PME-NA History and Goals

PME came into existence at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany in 1976. It is affiliated with the International Commission for Mathematical Instruction. PME-NA is the North American Chapter of the International Group of Psychology of Mathematics Education. The first PME-NA conference was held in Evanston, Illinois in 1979.

The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers;
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME-NA Membership

Membership is open to people involved in active research consistent with PME-NA's aims or professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website at http://pmena.org. For information about membership in PME, go to http://www.igpme.org and click on "Membership" at the left of the screen.

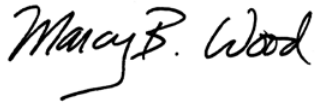
Preface


Welcome

On behalf of the 2016 PME-NA Steering Committee, the 2016 PME-NA Local Organizing Committee, and the University of Arizona, we welcome you to the 38th Annual Meeting of the International Group for the Psychology of Mathematics Education – North American Chapter held at the Marriott Starr Pass Resort in Tucson, Arizona.

The theme of this year's conference is *Sin Fronteras: Questioning Borders with(in) Mathematics Education*. This theme is intended to encourage research presentations, discussion, and reflection on the variety of borders within mathematics education, as well as those that might be probed, challenged, explained, enhanced and/or potentially transformed by mathematics education. Sessions examine topics such as geographic, political, cultural and language borders with(in) mathematics education, as well as borders between mathematical content areas and grade levels, and how borders can limit access to mathematical content or impact mathematics teaching practices.

To catalyze conversations about the conference theme, we organized three plenary talks that each address different perspectives on borders with(in) mathematics education. In the Thursday evening plenary*, Sandra Crespo* reflects on three intellectual divides that have challenged and motivated her scholarship across her many years of participation in PME-NA. *Anna Sfard* will follow with comments, and further discussion of the conference theme. In the Friday joint plenary session, *Maria Trigueros Gaisman* and *Chris Rasmussen* discuss their respective work in coordinating multiple theoretical perspectives and frameworks in analyzing mathematics learning at the undergraduate level. In the Saturday panel plenary session, scholars that represent the three PME-NA member countries (*Julia Aguirre, Lisa Lunney Borden*, and *Olimpia Figueras*) will address the idea of challenging borders in mathematics education from different perspectives (e.g., a focus on students, focus on teachers) and in different contexts (Canada, Mexico, US).

We are thrilled to report record attendance for PME-NA 2016! This year's conference will be attended by over 550 researchers, faculty and graduate students from around the world including the US, Mexico, Canada, Sweden, Australia, Chile, Puerto Rico, Israel, Trinidad and Tobago, and Germany. We received 581 submissions. The acceptance rate was 92% for working groups, 48% for research reports, 36% for brief research reports and 61% for posters. The conference program includes 104 Research Report sessions, 102 Brief Research Report sessions, 222 Posters, and 11 Working Groups. A significant aspect of this year's conference is that for the first time in PME-NA, there will be some presentations in Spanish, as well as simultaneous oral interpretation (from English to Spanish, and from Spanish to English) for selected sessions, thus embracing the theme of the conference, Sin Fronteras/Without Borders. It is the hope of the organizers that this would a model to follow in future PME-NA conferences.

We would also like to thank the many people who generously volunteered their time over the past year in preparation for this conference. This includes members of the PME-NA Local Organizing Committee, the PME-NA Steering Community, UA Continuing and Professional Education, strand leaders, proposal authors and reviewers. We appreciate all of your hard work and dedication, and your commitment to ensuring a high-quality conference program. We also wish to thank the generous financial support of the University of Arizona (UA) College of Education, the UA Department of Mathematics, and Visit Tucson.

Plenary Papers

EN LA LUCHA/IN THE STRUGGLE: RESEARCHING TO MAKE A DIFFERENCE IN MATHEMATICS EDUCATION

Sandra Crespo
Michigan State University
crespo@msu.edu

In this plenary I reflect on the research I have shared over the past many years of participating and presenting in PME and PME-NA conferences to identify three intellectual divides that continually challenge and motivate my scholarship. I discuss how these intellectual borders (mathematics/education; expert/novice; research/teaching) create adversarial relationships and unwarranted hierarchies in our field and among ourselves. Although these divides have been with us for a long time, I contend that these are far more dangerous than we might realize. These divides prevent us individually and collectively from imagining new and creative solutions to the perennial question about how to improve the quality and equity of mathematics education. I propose a reflexive and collaborative approach to identifying and problematizing the intellectual divides that challenge our goals and commitments to pursuing research that makes a difference in the very communities that we seek to serve.

En esta plenaria reflexiono sobre las investigaciones que he compartido durante los muchos años que he participado y presentado en las conferecias de PME y PME-NA para identificar tres divisiones intelectuales que continuamente retan y motivan mi trabajo académico. Discuto cómo estas fronteras intelectuales (matemáticas/educación; expert(a)/novato(a); investigación/enseñanza) crean relaciones adversas y jerarquías injustificadas en nuestro campo y entre nosotros(as). A pesar de que estas divisiones hace mucho tiempo que están con nosotros(as), sostengo que éstas son mucho más peligrosas de lo que podríamos darnos cuenta. Estas divisiones nos impiden individual y colectivamente imaginar soluciones nuevas y creativas a la eterna pregunta de cómo mejorar la calidad y equidad de la educación matemática. Propongo un enfoque reflexivo y colaborativo para identificar y problematizar divisiones intelectuales que desafían nuestras metas y compromisos de hacer investigación para contribuir a las comunidades que queremos servir.

Keywords: Equity and Diversity, Policy Matters, Research Methods

Introduction

I became a member of this organization in the year 2000 when I attended and presented at my very first PME-NA conference in Tucson, AZ. I was an early career faculty then and had just become a new mom. I traveled with my 5-month old in tow and my mother who looked after baby while I was presenting and attending the conference. I have fond memories of Tucson and continue to have a feeling of being *con familia* within this organization. Little did I know then that I would be back in Tucson 16 years later as a plenary speaker at this very conference. PME-NA has been a nurturing community in which to share my works in progress, test out my ideas, and learn and grow as a scholar. I have attended almost every year since the year 2000, in fact I counted a total of 18 publications in PME and PME-NA proceedings.

It is with trepidation that I accepted the invitation to deliver this year's PME-NA plenary address. I admit that plenaries are not my thing. Delivering a conference plenary has never been one of my professional aspirations. I much prefer dialogical and more interactive presentations and workshops where I can engage with the audience rather than standing in a podium talking at the audience. When I asked the program committee why they had chosen me the response was that I am the poster child for this year's conference theme: *"Sin Fronteras! - Without Borders!"* as I am someone who is constantly crossing geographical, cultural, linguistic, and intellectual borders. I could see their point

and decided to accept the invitation. After all I am not one to back down from a challenge or from stretching myself beyond my comfort zone.

I am engaged in mathematics education research because I strive to contribute to improving mathematics education in ways that align with the goals and values of democratic and anti-oppressive education. I am especially interested in learning and teaching practices that redistribute power and challenge stereotypes and hierarchies in the mathematics classroom, and this has pushed me to see social interactions from multiple perspectives and theoretical lenses. I approach my work in collaboration with colleagues, schools, and teachers committed to social change. I do this work across three countries, Dominican Republic, Canada, and the U.S. Within mathematics education I straddle the worlds of elementary/secondary education, of formal/informal mathematics, of theory/practice and of equity/excellence debates and debacles. More importantly, I have learned to embrace the tension and burden of working within and across these many communities and boundaries.

While it is true that my work crosses boundaries this is not unique to my scholarship. I would argue that we are all in some way or another navigating multiple personal and professional communities that require us to negotiate interactions that challenge us and that nurture us. So I am here not to claim that I have something unique to share or to stake claim to a piece of intellectual property that is solely my own. To the contrary, the work I have done over the past 20+ years as a mathematics educator has been possible because it has taken a whole village of collaborators who have helped me to keep front and center my commitment to anti-oppressive education and to remain hopeful that as math educators we can make a difference. So my approach to this plenary is to reflect on the kinds of boundaries I have had to cross throughout my career, taking stock of the work I have presented and published at PME-NA, to make visible intellectual divides that I consider dangerous and worthy of bridging and eventually take down.

I use "in the struggle/en la lucha" in the title of this plenary to remind myself of Paulo Freire's (1970) pedagogy of hope in which he discusses our struggle as educators to work within the system that oppresses us and that we seek to change. I am also channeling bell hooks' (1990) idea of teaching to transgress where she calls on educators to challenge ourselves to find new ways of thinking about teaching and about learning so that our work "does not reinforce systems of domination, imperialism, racism, sexism, elitism." (p. xx). It is in that spirit, of dreaming big and dreaming the impossible that I then take the opportunity of this plenary to identify intellectual divides that continually push me and my scholarship and that unnecessarily drain our collective energy to address the problems facing public education today. I use this opportunity to reflect on my own work and how it has been challenged by pernicious intellectual divides that create adversarial relationship and unwarranted hierarchies in our field and among ourselves.

Fronteras Intelectuales and Dangerous Divides

Towards the middle of last century, in an influential lecture, C. P. Snow (1959) identified "two cultures" within academic circles that threatened the whole enterprise of the University as a place that values diversity of intellectual pursuits and epistemologies. A border crosser himself Snow spoke as a participant in both literary and scientific communities about the deep rooted divide between two fields —the literary intellectuals and the scientists—and how each exalted its own virtues by vilifying the other's values. He described them as two polar groups: the literary intellectuals at one pole and at the other the scientists. "Between the two a gulf of mutual incomprehension. They have a curious distorted image of each other." (Snow, 1959, p.4). Snow's characterization highlighted that the literary intellectuals value nuance, subtlety, depth, responsiveness and imagination, whereas scientists will talk about those qualities as touchy-feely and fuzzy-minded subjectivism. Similarly, the scientists value rationality, objectivity and functional prose

while literary scholars consider those qualities dull, literal minded, and lacking depth of understanding.

In "Disciplinary Cultures and Tribal Warfare," a chapter in her book "Scandalous Knowledge," Herrstein Smith (2006) explains the dangers of creating intellectual camps and hierarchies and revisits C. P. Snow's two cultures adding that the tendency to polarize, compare, and rank ourselves is part of what all social groups do, including academics and intellectuals. In academic circles this is known as the ideology of the two cultures and refers to our tendency to identify ourselves with one or more social groups (e.g., religious, ethnic, political, professional), to experience that identity through contrast and comparison to one or more other groups - or, in other words, to experience the world in terms of 'us' and 'them'. This is known as a tendency to self-standardize and other-pathologize, said another way "to see the practices, preferences and beliefs of one's own group as natural, sensible and mature and to see the divergent practices, preferences and beliefs of members of other groups, especially those considered as the 'other', as absurd, perverse, undeveloped or degenerate" (Herrstein Smith, 2006; p. 113). Another consideration is that this tendency to pathologize the other is self-perpetuating in that these are invoked and circulated as ideological narratives within and across various communities.

In mathematics education there are numerous intellectual divides to choose from (see Stinson & Bullock, 2012; Davis, 2004; Davis, Sumara, & Luce-Kapler, 2015). In the 80's the quantitative/qualitative debate took center stage as did the constructivism vs. social theories of learning. The 90's witnessed the cognition vs. communication, and acquisition vs. participation debates (Sfard, 1998), while the 2000's experienced the sociocultural vs. sociopolitical divide (Gutiérrez, 2013). These debates have been played out in the intellectual domain and among academics and eventually have slipped into the everyday conversations of schools and universities as ideological narratives that cast polar opposite characters (reform vs. traditional) battling out intellectual wars. Although these debates have faded they still frame current conversations and practices in mathematics education. Furthermore, they fall into the dualistic intellectual tradition that Snow (1959) characterized as the ideology of the two cultures and that Herrstein Smith (2006) describes in her writings as the tendency to self-standardize and other-pathologize.

I will focus here on three enduring divides that have not had as much play as those named above but are ever present in our everyday practices as mathematics educators and fuel an "us vs. them" mentality as described in the ideology of the two cultures. These are: a) Mathematics/Education, (b) Expert/Novice, and (c) Research/Teaching. I contend that these divides may seem innocuous but are nevertheless more dangerous than they appear to be. As I looked back across my PME and PME-NA publications with these three divides in mind, I could see how these have been and still continue to be a challenge in my own scholarship but also to our field more broadly. Although I could see all three divides in each of these articles, when I considered which divide was most foregrounded the following groupings emerged—7 articles foregrounding (a) [the mathematics/education divide], 5 of them foregrounding (b) [the expert/novice divide], and 6 articles foregrounding (c) [the research/teaching divide]. Rather than synthesizing the three groupings I use one representative article (see below) to springboard the discussion on each intellectual divide. I purposefully picked articles that are 6-7 years apart so that they represent broadly the scholarship that I have been engaged in over the many years I have been a part of the PME and PME-NA organization.

The Mathematics/Education Divide

Looking back at my very first PME-NA presentation I can see the mathematics/education divide prominently highlighting the separation between where and how teacher candidates can learn mathematics in their teacher preparation programs. I experienced this divide both in my own undergraduate education as I traveled from one side of campus, where I was studying mathematics and physics to the other side of campus where I was taking education classes. This structural divide continues to persist and is very present in my own practice as a mathematics teacher educator. The very structure of teacher preparation programs in general continues to reaffirm the mathematics/education divide by locating the learning of mathematics content in designated math courses and separating it from the learning of teaching methods contained in education courses. Embedded within the structure is also the assumption that learning to teach entails learning the content first and the teaching methods second (rather than concurrently).

In *Learning mathematics while learning to teach: Mathematical insights prospective teachers experience when working with students* (Crespo, 2000), I argued that prospective teachers engage in mathematical inquiry within their education courses and in particular when working directly with students. I provided three examples—posing tasks, analyzing students' work, and providing mathematical explanations—where teacher candidates could gain mathematical insights while learning educational methods and theories. This surely is no longer a controversial point, but at the time mathematics educators were just beginning to consider Ma's (1999) work and Ball and Bass' (2000) work describing the profound understanding of mathematics entailed in the work of elementary mathematics teaching. The push back from mathematics educators who dug their feet firmly into the mathematics side of the divide was intense, making anything that they did not recognize as mathematical sound crazy or simply stupid. Therefore, the process of selecting examples that were recognizable as mathematical by those holding dominant perspectives about mathematics was a challenge.

Let me provide a few illustrations. In Crespo (2000) I included several examples to illustrate the ways in which mathematical questions and insights arise when prospective teachers work on teacher preparation course projects that have them exploring mathematics with students. In one example I shared how, when interviewing a 2nd Grader about her strategies for sharing cookies among different number of people, a prospective teacher found her student conjecturing that if the number of cookies was even, it could be shared evenly among people, and that if the number of cookies was odd, it could not. The young student concluded this after having shared several even numbers of cookies, such as sharing 30 cookies among 3 and then 5 people. In this situation the prospective teacher found herself in a position of exploring this student's conjecture by offering her several more examples to have the student test her conjecture and see whether or not it does or does not work for other cases.

In another example a prospective teacher had adapted a mathematics problem (Watson, 1988) we had explored in our university class to try it out with fifth graders in her field placement. This problem read:

> Three tired and hungry monsters went to sleep with a bag of cookies. One monster woke up and ate *1/3* of the cookies, then went back to sleep. Later a second monster woke up and ate *1/3* of the remaining cookies, then went back to sleep. Finally, the third monster woke up and ate *1/3* of the remaining cookies. When she was finished there were 8 cookies left. How many cookies were in the bag originally?

The prospective teacher chose to rescale the problem by changing the fractional number in the problem from *1/3* to **1/2**. By doing so, she made an interesting discovery, that is, that her students were able to arrive at the correct answer by using a restrictive solution method that in fact does not work for the original version of the problem. Students had approached the problem by multiplying the left over cookies by 2 (8x2x2x2), basically doubling the left over cookies three times. Yet, even though this method works for halves, it yields an incorrect answer for thirds, fourths, and any other fractional part. This unexpected outcome launched the prospective teacher into her own mathematical investigation into the reasons for how and why such a minor numerical change could alter the nature of the original problem (Crespo, 2000).

I have made similar and related arguments about mathematics as a practice that occurs and is learned everywhere not solely inside mathematics classrooms and most definitely not solely in coursework offered in mathematics departments. I recognize the history of why and how disciplinary knowledge broke off and was elevated from the everyday knowledge and practices and the privileges that this affords to those of us in the field of mathematics education. However, to me mathematics is a human practice that belongs to all of us not solely to mathematicians (Bishop, 1990). Hence throughout my career I have argued that it is especially important for prospective teachers to consider their teaching as a site for mathematical inquiry and for problem posing with their students and to find ways to explore the mathematics that students learn in their communities and in out of school contexts. I have continued to address the mathematics/education divide in multiple ways and especially as I have increasingly foregrounded educational equity within the curriculum and pedagogy of the mathematics education courses for future elementary and secondary mathematics teachers. If concerns and push back about "where is the mathematics?" or "how is this mathematics?" were raised with regards to learning mathematics through learning mathematics pedagogy, the push back to infusing educational equity in the teaching of mathematics has been even that more forceful.

The divide between mathematics and education continues to be reflected in the intellectual but also in the physical divide found on most University campuses. This divide contributes to the lack of coherence and continuity in the curriculum and pedagogy of teacher preparation (Feiman-Nemser, 2001). Mathematics courses are offered in mathematics departments, taught by instructors who do not address questions that concern educators. Education courses in turn are offered in colleges of education and are typically focused on educational issues without attending to specific content issues. The mathematics methods course is also influenced by this divide. Instructors of these courses often assume that teacher candidates have to "unlearn" oppressive approaches to the teaching and learning of mathematics that they have picked up in the math courses they have taken. The rift between mathematics educators who work in colleges of natural science and mathematics educators who work in colleges of education is very palpable at my current institution and I suspect across many other institutions as well.

As a mathematics educator who has colleagues in the college of natural science and in the college of education I am constantly challenged by both sides to see their perspective while neither side seems to see their own biases and entrenched ideologies. One side asks and insists on raising the question of "where is the math" whenever the conversation is focused on educational issues that transcend the narrow particulars of the discipline of mathematics as constructed and practiced by research mathematicians. I constantly hear the "where is the math" question raised in faculty

meetings, in students' comprehensive exams, in dissertations, and in colloquia. My education colleagues, on the other hand, ask and insist on raising questions about whether mathematics as a discipline can be trusted to embrace democratic ideals when so much of what is wrong and objectionable about today's public schooling can be attributed to the way mathematics is used to exclude and deny access to college to a large majority of non-white students, not to mention the oppressive ways in which mathematics continues to be taught and learned in schools.

To be clear, I consider the mathematics/education divide as dangerous because it shapes interactions among ourselves with colleagues on our campuses and members of various other communities. It instantiates the tendency to self-standardize and other-pathologize discussed earlier. It forcefully comes into play when faculty is engaged in doctoral admissions or discussing prospective colleagues who have or do not have a so called "strong" mathematical background or do not have a so called "substantial" classroom teaching experience. With each side digging their heels more deeply into their own camp they continue to reproduce their perspectives and pathologize the other. The danger lies in how this divide breeds toxic and deficit discourses within our own academic communities which not surprisingly is expressed outwardly through our research onto the very communities we are hoping to help (Shields, Bishop, & Mazawi, 2005). This intellectual divide becomes normalized and replicated in our teacher prepraration programs and travels to our partner schools. It undermines our goals to make mathematics a subject that many and more diverse groups of students engage with and enjoy, and a subject that supports the democratic values and ideals of public education. Not challenging this divide propagates the ideology that one field of study is more important than the other. It generates categories of students which are liberally applied to elementary prospective teachers and breeds the dominant narrative about elementary teacher candidates' "lack of knowledge" of mathematics. This issue speaks to the next divide — the expert/novice divide—which I discuss next.

The Expert/Novice Divide

Another divide always present in mathematics education is the categorization of experts and novices. I consider this to be another dangerous divide because the experts become the norm by which everyone else is judged and evaluated. It creates a hierarchy and a social reward system that promotes a rush to mastery which undermine and shortchanges the process of learning. Additionally, if the category of expert is associated with natural talent as it is often the case for mathematics and for teaching, gaining such expertise becomes unattainable for novices—let those be elementary age students or teacher candidates in undergraduate mathematics content or methods courses. Worse still, it suggests that only a few can ever be experts in the teaching and learning of mathematics.

In *Studying elementary preservice teachers' learning of mathematics teaching: Preliminary insights* (Crespo, Oslund, & Parks, 2007), I worked to conceptualize a study that explored how prospective teachers learn to enact the practices of posing, interpreting, and responding (PIR project) during teacher preparation courses and experiences (Crespo, 2006). In that PME-NA presentation I argued that prospective teachers were most likely learning mathematics teaching practices that had not yet been documented in the mathematics education literature because the dominant research frames and tools were focused on a very narrow set of desirable teaching practices. If the window for what constitutes an expert performance is narrowly defined, then the bulk of what can and will be observed would be classified as not meeting expert quality, and by default they become novice performances or worse considered as examples of not very good teaching.

In the 2007 PME-NA research presentation (and at a later PME-NA presentation in Crespo et al., 2009) I discussed how and why we decided to revise our initial assumptions about expert/novice enactments of teaching practice. As a member of another research project, the TNE project (Battista et al., 2007), I was able to use similar research tools in order to explore the relation between mathematics knowledge for teaching (MKT) and PIR practices (see Table 1). Working on both these

projects at the same time allowed me to see quite a few strange results that called into question assumptions about what experts and novices do/don't know and can/cannot do in their teaching of mathematics. Results from the TNE-Math surveys for example which were administered concurrently to prospective teachers at different stages in the program (studying math content and study math methods) had us looking at a number of very strange results such as a decline in mathematics knowledge for teaching (MKT) as prospective teachers transitioned from learning about content to learning about teaching practice.

Table 1: TNE and PIR teaching scenarios focused on two-digit subtraction

TNE Project – MKT Scenario	PIR Project – Teaching Practice Scenario
W1. *Imagine that one of your students shows you the following strategy for subtracting whole numbers.* $$\begin{array}{r} 37 \\ \underline{-19} \\ -\ 2 \\ \underline{20} \\ 18 \end{array}$$ **W1a**. *Do you think that this strategy will work for any two whole numbers?* Yes No I don't know **W1b.** *How do you think the student would use this strategy in the problem below?* $$\begin{array}{r} 423 \\ \underline{-167} \end{array}$$	**PIR2a.** Imagine you are teaching a lesson about two-digit subtraction and you ask the class to explore different ways to solve the following subtraction. The students look puzzled. What do you imagine <u>saying</u> and <u>doing</u> next? $$\begin{array}{r} 37 \\ \underline{-19} \end{array}$$ **PIR2b.** After giving students some time to work on the task you call on their attention and ask for volunteers to share their strategies. Imagine that one of the students shows the following strategy. What can you imagine <u>saying</u> and <u>doing</u>? Say a bit about what you would want to accomplish by saying and doing so. $$\begin{array}{r} 37 \\ \underline{-19} \\ -\ 2 \\ \underline{20} \\ 18 \end{array}$$

Another curious result was uncovered when the PIR team compared the prospective teachers' MKT and PIR responses to tasks such as those in Table 1. In his 2009 PME-NA presentation Brakoniecki (2009), then a graduate research assistant to both projects, reported on prospective teachers who had participated in both the TNE and PIR projects. He showcased three prospective teachers who had correctly addressed the MKT question about generalizing a student subtraction algorithm using negative numbers (see Table 2). All three teacher candidates showed that they could apply the alternative algorithm to a new example. However, their instructional responses to the PIR teaching scenario were all very different (see Table 2) and raised all sorts of questions for the PIR team about the relationship between MKT and PIR practices. So here we have three novices, Dean, Becky, and Lisa (all pseudonyms), who demonstrate that they can do the mathematics that is required to assess the validity and generalizability of an alternative computation algorithm that a student may offer in their classroom, but each of them responds quite differently to a hypothetical teaching scenario. Becky disapproves and does not seem to appreciate the value of this algorithm, Dean seems willing to accept students' algorithms as long as they can show and explain their work, and Lisa makes connections between the standard and alternative algorithms as she expresses her view that there are "more than one way to solve a problem."

Table 2: Three prospective teachers' responses to MKT task and PIR teaching scenario

Responses to MKT task	Dean Response to PIR task	Becky Response to PIR task	Lisa Response to PIR task
Correct Responses to TNE task $\begin{array}{r} 423 \\ -167 \\ \hline -4 \\ -40 \\ 300 \\ \hline 256 \end{array}$	I would ask the student to re-write the problem and show each step they took to get to their answer. I would want the students to learn the importance of showing their work and how they can use it to retrace their steps in a problem	I do not like this way – Math for higher on is going to be a lot harder if they learn this now.	This strategy can work. The student knows that we start in the ones column. 7-9= -2. The tens column is also correct, as 30-10=20. Now what the student did was combine -2 and 20, to get 18. We got the same answer. I would want to let the class know that there is more than one way to solve a problem, and it is important to remember that subtraction of multiple digit numbers involves multiple subtractions, depending on how many places are in the number.

So what is a mathematics educator to do with these prospective teachers' responses, classify them as high MKT but then low (Becky), medium (Dean), and high (Lisa) with respect to their instructional practice? What are we to do with prospective teachers like Becky in our teacher preparation courses? Fail them and tell them they are not qualified to teach students? We seem to be willing to do so when they do not know the mathematics and not so willing to take such a stance when they do not know teaching practice. These initial insights made it clear to us that without reframing our assumptions about expert and novice performances of PIR practices we would continue to recreate and reinforce the same type of instruments and make the same kinds of claims about prospective elementary teachers. This would mean and we would continue to propagate the circular and dead-end deficit discourse about students and their teachers (Comber & Kamler, 2004). In Crespo, Oslund, and Parks (2007) we shared our revised definitions which then led us to design new kinds of teaching scenario instruments, ones that invited teacher candidates to provide multiple not just one response to the teaching scenarios, and ones that invited a more dialogical representation of their practice (see Crespo, Oslund, & Parks, 2011).

In the PIR project we were then able to document more of prospective teachers' strengths (could do and were able to do) than deficits. More importantly, it led us to propose another type of teaching scenario tasks that positioned prospective teachers as creators (not just as reproducers) of teaching practice. In this new type of teaching scenario prompt prospective teachers represented a whole class mathematical discussion in the form of a classroom dialogue. I argue that these kinds of dialogical scenarios elicit different kinds of representations from prospective teachers that make visible more of the complex and nuanced ways in which they imagine mathematics teaching practice. Unlike much of the research on prospective and practicing teachers of elementary school mathematics, my PIR project documented many ways in which prospective teachers take up the student-centered and equity-oriented pedagogies they are studying during teacher preparation. I argued that by researching

dialogical representations of mathematics teaching researchers and teacher educators can learn more about how prospective teachers transform what they are studying in teacher preparation courses into purposeful and principled teaching actions. This new insight would not have been possible without challenging and questioning the expert/novice divide that is so engrained within mathematics education's research/teaching practices, which is another divide I discuss next.

The Research/Teaching Divide

The research/teaching divide has been in the education research landscape for a long time as educational research was initially conceived as research **on** teaching and not **with** or **by** teachers. The animosity and distrust between teachers and researchers in the past and still in the present is reminiscent of Snow's (1959) characterization of the two cultures and it can be related to the longstanding divide between the theoretical and the practical. Researchers characterize teaching as resisting change and teachers characterize educational research as irrelevant to their problems of practice. The research/teaching divide became even more heated when some educational researchers proposed the notion of the teacher as researcher, which raised all sorts of debates, push back, and controversy (Cochran-Smith & Lyttle, 1990; 1999). As someone who studies her own teaching practice and who collaborates with teachers and students in the research process I have had to negotiate this divide and address questions about whether my scholarship counts as research or whether my research has made any impact in the everyday practice of teachers. These are questions rooted in the process of self-standardizing and other-pathologizing that I alluded to earlier. The tendency to vilify other perspectives rather than embrace the diversity in our field is very much alive and well in our own academic backyards.

The research/teaching divide has always puzzled me. As a teacher I have always considered myself a researcher of the mathematics I was teaching and of my students' learning, simply stated I considered myself a student of my students' mathematical thinking and learning. Therefore, I find the divide between education practitioners and researchers to be unhelpful and unnecessarily elitist. As a doctoral student I wrote a comprehensive exam paper titled *"What does research got to do with teaching?"* where I explored the contentious relationship between research and teaching and argued that the two had more things alike than things that were different. To me learning, teaching and researching are similar practices rooted in people's desire to inquire and understand what they do not know. Hence, research is no more than another learning practice that has been uprooted from the everyday practices of people and their communities (this is a similar point to the one I made earlier in relation to the mathematics and education divide).

As a researcher interested in educational experiences that are empowering and transformational for students and their teachers I see the boundary between teaching and researching as an unproductive divide. In my work, teaching involves research and research involves teaching, the two are deeply intertwined. In *Getting smarter together about complex instruction in the mathematics classroom* (Crespo 2013), I describe an example in my scholarship where research and teaching seamlessly collaborate to advance the goal of promoting equity in the mathematics classroom. Complex instruction (CI) is a collaborative teaching method that addresses inequitable teaching and learning. Applying the theory of status generalization to classroom interactions Elizabeth Cohen (1994) interpreted students' unequal participation in the classroom as a problem of unequal status. Unequal status breeds competitive behavior which in turn undermine everyone's learning. Status issues are rooted in societal expectations of competence for students who fit and do not fit the dominant culture's views about who is and not intellectually capable. In the mathematics classroom status issues come into play when students from non-dominant groups participate (or not) in learning activities. Rather than seeing students who under participate in the classroom as either disengaged or unmotivated, Cohen (1994) saw these students as systematically excluded from learning

opportunities not only by their teacher but also their peers, but more importantly by the classroom structures which endorsed rather than disrupt competitive forms of interactions among students.

But complex instruction seeks to not only understand unequal participation in the classroom, it seeks to engineer instructional structures and practices that could disrupt unequal peer interactions in the classroom and to promote a more collaborative learning environment. Rather than setting up the classroom as a competitive space for learning where some students rise to the top and some sink to the bottom, complex instruction sets up the classroom for collaboration and as a place where everyone is expected to succeed and to contribute to a greater understanding than it would be possible by one person alone. In a complex instruction classroom, no one is seen as more or less smart. Instead everyone's capacities, abilities, and experiences are acknowledged, valued, and nurtured as resources in the classroom.

Consistent with CI's theory about collaborative participatory learning —that no one is as smart as all of us together—my complex instruction colleagues and I have engaged in this work in ways that require and value each other's perspectives. We realize that simply talking about these issues and becoming aware of them is not enough. This work entails inviting practicing and prospective teachers to work with us on these ideas in the context of learning about lesson studies, which is unsurprisingly also a collaborative approach to teachers' professional learning. We design together complex instruction math lessons and investigate together questions about students' access, participation, and learning in collaborative mathematics lessons (see Crespo & Featherstone, 2012; and Featherstone et al., 2011). This has created a collaborative network of researchers and practitioners with a common goal and who share teaching and research insights across institutional settings using all sorts of communication outlets including social media, teacher blogs, research and practitioner journal articles, book chapters and books, workshops, talleres, and community forums.

En La Lucha/In the Struggle—Mathematics Educators Sin Fronteras

Returning now to the theme of this conference "Sin Fronteras/Without Borders" and how it might be possible to value and embrace diversity of perspectives in light of the issues I have raised here about the intellectual divides we manage to erect in the process of rationalizing and justifying our work as mathematics educators. Here I conclude with two approaches I have taken to counter my own tendency to self-standardize and other-pathologize by pursuing instead a more reflexive and collaborative mathematics education scholarship. A reflexive approach to mathematics education entails holding the mirror back to ourselves to identify ways in which we are complicit in the very things we criticize and seek to change. A reflexive researcher bluntly asks themselves whether their research is making things better or worse (Kleinsasser, 2010). In this case, consider how it is that we create intellectual divides with our own scholarship and practices. As I consider, for example, the extent to which my research reflects my commitments to anti-oppressive mathematics education, I have to wonder how to best represent these commitments through my research methods and practices, and whether my choices and approaches are making things better or worse.

For example, one important commitment I made early on in my career was to write and speak in ways that are accessible, inviting, and free of academic jargon inasmuch as that is possible. This was partially rooted in my own experiences as a non-native speaker of English and the challenges of reading academic papers in a non-native language. Also as a teacher of mathematics I worked hard to demystify the aura of super human intellect that is associated with the very compressed shorthand of mathematical symbolism that keeps so many students in the dark and excluded from using and conversing in mathematics. More importantly, I am continually reminded to question my motives and my hopes for the educational research I choose to pursue by the words of Elliot (1989) one of the authors I read in grad school.

Rather than playing the role of theoretical handmaiden of practitioners by helping them clarify, test, develop, and disseminate the ideas which underpin their practices, academics tend to behave like terrorists. We take an idea which underpins teachers' practices, distort it through translation into academic jargon, and thereby "highjack" it from its practical context and the web of interlocking ideas which operate in that context. (Elliot, 1989; p. 7)

Yet as I hold on to this commitment I also consider the critiques other scholars raise about taking what seems to be a reductionist and simplistic route to explaining complex educational issues. In their view, such an approach to scholarship feeds into rather than challenge the distrust people have of academics and anything that sounds too intellectual or overly complex whether those ideas come from science or the humanities (e.g., Davis et al., 2014). I also understand that our words are critical and that how we name and talk about people, communities, and students matter and shape our thinking and practices. Therefore, I also participate in discussions that seek to clarify, object, and subvert particular terms and language commonly used in research and in practice, especially language that is offensive and degrading to the very students and communities that need us the most.

The point here is that I have come to accept that there is inherent tension and contradictions within the work we do as researchers in mathematics education and appreciate Elbow's (1983; 2000) notion of embracing contraries as a way to see beyond our tendency to polarize and take sides without fully understanding and considering opposing views. Sfard's (1998) discussion of two metaphors for learning (as acquisition and participation) also takes a similar stance about opposing and contradictory perspectives. I have tried out Elbow's ideas in a recent editorial (Crespo, 2016a) for the *Mathematics Teacher Educator* journal which I am currently serving as editor to promote a more educative rather than adversarial approach to reviewing manuscript submissions to the journal. I also explored Elbow's embracing of contraries in a recent publication (Crespo, 2016b) focusing on the challenge to disrupt our tendency to polarize mathematics teaching practice when selecting and using video representations of mathematics teaching. This is an issue that the National Council of Teachers of Mathematics (NCTM) Research Committee (2016) recently discussed and identified as a pernicious storyline that circulate and influence the public perception about mathematics education.

Collaborative research is another way in which I have chosen to pursue research in mathematics education. This is one approach that discourages me from building intellectual divides. I have come to the point of realizing that educational problems are much too big for any one of us to take on and solve by ourselves and that it will take literally a whole village of committed mathematics educators to make the kinds of changes we are all striving to make. All this within a world of higher education and academia that is driven by competitive policies and reward systems. Although this can create hostile working environments for faculty, it is worth investing in developing collaborative networks with colleagues. Operating under the tenants of complex instruction that together we can learn more than individually, and that each collaborator needs to be willing to learn from each other's perspectives, I continually renew my belief and commitment in collaborative mathematics education research. And as I alluded to earlier, my work is only possible by collaborating with colleagues from all walks of life that are committed to social change.

In addition to the example I offered earlier with my complex instruction colleagues with whom I wrote the book *"Smarter Together,"* (Featherstone et al., 2011) I have also collaborated with another network of educators committed to identifying and challenging oppressive forms of mathematics education research and to making our field more inclusive of diverse perspectives and practices (see Herbel-Eisenmann et al., 2013). Another more recent collaboration is a book of cases for mathematics teacher educators (White, Crespo, & Civil, 2016) which includes a collection of 19 cases from different authors highlighting dilemmas they experienced while teaching about inequities in mathematics education in the contexts of content and methods courses and professional development contexts. Each case includes commentaries from three different authors. Altogether the

perspectives of over 80 mathematics educators are included in this book. The conversations that we have had and that will continue to have around these cases are very exciting to me and gives me hope that together we can and will make a difference in shaping the future of mathematics education research. I am also hopeful that the future generation of mathematics educators will engage with diverse perspectives by embracing contraries, said another way, by building bridges rather than walls.

EXAMINING INDIVIDUAL AND COLLECTIVE LEVEL MATHEMATICAL PROGRESS

Chris Rasmussen
San Diego State University
crasmussen@mail.sdsu.edu

A challenge in mathematics education research is to coordinate different analyses to develop a more comprehensive account of teaching and learning. I contribute to these efforts by expanding the constructs in Cobb and Yackel's (1996) interpretive framework that allow for coordinating social and individual perspectives. This expansion involves four different constructs: disciplinary practices, classroom mathematical practices, individual participation in mathematical activity, and mathematical conceptions that individuals bring to bear in their mathematical work. I illustrate these four constructs for making sense of students' mathematical progress using data from an undergraduate mathematics course in differential equations.

Un reto en la investigación en educación matemática es la coordinación de diferentes análisis para desarrollar una descripción más amplia de la enseñanza y el aprendizaje. Contribuyo a estos esfuerzos mediante la ampliación de los constructos del marco interpretativo de Cobb y Yackel (1996), los cuales permiten la coordinación de las perspectivas social e individual. Esta ampliación involucra cuatro constructos diferentes: las prácticas disciplinares, las prácticas matemáticas del aula, la participación individual en la actividad matemática y las concepciones matemáticas que las personas utilizan en su trabajo matemático. Ejemplifico estos cuatro constructos para dar sentido al progreso matemático de los estudiantes con datos de un curso universitario de ecuaciones diferenciales.

Keywords: Research Methods, Classroom Discourse, Cognition

Recent work in mathematics education research has sought to integrate different theoretical perspectives to develop a more comprehensive account of teaching and learning (Bikner-Ahsbahs & Prediger, 2014; Cobb, 2007; Hershkowitz, Tabach, Rasmussen, & Dreyfus, 2014; Prediger, Bikner-Ahsbahs, & Arzarello, 2008; Rasmussen, Wawro, & Zandieh, 2015; Saxe et al., 2009). An early effort at integrating different theoretical perspectives is Cobb and Yackel's (1996) emergent perspective and accompanying interpretive framework. In this paper I expand the interpretive framework for coordinating social and individual perspectives by offering a set of constructs to examine the mathematical progress of both the collective and the individual. I illustrate these constructs by conducting four parallel analyses and make initial steps toward coordinating across the analyses.

The emergent perspective is a version of social constructivism that coordinates the individual cognitive perspective of constructivism (von Glasersfeld, 1995) and the sociocultural perspective based on symbolic interactionism (Blumer, 1969). A primary assumption from this point of view is that mathematical development is a process of active individual construction and a process of mathematical enculturation (Cobb & Yackel, 1996). The interpretive framework, shown in Figure 1, lays out the constructs in the emergent perspective. The significance of accounting for both individual and collective activity is highlighted by Saxe (2002), who points out that, "individual and collective activities are reciprocally related. Individual activities are constitutive of collective practices. At the same time, the joint activity of the collective gives shape and purpose to individuals' goal-directed activities" (p. 276-277).

