffie, Aguirre, Bartell & Foote, 2012). This subgroup will build on this prior work and engage with the following questions during Working Group sessions.

- How are we preparing preservice teachers to work with ELs in their future mathematics classrooms?
- What kinds of clinical experiences best allow preservice teachers to grapple with issues facing ELs and design instructional approaches to support ELs?
- How can we use mathematical discussions with future teachers to facilitate their understanding of ELs?

Inservice Teacher Education

Despite findings that suggest ELs develop academic language in the content areas over a period of about 5-7 years, many ELs are mainstreamed within two years. Thus, it is essential that teachers support ELs in learning content in mainstream mathematics classes while also providing support to develop their academic language. Most inservice teachers have had few, if any, professional learning experiences around working with ELs in mathematics classrooms (Ballantyne et al., 2008). In fact, many mathematics teachers struggle to understand their role in supporting ELs' mathematics language development (Willey, 2013). As the number of ELs grows in classrooms across the country, it is imperative to create and study such learning experiences, while also developing teacher leaders and facilitators to lead these learning experiences.

Much of the prior work on inservice teacher education related to ELs has focused on more general strategies (e.g., sheltered instruction, as in Echevarria & Graves, 1998), such as using visuals, modifying texts or assignments, and using slower speech. We argue there is a need for content specific support for mathematics teachers of ELs. This subgroup will investigate work related to inservice teacher development. The following questions will guide the group's discussions about inservice mathematics teacher education:

- How are mathematics teacher educators supporting inservice teachers to support ELs in mathematics classrooms?
- What resources do teachers bring to professional learning experiences about how to support ELs in their mathematics classrooms?
- How do teachers develop or select mathematics specific supports for ELs?
- How do we develop professional development facilitators to lead professional learning experiences around supporting ELs in mathematics?
- How do facilitators position mathematics teachers to support ELs in their classrooms and instruction?

Family and Community Resources

Families and communities can serve as resources for ELs in their mathematics learning in myriad ways. Families can advocate for their children and provide and support learning experiences both in and out of the classroom. Communities can also provide a wealth of support mechanisms and learning possibilities. For example, teachers can activate student and community resources and can draw on the funds of knowledge of the community by using parents' and students' experiences (Moll, Amanti, Neff, & Gonzalez, 1992). Moll et al. described how students studied candy making and selling within their neighborhood to explore mathematics within this context, such as discussing and analyzing production and consumption. In doing so, the teachers and students acknowledged the value of these community experiences. Additionally, Civil and Bernier (2006) explored the challenges and possibilities of involving parents in facilitating workshops for other parents around key math topics. These studies and others like them illustrate the promising impact of family and community resources in fostering ELs' mathematics learning. The Working Group will explore prior studies on family and community resources as related to ELs in mathematics using the following questions:

- What are the implications of different language policies on parental engagement in mathematics, particularly for ELs?
- How can teachers / teacher education programs build on family and community resources towards the mathematics education of ELs?

Curriculum

Curriculum plays a key role in the teaching and learning of mathematics and teachers play a pivotal role in selecting and enacting curriculum materials for students. The choice of curriculum materials impacts students' opportunities for learning in the mathematics classroom (Kloosterman & Walcott, 2010). Early work on curriculum and English learners focused specifically on the challenges ELs encounter when completing or interpreting word problems (Téllez, Moschkovich, & Civil, 2011). More recent work that centers on both ELs and curriculum has focused on culturally relevant curricula. A rather recent subset of mathematics education, called ethnomathematics, focuses on this area (Barton, 1996; D'Ambrosio, 2006). Other studies have focused on the development of curriculum materials for ELs (e.g., Freeman & Crawford, 2008) or the evaluation of a curriculum's appropriateness for ELs (e.g., Khisty & Radosavljevic, 2010; Lipka et al., 2005). More recently, work related to ELs and curriculum has begun to look at teachers' use of curriculum (e.g., de Araujo, 2012). The Working Group will investigate the intersection of teachers, curriculum, and ELs. The following questions will guide the group's work related to curriculum and ELs.

- How do mathematics curricula and instruction address the needs of English Learners?
- How do ELs interact with curriculum materials? How do English learners learn to read different mathematical texts (textbooks, word problems, etc.)?
- How can teachers' modifications to mathematics curriculum materials support ELs?
- How can teacher educators support teachers' understandings of mathematics curriculum use with ELs?

Language Perspectives

Teachers' and researchers' conceptions of language, second language acquisition, and bilingualism impact teaching and learning mathematics for ELs. The Working Group will consider how perspectives of language, second language acquisition, and bilingualism appear in both theory and practice. We will consider, in particular, how work focused on ELs can draw on current work on language and communication in mathematics classrooms, classroom discourse, and linguistics. Looking for these intersections and connections is crucial; it will ensure that work in mathematics education is both theoretically and empirically grounded in relevant research, and it will prevent researchers from reinventing wheels. The following questions will guide the group's work related to this theme:

- Which constructs do we use to describe and examine language(s) in mathematics classrooms? Although some studies use the term "Academic English" (Scarcella, 2003), it is not clear what this terms means for mathematics, what constitutes "Academic English" in mathematics, or whether other constructs might be more useful for research and practice.
- What constitutes competency in "Academic English" for mathematics in both written and oral modes? If it is the case that "Academic English" is different for different mathematical domains or genres of mathematical texts, then these differences need to be examined.

- How do teachers' views of second language acquisition impact the practice of teaching mathematics for ELs? How can we support teachers in expanding their views of second language acquisition in mathematics classrooms?
- What are students' experiences learning mathematics in their first, second, and both languages? How do different proficiencies in a first language (oral, reading, written, academic English) and previous mathematics instruction in a first language impact students' learning mathematics in English?
- How do students learn to read mathematical texts and use vocabulary to do mathematics? How do ELs learn to read different mathematical texts (textbooks, word problems, etc.)? How can instruction distinguish between children who are competent readers in a first language and those children who are not?

Working Group Plan

The overarching goal of the Working Group is to foster the collaboration of mathematics educators around scholarship related to the mathematics education of English learners. In particular, the following goals will frame the Working Group's activities:

1. Develop a shared understanding of the research questions, issues, challenges, and contributions that research studies focusing on English Learners can make to research in mathematics education
2. Develop a plan for supporting further connections among research projects in the future.

In focusing on current research in this area, with an eye towards further study, the Working Group will address the enduring challenge of providing quality mathematics education for English learners.

During the three sessions, participants will examine and discuss the design of several research studies, analyze sample data collected in at least one of these studies, and discuss future plans for the Working Group. These activities are intended to support participants in a) clarifying research questions, b) refining research tools, methods, and analyses, c) exploring connections among different projects and studies, and d) discussing further collaborations and research on learning and teaching mathematics in classroom with English learners. All work and documents will be shared and distributed via a Google Community. The use of Google Community will allow members to create an institutional memory of activities during the Working Group that members will continue to build upon after the conclusion of the conference.

The planned activities will support these goals in several ways and will be grounded in discussions of sample research designs, data sampling, and sample curricula. The anticipated follow-up activities for this Working Group include planning for a continuation of the Working Group at PME-NA in 2016 and organizing one or more collaborative writing projects on this topic.

Overview of Proposed Working Group Sessions

<table>
<tr><td rowspan="2">SESSION 1</td><td colspan="2">INTRODUCTION, FRAMING THE ISSUES, & CLARIFYING AIMS</td></tr>
<tr><td>ACTIVITIES
1. Introduction and overview of the Working Group including introduction to the Google Community.
2. Brief presentations by panel members from each of the subgroups providing overviews of research projects with specific examples of how researchers have designed the studies. The purpose is to provide an overview of work related to mathematics education of ELs and to introduce the six subgroups in a structured way.
3. Participants will break into subgroups and will analyze and discuss sample data from at least one of the studies presented. This will give participants an opportunity to share their own experiences in designing research studies, collecting data, and analyzing data.
4. Distribution of one or two readings for each subgroup for the next session.</td><td>GUIDING QUESTIONS
1. What research is being done in relation to each of the subgroups?
2. Which aspects of studies focusing on English learners do you find most puzzling? Most useful? Most misunderstood?
3. How have you approached defining the research questions for studies?</td></tr>
</table>

<table>
<tr><td rowspan="2">SESSION 2</td><td colspan="2">PERSPECTIVES, METHODOLOGIES, & INQUIRY</td></tr>
<tr><td>ACTIVITIES
1. Using the questions in the adjacent column, subgroups will discuss the reading(s).
2. Brief whole group discussion that highlights key ideas brought up in the subgroups.
3. Participants work in subgroups to frame new research questions related to their subgroup's focus and develop goals for the final session.
4. Whole group discussion of subgroups' progress.</td><td>GUIDING QUESTIONS
1. What theories and theoretical frameworks have informed the design of your research project(s)?
2. How might your work inform theory in mathematics learning and teaching? How can work on this student population expand our theoretical lenses?
3. What issues and challenges have you faced in designing studies?
4. How have you approached data analysis for studies?</td></tr>
</table>

SESSION 3	PURSUING FURTHER STUDY	
	ACTIVITIES 1. Work time for the subgroups to discuss directions for continued collaboration. Subgroups will also develop next steps as they plan for continued work. 2. Whole group discussion in which subgroups share goals and next steps developed by the subgroups 3. Establish next steps for continued collaboration, including the Google Community	GUIDING QUESTIONS 1. How might other researchers pursue research projects on this topic and what can they learn from the work done so far? 2. What aspects of your research do you expect will be most useful to informing practice (curriculum development, teacher professional development, work with parents, etc.)? 3. How might your work inform not only instructional practices for this population but also instructional practices for other populations?

Follow-up Activities

We anticipate that this Working Group will attract other researchers interested in issues related to the mathematics education of ELs. Therefore, an important component of this initial meeting of the Working Group will be establishing connections with other interested researchers and building opportunities for future collaborations. We will provide space for new researchers to contribute to our work, to suggest new directions, and to add to the growing body of research on mathematics and ELs. At the first meeting of our Working Group, we will establish an online community using Google applications (Plus, Hangout, Groups, Drive, etc.). Google's applications are freely available and allow for a number of collaborative opportunities, including video conferencing, group messaging, collaborative document development, and shared web and social media space. Through this collaborative Google Community, we will organize follow up face-to-face meetings at conferences such as AMTE and the NCTM Research conference. These meetings, both face-to-face and virtual, will allow us to set concrete goals in preparation for the creation of a Working Group proposal for PME-NA 2016 to continue our work.

In addition to these short-term goals, we have several longer-term goals for this Working Group. First, we would like to seek funding for a conference where we can share the results of our work with other researchers and practitioners. A number of the panelists attended the TODOS: Mathematics for All Conference in the summer of 2014, and we expect to have a strong presence at the June 2016 TODOS conference as well. The TODOS conference brings together both practitioners and researchers and provides a venue for the dissemination and discussion of important ideas and issues related to the mathematics education of diverse groups of learners. A related conference specifically focused on ELs would be of great benefit to a multitude of stakeholders as we continue to examine how to best support ELs. In addition to the conference, we will also propose a special edition of a journal focused on issues related to mathematics education and ELs. This would allow for the broader mathematics educational research audience access to current work being done in this area.

ceames@siue.edu

Modeling has recently received much attention as the Common Core State Standards have included it as one of eight core mathematical practices. The Models and Modeling Working Group builds on a long history of collaboration among researchers studying models and modeling. This year's session will focus on building capacity within the broad community of researchers who are interested in theoretical and practical perspectives related to models and modeling. We will begin by engaging with a modeling activity and some closely related materials. This experience will serve to ground our discussions and provide a concrete common reference for participants. We will also draw the group's attention to a new resource: a course-sized repository of such materials, intended to support studies of learning in the areas of data modeling, statistics, and quantification. Next, we will break out into interest groups to discuss research questions and agendas that can make use of available resources and foster cross-institutional collaboration. We will close by sharing these questions and articulating plans for the coming year.

Keywords: Modeling; Problem-Solving; Design Experiments; Research Methods

The *Models and Modeling* Working Group has been a significant presence at the PME-NA Conference since both the Group and the Conference were inaugurated in 1978. Over that time it has supported the pursuit of high-quality research projects and programs, and it has acted as a means of convening a diverse set researchers to work collaboratively on larger projects and research problems. The historical purpose of the Group is to discuss and extend the ways in which models are used both to learn mathematics and applied science and to study those learning processes in action. We propose convening the Group at PME-NA 37 to build capacity within the Models and Modeling Perspective (M&MP) research community and to establish key components of a research agenda for studying modeling at longer timescales. The immediate occasions for this work are the retirement of a founding voice in the community and the publication of a course-sized body of materials to support M&MP research along a variety of dimensions. As a capacity-building effort, the three sessions of the Working Group will both (a) introduce new researchers to the M&MP approach, community, and materials; (b) develop the M&MP research agenda, articulating questions that the community recognizes as important; and (c) identify opportunities for collaborative projects and proposals in the upcoming year.

Significance of the Models and Modeling Perspective

For nearly forty years, M&MP researchers and educators have engaged in design research directed at understanding the development of mathematical ideas. A fundamental principle underlying this work has been that learners' ideas develop in coherent conceptual entities, called *models*. In this context, models are defined as conceptual systems, which are expressed using external representational media or notation systems, and which are used to construct, describe, or explain the behaviors of other systems—often to understand, predict, manipulate, or improve them. Models are thus conceptual and representational tools that have the additional advantage of illuminating how students, teachers, and researchers learn, develop, and apply relevant mathematical concepts(Lesh & Doerr, 2003; Lesh, Doerr, Carmona, & Hjalmarson, 2003).

Under appropriate conditions, these models can be evoked and expressed: in such settings, they can become objects for reflection by learners and collaborative groups, and they can form the basis for rich communication. In particular, when individuals and groups encounter problem situations with specifications that demand a model-rich response, their models are observed to grow through relatively rapid cycles of development toward solutions that satisfy these specifications. Models are thus powerful elements both for creating educational activities and for conducting research into learning.

Originally, the M&MP tradition was focused squarely on investigating the *development of ideas and knowledge* in teachers and students. Thus, the resources and tools produced were first and foremost designed to *study* idea development (as opposed to serving teaching or curricular goals). However, by producing materials that fostered the rapid development of ideas, M&MP designers also laid the foundation for extremely effective instructional sequences addressing big ideas in important mathematical domains. Over time, however, the M&MP community has refined its techniques for creating situations that provoke students to express and improve their models. The results of this work include a body of *Model-Eliciting Activities* (MEAs), which have consistently proven to support students in the modeling cycles described above. In MEAs, students are presented with authentic, real-world situations where they repeatedly express, test, and refine or revise their current ways of thinking as they endeavor to generate a structurally significant product—that is, a model, comprising conceptual structures for solving the given problem. These activities give students the opportunity to create, apply and adapt scientific and mathematical models in interpreting, explaining, and predicting the behavior of real-world systems. Extensive research with MEAs has produced accounts of learning in these environments (Lesh, Hoover, Hole, Kelly, & Post 2000; Lesh & Doerr, 2003), design principles to guide MEA development (Hjalmarson & Lesh, 2008; Doerr & English 2006; Lesh, et. al. 2000; Lesh, Hoover, & Kelly 1992) and accounts and reflections on the design process of MEAs (Zawojewski et al., 2008).

An Example MEA: Volleyball

Students are usually introduced to the Volleyball Problem by reading a "math rich newspaper article" that describes a summer sports camp specializing in girls' volleyball. The newspaper article explains how issues arose in the past because it was difficult for the camp councilors to form fair teams that could remain together throughout two weeks of camp. The students' goal in the volleyball problem is to develop a procedure that the camp councilors can use to form teams that are as equivalent as possible—based on information that is gathered during try-out activities that occur during the first day of the camp. After breaking into groups, students are presented with the problem statement:

> **The Volleyball Problem.** Organizers of the volleyball camp need a way to divide the campers into fair teams. They have decided to get information from the girls' coaches – and to use information from try-out activities that will be given on the first day of the camp. The table below shows a sample of the kind of information that will be gathered from the try-out activities. Your task is to write a letter to the organizers where you: (1) describe a procedure for using information like the kind that is given below to divide more that 200 players into teams that will be fair, and (2) show how your procedures works by using it to divide these 18 girls into three fair teams.

Figure 1. The Volleyball Problem

Along with the introduction and statement of the problem, student groups are given tryout data for a sample of 18 players. This data includes some information that is easily represented in tabular form (player's height, measured vertical leap, 40-meter dash time, etc.), as well as some that is not (players' performance in a spiking trial, and brief summative comments about their strengths and weaknesses from the coach of their home team). These data elements are chosen so as to present fundamental challenges to students, involving the nature of data (categorical versus numerical); scaling (e.g., the vertical leap where "large is good" versus the 40-meter dash where "small is good"); units (vertical leap is given in raw inches; height in feet-and-inches); and so on.

Student groups iteratively develop solutions to this problem in the time allotted—usually 60 minutes for this MEA. Afterwards, the class gathers together for a structured "poster session" event. One member in each 3-person group hosts a poster presentation showing the results of their group. The other two students use a Quality Assurance Guide to assess the quality of the results produced by other groups in the class. These instruments are submitted to the teacher and contribute to assessment in various ways, providing evidence for the achievements of both individuals and groups.

Multi-Tiered Design Research

In parallel with student-focused research using MEAs, researchers also have observed that teachers' efforts to understand their students' thinking involve yet another process of modeling: In this case, teachers engage in building models of student understanding. Although these teacher-level models are of a different category from student-level models, students' work while engaged in MEAs does provide a particularly rich context for teachers' modeling processes. Following this line of inquiry, the M&MP community has also produced tools and frameworks that can be useful to teachers in making full use of MEAs in classroom settings, while also providing *researchers* with insights into *teachers'* thinking.

Finally, at a third level of inquiry, researchers' own understandings of the actions and interactions in curricular activity systems (Roschelle, Knudsen, & Hegedus, 2010) involving students, teachers, and other participants in the educational process can also be studied through the lens of model development. Multi-tier design experiments in the M&MP tradition have done precisely this, involving researcher teams in self-reflection and iterative development as well (Lesh, 2002). Therefore, multi-tier design research involves three levels of investigators— students, teachers, and researchers—all of whom are engaged in developing models that can be used to describe, explain, and evaluate their own situations, including real-life contexts, students' modeling activities, and teachers' and students' modeling behaviors, respectively.

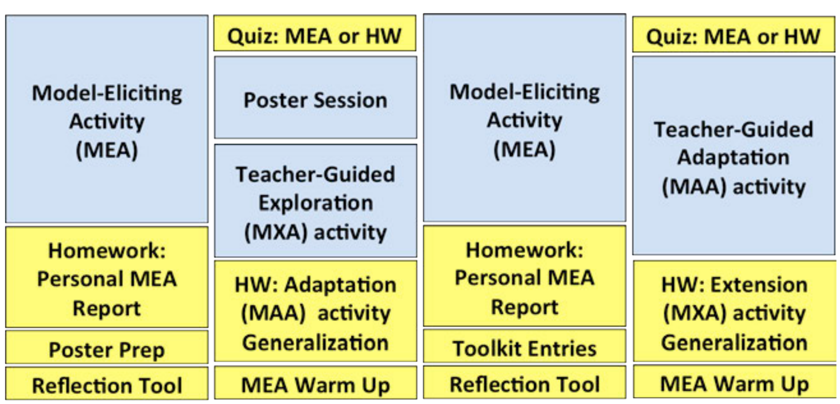
Curricular Materials from the Models and Modeling Perspective

Over the past 10 years, M&MP researchers have continued this direction of work in their own teaching and in partnerships with K-12 classroom teachers. Within the domain of statistical thinking in particular, this effort has flourished, producing resources and tools sufficient to support *entire courses* in several versions and including accompanying materials related to learning and assessment aimed at both student development and teacher development. These course materials were initially focused exclusively on data modeling, engaging with most of the content usually covered in an introductory graduate-level course on statistics and probability for education researchers. But as the collection evolved, modules were added dealing with closely related "big ideas" in algebra, calculus, geometry, and complex systems theory. Furthermore, because the courses supported by these materials were designed explicitly to be used as research sites for investigating the interacting development of students' and teachers' ways of thinking, the materials were modularized so that important components could be easily modified or rearranged for a variety of purposes in different implementations. In particular, by selecting from and adapting *the same basic bank of materials*, parallel versions of the course have been developed for: (a) middle- or high-school students, (b) college-level elementary or secondary education students, and (c) workshops for in-service teachers. When these courses have been taught by M&MP researchers familiar with the underlying theory, they have produced astounding "six sigma" gains (Lesh, Carmona, & Moore, 2009).