My and my colleagues' prior work with the interpretative framework (e.g., Rasmussen, Zandieh, & Wawro, 2009; Stephan & Rasmussen, 2002; Yackel, Rasmussen, & King, 2000) has raised our awareness of the opportunity (and occasional need) to extend the constructs in the interpretative

framework. In particular, in Rasmussen, Wawro, and Zandieh (2015), we expand the ways to analyze individual and collective mathematical progress. We use the phrase "mathematical progress" instead of "learning" as an umbrella term that admits analyses of collective mathematical development and individual meanings and activity. That is, while it might make sense to speak of individual student learning, it makes less sense to speak of collective learning because this incorrectly implies a deterministic, one size fits all approach. The phrase mathematical progress, on the other hand, offers a way to address both the collective and the individual without suggesting a deterministic stance toward the collective.

Social Perspective	Individual Perspective
Classroom social norms	Beliefs about own role, others' roles, and the general nature of mathematical activity
Sociomathematical norms	Mathematical beliefs and values
Classroom mathematical practices	Mathematical conceptions and activity

Figure 1. The interpretive framework**.**

On the bottom left hand side of the interpretive framework (Figure 1), the construct of classroom mathematical practices is a way to conceptualize the collective mathematical progress of the local classroom community. In particular, such an analysis answers the question: What are the normative ways of reasoning that emerge in a particular classroom? Such normative ways of reasoning are said to be reflexively related to individual students' mathematical conceptions and activity. In prior work that has used the interpretive framework, individual conceptions and activity has been treated as a single construct that frames the ways that individual students participate in classroom mathematical practices (e.g., Bowers, Cobb, & McClain, 1999; Cobb, 1999; Stephan, Cobb, & Gravemeijer, 2003). Such a framing of the individual is, in our view, compatible with what Sfard (1998) refers to as the "participation metaphor" for learning.

In an effort to be more inclusive of a cognitive framing that would posit particular ways that students think about an idea, Rasmussen, Wawro, & Zandieh (2015) split the bottom right hand cell into two constructs, one for individual participation in mathematical activity and one for mathematical conceptions that individual students bring to bear in their mathematical work. With these two constructs for individual progress one now can ask the following two questions: How do individual students contribute to mathematical progress that occurs across small group and whole class settings? And what mathematical meanings do individual students develop and bring to bear in their mathematical work?

Work at the undergraduate level has also highlighted the fact that, in comparison to K-12 students, university mathematics and science majors are more intensely and explicitly participating in the discipline of mathematics. However, the notion of a classroom mathematical practice was never intended to capture the ways in which the emergent, normative ways of reasoning relate to various disciplinary practices (Stephan & Cobb, 2003). In order to more fully account for what often occurs at the undergraduate level, we expand the interpretive framework to explicate how the classroom collective activity reflects and constitutes more general disciplinary practices. Thus there is an additional cell to the bottom left row of the interpretive framework, disciplinary practices. One can now answer the following two questions about collective mathematical progress: What is the mathematical progress of the classroom community in terms of the disciplinary practices of mathematics? And what are the normative ways of reasoning that emerge in a particular classroom?

To summarize, Figure 2 shows the expansion of the bottom row of the interpretive framework, which now entails four different constructs: disciplinary practices, classroom mathematical practices, individual participation in mathematical activity, and mathematical meanings.

Social Perspective		Individual Perspective	
Classroom social norms		Beliefs about own role, others' roles, and the general nature of mathematical activity	
Sociomathematical norms		Mathematical beliefs and values	
Disciplinary practices	Classroom mathematical practices	Participation in mathematical activity	Mathematical meanings

Figure 2. Expanded interpretive framework.

The left hand side of the bottom row comprises two different constructs for examining the mathematical progress of the classroom community, while the right hand side comprises two different constructs for examining the mathematical progress of individuals. The contribution that this expansion makes is in providing researchers with a more comprehensive means of bringing together analyses from social and individual perspectives. In particular, the expanded interpretive framework enables a researcher to answer the questions listed in Figure 3.

Disciplinary practices	Classroom mathematical practices	Participation in mathematical activity	Mathematical meanings
What is the collective mathematical progress in terms of the disciplinary practices?	What are the normative ways of reasoning that emerge in a particular classroom?	How do individual students contribute to the collective mathematical progress?	What meanings do individual students develop and bring to bear in their work?

Figure 3. Four constructs for analyzing mathematical progress and respective research questions.

Theoretical and Methodological Background

Classroom mathematical practices

Classroom mathematical practices refer to the normative ways of reasoning that emerge as learners solve problems, explain their thinking, represent their ideas, etc. By normative I mean that there is empirical evidence that an idea or way of reasoning functions as if it is a mathematical truth in the classroom. This means that particular ideas or ways of reasoning are functioning in classroom discourse as if everyone has similar understandings, even though individual differences in understanding may exist. The empirical evidence needed to document normative ways of reasoning is garnered using the approach developed by Rasmussen and Stephan (2008) and furthered by Cole et al. (2012). This approach, which we refer to as the documenting collective activity method, applies Toulmin's (1958) argumentation scheme to document the mathematical progress using three well-developed criteria, all of which involve tracing over time how ideas are used by students. In brief, central to Toulmin's scheme is the core of an argument, which consists of a Claim, Data to support that Claim, and a Warrant that explains the relevance of the Data to the Claim.

Disciplinary practices

Disciplinary practices refer to the ways in which mathematicians typically go about their professional practice. The following disciplinary practices are among those core to the activity of professional mathematicians: defining, algorithmatizing, symbolizing, and theoremizing (Rasmussen, Zandieh, King, & Teppo, 2005). Not all classroom mathematical practices are easily or sensibly characterized in terms of a disciplinary practice. This is because classroom mathematical practices capture the emergent and potentially idiosyncratic collective mathematical progress, whereas a

disciplinary practice analysis seeks to analyze collective progress as reflecting and embodying core disciplinary practices. In this report I focus on algorithmatizing, the practice of creating and using algorithms. Our method for documenting disciplinary practices builds on prior work that has examined theoremizing, symbolizing, and defining (Rasmussen, Zandieh, King, & Teppo, 2005; Rasmussen, Wawro, & Zandieh, 2015; Zandieh & Rasmussen, 2010).

Mathematical meanings

As students solve problems, explain their thinking, represent their ideas, and make sense of others' ideas, they necessarily bring forth various meanings of the ideas being discussed and potentially modify these meanings (Thompson, 2013). Our analysis of individual student meanings makes use of analyses from prior work that have characterized different ways that students think about the relevant mathematical ideas (e.g., Carlson, Jacobs, Coe, Larsen, & Hu, 2002; Habre, 2000; Harel & Dubinsky, 1992; Thompson, 1994; Trigueros, 2001; Rasmussen, 2001; Zandieh, 2000).

Participation in mathematical activity

This analysis draws on recent work by Krummheuer (2007, 2011), who characterizes individual learning as participation within a mathematics classroom using the constructs of production roles and recipient roles. In the production framing, individual speakers take on various roles, which are dependent on the originality of the content and form of the utterance. The title of author is given when a speaker is responsible for both the content and formulation of an utterance. The title of relayer is assigned when a speaker is not responsible for the originality of either the content nor the formulation of an utterance. A ghostee takes part of the content of a previous utterance and attempts to express a new idea, and a spokesman is one who attempts to express the content of a previous utterance in his/her own words. Within the recipient framing of learning-as-participation, Krummheuer (2011) defines four roles: conversation partner, co-hearer, over-hearer, and eavesdropper. A conversation partner is the listener to whom the speaker seems to allocate the subsequent talking turn. Listeners who are also directly addressed but do not seem to be treated as the next speaker are called co-hearers. Those who seem tolerated by the speaker but do not participate in the conversation are over-hearers, and listeners deliberately excluded by the speaker from conversation are eavesdroppers.

Setting and Participants

I illustrate the four constructs and address the respective research questions from Figure 3 using data from a semester-long classroom teaching experiment (Cobb, 2000) in differential equations conducted at a medium sized public university in the Midwestern United States. I selected a 10-minute small group episode from the second day of class based on its potential to illustrate all four constructs. There were four students in this group, Liz, Deb, Jeff, and Joe (all names are pseudonyms).

There were 29 students in the class. Class met four days per week for 50-minute class sessions for a total of 15 weeks. The classroom had movable small desks that allowed for both lecture and small group work. The classroom teaching experiment was part of a larger design based research project that explored ways of building on students' current ways of reasoning to develop more formal and conventional ways of reasoning (Rasmussen & Kwon, 2007). A goal of the project was to explore the adaptation of the instructional design theory of Realistic Mathematics Education (RME) to the undergraduate level. Central to RME is the design of instructional sequences that challenge learners to organize key subject matter at one level to produce new understanding at a higher level (Freudenthal, 1991). In this process, graphs, algorithms, and definitions become useful tools when students build them from the bottom up through a process of suitably guided reinvention (e.g., Rasmussen & Blumenfeld, 2007; Rasmussen & Marrongelle, 2006; Rasmussen, Zandieh, King, &

Teppo, 2005).

Results and Discussion

As previously stated, the analysis comes from video recorded work of a small group of four students, Liz, Deb, Jeff, and Joe, on the second day of class. Just prior to the small group work students completed the following task: The previous problem dealt with a complex situation with two interacting species. To develop the ideas and tools that we will need to further analyze complex situations like these, we will simplify the situation by making the following assumptions:

- There is only one species
- The species have been in the lake for some time before what we are calling time t = 0
- The resources (food, land, water, etc.) are unlimited
- The species reproduces continuously

Given these assumptions for a certain lake with fish, sketch three different population versus time graphs (one starting at P = 10, one starting at P = 20, and the third starting at P = 30).

This task was relatively straightforward for students and brought forth an imagery of exponential growth and the graphs they sketched were consistent with this imagery. The instructor then used their graphs as an opportunity to introduce the rate of change equation $dP/dt = 3P$ as a differential equation that was consistent with their graphs. In particular, as P values increase, so does the slope of the graph of P vs. t.

The follow up task, which students worked on for approximately 10 minutes, however, was much more cognitively demanding for students.

Consider the following rate of change equation, where P(t) is the number of rabbits at time t (in years): dP/dt = 3P(t) or in shorthand notation dP/dt = 3P. Suppose that at time t = 0 we have 10 rabbits (think of this as scaled, so we might actually have 1000 or 10,000 rabbits). Figure out a way to use this rate of change equation to approximate the future number of rabbits.

At t = 0.5 and t = 1.
At t = 0.25, t = 0.5, t = 0.75, and t = 1

Be prepared to share the reasoning behind your approach with the rest of the class. Organize your results in tabular and graphical form.

Recall that this is only the second day of class and students have not been introduced to any analytical, numerical, or graphical techniques for analyzing differential equations. In a related analysis, Tabach, Rasmussen, Hershkowitz, and Dreyfus (2015) provide the following a priori analysis of the knowledge elements that we expect students to construct when solving this task:

- Csy – establishing connection between P and dP/dt (if you know P you can find dP/dt)
- Cpit – population iteration (given P and dP/dt at a moment in time allows one to find P at a later time)
- Crit – rate of change iteration (applying Csy at that later time one can find the corresponding dP/dt)
- Cit – Cpit and Crit can be combined into a repeating loop.

To illustrate how these knowledge elements play out in student discourse, consider the following except from Liz which occurred near the end of the 10-minute small group work:

> *Liz*: What I understand is that we found our rate of change initially at time zero and that we are using that to find out what our population is after half a year. If we are expected to grow by 30 rabbits in a year then, in a half a year we grow by 15 rabbits. So we'll have 15, I mean 25 because 15 plus 10 is 25. Then you start over again, so it's kind of like our new initial population. We could label it time equals zero if we wanted to.

An example of Csy occurs when Liz says, "grow by 30 rabbits in a year" because in order to get the value of 30, Liz had to use the initial population value of 10, plug this into the rate of change equation to get 30. Cpit is illustrated by Liz when she says, "in a half year we grow by 15 rabbits. So we'll have 15, I mean 25 because 15 plus 10 is 25." That is, she uses what she knows about the population at the initial time and her knowledge of dP/dt at the initial time to compute how many rabbits there will be half a year later. Finally, when Liz says, "The you start all over again," she demonstrates an understanding that Cpit and Crit can be combined into a repeating loop to compute the population after another half year.

As a reminder, the primary research goal here is to demonstrate an approach for coordinating collective and individual analyses to gain greater explanatory and descriptive power, with the intention to better understand the individual and collective meaning making processes. I will therefore begin with analyzing the collective small group mathematical progress using the previously mentioned documenting collective activity method.

Small group collective mathematical progress

Using the documenting collective activity method I identified the following three ideas that functioned as if shared in this particular small group: dP/dt can be determined from P values (Csy), a value for dP/dt refers to the amount of change over 1 year, Cpit and Crit can be combined into a repeating loop. All three of these findings made use of the second criteria, namely that what was originally a Claim in one argument later functions as Data in a subsequent argument (Rasmussen & Stephan, 2008). In other words, an idea that initially required some form of justification is later used a means to justify new claims. Figure 4 shows the Toulmin analysis for first argument and Figure 5 shows the Toulmin analysis for the fifth argument made in this particular small group.

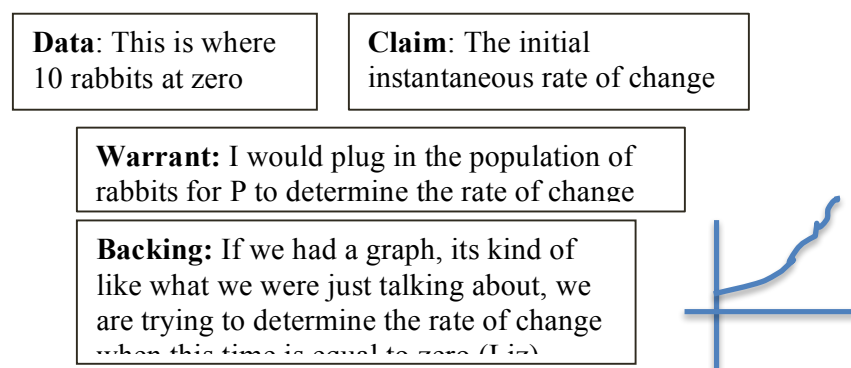

Figure 4. Toulmin analysis for Argument 1.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Data: We have the 30. Three times ten would give us our rate of change. Say 0.5 years	**Claim**: which will give us what, the new amount of rabbits plus the old amount

| **Warrant:** Warrant: This is our rate of change. Then we'll take that 0.5 times the rate of change (Deb) |
|---|

Figure 5. Toulmin analysis for Arguments 5.

We see here in the first argument that Liz makes the Claim that the initial instantaneous rate of change is 30 (note that this is Csy) and then in the fifth argument Deb uses as a fact that the initial rate of change is 30 as Data to support a new claim. Thus per the second criteria it is concluded that one can determine dP/dt from P values functions as if shared in this small group. Full consideration of the data indicate that Liz, Deb, and Jeff (but not Joe) made individual progress compatible with the collective mathematical progress. That is, when a researcher determines that an idea functions as if shared, it does not mean that everyone shares exactly the same way of thinking.

I next step back from the specifics of the Toulmin analysis across the 10-minute episode to highlight overall trends in the discourse. In terms of talk turns, Liz spoke 26 times, Deb spoke 18 times, Jeff 13 times, and Joe 8 times. Thus Liz and Deb were the primary contributors, with Jeff often highlighting a final answer. Overall there were 14 different arguments (à la Toulmin) that consisted of at least Data and Claim. The following table shows the distribution of contributions (some contributions co-constructed).

Table 1: Toulmin argument contributions by student

	Liz	Deb	Jeff	Joe
Data	6	5	1	4
Claim	5	5	5	2
Warrant	2	5	1	0
Backing	2	1	0	0

In light of the collective small group mathematical progress, I next begin to address the following coordination questions: What meanings for dP/dt emerged and who expressed these meanings? What part did these meanings play in the collective mathematical progress? What roles did Liz, Deb, Joe, and Jeff play in all of this? In what ways did students' mathematical work reflect disciplinary practices?

Engaging different meanings for dP/dt

Across the 10-minute episode I identified seven different meanings for dP/dt used by one or more of the fours students. These seven meanings and who within the 10-minute episode engaged these meanings are: as steepness (Liz), ratio (Liz and Jeff), population length (Liz and Deb), tool (Liz), function (Deb), proportion (Deb), and fraction (Jeff). Thus, not only did Liz and Deb have more talk turns, they also engaged more and different meanings for dP/dt compared to Jeff and Joe. I next illustrate how students engaged these meanings, but due to space constraints a complete detailing is not possible.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

17 Liz: So if we have that [initial rate of change is 30], the question is how can we use that to help us figure out the population after a half unit elapsed?

22 Deb: You said the population is 10 right [Liz: Um hmm]. So three times ten would give us our rate of change. Say 0.5 years passes, this is our rate of change. Then we'll take that 0.5 times the rate of change which will give us what [slight pause looks up to Jeff and Joe], the new amount of rabbits plus the old amount of rabbits.

In line 17 we see Liz wonder out loud how knowing that 30 is the initial rate of change can be used to achieve their goal of determining the population a half year later. That is, Liz would like to somehow engage rate of change as a tool to do work for them. Shortly thereafter Deb takes Liz up on how they might use rate of change as a tool and suggests that they could take the 30 and multiply it by 0.5. It is not entirely clear the meaning that Deb is making use of here, but one possibility is that she is engaging in a form of proportional reasoning. Continuing their discussion, we see an important conceptual advance.

25 Liz: So the old amount of rabbits is 10.

26 Deb: Am I making sense?

27 Jeff: I think so, so that would be 25, is that what you're saying?

28: Liz: Okay I think I get what you're saying. Ok, so like we're at time zero and we have 10 rabbits, and supposedly the rate of change, well not supposedly, we're saying that the rate of change is 30 [Jeff: yeah for the] at time zero. So its going to grow at a rate of, I don't know if I'm going to say this right, at 30 rabbits per year? [looks up at Deb]

In line 27 we see Jeff contributing to the discussion by highlighting final computations. Thus, while Jeff is not necessarily leading the intellectual work, he is following along and adding to the discussion. Then in line 28 we see Liz make an interpretation for 30, the initial rate of change, that later serves her and her group well. In particular, she interprets 30 as the amount of rabbits that will accrue over a one year time increment. I refer to such a meaning as a "population length." This is similar to how Thompson documented early meanings of rate as a "speed length" where a student thinks of say, 60 mph, as going 60 miles in one hour. Deb next picks up on what Liz says and then in line 32 Liz returns to how one might use rate of change as a tool for figuring out the number of rabbits a half year later.

29 Deb: Right. [Liz: Ok] So we'll have 30 more rabbits.

32 Liz: And so we're really not figuring out the rate of change we figuring…Well this is the rate of change and we're using the rate of change to figure out the number of rabbits we are going to increase by in half a year.

As the students continue, we see Deb leading the intellectual work of figuring out how to use the 30 to achieve their goal.

38 Deb: This is what I did. First I looked at the fact that this is a rate of change equation. So this is telling me how many rabbits are being produced every year. So If I know 3 times the original population is produced every year, then I have 3 times 10 is produced every year. But I want to know how many is produced in 0.5 years. So I know how many rabbits are produced per year, so if I multiply that by 0.5 then I'll know how many more rabbits have been produced. So I take that new number that I get and add it to the old population.

43 Jeff: I think you can go dp/dt=30, actually your dt will be 0.5, and then you add that to the old and then you do it again for the next one.

In line 38 Deb expresses three different meanings for rate of change. She starts off by saying that the rate of change equation tells one how many rabbits are produced every year. This is similar to a

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

function meaning for rate of change and relates closely to Csy. Given an input you get an output. And the meaning of the output in this case is a population length ("so I know how many rabbits are produced per year"). Deb then engages in some proportional reasoning to determine how many more rabbits there will be in a half year. In line 43 Jeff shows that he is following the discussion and seems to treat dP/dt as a fraction. Soon thereafter Liz recapitulates their line of reasoning as follows, engaging both meaning of rate of change as population length and rate of change as proportion.

> *48 Liz*: Okay, so basically, I get you up into the point where you say you want to put in, what I understand is that we found our rate of change initially at time zero and I understand using that to find out what our population is after half a year. If we are expected to grow by 30 rabbits in a year then, in a half a year we grow by 15 rabbits. So we'll have 15

I now turn to reflecting on the roles these various meanings played in the collective mathematical progress. As we saw, there is a shift in the meaning of dP/dt - from steepness to a "population length" (clearly for Liz and likely for Deb). This shift coincided with "a value for dP/dt refers to the amount of change over 1 year" functioning as if shared AND the initial articulation of how to find the estimate for the population at t = 0.5. In relation to other work, the principle of a form-function-shift (Saxe, 2002) of notations in use is particularly suitable for analyzing the interplay between tool use (in this case dP/dt = 3P) and conceptual development. In particular, the form-function-shift describes the interplay between cultural forms (external representations) and the meanings that develop for structuring and accomplishing specific goals, not unlike what we saw happening with the individual meaning and collective production of meaning.

What roles did Liz, Deb, Jeff, and Joe play in the collective mathematical progress?

Drawing on Krummheuer (2007, 2011), I characterize student participation in the collective mathematical progress in terms of production roles (author, relayer, ghostee, spokesman) and recipient roles (conversation partner, co-hearer, overhearer, eavesdropper). Previously I specified the number of talk turns for each student: Liz 26; Deb 18; Jeff 13; Joe 8. The raw count of co-author shows that there was fairly even distribution (Liz 6/14; Deb 5/14; Jeff 6/14; Joe 4/14). However, a more nuanced look however reveals important differences: Joe offered 2 incorrect arguments, Jeff often revoiced (with and without reformulation), Liz and Deb did the main intellectual lifting (as was evident in the excerpts). For example, Liz was primary author (core of argument) for Csy and as Spokesman for meaning of dP/dt as population length. Deb, on the other hand, was the primary author for Cit The following excerpt provides a snapshot illustration of how the entire 10-minute episode was coded.

> *26 Deb*: [articulates the main iteration idea but without a numerical result – omitted here for space considerations] Am I making sense?
> *27 Jeff*: I think so, so that would be 25, is that what you're saying?
> *28: Liz*: Okay I think I get what you're saying. Ok, so like we're at time zero and we have 10 rabbits, and supposedly the rate of change, well not supposedly, we're saying that the rate of change is 30 [Jeff: yeah for the] at time zero. So its going to grow at a rate of, I don't know if I'm going to say this right, at 30 rabbits per year? [looks up at Deb]

In line 25 Jeff functions as a relayer as he was not responsible for either the content or the formulation of the idea. In line 28 we see Liz function as spokesman for this is the first time anyone has engaged the meaning of rate of change as population length. As such Liz is responsible for both the content and the formulation.

Regarding recipient design roles, Liz, Deb, and Jeff were for the most part conversation partners and co-hearers. Joe was mostly a co-hearer and at times an over-hearer. While the constructs of production and recipient roles were useful in distinguishing individual differences, I found them to be

insufficient to account for the different ways these four students participated in mathematical discourse. In particular, my analysis suggested a third role – that of facilitator roles. More specifically, I identified four different ways in which these students facilitated the flow of ideas in their small group. These four roles are:

- Focuser is assigned when a speaker directs attention to a particular mathematical issue
- Elicitor is given when a speaker attempts to bring out another's idea
- Checker is one who seeks agreement or sensibility of an utterance
- Summarizer pulls ideas together

For example, consider the following excerpts:

17 Liz: So if we have that [initial rate of change is 30], the question is how can we use that to help us figure out the population after a half unit elapsed? [32 sec pause, everyone looking down at their papers and making marks]
18 Jeff: So I was just going to say how would we work time into the equation to get the next, uh, population or change in population?
40 Liz: Yeah I get it, do you guys get what Deb is saying?
41 Jeff: Yeah you get 25 and then you get 55.
46 Liz: And the reason for putting in the new population would be what?
48 Liz: Okay, so basically, I get you up into the point where you say you want to put in, what I understand is that …..
53 Deb: Everybody agree?

In line 17 Liz functions as a focuser when she directs her group's attention to how they can use the initial rate of change as a tool for figuring out the population after a half year. In line 18 Jeff also serves the role of focuser when he directs the group's attention to how time gets integrated into their work. In line 40 Liz acts a checker when she queries the group to see if everyone gets what Deb is saying. Similarly Deb acts as a checker in line 53. In line 46 Liz functions as elicitor when she requests the rationale for carrying out a particular mathematical computation. Finally, in line 48 Liz pulls the ideas together and thus functions as a summarizer.

To conclude this section, I reflect on the ways in which students' mathematical work reflects the disciplinary practice of creating and using algorithms, or algorithmatizing.

The disciplinary practice of algorithmatizing

In the analysis previously presented we see the group of four students engaging in the first stage of creating an algorithm. These first steps lay the relational foundation for how to use P values and dP/dt values to approximate a future population value. An expert will recognize students' work as Euler's method, although the students do not as of yet know that what they have produced is in fact related to Euler's method. In the subsequent whole class discussion the different groups in the class discussed their work and together the class created the following algorithm: $P_{next} = P_{now} + \left(\frac{dP}{dt}\right)_{now} \times \Delta t$. The instructor then explained to the class that this algorithm is conventionally know as Euler's method and is an example of a numerical approximation. In subsequent classes students used this algorithm both with and without contexts and investigated the relationship between approximate solutions and exact solutions that are concave up, concave down, and that have a constant rate of change. Students also investigated how approximation graphs with different step sizes compared to each other and even different ways to improve Euler's method. Such mathematical progress reflects the disciplinary practice of creating and using algorithms, or what we refer to algorithmatizing.

More specifically, students' creation of the Euler method algorithm involved the following:

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

engaging in goal directed activity, isolating attributes, forming quantities, creating relationships between quantities, and expressing these relationships symbolically. For example, Liz helped her group focus on a specific goal directed activity when she asked her group mates, "So if we have that [initial rate of change is 30], the question is how can we use that to help us figure out the population after a half unit elapsed?" This led to their group to think about 30, the initial rate of change, as the amount of rabbits that would be added in one year. Previously I referred to this meaning as a population length, which is an example of isolating an attribute and forming a quantity for this attribute. The population length was further refined when the group related this quantity to a time interval of a half year. The relationship between change and in time and population length was then further quantified. As pointed to previously, these relationships then formed the basis for Cpit and Crit functioning as if shared in this small group. Expressing these relationships symbolically occurred after the 10-minute small group work analyzed here.

Conclusion

In this section I first consider implications for practice and then implications for research. Regarding instructional design considerations, the analysis presented here raises the possibility of including in the student materials questions that focus student attention on the attributes that Deb and her group found particularly useful. Questions such as the following might be woven into the student materials: What is the initial rate of change? What does this value mean to you? How can you use the 30 to figure out the population after half unit of time? Of course this would have to be done in a way that does not take away from the challenge and cognitive demand of the task. Alternatively, such questions could be folded into instructor resource materials that support mathematics faculty in implementing inquiry-oriented curriculum. Indeed, efforts are underway by Estrella Johnson, Karen Keene, and Christine Larson to create such materials for differential equations, linear algebra, and abstract algebra (see http://times.math.vt.edu/).

Another instructional implication that this analysis raises is the how to help promote productive interactions between small group members. In this particular class the small group analysed worked extremely well together, even on the second day of class. This was largely good fortune. So then what might an instructor do to facilitate more productive interactions in small groups that do not function as well as Liz, Deb, Joe, and Jeff?

I now turn to discussing some implications for research. In addition to using various combinations of the four constructs to more fully account for students' mathematical progress, there exist multiple ways in which coordination across the four constructs is possible. For instance, one could choose an individual student within the classroom community and trace his/her utterances for the ways in which they contributed to the emergence of various normative ways of reasoning and/or disciplinary practices. Alternatively, when considering a normative way of reasoning, a researcher could investigate who the various individual students are that are offering the claims, data, warrants, and backing in the Toulmin analysis used to document normative ways of reasoning. How do those contributions coordinate with those students' production roles within the individual participation construct? For instance, does a student ever utilize an utterance that a different student authored as data for a new claim that he is authoring, and in what ways may that capture or be distinct from other students' individual mathematical meanings? One might also imagine ways to coordinate across the two individual constructs as well as across the two collective constructs. For example, how do patterns over time in how student participation in class sessions relate to growth in their mathematical meanings? Are different participation patterns correlated with different mathematical progress trajectories? In what ways are particular classroom mathematical practices consistent (or even inconsistent) with various disciplinary practices? Finally, future research could take up more directly the role of the teacher in relation to the four constructs.

I anticipate that future work will more carefully delineate methodological steps needed to carry out the various ways in which analyses using the different combinations of the four constructs can be coordinated. Indeed, this report is a first step in developing a more robust theoretical-methodological approach to analyzing individual and collective mathematical progress.

TENDIENDO PUENTES ENTRE TEORIAS: ¿QUÉ PUEDE LOGRARSE?

BUILDING BRIDGES BETWEEN THEORIES: WHAT CAN BE ACHIEVED?

María Trigueros
Instituto Tecnológio Autónomo de México (ITAM)
trigue@itam.mx

El interés por entender el fenómeno del aprendizaje y la enseñanza de las matemáticas y por desarrollar nuevas y más efectivas metodologías de enseñanza del Cálculo Diferencial y del Álgebra Lineal me condujo a establecer diálogos entre la teoría APOE y otras teorías de la Educación Matemática. Esta iniciativa hizo posible entenderlas mejor. Se construyeron puentes entre ellas permitieron encontrar puntos de contacto, y expandir sus fronteras sin cambiar sus hipótesis fundamentales. En este trabajo se ilustra una reflexión sobre las posibles implicaciones del diálogo entre teorías y, a través de tres ejemplos, se muestra cómo puede promover experiencias enriquecedoras para los investigadores y propiciar la creatividad de los estudiantes. Se muestra también cómo es posible obtener resultados positivos en términos del aprendizaje de los alumnos y en el desarrollo de materiales didácticos efectivos.

Palabras clave: Pensamiento Matemático Avanzado, Teorías del Aprendizaje, Modelación

Hacer investigación en educación matemática implica el análisis de un fenómeno didáctico en términos de un punto de vista teórico específico. La elección debe hacerse entre una enorme cantidad de teorías que asumen perspectivas diversas frente a los complejos fenómenos del aprendizaje y la enseñanza de las matemáticas. Cada teoría se constituye en un campo delimitado por sus propias hipótesis, sus estructuras conceptuales y su metodología de trabajo desde el cual se definen y se abordan los problemas de interés. Así lo que aparenta ser un mismo fenómeno se define de distinta manera en cada teoría y las explicaciones de los mismos están acotadas por las limitaciones propias de cada una de ellas.

Recientemente ha surgido un interés creciente por tender puentes entre diversas teorías y analizar su posible complementariedad a través del estudio comparado de un mismo fenómeno o de su posible articulación en un nuevo y más extenso marco teórico (Artigue, Bosch & Gascón, 2011). Este interés puede ser teórico o puede resultar de una necesidad de análisis que surge en el contexto de una investigación, pero resulta problemático puesto que cada problema se construye en el marco conceptual de una teoría y con dicha teoría se trabaja y se interpretan los resultados utilizando herramientas específicas desarrolladas para ello (Trigueros, Bosch & Gascón, 2011). En este contexto surgen nuevas preguntas: ¿Por qué o para qué cruzar fronteras teóricas? ¿Cómo establecer un diálogo entre teorías que permita cruzar sus fronteras sin alterar los principios básicos de cada una de ellas? ¿Cómo construir puentes entre ellas o flexibilizar sus fronteras de manera que no se pierda la coherencia interna de cada una de ellas?

Intentaré, en lo que sigue, dar respuesta a este tipo de preguntas a través de los resultados de mi propia experiencia. Para ello discutiré algunos ejemplos específicos tomados de mi trabajo de investigación.

Cruzar fronteras entre teorías: Posibilidad de ampliación de dominios de aplicación

¿Cómo cruzar las fronteras de una teoría específica? ¿Qué se puede ganar con ello? Comenzaré por intentar dar una primera respuesta a estas preguntas. Un poco de mi historia personal puede ayudar a conformar algunas respuestas tentativas.

Mi trabajo de investigación en educación matemática ha utilizado como marco teórico la teoría APOE (Acción, Proceso, Objeto, Esquema) que es una teoría cognitiva que intenta explicar cómo los

estudiantes construyen los distintos conceptos matemáticos (Arnon et al. 2014). El interés personal por buscar nuevas metodologías de enseñanza, de acercar a los estudiantes a las matemáticas y de promover que aprendan y puedan utilizar ese conocimiento me condujo a explorar otras teorías y a buscar establecer un diálogo entre algunas de ellas y APOE. ¿Qué implica esta exploración? En mi experiencia la exploración se hizo desde la consideración de la posibilidad de analizar las teorías y pensar en las fronteras no como límites rígidos sino como algo flexible y dinámico. Esta idea me condujo a pensar cómo pueden complementarse las teorías y cómo se pueden enriquecer mutuamente cuando se establece entre ellas un diálogo que permite extender sus límites teóricos o metodológicos y ampliar las posibilidades de análisis de los fenómenos didácticos de interés.

En todos los ejemplos de diálogo que describiré a continuación una de las teorías involucradas es la teoría APOE. Comenzaré por describirla muy brevemente: La teoría APOE está basada en la epistemología de Piaget, en particular en el mecanismo de abstracción reflexiva. Su nombre es un acrónimo de los tipos de estructuras mentales que se supone construyen los estudiantes conforme realizan actividad matemática. Una Acción es una transformación de objetos construidos previamente siguiendo instrucciones explícitas que el estudiante considera como externas. Las acciones pueden interiorizarse, mediante la reflexión, en un Proceso que consiste en la posibilidad de describir, imaginar o llevar a cabo las transformaciones sin necesidad de hacer todos pasos explícitamente. Los procesos se pueden revertir o coordinar unos con otros para construir nuevos procesos. Cuando el estudiante es consciente de un proceso como una totalidad y puede realizar acciones sobre él, éste se encapsula en un Objeto que puede desencapsularse, en caso de necesidad, en el proceso que le dio origen. Los Esquemas se desarrollan mediante la construcción de relaciones entre acciones, procesos, objetos y esquemas construidos previamente y se considera, consciente o inconscientemente, como un marco coherente que se utiliza para resolver problemas matemáticos relacionados entre sí. Cuando el estudiante requiere hacer acciones sobre el esquema, éste puede tematizarse en un objeto.

En APOE se considera que la tendencia general del estudiante cuando trabaja con una serie de situaciones relacionadas con una noción matemática específica es diferente dependiendo del tipo de estructuras que muestra en su trabajo. Además de las estructuras teóricas descritas, la teoría APOE incluye un modelo que describe una forma posible de construir los conceptos matemáticos de interés en términos de las estructuras de la teoría. Este modelo, conocido como descomposición genética (DG) no es único y debe validarse a partir de resultados experimentales. Por ello la metodología de investigación de la teoría incluye ciclos de investigación en los que la DG se refina hasta que se considera estable.

La teoría APOE incluye también un ciclo de enseñanza: Actividades diseñadas de acuerdo a la DG, discusión en Clase y Ejercicios (ACE) para promover la construcción de los conceptos de interés en el aula. En él se utilizan actividades para la enseñanza diseñadas tomando la DG como base y que se reconsideran conforme ésta se refina.

Búsqueda de detalle en el análisis de la actividad matemática de los estudiantes

En el contexto de un proyecto sobre la construcción de los conceptos del Cálculo Diferencial e Integral de funciones de dos variables, conjuntamente con Rafael Martínez- Planell, estudiamos el aprendizaje de las funciones de dos variables (Trigueros & Martínez-Planell, 2010; Trigueros, M., & Martínez-Planell, 2012). El análisis de los datos obtenidos en el primer ciclo del proyecto puso de manifiesto la necesidad de profundizar tanto en el uso del lenguaje utilizado en la enseñanza como en la representación geométrica de estas funciones y su papel en la construcción de este concepto, para poder interpretar las respuestas de los estudiantes. Por ejemplo, ante la instrucción de esbozar la gráfica de la función $z = x^2 + y^2$ en R^3 cuando $z = 3$, muchos estudiantes respondían "*Es un cilindro*" y dibujaban gráficas como la que se muestra en la Figura 1.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figura 1. La gráfica de $3 = x^2 + y^2$ dibujada por muchos estudiantes.

Fue así que nos acercamos a una teoría cognitiva que detalla el papel de la relación entre distintas representaciones de un mismo concepto en el aprendizaje del mismo: La teoría de las Representaciones Semióticas (TRS) propuesta por Duval (2006). En ella se considera que el proceso de pensar matemáticamente requiere de la coordinación cognitiva de distintas representaciones mediante su comparación y análisis. Propone dos tipos de transformaciones de representaciones semióticas: tratamientos que consisten en cambios de representaciones que se encuentran en un mismo registro y conversiones que involucran cambios de registros de representación sin que se cambie el objeto denotado en ellas. Para discriminar los valores cognitivamente significativos de un objeto matemático mediante la comparación de representaciones similares es necesario hacer tratamientos, mientras que las conversiones permiten disociar el objeto representado del contenido de una representación particular e impedir que los diferentes registros queden en compartimentos ajenos para el aprendiz.

El análisis de las posibilidades de tender puentes entre las teorías APOE y TRS partió de la consideración del papel de las representaciones en la construcción de conocimiento en ambas teorías. En la TRS, los registros de representación y las transformaciones entre registros son centrales en la comprensión de los objetos matemáticos. En la teoría APOE las transformaciones entre representaciones y su relación están ligadas a distintas construcciones mentales que pueden ser descritas mediante los mecanismos de interiorización, coordinación, reversión o encapsulación. Así, es posible considerar que los tratamientos podrían describirse parcialmente en términos de acciones sobre un objeto en un registro de representación determinado y que la reflexión sobre ellas puede permitir destacar aspectos o propiedades significativas del objeto cuando estas acciones se interiorizan en procesos. La interacción con la TRS permite destacar el tipo y el papel de esas acciones al enfatizar la necesidad de discriminar entre las distintas características del objeto representado en el registro en el que se hacen las acciones. Consideremos, por ejemplo, la acción de sustituir la x por el número 1 en la función $z = x^2 + y^2$. Los estudiantes pueden reconocer a z como una función cuadrática en R^2. Mediante las acciones de sustituir distintos números en x pueden identificar una familia de funciones cuadráticas similares entre sí. Estas acciones pueden interiorizarse en el proceso de construcción de la familia de parábolas $z = a + y^2$. En este ejemplo, la TRS permite identificar el papel de esas acciones en la construcción de conocimiento sobre funciones que resulta fundamental cuando se consideran funciones de dos variables.

Por su parte, las conversiones pueden describirse en APOS como la interiorización del proceso que hace posible considerar las acciones de comparación e identificación de un objeto en registros diferentes de representación como una asociación; pero la interacción con la teoría de representaciones semióticas remarca la necesidad de incluir estos procesos en la DG por su importancia en términos cognitivos. Regresando al ejemplo anterior, la gráfica de las funciones $z = a + y^2$ en el plano permite subrayar aquellos aspectos de las gráficas como objetos que permanecen invariantes en los tratamientos y su relación con el parámetro en la representación analítica. Los procesos construidos mediante estas acciones pueden coordinarse con el proceso de representación de planos en R^3 en un nuevo proceso que permite representar las funciones cuadráticas sobre distintos planos fundamentales $x = a$ y en el proceso de construcción de la superficie correspondiente a la gráfica de la función. El puente entre las teorías permite, así, utilizar las nociones de tratamiento y conversión en la teoría APOE sin perder de vista su perspectiva genética y considerar la

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

flexibilidad en el tránsito entre representaciones mediante la incorporación de especificidad en el análisis.

Tender un puente entre las dos teorías hizo posible un análisis más minucioso del trabajo de los estudiantes en tareas planteadas en una misma representación o que incluyen la conversión entre representaciones y las complejidades involucradas en él. Este análisis repercutió en un refinamiento de la DG. Permitió también mostrar que la generalización de la comprensión de las funciones de una variable a las funciones de dos variables no es directa, dado que los estudiantes no necesariamente perciben las analogías esperadas.

¿Cómo puede establecerse un diálogo fructífero entre teorías?

La posibilidad de coordinar teorías que examinan los fenómenos de la educación matemática desde muy distintas perspectivas puede parecer imposible. ¿Cómo tender puentes entre ellas? ¿Por dónde empezar a dialogar? En un esfuerzo por responder estas preguntas y tender puentes entre las fronteras de estas teorías, conjuntamente con Marianna Bosch y Josep Gascón, decidimos analizar las condiciones que debería satisfacer un diálogo entre teorías y aplicarlas a una conversación entre las teorías APOE y la Teoría Antropológica de lo Didáctico (TAD) (Trigueros, Bosch & Gascón, 2011).

El objeto primario de investigación de la TAD es la actividad matemática institucionalizada, es decir, cuestiona y modela los procesos de génesis y difusión intra-institucional e inter-institucional de las praxeologías (Chevallard, 1992). Éstas están compuestas por una parte práctica y una parte teórica. La primera puede describirse en términos de tareas y técnicas involucradas en la actividad y la segunda en términos de tecnologías y teorías que sustentan las tareas y las técnicas empleadas. El programa de investigación de la TAD requiere explicitar un modelo epistemológico (MER) de las matemáticas que sirve como referencia para analizar la actividad matemática institucionalizada y se basa en el proceso de transposición didáctica que establece las transformaciones que se pueden hacer sobre el conocimiento matemático para hacerlo "enseñable" en una institución específica. El MER se utiliza también para analizar y diseñar actividades de enseñanza y aprendizaje que permiten, a su vez, validarlo (Bosch & Gascón 2005). El análisis praxeológico de la actividad matemática en la institución permite entender las restricciones institucionales que limitan o favorecen ciertos tipos de actividad y analizar el papel del equilibrio en las prácticas matemáticas en la institución.

En el diálogo de este proyecto, la noción de praxeología de la TAD se usa como un marco de análisis reinterpretando las teorías como praxeologías de investigación con el fin de asegurar la consideración de todas sus componentes en el proceso de un diálogo fructífero. De esta manera, el dialogo se puede establecer desde los problemas que abordan (tareas), los instrumentos metodológicos que usan para abordar los problemas (técnicas y tecnologías) y las estructuras propias de las teorías.

Ambas teorías incorporan un análisis de la matemática escolar como parte fundamental de su acercamiento a cualquier problema didáctico e incluyen modelos alternativos para el desarrollo de conocimientos matemático como parte de su metodología: La descomposición genética (DG) en el caso de APOE y el modelo epistemológico de referencia (MER) en el caso de la TAD. Este hecho puede considerarse como un punto de contacto entre ambas teorías. La diferencia fundamental entre estos modelos radica en que la DG se utiliza para estudiar el desarrollo cognitivo de los individuos mientras que el MER se usa para estudiar las condiciones institucionales que permiten que las actividades matemáticas existan en una institución; la unidad de análisis es distinta y eso tiene implicaciones metodológicas importantes. Con el fin de llevar a cabo el diálogo, desarrollamos, en primer término, la noción de "estudiante genérico de una institución" que relaciona al sujeto epistémico de APOE con el "estudiante en una posición institucional" de la TAD. De esta manera se extiende la noción en ambas teorías: La dimensión institucional del análisis con TAD se puede trabajar a través de la noción del estudiante genérico de APOE y la descripción cognitiva de APOE

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

puede integrarse a la de la TAD mediante el desarrollo de la posición del estudiante en una institución determinada.

El diálogo a partir de la componente técnico-tecnológica incluye las técnicas de investigación propias de cada teoría y los resultados que permiten, al interpretarse y generalizarse, acercarse a nuevos problemas. Este es un tipo de diálogo poco común en la educación matemática; en general no se discute cómo un resultado de una teoría se interpreta en términos de otra, ni se comparan resultados de distintas teorías. En el diálogo APOE-TAD observamos cómo cada una de las teorías se beneficia y amplía sus fronteras a partir de una reinterpretación de la metodología de la otra sin contradecir su lógica interna.

Las praxeologías en TAD hacen referencia a distintos niveles de análisis: puntuales (consisten en un tipo de tarea), locales (en el que varias tareas se agregan en una técnica) y así por agregaciones sucesivas se articulan las tareas hasta las regionales (se agregan distintas técnicas en una tecnología). La noción de tipos de concepción puede permitir una reformulación de este proceso de articulación de praxeologías mediante la distinción del tipo de técnicas que las componen como técnicas de tipo acción, proceso u objeto. Estos tipos de técnicas pertenecen a un continuo que describe el proceso institucional del desarrollo de las técnicas en la institución en la que se propone o se usa. Por ejemplo, al inicio de la preparatoria las derivadas de una función aparecen como una técnica acción constituida de gestos estereotipados basados en el cálculo de reglas memorizadas. Si los estudiantes son capaces de decidir entre dos reglas distintas a aplicar a la misma función en términos de su simplicidad o encontrar la antiderivada de alguna función, utilizan técnicas-proceso y cuando se cuestiona la aplicabilidad de la derivada a distintos tipos de funciones se usaría una técnica-objeto.

Por otra parte, la noción y los niveles de evolución de los esquemas en APOE puede relacionarse a la actividad que los sujetos llevan a cabo en la institución y podría ser utilizada para describir el desarrollo de las praxeologías de un sujeto en relación a las praxeologías en una institución. Regresando al caso del ejemplo de la derivada, podría considerarse que el nivel Intra- estaría asociado a la actividad matemática descrita mediante una colección de praxeologías aisladas o incompletas, como es el caso en que se presentan en la institución únicamente las reglas para construir gráficas de funciones utilizando las propiedades de la derivada como un algoritmo a seguir y no se requiere de justificación.

Por su parte la TAD contribuye a desarrollar en APOS la noción de relatividad institucional de la DG y así las herramientas de la TAD podrían apoyar el análisis de la DG en términos de sus posibilidades de existencia en una institución dada. En el caso de la derivada se podría ejemplificar por diferencias en las construcciones previstas para describir la forma en que se construye en la escuela secundaria o para quienes se forman como matemáticos en la universidad. En este caso las actividades para alumnos de secundaria no se referirían, por ejemplo, a las ecuaciones diferenciales, mientras ello sería indispensable en la formación de matemáticos.

El ciclo ACE (Actividades, discusión en Clase, Ejercicios) es un componente importante de la metodología de teoría APOE y está íntimamente relacionado con las estructuras conceptuales de esta teoría a través de la DG. Los seis momentos de estudio que describen los procesos de enseñanza y aprendizaje en términos de praxeologías didácticas en la TAD, podrían emplearse para analizar las actividades previstas para el ciclo ACE en términos praxeológicos para verificar si en la actividad prevista, como un todo, hay un equilibrio entre ellos que apoye la construcción del concepto de interés y permitirían contar con criterios de equilibrio y completitud desde el punto de vista institucional. En el ejemplo de la derivada podría darse el caso de que las actividades relacionadas con el momento del primer encuentro no incluyeran ninguna que permitiera a los estudiantes reflexionar sobre el objetivo de las acciones de cálculo de límites que permiten construir la definición del concepto, por lo que se requeriría del diseño de nuevas actividades.

Las aportaciones del diálogo a partir de las componentes teórica y técnico-tecnológica de APOE y TAD, tuvieron como resultado el desarrollo de nociones interesantes que surgen de un cambio de

focos de atención y de un análisis respetuoso y cuidadoso de las teorías; el diálogo puso en evidencia el alcance y las limitaciones de cada una de ellas y requirió de explicitar sus hipótesis implícitas mostrando que son más flexibles de lo que se podría haber considerado. Estas propuestas tienen el potencial de expandir las fronteras de cada una de las teorías sin violentar sus propuestas básicas. El diálogo partiendo de un problema formulado por una teoría quedó pendiente en esta parte del estudio y requiere de la reformulación del problema para hacer posible un análisis más global que permita poner en juego las nociones previamente presentadas. En otro proyecto se llevó a cabo parcialmente este diálogo y sus resultados se describen a continuación.

Diálogo a partir de un problema: Uso de algunos de los resultados anteriores
La investigación sobre la construcción de la noción de función de dos variables descrita anteriormente se continuó en dos ciclos adicionales en los que se incluyó la enseñanza mediante el ciclo ACE. Los resultados obtenidos permitieron refinar y validar la DG, así como diseñar un conjunto de actividades para su enseñanza. Con el objetivo de continuar con el diálogo entre las teorías APOE y TAD y de analizar el funcionamiento de las actividades en la enseñanza en una institución específica se decidió llevar a cabo una investigación utilizando las herramientas surgidas del diálogo como marco conceptual (Trigueros & Martínez- Planell, 2015).
Como primer paso se reformuló el problema de investigación de la siguiente manera: En una institución universitaria concreta ¿Qué características tienen las praxeologías que se utilizan en relación a interpretación de las gráficas de las funciones de dos variables? ¿Qué restricciones limitan que los estudiantes puedan recorrer los momentos didácticos y desarrollar las praxeologías adecuadas? ¿Qué se requiere en la realización de procesos didácticos para que las actividades diseñadas permitan el recorrido balanceado de los momentos de estudio y generen una praxeología matemática local ligada a dicha interpretación?
La investigación se inició con el uso de las herramientas aportadas en el diálogo a partir de las componentes teórica y tecnológico- técnica descritas anteriormente e incluyo varias fases: (a) Análisis de un texto ampliamente utilizado y observación de la forma en que el tema de interés se enseña en la institución concreta utilizando los momentos de estudio del ciclo ACE; (b) análisis de las actividades diseñadas mediante los momentos de estudio del ciclo ACE; (c) ciclos de rediseño de las actividades a partir de los resultados del análisis anterior y (d) evaluación de las actividades finales a través de los resultados obtenidos por los alumnos que las utilizaron.
Los resultados del análisis del texto y de la observación de la enseñanza evidenciaron un recorrido de los momentos de estudio sumamente pobre y desbalanceado. Los momentos de estudio relacionados al bloque práctico de las praxeologías se desarrollaban de forma superficial y muy limitada. La organización del estudio quedó limitada a unos cuantos ejemplos y explicaciones poco relacionados entre sí y, por tanto, resultó incompleta e inefectiva.
Esto permite explicar las dificultades de los estudiantes encontradas en el estudio con APOE presentado anteriormente. Si la organización del estudio no es coherente y no está balanceada, las posibilidades de aprendizaje quedan limitadas por la falta de oportunidades de reflexión.
Las actividades diseñadas para el ciclo ACE de APOE se agruparon en cuatro bloques relacionados respectivamente con la construcción de: (a) planos fundamentales y superficies; (b) cilindros; (c) gráficas y conceptos asociados a las funciones de dos variables y (d) mapas de contornos y familias de funciones. En todas ellas se enfatizaron las técnicas de construcción del espacio tridimensional y de las secciones trasversales, que mostraron ser fundamentales en los estudios realizados con la teoría APOS, para analizar y trazar gráficas.
Las primeras actividades del primer bloque pueden considerarse como pertenecientes al momento del primer encuentro del ciclo ACE y algunas correspondientes al momento de exploración. En ellas se inicia la construcción del espacio tridimensional, de curvas y planos fundamentales en R^3. A

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

continuación se muestra un ejemplo de actividad correspondiente al momento del primer encuentro cuyo objetivo consiste en hacer las primeras acciones para construir el esquema de R^3:

En esta actividad, moverse "hacia adelante" o "hacia atrás" es moverse en dirección de x positivo o negativo, respectivamente; "hacia la derecha" o "hacia la izquierda" es en dirección de *y* positivo o negativo, respectivamente; "hacia arriba" o "hacia abajo" es en dirección z positivo o negativo, respectivamente: Halle las coordenadas del punto donde termina si comienza en el punto *A(1,2,3)* y se mueve 5 unidades hacia adelante, 4 unidades a la izquierda y 2 unidades hacia arriba.

El análisis realizado también evidenció que la mayoría de las actividades de los bloques (a) y (b) pueden considerarse como pertenecientes al momento exploratorio. Entre las actividades del primer bloque hay algunas que se enfocan en la interpretación de expresiones con variables libres y en tratamientos y conversiones entre registros de representación, mientras que en las del segundo bloque los estudiantes hacen acciones sobre superficies en el espacio tridimensional, en particular sobre superficies descritas mediante dos variables. Todas estas actividades promueven la reflexión sobre los procesos incluidos en el trazo de la gráfica de distintas funciones a partir de la acción de representación punto a punto. Se detectó un gran número de actividades perteneciente al momento exploratorio. Esto no es sorprendente dado el énfasis que la teoría APOE hace en brindar oportunidades al sujeto genérico de la institución de reflexión sobre sus acciones para interiorizarlas en procesos.

Por su parte, los bloques (c) y (d) enfatizan el momento del trabajo de la técnica mediante la coordinación del proceso de construcción anterior con los procesos de sección trasversal, e intersección para construir e interpretar gráficas de diversas funciones e incluyen algunas actividades que se puede relacionar con el bloque tecnológico- teórico de la praxeoogía. A continuación se presenta una actividad que combina partes correspondientes al momento de exploración y otras correspondientes al momento de técnico-tecnológico. Su objetivo es hacer reflexionar a los estudiantes sobre las acciones correspondientes a las intersecciones de subespacios en R^3, al tiempo que introduce una técnica que incluye las acciones para construir una superficie en el espacio, además de oportunidades de construcción del proceso asociado a ellas:

En este problema dibujaremos la gráfica de $x = 9 - z^2$ en el espacio tres dimensional. Esta gráfica consiste de todos los puntos en el conjunto $\{(x,y,z): x = 9 - z^2\}$. Para ello:

1. Dibuje en el espacio tridimensional los puntos donde el plano *y = 0* interseca la gráfica de *x* $= 9 - z^2$.
2. Dibuje en el espacio tridimensional los puntos donde el plano *y = 1* interseca la gráfica de *x* $= 9 - z^2$.
3. Dibuje en el espacio tridimensional los puntos donde el plano *y = -1* interseca la gráfica de *x* $= 9 - z^2$.
4. ¿Qué sucede cuando se le dan a y más y más valores positivos y negativos?
5. Dibuje la gráfica de $x = 9 - z^2$ en el espacio tridimensional.
6. Reflexione sobre lo que hizo en las tres actividades anteriores. ¿Cómo, en general, se traza la gráfica en tres dimensiones de una función si en su representación analítica solo aparecen dos variables?

Todos los bloques contienen actividades de reflexión sobre estos procesos que pretenden favorecer su encapsulación en objetos y una construcción coherente de un esquema para R^3. Estas actividades pertenecen al momento tecnológico- teórico.

En todos los bloques se encontraron tareas de verificación de la correspondencia entre gráficas trazadas y representaciones analíticas mediante el trazo de curvas que forman parte de la superficie trazada. Estas actividades se consideraron como parte del momento de evaluación. La que se muestra

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

en la figura 2 pretende evaluar la construcción de los procesos de conversión del registro analítico al gráfico.

El conjunto de actividades no incluye específicamente la discusión de la teoría ya que juega un papel preponderante en la fase de discusión en grupo del ciclo ACE. Pero, se ofrecen oportunidades de justificación en las actividades que pueden considerarse como parte del momento de institucionalización.

En términos generales este análisis sugiere que el recorrido de los momentos de estudio está balanceado y que el uso de las actividades en el aula puede ser eficaz. Sin embargo, se presenta el reto de reducir el número de actividades asociadas al momento de exploración sin alterar las posibilidades de construcción de las estructuras previstas en la DG.

Las actividades se utilizaron en el aula sin la fase de discusión del ciclo ACE y se evaluaron a través de entrevistas a 9 estudiantes del grupo que las utilizó y de 6 de un grupo control. Los estudiantes fueron elegidos por sus maestros utilizando el mismo criterio de desempeño. El análisis de las entrevistas utilizando APOE mostró una clara diferencia entre los estudiantes de ambos grupos, lo que indica que el conjunto de actividades promueve una organización del proceso de estudio que tiene el potencial de estimular el aprendizaje de los estudiantes. Se puede concluir, a partir de estos resultados, que el uso de una praxeología didáctica en la que hay un balance entre los momentos de estudio contribuye a la construcción de las estructuras previstas en la DG. Este trabajo permitió mostrar también que existen puntos de contacto que permiten el acercamiento de las dos teorías.

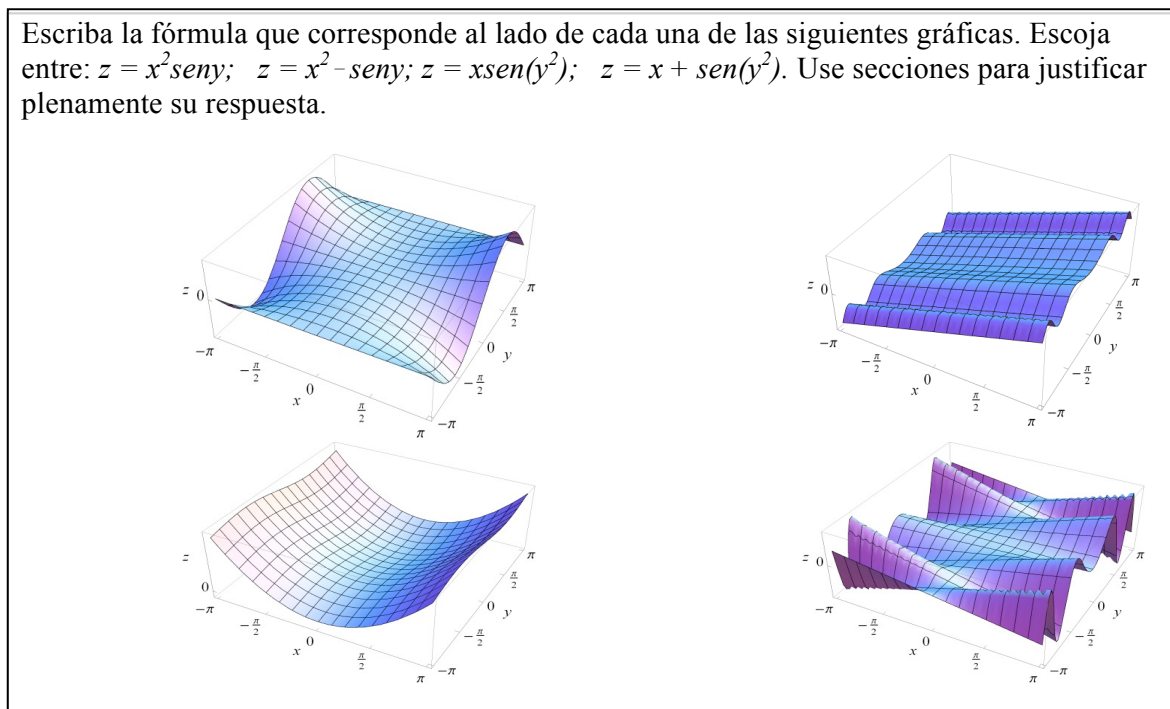
Escriba la fórmula que corresponde al lado de cada una de las siguientes gráficas. Escoja entre: $z = x^2 seny;$ $z = x^2 - seny;$ $z = xsen(y^2);$ $z = x + sen(y^2)$. Use secciones para justificar plenamente su respuesta.


Figura 2. Actividad de conversión y justificación.

Cruzando fronteras metodológicas: Uso de la modelación en la enseñanza de las Ecuaciones Diferenciales y del Álgebra Lineal.

El álgebra lineal y las ecuaciones diferenciales constituyen dos cursos básicos de las matemáticas universitarias que coinciden en su gran aplicabilidad tanto en temas de las matemáticas mismas como en problemas de otras disciplinas. Los desarrollos recientes de la investigación en matemáticas y de la tecnología imponen, en principio, la búsqueda de nuevas estrategias para su enseñanza que no han

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

sido tomadas en consideración por la comunidad universitaria en general. Los resultados de la investigación en educación matemática, por otra parte, ofrecen información sobre la forma en que los alumnos aprenden los conceptos de estas disciplinas y métodos de enseñanza que han probado ser efectivos, entre los que destaca el uso modelos (Por ejemplo, Rasmussen & Blumenfeld, 2007; English, Lesh, and Fennewald, 2008; Bas, Cetinkaya, and Kursat, 2009; Zandieh, & Rasmussen, 2010; Camacho, Perdomo, and Santos, 2012; Trigueros & Possani, 2013).

En un proyecto de investigación que se llevó a cabo durante cinco años, en la institución en la que trabajo, se intentó responder a las preguntas ¿Qué resultados se obtienen, en términos de aprendizaje, cuando se utilizan problemas de modelación en la enseñanza del álgebra lineal y de las ecuaciones diferenciales? ¿Qué aspectos del conocimiento de los estudiantes pueden recuperarse cuando se utilizan modelos en la clase?

Dado que las investigaciones con la teoría APOE no incluían hasta ese momento el uso de problemas de modelación en la enseñanza, se buscó la posibilidad de coordinar esta teoría con una teoría del ámbito de la modelación. Se seleccionó la teoría de Modelos y Modelación (TMM) (Lesh & Doerr, 2003) considerando dos criterios. Desde el punto de vista teórico, propone la posibilidad de construcción de conceptos matemáticos mediante el trabajo de los alumnos en la descripción del comportamiento de una situación en un contexto real o realista que les permita, por una parte utilizar su conocimiento previo y, por otra, construir nuevo conocimiento. Su metodología de enseñanza coincide con la de APOE en que la construcción de nuevo conocimiento se logra mediante trabajo en equipo y con discusiones en clase con el profesor. Por otra parte TMM postula un conjunto de principios que el problema planteado para la modelación debe satisfacer de modo que pueda ser aplicado exitosamente en el aula (Carlson, Larsen, & Lesh, 2003) que puede ser útil en el diseño de situaciones y que puede ayudar a extender la frontera de la teoría APOS de manera que la introducción de los problemas de modelación resulte natural en el ciclo ACE y que el desarrollo del conocimiento a partir de los conceptos previos utilizados por los estudiantes pueda ser descrito mediante una DG adecuada.

Desde el punto de vista teórico ambas teorías postulan formas de construcción del conocimiento. Es posible entonces proponer una posible coordinación entre ellas considerando que el trabajo sobre el problema original permite poner en juego un modelo matemático sobre el cual pueden hacerse dos tipos de actividad, una que permite analizar, desarrollar y validar el modelo matemático y otra en la que las acciones sobre el modelo matemático, libres o guiadas mediante actividades, pueden ser complementadas mediante actividades específicas diseñadas en términos de una DG. Estos dos tipos de actividad se pueden ir intercalando en ciclos l0,'9en los que la modelación da lugar a la necesidad de reflexión y a la construcción de las estructuras necesarias para el aprendizaje de los nuevos conceptos y éstos permiten mirar el trabajo sobre el modelo desde una perspectiva distinta que lo hace evolucionar. Desde el punto de vista metodológico la TMM puede utilizarse para validar el funcionamiento de la situación planteada en términos la promoción de nuevo conocimiento mientras que APOE puede utilizarse para analizar las construcciones de los alumnos y cómo podrían relacionarse con nuevas actividades que promuevan la construcción del conocimiento de interés pues, de acuerdo a esta teoría, el uso de conocimiento previo no es suficiente para garantizar la construcción de nuevos conocimientos. Los ciclos de enseñanza e investigación de APOE se insertan, además, de manera natural en los ciclos de modelación previstos por la TMM. Y así, ambas teorías pueden ampliar sus fronteras para plantear nuevas propuestas didácticas y de investigación. Con base en la coordinación de estas teorías se desarrolló un proyecto de uso de problemas de modelación en la enseñanza de las ecuaciones diferenciales y el álgebra lineal. Dos ejemplos ilustran los resultados que se pueden obtener de un diálogo de esta naturaleza, uno en el contexto de las ecuaciones diferenciales y otro en el de álgebra lineal.

Desarrollo de nuevas herramientas de análisis

En el primer caso (Trigueros, 2014) se planteó a los estudiantes el problema: *Una profesora, preocupada por la tendencia actual en la enseñanza y por el problema del manejo de información de los estudiantes, nos pide hacer un estudio sobre la memorización y el olvido a corto plazo. En particular le interesa un reporte en el que quede claro el tiempo que una persona puede retener información aprendida, el tiempo que tarda en olvidarla y cuáles son los factores de los que esto depende.*

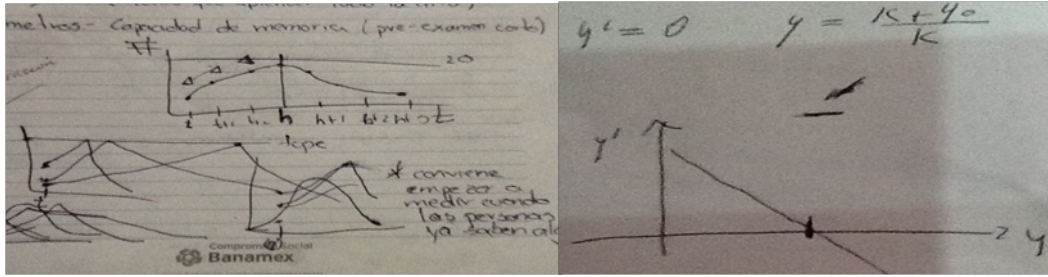
En el ciclo que denominamos de exploración gráfica del problema a partir de la experiencia propia de los estudiantes y del uso de su esquema de función emerge un primer modelo gráfico conjuntamente con la definición de variables (Figura 3a). Aunque de inicio los estudiantes intentan encontrar una expresión analítica para la función, en sus diálogos evocan su esquema de derivada para analizar la gráfica propuesta:

> *Rosa:* Se puede usar la derivada para especificar las propiedades que debe tener la función que proponemos en la gráfica, pero… no tenemos, nadie tiene, la expresión analítica y yo no sé cómo obtenerla de las propiedades, más bien sé al revés, sacar las propiedades si sé la regla de la función.

El siguiente ciclo se identifica mediante la introducción de la variación a la solución del problema que permite sugerir un posible modelo que puede ilustrarse mediante este diálogo:

> *Fer*: Si suponemos que cada persona tiene un coeficiente de memoria y… lo que han aprendido crece de aquí a acá, pero va creciendo menos rápido por pedazos (dibuja una curva poligonal con segmentos de recta), y luego empieza a decrecer también primero rápido y luego no tanto hasta que se le olvida todo, o casi todo…
>
> *Juan*: …Debe crecer más despacio acá y si la persona tiene cierta capacidad de memoria, un coeficiente, *k*, para que primero crezca más y luego menos, podría ser algo como… (escribe $y'=k(y-T)$) porque así no seguiría creciendo sino va parando…

La discusión en grupo gira en torno a las ventajas de escribir una ecuación que incluya la variación. Después de un ciclo de actividades diseñadas con la DG en el que se introducen las ecuaciones diferenciales y las funciones implícitas, como respuesta a las dudas de los alumnos frente a una ecuación que no contiene la variable independiente, se regresa al modelo. Se presenta entonces un ciclo caracterizado por el análisis del modelo. En este ciclo emergen en equipos distintos dos métodos de análisis de la ecuación que no se habían introducido anteriormente: la aproximación de la función solución usando la idea de derivada como aproximación lineal y el uso de la gráfica de la derivada de la función contra la función misma (plano fase) o su descripción verbal, como se muestra respectivamente en los párrafos siguientes.

> *Fer*: Aquí (señala la ecuación). Si le ponemos valores para más fácil, (escribe: $y'=.5(50-y)$). Y si usamos lo de antes, la derivada como pendiente, (escribe $y' = y-yo/t-to$), entonces del tiempo cero al dos, *y* prima es…(escribe $y'=.5(50-y)=y/2$), entonces ... nos queda $y=25$, o sea que en el segundo tiempo se sabe 25 datos y la recta iría de 0 a 2 y de 0 a 25, con pendiente 12.5. Luego hacemos lo mismo pero ahora empezamos con 2 y hasta por ejemplo 4 y *y* vale 25 entonces (hace cálculos, no audible) sale *y* es 37.5 y así le seguimos…
>
> *Nadia*: …Estoy pensando en que si graficamos esa función de *y'*… pero como función de *y*, ¿qué significaría?... A ver… esa gráfica (Figura 3b) es una recta, con pendiente positiva. Dice que $y'=0$ si $yo/k+1=y$. Pero no debe ser porque ¿dónde queremos que haya un punto crítico? yo creo que en el *1* porque es cuando se aprende todo y luego cuando olvida empieza a bajar, pero esto está más arriba.


Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figura 3(a). Exploración.   **Figura 3(b).** Análisis gráfico del modelo.

La actividad continúa mediante otros ciclos de actividades diseñadas con DG y de trabajo en el modelo hasta terminar la actividad con un ciclo caracterizado por la búsqueda experimental del valor de los parámetros del modelo.

Destaca en esta experiencia el papel que juega la representación gráfica de la función como detonador de un cambio en la manera de abordar el problema y en la emergencia de nuevas herramientas conceptuales desarrolladas de manera independiente por los estudiantes.

Construcción independiente de conceptos

En el contexto del álgebra lineal se planteó a los estudiantes un modelo de empleo (Salgado & Trigueros, 2015): *En una economía en la que la fuerza de trabajo permanece constante, hay un cierto número de personas con empleo en cada período de tiempo y un cierto número de personas desempleadas en ese mismo periodo. Si conocemos la probabilidad de que una persona desempleada encuentre un trabajo en el siguiente periodo de tiempo y la probabilidad de que una persona empleada pierda su empleo ¿Cómo podemos describir la dinámica del empleo en el tiempo y cómo se comportará en el largo plazo?*

En este caso algunos estudiantes utilizaron sus conocimientos previos, tanto del curso de álgebra lineal, en el que se había trabajado anteriormente un modelo de poblaciones para introducir las ecuaciones en diferencia de una variable, como de los cursos de economía para plantear una ecuación para el modelo:

A_2: … en cualquier momento hay un cierto número de empleados y de desempleados, pero ese número puede cambiar en el siguiente periodo…

A_3: Es cierto, podemos pensar en el número de empleados en el siguiente periodo y esos deben ser los que todavía tienen empleo menos los que ahora están desempleados…

A_1:… en mi opinión, los empleados en ese nuevo periodo deben ser una proporción de las personas que tienen empleo y lo conservan más el número de personas que estaban desempleadas y consiguen empleo…

A_2: Si, sabemos que p son los desempleados que consiguen trabajo y q los empleados que siguen empleados, bueno, más bien as probabilidades (anotan $x_{t+1} = qx_t + py_t \rightarrow$ empleo)

A_3: Entonces el modelo es un sistema, hay otra ecuación igual para el desempleo (escriben $y_{t+1} = (1 - q)x_t + (1 - p)y_t \rightarrow$ desempleo)

El trabajo en la validación de la solución propuesta para la ecuación del modelo, obtenida de la generalización de la solución para el modelo de poblaciones mediante la introducción de la matriz del sistema, condujo a estos estudiantes a usar su conocimiento previo sobre matrices y exponenciales para hacer un proceso sobre la ecuación resultante (Figura 4).

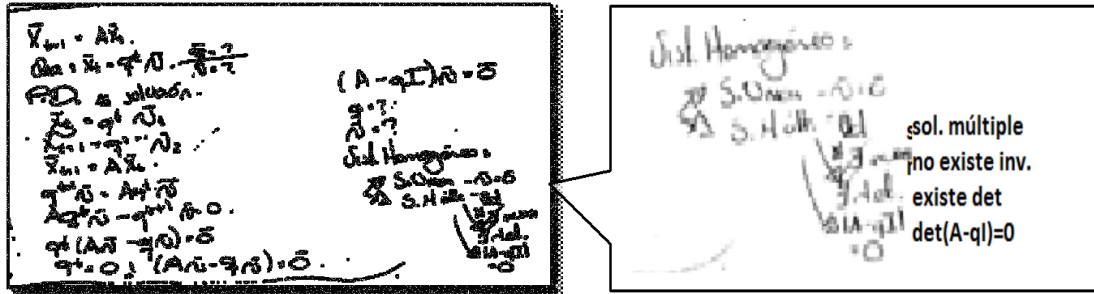
Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.


Figura 4. El uso del esquema conduce a la definición de los valores y vectores propios.

Su trabajo mostró evidencia de construcción de relaciones entre los conceptos desarrollados en el curso, lo que puede caracterizarse como la construcción de un esquema de conjunto solución de un sistema lineal de ecuaciones que incluye los conceptos de solución, de matriz, de independencia lineal, espacio nulo y determinante.

Este proceso los condujo a la definición de los conceptos de eigenvalores, eigenvectores y eigenespacios que no habían sido definidos con anterioridad. La reflexión de estos estudiantes sobre sus propias acciones permitió que construyeran estos conceptos como proceso. Con el trabajo en actividades diseñadas con la DG en las que se retomó y se institucionalizó su trabajo tuvieron oportunidad de construir estos conceptos como objetos.

Posteriormente calcularon los valores y vectores propios para valores específicos de los parámetros:

A_1: …para k_1 igual a uno los vectores tienen la forma $v = (2x_2/3, x_2)$ y x_2 es un parámetro; y para k_2 1/6, el vector es $v = (2x_2/3, x_2)$.

A_3: En ambos casos x_2 es arbitraria, o sea la familia de soluciones en el conjunto solución. ¿Es el parámetro el mismo en ambos casos?... No, entonces a uno le llamamos x_1…

A_2: Es cierto... entonces…solo para esos valores de k y esos valores de v, las funciones que propusimos son soluciones del sistema del modelo.

A_3: ¿Podemos usar un caso particular para cada familia de vectores?

A_1: No sé, pero en ese caso, un caso particular… para $k_1 = 1$, $v_1= (2/3,)$ y para $k_2 = 1/6$, $v_2= (2/3,)$ ¿estará bien?

A_3: Para cada k, los vectores generan una recta, pues solo hay una variable arbitraria en cada caso.

Después de un ciclo de actividades diseñadas con la DG para institucionalizar y brindar a todos los alumnos nuevas oportunidades de reflexión, durante la discusión los mismos estudiantes relacionaron estos conceptos con el problema a modelar.

A_3: … Encontramos que los eigenvalores eran $k_1 = 1$ y $k_2 = q - p$, o sea, diferentes, uno es independiente de las probabilidades dadas y el otro está relacionado con la diferencia de la probabilidad de que una persona continúe empleada y la de que un desempleado consiga trabajo…

A_2: Usamos esos valores y encontramos los eigenvectores, bueno, escogimos uno para cada k. Para $k_1=1$ encontramos $(p/(1-q), 1)$ así que está relacionado con la razón de la probabilidad de que una persona desempleada encuentre trabajo en el siguiente periodo y la de que un empleado pierda su trabajo en el siguiente periodo. Algo así como una razón de las probabilidades de cambiar de estado… para la otra k, $k_2 = q - p$ era independiente de los valores de las probabilidades, era $(-1, 1)$ y no pudimos explicar estos…también porque

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

hicimos una gráfica (Figura 5) y el espacio propio correspondiente siempre tiene vectores con una componente negativa…

A_3: Entonces las constantes no tienen relación con las condiciones iniciales, aunque en el problema de población esas condiciones aparecían en la solución y discutimos su papel en términos de la familia de soluciones. Pero aquí ¿dónde están las condiciones iniciales del problema? ¿No juegan ningún papel?

La maestra regresó la pregunta en su trabajo en equipos y les pidió predecir el comportamiento a largo plazo. En el trabajo en un nuevo ciclo de actividades diseñadas con la DG los alumnos hicieron referencia al concepto de base:

A_3: Escogimos un vector particular para cada conjunto solución por separado, pero ¿podríamos tomar uno de cada familia para hacer una combinación lineal y generar tal vez R^2.

Esto puso en evidencia que los estudiantes construyeron relaciones entre su conocimiento previo y el nuevo.
Figura 5. Comportamiento a largo plazo.

Los alumnos, en general, tuvieron dificultades para entender las funciones vectoriales resultantes, que no habían estudiado todavía. Algunos optaron por graficar para cada una de las componentes para encontrar el comportamiento a largo plazo y concluir a partir de ellas, que cada solución converge a una solución que corresponde al eigenespacio.

Destacan en esta experiencia la aparición de los conceptos de interés en el trabajo de los alumnos sin intervención alguna de la maestra y la construcción de un esquema por parte de algunos estudiantes en el que muestran haber construido relaciones entre los conceptos introducidos con anterioridad. Si bien en la entrevista posterior al curso se encontró que algunas dificultades persistieron en los casos de dimensión mayor, al menos 3 estudiantes mostraron una concepción objeto de los conceptos de interés.

Muchas investigaciones sobre el uso didáctico de la modelación insisten en la motivación que la solución de este tipo de problemas representa para el estudiante. Estas investigaciones lo confirman. Pero, demuestran además que cuando los estudiantes se involucran en problemas de interés y reflexionan libremente desarrollan nuevas estrategias que promueven la construcción de conceptos y de relaciones entre ellos. Los problemas de modelación pueden favorecer el aprendizaje de conceptos difíciles y abstractos y el nuevo conocimiento puede, a la vez, aplicarse a la solución de nuevos problemas. La ventaja de la coordinación de las dos teorías, por su parte, se hizo patente en la permeabilidad de sus fronteras y en la expansión de los problemas que cada una de ellas puede abordar.

Comentario final

Las experiencias de cruce de fronteras, diálogo y búsqueda de posibles maneras de coordinar teorías analizando cuidadosamente las hipótesis básicas y las posturas teóricas de cada una de ellas

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

mostraron en cada caso posibilidades alentadoras de acercamiento sin confrontación y de encontrar aportaciones que las enriquecen mutuamente. Ponen en relieve, además, que mediante un acercamiento serio y abierto es posible establecer diálogos entre teorías aun en casos en que las teorías parecen lejanas entre sí.

Además del enriquecimiento teórico resultante de tender puentes entre distintas teorías, la aplicación de las herramientas surgidas de los diferentes diálogos hizo patente sus posibilidades de aplicación en el diseño de estrategias de enseñanza que favorecen el aprendizaje de los alumnos y la posibilidad de pensar en el trabajo propio de investigación de forma diferente.