In the process of developing curricular materials to focus on modeling, research in the M&MP has investigated ways in which MEAs can be integrated within larger instructional sequences or Model Development Sequences or *MDSs* (Lesh et. al., 2003). MDSs offer classroom groups opportunities to unpack, analyze, and extend the models they have produced in MEAs, as well as to connect their ideas with formal constructs and conventional terminology. This unpacking work helps to ensure the lasting retention of concepts at a level of generality required for flexible use and application in novel situations. It also sets the stage for the critical connection between conceptual development (the centerpiece and focus of MEAs), and procedural knowledge that is also required for students to achieve well-rounded competence in any subject area.

Within an MDS, **reflection tools** support students in stepping back from their modeling processes and reflecting on this work as critical observers of both individual and group modeling behavior. We consider these tasks to be core to the learning processes in MEAs: when students interpret situations mathematically, M&MP research expects that they don't simply engage interpretation systems that are purely logical or mathematical in nature. Their interpretations also involve attitudes, values, beliefs, dispositions, and metacognitive processes. Moreover, the M&MP does not treat group roles and functioning as if they were fixed characteristics that determined students' behaviors. Instead, students are expected to develop a suite of problem-solving personae or profiles they themselves can learn to apply as the situation demands. Reflection tool activities encourage groups of learners to turn their attention to describing individual- and group-level processes, functions, roles, conceptions, and beliefs. Tools to support these activities include Ways of Thinking Sheets, various surveys and questionnaires, Concept Maps, Observation Sheets, Self-Reflection Guides, and Quality Assurance Guides for the products created in MEAs.

In **product classification** and **toolkit inventory** activities students continue the work of abstraction, characterizing and classifying the thinking they have done and identifying links among their solutions to different MEAs and between these solutions and the "big ideas" of the course. **Model exploration or Model extension activities** (MXAs) provide model-rich environments for introducing core concepts and skills from the broader curriculum that students need in order to formulate sophisticated models and present them to a mathematical community. In addition, these activities provide students with a vital opportunity to unpack the work they have done in the MEAs. These may use a combination of pointed YouTube videos and interactive simulations in dynamic mathematics software. (Approximately 50 of these YouTube videos have been produced, with



Bartell, T. G., Bieda, K. N., Putnam, R. T., Bradfield, K., & Dominguez, H. (Eds.). (2015). *Proceedings of the 37th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. East Lansing, MI: Michigan State University.

Figure 2. Example Structure of a Model Development Sequence (MDS). MEAs and other activities represent modular, re-orderable blocks of instructional time.

accompanying simulations. They are currently collected under the ProfRLesh channel.) Finally, **model adaptation activities** (MAAs) allow students to transfer ideas and techniques developed in MEAs to situations calling for similar performances. These MAA activities also provide smaller-timescale modeling scenarios that exercise concepts they have explored in other components of the MDS. They may be pursued individually or in small groups, depending on the nature of the task and the teacher's instructional or assessment goals.

All of these elements of an MDS are designed to be highly modular, to accommodate (as well as to reveal) the needs and intentions of the teacher as they appropriate and adapt the materials for their own use. An example of how this variety of activity types might be laid out in a given unit is shown in Figure 2.

A Course-Sized Resource Repository for Research in Data Modeling and Quantification

Early successes in teaching entire courses with MDS units (e.g., Lesh, Carmona, & Moore, 2009) also demonstrated that these MDSs were highly reconfigurable and re-orderable. The "big ideas" in statistics, data modeling, and quantification could be foregrounded in different orders, leading to a variety of possible longer-term modeling experiences for the students and teacher. In light of these findings, the construction of a course-sized repository became a compelling question for design research. A first-iteration version of this repository will be going live in the course of the Summer of 2015, and several of the activities of the proposed Working Group will focus on making innovative uses of these materials, to gain new illumination on longer-term modeling. At the same time, it is expected that researchers will be involved in the creation of new tools and resources to support research at this longer timescale.

Two important aspects of this effort are (1) a desire to serve the needs of a growing and diversifying M&MP community, and (2) a commitment to flexibility-in-use that we describe as *designing for scale*. In particular, our course materials are presented in modularized and easily modifiable, reconfigurable, and extendable components. Thus, the objective is for teachers and researchers to engage with these materials in a variety of ways, each embodying a unique (teacher- or researcher-level) model of the development of knowledge. The data and evidence produced by this diversity of models will help to support choices among them, to refine emerging assumptions and conjectures, and to iteratively shape the materials of the repository and their presentation. In other words, the development and iterative growth of the research repository should itself be a modeling process. At the same time, we aim for the introduction of this repository of research materials to advance the field by

- facilitating the development, sharing, and testing of new Research Tools for different facets of research into dimensions of learning as they emerge;
- offering a shared setting for the refinement of the *design principles* for research tools to produce evidence about learning at scales higher than the MEA;
- fostering the accumulation of knowledge in teacher and researcher communities, exposing our process and inviting broad participation in constructing the site; and
- encouraging the formation of collaborative communities of teachers and researchers, allowing participants to identify possible collaborators through shared interests in research tools and facets of problems of research or instruction.

Focus Areas of the Models & Modeling Perspective

Here we briefly indicate some of the ways in which M&MP lines of research have contributed in fundamental ways to research on learning, assessment, and teaching. We believe that the publication of a course-sized repository of research materials can facilitate further advances in each of these areas.

Learning

In order to study idea development in the context of real-world problem solving settings, M&MP researchers first used, and then went beyond Piagetian clinical interviews. This spurred an intense period of design research to construct a compelling genre of learning tasks that would (a) stimulate mathematical thinking representative of that which occurs in contexts outside of artificial school settings (Lesh, Caylor, & Gupta, 2007; Lesh & Caylor, 2007); (b) enable the growth of productive solutions through rapid modeling cycles; and (c) leave behind researchable traces of learners' ways of thinking during the process. This line of work produced the notion of Thought-Revealing Artifacts and Model-Eliciting Activities (MEAs) (Kelly & Lesh, 2000; English et. al, 2008; Kelly, Lesh & Baek, 2008). The success of MEAs as a research tool was both enabled by and illustrated by the articulation of a set of six design principles for such activities(Lesh, 2003; Lesh et. al, 2000; Hjalmarson & Lesh, 2008); these principles indicate the key structural and dynamical elements in MEAs as contexts for problem solving. Table below indicates "touchstone" tests for whether each of these six principles has been realized in a given implementation setting.

Table 5. Six MEA Design Principles and Touchstones

Principle	Touchstone Test for its Presence
Reality Principle	Students are able to make sense of the task and perceive it as meaningful, based on their own real-life experiences.
Model Construction Principle	To solve the problem, students must articulate an explicit and definite conceptual system (model).
Self-Evaluation Principle	Students are able to judge the adequacy of their in-process solution on their own, without recourse to the teacher or other "authority figure".
Model Generalizability Principle	Students' solutions are applicable to a whole range of problems, similar to the particular situation faced by the "client" in the MEA.
Model-Documentation Principle	Students generate external representations of their thinking during the problem-solving process.
Simplest Prototype Principle	The problem serves as a memorable representative of a kind of mathematical structure, which can be invoked by groups and by individuals in future problem solving.

Assessment

Although MEAs were developed as contexts for the study of idea development, they also have been shown to be powerful tools to support non-standard approaches to assessment. In part, this potential should be obvious from the model-documentation principle and the emphasis on creating researchable traces of thinking in the form of thought-revealing artifacts. When groups of students produce and negotiate external representations of their emerging thinking on meaningful problems, these artifacts can be expected to tell a rich and compelling story of what these students know and can do (Katims & Lesh, 1994). Furthermore, a common finding of assessment-oriented M&MP research has been that even groups of students whose mathematical abilities are rated low often produce impressive solutions that demonstrate an intuitive grasp of rather sophisticated forms of mathematical reasoning. Finally, when assessment is conceived of as including *formative* assessment, such student performances provide a fertile ground for future instructional work that can build upon intuitive understandings to enable more formalized learning (Borromeo-Ferri & Lesh, 2013; Lesh, Haines, Galbraith, & Hurford, 2010).

Teaching and Professional Development

Because MEAs are designed to engage small groups of learners in autonomous problem-solving work over extended periods of time, they open up the classroom in new ways as a space of reflection for *teachers*. Freed temporarily from the need to facilitate and manage the learning process as it occurs, teachers during MEAs can use the occasion to develop their observational skills and their abilities to detect and interpret their own students' ways of thinking. M&MP researchers have developed a range of Ways of Thinking Sheets and other Reflection Tools to capitalize on these opportunities, giving teachers (and even students) the perspective of analyzing idea development and group functioning.

For teachers, these analyses are compelling because (a) they are authentic and directly relevant to their experience: after all, *their own* students have developed these ideas and constituted these groups; (b) the findings are immediately applicable: analyzing in detail the thinking of one's students in solving a problem instantly suggests instructional strategies that can be enacted as soon as the following class period. These features indicate why viewing MEA implementations as *in-situ* professional development opportunities has been so powerful.

Documentation and Accumulating Shared Knowledge

In addition to the research work described above, the M&MP tradition has also been notable for documenting its progress in design and theory-building, as well as in more conventional, hypothesis-driven research studies. In particular, the community has produced a variety of edited volumes of research over the past four decades, dealing with a range of topics and issues raised in the M&MP work. These include volumes on the design of problem solving tasks, assessment, research design, teacher professional development, the changes in mathematics as a foundation for future work beyond school, and the application of models and modeling perspectives in engineering.

Future Work

Thus, M&MP research has covered an immense amount of ground in the past forty years. Nevertheless, there are also a number of important gaps that need to be addressed in order to maximize the impact that this tradition can have upon mainstream classroom practice. In particular, as described above, in the dimension of student learning much of the M&MP research has framed its interests in terms of *idea development*, where these ideas emerge and interact in the discourse of collaborating small groups and classrooms of learners. This frame is extremely powerful for supporting conceptual analyses of the nature of powerful ideas and the possible relations among them. However, it does not necessarily make claims about student learning or development.

Larger Timescales

When M&MP research engages with questions of the design and implementation of modeling sequences for classroom use that span weeks, months, and even years, it becomes possible (and necessary) to merge the perspective of idea development with that of student learning and cognitive development. Prior work within the M&MP tradition does provide powerful elements of a foundation and framework for this work, yet important theory-building work still remains to be done. Within a 60-minute MEA, idea development in student discourse can exhibit stages of development that Piagetian researchers observe as unfolding in learners' ways of thinking over a span of years. How is this rapid and flexible movement among ideas related to the development of more robust and characteristic ways of thinking?

Work towards creating a research infrastructure to support research at these scales has included an increasing emphasis on a *unit of design* beyond the MEA: at or beyond the MDS level. While any particular classroom realization of an MDS may have the appearance of a fixed curricular progression or teaching trajectory, the design intention is *not* to provide a single, "best" instructional path through the mathematical landscape in question. On the contrary, as with MEAs at the activity level, the goal is to provide a context in which it is possible to study the *range* of possible pathways that can be taken through this terrain, and to understand the fruits that these different choices yield.

Teacher Decision-Making

Though many aspects of design at the MDS level can leverage the history of work at the MEA level, the larger scale introduces new factors as well. Importantly, the teacher's role becomes much more varied and complex at this scale. The observation and analysis of student thinking during MEAs continues to be a critical feature of the teacher's work, but now these observations and findings can be traced as they inform instructional decision making throughout the MDS. In this space, implementations become an extraordinarily rich environment for understanding the values, beliefs, and ways of thinking of *teachers,* on a range of practical, high-consequence matters, such as: (a) what relationships exist between the development of conceptual skills and procedural skills? (b) what is the relative status of student intuitions and official terms, formulations, and algorithms? (c) what documentation or evidence of competence can the activities of an MDS generate at the individual and/or small-group levels, which can factor into classroom assessment practices? (d) how do supports for decision-making about curricular structure and representations of student performance impact teachers' planning behavior? or (e) how can facilitating MEAs, and becoming sensitive and aware of students' ways of thinking, be integrated into teacher preparation programs and communities of teaching practice?

Networks of Connections among Big Ideas

While larger-timescale research requires attention to learners' development and to the curriculum and activity systems represented by students, teachers, classrooms, and schools, it also enables a continuation of the research on "idea development" that characterized MEA-centered work. Indeed, this line of research may only reach satisfying conclusions at this larger timescale. This is because the *meaning* of any particular "big idea" in a subject area derives as much from the relations between that idea and the other ideas of the subject as from the internal structure of that idea in isolation. And, as René Thom once suggested, "the real problem, which confronts mathematical teaching, is not that of rigor, but the problem of the development of 'meaning'…." (Thom, 1973, p. 202). Thus, research at and beyond the level of the MDS, including research at developmental timescales, is alone positioned well to document the way that local modeling efforts in MEA settings can aggregate to support the construction of networks of connections among ideas, yielding structures that afford meaning.

Modeling and Mathematizing: Creating Links to Mainstream Curricular Structures

Finally, carrying the M&MP project forward at larger timescales will produce either connections or collisions with infrastructural elements of curricular structure such as the *Common Core State Standards for Mathematics*, the approaches of leading textbooks, and high-stakes assessments. For teachers it will not be possible to engage in longer-timescale implementations of M&MP materials, without an explicit connection between that work and the dominant structures of the curriculum that constitute the "law" of the instructional land. Fortunately, at least in the *letter* of this "law," modeling occupies a central role. It may be the case that the M&MP's definition of modeling as *mathematizing reality*; that is, "quantifying, dimensionalizing, coordinatizing, or (in general) mathematizing objects, relations, operations, patterns, and regularities which do not occur in pre-mathematized forms" (Lesh, Yoon, & Zawojewski, 2007, p. 346). Nevertheless, if the experience of modeling-as-mathematizing is a powerful one (as we know it is); if logistical and curricular barriers are removed, allowing teachers successfully to adopt materials that encourage this experience (as we believe they can be); and if the resulting curricular sequences are also efficient ways of gaining rich understandings of big ideas (as we believe they are), then it should be possible to make progress in introducing a more authentic version of modeling into the experience of mainstream teachers and students.

Workgroup Outline: Capacity Building

Capacity-building involves establishing both a shared historical sense of interests, theoretical commitments, and methodological approaches on one hand; and a shared research and development agenda for future work on the other. A challenge along the historical dimension of capacity-building in this sense is that the M&MP tradition extends over an extremely long period of time and spans a wide range of subject areas, age-levels, and geographical contexts. To address this challenge, and to lay the foundation for new collaborations, we propose to spend the first day's session engaged in experiencing one MEA and two related MDS activities from the learner's perspective. At prior PME and PME-NA conferences, similar approaches have been successful in orienting participants to the M&MP perspective and grounding discussions in features of student modeling activity.

Agenda-Development: On Day 2 we will break out into facilitated interest groups, based on participants' intended areas of research focus. Importantly, these discussions will actively involve not only the researchers who have played major roles in this development of the M&MP as a field and body of knowledge, but also a range of young researchers new to the field. Pairing these new voices with established researchers will enable an *activation* of the history of the M&MP in forging an agenda for research and development and identifying concrete possibilities for future work and collaborations.

Planning and Identifying Opportunities for Collaboration: On Day 3, interest groups will finalize their discussions on research agendas and report out to the larger group. In this discussion, the group will identify opportunities for organizing collaborative research projects and proposals. "Point people" for each opportunity will be identified, and we will establish the means for sustaining a continued conversation toward acting on these opportunities in the coming year.

This working group continues on the theme of prior years, the use of representations of practice in teacher education, and pays particular attention to the design of instruments to observe the learning of preservice teachers from their participation in interventions that use representations of practice.

Keywords: Teacher Education-Preservice; Assessment and Evaluation

Brief History of the Working Group

This is the fifth meeting at PMENA of this Representations of Mathematics Teaching (RMT) working group. The idea of this working group emerged during a series of three-day conferences on representations of mathematics teaching held in Ann Arbor, Michigan every year 2009-2012 (and earlier workshops in 2007 and 2008) organized by ThEMaT (Thought Experiments in Mathematics Teaching), an NSF-funded research and development project directed by Pat Herbst at the University of Michigan and Daniel Chazan at the University of Maryland. ThEMaT originally created animated representations of teaching with cartoon characters to be used for research, specifically to prompt experienced teachers to share the rationality they draw upon while teaching. With the assistance of later funding through a second NSF grant (referred to as ThEMaT II), the Michigan and Maryland groups developed tools and materials to share those animations online and to create further representations of practice, with the purpose of extending the use from its original context of research on the rationality of teaching to the wider context of research and development in teaching and teacher education. These efforts led to the development of the Lesson*Sketch* platform (www.lessonsketch.org), which we see as a prototype of a virtual laboratory for the study of teaching by practitioners and researchers. The Ann Arbor workshops and conferences conducted between 2008 and 2012 were conceived to begin creating a community of researchers and teacher educators who were interested in the use of representations of teaching and the analysis of data collected in response to these representations. These conferences gathered developers and users of all kinds of representations of teaching (including video, written cases, dialogues, photographs, comic strips, and animations) to present their work and discuss issues that might be common to using these representations in teacher education and education research. In 2010 we proposed a working group at PMENA in Columbus, again in Reno in 2011, Kalamazoo in 2012, and Chicago in 2013. These working groups focused on various issues associated with the elaboration and investigation of a pedagogical framework for teacher development that makes use of digital representations of teaching.

In 2013 Chazan and Herbst obtained a new NSF grant (referred as ThEMaT III; Chazan & Herbst, 2013) that enabled the creation of fellowships for mathematics teacher education faculty to engage in a process of creation of practice-based multimedia teacher education materials and their implementation in online or blended teacher education environments. Several earlier attendees of our PME-NA Working Group became fellows, to the point that now there are 12 fellows participating in this project, and they in turn have been recruiting colleagues to form inquiry groups around them. At this point among our fellows and their associates and our projects, we have a community of nearly 40 people working in 23 different states. We are all using the Lesson*Sketch* platform, developed by project ThEMaT II and in operation since 2011 as a prototype of a platform with which to author and disseminate online content for teacher education. The meeting of this year's working group is both an opportunity for fellows and inquiry group members to work face to face and for them to share their work with other individuals who might possibly be interested. The meetings will showcase the work that fellows of the project are doing and engage attendants in discussing how these online experiences with representations of practice can create opportunities for research on preservice teachers learning.

Specifically, this year's work will focus on how these online experiences with digital representations of practice can enable research on preservice teacher's learning of the practices they need to be able to do in order to teach mathematics.

Issues in the Psychology of Mathematics Education that Will Be the Focus of the Work

The work of this group relates to the third of the four enduring challenges in mathematics education identified by conference organizers--the role of assessment in teaching and learning--particularly as it relates to "innovative programs or interventions designed to address an enduring challenge" in the case of preservice teacher preparation. The use of representations of practice in teacher preparation is one of those innovative practices; Herbst, Chazan, Chen, Chieu, and Weiss (2011) provided a conceptualization of these representations of practice and argued for how work with representations of practice can serve to bring a laboratory-like approach to university-based classes for teachers, especially methods classes. This laboratory approach in teacher education, as originally conceived by John Dewey, was meant to engage prospective teachers with problems of practice in a context where they did not yet have to respond to all the demands of actual settings.

Teacher educators have constructed interventions into teacher education that use various representations of practice including students' written work, classroom video records, and storyboards; they have also made claims that such interventions create opportunities for preservice teachers to learn aspects of the work of teaching mathematics--including how to notice students' thinking and how to respond to students. We are interested in ways in which those claims can be verified through assessments of the competencies of preservice teachers who have been involved in such opportunities. The relationship between this working group and the enduring challenge of assessment in teaching and learning concerns therefore the challenge of assessing preservice teachers' learning of the practice of mathematics teaching--specifically, we endeavor to create a space for discussion of what kinds of assessments might well capture the kind of learning that preservice teachers can experience when they engage with representations of practice.

As noted above, the ThEMaT III project (Chazan & Herbst, 2013) has recruited a cadre of mathematics teacher educators who are designing interventions that use digital representations of practice in mathematics teacher education. These activities vary in terms of what they engage preservice teachers in and what kinds of opportunities to learn they might afford. In relation to that activity, we pose the question: How can we assess those opportunities to learn as well as the actual learning that the preservice teachers have done? In the 2010 PMENA discussion paper, Herbst, Bieda, Chazan, and González (2010) briefly reviewed the literature on the use of video records and written cases in teacher education. They noted that classroom scenarios sketched as cartoon animations have begun to be utilized for those purposes and argued that they have affordances that are distinct from those of video and written cases (see also Herbst, Chazan, Chen, Chieu, & Weiss, 2011). They argued that the increased capabilities of information technologies for creating, manipulating, and collaborating over multimedia point to a promising future for teacher development assisted by representations of practice. Yet the features of novel media and their use with digital technologies, for example in online or blended (face-to-face and online) interactions, may require other pedagogical strategies for teacher education that have not been sufficiently identified and explored. This year's gathering of the working group will showcase how four teacher educators affiliated with the ThEMaT III project (known as Lesson*Sketch* fellows) are using the authoring capabilities of the platform to create opportunities to learn for their preservice teachers. The working group will examine how those interventions can provide context for research on teacher learning, particularly as regards to the assessment of teacher learning. The following paragraphs describe the particulars of the instructional modules the four fellows are developing.