Las fronteras teóricas pueden aparecer en un diálogo respetuoso y tolerante como fronteras flexibles y dinámicas que permiten la ampliación de su dominio de aplicación y el intercambio de ideas sin perder su propia identidad. Fronteras que se abren y dejan aparecer fenómenos que serían imposibles de ver si se hubiera utilizado una sola de ellas. El reto que enfrentamos como comunidad es acercarse al estudio de los fenómenos de la educación matemática construyendo puentes de manera creativa que permitan conservar las fronteras que dividen a las diferentes teorías pero al mismo tiempo las hagan porosas para que la disciplina se enriquezca a través de las relaciones de colaboración.

Interest in understanding mathematics teaching and learning phenomena, and to develop new and effective methodologies to teach Differential Calculus and Linear Algebra led me to look for ways to dialogue between APOS Theory and other mathematics education theories. This enterprise has facilitated a better understanding of them. Bridges between them have been constructed that enable to find possible points of contact and to expand their borders without changing their fundamental hypothesis. In this paper, a reflection on what a dialog between theories entails is illustrated and, through three examples, it shows how it promotes enriching experiences for researchers and stimulates students' creativity. Results also underline how positive outcomes in terms of students learning and in the development of effective teaching resources can be obtained.

Keywords: Advanced Mathematical Thinking, Learning Theory, Modeling

Doing research in mathematics education implies analyzing a didactical phenomenon in terms of a specific theoretical approach. Its selection must be made among an enormous number of theories that assume a diversity of perspectives in face of the complex mathematics learning and teaching phenomena. Each theory constitutes a field defined by its own hypothesis, conceptual structures and methodology. The research problems of interest, and the way they are approached, are defined in those terms. So, something that can be thought of, apparently, as the same phenomenon, is defined differently within each theory, and the explanations provided are delimited by each theory's own restrictions.

A growing interest has emerged recently to look for the construction of bridges between different theories and to analyze their possible complementarities through comparative studies of the same phenomenon or through their possible articulation in a new and broader theoretical framework (Artigue, Bosch & Gascón, 2011).. This interest may be theoretical or may result from an analysis need arising in the context of research, but is problematic since each problem is constructed in terms of the structure of the theory. Furthermore, it is studied and its results are interpreted in terms of specific tools developed for that purpose (Trigueros, Bosch & Gascón, 2011). New questions arise in

---

this context: Why should we cross theoretical borders? How can a dialog between theories be established so that crossing their borders is possible without changing their basic principles? How can bridges be built from one to the other or how can their borders be made flexible so that the internal coherence of each theory is preserved?

In what follows I will try to respond to these kinds of questions through the results of my own experience. In order to do so, I will discuss some specific examples taken from my own research work.

Crossing borders between theories: Expandability of application domains.

How to cross the boundaries of a specific theory? What can be gained by doing so? I will start trying to give a first answer to these questions. A few words about my personal history can help shape some tentative answers.

My work on mathematics education research has used APOS (Action, Process, Object, Schema) theory as the theoretical framework. APOS theory is a cognitive theory that intends to explain how students construct different mathematical concepts (Arnon et al. 2014). My personal interest in looking for new teaching methodologies, to bring students to mathematics and to promote their learning and their possibilities to use their knowledge, led me to explore other theories and to seek to establish a dialogue between some of them and APOS. What does this exploration entail? In my experience the exploration was guided by considering the possibility to analyze the theories and think of their boundaries not as rigid limits, but as something flexible and dynamic. This idea brought me to consider how theories can complement each other and how they can enrich each other when a dialogue between them, that may extend their theoretical or methodological limits and expand their possibility of analysis of educational phenomena of interest, is established.

In all the dialogue examples that I will discuss, one of the theories involved is APOS theory. I will begin by giving a very brief description of this theory: APOS theory is based on Piaget's epistemology, in particular, on reflective abstraction mechanism. Its name is an acronym of the types of mental structures that are supposed to be constructed by students when they are involved in mathematical activities. An Action is a transformation of previously constructed objects by following explicit instructions that the student considers as something external. Actions may be interiorized, by means of reflection, into a Process which consists in the possibility to describe, imagine or perform those transformations without having to follow explicitly all the steps. Processes can be reversed or coordinated with other processes in order to construct new processes. When students are conscious of a process as a totality and can do actions on it, the process is encapsulated into an Object that may be de-encapsulated, when needed, in the process from which it originated. Schemas are developed by means of the construction of relations among actions, processes, objects and previously constructed schemas, and a schema is considered, consciously or unconsciously, as a coherent framework that can be used to solve mathematical problems related among them. When the student needs to do actions on a schema, it can be thematized into an object. APOS considers that the general tendency of students when they work on a series of situations related to a specific mathematical notion is different depending of the type of constructions they show in their work.

In addition to the theoretical structures described, APOS theory includes a model to describe a possible way of constructing the mathematical concepts of interest in terms of the structures of the theory. This model, know as genetic decomposition (GD), is not unique and most be validated in terms of experimental results. Therefore, the research methodology of the theory includes research cycles in which the GD is refined until it is considered to be stable.

APOS theory includes as well a teaching cycle: Activities designed with the GD as a basis, Class discussion and Exercises (ACE) to promote the construction of the intended concepts in the classroom. In it, teaching activities designed in accordance to the GD are used and they are reconsidered as the GD is refined.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Searching for detail in the analysis of students mathematical activity

In the context of a project about the construction of the concepts of the Differential and Integral Calculus of functions of two variables, together with Rafael Martínez- Planell, we studied students' learning of functions of two variables (Trigueros & Martínez-Planell, 2010; Trigueros, M., & Martínez-Planell, 2012). The analysis of the data obtained in the first cycle of the project highlighted that in order to be able to interpret students' responses more detail was needed, both in how language is used in teaching, and in these functions' geometric representation and its role in the construction of this concept,. For example, when asked to sketch the graph of the function $z = x^2 + y^2$ in R^3 when $z = 3$ many students responded *"It is a cylinder"* and they drew graphs similar to that shown in Figure 1.
Figure 1. The graph of $3 = x^2 + y^2$ according to many students.

That was how we approached a cognitive theory detailing the role of the relation between different representations of the same concept in its learning: Semiotic Representations Theory (SRT) was proposed by Duval (2006). This theory considers that the mathematical thinking process requires the cognitive coordination of different representation by means of their comparison and analysis. It proposes two types of transformations of semiotic representations: treatments which consist in changes of representations that are in the same representation register and conversions that involve changes from one representation register to another without changing the represented object denoted in them. In order to discriminate those values of a mathematical object that are cognitively significant by means of comparisons of similar representations, it is necessary to do treatments, while conversions allow to separate the represented object from the particular representation's content and prevent that the different registers stay separated for the learner.

The analysis of the possibilities to construct bridges between these theories started from the consideration of the role of representations in the construction of knowledge in both theories. In SRT, representation registers and transformations between registers are central in understanding mathematical objects. In APOS theory transformations between representations and their relation are linked to different mental constructions that can be described in terms of interiorization, coordination, reversal or encapsulation mechanisms. It is possible to consider that treatments could be described partially in terms of actions on an object in a given representation register and that reflection on them can make possible to highlight significant aspects or properties of the object when those actions are interiorized into processes. The interaction with semiotic representations theory makes it possible to point out the type and role of those actions by emphasizing the need to discriminate among different characteristics of the represented object in the register where the actions are performed. Let's consider, for example, the action of substituting number 1 for x in the function $z = x^2 + y^2$. Students may recognize z as a quadratic function in R^2. When substitution actions are repeated using different numbers, students can identify a family of similar quadratic functions. These action can be interiorized in the process of construction of a family of parabolas $z = a + y^2$. In this example SRT allows the identification of the role of those actions in the construction of knowledge about functions that is fundamental when considering functions of two variables.

Meanwhile, conversions can be described in APOS as the interiorization of the process that makes it possible to consider actions of comparison and identification of an object in different representation registers as an association; but the interaction with SRT underlines the need to include those processes in the GD because of their importance in cognitive terms. Going back to the previous

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

example, the graph of functions $z = a + y^2$ in the plane makes it possible to underline those aspects of the graphs as objects that remain invariant in treatments and their relation with the parameter in the analytic representation. The processes constructed by means of those actions can be coordinated with the representation of planes in R^3 in a new process of representation of the quadratic functions on different fundamental planes $x = a$, and in the process of construction of the surface corresponding to the graph of the function. The bridge between the theories enables to use the treatment and conversion notions in APOS theory without losing sight of its genetic perspective and to consider the flexibility in passing from one representation to other by incorporating specificity in the analysis.

Bridging between the two theories allowed a more thorough analysis of students' work on tasks set in the same representation or in those that need the conversion between representations, and the complexities involved in it. This analysis had repercussions on a refinement of the GD. It also allowed to show that generalization of the understanding of functions of one variable to functions of two variables is not direct, given that students do not necessarily perceive the expected analogies.

How can a fruitful dialogue between theories be conducted?

The possibility to coordinate theories that study the mathematics education phenomena from very different perspectives may seem impossible. How to bridge them? Where can a dialogue start from? In an effort to answer these questions and construct bridges between these theories, together with Marianna Bosch and Josep Gascón, we decided to analyze the conditions that a dialogue between theories must satisfy, and to apply them to a conversation between APOS theory and the Anthropological Theory of Didactics (ATD) (Trigueros, Bosch & Gascón, 2011).

The primary research object of ATD is the institutionalized mathematical activity; that is, this theory questions and models the intra-institutional and inter-institutional genesis and diffusion processes of praxeologies (Chevallard, 1992). Praxeologies are formed by a practical component and a theoretical component. The first one can be described in terms of the tasks and techniques involved in the activity, and the second one in terms of the technologies and theories that support the employed tasks and the techniques. ATD's research program requires making an epistemological model (EMR) of mathematics that is used as reference to analyze the institutionalized mathematical activity and is based explicitly on the didactic transposition process. This process proposes those transformations that can be performed on mathematical knowledge so that it can be taught in a specific institution. The EMR is also used to analyze and design teaching and learning activities which make it possible, simultaneously, to validate it (Bosch & Gascón 2005). The praxeologycal analysis of mathematical activity in the institutions allows understanding the institutional restrictions that limit or favor some types of activity, and analyze the role of equilibrium in mathematical practices in the institution.

In this project's dialogue, the notion of praxeology of ATD is used as a framework for analysis by reinterpreting theories as research praxeologies with the aim of making sure that all their components are taken into account in a fruitful dialogue. Thus, the dialogue can be conducted starting from the problems discussed (tasks), the methodological tools used to work on the problems (techniques and technologies) and the structures of the theories.

Both theories incorporate an analysis of school mathematics as a fundamental component of their approach to any didactical problem and include alternative models for the development of mathematical knowledge as part of their methodology: the GD in the case of APOS theory and the EMR in the case of ATD. This fact can be considered as a point of contact between both theories. The fundamental difference between these models is that the GD is used to study the cognitive development of individuals while the EMR is used to study the institutional conditions that make the existence of the mathematical activities possible in an institution; the analysis unit is different and that fact has important methodological implications. In order to carry out the dialogue, we first developed the notion of "generic student in an institution" which relates the epistemic subject of

APOS to the "student in an institutional position" of ATD. This way, the notion can be extended in both theories: the institutional dimension of ATD analysis can be worked through the notion of generic student of APOS and the cognitive description of APOS can be integrated into that of ATD by the consideration of the position of student at a specific institution.

The dialogue starting from the technical-technological component includes the research techniques of each theory and the results that allow to approach new problems when interpreted and generalized. This is an uncommon kind of dialogue in mathematics education; in general how a result of a theory can be interpreted in terms of other is not discussed and results of different theories are not compared. Through the APOS-TAD dialogue we observed how each theory can benefit and extend its boundaries starting from a reinterpretation of the other's methodology without contradicting its internal logic.

In ATD, praxeologies make reference to different levels of analysis: punctual (consists in one type of task), local (when several tasks are aggregated in a technique) and by making successive aggregations the tasks are articulated into regional praxeologies (aggregation of different techniques in a technology). The notion of different kinds of conceptions can allow a reformulation of this process of articulation of praxeologies by the distinction of the type of technique that compose them as action type techniques, process or objet. These types of techniques are part of a continuum that describes the institutional process of development of techniques in the institution where they are proposed or used. For example, at the beginning of high school derivatives of a function appear as an action technique constituted by stereotyped gestures based on the use of memorized rules. If students are capable to decide between two different rules that can be applied to the same function in terms of their simplicity or find the antiderivative of a function, they use process- techniques, and when they question the applicability of the derivative to different types of functions they would be using an object-technique.

The notion and the levels of development of schemas in APOS, on the other hand, can be related to the subjects' activity in the institution and could be used to describe the development of a subject's praxeologies related to an institution's praxeologies. Going back to the derivative example, it could be considered that the Intra- level would be associated to the mathematical activity described by a collection of isolated or incomplete praxeologies, as in the case where only the rules to sketch the graph of a function, based on the derivative properties, are presented in the institution as an algorithm for the student to follow without any justification.

Meanwhile, the ATD contributes to develop in APOS the notion of institutional relativity of the GD, and thus, the ATD tools could support the analysis of the GD in terms of its possibilities of existence in a given institution. In the case of the derivative, it could be exemplified by the differences in the expected constructions needed to describe the way in which the derivative is constructed in high school or in an undergraduate program in mathematics. In this case the activities for high school would not refer, for example, to differential equations, while this would be indispensable en the case of the mathematics program at the university.

The ACE cycle (Activities, Class discussion, Exercises) is an important component of the methodology of APOS theory and it is intimately related to the conceptual structures of this theory through the GD. The six moments of study describing the teaching and learning processes in terms of didactic praxeologies in ATD, could be used to analyze the activities anticipated for the ACE cycle in praxeological terms to verify if in the expected activity, as a whole, there is an equilibrium among them that supports the concept of interest's construction, and if they would enable disposing of equilibrium and completeness criteria from the institutional point of view. In the derivative example, it could happen that the activities related to the moment of the first encounter did not include any activity to help students reflect on the objective of the limit calculation actions needed to construct the definition of the concept, so it would be necessary to design new activities.

The contributions of the dialogue starting from the theoretical and technical- technological of APOS and ATD, had as a result the development of interesting notions that emerge from a change in attention focus and form a respectful and careful analysis of both theories. The dialogue evidenced the extent and the limitations of each theory and required making explicit their implicit hypothesis, showing that they are more flexible than what could be considered. These proposals have the potential to expand each theory's borders without violating their basic tenets. The dialogue starting from a problem formulated by one of the theories was not discussed in this part of the project and requires of the reformulation of the problem to make a more global analysis that will allow putting into play the previously presented notions. In another project this dialogue was partially carried out. Its results are described below.

Dialogue starting from a problem: using some results from the APOS-ATD dialogue
Research on the construction of the notion of function of two variables previously described was continued for two additional cycles where the teaching cycle was included. Results obtained were used to refine and validate the GD, and also to design a set of activities to be used in the teaching cycle. In order to continue the dialogue between APOS theory and ATD and with the goal of evaluating the designed activities in a specific institution, we decided to continue with a research using some of the tools developed in that dialogue as a conceptual framework (Trigueros & Martínez- Planell, 2015).

The first step in this research consisted in reformulating the research problem as follows: in a particular university as an institution, what are the characteristics of the praxeologies used in the interpretation of the graphs of two variables? What are the restrictions limiting students possibilities to go through the didactical moments and develop the associated praxeologies? What conditions are needed to warrant the development of a didactical process includes a balanced use of the study moments and generates a mathematical praxeology linked to that interpretation?

The research started with the use of the tools proposed in the dialogue starting from the theoretical and from the technological- technical components. It included several phases: (a) Analysis of a widely used textbook and observation of the way this topic is taught in the same institution using the moments of study of the ACE cycle; (b) analysis of the activities designed using the moments of study of the ACE cycle; (c) cycles to redesign the activities taking into account results from the previous analysis and (d) final evaluation of the final activities through the analysis of students results obtained by students who used them.

The results of the textbook analysis and the teaching observation evidenced a poor and unbalanced presence of the didactical moments. Those moments related to the practical part of the praxeologies were developed in a superficial and limited way. The study organization stayed limited to a few examples and explanations poorly related among them. So it proved to be incomplete and ineffective.

These results allow explaining the difficulties shown by students in the APOS study described above. If the study organization is not coherent and balanced, the learning opportunities remain limited due to the lack of reflection opportunities.

The designed activities for the cycle ACE of APOS theory were grouped in four sets related, respectively, with the construction of: (a) fundamental planes and surfaces; (b) cylinders; (c) graphs and concepts associated to functions of two variables and (d) contour maps and families of functions. In all of them, the construction of the tridimensional space and use of transversal sections techniques that were found to be fundamental in studies realized with APOS theory was emphasized in the analysis and sketching of graphs.

The first activities in set (a) can be considered as part of the exploration moment of the ACE cycle. In that set there are also activities corresponding to the exploration moment. In them, the construction of three-dimensional space, curves and fundamental planes in R[3] is introduced and

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

explored. The following is an example of an activity corresponding to the first encounter moment. Its goal is to make the first actions on the intuitive notion of space to construct the R^3 schema:

In this activity to move "forward" or "backwards" corresponds to moving in the direction of positive x (the x coordinate increases, the y and z remain the same) or negative x (the x coordinate decreases, the y and z remain the same), respectively; "to the right" or "to the left" is moving in the positive or negative y direction, respectively; "up" or "down" is moving in the positive or negative z direction, respectively. Find the coordinates of the point where one ends if one starts at point $A(1, 2, 3)$ and moves 5 units forward, 4 units to the left, and 2 units up.

The analysis of results showed as well that most of the activities in sets (a) and (b) can be considered as part of the exploratory moment. Among the activities of the first set, there are some that focus on the interpretation of expressions with free variables and on treatments and conversions between representation registers, while in those of the second set students do actions on surfaces in tridimensional space, in particular, on surfaces that are described by expressions with two variables. All these activities promote reflection on the processes needed in sketching the graph of different functions starting from the action of point to point representation. A large number of activities were found to be part of the exploratory moment. This is not surprising given the emphasis that APOS theory makes in offering the generic subject in the institution opportunities to reflect on his or her actions to interiorize them into processes.

Meanwhile, sets (c) and (d) emphasize the work on the moment of introduction of the technique through the coordination of the above mentioned construction process and the transversal section and intersection processes to construct and interpret graphs of a diversity of functions. They also include some activities that can be considered to be part of the technological-theoretical part of the praxeology. The following activity combines parts corresponding to the exploration moment and parts corresponding to the technical-technological moment. Its objective is promoting students reflection on those actions corresponding to the intersections of subspaces of R^3, and, at the same time, the introduction of a technique that includes actions to construct a surface and also opportunities to interiorize them in the corresponding process:

In this problem the graph of $x = 9 - z^2$ will be drawn in three-dimensional space. This graph consists of all points in the set $\{(x,y,z): x = 9 - z^2\}$.

1. Draw in three-dimensional space all points where the plane y = 0 intersects the graph of $x = 9 - z^2$.
2. Draw in three-dimensional space all points where the plane y =1 intersects the graph of $x = 9 - z^2$.
3. Draw in three-dimensional space all points where the plane y = −1 intersects the graph of $x = 9 - z^2$.
4. What happens as y is given more and more positive and negative values?
5. Draw the graph of $x = 9 - z^2$ in three-dimensional space.
6. Reflect on what you did in the previous three activities. How, in general, are graphs in three dimensions sketched when the function's rule includes only two variables?

All the sets include activities that promote reflection on the introduced processes to favor its encapsulation in objects, and a coherent construction of a schema for R^3. These activities are also related to the technological- theoretical moment.

Tasks related to verification of the correspondence between sketched graphs and analytic representations, by using sketches of curves belonging to the sketched surface, were found in all the activity sets. These activities were considered as part of the moment of evaluation. The activity shown in figure 2 intends to evaluate the construction of the conversion from the analytical to the graphical registers.

The activities sets do not include specifically the discussion about the theory because it plays an important role in the Class Discussion phase of ACE cycle. But opportunities to justify answers, that can be considered as part of the institutionalization moment are included in the all the sets.

This analysis suggests, in general, that the study moments are balanced and that that the activities sets can be used effectively in the classroom. However, the challenge to reduce the number of activities associated to the exploratory moment, without altering the potential of the sets to promote the constructions predicted by the GD remains.

The activities were used in the classroom but the phase of Class discussion of the ACE cycle was not used. They were evaluated through interviews to 9 students in the group where they were used, and 6 students from a control group. Students were selected by their teachers using the same performance criterion. The analysis of the interviews was done by using APOS theory. It showed a clear difference between students of both groups favoring the experimental one. This can be taken as an indication that the activities sets promote an organization of the study process that has the potential to stimulate students' learning. It can be concluded from these results that the use of a didactic praxeology where the study moments are balanced contributes to the construction of the structures described in the GD. This study enabled us to show that points of contact exist that make the approach of the two theories possible.

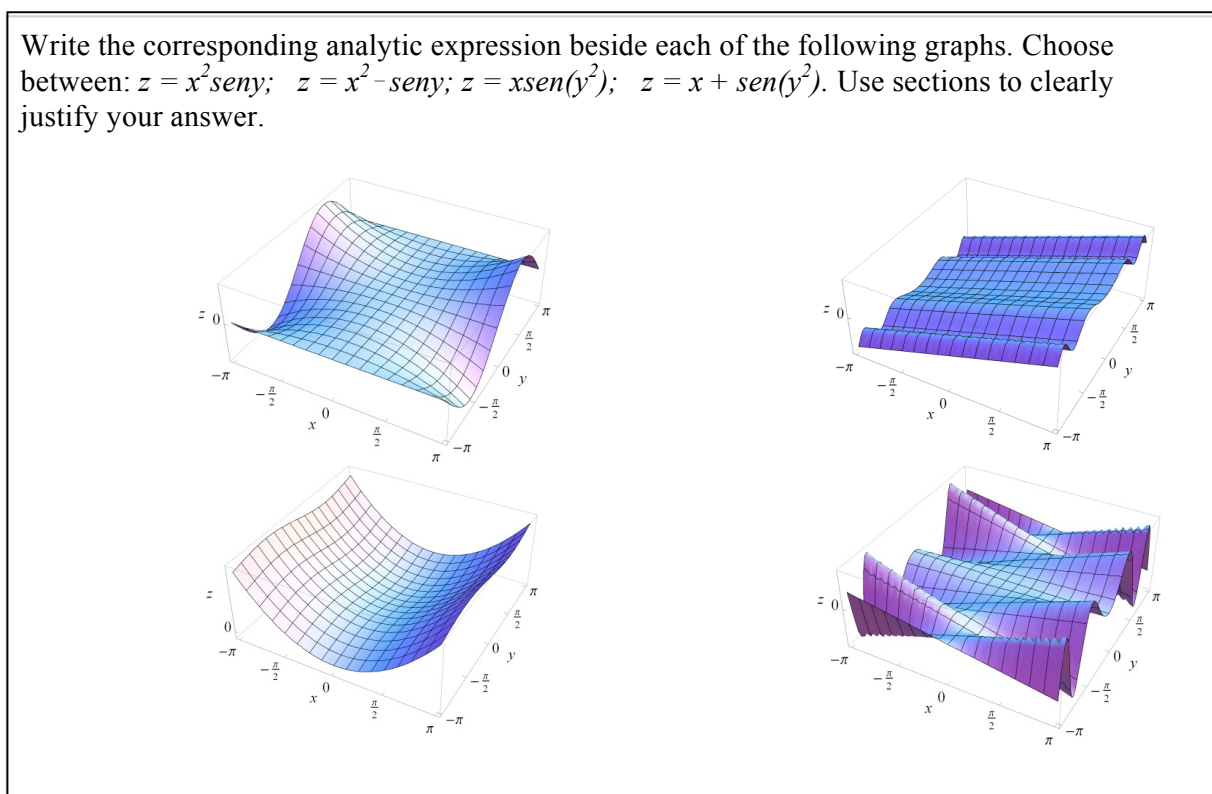
Write the corresponding analytic expression beside each of the following graphs. Choose between: $z = x^2 seny;$ $z = x^2 - seny;$ $z = xsen(y^2);$ $z = x + sen(y^2)$. Use sections to clearly justify your answer.


Figure 2. Conversion and justification activity.

Crossing methodological borders: Use of modeling in the teaching of Differential Equations and Linear Algebra

Linear Algebra and Differential equations are two basic courses in university mathematics that have a wide applicability both within mathematics themselves and in problems from other disciplines. Recent developments in mathematical research and in technology demand, at least in

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

principle, the search of new teaching strategies. This claim has not been taken into account by the university community in general. Results from research in mathematics education, on the other hand, offer information about how students learn many of the concepts of this discipline, and teaching methods that have proven to be effective. Modeling is a prominent one (For example, Rasmussen & Blumenfeld, 2007; English,Lesh, and Fennewald, 2008; Bas, Cetinkaya, & Kursat, 2009;Zandieh, & Rasmussen, 2010; Camacho, Perdomo, and Santos, 2012;Trigueros & Possani, 2013).

In a research project that was developed during five years in the institution where I work, we tried to respond to the questions: What results about students learning can be obtained when modeling problems are used in the teaching of linear algebra and differential equations? What aspect of students' knowledge can be recovered when they work on modeling problems in the classroom?

Research studies conducted with APOS theory did not include, up to that moment, the use of modeling problems in teaching; we looked for the possibility to coordinate this theory with a theory related to modeling. Models and modeling theory (MMT) (Lesh & Doerr, 2003) was selected considering two criteria. From the theoretical point of view it proposes the construction of mathematical concepts by means of the work of students in the description of the behavior of a situation in a real or realistic context which enables them, on the one hand, to use their knowledge, and on the other hand, to construct new knowledge. Its teaching methodology coincides with that of APOS in that both of them use collaborative work of students in small group and whole group discussion with the teacher as means to foster students' construction of new knowledge. Additionally MMT postulates a set of principles that the problem selected to develop a model must satisfy so that it can be successfully applied in the classroom (Carlson, Larsen, & Lesh, 2003). They can be useful in the design of situations. It can also help in extending APOS theory boundaries so that the introduction of modeling problems can be naturally inserted into the ACE cycle, and so that the development of knowledge from previously constructed concepts used by students can be described in terms of an adequate GD.

From the theoretical point of view, both theories postulate ways of constructing knowledge. It is thus possible to propose a possible coordination between them by considering that work on the original problem makes it possible to bring into play a mathematical model in which two types of activities can be done: one that can be used to analyze, develop and validate the mathematical model, and another in which the independent or guided activity on the mathematical model can be complemented by specific activities designed in terms of a GD. These two types of activities can be interspersed in cycles so that modeling results in the need for reflection and in the construction of those structures needed to the learning of new concepts, and these result in the possibility to look at the work done on the model from a different perspective that can foster the model's development. From the methodological point of view, MMT can be used to validate the way the proposed modeling problem works in terms of promoting new knowledge, while APOS theory can be used to analyze students' constructions and how they could be related to new activities that may promote the construction of the concepts of interest, since according to this theory, the use of previous knowledge is not enough to guarantee the construction of new knowledge. Moreover, APOS' teaching and research cycles can be naturally inserted in the modeling cycles proposed by MMT, and so, both theories can expand their borders to pose new teaching and research proposals. By using the coordination of these theories, a research project was developed where modeling problems were used in the teaching of differential equations and linear algebra. Two examples illustrate results that can be obtained through this type of dialogue, one in the context of differential equations and another in the context of linear algebra.

Development of new analysis tools

In the first case (Trigueros, 2014), the problem posed to students was: *A teacher, worried by the actual tendency in teaching and by students' management of information problem, has asked us to*

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

conduct a study about memorization and forgetfulness in the short run. In particular, she is interested in a report where the time that a person can keep the learnt information is made clear, as well as the time needed to forget it and what are the factors involved in those relations.

During a cycle of graphical exploration of the problem, as we called it, this exploration started from the students' own experience and the use of their schema for function. A first graphical model emerged together with the definition of variables (Figure 3a). Although at the beginning students tried to find an analytical expression for the function, in their dialogues they evoke their derivative schema in order to analyze the proposed graph:

> *Rosa:* The derivative can be used to specify the properties that the function we proposed must have, but… we don't have, nobody has the analytical expression and I don't know how to obtain it from the properties; I know for sure the other way around, to find the properties if I know the functions' rule.

The next cycle is identified by the introduction of variation into the solution of the problem. This enables students to suggest a possible model that can be illustrated by this dialogue:

> *Fer*: If we assume that each person can be assigned a memory coefficient and … what they have learnt grows from here to there but it is growing more slowly in each of these parts (he draws a polygonal curve with line segments), and then it starts decreasing, first quickly and then not so much until everything is forgotten, or almost everything …
>
> *Juan*: …It must grow more slowly here, and if the person has a certain memory capacity, a coefficient k, so that it first grows more and then less, it can be something like… (he writes $y'=k(y-T)$) because like this it cannot grow forever but will approach a point where it stops growing…

Group discussion is devoted to the advantages and disadvantages of writing an equation that includes variation. After a cycle where activities designed with the GD involving tasks for constructing differential equations and implicit functions are introduced, to respond to students' doubts when faced with an equation that does not contain the independent variable, students go back to work on the model. A cycle characterized by the analysis of the model's equation is identified. During this cycle two methods to analyze the proposed equation, that had not been previously introduced, emerge in different teams: the approximation of the solution function using the idea of derivative as a linear approximation, and the use of a graph of the derivative of the function against the function itself (phase plane) or its verbal description, as shown respectively in the next paragraphs:

> *Fer*: Here (showing the equation). If we use values to make it easier, (he writes: $y'=.5(50-y)$)… and if we use what we said before, the derivative as the slope, (he writes $y' = y-yo/t-to$), then from time zero to two, y prime is… …(he writes $y'=.5(50-y)=y/2$), then ... we have $y=25$, means that in the second time   he knows 25 data and the line would go from 0 to 2 and form 0 to 25, with slope 12.5. Then we do the same, but now we start with 2 and until, for example, 4 and y is 25, then (does calculations, not audible) we get y is 37.5 and we continue like that…
>
> *Nadia*: …I am thinking that if we graph that function y'… but as a function of $y,$ what would that mean?... Let's see … that graph (Figure 3b) is a line, its slope is positive. It says that $y'=0$ if $yo/k+1=y$. But it cannot be because where do we want a critical point? I think we want it in *1* because that means that everything has been learnt and then when she forgets it starts going down but this is up here.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 3(a). Exploration.   **Figure 3(b).** Graphical analysis of the model.

The activity continues with other cycles of activities designed with the GD and work on the model until the activity is finished with a cycle characterized by the experimental search of the model's parameters values.

In this experience it is worth highlighting the role played by the graph of the function as a trigger of a change in the way the problem is approached and in the emergence of new conceptual tools developed independently by students.

Independent constructions of concepts

In the context of linear algebra, a model for employment was presented to students (Salgado & Trigueros, 2015): *In an economy where the work force remains constant, there is a certain number of employed people in each period of time and a certain number of unemployed people in that same period. If we know the probability that an unemployed person finds a job in the next time period and the probability that an employed person looses it employment, how can we describe the dynamics of employment in time t? And, how will it behave in the long run?*

In this case some students used their previous knowledge, both from the linear algebra course, where they had previously worked on a population model to introduce difference equations in one variable, and from the economy courses to find an equation for the model:

A_2: … at each moment there is a certain number of employed and unemployed persons, but that number can change in the next time period …

A_3: It is true, we can think on the number of employed persons in the next period and that should be those who still are employed minus those that are now unemployed…

A_1: … in my opinion, the persons employed in that new period should be proportional to the number of persons that are employed and conserve it plus a proportion of those who were unemployed and get a job …

A_2: Yes, we know that p are the unemployed who find a job and q the employed that are still employed, well, I mean the probabilities (they write $x_{t+1} = qx_t + py_t \rightarrow$ employment)

A_3: Then the model is a system, there is another equal equation for unemployment (they write $y_{t+1} = (1 - q)x_t + (1 - p)y_t \rightarrow$ unemployment)

Students worked to validate a solution proposed for the model's equation, which was obtained as a generalization of the solution for the population model by introducing the system's matrix. During their work these students used their previous knowledge about matrices and exponentials to do a process on the resulting equation (Figure 4).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 4. Using a schema, students find the definition of eigenvectors and eigenvalues.

Their work showed evidence that they had constructed relations among the concepts introduced in the course. This can be characterized as the construction of a schema for the solution set of a linear system of equations that includes the concepts of solution, matrix, linear Independence, null space and determinant.

This process led the students to the definition of the concepts of eigenvalues, eigenvectors, and eigenspaces that had not been introduced before. Students' reflection on their actions led them to construct these concepts as processes. Work with activities designed with the GD, where students work was reconsidered and institutionalized, gave them an opportunity to construct these concepts as objects.

Later, students calculated eigenvalues and eigenvectors using numbers for the parameters:

A_1: …for k_1 equal to one, the vectors have this form $v = (2x_2/3, x_2)$ and x_2 is a parameter; and for $k_2 = 1/6$, the vector is $v = (2x_2/3, x_2)$.

A_3: In both cases x_2 is arbitrary, that is, the family of solutions in the solution set. Is the parameter the same in both cases?... No, then let's call one x_1…

A_2: That's true... then…only for those values for k and those values for v, the proposed functions are solutions of the model's system.

A_3: Can we use a specific case for each family of vectors?

A_1: I don't know, but, in this case, a particular case … for $k_1 = 1$, $v_1 = (2/3,)$ and for $k_2 = 1/6$, $v_2 = (2/3,)$. Is this right?

A_3: For each k, the vectors span a line since there is only one arbitrary variable in each case.

After a cycle with activities designed with the GD intended to institutionalize and give students new reflection opportunities, during the whole-group discussion, these same students related these concepts with the modeling problem.

A_3: … We found that eigenvalues were $k_1 = 1$ y $k_2 = q - p$, that is, different, one is independent of the given probabilities and the other is related to the difference of the probability that a person continues being employed and that for an unemployed person to get a job …

A_2: We used those values and found the eigenvectors. Well, we chose one for each k. For $k_1 = 1$ we found $(p/(1-q), 1)$ so it is related to the rate of the probability that an unemployed person finds a job in the next period and that an employed person loses the job in the next period- Something like a rate of the probabilities of changing status. … for the other k, $k_2 = q - p$ it was independent of the values of the probabilities, it was $(-1, 1)$ and we were not able to explain this …also, because we drew a graph (Figure 5) and the corresponding eigenspace's vectors always have a negative component …

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

A₃: Then the constants don't have a relation with initial conditions, although it was so in the population problem where those conditions appeared in the solution, and we discussed their role in terms of a family of solutions. But here, where are the initial conditions of the problem? Don't they play any role?

The teacher returned the question for students to work in teams and asked them to predict the behavior in the long run. During work on a new cycle of activities designed with the GD, students made reference to the concept of base:

A₃: We chose one particular vector for each solution set separately, but, could we take one of each family to write a linear combination and span, maybe, would be R^2…

This can be taken as evidence that these students constructed relations between their previous knowledge and the new one.
Figure 5. Long term behavior.

Students, in general showed difficulties to understand the resulting vector functions. They had not studied them yet. Some of them decided to graph each of the components to find conclusions from each of them, to find the long term behavior, and to conclude that it converges to a solution that corresponds to the eigenspace.

This experience put forward the emergence of the concepts of interest in the work of students, without any intervention from the teacher, and the construction of a schema by some students which shows that they had constructed relations among the concepts introduced before. Even though during the interviews conducted after the course it was found that some difficulties persisted in cases where dimensions were larger, at least three students showed evidence of having constructed on object conception of the concepts of interest.

Many research studies about the didactical use of modeling insist in the motivational aspect of these type of problems for students. These studies confirm this fact. However, they also demonstrate that when students are involved in interesting problems and are free to reflect, they can develop new strategies which promote the construction of concepts and of relations among them. Modeling problems can favor the learning of difficult and abstract concepts, and new knowledge can, in turn, be applied to the solution of new problems. The advantages of the coordination of the two theories, on the other hand, was made patent by the permeability of their boundaries and in the expansion of the problems that each of them can address.

Final Comments

The experiences of crossing borders, dialogue, and search for possible ways to coordinate theories by carefully analyzing their basic hypothesis and their theoretical positions showed, in each case, encouraging possibilities of approaching them without confrontation, and of finding contributions that mutually enrich them. They also underline that, a serious and open approach

enables the establishment of dialogues between theories even in those cases where the theories seem to be distant from each other.

Besides the theoretical enrichment resulting from constructing bridges between different theories, the application of the tools that emerged from each of the dialogues made clear their potential to be applied in the design of teaching strategies that can favor students' learning, and the possibility of thinking differently of our own research work.

The theoretical borders can appear in a respectful and tolerant dialogue as flexible and dynamic boundaries that make the enlargement of their application domain and the interchange of ideas possible, without losing their own identity. Borders that open themselves and let new phenomena appear. These phenomena would be impossible to perceive when only one theory is used. The challenge we face as a community is to approach the study of mathematical education phenomena by creatively building bridges so that even though borders between different theories remain, they can be made porous and let the discipline be enriched through collaborative relations.

Curriculum and Related Factors

IMPLEMENTATIONS OF CCSSM-ALIGNED LESSONS

We analyzed 52 middle school mathematics lessons from multiple states and curriculum contexts to understand how teachers were enacting the CCSSM. The teachers stated that all of the lessons were CCSSM-aligned. We categorized curriculum materials according to two approaches, with one approach associated with curriculum programs funded by NSF and the other representing curriculum programs commercially produced, typically from a large publisher. We analyzed the nature of mathematical activity and level of interactions in the lessons. We found significant differences across curriculum approaches in the mathematical activity categories related to cognitive demand and in the level of interaction. The implications are that curriculum programs strongly mediated the enactment of the CCSSM.

Keywords: Curriculum Analysis, Instructional Activities and Practices, Standards, Middle School Education

The *Common Core State Standards for Mathematics* (CCSSM) (National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010) were initially adopted by 45 states plus the District of Columbia, and, despite the rollback in some states, the CCSSM or CCSSM-based standards are still in place in most states. Thus, there is a relatively common articulation of content and the progression of content across the grades in the CCSSM-adopting states. This provides researchers an opportunity to consider the impact of curriculum programs on how the CCSSM get taken up by schools and teachers. Furthermore, the CCSSM framers were agnostic with respect to curriculum and instructional approaches (McCallum, 2012), which provides potentially enhanced roles to curriculum materials as teachers work to interpret and implement the standards. Consequently, the widespread adoption of the CCSSM presents an opportunity and need for researchers to understand how districts and teachers interpret standards and to understand the role of curriculum materials in the process of interpreting and enacting those standards.