Dr. Joel Amidon, from the University of Mississippi, has designed an intervention that gives access to a common space (Azul's classroom) where mathematics problems and problems of practice can be shared, discussed, and analyzed by pre-service teachers (PSTs). The result is a module that can be easily modified to utilize rich mathematical tasks, student work surrounding such tasks, or mathematics teaching scenarios that presented a problem of practice to either the PST or the mathematics teacher educator. Users of the module view tasks, student work, and scenarios through the analysis tools designed by the Teachers Empowered to Advance Change in Mathematics project (see McDuffie, Foote, Drake, Turner, Aguirre, Bartell, & Bolson, 2014). This lens requires users to account for the central mathematics of a task, the design of the task, the learning that can be observed, the actions of the teacher, the funds of knowledge students bring to the task, and the affordances and constraints on power and participation of the students. The template design of this module allows for various questions to be asked such as: (a) What are the features of a teaching scenario that PSTs and MTEs design into a representation? (b) What needs do MTEs seek to meet via this module? How do MTs and PSTs take up the TEACH Math analysis tool beyond the Lesson*Sketch* environment?

Dr. Orly Buchbinder from the University of New Hampshire has designed an intervention that aims at strengthening teachers' subject matter knowledge and understanding of proof as well as pedagogical knowledge for teaching it. The interactive, media-rich module "What can you infer from this example?" aims to support prospective teachers in developing and enhancing these types of knowledge. The module is grounded in research on secondary students' understanding of proof (Buchbinder & Zaslavsky, 2009) and involves multiple components that engage pre-service teachers with proof tasks and representations of classroom interactions around the same task. These representations provide pre-service teachers with opportunities to envision how reasoning and proof activities might unfold in regular classroom environment; anticipate and analyze student thinking; plan and enact possible teacher responses; discuss and evaluate implications of different teacher moves on students' engagement with proving. It is expected that interaction with the module will promote prospective teachers' content and pedagogical knowledge of reasoning and proving. The potential growth of content knowledge may include enhanced proficiency in analyzing the logical structure of mathematical statements and evaluating the validity of different kinds of reasoning in determining whether a certain statement is true or false. The potential growth of pedagogical knowledge will be evident in prospective teachers' proficiency to anticipate students' responses to proof-related tasks, analyze students' reasoning and evaluate whether it is logically sound, and pose follow-up questions that either challenge or support students' reasoning. The evidence will be collected through analysis of prospective teachers' responses as they progress through different module components, analysis of their forum interactions and a questionnaire administered after completion of the module.

Dr. Janet Walkoe from the University of Maryland has designed an intervention to engage pre-service teachers in the practices of questioning and listening to student thinking to interpret their understanding of proportions. There is evidence that a sustained focus on students' thinking has a positive impact on teachers' beliefs and instructional practices (Fennema, Carpenter, Franke, Levi, Jacobs, & Empson, 1996). The centerpiece of this module is a video of a clinical interview with a middle school student solving a problem related to proportions. Before and after watching the clinical video, preservice teachers examine a representation of a hypothetical classroom dialogue based on the clinical interview. During and following the clinical interview, the pre-service teachers have an opportunity to approximate the practices of listening to students' thinking and interpreting their understanding. After examining the follow up hypothetical classroom dialogue, pre-service teachers approximate the practices of questioning. The goal of the module is to improve pre-service teachers' practices of questioning middle school students about their mathematical thinking.

Dr. Rob Wieman, from Rowan University, is using the notion of psychological schema to describe the changes he seeks to produce in the preservice teachers under his care. Cognitive scientists have developed the idea of schema to help explain how experts make sense of complex situations and decide how to act. Wieman's intervention is designed to assess and change the schemas that teacher candidates use for making sense of and responding to student thinking. He notes that many mathematics teachers and teacher candidates have a relatively simplistic schema for diagnosing student thinking and formulating a response (Carter, 1990). In addition, the schema they do have is informal and idiosyncratic and that they do not describe it using a language that is widely shared in the profession (Carpenter, Fennema, Franke, Levi, & Empson, 2000; Carpenter, Fennema, Peterson, & Carey, 1988). The central activity of the module Wieman has created introduces teachers or teacher candidates to an expanded schema in the context of launching a rich mathematical task. After doing the task themselves, and anticipating student responses, participants are presented with a variety of student reactions. In a series of multiple-choice questions, participants are asked to diagnose student thinking and suggest a response to it. The answer choices represent a set of categories and teacher moves, categories that can act as an expanded schema. Pre- and post-tests measure whether this experience has expanded participants' schema, and whether it has supported groups of participants in developing a common language around student thinking and teacher moves. It is hypothesized that situating the introduction of this specific, expanded schema in the context of a teaching episode, and forcing participants to think about the categories of the expanded schema while making teaching diagnoses and decisions will support participants in expanding their own schema.

These interventions have in common the goal of helping clients, pre-service teachers and in some cases inservice teachers who return for masters degrees, learn to engage in particular practices of teaching. Some of the modules focus on practices that a teacher would typically engage in outside of instruction, such as the analysis of mathematical tasks; while others focus on practices that a teacher would typically engage within instruction, such as listening and responding to students' mathematical thinking. In all cases, the clients have the opportunity to approximate such practices by anticipating what they could do in particular circumstances. In Dr. Amidon's module, pre-service teachers collectively analyze a mathematical task using annotation tools within shared documents. In other instances, the fellows have used the capabilities within the online multimedia environment to capture clients' approximations. For example, in Dr. Walkoe's module, pre-service teachers approximate the practice of listening and responding to students' thinking by answering questions about what they noticed about a student's reasoning in the context of a clinical interview and adding teacher dialogue to a pre-existing classroom depiction. In Dr. Wieman's module, teachers approximate the practices of listening and responding by answering multiple choice questions whose answers represent several categories of student thinking and responding moves respectively. In Dr. Buchbinder's module, teachers approximate the practice of responding to student thinking by elaborating on how a teacher could challenge students' example-based conjectures. While there is a common thread of engaging clients in the approximations of practice, there is much variation across the fellows' project in terms of the goals for learning as well as the types of evidence that could be captured to support claims of client learning. In the cases discussed, fellows look for evidence of learning in the immediate context of PST's response to the activities presented. But evidence of learning could and should be gathered outside of these learning activities as well--in the PST's simulated practices (in front of their peers), as well as in their classroom practice (in their practicum placements). The working group will discuss the ways in which various artifacts collected by the fellows in the context of their clients' navigation of the modules as well as evidence from the work they do outside of the modules could be analyzed to gauge what their clients have learned.

Two sets of resources are planned as potential supports for research on the PST's learning from their participation on the modules. One consists of a set of suggestions for how to code the artifacts that PSTs create when they participate in the online modules created by fellows. Within this set we encounter ways of examining PSTs entries in forums and discussions using elements of systemic functional linguistics to identify instances of reflection and consideration of alternatives, as illustrated by Chieu, Kosko, and Herbst (2015). Within that set we also encounter ways of coding the changes shown by PST's in the representations of practice they create, for example when they use the Depict software to author a classroom scenario; we bring in some lessons learned from a study by Rougee and Herbst (2015) in which storyboard representations of practice were compared with representations realized in the form of text dialogues. These sets of resources for research can support the way the fellows and other users of Lesson*Sketch* are looking at their clients' work on online modules.

A second set of resources takes into consideration that PSTs learning must extend beyond the particular realizations they have in the context of online modules and into their practices with students. How can those practices be inspected for evidence of learning? Obviously one such way is to conduct observations of the instruction that the PSTs lead, but in the working group session we want to give attention to how the authoring and sharing tools of the Lesson*Sketch* platform can provide resources for PSTs to narrate what they did in their lessons. We plan to include two demonstrations in the second meeting of the working group. One of those demonstrations is the use of Depict as a resource for eliciting from PSTs a narration of how their lesson went. Depict is an authoring tool that permits the representation of lessons in the form of storyboards with cartoon characters. We believe that in the event that observations or video recordings of lessons are not available, teacher educators can use Depict in the context of interviews with preservice teachers, representing with it how the lesson developed. But in that context it is important to understand how the activity of jointly depicting a lesson can be described as compatible with an interview--what should the interviewer say and do in order to elicit from the interviewee information about a lesson they taught? A second set of resources comes from another authoring tool, Plan, with which teacher education researchers can create scenario-based questionnaires. Teacher educators can use them to create self reporting instruments that PSTs can use to document what they do. The literature on classroom research has used self report instruments such as surveys (e.g., Blank, 2002), logs (e.g., Rowan, Harrison, & Hayes, 2004), and text based vignettes (e.g., Stecher et al., 2006) to collect information on teachers' practices. For example, in their lesson log, Rowan et al. (2004) asked their respondents to focus on one student and check among options for the question "What was the target student asked to do during the work on number concepts?" and given options such as "Listen to me present the definition for a term or the steps of a procedure" or "explain an answer or a solution method for a particular problem" (p. 123). While some of those statements of practice may be reliably conveyed through text, others might better be conveyed through a combination of text and graphics. Plan is an authoring tool that can be leveraged to author any one of those self report instruments, with the added possibility that the practices that the respondent can be asked to comment on can also be rendered graphically. We envision that the second session will include discussions of self reporting instruments that could be used to get pre-service teachers to document how their classroom teaching performance shows evidence of their learning in the context of the interventions designed by the fellows.

Plan for Engagement

The working group will meet during PMENA in East Lansing to explore how teacher educators can produce evidence of their PSTs learning from their use of representations of practice in practice-based teacher education. This will begin with a presentation by the organizers of the variety of ways that teacher educators have developed materials to carry out practice-based pedagogy within an online multimedia environment. In the first session we will start with a brief and broad description of modules generated by twelve mathematics teacher educators, highlighting the variety of ways the materials provide pre-service teachers opportunities to learn about and engage in instructional practice. Next, the four teacher educators whose work is featured (Amidon, Buchbinder, Walkoe, and Wieman) will each provide a 10-minute presentation to describe the goal and contents of their modules. Each presenter will share materials they have developed to target distinct instructional practices including analyzing mathematical tasks, listening and responding to students' thinking in the context of a launch, listening to and interpreting students' mathematical thinking in the context of a clinical interview, and developing conjectures from examples. They will also provide artifacts of client's approximations of those practices. Following these presentations, during the first meeting of the working group, the group will discuss what are the learning claims that educators would like to make and will engage the attendants in identifying the evidence they would be looking for and in brainstorming the kinds of instruments that should be created to document such learning.