Teachers' initial interpretations of the CCSSM, when compared to prior state standards, were that the CCSSM required a greater emphasis on problem-solving, discovery, communication, and conceptually-driven instruction (Davis, Choppin, Roth McDuffie, & Drake, 2013; Choppin, Davis, Drake, & Roth McDuffie, 2013). Although teachers expressed a relatively strong view of the student-centered nature of the CCSSM, prior research based on teachers' enactments of similar recommendations in the National Council of Teachers of Mathematics (NCTM) Standards documents (NCTM 1989, 1991) shows that even the most reform-minded teachers did not implement the recommendations in ways beyond superficial features (Spillane & Zeuli, 1999). However, much of the research on the implementation of the recommendations in the NCTM Standards primarily occurred before curriculum programs based on those documents were developed and widely disseminated. In this study, we explore the association between district-adopted curriculum programs (e.g., *the designated curriculum* [Remillard & Heck, 2014]) and instruction that resulted when teachers used those programs to plan and enact lessons (e.g., *the enacted curriculum*). These lessons

– and the designated curriculum – were ostensibly aligned with the CCSSM (e.g., *the official curriculum*).

Framework

We frame our analysis by distinguishing between two broad approaches to curriculum and instruction. In describing each approach, we connect conceptions of curriculum design to conceptions of classroom instruction. In the first approach, we connect the notion of *curriculum as delivery mechanism* to that of *direct instruction*. In the *curriculum as delivery mechanism* approach, knowledge is detached from an authority or expert (i.e., textbook, teacher) and transmitted to novice learners (students), allowing those far from classrooms to exert control over content (Datnow & Park, 2009). Curriculum design is based on explaining and modeling concepts and procedures and presumes that learners have minimal understanding of the subject matter or intuitive understandings. Mastery focuses at the level of lesson or topic, with fluency expected on one topic before proceeding to the next. The treatment of language in curriculum materials from this approach mirrors the treatment of mathematics content. There is typically an emphasis on early formalization and precision, with little validation of less formal or everyday terminology, and terms are defined and explained before students have opportunities to explore the content. These conceptions of curriculum align with models of direct instruction, as defined by Munter, Stein, and Smith (in press). Munter and colleagues explain that direct instruction is dominated by teacher explanation and demonstration of procedures or definitions, which students then practice to develop accurate and fluent reproduction of those procedures or definitions.

In the second approach, we connect *curriculum as epistemic device* to *dialogic instruction*. In considering curriculum as epistemic device, the primary goal of curriculum is to provoke interactions that generate understanding. The role of tasks in curriculum materials is to elicit and progressively refine student thinking, individually *and* collectively, as contrasted with serving as a delivery mechanism for content. This conceptualization of curriculum design builds from a notion of text as *thinking device* that promotes dialogic interaction (Wertsch & Toma, 1995). A primary characteristic that shapes task affordances is the potential for heterogeneous approaches that vary in terms of their entry points and sophistication, or what has been called *low-threshold, high ceiling* tasks. This metaphor aligns with *dialogic instruction*, as described by Munter and colleagues (in press), which emphasizes students' collaborative work on challenging tasks and the positioning of students as co-participants in classroom discourse and as emerging mathematical authorities. These distinctions allow us to parsimoniously characterize distinct approaches evident in teachers' interpretations and enactments of the CCSSM, and to tie characteristics of curriculum to characteristics of instruction.

Curriculum Types

Building from the two approaches outlined above, we characterized curriculum programs into two types. Programs developed in ways aligned with the epistemic device approach, comprised exclusively of National Science Foundation (NSF)-funded curriculum programs, we labeled as ED Programs. These programs have some or all of the following characteristics:

- Problem contexts serve as the basis of exploration for multiple lessons.
- Students explore a problem and/or mathematical concept *before* concepts, procedures, and/or mathematical terms are formalized.
- Mathematical practices, particularly problem solving, reasoning, and argumentation, are considered essential in teaching and learning.
- Representational fluency is promoted through work with individual representations and the connections among representations.

- Grouped work is collaborative, used for high level tasks, and often involves a group product and/or presentation (Lappan & Phillips, 2009).

Programs aligned with the delivery mechanism approach, we labeled as DM Programs. These programs, comprised almost exclusively of publisher-produced programs, are geared primarily towards procedural fluency, with characteristics of direct instruction, including:

- Problems may be set in context, but the contexts vary with each problem are not focused on students reasoning analogically about the mathematics.
- Problem solving steps and procedure are described or provided through examples.
- Formal definitions are presented before students use terms or constructs associated with specific terms, and precise use of language and efficient procedures are considered essential to developing conceptual understanding.
- Group work and/or seat work are used primarily to practice problems demonstrated by the teacher (*cf*., Battista, 1999).

Methods

We analyzed 52 lessons from the video recordings of the lessons. The teachers stated that the materials and lessons were aligned with the CCSSM content and practice standards. We developed an observation tool designed to distinguish between direct and dialogic forms of classroom instruction. The tool was originally adapted from the instrument used in a large scale study (Tarr et al., 2008) to characterize the extent to which lessons aligned with what they termed *standards-based instruction*. To that end, the instrument emphasized conceptual understanding, multiple solutions and representations, and recognizing and building from student thinking. We ultimately transformed the instrument and associated analytic techniques by utilizing a modified time-sampling approach. We transcribed most of the whole class portions of the lessons and group work as the audio quality permitted. We parsed the transcripts into roughly two- to four-minute chunks delineated by participation structures and topical foci. We bounded the analytic segments first by participation structures (e.g., seat work, whole class discussion, group work), then by a combination of duration and topical focus, similar to what Mehan (1979) termed a *topically related set*. Given that lesson ratings were derived as a ratio of the number of lesson segments in which a code occurred divided by the total number of lesson segments, we wanted to maintain roughly similar time intervals for each lesson segment. Consequently, if a discussion around one problem extended beyond three or more minutes, we divided that discussion into multiple segments of roughly two minutes each. Similarly, if there were a series of rapid resolutions to a set of problems that were based on the same kind of mathematical activity, we combined these sets into one segment for analytic purposes. Further description of how we coded each segment is described below.

Data Sources

The data came from a larger NSF-funded study that explored teachers' perceptions of the CCSSM, the ways teachers were prepared to teach the CCSSM, how teachers drew upon curriculum materials to plan lessons they viewed as CCSSM-aligned, and how they enacted those lesson plans. We had comprehensive data sets for 52 teachers, including lesson observations from the 2013-2014 School Year. Of the 52, 21 of the lessons came from teachers using ED materials, and 31 came from teachers using DM materials. Sixteen of the ED lessons involved the second (CMP2) or third (CMP3) edition of Connected Mathematics Program, four of the lessons involved College Preparatory Mathematics (CPM), and one involved Core-Plus Mathematics. For the DM materials, 13 used Glencoe, five used *digits*, four used Prentice Hall, three used Math in Focus, and others used similarly organized curriculum programs. For 13 of the teachers using ED programs, their districts

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

had recently adopted the programs specifically to address the CCSSM. Districts for seven of the other teachers had adopted programs before the CCSSM were adopted. Twenty-five of the 31 teachers using DM programs worked in districts that had recently adopted the programs specifically to address the CCSSM. Of those 25, eight used other materials regularly, including in the lessons we observed. Six of the DM teachers' districts had not adopted new materials; these teachers used a range of materials aligned with the DM approach.

Data Analysis

We coded lessons using three broad sets of analytic categories. We coded lessons using three broad sets of analytic categories. The categories were: *Nature of Mathematical Activity*, *Lesson Mode*, and *Elicitation and Presentation of Student Explanations*. The first set, *Nature of Mathematical Activity*, included five sub-categories, three based on levels of cognitive demand from the work of Stein and colleagues (Stein, Grover, & Henningsen, 1996), and two that were inductively developed as a result of the data analysis, as described below. The categories derived from the cognitive demand literature included: *recall, memorization, or basic application of definition or rule*; *procedural or computational routine*; and *procedure plus*. These three categories correspond to the first three cognitive demand categories of *memorization*, *procedures without connections*, and *procedures with connections*, respectively, but were revised to provide additional descriptive detail to facilitate coding and to reflect trends that emerged in our data. We developed two new categories to represent patterns identified in the mathematical activities observed in the lessons. The first, *interpreting or generating representations*, refers to tasks that involved creating or interpreting information a table, graph, equation, or other representation. This category involved mathematical activity that required students to translate information across types of representations or to extract and describe a pattern evident in a representation. As such, the activity extended beyond simple recall or application but did not necessarily involve a procedure. Consequently, we deemed it as higher cognitive demand than the *recall* category and aligned more with *procedure plus*, though it didn't involve a procedure. The second new category, *developing definitions or formulas*, refers to when tasks involved creating a definition or formula. This is different from when the teacher simply provided a definition, which was categorized as recall or memorization. We found this category most often occurred in geometry lessons, though Munter et al. (in press) emphasize the need for teachers and students to co-construct definitions across all strands when appropriate.

The Lessons Mode categories were used to make two distinctions. The first distinction was whether a segment predominantly occurred before students had an opportunity to work (alone or in groups) on a problem or occurred after students had an opportunity to work on a task. We considered cases when the teacher presented and explained examples in whole class discussions as having occurred before students had an opportunity to work on a problem, even if the teacher engaged in recitation-style interactions with students. The second distinction characterized the interactions within the segment. If the teacher strictly or primarily engaged in Initiate-Respond-Evaluate (IRE) interactions or spent the entire segment explaining the mathematics or the solutions to problems, then we characterized that as low-interactive. Segments were characterized as low-interactive if they were primarily comprised of a series of rapid evaluations of the accuracy of students' responses. A segment was considered high-interactive if the teacher elicited responses without engaging in immediate evaluation and if the teacher pressed students to explain their answers and to respond to the answers of other students. These two distinctions produced four modes, a pre- and post-work low interactive, and a pre- and post-work high interactive. We also included a fifth lesson mode, termed *directions or administrivia*, to code segments when the teacher was providing directions, taking attendance, attending to classroom rules, or the like. These lesson modes provided us a way to characterize the lessons as involving direct or dialogic instruction.

The third set of codes, Elicitation and Presentation of Student Explanations, included three categories that are relatively self-explanatory: teacher elicited student strategies or interpretations; teacher pressed students for steps and justification for steps; and students explained solution strategies.

We coded each segment with at most one code from the Mathematical Activity and Mode categories, and as many as appropriate from the Student Explanations categories. There were segments for which the nature of mathematical activity was not clear, so no code was applied. For each lesson, we divided the number of segments in which a code occurred by the total number of segments and then multiplied by eight in order to avoid having the ratings clump around one rating number, usually the lowest numbers in the scale given the relatively low occurrence of some codes. We added a one to each rating to avoid having values of zero, and rounded each rating to get an integer scale from one to nine. We then averaged the codes for each category across each curriculum type and used Excel to apply a two-tailed t-test of different samples of equal variance, with a significance level of 0.05.

Results

We found significant differences in the lesson segment codes across the ED and DM materials. In terms of the Nature of Mathematical Activity, the ED lessons had significantly fewer segments coded as *recall, etc.* ($p < 0.01$) or *procedural or computational routine* ($p < 0.01$) and significantly more segments coded as *interpreting or generating representations* ($p < 0.05$) and *procedure plus* ($p < 0.05$). Although there were relatively more ED than DM segments coded as *developing definitions or formulas*, the **difference was not significant** ($p < .225$). See Table 1 for a summary of the Mathematical Activity categories.

Table 1: Frequency and p-value for Mathematical Activity Categories

	Recall, memorization, or basic application of definition or rule	Interpreting or generating representations	Developing definition or formula	Procedural or computational routine	Procedure Plus
Frequency - ED	2.0	2.7	1.7	1.8	2.2
Frequency - DM	3.4	1.6	1.3	3.1	1.4
p-value	0.002	0.015	0.225	0.006	0.04

Similarly, in the Lesson Mode categories, there were significantly fewer ED segments coded as low-interactive / pre-work ($p < 0.01$) and significantly more ED segments coded as interactive (both pre- and post-work) ($p < 0.01$ in both cases). The only codes not significant were low-interactive post-work, though there were relatively fewer ED segments with this code ($p = 0.17$), and *directions or administrivia*, which occurred relatively equally across types $p = .33$). See Table 2 for a summary of the Lesson Mode results.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 2: Frequency and p-value for Lesson Modes

	Presentation and explanation of task and mathematics in the task, primarily characterized by teacher explanation and IRE exchanges that evaluate students' understanding of facts and procedural knowledge (pre-work, non-interactive)	Teacher engages students in non-evaluative exchanges to establish the meaning of the problem context or to establish the mathematical focus of the task (pre-work, interactive)	Explanation of task and mathematics, typically after students had an opportunity to do work, primarily characterized by teacher explanation and IRE exchanges that evaluate students' accurate completion of the task (post-work, non-interactive)	Probing for, sharing of, or discussion of student strategies, characterized by non-evaluative exchanges in which the teacher elicits and probes student understanding of the task or strategies (post-work, interactive)
Frequency – ED	2.9	1.9	2.6	2.9
Frequency – DM	4.9	1.1	3.3	1.16
p-value	0.0004	0.002	0.17	0.0001

In the Elicitation and Presentation of Student Explanations categories, there were significantly more ED lesson segments coded as *teacher elicited student strategies or interpretations* ($p < 0.01$) and *teacher pressed students for steps and justification for steps* ($p < 0.01$). Though there were more ED segments coded as *students explained solution strategies*, the difference was not significant ($p = 0.15$).

Discussion

There was a strong association between curriculum types and the type of instruction, as characterized by the nature of mathematical activity, the level of interactivity, and emphasis on student explanations. That is, curricula deemed as aligning with curriculum as delivery mechanism were strongly associated with instructional forms that were predominantly encapsulated by Munter and colleagues' (in press) description of direct instruction, and curricula deemed as aligning with curriculum as epistemic device were strongly associated with instructional forms that were predominantly encapsulated by Munter and colleagues' description of dialogic instruction This finding is consistent with earlier case studies of eight teachers using two different curriculum programs, as part of the larger project. This occurred even though multiple curriculum programs, schools, and states were present in each of the Type 1 and Type 2 samples. Even though some of the differences may be due to underlying perceptions of the CCSSM (which we are exploring), the results lend credence to the notion that curriculum materials are strong mediating factors in enactments of the CCSSM, and more generally, that the designated curriculum is a strong mediating factor between the official curriculum and the enacted curriculum.

Although strong majorities of participants in the survey samples and interview samples from the larger study reported that the CCSSM required more communication, problem solving, exploration, and overall rigor than past standards (Davis, Choppin, Roth McDuffie, & Drake, 2013; Choppin, Davis, Drake, & Roth McDuffie, 2013), the lessons involving Type 2 materials typically lacked these features. Few teachers using the Type 2 programs expressed dissatisfaction with the fit between their materials and the CCSSM, suggesting that the designated curriculum served as the de facto representation of the official curriculum, and the teachers felt as long as they were using the materials, they were addressing the CCSSM. The results from the Type 2 teachers are consistent with results from lessons observed soon after the release of the NCTM Standards documents in which most teachers struggled to incorporate the recommendations in their lessons beyond surface features (Spillane & Zeuli, 1999), lessons conducted without the benefit of curriculum programs designed to comprehensively integrate the recommendations.

A plausible explanation for the differences in the observed instruction is that there are characteristics of the Type 1 materials that contribute to instruction rated as having higher cognitive demand mathematical activity, greater emphasis on interactivity, and a greater focus on student explanations. One possible explanation is that the materials convey underlying pedagogical messages, and the teachers create more opportunities for exploration and communication to follow what they perceive as the wishes of the curriculum designers. A second possible characteristic is the inclusion of task sequences in which students are first presented tasks "to which students do not have an immediate solution, but must wrestle with for a while without the teacher's interference" and then presented tasks that "help them become more competent with what they already know" (Munter et al., in press, p. xx). These design features are built into the Type 1 programs (Lappan & Phillips, 2009), and, even though there is typically wide variation in which these features are taken up by teachers (Tarr et al., 2008), there was nevertheless a stark overall contrast in our data between the Type 1 and Type 2 lessons, suggesting the presence of such features contributed to teachers' instructional decisions.

There were four categories that did not result in significant differences. The first, *developing definitions or formulas*, was most strongly associated with geometry lessons, of which there were few, and the lack of presence of this activity in other strands made the overall mean low across both types. The lack of significant difference in the post-work non-interactive Lesson Mode reflects the relatively even distribution in the Type 1 post-work lesson segments between interactive and non-interactive segments. That is, teachers using Type 1 materials engaged in IRE-style interactions and teacher-led explanations almost as much as they facilitated more interactions or emphasized student explanations. This compared to the Type 2 lessons, in which post-work lesson segments were rated as non-interactive fourteen times as much as they were rated interactive. Nevertheless, the Type 1 lessons included a similar quantity of non-interactive segments, so the difference between types was not significant. The third category whose difference was not significant was *directions or administrivia*, reflecting the relatively equal occurrence of this code across both types, suggesting that providing directions, taking attendance, managing behavior, and so forth is a staple of all lessons. The fourth category, *students explained solution strategies*, like the *developing definitions or formulas* code, did not occur frequently, with low means across both types. So, while teachers often elicited and probed students' explanations, there was either inadequate follow-up so that the student actually provided a full explanation, or the students were not able to provide a full explanation. Nevertheless, the low means (1.62 for ED, and 1.19 for DM, with 1 indicating no occurrence) across both types suggests that students still rarely have opportunities to provide comprehensive explanations for their solutions, approaches, or strategies.

The consistent presence of interactive forms of instruction in the ED lessons deviates in substantive ways from prior results of large-scale observations of middle school classrooms (Jacobs et al., 2006; Stigler & Hiebert, 1999), studies that largely took place before the widespread dissemination of NSF-funded materials. The results, however, are more in line with the findings of Tarr et al. (2008), whose study included NSF-funded programs. Our results, along with those of Tarr et al. (2008), suggest that NSF-funded programs can mediate longstanding lesson structures to make instruction more focused on student thinking and students' explanations.

Implications

An implication from our findings is that the choice of curriculum programs – whether by district, school, or teacher – is associated with instructional approach. An underlying question, then, is what these entities were responding to in their choice of curriculum programs, especially if the ostensible goal – to align instruction with the CCSSM – was the same across the contexts we studied. What messages or information were the schools and districts responding to, and what messages did they

want to send with their choice of programs? What does their choice of curriculum program say about the depth with which or the evidence with which decisions about curriculum programs were based?

A second implication is that interpretations of the official curriculum – the CCSSM – are heavily mediated by decisions and curricular choices at the local level. That is, the designated curriculum is potentially the strongest mediating factor in the ways that the CCSSM are being enacted. This suggests challenges for policy makers who hope to change classroom instruction without providing a stronger articulation of what classroom practices should look like or providing materials that have been developed with these practices in mind.

WOO! AESTHETIC VARIATIONS OF THE "SAME" LESSON

Efforts to enhance the aesthetic impact of mathematics lessons must account for the role of teachers in shaping the unfolding mathematical content of their enacted lessons. In this paper, we draw from Dietiker (2015) to describe differences in the mathematical stories of the enacted lessons of two veteran teachers teaching the same lesson. We identify connections between these differences and the variations in student experiences as illustrated by visible student reactions.

Keywords: Curriculum, Curriculum Analysis, Affect, Emotion, Beliefs, and Attitudes

How a story is told matters. For example, learning at the beginning of the play that Romeo and Juliet will die (e.g., in Shakespeare's play) offers an audience a very different aesthetic experience than when the storyteller chooses to withhold this information (e.g., in the 1968 movie). When mathematics lessons are interpreted as stories (Dietiker, 2013, 2015), the same dynamic can be recognized. The way in which information in a mathematical story is withheld and revealed can significantly impact the aesthetic experience of the students.

The aesthetic nature of mathematics teaching and learning has been largely ignored and needs more study. Although research has begun to understand the aesthetic dimensions of mathematical learning (e.g., Sinclair, 2004), little is known about how mathematics lessons can be crafted to take advantage of aesthetic opportunities. We use the term "craft" to describe the role of both designing curriculum and of teaching. Interpreting teaching as creative work is consistent with Brown (2009), who suggests that teaching with written curricula is similar to how musicians perform with sheet music. He argues that, "practitioners bring to life the composer's initial concept through a process of interpretation and adaptation… In both cases, no two renditions of practice are exactly alike" (Brown, 2009, p. 17).

In this paper, we demonstrate that in a mathematics classroom, how a story is told is just as important to its aesthetic impact as the story itself. That is, if we want to create opportunities for surprise or anticipation, we need to do more than design new mathematics curriculum and instead must consider the ways teachers enable and constrain how the content unfolds throughout the lesson. We present a case study of two veteran teachers teaching the same lesson from the same textbook with notably different student reactions to demonstrate the aesthetic variations of telling the "same" mathematical story. We also explain how these aesthetic differences resulted from the way in which the mathematical content unfolded throughout the lesson enactments.

Theoretical Framework

Mathematical lessons can be interpreted as mathematical stories (Dietiker, 2015). This interpretation specifically offers a way to recognize the logical and aesthetic dimensions of the unfolding mathematical content of a lesson. Not limited to contextual story problems, this framing foregrounds sequential changes that occur over time ("acts"), defined as the distinct portions of the mathematical lesson which can be identified by changes in the mathematical characters (the objects of the lesson, such as a quadratic function), actions (the acts by a student or teacher to manipulate an object), and/or settings (the representational "space" in which the mathematical characters and

actions are found). Just as literary stories are "told" by a narrator, mathematical stories are narrated by the utterances of the teachers and students.

In order to recognize the aesthetic dimensions of a mathematical story, we focus on the mathematical plot, which in literature is the tension felt by students between what is known and what is desired to be known in the story (Nodelman & Reimer, 2003). Analyzing the mathematical plot enables the investigation of how a mathematical sequence can generate suspense and surprise. Barthes' (1974) describes the transition from question to answer with codes: *question formulation*, *promise of an answer*, *snare* (misleading direction), *equivocation* (misleading ambiguity), *jamming* (the question is unanswerable), *suspended answer* (the delay of the answer), *partial answer* (progress), and *disclosure of the answer* (endorsing the answer). The transition from asking to answering a question forms a story arc. In mathematics classrooms, story arcs include questions asked by teachers, students, and curriculum. In addition, some story arcs may be based on implicit questions, raised by the goals of an activity but never stated.

Just as is the case with literary stories, the aesthetic value of a mathematical story varies by individual. That is, there is no "best" way a story can be told for everyone. However, literary theory suggests that there is a relationship between the form and function of narrative. It is thus an assumption of the mathematical story framework that distinguishing the different forms of the unfolding mathematical content throughout a lesson can identify how observed aesthetic reactions of students can be understood. For example, long story arcs containing nested shorter story arcs may give a larger purpose to the shorter questions and, thus, coherence for the lesson. In fact, without long story arcs, a long sequence of short story arcs may prevent a student/reader from recognizing a purpose for each question. Longer story arcs may also create opportunities for twists in the plot that lead to surprise and anticipation. In this study, we examine the relationship between the form of the mathematical plot and the evident aesthetic of an enacted lesson by asking the question, "How can enactments of the same written curriculum differ and what role do these differences play in the aesthetic reactions of the students?"

Methods

The current study compares two enactments by different algebra teachers based on the same textbook lesson. The goal of this research project is to learn more about the different ways that expert teachers, from diverse settings and communities, enact the "same" curriculum lessons in their respective classrooms. The lesson selected for this analysis focused on a method of solving quadratic equations by factoring using the zero product property.

In order to minimize the interference of classroom management issues on curriculum enactment, or unfamiliarity with the same written curriculum (Kysh, Dietiker, Sallee, Hamada, & Hoey, 2012), the teacher participants were required to have at least five years experience teaching mathematics, at least three years of which must have involved the selected written curriculum. Additionally, participants were selected only if they had a strong record of excellence in teaching (e.g. National Board certification, receiving a teaching award, a regular leader of professional development, etc.). The selected enactments were taught by two teachers in two different geographical regions (Mr. J and Ms. W) with 8 and 20 years of teaching, respectively, and 4 and 10 years experience, respectively, using the textbook.

The enactments were observed and videotaped in Spring, 2015, which included the video recording of the whole class as well as one focal student group within each class. Since a portion of each enacted lesson contained group work, the mathematical plots described in this paper represent the mathematical stories from the perspective of this selected group of students, including both whole class discussion and small group discourse.

To interpret the mathematical plots, the videos were transcribed and then analyzed to identify where acts start and stop by identifying when the mathematical characters, actions, and/or settings

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

changed and the mathematical story advanced. Next, the researchers identified all of the mathematical questions formulated throughout the lesson, identifying questions that were asked by the teacher, student, or curriculum. Finally, each of the acts were coded using Barthes' codes (described earlier) by researchers in pairs who then came together as a whole group to resolve differences. The resulting mathematical plot diagrams for the two enactments are displayed in Figure 1 (for Ms. W's lesson) and Figure 2 (for Mr. J's lesson). In these diagrams, a shaded cell without a code means the question is still open. Note that the colors were used to highlight formulated questions that were common to both lessons. In addition, the width of the columns containing the acts do not signify increments of time. Rather, the columns represent the acts, which are portions of the lesson for which the story changes. These acts vary in elapsed time, which can be seen in the elapsed times provided in these diagrams.

Figure 2. Mr. J's mathematical plot. See the caption in Figure 1 for the coding reference. Colors other than light grey indicate a question that was identified in both enactments.

Findings

On the surface, these lesson enactments appear very similar. Both enactments contained 13 acts and were approximately the same length (Mr. J: 39 minutes, Ms. W: 37 minutes). Both teachers focused their lessons on the same set of tasks in the algebra textbook, omitting the same task at the end of the lesson. Sixteen mathematical questions were common to both lessons and, with the exception of two questions, these were all introduced in the same order. A structural analysis of these diagrams can be found in Richman, Dietiker, and Brakoniecki (2016).

Despite these similarities, interesting differences in how the mathematical ideas unfolded across the lessons are evident. For example, Mr. J's lesson contained 54 story arcs while Ms. W's had 42. Ms. W's enactment contained a higher proportion of story arcs that remained open for multiple acts (52% compared to 30%) and yet her story arcs collectively demonstrate that her lesson contained two separate and disjointed activities while Mr. J's lesson had story arcs that unified the two activities. In addition, Mr. J's enactment had more story arcs open per act (an average of 9.4 story arcs open per act as compared to Ms. W's 6.8).

At this top level, it may be difficult to recognize how and why particular moments of a lesson occurred. Thus, comparisons of the two activities are next described to explain potential aesthetic differences for students in these two enactments.

Determining a Parabola

Both teachers began with the first task of the textbook lesson. The task prompted students to consider the number of points needed to determine a parabola. In both enactments, the same question (*What information is sufficient to sketch a parabola?*) arose, yet the way in which this question played out in the two classrooms was different. Ms. W's enactment enabled the question to arise early and remain open for Acts 1 through 5. In contrast, this question did not emerge in Mr. J's enactment until Act 3, after which it was answered quickly (see Figure 3). As with the plot diagrams in Figures 1 and 2, the width of each cell does not indicate the amount of time elapsed for the given act. Instead, the diagram is formatted to have the same overall width so that Acts 1-5 of Ms. W's lesson represents the same activity as Acts 1-3 of Mr. J's lesson.

What information is sufficient to sketch a parabola?

Ms. W's Lesson	1	2	3	4	5
Question #3	163	63	3		3A

Mr. J's Lesson	1		2		3
Question #15					13A

Figure 3. Story arcs representing how the question "What information is sufficient to sketch a parabola?" was raised and answered in two different enactments. See the caption of Figure 1 for the reference of numerical codes.

Ms. W. In Act 1, Ms. W revealed the *y*-intercept of an unknown parabola and asked students to sketch it. When students encountered difficulty, "What information is sufficient to sketch a parabola?" was implicitly raised (*formulated question,* code 1). The ambiguity on whether the information given was sufficient, was evident by students, "Wait, that's the only clue we get?" (*equivocation*, code 6). Another student notes, "It could be so many things!" (*progress*, code 3). Next, [Act 2] the teacher challenged the students to sketch a second parabola with only the *x*-intercepts (*equivocation*, code 6). Anticipation was evident in the celebration by two students when they guessed correctly with high fives and "Woo!" (*progress*, code 3). During the third challenge [Act 3], a student described his struggle to sketch a parabola with symmetry (*progress,* code 3). In Act 4, Ms. W asked this student to recount his progress to the class (*no new information*). In a discussion [Act 5], a student noted that with only one or two points the parabola could point up or down (*progress*, code 3). The answer to "What information is sufficient to sketch a parabola?" was finally disclosed when, in response to a student question, Ms. W revealed her parabolas (*disclosure,* code A). Ms. W then explained that the students who guessed the second parabola got lucky since the exact graph could only be determined with three points.

Mr. J. Mr. J prompted students to sketch a parabola when given the *y*-intercept [Act 1] and then asked students to compare with a peer. He repeated this process with two *x*-intercepts, and then *x*- and *y*-intercepts [Acts 2 and 3, respectively]. With this framing, the question of whether there was enough information to sketch a particular parabola was not even raised (which is why there are no codes for this story arc during Acts 1 and 2). Instead, the driving questions were "what parabola passes through ____?" and "are the parabolas the same?" As a consequence, the question of how many points are necessary to determine a parabola was not raised until the end of the activity, in Act 3, when Mr. J said "So, how many points are needed to draw a parabola?" (*formulated question,* code 1) to which the students responded "3" (*progress*, code 3). The teacher endorsed this response, disclosing the question (*disclosure*, code A).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Identifying the Roots of a Parabola

Next, both teachers prompted student groups to work on the same task, asking students how they could use what they know about intercepts (e.g., for the y-intercept, $x = 0$) to solve a quadratic equation for its roots. In both enactments, the same question based on this task arose, yet its resolution was again strikingly different (see Figure 4). In Ms. W's enactment, the question was considered in Acts 6 and 7, was interrupted by another activity, and then re-appeared in Acts 11 and 12. In contrast, in Mr. J's enactment, the question was raised in Act 7 and remained open until Act 11. Even more striking, however, were the differences in the way in which the question was answered over the course of this portion of the lesson, as is evident by the differences in the types and distribution of codes. These differences are described below.

How can we solve the equation $2x^2 + 5x - 12 = 0$?

Ms. W's Lesson	6	7	8	9	10	11	12
Question #24	13	43C				5393	43

Mr. J's Lesson	4	5	6	7	8	9	10	11	12
Question #30				23	7	34	3	3A	

Figure 4. Story arcs representing how the question "How can we solve the equation $2x^2 + 5x - 12 = 0$?" was raised and answered in two different enactments. See the caption of Figure 1 for the reference of numerical codes.

Ms. W. At the start of Act 6, Ms. W assigned the task (*formulated question,* code 1) and students worked in groups while the teacher circulated (*progress*, code 3). The focal group began to consider what values would make $2x^2 + 5x$ equal to 12. Ms. W called the class back together [Act 7] and indicated that students should be trying to solve $0 = 2x^2 + 5x - 12$ (*progress,* code 4). A student from the focal group shared that they were able to determine solutions $x = -4$ and $x = 1.5$ by guess and check (*progress*, code 3). Ms. W then shifted their attention (*suspended answer,* code C) to a game that appeared unrelated at the time [Acts 8, 9, and 10]. During this, she assigned volunteers "secret" numbers and asked them to reveal the product of the numbers. With the product, the rest of class had to guess what the secret numbers were. Through this activity, the students realized that when the product of two or more numbers is zero, at least one of the numbers must be zero. Ms. W then [Act 11] had her students return to the task, indicating that this property can help find the solution to $0 = 2x^2 + 5x - 12$ (*promise*, code 5). The focal group struggled; after factoring the expression (*progress*, code 3), they substituted 0 for x in the factored expression (*snare*, code 9). One student gasped audibly and exclaimed "Oh my god, guys!" upon recognizing that doing this yields the number -12, which is the y-intercept of the equation. The group then realized that the x-intercepts occur when y equals zero, (*progress,* code 3) and shifted to solving $0 = 2x^2 + 5x - 12$. They knew that something had to be done with a factored form, so they tried a mixture of manipulations to rewrite the quadratic expression to no avail. The teacher arrived at the group and the students asked for help [Act 12]. A student said she got the answer $x = 1.5$ by guessing. The teacher then reminded the students of the game from Acts 8, 9, and 10 (*progress*, code 4), after which one of the students connected this answer to the solution of $2x - 3 = 0$ (*progress,* code 3).

Mr. J. Mr. J began this activity by focusing students on the definitions [Acts 4 and 5] and misconceptions [Act 6] regarding x- and y-intercepts. Groups then collaborated on solving $0 = 2x^2 + 5x - 12$, asking each other questions about strategy [*formulated question* and *progress,* codes 2 and 3, Act 7]. Mr. J again called the students back together and indicated that this task should

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

be challenging, indicating perhaps it is unsolvable [*jamming,* code 7, Act 8]. He then reviewed the definitions of *x*- and *y*-intercepts and to discuss how to find the *y*-intercept of $y = 2x^2 + 5x - 12$. Next [Act 9], he asked students to try different algebraic strategies in an attempt to solve $0 = 2x^2 + 5x - 12$ (*progress,* code 3). When students struggled, Mr. J had students focus on how strategies that work for other equations do not work for quadratics (*progress,* code 4). In Act 10, Mr. J displayed a sheet of missing factor multiplication problems whose products are all 0. Students responded that the missing factor had to be zero in these problems (*progress,* code 3). Mr. J returned the class to $0 = 2x^2 + 5x - 12$ and reviewed with the class how to factor the expression to be the product of two binomials $(x + 4)(2x - 3)$, and then use the zero product property to figure out the roots. He then reveals the answers to be $(-4, 0)$ or $(1.5, 0)$ [*disclosure,* code A, Act 11]. Mr. J then had his students copy definitions into their notebooks for roots, zeros, *x*-intercepts, and the zero product property [no new progress, Act 12].

Differences in Storytelling

Collectively, these two episodes, which were based closely on the same written tasks, demonstrate that teachers influence the way that mathematical content unfolds throughout their lessons. Together with the students, the teachers craft a mathematical story that has aesthetic dimensions. Despite having so many similarities at a lesson level, the structures of the plot diagrams of these two mathematical stories are strikingly different.

As described in this paper, Ms. W's framing of the parabola sketching activity as a prolonged challenge led to several important aesthetic and mathematical differences. The question "What information is sufficient to sketch a parabola?" was introduced at the start and, as a result, this question was the driving mathematical focus of the activity. That is, the challenge to figure out the teacher's parabola gave purpose to the mathematical inquiry. Thus, the mathematical story in Ms. W's class included mathematical revelations of why only having the *y*-intercept or only having the two *x*-intercepts are insufficient. That different parabolas could result when given insufficient information was part of Mr. J's lesson, however, why that is the case was not. In the aesthetic dimensions of these enactments, Ms. W's framing enabled the students to be surprised by the lack of information and curious about the result (by later asking for the answer). This approach engaged students and resulted in visible celebration. In contrast, since Mr. J did not pose this question until after the parabola sketching activity, his students (while attentive and cooperative through the activity) barely participated in addressing the question of the number of points that are necessary to determine a parabola when finally asked.

When looking at the plot diagrams for the question "How can we solve the equation $0 = 2x^2 + 5x - 12$?" (Figure 4), we see a different structure than the plot diagrams during the parabola sketching activity (Figure 3). In Ms. W's classroom, the question was under consideration until it became temporarily suspended when attention was shifted to a seemingly unrelated game. Upon completion of this exploration, Ms. W's released her class to reconsider the question again, but now taking into consideration some takeaways from the zero product property game. It was through this open exploration that the students in the group experimented with different strategies and were able to have a visible aesthetic reaction to finding out that substituting in zero for *x* in the factored form of an equation still yields the *y*-intercept of the equation. In contrast, in Mr. J's classroom, the development of the mathematical ideas related to solving this question primarily flowed through Mr. J. He focused students' attention toward the problem for exploration, recapped what they already knew and don't know, helped discover a relevant property, and showed how this property could be used to solve the original problem. When this question was under consideration, the students in Ms. W's classroom were what could be called the mathematical actors, while in Mr. J's classroom, the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Tucson, AZ: The University of Arizona.

teacher was the leading actor of the mathematical story. This could explain the students' aesthetic reaction to their mathematical discovery in Ms. W's classroom, and the apparent absence of one in Mr. J's classroom.

While the analyses of the plot diagrams of these individual questions help highlight possible influences on the aesthetic reactions and opportunities for students, analyses of the plot diagrams of the entire lesson yield other insights. Just as Ms. W's overarching question of "What information is sufficient to sketch a parabola?" offered coherence and purpose to the parabola sketching activity, Mr. J's whole mathematical story included multiple overarching questions that together gave purpose and meaning for the entire lesson (particularly "How can I find the roots of a parabola" and "How can I sketch a parabola with the x-intercepts and y-intercept?"). Although there was no visible aesthetic effect to this crafting of the content, we suspect that there was coherence by the end of the lesson that enabled students to recognize that both episodes together were needed to achieve the lesson goal; namely, to sketch a parabola by its intercepts.

Discussion

If mathematics educators want to change the aesthetic nature of mathematics classrooms, can we just change the curriculum? Our answer is no. As shown in this study, the curriculum is not the only factor that determines the aesthetic impact of the enactment. When mathematics lessons are interpreted as mathematical stories and are compared in this way, differences in the experiences of students can not only be noticed but also understood. This recognition enables future research to focus on the storytelling; that is, to explore how mathematics teachers can craft lessons that can offer engaging learning experiences for students.

THE DEFINITIONS OF SPATIAL QUANTITIES IN ELEMENTARY CURRICULUM MATERIALS

Research indicates that U.S. students have misunderstandings in measurement, and one reason is the highly procedural focus of elementary curricula. Because the definitions of quantities are basic conceptual content, we examined definitional-type expressions (related to formal mathematical definitions) for spatial quantities (length, area and volume) within and across elementary curricula with special attention to the inclusion of units, quantification, and exhausting space. We found inconsistencies in the ways these conceptual aspects were presented. In some cases, the inclusion of particular conceptual content depended on the type of quantity, (e.g. "exhausting space" was strongly emphasized in area measure, but less so in length and volume).

Keywords: Curriculum, Elementary School Education, Measurement

Background

Definitions hold a central place in mathematics. They are distinguished from theorems because definitions cannot be proven true or false, and they are different from axioms because definitions can be contested (Kobiela & Lehrer, 2015). *The Common Core State Standards for Mathematics* indicates in the *Attend to Precision* standard that students should, "…use clear definitions in discussion with others and in their own reasoning" (NGA-CCSSO, 2010, p. 7). The practice of defining is potentially rich as a classroom activity (Gilbertson, 2015); yet, many students encounter definitions as simply being presented by the teacher or their textbook. In some ways this approach is sensible, given the inherent messiness of involving students in the defining process to create precise and meaningful definitions which are both mathematically accurate and useful for testing whether a mathematical object fits the definition or not.