In the second meeting of the working group, members of the Lesson*Sketch* team will illustrate how the tools in the platform can be used in the context of (1) interviewing a PST about a lesson that they taught, (2) creating a lesson log that reports on recurrent practices the PST engages in, and (3) creating a scenario based questionnaire that the PST can use to report on the quality of their practices. They will then engage the audience in trying out the platform in one of those assessment contexts. Attendants will be able to work with a specific module and the fellow who developed the module, and in that context they will be able to try their hand at designing an assessment instrument or activity that could be deployed in the LessonSketch platform.

In the third meeting of the working group, fellows and attendants will share the assessment ideas they developed. There will be an opportunity to discuss features of the platform that enable (or perhaps constrain) the deployment of those assessment instruments.

Anticipated Follow Up Activities

The ThEMaT III project uses inquiry groups centered around the LessonSketch fellows to implement and further develop the modules. Thus, beyond the immediate goal of learning and creating community around common activities, the working group has rather practical goals for follow up activities. We expect that participants will leave the conference poised to use these modules in teacher education and professional development settings or to collect and analyze data regarding how well the materials created windows into teacher learning. We also expect that participants will be interested in reconvening at future PMENA conferences to share information about the effectiveness of interventions that may inform further refinement of these materials for future use. Over time we anticipate this kind of development could converge to have commonly available practice-based curriculum materials that could be used for the purposes of teacher preparation and professional development. We expect that the instruments used to collect this evidence will be made available in repositories such as shared folders and collections in the Lesson*Sketch* platform.

Building on Prior Work

The proposed work builds on prior work of this group in that it continues to address issues on teacher preparation for which representations of practice are usable. It also adds an entirely new direction, possibly useful to other PMENA researchers interested in studying learning, of how to instrument the documentation of learning gains by preservice teachers.

Approximately 7% of children and adolescents have a mathematical learning disability (MLD) and another 10% show persistent low achievement in mathematics despite average abilities in most other areas. Research on these two groups of students with math difficulties (MD) has traditionally focused on procedural skills. This working group is rooted in a twofold premise: (1) students with MD are capable of and need to develop conceptual understanding and mathematical reasoning skills, and (2) special education instruction and assessment needs to transition toward this focus. Participants will (a) continue to develop and refine the research agenda for the group, (b) brainstorm specific research questions that will address that agenda, (c) explore research methodologies that can answer the potential research questions, (d) discuss collaborations to carry out these studies, and (e) set up a plan for publishing and securing funding.

Overview of the Working Group

The purpose of our working group is to explore issues of research around the intersection of mathematics education and special education. Substantial work exists that focuses on mathematical cognition, development, and reasoning of students in general education. However, much less is known about the mathematical development of students with disabilities or how to support the learning of these students. The absence of research addressing this subset of students may be due in part to the incompatibility of the theoretical perspectives driving research and practice of mathematics education versus special education. Our working group is designed to create sustainable opportunities for researchers and practitioners interested in learning disability/difficulties and mathematics to move this important dimension of the psychology of mathematics education forward.

Understanding how students with disabilities/difficulties develop mathematics concepts and skills has several implications for both research and practice. First, practitioners in both general and special education can gain essential knowledge of how to approach instruction for diverse learners who may rely upon alternative pathways of understanding mathematics concepts. Second, researchers stand to gain a richer understanding of how cognitive processes involved in learning essential mathematical concepts emerge by studying atypical development. Finally, active study of the development of mathematics concepts and skills for students with disabilities provides both researchers and practitioners with mechanisms for moving toward a methodological focus on pedagogy rooted in assessment of what students with disabilities are capable of learning.

For the purposes of continuing the conversation around mathematics in special education, this group is concerned with students who have significant issues with mathematics, including:

- students with learning disabilities specific to mathematics
- students with cognitive differences in how they understand and process number
- students who are placed in special education and have difficulties with mathematics

We refer to these students as having "math difficulties" (MD) in the remainder of this paper.

History of the Working Group

Our PMENA/PME working group has met three times; each year our group had good participation of both returning and new members. In 2012, 15 researchers (faculty and graduate students) and 2 practitioners met during PME-NA in Kalamazoo, MI. This first meeting was specifically focused on better understanding mathematical learning disabilities (MLD). The working group began with a discussion of the issues around identification and definition of MLD. In particular, the group discussed the unique characteristics of students with MLD (e.g., slow speed of processing despite average reasoning; fundamental issues with number sense; over learning of procedural knowledge at the expense of mathematical reasoning) and implications for instruction and assessment. We took up a theoretical stance that positioned disability as an issue of diversity and considered the origin of the disability as the inaccessibility of instruction rather than a defect within the individual. Members shared videotapes of various students with MLD solving problems in assessment and teaching situations and discussed the need for teachers to target and teach toward the specific mathematical strengths and weaknesses demonstrated by the student. We further discussed at what point(s) the learning paths of students with MLD may differ from what is documented among students in general education, how existing developmental trajectories may or may not fit the population of students with MLD, and the need to expand or further document current trajectories to include students with MLD. Moreover, discussions focused on issues surrounding motivation related to the design and use of instruction, mathematical tools, and mathematical tasks. A rich discussion was held concerning the nature and sequencing of mathematical tasks, the use of concrete and pictorial representations and the extent to which they are and are not supportive of the abstraction of mathematical concepts for this population, and the need for increased research to inform the creation of practitioner tools and resources.

In the first year of our working group our focus was specifically on MLD - those students with a biological and cognitively-based difference in how their brain processes numerical information. Based on our discussions during the first year of our working group we decided to expand from a narrow focus on MLD to a more inclusive focus on students in special education who struggle with mathematics. This not only avoids the definitional issues at the forefront of the field (i.e., the lack of assessments to accurately identify students with MLDs and the resulting conflation of low achievement and MLDs), but also more accurately reflects the diversity of interests of the members of this group.

In the second year of our working group (2013) fourteen participants focused on a collaboration that was a result of the contacts that were made during the first working group. In this collaboration two faculty members worked together on a teaching experiment about fraction knowledge, a compliment to a 2012 funded National Science Foundation (NSF) CAREER project (Hunt, 2012). Their collaboration resulted in each bringing unique expertise; the mathematics education faculty member brought insight into the mathematical thinking of the student, while the special education faculty member brought insight into learning differences. The goal of the teaching experiment was to document how the foundation scheme of unit fractions (1/n) evolves in the mathematical activity of two cases of students with learning disabilities. The students' evolving conceptions were supported by constructivist-oriented pedagogy. Video data segments (i.e., each girl's conceptualization of the multiplicative nature of and inverse relation ($1/m > 1/n$ if $m < n$) among unit fractions; the girls' solutions to novel problems) from this project served as starting points for discussions in the subsequent PME-NA working group meeting. Specifically, working group members used the video segments and descriptions of the collaboration as a springboard for discussing possible research questions and methods of data analysis to employ in future, collaborative work. It is collaborations like these that this working group is designed to foster.

In 2014 we met as a working group at the joint PME and PME-NA conference in Vancouver. There our working group continued to expand to 25 members, now including international members from outside of North America. During the meeting, two working group members (one from math education and one from special education) shared a multiplicative reasoning assessment tool (*Multiplicative Reasoning Assessment Instrument,* Purdue Research Foundation, 2011) resulting from their NSF-funded research project (Xin, Tzur, and Si, 2008). Upon examining this instrument, the group discussed alternative ways for assessing students with MD and implications for intervention development. As a result of our collaboration in Vancouver, we had two main accomplishments. First, as a group we identified three research subgroups: (a) cognitive characteristics of students with MD, (b) interventions for students with MD, and (c) teacher preparation or professional development, that represented the interests of the members. Each research subgroup identified pertinent research questions and an agenda for further collaboration. Second, as a group, we proposed an idea for developing a proposal for a special issue to be published in a special education journal to address the research around the intersection of math and special education. Later in the year, members of the working group have developed a proposal and identified potential contributing works from the working group members. In addition, we have invited a well-known scholar to be part of the guest editorial board for this special issue. Currently, it is in the process of negotiating with a special education journal outlet for potential publication of this special issue

In this coming year we plan to continue and expand collaborations between members of this working group, by focusing discussions around two central themes: (a) math concept development and corresponding methodologies for studying its emergence in students with special needs, and (b) designing research questions and writing a research plan around this topic. We invite interested researchers and educators to participate. We anticipate that there will be several new members to this working group. Our prior working groups' members have continued to grow and generate momentum around research at the intersection of special education and math education, both in North America as well as internationally (PME working group papers 2014, 2015). We hope that the PME-NA working group can provide a synergistic place for an ever-growing number of researchers to come together to begin collaborations around these challenging issues.

Issues Relating to Psychology of Mathematics Education

Historically, special education researchers and teachers focused almost exclusively on students' mastery of procedural skills, such as basic number combinations and ability to execute mathematical algorithms (Jackson & Neel, 2006; Fuchs et al., 2005; Geary, 2010; Swanson, 2007; Kameenui & Carnine, 1998). A recent literature review comparing instructional domains for students with disabilities found that the majority of research conducted in the field of special education addressed basic computation and problem solving, with the primary focus placed on mnemonics, cognitive strategy instruction (e.g., general heuristic four-step strategy: read, plan, solve, and check), or curriculum-based measurement (Van Garderen, Scheuermann, Jackson, & Hampton, 2009). Instructional practices either focused on task analysis (breaking up skills into decontextualized steps that need to be memorized and followed), flash cards, or general heuristics that do not help with domain knowledge learning and concept development (Cole & Washburn-Moses, 2010). In particular, the focus on primarily procedures-driven instruction and rote memorization of skills seems to result in students' incomplete and inaccurate understanding of fundamental mathematics concepts as well as a lack of retention and/or transfer (Baroody, 2011).

Importance of Both Conceptual and Procedural Knowledge

Crucial for rich mathematical understandings that enable retention and transfer of fundamental concepts is the iterative development of conceptual understanding along with procedural proficiency (Rittle-Johnson, Siegler, & Alibali, 2001; Rittle-Johnson & Koedinger, 2005). Rittle-Johnson and Alibali (1999) noted that conceptual knowledge supports procedural generalization. In particular, conceptual knowledge could aid children in mindfully avoiding the use of procedures that fail to work in novel situations. Additionally, an ability to understand and manipulate different mathematical representations to conceptually navigate a mathematical context contributes to conceptual understanding and procedural skill (Ball, 1993; Kaput, 1987; Rittle-Johnson et al., 2001). It seems that any investigation into mathematical cognition, whether related to disability or not, must fundamentally engage with issues of conceptual understanding (Hunt & Empson, 2014).