Complicating the issue is that some mathematical ideas span multiple grade levels, meaning that students may have multiple exposures to definitions of the same concept. This creates a dilemma particularly for textbook authors because they must maintain consistency, while using language that is age-appropriate and meaningful to students based on their mathematical experiences. The definition of a mathematical function, for example, might look quite different to a middle school student than a student in an abstract algebra course. *Consistency* is not meant to imply the definitions are identical, rather that the definitions convey similar meaning noting important characteristics of the object being defined. This raises the question as to how fundamental mathematical ideas are conveyed to students across grade levels, and the extent to which these are done consistently or inconsistently.

One approach to study this phenomenon would be to study how teachers define mathematical ideas in their own classrooms. We chose instead to study written curriculum materials because these materials comprise the main mediating tool between the ideas of the broader mathematical community and the ideas developed in classroom interactions. Although one limitation of studying written materials is the variation of implementation across classrooms (Tarr et al., 2008), written curriculum plays an important role in what teachers teach, the opportunities they present for

mathematical sense-making (Stein, Remillard, & Smith, 2007) and their profound impact on K-12 classroom instruction (McCrory, Francis, & Young, 2008).

Instead of studying definitions across content domains, we selected one particular topic and grade band with documented issues of student learning to investigate the extent to which definitions could possibly support or hinder opportunities for student understanding. We chose to study definitions of spatial measurement at the elementary level because educational researchers (e.g., Kamii & Kysh, 2006) and national assessments (e.g., NAEP) have indicated deficiencies in elementary students' conceptual understanding of spatial measurement such as confusing the meaning of area and perimeter (e.g., Bamberger & Oberdorf, 2010; Barrett & Clements, 2003; Woodward & Byrd, 1983) amongst many other issues. Additionally, the lack of clarity about the quantity to be measured and what constitutes a measure of that quantity significantly increases the challenges that students face in understanding the measurement process (Smith, Males, Dietiker, Lee, & Mosier, 2013). Curricular analyses of spatial measurement (e.g. Smith et al., 2013), have argued that deficiencies in written curriculum materials may be a contributing factor to these conceptual deficiencies. Since definitions are central to describing the meaning of terms, it raises the question as to how definitions can be presented to contribute in some way to students' conceptual issues.

Purpose and Research Questions

The purpose of this study is to describe opportunities for students to understand definitions of length, area, and volume in written curriculum materials, with specific attention to the consistencies and inconsistencies across grade levels and materials. We use the term, *definitional-type expression* [DTE] to designate any written description of a term that aims to support students in understanding a term's definition. These include all explicit definitions in the text along with other expressions that describe or delimit a quantity or its measure. In elementary textbooks in particular, it is not always the case that formal definitions appear as explicitly as one might see in higher grade levels (e.g. "The definition of a square is…"). Thus, our broader interpretation of definitions includes expressions which aim to define or support defining, but may not be explicitly indicated by the materials as a "definition." Specifically, for spatial measurement, we define DTEs as (a) expressions of meaning for length/area/volume as *spatial characteristics*, (b) expressions of meaning of length/area/volume as *measure* of characteristics, or (c) expressions which clarify the meanings of spatial characteristics or their measures (e.g., "area is not perimeter"). Framing our inquiry were the following questions:

- *What characteristics of DTEs are found in elementary curricula across spatial measurement topics, e.g., length, area, and volume?*
- *What similarities/differences exist across curricula and measures with respect to DTEs?*

Methods and Data Sources

Textbooks chosen for this study were from three elementary textbook series (Grades K-5): (a) The University of Chicago School Mathematics Project's *Everyday Mathematics* (2007)—henceforth *EM*, (b) Scott Foresman/Addison Wesley's *Mathematics*, Michigan edition (Charles, Crown, & Fennell, 2008)—*SFAW*, and (c) Saxon Publishers' *Saxon Math* (Larson, 2004)—*Saxon*. Selection of the textbooks was based on a large market share (e.g., *EM* and *SFAW*) and variance in features of textbooks (e.g., *EM* is Standards-based and *Saxon* is unique in its direct instruction approach). We explored DTEs for *length* in grades K through 3, *area* in K through 4, and *volume and capacity* in K through 5. The coding stopped at certain grades (e.g., length at grade 3) because the central processes, concepts, and tools for the measurement (e.g., length) had been presented by that grade level.

Four researchers divided into pairs with one pair examining DTEs of volume and another pair examining DTEs of area and length. After comparing and discussing characteristics of DTEs in

length, area, and volume, we agreed on a final list of emergent DTE characteristics: (a) dimensionality, (b) units, (c) continuous versus discrete materials, (d) exhausting the space, (e) specific shapes, (f) boundary, (g) quantification (e.g., counting, applying a formula), (h) tool use, and (i) space. Each pair analyzed each group of DTEs for the listed characteristics and resolved disagreements together or brought to the whole research team for resolution. Typically, the coded unit of curricular content was either a single full sentence, or a clause of a sentence.

Table 1: Analytical Framework for Coding Definitional-Type Expressions in Measurement

Aspects	Coding Questions
Dimensionality	Is dimensionality explicitly stated (i.e. terms such as "3-dimensional" appear in the text)? If yes, what dimensionality? (e.g. 1, 2 or 3 dimensions)
Units	Are units of measurement indicated (e.g. gallons, cm^2, feet)? If yes, which units?
Continuous vs. Discrete	What type of substance/object fills the space being measured (e.g., a continuous quantity of liquid or a discrete number of linking cubes)?
Exhausting the Space	Is there mention of the need to completely fill, cover or tile the space (e.g. cover the surface with square tiles without gaps and overlaps)?
Specific shape	Is the measure referenced for a specific shape or object (e.g. a rectangular solid, a triangle)?
Boundary	Is there mention of end-points or other enclosure of the space (e.g. a length measure defined as the distance between two points)?
Quantification	Is there mention of counting, layering, reading a tool or applying a formula (e.g. the volume of an object is the number of cubic units)?
Procedural tool use	Is a specific measurement method using a tool and/or unit indicated (e.g. using a ruler to measure length)?
Space	Is the word "space" explicitly mentioned?

While all these categories potentially contribute to students' understanding of measurement concepts via definitional expressions, we focus our attention on three categories that seem to be most relevant for students' meaningfully understanding measurement. Specifically, we focus on the categories: (b) *units,* (d) *exhausting the space*, and (g) *quantification.* These three categories are central to understanding quantities and their measures; as any measure of space involves a choice of a unit, and that the measure is a quantification of the units that completely exhaust the space. Results for this paper will focus primarily on these three categories. Table 2 (below) describes examples of coding for these categories.

Table 2: Analytical Framework Used to Code Aspects of Measurement in DTEs

Aspects	Questions and Examples
Units	Are units of measurement indicated? If yes, which units? Yes:... *measure in gallons...* (Volume: SFAW, gr. 5, p. SRB157) Yes:...*number of unit squares...* (Area: EM, gr. 4, p. 671 Yes:…*unit of measure will be a linking cube...* (Length: Saxon, gr. 1, 35-2-4) No: … *measure how much space there is…* (Length: EM, gr. 3, p. SRB2)
Exhausting the Space	Is there mention of the need to completely fill, cover or tile the space? Yes:...*fill the space taken up by the object...* (Volume: EM, gr. 4, p. 868) Yes:...*cover the surface without overlaps and/or gaps...* (Area: EM, gr. 4, p. 671) Yes:…*must be marked off "end to end," without leaving spaces...* (Length: EM, gr. 1, p. 282) No: …*To find the area, count the squares inside the shape.* (Area: SFAW, gr. 2, p. 351A)
Quantification	Is there mention of counting, layering, reading a tool or applying a formula (specification of procedure is not necessary)? Yes:… *by counting how many*… (Volume: SFAW, gr. 5, p. 610) Yes:…*count the number of tiles...* (Area: Saxon, gr. 3, 88-5) Yes:…*count the cubes*… (Length: SFAW, gr. K, p. 139) No: …*area is the measurement inside...* (Area: SFAW, gr. 4, p. 485)

Results

We provide percentage and frequency distributions for DTEs across curricula for length, area, and volume, and summarize findings for each quantity (e.g., length) regarding curricular attention to each characteristic (e.g., units). Note that DTEs could (and did) address multiple characteristics. We provide percentage distributions representing the proportion of DTEs that mention a characteristic across grades for each curriculum (i.e., *SFAW*, *Saxon*, and *EM*) and for each measurement (i.e., length, area and volume) in Figures 1, 2, and 3 below. Over 200 DTEs were found across the three curricula and three measures, with few for length (20), more for area (60) and even more for volume (131). Thus, students have more opportunities to learn definitions for spatial quantities as dimensionality increases, which may be a result of having more procedures as this occurs (e.g. for volume one can count cubes, using various multiplication formulas, and pour liquid in the case of liquid volume).

Across curricula and measures, many DTEs failed to include all three components in any one expression. Additionally, there was inconsistency within each measure and curriculum as to whether the inclusion of units, the inclusion of exhausting space, or the inclusion of quantification was necessary in defining the measure. This was generally true with the exception of *Saxon*. One exception occurred in their description of length measure, where all DTEs included reference to a unit and quantification. The other exception occurred in *Saxon's* exclusion of needing to specify exhausting space in length and volume.

This last result points to a more general issue of how some curricula placed increased emphasis on particular conceptual knowledge based on the measure. For example, the DTEs in *EM* placed stronger emphasis exhausting space in length and area (greater than 70% of DTEs in both cases), but de-emphasized this conceptual aspect in volume (less than 20% of DTEs). *SFAW* had variation as well in the exhausting space category, with nearly 70% of DTEs in area compared to less than 15% in volume. In the case of emphasizing a particular conceptual aspect in length, this may be attributed to the fact that length is typically emphasized in earlier grades before area and volume, meaning that the development of the concept is necessarily deeper for length compared to the other two measures.

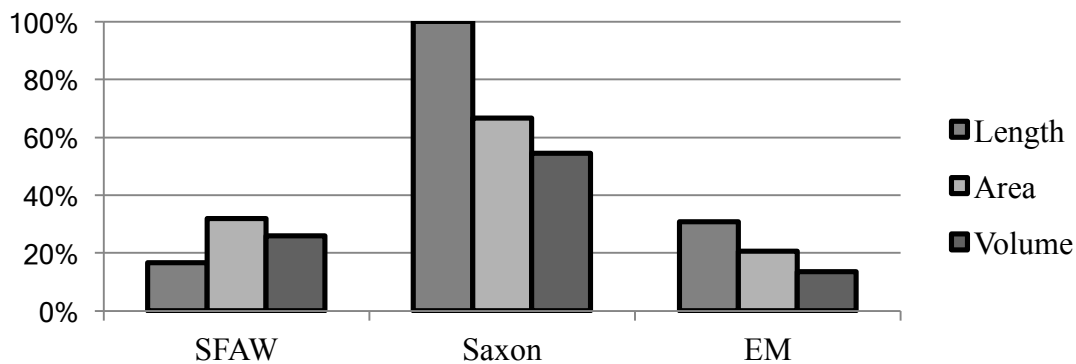
It does however, raise the question as to whether students are able to sufficiently connect conceptual aspects across measures, namely that unitizing, quantification, and exhausting space are essential for all measures, not just the particular ones emphasized in the curriculum.
Figure 1. Percentage of DTEs that reference "Units" of measurement.
Figure 2. Percentage of DTEs coded as "Exhausting the Space".


Figure 3: Percentage of DTEs coded for "Quantification".

Length

Across the three curricula, we found 20 DTEs in length measurement in grades K through 3: *SFAW* (6), *Saxon* (1), and *EM* (13). These DTEs appeared more in teacher pages and in the form of declarative statements about measurement (as opposed to questions or problems to pose to the students). The curricular emphasis was in Grades 2 and 3 because 75% of the DTEs appeared in

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

these grades. Slightly more than half of these DTEs (11 out of 20) were associated with length measurement with specific units. Slightly over half of these DTEs were associated with specific units (11) or covering of space or distance (12).

Area

In area measurement we found 60 DTEs, with *Saxon* (6), *SFAW* (25), and *EM* (29). Of all DTEs, 45% mentioned units, 32% implicitly referenced quantification (e.g., counting), and 78% addressed exhausting space. *Saxon*'s area DTEs mentioned exhausting the space, where its length and volume DTEs did not (see Figure 2). We found a clear distinction in references to units between *EM* ("unit squares") and *SFAW* ("square units").

Volume

Across the three curricula, we coded 131 volume DTEs. Only four appeared in kindergarten and first grade, with a range of 21 to 46 DTEs appearing in Grades 2-5, with higher frequencies in higher grades. Of the 131 DTEs, 24% mentioned units, 22% mentioned quantification, and 12% mentioned exhausting space. One inconsistent characteristic common to all three curricula was in differentiating the meaning of "volume" and "capacity". In some cases, the inconsistency manifested as DTEs that viewed volume and capacity as essentially equivalent and in other places different. As one set of examples, *SFAW* stated in the student materials, "Capacity is the amount a container can hold" (Grade 2, p. 353; Grade 4, p. 609), and later in the teacher materials "Discuss the meaning of the word volume, explaining that it is the amount a container can hold" (Grade 2, p. 69B). Later on students are asked to, "Explain the difference between volume and capacity" (Grade 5, p. 618). Thus, while the terms are seen as essentially the same, it is not clear what the intended differences are in relation to these two terms.

Discussion

The motivation for this study was assessing the extent to which DTEs might contribute to students weak conceptual understanding of measurement. Different from definitions where being minimal is a requirement (Vinner, 1991), our analysis focused on conceptual aspects of definitions because we want to describe how curriculum materials provide a body of knowledge in developing concepts of length, area and volume. We found the lack of consistency in including or excluding aspects of measurement (e.g. units, quantification, exhausting space) in many DTEs, a pattern that may add to students' challenges in learning the meaning of spatial quantities and their measures. For example, if a procedure such as "counting squares" is given in one DTE, and is later omitted in another DTE this raises the question if the student associates a count of squares as a necessary aspect of the definition or simply one of many ways to understand the meaning of area.

Perhaps more troubling is that the inclusion or exclusion of certain conceptual aspects depend (to a great extent) on a particular measure. This may be an example of a lost opportunity for students to see the underlying conceptual structures that exist across measures, making them appear more different than they are similar. At the onset, we hoped to see consistency across particular types of DTEs, but our analysis has shown trends of inconsistency both within curriculum materials, and across measures.

The emphasis (or lack thereof) on certain aspects of measurement in these DTEs might have potential to shape the meaning students make from these definitional expressions. Textbooks have the benefit of providing opportunities to develop students' ideas over extended periods of time, so one might not expect any singular definition to sacrifice readability and meaningfulness to young students for the sake of mathematical precision. This being said, one would hope to see consistency across definitions in relation to their conceptual underpinnings, something we did not find as strongly as we initially expected.

Curriculum materials are integral to the teaching and learning of mathematics and have been described as having the most influence on what teachers actually plan for and enact in their classrooms. In this paper we describe how two teachers with varying years of experience, but similar experiences with curriculum materials, use curriculum materials in planning. Through a semi-structured think aloud interview, we describe what teachers attended to, how they interpreted what they attended to, and how they decided to respond to the curriculum materials when planning a hypothetical lesson on slope.

Keywords: Instructional Activities and Practices, Curriculum, Teacher Knowledge

Curriculum materials are integral to mathematics instruction. In fact, more than 80% of K-12 teachers use a textbook or curricular program for mathematics instruction (Banilower et al. 2013). Furthermore, curriculum materials have the most direct influence on what teachers actually plan for and enact in their classrooms (Brown & Edelson, 2003) and, although research does describe what teachers do with materials, we do not necessarily know the process by which teachers make decisions about what to do and how to do it (Stein, Remillard, & Smith, 2007).

In this paper, we consider how we might gain insight into the process by which teachers make decisions about the use of curriculum materials while planning. We draw on a framework called Curricular Noticing (Males, Earnest, Amador, & Dietiker, 2015) to describe what teachers attend to, their interpretations of what they attend to, and how they respond to (or make decisions) about how to use curriculum materials to plan lessons.

Background and Theoretical Framing

Phases of Curriculum Use: From Written to Intended

The influence of written curriculum on student learning is not straightforward. Figure 1 illustrates that before a written curriculum is experienced by students, it goes through a series of transformations; the first occurs when the teacher interacts with the written curriculum to produce the intended curriculum, or the teacher's plan. These phases are mediated by a variety of factors, such as teachers' knowledge and beliefs, orientation toward curriculum, classroom structures and norms, and organizational and policy contexts. Therefore, while the written curriculum materials themselves have an influence on student learning, this influence is not direct because the written curriculum is transformed by teachers before students access it. Although the enacted curriculum is the phase that researchers indicate most directly influences students mathematical experience and ultimately what they learn (Remillard & Heck, 2014), it is within the enacted curriculum or the "design-in-use" (Pepin, Gueudet, & Trouche, 2013) phase that teachers draw on the plan that they developed when interacting with the written curriculum.
Figure 1: Temporal Phases of Curriculum Use.
(Adapted from Stein, Remillard, & Smith, 2007, p. 322)

In this paper, we focus on planning, specifically the transformation from written to intended curriculum, because this is one of the most critical activities in improving teaching (Morris, Hiebert, & Spitzer, 2009). Furthermore, understanding how teachers use curriculum in planning is imperative in understanding how curriculum influences student learning because it is within this transformation that important variations in written curriculum get introduced. These variations shape the opportunities and experiences students have and therefore, ultimately shape what students learn.

Teachers' Use of Curriculum Materials

Research on teachers' uses of curriculum materials has presented us with a foundation for describing what teachers do with materials. In the midst of planning and enacting instruction, teachers engage in a variety of activities with curriculum. Remillard (2005) describes the teacher-curriculum relationship as a dynamic transaction in which teachers participate with the materials. The socio-cultural conception of this relationship emphasizes the fact that both the teacher and the curriculum influence what and how curriculum materials are used. Using this conception, researchers have outlined ways in which teachers participate with curriculum, including the activities teachers engage in such as reading, evaluating, and adapting (Drake & Sherin, 2009) and what Brown (2009) describes as offloading, adapting, and improvising. When considering the transition between the written and intended curriculum, the role of the teacher is that of a designer (Brown, 2009). In the pursuit of instructional goals, teachers must perceive and interpret existing resources, evaluate the classroom environment, balance tradeoffs, and devise strategies. Thus, there is an integral relationship between agents (teachers) and tools (e.g., curriculum materials); curriculum materials play a role in affording and constraining teachers' actions. It is this design activity that is the focus of this paper.

Curricular Noticing

Curricular noticing is the process through which teachers make sense of the complexity of content and pedagogical opportunities in written or digital curricular materials (Males et al., 2015) and involves sets of skills that unfold in the following three phases: *Curricular Attending, Curricular Interpreting,* and *Curricular Responding*. See Figure 2.
Figure 2: The Curricular Noticing Framework.

First, teachers attend to or perceive and recognize information on the page. Second, they interpret, or make sense of, what they attended to. Finally, teachers decide to respond in a particular way based on their interpretations of what they attended to. It is reasonable to assume that the more curricular opportunities noted by teachers in their curriculum materials, the more supported the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

teachers are to design and enact lessons that involve the types of mathematical experiences they want for their students. Although we describe a process that seems linear, we hypothesize that the process does not always occur in this linear fashion. For example, as a teacher interprets a portion of their textbook, this may trigger her desire to find an additional resource and therefore, she may attend anew before further interpretations or responses are made.

Research Focus and Questions

The focus of this study was to describe how two mathematics teachers with varying years of experience, but similar experiences with curriculum, use curriculum materials in planning. Specifically, we address the following research question: When planning a lesson with curriculum materials, what do two teachers with varying number of years of experience attend to, how do they interpret what they attend to, and what responses do they make (i.e., what do they decide to do and how do they decide to do it)?

Methods

Participants and Context

Participants. This paper focuses on two teachers, Aaron and Evan, teaching in two different high-needs urban high schools in the same district in a mid-western city. Both teachers were part of a cohort of Noyce Fellows. The Robert Noyce Teacher Scholarship Program, funded by the National Science Foundation (NSF), targets the needs of creating and retaining high-quality teachers by funding fellowships for qualified individuals to become or remain mathematics (and science) teachers and commit to teaching in high-need schools. NSF [DUE-1439867] funded 30 Master Teaching Fellows and 13 Teaching Fellows (preservice teachers) who participated in a 14-month Masters + Certification program. Aaron is one of seven Noyce Master Teaching Fellows who participated in this study. At the time of the study, Aaron, a National Professional Board Certified Teacher, had just completed 13 years of teaching. Evan was one of two Noyce Teaching Fellows who participated in this study. At the time of this study, Evan had completed two years of teaching.

These two teachers were purposefully chosen to examine the potential influence of experience on the ways in which curriculum materials are used during planning by keeping other characteristics similar. Although their number of years of teaching experienced differed significantly between the two teachers, both teachers have taught a variety of content at the high school level, ranging from classes for students who struggle to advanced/honors classes. Both had experience teaching slope, the focus of the lesson we gave them to use in planning. In addition, in the last two years, both teachers participated in a course focused on curricular issues, with a specific focus on learning opportunities in written curriculum materials, taught by the first author of this paper. Both teachers had never used the curriculum materials utilized in the staged planning as their primary course materials, but both had heard of the materials. Evan mentioned in the pre-lesson planning portion of the interview that he had seen them in a class taught by the first author, "but I haven't really studied them too much." Aaron had analyzed a portion of the materials (different from what we provided in this study) with a partner for a curriculum analysis assignment and has used activities similar to the activities in these materials in his classroom.

Context. The urban district serves approximately 40,000 students in a Midwestern city. There are six high schools and one alternative community school. The demographics for Aaron's and Evan's schools can be seen in Table 1.

Table 1: High School Demographics

School	Enrollment	% White	Free/Red Lunch	Special Needs	ELL students	Gifted
Aaron's School	1,750	46%	59%	17%	12%	17%
Evan's School	1,978	62%	53%	15%	6%	14%

Curricular Context. At the high school level, the textbook series in use by the district include those published by Pearson, Holt McDougal, McGraw Hill, and Wiley. Teachers teaching the same course throughout the district use the same book and are expected to follow generally the same progression of topics as guided by a list of course objectives written by district math curriculum specialists. Students are assessed using district common assessments written by curriculum specialists and district-selected teams of teachers. These assessments are written to align with the course objectives. In addition, during the semester in which this study took place, the state had recently adopted newly revised state college and career-ready standards for mathematics. Unlike previous versions of the standards, this new revision includes both a set of content standards, but also a set of processes.

Data Collection & Analysis

Data Collection Procedures. Three researchers (one mathematics teacher educator researcher, one mathematics education graduate student, and one undergraduate mathematics education preservice teacher) conducted semi-structured staged planning interviews with nine Noyce Fellows. Recently, staged planning interviews have been used by researchers (Mcduffie, 2015; Reinke & Hoe, 2011) to gain insight into teachers' use of curriculum materials. In a staged planning interview teachers are asked to produce a hypothetical lesson plan, meaning that the plan produced by teachers is not necessarily something that they plan to enact. The advantage to this is that teachers do not have to be tied to district policies and can feel free to use the curriculum materials as they wish. For the staged planning interview, we used a semi-structured think aloud interview protocol that included teachers planning a hypothetical lesson using as a resource Dietiker, Kysh, Sallee, and Hoey's (2013) *Algebra Core Connections* Lesson 2.1.2 How can I measure steepness? These interviews lasted approximately 50 to 120 minutes.

After explaining the procedures to teachers, including telling them what lesson they would be using from the materials, we gave them five minutes to familiarize themselves with the curriculum materials. We then provided teachers with a single-sided copy of both the teacher and student materials for Lesson 2.1.2. We asked teachers to imagine that these were newly adopted materials in the district and that they were planning a lesson that they would enact the next day. We asked them to develop a written plan even if they do not normally write out a plan. In addition, we asked teachers to indicate aspects of the materials that they were reading (highlight in yellow), planning to use as is (bracket in red), and adapt (bracket in green), and to continuously talk out loud as they did this. Once teachers completed the plan we asked follow-up questions, such as how they anticipated students would work through the lesson, what aspects of the materials helped them make decisions about how to plan the lesson, what, if any, portions of the materials did they skim or skip, what portions of the materials did they find most helpful, and how similar or different was what we did today from their typical planning process. During both the pre-lesson planning portion and the lesson planning portion, the researchers remained silent. All interviews were recorded using two video cameras, one focused on the teacher and one focused on the materials. All written materials, including the written or typed plan, any additional written work, and the student and teacher curriculum materials were collected.

Data Analysis. Written materials were electronically scanned in color and video was uploaded to a network server. Video and written materials were imported into MAXQDA12, a qualitative data analysis program. The first three authors independently coded each of the teachers' interviews in MAXQDA by selecting portions of the video in which teachers attended, interpreted, and responded. Attending codes were assigned when there was explicit evidence that the teacher saw something on the page as evidenced by reading aloud and/or highlighting the text. Interpreting codes were assigned when a teacher visibly or audibly attempted to comprehend or made sense of the content. Finally, responding was assigned when the teacher made a decision to do something, such as indicating an aspect of the lesson materials they would choose to use. During the analysis, an additional code was created to capture instances when the teacher described what they were doing.

To facilitate coding, each sentence of the teacher and student lesson materials was given a unique identifier made up of a number identifying the paragraph and a letter identifying the sentence within that paragraph (e.g., 01-A, 01-B, 02-C). These unique identifiers enabled the researchers to assign codes for teachers' attention to, interpretations of, and responses with respect to particular portions of both the teacher and student materials. After independently coding each of the interviews, coders met to discuss and come to consensus on the coding.

Results & Discussion

We first describe the process that each teacher followed to plan their lesson. The process by which the teachers engaged in the planning activity was not only visible, but both teachers verbally expressed how they planned to use the materials while planning the lesson. We follow this by describing how teachers responded to the materials by describing their plans. We then follow this with a description of what each teacher attended to and how they interpreted what they attended and, when possible, how this attention and interpretation connected to their responses.

Teachers Planning Processes

Although we did not explicitly ask teachers to describe the process that they planned to use to plan their lessons each teacher explicitly commented on how they were going to plan the lesson either from the start or within the first few minutes of beginning the planning portion interview.

Aaron. Aaron began by laying out the teacher and student materials side-by-side and stated "So I'm gonna start by just kind of reading through the teacher materials and possibly flipping through the student stuff as I read the teacher materials." Aaron did this until about 22 minutes into the interview at which point he decided to turn his attention solely to the teacher materials as he found it "a little confusing to translate from this [the teacher materials] to this [student materials] … So I'm thinking I'm gonna take the relevant information from here [teacher materials], thinking about it in terms of students."

Evan. Unlike Aaron, Evan did not at first place the student and teacher materials side-by-side. He placed the teacher materials in a pile in front of him with the student materials off to the side not in view of the camera. He then began to read through the teacher materials. Once Evan remembered he was supposed to be talking out loud as he planned, he provided insight into his process by stating

> I'm just reading what the lesson is all about and how the curriculum creators made this lesson. So, I'm just getting a sense of how I'm gonna start the lesson or how they're going to have me start the lesson and then just going from there. So, I'm just reading the information not making any decisions right now.

The notion of not making decisions early in the planning was true for both Aaron and Evan. Although both teachers made some decisions as they worked their way through the text about which problem they would use as is and which they might adapt, neither teacher began to write their plan

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

until approximately 40 minutes into the interview. As both teachers wrote the plan, they attended again to the text in the teacher and student material at a quicker pace.

Responses to the Curriculum Materials: The Lesson Plan

These lesson plans produced by each teacher can be seen in Figure 3.

Aaron's Lesson Plan	**Evan's Lesson Plan**
- Objective: Understand slope - Intro: Students read questions - Do 2-11, 2-12, 2-13 - Discuss 2-13 (maybe) – Float: Struggling with 2-11, 2-12, 2-13 – Focus on graph - Do 2-14 as a team - Do 2-15 - Discuss 2-15 - Do 2-16 - Discuss 2-16 - What else could happen? - Check for Understanding 2-19 or 2-10 (similar to 2-14, 2-15) - Homework: Assign 2-21, 2-22, 2-24	- Objective: Introduction to slope - Materials: Student - Handout/Resource (Modified) - Students will be groups in teams of 3-4 at tables - Students read focus questions - Teams working on questions - Think, write, team share on 2-11 (3 min) - Think, write, team share on 2-12 (1-2 min) - Intro 2-13 as class, team work time - Monitor and push teams to read graph and not rely on table - Students work on modified 2-14 as team to think about growth/slope triangle for figure numbers Draw connection on part c compared with part a - Begin discussion of steepness and how line is steeper or less steep using arms - Do 2-15 as whole group. Emphasize vocab - Let teams work together on 2-16 focusing on steepness again using their vocab - Students work on 2-17 and discuss $A_y = 0$ & $A_x = 0$ - Discuss 2-18 with teams as error analysis to extension to idea of negative slope - Assign 2-19, 2-20 a & c, 2-21, 2-22, 2-23, 2-24, a teacher-created problem addressing negative slope

Figure 3: Final Lesson Plans

First, when looking at the lesson plans we see that Evan's has more detail than Aaron's. Although analyzing the level of detail is not a specific focus of this study it provides us with interesting methodological considerations as it makes it somewhat hard to analyze how Aaron interpreted some of the suggestions in the teacher's materials from reading his plan, particularly with respect to participation structures (i.e., teams, whole-class). That said, even Evan's more detailed plans leaves some of these questions unanswerable as he does not always include what groupings students will be working within, nor did he always verbalize this.

Second, we see a number of similarities in the plans. Both teachers decided to have students read the focus questions, do problems 2-11, 2-12, 2-13 as is (with no modification), discuss problem 2-15, and do problem 2-16, assign three of the same homework problems 2-21, 2-22, and 2-24, and focus students on reading graphs. One important point to make, however, is that although these decisions to have students engage with this content is the same it is unclear that the teachers expect the students to engage in the same way. For example, both teachers will use problem 2-15 and we know that Evan decided to complete this via a whole-group discussion, but it is not clear how Aaron will engage his students with this same problem.

Finally, we see some differences, beginning with the objectives. The objective as written in the teacher materials states

Students will gain an abstract understanding of slope as they discover that slope is the change in *y* (referred to as Δ*y*) divided by the change in *x* (referred to as Δ*x*) between any two points on a line.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

They will continue to connect growth and starting value to multiple representations of a linear function.

Both Aaron's and Evan's objectives are simplified with Evan opting to use the word "introduction" rather than "understand." In addition, Aaron does not have students share or discuss problems 2-11, 2-12, and is undecided about 2-13. He also chooses to have students do problem 2-14, but Evan decides to have his students do a modified version of the problem. We discuss this modification in the next section. Evan also decides to have his students complete problems 2-17 and 2-18, which Aaron does not, and give students additional homework problems including a teacher-generated problem that address the concept of negative slope. Although Aaron does not assign all of the additional homework problems Evan does, he does decide he will use one of these, either 2-19 or 2-20 as a check for understanding at the end of class because these problem are similar to two problems students had done in class.

Attention and Interpretation

Capturing teachers' attention proved to be somewhat difficult, particularly when teachers were not talking out loud and/or highlighting as they read. That said, we coded a teachers' attention whenever they highlighted a portion of the text or read the text out loud, meaning that it is possible that we missed aspects of the text to which a teacher attended. We coded teachers' interpretations whenever the teacher was attempting to make sense of the content. This included working out the mathematics in written form or discussing the mathematics or pedagogical structure or suggestions in the text.

Both Aaron and Evan attended to all text in the teacher edition, with the exception of the portion that outlined the mathematical practices, length of activity, core problems, and materials. Evan did not seem to attend to this. Interpretations made of the text in the teacher's guide were most often related to pedagogical suggestions and whether they were good or not. Both teachers also attended to all of the student text and although they did not seem to work through each problem, they tended to solve or work through the same problems. One such example was problem 2-14 in the student materials that asked students to examine a graph that depicts a line for a tile pattern and describe how the line was growing. As both teachers attended to this problem they worked out the slope and found that it was 27/3 or 9/1 and interpreted this problem to be a useful problem in helping student make connections to previous or future content such as the notion of a unit growth rate. This problem was an example of a problem in which both teachers took a few minutes to make sense of what the graph was representing. Although both teachers interpreted the graph in the problem to be a representation of some kind of tile pattern, Evan initially interpreted this to be connected to the earlier tile pattern in problem 2-11 creating a disconnect for him as the number of tiles did not seem to match. When Evan first attended to this problem he stated, "I'm getting stumped. Maybe I won't have my students do that or maybe I will if I can figure it out." After returning to the problem before writing his final plan he decides to add points onto the line because it is "tough" and mentions that he "doesn't think there is a connection [to problem 2-11]… maybe someone can tell me" His difficulty in interpreting this problem may have influenced his addition of the points, but it is not clear how this modification allowed him to see the connection he was looking for nor provided him with a reason to include the problem in his lesson plan.

Conclusion

This preliminary work has enabled us to gain insight into how teachers with different years of experience plan using the same curriculum materials. Not only could we identify similarities sand difference in their plans, but we were able to capture what these teachers attended to, how they interpreted what they attended to, and begin to explore how these interpretations influenced the intended curriculum, or their plan. We hope that future research can enhance the methods used in this

study to capture and report more details about the interactions between the three curricular noticing phases and expand this research determine how curricular noticing influences the enacted curriculum and eventually students' opportunities to learn.

CONSIDERING COGNITIVE FACTORS IN INTEREST RESEARCH: CONTEXT PERSONALIZATION AND ILLUSTRATIONS IN MATH CURRICULA

Candace Walkington	Virginia Clinton	Leigh Mingle
Southern Methodist University	University of North Dakota	Reasoning Mind Inc.
cwalkington@smu.edu	virginia.clinton@und.edu	Leigh.Mingle@ReasoningMind.org

This paper examines two factors that have been shown in previous literature to enhance students' interest in learning mathematics – personalization of problems to students' interest areas, and the addition of visual representations such as decorative illustrations. In two studies taking place within an online curriculum for middle school mathematics, students receive problem types that vary with respect to these factors. Results show that while these interest-enhancing interventions may benefit students in the short-term as they solve modified problems, there is little evidence they allow students to understand key mathematics concepts more deeply.

Keywords: Middle School Education, Curriculum, Technology

Research has revealed how many students tend to disengage with mathematics over adolescence (Fredicks & Eccles, 2002; Frenzel, Gotez, Pekrun, & Watt, 2010), and increasingly have difficulty seeing the relevance of mathematics to their lives (McCoy, 2005). Accordingly, research on how interest can be activated and maintained in classrooms has become prevalent in educational psychology. Some interventions to enhance students' interest in curricular materials include adding colorful illustrations (Durik & Harackiewicz, 2007), personalizing instruction to students' out-of-school interests in topics like sports or music (Walkington, 2013), and giving learners choice in their learning activities (Patall, 2013; Potvin & Hasni, 2014). Visual representations that enhance interest may promote persistence and focus of attention, and sometimes they directly provide mathematical information to support students. Personalizing problems may also enhance interest, and allow learners to draw upon prior knowledge of concrete, relatable situations. While these interventions have shown promise for eliciting interest, consideration is not always given to the cognitive implications of the modifications. Specifically, features designed to enhance interest may distract learners from grappling with the mathematical concepts that should be the central focus, a phenomenon known as the *seductive details effect* (Harp & Mayer, 1998; Lehman, Schraw, McCrudden, & Hartley, 2007). Also, if learners become accustomed to these kind of interest-enhancing supports, they may struggle in situations where they must solve abstract mathematics problems. Research on desirable difficulties (Schmidt & Bjork, 1992) suggests that learners may benefit more in the long term from a lack of support in their learning environment, as this forces them to grapple with concepts and make important connections on their own. Further, research on simple symbols suggests that teaching concepts using abstract formalisms – rather than concrete applications – allows for better transfer of learning of the underlying mathematical ideas (Sloutsky, Kaminski, & Heckler, 2005).

Here we examine interest-enhancing interventions – personalization, choice, and the use of illustrations – in a curriculum for 6th grade math. We examine the short term effects of these modifications – whether the interest enhancement is supportive or seductive – and well as the long term effects on student learning – whether the interest enhancement is a crutch or a scaffold.

Literature Review

Visual Representations

Considerable research shows that learners benefit from visual representations (e.g., Mayer, 2009), and effectively using visual representations improves problem solving (Woodward et al.,

2012). Research into the effects of diagrams, one form of visual representations, in middle school mathematics includes topics such as the creation of schematic diagrams for spatially-oriented arithmetic word problems (Boonen et al., 2014), the use of diagrams in algebra word problems (Booth & Koedinger, 2012), and the use of diagrams in proportional reasoning tasks (Jitendra & Star, 2012). While there are some positive findings for diagrams, overall findings are mixed (Booth & Koedinger, 2012). More research is warranted to evaluate when, where, and how such diagrams will be most helpful. There are also mixed findings regarding the impact of decorative illustrations (Berends & van Lieshout, 2009; Jaeger & Wiley, 2014). Considerable support (Harp & Mayer, 1998; for a review, see Rey, 2012) has been found for the *coherence principle* (Mayer, 2009), which suggests that removing interesting but irrelevant information contained in purely decorative illustrations fosters learning. There are also mixed findings for decorative illustrations that contain no mathematical information, but that illustrate the context of a problem – they have been found to have no influence on problem solving (Dewolf, van Dooren, EvCimen, & Verschaffel, 2014) or be helpful (Elia & Philippou, 2004). Here, we use illustrations that have diagrammatic features that give mathematical information, as well as purely decorative illustrations that illustrate or do not illustrate the story context.

Personalization and Choice

We define personalization as an instructional approach that connects math tasks to students' out-of-school interests in broad topics such as sports, shopping, and video games (Walkington, 2013). Research on personalization in mathematics has yielded mixed findings – there is some evidence that personalization carefully accomplished through student interest interviews and open-ended surveys can promote achievement gains in algebra (Walkington, 2013), and that deeper and more authentic personalization can be more effective than shallow approaches in which a few words are simply swapped out of story problems and replaced with words related to an interest topic (Walkington & Bernacki, under review). Other research suggests that even very shallow attempts at personalization can promote student performance and learning (Anand & Ross, 1987; Cordova & Lepper, 1996). However, more recent studies have challenged whether personalization is even worth doing if there is not deep engagement with the actual quantitative knowledge that students actually use as they pursue their interests (e.g., Fancsali & Ritter, 2014). Finally, complementary research also shows that the facilitation of learner control or choice in a learning environment has the potential to enhance interest and motivation (Linnenbrink-Garcia et al., 2013; Patall, 2013; Potvin & Hasni, 2014), as well as learning (Cordova & Lepper, 1996).

Research Purpose

In prior work (Walkington, Cooper, & Howell, 2013; Walkington, Cooper, Nathan, & Alibali, 2015), we found that personalization and illustrations used in worksheets covering middle school mathematics concepts enhanced students' interest, but did not affect their performance. Here, we expand this research by examining several different types of illustrations and several different approaches to personalization in an online, adaptive mathematics curriculum, and examine the effect not only on short-term performance but on long-term learning. Our research questions are: How do different types of illustrations impact students' accuracy on the illustrated problems and their performance on a post-test without illustrations? How do different approaches to personalization impact students' accuracy on personalized problems and their performance on a non-personalized post-test?

Method

Both studies took place within the *Reasoning Mind* 6th grade curriculum. Reasoning Mind is a mathematics blended learning system developed by a nonprofit organization. Within this system,

---

students use computers during their math class while their teacher conducts targeted interventions with students who are struggling. The student is immersed in a lesson environment that includes a tutor character, two other student characters, and a virtual blackboard. The student characters make common mistakes which the real student is asked to correct, they help the real student when he or she gets stuck, and they interact with the real student and the tutor in ways that are intended to promote beneficial mathematical attitudes and beliefs. Both studies took place in two small urban middle schools in Texas. Study 1 involved 265 6th grade students, while Study 2 involved 223 6th grade students (demographics in Table 1).

Table 1: School Demographics and Performance

Demographic Group	% in School A	% in School B
Hispanic/Latino	33.1	97.4
Asian	6.0	0
Black or African American	17.3	1.5
Native Hawaiian or other Pacific Islander	0.4	0
White	36.7	1.1
Two or more races	6.0	0
Economically disadvantaged	69.8	92.2
Limited English Proficient (LEP)	10.9	23.5
2014 STAAR Mathematics Passing Rate	30.2	24.3

Study 1: Visuals

Study 1 included 4 fractions problems in Lessons 88 and 89 of the curriculum. All problems gave a fractional measurement (e.g., 3/8 of a meter), and then described what part of a whole this measurement was (e.g., was 21/40 of the whole length). The students then had to solve for the whole. Students were randomly assigned to one of five conditions (see Figure 1): 1) a control condition with no illustrations for the 4 problems, 2) a condition with diagrammatic illustrations that contained mathematical information in the form of a number line (e.g., in Figure 1, the cord could be thought of as a number line with a certain amount of the whole line indicated by being "chewed") or a shaded area model (e.g., an illustration showing how much grass in a whole field had been mowed), 3) a condition with contextual illustrations that simply showed part of the story context and contained no mathematical information, 4) a condition with misleading diagrammatic illustrations that contained incorrect mathematical information (e.g., in Figure 2 the illustration makes it look like most of the cord is chewed, when the answer shows that only a small portion has been chewed), and 5) a condition with irrelevant illustrations that had nothing to do with the story context. The misleading illustration condition was added based on the observation that some of the illustrations already in the curriculum were actually misleading – for example, there would be a problem about a snake who had one third of his length wrapped around a pole, but the illustration would display a snake completely wrapped around a pole. The diagrams were designed to be *supportive* rather than *essential* (i.e., the problem could be solved without looking at them). This is common in math curricula, and it allowed for the problems to still be solvable in conditions where the visuals were purely decorative.

Study 2: Personalization & Choice

Study 2 involved two more extended problem scenarios involving rates in Lesson 103 of the Reasoning Mind curriculum. Students were randomly assigned to one of four conditions: 1) a control condition with the standard story problems already in the unit (shown in Figure 2), 2) a condition where the problem topic is modified and assigned based on students' highest reported interest across four personalized topics (sports, food, shopping, and video games) on an interest survey given to all conditions, 3) a condition where students are randomly assigned to one of the four personalized

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

versions of the problem, and 4) a condition where the student is able to choose the problem topic from the four personalized topics before working on the problems.

Figure 1. Example of conditions in Study 1 (there was also a "No Illustration" condition).

Depending on condition, students were given one of five versions of the same problem. In each version, the numbers and question remained the same, but the topic was changed. The control problems are in Figure 2. The other four versions were personalized and changed the topic to sports, shopping, video games, or food. For the first problem (Figure 2, top), the personalization was shallow and involved swapping out "books" for another noun – footballs, lollipops, necklaces, and crystals. For the second problem (Figure 2, bottom), the personalization was deeper as more words were swapped – each of the locations was replaced with a setting that someone who engaged in the personalized topic would be interested in. For example, the video game variation discussed Kayla traveling to an Enchanted Forest, Dragon Cave, and Wizard's Tower while playing a video game. Readability factors were kept consistent among personalized variations and between personalized and control group problems, as was the presence and type of illustrations. For the first problem, all versions had two illustrations – one with an image of the object that had been swapped out for the pile of books (e.g., footballs), and one with a pile of dollar bills. For the second problem, all versions had the same diagram, but the images of each location were redrawn to match the locations given in the modified story (e.g., a dragon cave).

Let's use a table to investigate how the number of books I buy relates to the cost. I was at the bookstore the other day. I bought 1 book, which cost 4 dollars. Then I decided that I wanted two copies of the book. How much will two books cost?

Kayla walks at a speed of 50 meters per minute. It takes Kayla 10 minutes to walk the distance of 500 meters to school. After school, it takes her 20 minutes to walk the distance of 1000 meters to the library. After the library, Kayla walks to volleyball practice. The distance to volleyball practice is three times the distance she walks to school. If Kayla's speed did not change, and the distance increased by a factor of 3, then what do you think happened to the time?

Figure 2. Control (non-personalized) problems utilized in Study 2.

Data Analysis

In both studies, data were analyzed using linear regression models that predicted accuracy on each of the intervention problems and percentage of problems correct on the post test. The accuracy for individual problems was computed by assigning one point to each prompt the tutor asked students to type a numerical response into, and averaging performance across all such prompts. Predictors included Condition (4 or 5 levels), as well as controls for prior knowledge differences between conditions. We had slightly different prior knowledge data available in each study – in Study 1, we included performance on the previous unit test and previous lesson as controls. In Study 2, rather than prior test performance, we had available Guided Study Accuracy (an overall in-tutor measure of knowledge). The post-test measures for each study also varied slightly. In Study 1, there was a quiz immediately after the two intervention units that could be utilized. However, in Study 2 there was just a unit test available in the software that covered all the proportion lessons in the tutor, and no subsequent quiz. Although we used the unit test for long-term learning outcomes in Study 2, we also did supplementary analyses of individual items on the unit test that better aligned to the units where the intervention was placed. However, when analyses were done using individual items or sets of individual items, no additional significant effects were detected – thus we use the score on the entire test.

Results

Study 1: Visual Representations

Results showed that for the second problem, which is the one used as an example in Figure 1, having diagrammatic illustration significantly improved performance, compared to the other four conditions ($B = 14.97$, $p = 0.003$). However, there were no differences between the different conditions for models predicting performance on the other problems ($ps > 0.1$). The differing behavior of problem 2 was also shown by a problem by condition interaction when the data was analyzed with all the problems together. The illustrative diagrams were significantly more beneficial to performance on problem 2, compared to the other 3 problems ($Bs = 12.82, 13.95, 12.54$; $ps = 0.014, 0.007, 0.014$). Anecdotally, the diagrammatic illustration for Problem 2 may have been particularly effective because Pawthagoras is a fun and well-liked character within Reasoning Mind so students may be more likely to focus on the information in the diagram.

Also examined was performance on the post-quiz at the end of Lesson 89. Results showed that students who had received no visual images for the four problems while receiving their learning

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

materials significantly outperformed the other conditions on the quiz ($B = 12.03$, $p = 0.030$). Thus while there was some evidence from one of the problems that diagrammatic illustrations allowed students to perform better in the short term, in the long term, not having any visual representations at all facilitated post-test performance.

Data were also available for students' response to the prompt "How much did you like this lesson?" on a 5 point scale (Terrible, Bad, OK, Good, Great) for lessons 88 and 89. Students' two ratings were averaged, and entered into a linear regression model predicting average lesson rating based on Condition as well as their ratings of the four prior lessons as controls. Data for 49 students were missing due to the student not answering the prompt for either of the lessons. Results showed that students who received illustrations that contained no mathematical information (i.e., Contextual Illustrations and Irrelevant Illustrations) rated that they liked the lessons significantly more than other students (B = 0.328, p = .0185). Thus illustrations added purely for decorative purposes seemed to enhance students' ratings of the lessons, although the effect was relatively modest (0.3 on a 5-point scale).

Study 2: Personalization & Choice

Results for performance on the different versions of the shallow personalized problem (Q1 in Figure 2) showed no significant differences by Condition (ps > 0.1). Results for the different versions of the deep personalized problem (Q2 in Figure 2) showed that students who received personalization by choosing immediately before the problem significantly outperformed the control condition on this problem ($B = 11.82$, $p = 0.005$), and students who received personalization based on a survey also outperformed the control ($B = 8.76$, $p = 0.035$). The benefit of receiving a personalized problem randomly assigned over the control condition did not reach significance ($p = 0.088$); no further contrasts were significant (ps > 0.1). Thus personalization, whether accomplished through choice or survey assignment, boosted students' performance relative to solving a non-personalized problem.

On the unit test, although students who received personalization and choice numerically scored highest, this difference did not near significance when compared to the control condition ($p = 0.305$). The only significant contrast for this model suggested that students who receive personalization and choice score significantly higher on the post-test than students who receive a random personalized problem ($B = 12.92$, $p = 0.033$). Thus there is further evidence that personalized versions of problems in the absence of some sort of intelligent selection system to assign them based on student interests are not particularly useful. However, there is little evidence to suggest that personalization acted as a crutch that hindered students' performance when later solving non-personalized problems.

Discussion & Conclusion

Study 1 gave fascinating results as to how visual representations interact with students' performance, attitudes, and long-term learning. Diagrams that contain mathematical information enhanced student performance for one of the problems, but only in the short term. This suggests that for some students, these representations may be a crutch when taking a post-assessment with no visuals. Purely decorative visuals were liked better by students, but there was no evidence they enhanced performance or learning. Finally, the absence of visuals altogether seemed to allow students to learn best from the materials. However, while learning is certainly important, having students enjoy working in their math curriculum, rather than find it tedious or boring, is an outcome that should not be dismissed as irrelevant. Study 2 suggests that personalization accomplished through intelligent selection of interest-based problems (either through a survey or learner choice) can enhance performance in the short term, but only for problems where the personalization is more deeply and thoughtfully accomplished. In the long term, receiving personalization did not show any advantage over receiving non-personalized versions of problems. Attitudinal measures were not

available in Study 2, so it would be interesting to observe in future work how different approaches to personalization impact lesson ratings.

Taken together, the results from both studies suggests that curriculum designers need to think critically about the outcomes they most value, and how those outcomes may be at odds with each other when considering interest-enhancing interventions. In some cases, interest enhancements that boost performance and interest in the short term as students are solving problems may not transfer to assessments of learning, and could even potentially harm learning compared to materials without the enhancements. Our results for visuals suggest that the absence of visuals may be a desirable difficulty that forces students to become accustomed to solving unadorned problems without visual supports or cues. Our results for personalization suggest that the addition of interest-based content is not seductive or distracting, and that it may help in the short term if it is well-matched to learners' actual preferences. However, the type of personalization we implemented here where words were simply swapped out of the stories may not be effective for promoting long-term learning. Instead, if long-term learning is the goal for personalization, research suggests that considering how students actually use quantities in their day-to-day life when pursuing their interests might be most effective (Walkington & Bernacki, 2015). Both studies also suggest that all approaches to interest-enhancement are not created equal – for visuals, whether the visual contains mathematical information is key; for personalization, the depth of the personalization and how problems are assigned to students are important. This suggests that when compiling data from multiple studies on interest enhancements, it is critical to pay close attention to how the enhancement was actually implemented in the curriculum.

Students' interest in learning mathematics can wane over the middle grades, and curriculum developers are increasingly drawn towards quick solutions to attempt increase student engagement with their materials. Many of these solutions can involve considerable cost to the curriculum developer (e.g., hiring an artist or writing multiple versions of each problem), thus it is important to consider how motivational enhancements impact students' understanding of mathematical ideas. Future research should delineate the most effective interest-enhancing supports for different profiles of learners, and for different mathematical content areas.

SENSE-MAKING PRACTICES OF EXPERT AND NOVICE READERS

Aaron Weinberg	Emilie Wiesner	John Barr
Ithaca College	Ithaca College	Ithaca College
aweinberg@ithaca.edu	ewiesner@ithaca.edu	barr@ithaca.edu

Mathematics textbooks are a significant pedagogical tool, particularly in light of the growing interest in "flipped" classrooms. However, there has been little research on how mathematics students read and comprehend textbooks. This article uses the ideas of the implied reader, sense-making frames, and sense-making gaps to analyze students' reading of a section of a calculus textbook. In order distinguish potential weaknesses in students' content knowledge from their reading abilities, the article also compares students' reading strategies to the reading strategies of "expert" readers: professors in technical fields other than mathematics.

Keywords: Cognition, Post-Secondary Education

As "flipped" and blended classroom pedagogies become more widely used, students are increasingly expected to read and learn from various text materials (e.g., Staumsheim, 2013). However, research has suggested that mathematics students struggle to read their textbooks effectively (e.g., Shepherd, Selden, & Selden, 2012). Consequently, it is important for us to understand how students make sense of reading mathematics text materials.

As Osterholm (2008) noted, there is little research that describes how students read and comprehend mathematical texts. Shepherd, Selden, and Selden (2012) found that undergraduate calculus and precalculus students struggled to read their textbooks effectively. Shepherd and van de Sande (2014) compared the reading practices of first-year mathematics students, mathematics graduate students, and mathematicians, and characterized their reading strategies based on background knowledge, use of resources, and self-monitoring of comprehension.

We aim to expand the current research on how students read and understand mathematics textbooks by exploring the ways that students make sense of mathematical texts and to distinguish the role of content knowledge from the role of reading ability by comparing the students reading practices with those of "experts."

Theoretical Framework

Sense-making

In order to describe the aspects of the text that students focus on and the ways in which they interpret the text, we use the idea of a *conceptual frame*, which is "a mental structure that filters and structures an individual's perception of the world by causing aspects of a particular situation to be perceived and interpreted in a particular way" (Weinberg, Wiesner, & Fukawa-Connelly, 2014, p. 169). From this perspective, readers experience and seek to organize a collection of phenomena as they read texts; they use their knowledge and experience to create frames, and these frames then determine which phenomena are noticed and how they are interpreted.

Also central to the sense-making process are the ideas of gaps and bridges. Gaps are "questions that must be answered in order for the student to engage in or construct meaning for the mathematical situation or activity" (Weinberg, Wiesner, & Fukawa-Connelly, 2014, p. 170). A bridge is the answer that the student constructs. The ideas of frames, gaps, and bridges are complementary: the frame influences the nature of the gaps that arise, and, after constructing a bridge the student may notice different aspects of the text or interpret aspects of the text in a new way. Weinberg, Wiesner, and Fukawa-Connelly (2014) identified four types of frames:

- *Content*: Noticing mathematical aspects of the situation (e.g., symbols, definitions, facts, and concepts) and seeking to understand the meaning of the mathematical content or how to use it in an example that is being presented.
- *Communication*: Noticing the instructor's spoken, written, and gestural actions for organizing and presenting mathematical ideas and seeking to understand the ways the instructor is categorizing or connecting ideas, the ideas communicated by board layout, and the instructor's organizational cues.
- *Situating-mathematical purpose*: Noticing mathematical aspects of the situation and seeking to understand the usefulness or mathematical significance of the concept.
- *Situating-pedagogical purpose*: Noticing communicational aspects of the situation and seeking to understand how the instructor's pedagogical actions and decisions—such as choosing and ordering lecture content—are related to the meaning or significance of the mathematical ideas.

Implied and Empirical Readers

One of our goals is to identify the characteristics of the reader that might explain the differences in what people actually learn from reading a textbook. To do this, we use the idea of the *implied reader* of the text, which is "the embodiment of the behaviors, codes, and competencies that are required for an empirical reader to respond to the text in a way that is both meaningful and accurate" (Weinberg & Wiesner, 2011, p. 52). A *code* is "a way of ascribing meaning" to the symbols, words, and formatting (Weinberg & Wiesner, 2011, p. 53). *Competencies* are the "mathematical knowledge, skills, and understandings [that are required] to work within the established context" (Weinberg & Wiesner, 2011, p. 55). For example, in order to understand a description of the limit definition of the derivative, a reader would need to have some knowledge of functions, limits, rates of change, and their various representations.

Research Questions

Based on the goals and theoretical framework, our research questions are:

- What gaps do students encounter as they read a math textbook, and how do they bridge these gaps?
- What sense-making frames do students use while reading?
- How can mismatches between the implied reader and the actual reader explain the gaps that students encounter and the bridges they construct?
- How do the practices of "expert" readers compare to the students?

Methodology and Methods

Student Participants

All 22 students in the second author's second-semester calculus class were invited to participate in the study. Five students volunteered and participated in the interviews. All of the students had previously completed a standard first-semester calculus course in college or received AP credit for first-semester calculus.

The textbook used in the class—and the interviews—was *Calculus: Single Variable* (Hughes-Hallett et al., 2012). Throughout the semester, the students had been regularly asked to read sections of the textbook outside of class and complete various activities, such as annotating the textbook and writing summaries of textbook sections in groups. Thus, by the time the students participated in the interviews, they had considerable experience reading their textbook.

Faculty Participants

In order to distinguish the role of content knowledge from the role of reading ability, we compared students with "expert" readers. We thought of an "expert" reader as a person who was used to reading dense, technical articles—and had some background in the concepts of calculus—but was neither a mathematician nor an expert in the specific concepts in the texts.

To recruit "expert" readers, we contacted colleagues in the physics, chemistry, biology, economics, and computer science departments at our institution. All contacted professors agreed to participate: two from the physics department, and one each from chemistry, biology, economics, and computer science. With the exception of the physicists, the professors interviewed had not actively engaged with introductory calculus ideas for (at least) the past ten years. The physics professors had encountered introductory calculus concepts in their teaching but had not recently encountered the specific topics we used in the interviews.

Texts

Our goal in selecting excerpts of the textbook was to find sections for which students should have the necessary background knowledge and weren't purely procedural (i.e., only presenting a formula or a step-by-step procedure). We selected the excerpts from the "applications of integration" and "systems of differential equations" chapters that presented formulas as well as conceptual explanations for how these formulas were derived. In this report, we describe an interview based on sections from Hughes-Hallett et al. (2012) Chapter 8.2, *Applications* [of the integral] *to Geometry*": the introduction and the section "*Arc Length*".

Interview Methods

Each student participated in two interviews, approximately five and ten weeks into the (15-week) semester. Each professor participated in a single interview. The interviews were video-recorded to capture the interviewee's gestures and writing, and the audio was transcribed.

In order to elicit the interviewee's perspective and experience of reading the textbook, our methods involved interviewing participants to identify (1) how they perceived the situation; (2) the gaps they encountered; and (3) they way they drew upon their resources to bridge the gaps. We used a *message q/ing* protocol (Dervin, 1983), where participants were asked to read the text and stop at places where they had questions or were confused, and engage in discussion. When they were finished reading the text, the participants were asked to describe the main ideas of the section. Then, we interviewed the participants using an *abbreviated timeline* method (Dervin, 1983): we asked them to explain the meaning of each graph and/or formula, how the terms in the graphs and formulas had been derived, how the graphs and formulas were connected to each other, and why the text's explanation of the connections and derivations made sense.

Analytical Methods

Sense-making frames, gaps, and bridges. We viewed a gap as a question that a reader has while reading the text. However, a reader may not be consciously aware of the gap when it occurs, and is unlikely to consciously think of it in terms of an explicit question. Thus, gaps may be either recognized by the reader while reading the text or during the subsequent interview.

To identify gaps, we individually read each transcript line-by-line and identified collections of utterances that appeared to be evidence that the reader had had an explicit question about the text, had constructed a bridge, or where there were verbal hesitations or pauses. In order to identify the sense-making frame that the reader used, we identified the aspects of the text that were the focus of the explanation or question.

Implied reader. We used the concept of the implied reader as a tool to provide theoretically-grounded explanations for why a particular reader may succeed or fail to construct mathematically

correct conceptions from the text. We compared all of the interviews to identify places where at least one interviewee experienced a gap or described the concepts incorrectly. Then, we described the various behaviors, codes, and competencies that might be required to construct a mathematically accurate interpretation of these aspects of the text and used these descriptions as a working hypothesis for why some interviewees struggled while others did not.

Results

Types of Gaps

In many cases, the gaps that students and professors experienced appeared to be related to their lacking one or more of the aspects of the implied reader. Most of the were related to missing mathematical competencies: the meaning of derivatives of functions and approximating a derivative at a point, the meaning of Riemann sums and their connection to definite integrals, and the reasoning underlying the derivations of formulas. The interviewees typically used content sense-making frames when they identified these gaps. For example, when Frank read the text's explanation of arc length, he appeared to think of the Riemann sum as computing area under the curve shown in Figure 1 and described several options for the method that you could use to do this—specifically, using left-hand, right-hand, or trapezoid rules. Thus, he encountered a gap in which he appeared to ask "which type of Riemann sum is being used?" This gap may be attributable to Frank's lack of understanding of Riemann sums as a general computational tool that isn't tied to a specific geometric method:

A definite integral can be used to compute the *arc length*, or length, of a curve. To compute the length of the curve $y = f(x)$ from $x = a$ to $x = b$, where $a < b$, we divide the curve into small pieces, each one approximately straight.
Figure 1. Excerpt from text showing construction of arc length approximation.

Frank: If you have, um, like a left or a right hand sum, where it's just a bunch of blocks, you know, making up the curve, um, it's kinda hard to imagine a curved line going through those blocks. But when you have a Riemann sum—more specifically, the Trapezoid Rule—it's a little easier, I guess, to envision, that like a bunch of, um, angled lines making up a curved line, as opposed to just a bunch of boxes making up a curved line.

Interviewer: Hmm. And you've mentioned the Trapezoid Rule. So how are they using the Trapezoid rule, where do you see that in their explanation?

Frank: Well it's… I'm not really seeing it, but I know that the Trapezoid Rule is really just a way of instead of drawing boxes, to calculate the area under a curve, you draw it, kind of triangles to represent the area under the curve. Draw a box, and then, like, a triangle on top of it connecting two points on the line, and if you were to look side by side, like a left and right hand sum, versus a trapezoid rule, um, to find the length of a curve like this, it would, uh,

look a little more natural, I guess. But, I don't know, that's just what I thought of when I saw that they were using Pythagorean Theorem to calculate the arc length.

Unlike the professors—who were usually able to identify the source of their gaps—the students' missing competencies resulted in their being unable to identify the origins of their gaps. For example, Frank appeared to believe that Riemann sums could only be used to find areas; this resulted in his gap being a question of *which* type of area approximation was being used, rather than what the Riemann sum represented; this led to a mathematically incorrect bridge.

Most professors and students experienced a gap when they encountered the formula $\Delta y \approx f'(x)\Delta x$, as shown in Figure 1. This gap appears to have originated due to their not possessing one or more required competencies related to understanding the derivative and how it is related to slopes of secant lines. For example, in the excerpt below, Professor D., a computer scientist, initially attempted to bridge this gap by drawing on his knowledge of other mathematical concepts (specifically, linear functions), but eventually felt that this bridge was insufficient:

> *Professor D.*: I'm still not sure why the change in *y* is roughly…. And it has to do with the linearity assumption, like piecewise linear sort of functions. And I just forget why.... You know, it's like *y=mx+b* kind of thing. So the derivative is like the *m* and the *b* is zero, because it's just a change from your point. So it's something like that, but that's just the only part that I'm like, not... I'm sure they explained that earlier in the book too.

Professor K., a physicist, experienced the same gap, but was unable to construct a bridge:

> *Professor K.*: So the one thing that I am puzzling to remember is why delta-*y* is *f*-prime *x* times delta *x*. Otherwise this all makes good sense.
> *Interviewer*: And so is it just the assertion that this is true, or how they...?
> *Professor K.*: No, how they use it is fine. This is all very clear. But this assertion... I don't remember.
> *Interviewer*: Is it just the notation, or is there something about the concept behind that?
> *Professor K.*: Yeah, the notation is fine, it's just remembering why *y* is going to be equal to the derivative of *x* times delta *x*.
> *Interviewer*: But then once you assume that's true, then everything else…?
> *Professor K.*: Everything else is fine, yeah.

Although most students appeared to experience the same competency-related gaps as the professors, they often did not recognize these gaps until the interviewer explicitly asked them about the section of the text. For example, Peter's initial hesitation in his response suggests that he did not experience a gap while he read; he recognized this gap during the interview, but was unable to construct a bridge and experienced a lack of understanding:

> *Interviewer*: Did it make sense when they said that the change in y was just f-prime-x times the change in x?
> *Peter*: Um… not entirely. I don't really know... Like yeah, they kinda just threw that in there without really explaining it.

In addition to experiencing gaps related to mathematical competencies, most of the interviewees also experienced gaps related to mathematical codes. For example, several students expressed confusion about the role the symbols *a* and *b* played in Figure 1. Among the professors, these appeared to primarily include (missing) codes related to mathematical terminology and notation. For example, Professor I., a biologist, experienced gaps when reading "integrand" and "elementary antiderivative."

Professor I.: Well I would need to go back up and look at some of these vocabs. But I guess an integrand is the solution of this integral problem. Um… but this elementary antiderivative. I guess to find an integral, you have to find the antiderivative? But I don't know what an elementary antiderivative is. Um… so I was a little bit worried about that.

Bridging and "Jumping" Gaps

As shown in several of the examples above, there were numerous instances where students and professors experienced gaps that they were unable to bridge; they continued reading by "jumping" the gap. However, the professors were much more likely to make the un-bridged gap an object of reflection, and to both acknowledge the lack of a bridge and make conjectures about what a bridge might look like or how the un-bridged gap might impact their understanding. For example, Professor I. made educated guesses about how "elementary antiderivatives" might be used, and Professor K. appeared to recognize how not knowing why $\Delta y = f'(x)\Delta x$ might impact her understanding. In contrast, Peter didn't recognize his own lack of understanding about this equation, and did not appear to reflect on how this unbridged gap might impact his interpretation of the text.

Sense-Making Frames

All of the students and professors tended to use a content sense-making frame for much of the reading. However, a few of the students and all professors used *multiple* sense-making frames while reading. For example, Professor K. used and coordinated content, communication, and situating-pedagogy frames to understand the derivation of arc length:

Interviewer: Okay. How would you describe the book's method for finding arc length?
Professor K.: How would I describe the method... Um... I'm not quite sure how to describe it, except that they're following the same steps that they suggested in their box. So the first step that they have here is that they show how you can find the length by breaking this up into small pieces. So in delta-*x* it's a two-dimensional function, and so delta-*x* and delta-*y*. So they show how you could approximate it. And then they take that into a summation over very small pieces. So you go from these delta-*y*'s to derivatives. So that gives me very small pieces. And then they take that sum, and they turn it into an integral. So they're following their own steps and laying out their procedure. And then they give me a nice boxed equation that I can just go to and work from.

In examining the details of the calculation, Professor K. employed a content frame. Her reference to following steps and laying out a procedure suggest a situating-pedagogical frame, and her discussion of the boxed equation suggested she was using a communication frame.

All of the professors regularly used multiple sense-making frames—in particular, situating-pedagogical frames—and this appeared to be associated with their ability to recognize more gaps, construct (mathematically correct) bridges, and to use various resources to create these bridges. Using these frames appeared to enable the professors to bridge content-related gaps, even when they lacked some of the competencies or codes of the implied reader. In contrast, the students relied almost exclusively on content sense-making frames.

Drawing on Other Knowledge

In addition to using multiple sense-making frames, professors tended to draw on informal knowledge and their own disciplinary knowledge to make sense of the mathematical ideas. For example, Professor D., who was a computer scientist, encountered gaps related to understand the limiting process of transforming a Riemann sum into a definite integral. He described his bridge as based on understanding the integral as a sum of discrete entities:

Professor D.: I guess I see an integral just being a sum of a bunch of discrete things, because I'm a computer scientist. I'm, you know, discrete math instead of continuous math. So I actually really see the thing above it. The summation of all of these little hypotenuses being summed together. So uh, this notion of like having a discrete sum, and then as you integrate—as you integrate from, you know, you integrate the number of sections, and those go to infinity and the size of the section goes to zero, like it's kind of the same thing. And it's just summation and integral are basically the same symbol in my head.

Professor M., a chemist, lacked some of the implied reader's competencies for limits and Riemann sums. Rather than draw on his disciplinary knowledge, he used informal knowledge to bridge gaps he encountered when trying to understand how to approximate volume of a sphere:

Professor M.: If we're approximating this volume with a, with um, with a bunch of little cubes, you know, um... And smoothing it out to make a round shape, then that would be maybe what this is trying to do. I have no idea if that's right. That's... That's kinda what I'm thinking about... So if we were doing this sphere, we're taking, and we're like breaking it into Lego blocks, those blocks are easy volumes to calculate, so we take those, add up all those blocks together, and then we have to... [makes a rounding shape with his hands] to smooth out the edges.

Discussion

There were numerous similarities between the "novice" and "expert" readers. Both groups primarily used content sense-making frames and experienced numerous gaps. Most professors interviewed were not familiar with the formal notions of Riemann sums or limits and frequently did not recognize terminology; this could be, in part, due to their not having actively thought about calculus concepts since they were students in college. Although the students had recently discussed ideas of Riemann sums and limits, they also often experienced gaps that appeared to be related to the same calculus concepts as the professors.

These gaps can be viewed as the result of discrepancies between the implied and empirical readers—that is, the students and professors lacked particular competencies and codes that were required to construct mathematically accurate interpretations of the text. For the students, lacking some of the competencies resulted in them mis-identifying the source of their gaps, being unable to bridge the gaps, or constructing bridges that were mathematically incorrect.

The professors were generally better at recognizing gaps while they were reading the text. In contrast, the students tended to only notice the gaps when they were asked to focus on a specific section of the text or asked directed questions. This suggests that the professors tended to employ behaviors that enabled them to monitor their own understanding as they read, whereas the students did this less frequently.

In contrast to the students, the professors were often able to construct mathematically accurate codes and competencies in order to bridge gaps related to their lack of knowledge of calculus concepts. They appeared to identify the sources of their gaps; they drew on their other mathematical knowledge to construct bridges; they drew on both informal knowledge and knowledge from their own discipline to construct bridges; and they employed multiple sense-making frames—in particular situating-pedagogy frames. These practices appeared to enable them to generate accurate interpretations of the text, to construct missing codes and competencies in some places, and to recognize the limitations of their interpretations.

Taken together these results suggest that constructing accurate interpretations of a mathematical text requires particular background knowledge and ways of interpreting the various symbols and technical terms. However, a lack of background knowledge can be overcome in several ways. In particular, the examples here highlight the importance of attending not just to the mathematical

content, but the way it is communicated and organized. This analysis suggests various ways of helping students structure their reading experience—such as asking questions that help students focus on non-content aspects of the text. It also suggests that students need help recognizing when they encounter a gap and developing strategies to bridge gaps. However, some of the practices of the "expert" readers, such as making connections with previous mathematical knowledge, might be more difficult to help students do.

These results build on the prior literature by beginning to disentangle the impact of content knowledge from reading practices. For example, Shepherd and van de Sande (2014) found that *mathematicians* employed many of the effective practices reported in this study. However, our results suggest that readers who are less familiar with the content (i.e., the professors) might read less effectively than people who are more familiar (i.e., the students who were currently taking calculus). Furthermore, using multiple sense-making frames and reading reflectively might enable readers to overcome deficiencies in background knowledge. These results highlight the importance of attending to both knowledge and reading practices when asking students to learn from reading mathematical texts.

SECONDARY SCHOOL STUDENTS' CONCEPTIONS OF PROOF IN TRINIDAD AND TOBAGO

Andrew A. Hunte
University of Trinidad and Tobago
andrew.hunte@utt.edu.tt

This study examines students' conceptions of proof in Trinidad and Tobago. I conduct semi-structured interviews with 21 secondary school students, to investigate their opinions of (a) the purposes of proof in mathematics and (b) the type opportunities for proving in geometry in the Caribbean Secondary Education Certificate (CSEC) examinations. My analysis suggests that students identified the roles of verification, explanation, systemization, and appreciation within the work of mathematicians or school mathematics. The latter role suggests students' understanding of the intellectual need of proof in their mathematical learning. All 21 students considered the calculations with explanations questions in the CSEC examinations as informal opportunities to construct proofs. The development of these non-proof arguments has the potential to go beyond the borders of this reasoning and proof activity to evolve into opportunities for construction of proofs.

Keywords: Reasoning and Proof, Curriculum, High School Education

Introduction

The reformers of mathematics education in Trinidad and Tobago suggest that students should have more opportunities with proof in their secondary school mathematical experiences (Republic of Trinidad and Tobago, 2009). In Trinidad and Tobago, researchers are working to understand students' perspectives about what constitutes a proof and the roles of proof in school mathematics. Researchers are also interested in how the new reform-oriented mathematics curriculum, Caribbean Secondary Education Certificate (CSEC) examination materials, and teachers' instruction influence students' notions of proof in school mathematics. To date, there are no existing studies, which examine students' mathematical learning in the post-implementation period of the reform-based curriculum. Furthermore, the recent CSEC examinations offer more calculate and explain type of questions rather than directly asking students to prove (Caribbean Examination Council [CEC], 2014). As a result of these concerns, there exists a need to investigate students' perceptions of (a) the purpose of proof in school mathematics and (b) their opinions of the opportunities to do proofs in their textbooks and CSEC assessment materials.

Research Questions

The research questions, which drive my inquiry, are:

RQ.1 How do students in Trinidad and Tobago view the purposes of proof in mathematics and secondary school mathematics?

RQ.2 What are students' conceptions about the type opportunities for proving in geometry in the CSEC examinations?

Theoretical Perspectives

In this study I use a framework previously used by McCrone and Martin (2009) and Dreyfus and Hadas (1987) to help investigate students' conceptions of proof. This framework entitled: The Six Principles of Proof and Understanding describes the knowledge any person within an informed mathematics community should possess about the roles, structure, validity, and generality of a proof. In this brief report, I discuss the findings associated with the roles of proof in mathematics, school mathematics, and assessment materials.

Methodology

In this study, I conducted semi-structured interviews with 21 students (male or female who are 13 to 16 years old) in forms three (ages 13-14), four (ages 14-15), and five (ages 15-16) from three selected school sites. For each school, I randomly selected seven students from those who provided voluntary assent and parental consent to participate in the student interviews. Additionally, these students also participated in the proof-based lessons on Congruency of Triangles, I observed in another study examining the teaching of reasoning and proof. The selection of the seven students from each school was according to the grade level I observed at the respective school. Each interview lasted 45 minutes to one hour.

Results

According to students' responses, the roles of proof in mathematics included verification, explanation, and systemization. In Table 1, I present a summary of the meaning of each of these roles of proof students identified in mathematics. I also present counts of the number of students identifying each role. These counts do not indicate the number of times a student mentioned a role but the number of students who talked about a specific role.

Table 1: Roles of Proof in Mathematics

Role of proof	Description	No. of Students
Verification	To verify that a statement of conjecture is true	9
Explanation	To give insight into why a statement is true	15
Systemization	To build an axiomatic system of results	2

Representative Quotes of Students' Conceptions of the Roles of Proof in Mathematics

When I asked the question "In your opinion, why do mathematicians write proofs?" The following students, stated:

Ava: Mathematicians write proofs to explain. I mean that proof explains the things a lot easier for other people like other mathematicians and people who will read the proof see exactly how other mathematical concepts make up reasons supporting why the result is true rather than just showing it is true. (Explanation)

Ray: To back up themselves to show they are right and really this is important because of how mathematics topics are usually connected, he may need to verify that his Theorem is right so that he can use it to prove other results later on. (Verification & Systemization)

Roles of Proof in School Mathematics

In their responses, students identified two roles of proof in school mathematics. By school mathematics, I refer to the proof opportunities in school during the teaching of various secondary school mathematics topics. Students stated the following roles (a) promoting understanding and (b) appreciation of mathematics. Of the 21 students, 19 students talked about the promotion of understanding. According to the students, three main themes emerged in their discussions of this role of proof. Students claimed that through the promotion of understanding they can develop (a) insight into why a theorem is true, (b) knowledge of the utility of a proven result, and (c) habitual inclinations for their own proof writing practices.

Of the 21 students I interviewed, 5 students talked about the role of appreciation. This role is an interesting finding because it demonstrates a unique conception of proof held by students in Trinidad and Tobago. According to these students, the teaching of proof allows them to appreciate the usefulness of the underlying axioms and other mathematical results used to construct a proof. For example, when I asked, "In your opinion, could you provide reasons why you are taught proof in mathematics?" the following students explained:

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Danni: I think Miss really shows us the proof even though it is not required, to help us appreciate the mathematics you are learning like where it came from and how to use it to solve problems.

Melissa: Well the teaching of proof helps us to really value the usefulness of mathematics when you see how Miss apply some other results we learned before to prove some result we are now learning.

Taylor: To help us understand and appreciate the mathematics we are doing cause if she does not show us the proof for a result we will just write it down and not really understand the purpose of it and how to connect it to other stuff and we would really be excited about it.

Overall, these students demonstrated through their opinions that the appreciation of mathematics is an important component to their learning in school. Each student articulated how the role of appreciation motivates an awareness of the usefulness of their pre-existing knowledge and the application of a new result. In particular, Taylor emphasized that her appreciation of a new result allows her to see the connections to previous knowledge. Melissa emphasized that through her teacher's application of previous knowledge when writing a proof, she valued the usefulness of her previous knowledge. As a result, Melissa noticed the links between her previous knowledge with the new knowledge she learned. Danni asserted that through the appreciation of a mathematical formula, he became aware of its' utility during problem solving.

Opportunities for Proof in CSEC Examination

In the introduction of this report, I highlighted the prevalence of calculate and explain type of questions in the CSEC mathematics examination. Given the high stakes of this exam in determining students' future engagement with higher-level mathematics, it is important to investigate whether students consider that the informal explanations required by these exercises, are potential opportunities for constructing a proof.

Of the 21 students in this study, all students claimed that response to this type of question would qualify as a proof. Students provided the following reasons, (a) a clear explanation of why your answer is true is a proof, (b) a proof is an explanation that supports your answer, and (c) an explanation that promotes insight into your thinking is a proof.

When I asked Sean the question, "Consider the question taken from the January 2014, CSEC Mathematics examination. The question has a pair of parallel lines with a transversal cutting across the two lines at an angle of 24^0. You are required to find the missing angles and provide reasons supporting your answer. In your opinion why or why not would you consider an answer to this question as a proof?" He responded:

Sean: Well thinking about it, the question specified that you must provide supporting reasons for your calculations. In this case, I really think they [the examiners] want you to give a clear explanation supporting why your answer came out to be that way. Well to me explaining why is a proof of your claim. I believe by explaining this the examiners will understand your thinking.

Sean reflected on the examiner's requirement of providing supporting reasons for calculations. When Sean stated: "I really think they [the examiners] want you to give a clear explanation supporting why your answer came out to be that way" he suggested that the examiners expected students to provide supporting reasons for the steps taken to calculate the unknown values. As Sean stated "to me explaining why is a proof of your claim" he voiced the opinion that providing an explanation of why a claim is valid qualifies as a proof. Sean explained further the necessity for providing a clear explanation. For example, when he stated, "I believe by explaining the examiners will understand your thinking" Sean suggested that the examiners will understand the line of

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

reasoning students use to compute the unknown values. This latter quote also demonstrated that Sean saw the intellectual need of explaining one's thinking when proving.