A focus on procedural skills limits students with disabilities' access to the general education curriculum, which is a requirement of the Individuals with Disabilities Educational Improvement Act (Maccini & Gagnon, 2002). In mathematics, access to the general education curriculum means addressing problem-solving, mathematical modeling, higher order thinking and reasoning, and algebra readiness as required by the new Common Core Standards (CCSSI, 2012). To accomplish these Standards, mathematics educators need to actively engage students in making conjectures, justifying and questioning each other's ideas, and operating in ways that lead to deep levels of mathematical understanding (Kazemi & Stipek, 2001; Lampert, 1990; Martino & Maher, 1999; Yackel, 2002).

Conceptual Diagnosis Based Pedagogy

A pedagogical approach to be explored and advanced during this Working Group's meetings is one that focuses on promoting conceptual learning in students with MD. This approach is rooted in a constructivist stance (Piaget, 1985; von Glasersfeld, 1995), particularly the notion of assimilation, which stresses the need to build instruction on what students already know and are able to think/do. That is, teaching needs to be sensitive, relevant, and adaptive to students' available ways of operating mathematically (Steffe, 1990). To this end, teachers must learn how to: (a) diagnose students' available conceptions, and (b) design and use learning situations that both reactivate these conceptions and lead to intended transformations in these conceptions.

Building on Simon (2006)'s core idea of hypothetical learning trajectories, Tzur (2008) has articulated such an adaptive pedagogy, which revolves around the Teaching Triad notion: (a) students' current conceptions, (b) goals for students' learning (intended math), and (c) tasks/activities to promote progression from the former to the latter. Key here is that in designing every lesson one proceeds from conceptual diagnosis of the mathematics students are capable of thinking/doing. That is, assessment methods need to focus on dynamic (formative) inquiry into student understandings, as opposed to on testing correct and incorrect answers per se. This day-to-day diagnosis, obtained via engaging students in solving tasks and probing for their reasoning processes, gives way to selecting goals for students' intended learning. Building on this diagnosis, a mathematics lesson begins with problems that students can successfully solve on their own, which Vygotsky (1978) referred as the Zone of Actual Development (see also Tzur & Lambert, 2011). Recent studies of mathematics teaching in China (Jin, 2012; Jin & Tzur, 2011) revealed a strategic, targeted method, bridging, which is geared specifically toward both: (a) reactivating mathematical conceptions the teacher supposes all students know, and (b) directing their thinking to the new, intended ideas.

Exemplar Research Activities with Students with MD

Since 2008, two members of this working group (one from math education and one from special education) have been working collaboratively on a federal funded grant project (Xin, Tzur, & Si, 2008). This project integrated research-based practices from mathematics education and special education and was aimed to promote multiplicative reasoning and problem solving of elementary students with MD. As an outcome of this collaborative project, the research team has developed an intelligent tutor, PGBM-COMPS. The PGBM-COMPS intelligent tutor draws on three research-based frameworks: a constructivist view of learning from mathematics education (Steffe & D'Ambrosio, 1995), data (or statistical) learning from computer sciences (Sebastiani, 2002), and Conceptual Model-based Problem Solving (COMPS) Xin, 2012) that generalizes word-problem underlying structures from special education.

Rooted in a constructivist perspective on learning (Piaget, 1985; von Glasersfeld, 1995), the PGBM part of the intelligent tutor focused on how a student-adaptive teaching approach (Steffe, 1990), which tailors goals and activities for students' learning to their available conceptions, can foster advances in multiplicative reasoning. This approach eschews a deficit view of students with learning disabilities. Rather, it focuses on and begins from what they do know and uses task-based activities to foster transformation into advanced, more powerful ways of knowing. On the other hand, intelligent computer systems can play an important role in students' learning by effectively modeling their thinking and dynamically recommending tasks tailored to their conceptual profiles. Going hand-in-hand, the COMPS part of the program (Xin, 2012) generalizes students' understanding of multiplicative reasoning to the level of mathematical models. At this stage, students no longer rely on concrete or semi-concrete models for problem solving; rather, the mathematical models directly drive the solution plan.

The collaborative research team has conducted several piloting studies to field test the PGBM-COMPS intelligent tutor with elementary students with MD. The preliminary studies have shown promising results—participating students with MD who interacted with this intelligent tutor not only enhanced their problem solving skills on a researcher-designed criterion test but also a norm-reference standardized test (Xin et al., 2013). In addition, the results of these piloting studies have shown success in promoting students' substantial conceptual advances (e.g., concept of number, multiplicative reasoning).

In another project, another working group member is documenting learning trajectories of elementary school children with MD as they come to understand fractions as quantities (Hunt, 2012). In its first year, the goal of this work is to produce models of children's key developmental understandings, or critical transitions in how children may conceive of a mathematical idea (Simon, 2006), along a carefully sequenced combination of tasks and varying instructional guidance necessary to grow conceptual knowledge not yet well formed (Daro, Mosher, and Corcoran, 2011). The researcher will illustrate varying level of a student's informal notions of fractions, how the mathematical ideas can be elicited, the grappling of ideas a student might experience, and how more solidified notions of mathematics form through a student's activity (i.e., external manipulation or representation; internal mental activity; actions; strategies for problem solving). It is the goal of this research that the mapped trajectories can assist educators looking to individualize instruction for students with MD and improve students' conceptual understanding of fractions.

As part of this grant's Year 1 activities, the research team has documented an initial trajectory from semi-structured interviews with 50 second, third, fourth, and fifth graders with MD. Interviews followed a protocol that established a basis for questioning but also allowed for maximum researcher flexibility to fully examine student thinking. Information pertaining to the children's specific needs was also collected to allow for an examination of any trends occurring across similar cognitive profiles. The constructed trajectory is also being tested with a smaller subset of four students and an expanded group of tasks from which the trajectory is based. Data collected from mini-interventions will undergo analysis (Siegler, 2006) to confirm the robustness of the preliminary trajectory. This grant's Year 2 activities will take up teaching experiment methodologies, much like those used in the collaborative pilot that resulted from this working group, to document how children with MD construct conceptions of fractions.

Working group participants will use artifacts from projects described above as possible starting points to illuminate and further explore possible applications of student-adaptive pedagogy (conceptual diagnosis based) as well as conceptual development trajectories in the design of effective/efficient assessment and intervention programs for students with MD.

We believe such approaches are complimentary and have the potential to become core methodological approaches for teaching and studying the conceptual understandings of students with MD. In a similar way, this working group provides a venue to give and receive feedback on ongoing cutting edge empirical work, which is reshaping how students with MD are researched.

Plan for Working Group

The aim of this working group is to facilitate collaboration amongst researchers and educators concerned with mathematics education for students with MD. The main goal is to promote basic research into how students with special needs think about mathematics and develop mathematical concepts. This working group intends to accomplish the following: (a) continue to develop and refine a research agenda for the group, (b) brainstorm specific research questions that will address that agenda, (c) explore research methodologies that can answer the potential research questions, (d) discuss the logistics of collaborations to carrying out these studies, and (e) embark upon collaborations leading to additional publication and funding opportunities.

These goals are further outlined across sessions as follows:

Session 1: Introductions and Progress-to-date

GOAL: To identify participant's affinity for established sub-groups and identify potential new sub-group possibilities.

- Prior members will briefly introduce the working group's history and describe the collaborations that have emerged in prior years.
- Participants will each introduce themselves and their current research and interest in students with MD.
- As a large group we will discuss whether the previously established sub-groups (i.e., *cognitive characteristics of students with MD, interventions for students with MD, and teacher preparation or professional development*) are representative of the interests of the members. If not, new sub-groups will be created.
- Participants will join the sub-group that is most aligned with their research interests and begin to discuss the overlap in research agenda and current work and potential research agendas the sub-group is interested in exploring.

Session 2: Methodologies / Sharing Data Artifacts

GOAL: Engage in discussions around methodological and analytic approaches to studying MD with examples from working group member's research artifacts.

- Within sub-groups we will:
    - Articulate the overarching research agenda for the sub-group based on the previous day's discussion,
    - Articulate potential research questions that the group would like to address through collaborative work.
    - Explore a variety of methodological and analytic approaches that can be leveraged to address the research questions. To accomplish this, subgroups may:

        - View artifacts (e.g., video, written work, etc.) of work already conducted to highlight possible methodologies for future studies.
        - Discuss which methodologies and analytic approaches best align with the proposed research agenda.
- Within a whole group discussion we will:
    - Share out potential research agendas and methodological discussions from small group discussions

Session 3: Planning and Writing
GOAL: Establish next steps for both the sub-groups and the whole working group.

- Within sub-groups we will:
    - Work on written product of research agenda
    - Develop a project plan for any cross-institutional collaborative work that has developed from the subgroups.
- Within a whole group discussion we will:
    - Share progress and commitments from small group discussion
    - Finalize a plan for individual groups to continue updating progress to the larger group (website).
    - Determine what our next whole group meeting will entail (e.g., PMENA working group for the following year.)

Anticipated Follow-up Activities

Throughout the year, the members of this working group will continue working on research problems of common interest. They will contribute to a common website in which they will update other members of the working group about the progress of the various research collaborations. We will continue our effort in disseminating the collaborative work resulting from this working group to broaden its impact in the field of mathematics education for students with MD.

The practice of teacher noticing has been the subject of considerable attention within the research community; however, conceptualizations of noticing appear somewhat variable. Similarly, measurements of teachers' noticing capacities tend to vary as well. This working group proposal is organized around continuing the work of past PME teacher noticing working groups (PME-NA, 2013; PME-IG, 2014) and further expanding and focusing effort to address key challenges associated with the measurement of noticing skills.

Keywords: Assessment and Evaluation; Measurement; Teacher Education-Inservice (Professional Development); Teacher Education-Preservice

Introduction

High leverage teaching practices which facilitate the development of students' mathematical development have been the subject of considerable attention (Ball, Sleep, Boerst, & Bass, 2009, Cobb & Jackson, 2011; Lampert, Beasley, Ghousseini, Kazemi, & Franke, 2010). One such practice, professional noticing, involves "instruction that attends closely to children's ideas" (Ball & Forzani, 2011, p.19). Sometimes referred to as teacher noticing, professional noticing [of children's thinking] has been the subject of examination for some time (Erikson, 2011); however, over the past several years, this area of inquiry has experienced renewed interest among scholars (Fisher, Schack, Thomas, Jong, Eisenhardt, Yoder, & Tassell, 2014a; Jacobs, Lamb, & Philipp, 2010; Schack, Fisher, Thomas, Eisenhardt, Tassell, & Yoder, 2013; Sherin, Jacobs, & Philipp, 2011; Thomas, Fisher, Eisenhardt, Schack, Tassell, & Yoder, 2014/2015).Moreover, professional noticing has been the topic for working group sessions at previous meetings of both the North America and International Groups of the Psychology of Mathematics Education organization (Jacobs, Sherin, & Philipp, 2013; Fisher, Schack, Wilhelm, Thomas, & McNall-Krall, 2014b). The purpose of this proposal is to provide a rationale for maintaining the momentum of past PME-NA working groups focused on this topic while providing the opportunity to extend the scope of activity into the measurement of professional noticing capacities.

History of Professional Noticing Working Group Activities

This working group was initiated by Jacobs, Sherin, and Philipp at the 2013 PME-NA conference in Chicago (2013). At the closing of this event, the working group had identified two areas upon which to focus continued efforts. These areas of focus were: 1) the planning and implementation of a conference on teacher noticing, and 2) the development of a strong internet presence regarding the topic of teacher noticing.

At the 2014 PME-IG conference in Vancouver, the working group continued to make progress on furthering these efforts as well as adding a third goal of the construction of a monograph on teacher noticing (Fisher et al., 2014b). At this conference three teams were formed around the three goals. The need for a fourth team arose during the working session to accommodate those participants who were seeking more information about the construct of teacher noticing.

The teacher noticing conference team decided to apply for funding to support a conference centered around teacher noticing research. This team plans to secure external funding (e.g., AERA Conference Grant), and their goal is to hold the conference as a pre-session to an established STEM education conference. With this manner of organization, attendees could combine travel efforts and attend both conferences in one visit.

The monograph team focused on discussions to extend mathematical teacher noticing to science and include an international context in a monograph. The facilitators of the working session had the good fortune to meet with Jinfa Cai, co-editor, with James Middleton, of the Springer series, *Research in Mathematics Education.* During this meeting we discussed with Dr. Cai the purpose of the monograph as defined by the working group participants. From this we developed a proposed outline of the monograph. The proposed monograph will build upon the work of Sherin, Jacobs, and Philipp's *Mathematics Teacher Noticing: Seeing Through Teachers' Eyes* (2011). At the suggestion of Dr. Cai, we are working to include both seasoned and promising researchers/authors for the chapters of the monograph. Additionally, the chapter authors will include international mathematics and science education researchers. The sections of the book will include a commentary on the chapters within that section. We sent an initial invitation to some of the top researchers in this field, receiving a number of positive responses and chapter abstracts. We disseminated a call for chapter proposals from the participants in the working sessions at both the 2013 and 2014 conferences as well as a broader call for chapters. To date, we have received 31 chapter proposals. The first round of the review process for chapter proposals is underway with each chapter proposal being reviewed by three reviewers. We anticipate submitting a monograph proposal, with chapter recommendations, to the Springer series, *Research in Mathematics Education,* by early summer 2015.

The internet presence team discussed strategies such as a website on teacher noticing, social media groups for discussion, blogs or wikis to post information, and email listservs. At this point, the email listserv has been established that combines the 2013 working group attendees with the 2014 working group attendees and communication has begun with those groups. Additionally, a Facebook page (https://www.facebook.com/groups/182002372007275/) has been created to bolster teacher noticing discussions. Thus far it has been used for the monograph proposal and reviewer calls and will continue to be advertised and used for communications of the monograph and conference teams.

It is our intent that these three teams continue to work synergistically as the chapter authors in the monograph will be invited to speak at the conference, and presentations at the conference may be leveraged to inform monograph materials. All of these efforts will be advertised using social media outlets, email listservs, and websites that will be administered by the technology sub-group.

Measurement of Professional Noticing Capacities

In addition to continuing the processes initiated in previous teacher noticing working groups, this proposed 2015 working group would intentionally address the challenge of noticing measurement. Schack, Fisher, & Thomas (in press) note the varying manner in which noticing has been operationalized in a number of inquiries. For example, some researchers conceive of noticing as the interrelated skills of attending, interpreting, and deciding (Jacobs et al., 2010; Jacobs, Lamb, & Philipp, & Schappelle, 2011) while others focus solely on a single skill such as attending (Star, Lynch, & Perova, 2011).

Moreover, the temporal situation of teacher noticing also changes depending on the inquiry, with noticing positioned as an in-the-moment practice in some studies (Schack et al., 2013; Sherin, Russ, & Colestock, 2011; Stockero, 2014) while other research characterizes the practice of noticing in more retrospective terms (Goldsmith & Seago, 2011). Leatham, Peterson, Stockero, and Van Zoest (2015) characterized instances of student thinking that had significant potential to enhance student learning if teachers acted on them in-the-moment, rather than selecting and sequencing (Smith &

Stein, 2011) the event for later classroom discussion. From these disparities, it follows that measurement of teachers' noticing capacities also appears quite variable within the extant literature. Although the use of video-excerpts seems to be a common element among many measures (Berliner, 1994; Jacobs et al., 2010; Sherin & van Es, 2009; Star & Strickland, 2008), the manner in which such videos are used differs significantly. While some researchers develop inductive scoring rubrics for open-ended teacher responses to video excerpts (Schack et al., 2013), others employ automated scoring mechanisms for similarly open-ended responses (Kersting, Sherin, & Stigler, 2014). The length and context of the videos used for assessment also contributes to the variation in measures. For example, Schack et al. (2013) employed a brief individual interview video excerpt while others have used full class video in terms of both time and context. (Leatham et al., 2015; Star et al., 2011; Star & Strickland, 2008).

Further, some researchers adopt video-based measurement approaches predicated on highly specific progressions of learning (Schack et al., 2013) while others employ more generalized systems of measurement (Goldsmith & Seago, 2011; Santagata, 2011; van Es, 2011). Leatham et al. have focused on mathematically significant events (2015).

Kaiser, Buth, Hoth, König, and Blömeke (2015) have examined the theoretical complexities of video-based measures and identified specific challenges which include the following: 1) Issues related to video perspective (e.g., whether or not the teacher is included in the video or if the video is from the teachers' point of view), 2) Evaluating the "correctness" of responses (e.g., identifying viable theoretical lenses and measurement structures to accommodate unexpected yet "correct" responses), 3) Achieving acceptable psychometric quality (e.g., balancing reliability and validity concerns with reasonable measurement administration protocols and costs). While Kaiser et al., present potential solutions to these challenges, given the variability of scholarship with respect to teacher noticing, additional perspectives on the vexing challenges of measuring teachers' noticing capacities are worthy of exploration.

Plan for Engaging Professional Noticing Assessment Issues

To productively address issues of assessment of professional noticing identified in the previous section, the group will engage in both small and large group discussions and action plans. While an overview of the topics with research and practice-based examples will be presented, we want to primarily take an inductive approach by using the group's collective knowledge about and experience with the assessment issues. Thus, the plans for the sessions are as follows:

Session 1 will include a very brief overview of teacher noticing for participants new to the construct. The primary focus of this session, however, will be on methods and challenges of assessing or evaluating teacher noticing. Several tools, frameworks, rubrics, progressions from various contexts will be shared for discussion with the audience applying one or more to presented scenarios. The facilitators expect discussion around 1) in what contexts has teacher noticing been studied, 2) what tools, frameworks, rubrics, progressions have been used to notice teacher noticing, 3) are there tools that can reliably and validly assess teacher noticing, and 4) what are the potential benefits, challenges, and consequences to assessing teacher noticing? The specific agenda will be narrowed with input from working group participants.

Session 2 will begin with a quick synopsis of session 1, outlining the proposed agenda for studying assessment of teacher noticing. Based on the proposed agenda, participants will work in small groups to continue discussing and reflecting on a specific aspect of assessing professional noticing. This will allow for deeper reflections and connections within the smaller groups. By the end of Session 2, small groups will briefly report on their discussions, progress, and challenges of teacher noticing assessment to the larger group.

Session 3 will focus on developing an action plan for work beyond the conference. Small group goals and activities will be communicated beyond the conference through the already present Teacher Noticing Facebook page. The discussion and goals will inform a future teacher noticing conference for which the 2013/2014 working groups are in the early planning stages. Another possible outcome of the working group might be a compendium of methods used to assess teacher noticing.

Anticipated Follow-up Activities

The primary goal of this working group is to examine and further refine the research on assessment of teacher noticing with the ultimate goal of using such knowledge to support teachers in the development of their professional noticing for the benefit of students' mathematical understanding. The working group will create an environment where participants and small groups can network and create mutually beneficial collaborations that have the potential to further inform future teacher noticing research and practice. It will be encouraged for small groups to think of next steps that are appropriate for their topic, whether they be the development of a measurement tool or multi-site research projects. The group will continue to update information on professional noticing on the Internet, including the Facebook group. Participants will also be kept in communication regarding any updates on the professional noticing monograph, and potentially participating in a focused conference on professional noticing.

Extensions of Previous Working Group Activities

Assessing professional noticing capacities is an increasingly vexing challenge; thus, we think this focus is a timely way to extend previous working group activities. Kaiser, Busse, Hoth, König, & Blömeke (2015) recently highlighted the various theoretical and methodological complexities of video-based assessments of teachers' competence. Even when a theoretical framework guides the development of an assessment, specific content and pedagogical practices need to be selected (Leatham et al., 2015). Kaiser, et al. (2015) point out that there needs to be a balance between reliability and validity by taking feasibility into consideration in terms of the assessment length, grades, and number of classroom situations. They also argue that *noticing* can be linked to other concepts and knowledge frameworks because it has a very action-oriented view of teaching. While they viewed video-based assessments as promising, there were still challenges in developing questions, coding and eliciting responses that reflect practices. To scale up video-based assessments, Kersting, Sherin, & Stigler (2014) used a machine to automatically code short answer responses. The machine scores were highly correlated to human scores and provided insights into task clarity and scoring rubrics.

Teaching mathematics is complex; thus, assessing professional noticing poses many challenges. By engaging in meaningful conversations around assessment, the working group's collective knowledge will be able to get at strategies for addressing and overcoming some of the challenges to measuring noticing capacities.