Conclusion

The students' conceptions of the role of appreciation of mathematics demonstrated their understanding of the intellectual necessity of the mathematical knowledge they acquire at school. Harel and Tall (1991) identified the intellectual necessity principle as a standard for pedagogy that involves presenting subject matter in a way that encourages learners to see its intellectual necessity in their mathematical experiences. Therefore, students seemed to understand the role of proof based on their teachers' construction of proof arguments. The habitual inclinations for students to write proofs that provide insight and allow all readers to follow the line of reasoning is important for student's future metacognitive development of proof writing skills. The informal calculate and explain opportunities in the CSEC examinations do provide opportunities for students to construct proof arguments. Although these questions do not explicitly state the word "Prove," they provide the necessary scaffolding to develop rationales for reasoning that could eventually go beyond the border of this activity and evolve into formal proof arguments.

OPPORTUNITIES CREATED BY MISDIRECTION IN MATHEMATICS LESSONS

Andrew Richman
Boston University
asrich@bu.edu

Leslie Dietiker
Boston University
dietiker@bu.edu

This study provides evidence that enacted lessons based on written curriculum do not need to follow a direct curricular path from beginning to end. Deviations in this path, which we refer to as misdirection, can create opportunities for enhanced student interest in mathematical questions. We present three examples of misdirection from two enacted lessons and describe how they intensified student investment in the mathematics by creating contradictions that inspired students to ask their own mathematical questions. These examples can serve as models to teachers and curriculum writers who seek ways to motivate students to pursue mathematical understanding.

Keywords: Curriculum, Curriculum Analysis, Affect, Emotion, Beliefs, and Attitudes

It is often assumed that the role of curriculum is to provide students with a direct path from what they already know to what they need to know (Tyler, 1949). The recent focus on spatial metaphors of curriculum, such as a trajectory (e.g., Clements & Sarama, 2004; Gravemeijer, Bowers, & Stephan, 2003; Simon, 1995) is consistent with this assumption. This increasingly popular metaphor draws attention to an initial point, described as the "teachers' hypotheses about the students' mathematical knowledge" (Simon, 1995, p. 138), and a target (i.e., a learning goal). This perspective highlights the instantaneous decisions of direction that teachers make as they guide their classes along anticipated "learning routes" toward a target and adjust instruction in order "get back on track" when necessary (Gravemeijer et al., 2003, p. 55).

Yet, in our analyses of mathematics curricula as they unfold in classrooms, we regularly see "learning routes" that are not linear and that do not progress smoothly. In fact, we have found some paths that appear to change direction, double back on themselves, or skew away from the target. We refer to these indirect paths as instances of "misdirection." Rather than conceptualize these paths as a problem with curriculum design, we instead recognize misdirection as potentially beneficial and generative for learning. Understanding these moments of misdirection can inform the crafting of mathematics curricula (written and enacted) that stimulate student curiosity. In this paper, we describe moments in mathematics classrooms during which obstructions toward the mathematical goal of the lesson motivated students to become invested in the pursuit of mathematical understanding. Our goal is to use these analyses to complicate curricular assumptions and suggest a new curricular metaphor that offers insight into this complexity.

Theoretical Framework

The complex ways that information can unfold across a sequence have been studied in narrative by literary theorists since Aristotle. Conceptualizing mathematics lessons as *mathematical stories* allows us to capitalize on this work. With this framing, we gain new analytic tools to interpret the way mathematical ideas emerge and unfold across a temporal sequence from beginning to end (Dietiker, 2015). This framework is not a focus on contextual story problems, but interprets all of the mathematical content of a lesson as a sequence of revelations. Although mathematical stories can be recognized in written mathematics curriculum materials (i.e., the intended curriculum), our focus is on the mathematical stories that are found in the complex realm of the classroom (i.e., the enacted

curriculum). In this framework, the students and teachers are the actors in enacted mathematical stories.

Literary stories engage an audience by provoking questions and then slowly revealing the answers in ways that both inform and entertain (Nodelman & Reimer, 2003). Stories that contain twists in the plot misdirect a reader into answering questions incorrectly, setting up opportunities for surprise when their predictions are later shown to be false. Framing mathematics curriculum as a story enables an analyst to understand how misdirection can occur. This framing also helps to illuminate the logical and aesthetic roles that misdirection can play in the experience of the students.

To analyze the narrative structure in mathematical stories, we employ the hermeneutic codes developed by Roland Barthes (1974). These codes were designed to describe the way in which literary plots unfold. With these codes, the emergence and progress made for any mathematical questions of a lesson are tracked, allowing for the identification of misdirection that occurs along the way as well as the factors that enabled the misdirection. Three codes in particular relate to misdirection -- equivocation, snare and jamming.

An *equivocation* describes a moment in a story when a reader can identify, upon reflection, that she or he was misled through ambiguity. The narrator of the story does not overtly lie, as the information presented is technically accurate. However, the telling of the story allows or arranges for a misunderstanding to occur. A *snare* describes a moment in a story when a reader can later identify, upon reflection, that she or he was explicitly misled. While equivocations are lies by omission, snares are lies by commission. *Jamming* is the interruption of progress on a question in a way that suggestions the question cannot or will not be answered.

It is important to note that students, as well as teachers, can be responsible for misdirection in a mathematical story. This conflicts with the common assumption that students in the classroom are solely the audience, not the actors, in the story. While students can be both actor and audience, we analyze the plot of a mathematical story by interpreting the potential mathematical story available to a hypothetical, silent, intellectually engaged learner.

Methods

The data presented in this study are from observations of two algebra classrooms in different regions of the United States using the same inquiry-based algebra curriculum materials (CPM Educational Program). The teachers, whom we will call Ms. Becker and Ms. Wilson, have 20+ and 30+ years of teaching experience respectively, and each has been using CPM materials for at least 5 years. Ms. Becker teaches at a public middle school in the South and Ms. Wilson at a private high school in the Northeast. Each teacher was video and audio recorded while enacting lessons from the same written materials. The three selected lessons focused on: 1) solving systems of equations by substitution, 2) different representations of quadratic functions, and 3) the zero product property.

The videos were transcribed to capture the whole class dialogue as well as the dialogue from one group of students in each classroom as they worked together on assigned problems. From the transcripts, a team of four researchers worked in pairs to identify questions that were formulated by the teacher, students, or textbooks. The two pairs then came together to resolve discrepancies. Next, researchers used Barthes' codes to identify progress toward the answering of the questions from the formulation of each question to its disclosure. With this coding, instances of equivocations, snares, or jamming, defined above, were identified and compared in order to answer the question "How does misdirection occur in high school algebra classrooms and how can its role in the student's experience be explained?"

Findings

Our analysis of these lessons revealed examples of all three types of misdirection. Below, we provide an example of each form of misdirection and explain how each one created surprise when a

contradiction was revealed. We then show how each contradiction led students to ask their own questions about the mathematics, thus increasing their investment in the outcome of the lesson.

Equivocation

An example of equivocation occurred in the first part of a lesson in Ms. Wilson's class on identifying the roots of a quadratic equation using the zero product property. The goal of this part of this lesson was for students to understand that three non-collinear points are required to uniquely identify a parabola. In order to introduce this idea, Ms. Wilson engaged the students in three rounds of a "guess my parabola" game. In each round, the teacher thought of a parabola, gave them information about that parabola and challenged them to guess her parabola. In the first round she gave them the y-intercept, in the second round she gave the two x-intercepts and in the third round she gave the y and both x-intercepts. The equivocation in this sequence of activities was the assumption from the beginning of the game that it was reasonable for someone to determine her parabolas with only one or two points. This was misleading in the first two rounds because there were an infinite number of parabolas that fit these conditions.

Rather than simply revealing to the students at the beginning of the activity that knowing three points of a parabola would uniquely identify it, this teacher created the expectation that it might take fewer. Students were then surprised when they discovered that it is unlikely for them to guess her parabola with just one or two points. This surprise gave way to curiosity and then various levels of understanding as students realized why they were having so much difficulty. Student investment in the mathematical questions was evident by the energy with which they expressed their realizations and how hard they pressed the teacher for more clues, and eventually the answer.

Snare

A dramatic example of what can happen as the result of a snare occurred in another of Ms. Wilson's classes during a lesson on different representations of quadratic functions. Students were trying to graph the parabolic path of a water balloon from an equation. One student made a calculation error that resulted in a large negative value for y, suggesting that after the balloon was launched it was underground. In response to this snare, a second student addressed the contradiction between the expected y-value [i.e., a positive value] and the calculated y-value by creating an inventive interpretation of the situation in the context of the mistake. The absurdity of the story that resulted, involving a bird and a remote control plane, possibly convinced the student to re-evaluate his calculation and thus catch his error. The twist in this mathematical plot, this time a misleading error, inspired these students to construct additional explanatory stories and persevere to resolve the contradiction.

Jamming

One example of jamming occurred in Ms. Becker's lesson on the substitution method for solving systems of equations. At the beginning of this lesson, the class was attempting to solve a system of equations using the previously learned equal values method (i.e. solve each equation for the same variable, set them equal to each other, and solve the resulting one-variable equation). The new system was different than other systems students had previously solved using this method because isolating a variable in the second equation led to non-integer coefficients. This complication led students to assume the problem was unsolvable using the method that they knew–they were "jammed." Later, when Ms. Becker introduced substitution — the method that solves this system in a more efficient way — the students demonstrated clear relief. By introducing a problem that led to jamming, Ms. Becker enabled the students to become invested in finding an alternate way to solve the system.

Discussion

In this paper we used a mathematical story framework to illustrate the counterintuitive proposition that misdirection in the mathematics classroom can be beneficial. Thus, we propose that studying how misdirection can be used effectively in mathematics lessons will offer potential solutions to how curriculum might improve student attitudes toward learning mathematics.

Misdirection, however, is just one of many devices that storywriters use to create captivating narratives (e.g. foreshadowing, suspense, etc.). Framing mathematics lessons as stories provides mathematics educators access to this valuable set of tools. We encourage teachers, other curriculum designers, and mathematics education researchers to extend this work—to seek new ways that powerful storytelling techniques can be used to design lessons that capture student attention and inspire students to become invested in mathematical outcomes.

Palabras clave: Currículum, Geometría y Pensamiento Geométrico y Espacial

Los libros de texto de matemáticas son una herramienta fundamental para el docente ya que pretenden fijar, organizar y estructurar los conocimientos que son requeridos para familiarizarse con una disciplina o un campo de conocimiento (Alzate, 2000). En investigaciones pasadas, como la de Santanero (2011), se demostró que los problemas propuestos en libros de texto de secundaria no son auténticos, es decir, el contexto en el cual se desarrollan no es del todo real. Además, Santiago, Slisko y Nolasco (2011) afirman que los contextos artificiales generan actitudes negativas en los estudiantes. Por esta razón, analizamos 29 problemas de un libro de Geometría y Trigonometría de Nivel Medio Superior (Martínez S., Espidio M., Santiago G. y Álvarez R., 2013) para explorar si en esta asignatura y nivel se utilizan problemas auténticos. Nos basamos en la teoría de Palm (2006) la cual tiene 8 criterios que el problema debe cumplir, pero sólo consideramos 3 los cuales son:

- **Evento**. Este aspecto se refiere al evento descrito en la tarea. En la simulación de una situación del mundo real es un requisito previo que el acontecimiento descrito en la tarea de la escuela ha ocurrido o tiene una ocasión justa de ocurrir.
- **Pregunta**. Este aspecto refiere a la concordancia entre la asignación dada en la tarea escolar y en una situación extraescolar correspondiente. La pregunta en la tarea escolar es una que se pudo presentar realmente en el acontecimiento del mundo real descrito, es un requisito previo para que una situación del mundo real correspondiente exista.
- **Información/datos**. Este aspecto se refiere a la información y a los datos en la tarea e incluye valores, modelos y condiciones dadas.

Si el problema no cumple con uno de estos criterios se considera como no auténtico. Se seleccionaron los problemas que tuvieran una imagen para ayudar a entender el contexto descrito en el texto. Lo anterior fue también con la intención de analizar el modelo situacional propuesto por el autor, y nos preguntamos si tal imagen ayudaría a los estudiantes a entender el contexto del problema y a resolverlo de manera correcta.

La mayoría de los problemas analizados no cumplen con la teoría de Palm (2006). Los autores de este libro de texto no consideran la autenticidad de problemas ya que los contextos mostrados no cumplen con la teoría de Palm. Además las imágenes mostradas tampoco ayudan ya que, en algunos casos, no muestran las situaciones descritas.

Keywords: Curriculum, Geometry and Geometrical and Spatial Thinking

Mathematics textbooks are essential tools for teachers. They aim to establish, organize and structure knowledge that is required to become familiar with a discipline or field of knowledge (Alzate, 2000). In past investigations like Santanero (2011) we see that the problems posed to reaffirm knowledge are not authentic, that is, the context in which they develop is not entirely real. In addition, Velázquez, Slisko and Nolasco (2011) argue that artificial contexts generate negative attitudes in students. For this reason, we analyzed 29 problems from a high school level Geometry and Trigonometry textbook (Martínez, Espidio, Santiago, & Álvarez, 2013) to examine whether authentic problems were utilized in this subject and level. We rely on the theory of Palm (2006) which has eight criteria that the problem must meet, but we consider only three of which are:

- **Event**. This refers to the event described in the task. In simulating a real-world situation, it is a prerequisite that the event described in the task has occurred or has a fair chance to occur.
- **Question**. This aspect refers to the agreement between the assignment given in task and in a corresponding formal situation. The question in the task is one that might actually occur in the real world event described is a prerequisite for a situation that exists in the real world.
- **Information/data**. This refers to information and data in the task and includes values, models and given conditions.

If the problem does not meet one of these criteria it cannot be considered as authentic. The problems selected had an image to help understand the context described in the text. This is to analyze whether the author can give a good picture of the situation and thus help students to understand the context of the problem and can solve it correctly.

Most problems discussed do not meet the theory of Palm (2006). The authors of this textbook do not consider the authenticity of problems as the contexts shown do not meet Palm's criteria. Also displayed images do not help because, in some cases, they do not show the situations described.

EXAMINING HOW MATHEMATICS CURRICULUM MATERIALS ENCOURAGE STUDENT PERSEVERANCE

Joseph DiNapoli
University of Delaware
jdinap@udel.edu

The first Common Core State Standard (CCSS) for Mathematical Practice requires students to "make sense of problems and persevere in solving them" (CCSS, 2010, p. 6). While engaging with mathematical tasks, perseverance requires tenacity, the use of good strategies, and the flexibility to alter those strategies when necessary (Middleton et al., 2015). These components of perseverance help students overcome inevitable learning obstacles as they struggle to make sense of important mathematical ideas that are not immediately apparent (Hiebert & Grouws, 2007).

Curriculum materials can play a substantial role in nurturing student perseverance by providing opportunities for initial and sustained engagement with challenging mathematical tasks. Perseverance is not a rigid character trait; instead, students can become more perseverant by engaging with difficult mathematics tasks (Bass & Ball, 2015). Since the textbook is often the chief object of students' engagement with mathematics (Reys, Reys, & Chavez, 2004), curricular tasks should include features that can cultivate student perseverance. Such features include low-floors/high-ceilings, collaboration opportunities, and perceptions of student autonomy.

This study's purpose is to consider how CCSS-aligned mathematics curriculum materials support perseverant learners. Two analogous Algebra 1 textbooks are examined for how they offer opportunities to foster perseverance via student tasks. These opportunities were measured by targeting specific curricular features of mathematical tasks. The analytic framework identified task features such as low-floor/high-ceiling (*does the task invite student engagement and/or require higher-level cognitive demands?*), collaborative learning (*does the task explicitly incorporate group work?*), and perceptions of autonomy (*does the task allow for student choice?*).

The results indicate that though each curricula self-reported CCSS-alignment, the texts varied greatly in perseverance development opportunities. These findings suggest that textbook tasks do not solely provide opportunities for perseverance development through student mathematical tasks and teachers may need to provide additional supports. Also, claims about CCSS-alignment may be focused on the content standards alone and more precise alignment guidelines for the Standards of Mathematical Practice are needed. Thus, curriculum developers may need to provide more explicit guidelines as to how mathematical tasks can cultivate perseverant learners.

THE IMPORTANCE OF A QUANTITATIVE REASONING EDUCATION

Emily Elrod
Florida Institute of Technology
eelrod2009@my.fit.edu

Jesse Wilkins (2000) stated that, in the 21st century, the constitution of a person's functional literacy must extend beyond reading and writing, and include the ability to cope with quantitative information. Quantitative reasoning, also known as quantitative literacy, can be defined as "the skill set necessary to process quantitative information and the capacity to critique, reflect upon, and apply quantitative information in making decisions" (Gaze et al., 2014, p. 3).

Traditionally, college students were required to take algebra-laden courses to meet the math core curriculum requirement. But, in the past decade institutions have been shifting the focus of introductory/general education math courses toward Quantitative Literacy/Reasoning, or QLR, as an alternative to the algebra sequence for Liberal Arts students (Gaze et al., 2014). With research indicating the need of a quantitative reasoning education for individuals to function within our society (Madison & Steen, 2003; Steen, 2001; Steen, 2004), are we just to assume the STEM students who are in the calculus pipeline are somehow indirectly obtaining these skills? The questions this study intends to address are:

1. Is there a difference in quantitative reasoning ability in Liberal Arts students taking quantitative reasoning and STEM students completing the algebra sequence?
2. To what extent does taking a quantitative reasoning course explain students' QR skills controlling for gender, race, degree major, and other math courses taken?

Participants were selected from one campus of a mid-size college in central Florida with an open enrollment policy and a very diverse student population. Two intact classes of Calculus 1 and two intact classes of Liberal Arts Math in the Fall 2015 were selected. The instrument used in this study was the Quantitative Literacy & Reasoning Assessment (QLRA), an instrument that is both valid and reliable for measurement of quantitative literacy (Gaze et al., 2014).

The mean score for the Calculus 1 students was 37.78% (n = 36), while the mean score for the Liberal Arts Math students was 26.84% (n = 49). A two-tailed t-test determined that there is a statistically significant difference in the averages on the assessment ($p < 0.0014$). Multiple regression was performed to determine the extent a quantitative reasoning course explains a person's ability to reason quantitatively, controlling for gender, race, years in school, degree major and other math courses taken. It was found that taking a quantitative reasoning course was not a significant factor, while gender was significant, with women having a 14% lower score than men. It is the researcher's belief that the student's attitude towards mathematics might have played a significant role in the findings, as many students in the Liberal Arts classes did not take the assessment seriously.

LA FUNCIÓN LINEAL EN EL BACHILLERATO TECNOLÓGICO: UNA MIRADA DESDE SU IMPLEMENTACIÓN

LINEAR FUNCTIONS IN TECHNOLOGICAL HIGH SCHOOLS: A VIEW SINCE ITS IMPLEMENTATIONS

Rebeca Flores García
CICATA- Instituto Politécnico Nacional, México
rebefg@gmail.com

Keywords: Currículum, Educación Media Superior, Conocimiento del Profesor

Por sus múltiples aplicaciones, el concepto de función es fundamental en el estudio de cualquier rama científica. En el caso específico de las funciones lineales, las crecientes investigaciones revelan que los investigadores están reorientando su atención no sólo a explorar sobre las dificultades que tienen los estudiantes para comprender a las funciones lineales, como lo señala Birgin (2012), sino que también están preocupados por las concepciones de los profesores (Lloyd y Wilson, 1993) y por el uso de materiales curriculares (Chavéz, Grouws, Tar, Ross y McNaught ,2009).

Esta investigación busca articularse a los estudios que sobre función lineal se están desarrollando en el área de la matemática educativa considerando un punto de vista curricular, de ahí que la pregunta de investigación indaga ¿Cuáles son las transformaciones o cambios que tres profesores de matemáticas de bachillerato tecnológico generan al enseñar función lineal en el curso de Pensamiento Algebraico y de Funciones?

El estudio utilizó como marco teórico el modelo curricular de Stein, Remillard y Smith (2007) que incluye cuatro componentes: currículum escrito, planeado, implementado y el aprendizaje de los estudiantes y sólo los tres primeros componentes son utilizados en la investigación, ya que el estudio se centra en el profesor. Se empleó el estudio de casos como método para la recolección de los datos, lo cual incluyó la revisión tanto del plan de estudios oficial, las planeaciones de clase y la videograbación de clases. Los resultados obtenidos revelan que los profesores realizan transformaciones tanto en el currículum planeado como en el currículum implementado. Las transformaciones son generadas principalmente por dos razones: La primera tiene que ver con que el plan de estudios oficial, no precisa qué de función lineal debe ser enseñado y la segunda, está relacionada con la formación académica de los 3 profesores, implicando así, que agreguen u omitan contenidos relacionados con la función lineal, o que modifiquen el concepto.

Keywords: Curriculum, High School Education, Teacher Knowledge

Due to its variety of applications, the concept of linear function is essential to study any of the science fields. In the particular case of linear functions, increasing research shows that researchers are redirecting their attention not only to the exploration of the difficulties students face to understand linear functions, as it is stated by Birgin (2012), but also to teachers' conceptions (Lloyd & Wilson, 1993) and the use of curricular materials (Chavéz, Grouws, Tar, Ross, & McNaught, 2009).

The aim of this research is to connect to the studies that have been developing on linear functions in mathematics education, taking into account the curricular point of view. Hence the question that this research study investigates is: What are the transformations or changes that three mathematics teachers in Technological High schools make when teaching linear function in the course called "Algebraic Thinking and Functions"?

The research used as a theoretical framework the curricular model of Stein, Remillard, and Smith (2007) that includes four components: written, planned and implemented curriculum as well as the students' learning, but only the first three components are used in this investigation, since this research is focused on the teacher. The case study was used as a method for data collection, which also included the review of the official school curriculum, lesson plans and class video recordings. The results obtained show that teachers make changes in the planned curriculum as well as in the implemented curriculum. These changes are made for two main reasons: The first one is related to the official school curriculum, which does not specify what must be taught about linear functions, and the second one is related to the academic training of the three teachers, which implies that they add or omit content related to the linear functions, or even change the concept.

Key words: Curriculum Analysis, Learning Trajectories (or Progressions)

Recently, many researchers have been paying much attention to Learning trajectories (LT) in mathematics education, especially in advancing recommendations for standards, curriculum, and instruction (Clements, Spitler, Lange & Wolfe, 2011; Wilson, Sztajn, Edgington & Myers, 2015). Since LT is about students' natural progressions in specific mathematical domain, researchers believe that it is more effective, efficient and generative for the students to have learning that consistent with such natural developmental progressions than learning that does not follow these paths (Clements & Sarama, 2004). One important component of LT is designing sequence of instructional tasks that correspond to the order of LT (Clements & Sarama, 2004). Clements (2007) developed Curriculum Research Framework (CRF) and stated that having tasks sequenced according to LT can avoid the fragmentation common in U.S. textbooks. Thus, it is beneficial to have mathematical tasks in textbooks aligned to LT. The purpose of this study is to examine alignment of mathematical tasks in Common Core textbooks to the specific LT. This study uses the Surveys of Enacted Curriculum (SEC) which was previously used in textbook and curriculum analysis (Porter et al., 2012; Polikoff, 2015). Among many topics in mathematics, we have selected area and volume lessons because geometry topics have connections to other areas of mathematics and to students' experiences with the physical world (Sarama & Clements, 2009).

The Pedagogical Challenge

How can a visual game improve mathematics and language learning for English-language learners (ELL)? This APS-funded exploratory study provides educators with the opportunity to learn ways to capitalize on the visual-learning features of ST MATH, an innovative game-based curriculum, to support mathematics and literacy development for second-language learners.

Conceptual and Theoretical Perspective

Cognitive and semiotic theories of mathematics learning contend that the human mind understands abstract mathematical ideas through concrete representations. Yet, a common approach to mathematics learning for second-language learners is to introduce mathematical concepts through words. Building on the success of Warren, Harris, and Miller (2014) in developing teaching methods that support mathematics and literacy development for Australian ELL students, this study hypothesizes that order of instruction – visual experience of concepts before verbal – favors both mathematics-concept and language learning.

Research Design, Data and Analysis

How can teachers use ST Math games to support students' mathematics-concept and second-language development? How does the order of ST Math Game instruction influence student learning and teachers' use of ST Math in the classroom? To investigate these questions the study proposes a cycle of instruction that includes individual, pairs, and whole-class discussion of the math concepts embedded in the game but varies the order of ST Math game instruction. Experimental teachers ($n = 2$) will use an ST Math game to *introduce* a new fraction concept whereas Control teachers ($n = 2$) will use the target ST Math game(s) for *practice and extension* of the chosen study concept. In the first instance, ST Math is a *concept development* tool, and in the second, an *assessment, practice, and elaboration* tool. Data include instructional and student interview videos; pre/post student fraction test, attitude survey, teacher surveys; fraction lesson plans; and researcher notes. We propose open coding and frameworks related to question types and teaching moves for analyzing videos of ST Math teaching and interviews with ELL students.

Summary of Findings

Preliminary findings of this ongoing study challenge existing theoretical and pedagogical boundaries in the fields of mathematics education and second-language learning. Early results favor teaching approaches that explore math concepts and foster language development by using a variety of concrete and virtual math representations in conjunction with – but prior to - oral language over teaching approaches that focus on repetition and acquisition of math vocabulary.

THE IMPACT OF DIRECT INSTRUCTION ON MARGINALIZED, HIGHLY MOBILE STUDENTS

Jennifer Kinser-Traut
University of Arizona
jkinser@email.arizona.edu

Marginalized youth score significantly lower than other students on standardized tests with mathematics often acting as a gate-keeper (Schoenfeld, 2004). At the forefront of this concern is a debate over which curricular strategy is best for these students: direct instruction or a reform model of instruction. While many schools have adopted conceptual-based approaches, a gap in access to reform teaching exists between lower SES, and/or minority students and their higher SES peers (Desimone & Long, 2010). A better understanding of the various inequities connected with access to reform instruction is especially crucial for highly mobile youth, as high mobility can also hinder educational progress (Ream, 2003). Few studies have explored this intersection. Thus, this poster examines the learning experiences of one highly mobile, marginalized youth.

I adapted an analytic framework to foreground students' mathematical empowerment (Alsop, Bertelsen, & Holland, 2006). A key component of this framework is the importance of opportunity structures (i.e., curricular strategies). Using interpretative methods, I analyzed one student's recalled experiences of curricular structures in her classrooms, specifically direct or procedural forms of instruction. Data sources included eighteen study sessions, pre- and post-interviews, and school records. I coded talk related to pedagogy and mathematical learning in each interview, wrote analytic memos across the data, and sought to understand her mathematical empowerment as connected to the curricular structures she recalled experiencing.

In this poster, I present the mathematical learning experiences of Sofia, a 16-year-old highly mobile Mexican-American sophomore. Like many marginalized students, Sofia reported experiencing only the opportunity structure of direct mathematics instruction, which led her to develop an understanding of mathematics as a speed-based, procedural discipline. For example, drawing from her own experience, she explained that students often "have to *hurry up* and try to learn everything *fast* and get it all wrong just *to keep up* with the rest of the people" (line 670). When Sofia became highly-mobile, starting in eighth grade, this understanding of mathematics became especially problematic. She explained, "I learned one math, how to do it one way, and the other teacher [at the new school] was like 'that's not how you do it,'" which led Sofia to ask, "Which is the right work, you know?," (line 654). Sofia felt she had to learn all new procedures, essentially starting over again learning mathematics when she transferred schools. Further research is vital, to enhance our understanding of the interrelationship, and resulting outcomes, of school choice and curricular strategies marginalized, highly mobile youth experience.

Ball and Cohen (1996) made the case for positioning curriculum materials as potential agents for impacting teacher learning as, in their view, curriculum materials are "concrete and daily", "scaled up", and have "reach" in the system (p. 6). Davis and Krajcik (2005) then put forth a set of high-level guidelines for the design of educative curriculum materials. Drake, Land, & Tyminski (2014) built upon the work of Ball and Cohen and Davis and Krajcik to address how teacher educators can support prospective teachers' (PTs) reading and use of educative curriculum materials in ways that support them in acquiring the knowledge needed for teaching. Because the educative guidelines set forth by Davis and Krajcik (2005) were not specific to mathematics, examination of how these guidelines might be evident or applied within mathematics curriculum is necessary in order to further research on supporting PTs' curriculum use. We focused on the first educative guideline only – "educative curriculum materials could help teachers learn how to anticipate and interpret what learners may think about or do in response to instructional activities" (Davis & Krajcik, 2005, p. 5).

Methodology and Results
We used the literature base to outline a preliminary frame for the first educative guideline in terms of mathematics curriculum. We used our framework to determine: 1) lesson features indicative of educative guideline one; 2) the manner in which they were educative; and 3) how these features might be modified to address other aspects of the guideline in three lessons. This process allowed us to operationalize the first educative guideline.

Discussion and Implications
Operationalizing Davis and Krajick's (2005) first guideline for mathematics allows the field to better understand and support PTs' reading of educative curriculum features. Specifically, our framework could be used as a tool for identifying how a feature is intended to be educative specific to mathematics. This identification could support PTs in orienting to curriculum materials and could support researchers in understanding PTs' reading of curriculum.

CONFLICTING VISIONS OF GOOD TEACHING: NEW CURRICULUM, TEACHER BELIEFS, AND TEACHING PRACTICES

JinHee Lee
Michigan State University
leejin18@msu.edu

Keywords: Curriculum, Teacher Beliefs, Elementary School Education

In this study, I examined the relationship between new curriculum, teacher beliefs, and teaching practices. Along with the development of a new mathematics curriculum at the national level, new Korean textbooks aim for students' conceptual understanding through engagement in mathematical processes such as reasoning, problem solving, and communication. However, no one can simply say that the curricular intentions could be translated into purposive change in instructional practices. The possibility of this discrepancy is related to teachers because the teachers are responsible for designing their lessons. Therefore, I attend to the participatory relationship between curriculum and a teacher focused on beliefs (Remilliard, 2005).

In particular, I investigated the gap between an intended and enacted curriculum with a particular focus on teacher beliefs and teaching practices. Teachers' beliefs should be worthy of notice, considering their influences on mediation of knowledge, pedagogical decisions and implementation, and teaching practices (Thompson, 1992). It is also necessary to consider the influence of teachers' varying contexts on teaching practices (Kennedy, 2010). These all contributed to developing the conceptual framework about the interactions among espoused and enacted beliefs, an intended and enacted curriculum, and teaching practices.

This study employed a case study design with three elementary teachers, using a survey, interviews, and classroom observations. For data analysis, I relied on the literature for five framing codes: nature of mathematics, mathematics understanding, mathematics learning, teacher's role, and use of curriculum. Based on these framing codes, I created focused codes through opening coding from each teacher's beliefs, teaching and curriculum. And then, with the focused codes, I analyzed their (in)consistencies along with why they occurred. The primary means for this analysis involved moving between conjectures and refutations.

This study has three preliminary findings. First, teachers had similar beliefs of mathematics understanding but different conceptions of mathematics learning. Second, the curricular intentions were not embodied in teaching practices when teachers failed to recognize the intentions in spite of positively evaluating and rigidly following textbooks. Third, teachers had challenges such as lack of knowledge, students' low academic level, and educational atmosphere overemphasizing test outcomes, which places them on conflicting visions of good teaching within or between their beliefs, the curriculum, and teaching practices. It is recommended for teachers to have an opportunity of learning to teach to lessen challenges of the high-quality instruction that the new curriculum intends.

STUDENT TRACKING USING DIFFERENTIATED EXAMINATIONS

Richelle Marynowski
University of Lethbridge
Richelle.marynowski@uleth.ca

Keywords: Assessment and Evaluation, High School Education, Equity and Diversity

Student tracking or ability grouping in mathematics has been of interest to researchers over several decades. Specific in areas of study have been with respect to student achievement (eg: Ireson, Hallam, Hack, Clark & Plewis, 2002), student self-esteem (eg: Van Houtte, Demanet, & Stevens, 2012), and equity (eg: Forgasz, 2010). In addition, mathematics has been identified as a gatekeeper (Sriraman, & Steinthorsdottir, 2007) for students entering post-secondary programs. Equity concerns have been raised over when and should students be tracked in mathematics (Chmielewski, 2014) and if tracking students is contributing to inequity of access to post-secondary programs. The poster describes teachers' use of differentiated examinations to support students in selecting a mathematics stream. The main research question was: Can differentiating summative unit examinations assist students in choosing the mathematics course (stream) that best suits their abilities and interests?

This project took place in a Western Canadian province where, in Grade 11, students can choose one of two streams of general mathematics courses: pre-calculus or foundations in mathematics. The teachers in this study integrated the two courses to begin the semester for the three units of overlapping content and provided students with differentiated unit examinations. The purpose of the differentiated examinations was to allow students to experience the type of summative assessment that was expected in each stream. The poster will illustrate the different kinds of questions that were included on each part of the examination.

Based on a student survey, post-secondary requirements over-rid all other potential influences on student choice of mathematics course. Students who were unsure of which course to take, generally appreciated the opportunity to experience the different types of assessment for each course. Students that had already made a firm decision as to which math course they needed to take felt slightly disadvantaged by having the first three units of the course not specifically tailored to their needs. Differentiating examinations can play a role in assisting students to choose an appropriate mathematics course for them; however, the examinations are not the most influential factor in student choice.

EXAMINING "VOICE" IN REFORM REMEDIAL MATHEMATICS TEXTS: A COMPARATIVE LINGUISTICS ANALYSIS

Angela Stoltz
University of Maryland
astoltz@umd.edu

Keywords: Curriculum Analysis, Equity and Diversity, Post-Secondary Education

In this study, a critical discourse analysis of textual features was conducted to answer the question: In what ways do the linguistic and structural features of Statway and the University of Maryland's (UM) remedial mathematics curriculum speak to and position developmental mathematics students in the introductory units of study? Beth Herbel-Eisenmann's text analysis framework (2007) guided the analysis. Interpersonal, ideational, and textual functions were examined to identify the potential of the intended curricula (Halliday, 1978; Remillard, 2005). Word counts and word searches were used to identify imperatives, modality and pronouns within the curricula. Images, cohesiveness and nominalizations were also examined. The results of the analysis suggest that Statway has greater potential to position students as members of a mathematics community. This positioning may be further encouraged by the way students are intended to experience the curriculum, through group work and relationship building. In addition, the text features suggest Statway has the potential to promote student agency by engaging them in tasks that represent and model human beings who use mathematics to make sense of the world they live in, and by calling on the reader to do so as well. The cohesiveness of Statway implies that mathematics is a collection of interrelated concepts that are useful in making sense of and solving relevant issues.

UM's remedial curriculum could potentially send conflicting messages to students about their role as learners and the role mathematics plays in their daily lives. The use of predominantly exclusive imperatives and limited expression of human agency could potentially lead developmental mathematics students to conclude they are artificially being inducted into a mathematics community in order to follow expected rules. This perception may be reinforced through the student's experience of the curriculum, where they work independently through their materials in a computer lab. The lack of cohesiveness could potentially lead developmental students to infer that mathematics is a set of discrete facts which must be followed, but don't necessarily connect to their lives or their ability to make sense of the world around them. Findings and suggestions for improving both texts, as well as suggestions for future research will be discussed in this poster presentation.

UNSPOKEN MESSAGES: AN ANALYSIS OF IMAGES USED IN THE GRADE 1-2 INTEGRATED KOREAN CURRICULUM

Heejoo Suh
Michigan State University
suhhj@msu.edu

JinHee Lee
Michigan State University
leejin18@msu.edu

Keywords: Elementary School Education, Curriculum Analysis, Equity and Diversity

In this study, we examined images used in a mathematics curriculum to understand how the curriculum is supporting students' learning. Textbooks as curriculum materials have been considered an influential factor for school mathematics because they offer a blueprint for teaching and learning of mathematics in classrooms. Recently Korea reformed mathematics textbooks that introduce storytelling including stories and images. Storytelling aims for effective mathematics instruction by providing meaningful mathematics contexts that connect mathematics with students' personalized situations (Davis-Dorsey et al., 1991). Moreover, given the diversity of students, it is necessary to give attention to the possibility that textbooks are oppressive to certain groups of students in terms of cultural identity (Kumashiro, 2008). In this study, we attend to the role of curriculum that shapes students' learning with a particular focus on the images attached to the stories used in the chapters in a reformed Korean mathematics curriculum for grade 1-2, which consists of 23 chapters.

The curriculum does not provide a written version of the story. Students have to rely on teachers' reading of the story and the image. Because of students' direct contact with the image rather than the story, we carefully examined the image used. We followed Dowling's (2002) classification of signifying modes, referring to "a form of the relationship between expression and content that is implicated in sign production" (p. 151), such as an *icon*, an *index*, or a *symbol*. An index is abstract enough so that it does not signify the reader's presence, but it allows the readers to immediately do mathematics with it. In addition, we examined the setting of the story. Dowling suggested a loose system for classifying the space for social practice in mathematics textbooks. This system includes domestic settings, work settings, school settings, and travel settings. We add here imaginary settings and literature settings.

From the analysis, we learned that seven chapters were indexical. Three indexical representations were similar in that they all presented geometric shapes. Four chapters arranged objects in rows so that students can start counting them. When it came to the settings, five chapters were imaginary settings, four were literature settings, three were school settings, three were domestic settings. Some chapters had two overlapping settings. People in all chapters, except for the three chapters with literature settings, had dark hair and black eyes, which are typical to Koreans. The three chapters using literature settings presented European people. The curriculum may want to consider using indexical representation with topics other than geometric shapes. In addition, the curriculum could consider diversifying ethnicity of people in the images.

INCORPORATING MODELING INVESTIGATIONS TO ENHANCE TRADITIONAL ALGEBRA I MATERIALS

Linda Venenciano
University of Hawaiʻi at Mānoa
lhirashi@hawaii.edu

Fay Zenigami
University of Hawaiʻi at Mānoa
zenigami@hawaii.edu

Keywords: Algebra and Algebraic Thinking, Modeling, Teacher Beliefs

Given the vast array of resources now available to teachers, understanding how teachers select supplementary materials to enhance their existing programs can inform the work in teacher education. This case study looks at issues that arise when a teacher selects and incorporates lessons designed for student-centered learning into the school's program. The poster will share findings from the study on an eighth-grade teacher's incorporation of selected investigations, chosen from a curriculum designed to promote a modeling approach to algebra, to supplement lessons from the school's traditional Algebra I program. Data were collected from the selected modeling lessons, the planning and adaptations the teacher incorporated into the lessons prior to teaching them, questions the teacher asked to engage students in the investigations, and teacher reflections on the impact of the lessons. In particular, questions posed by the teacher during instruction of the selected investigations were analyzed relative to the modeling cycle as described in the high school modeling standard of the Common Core State Standards (NGAC & CCSSO, 2010) to provide insights into challenges faced by a teacher juggling curricular choices.

The algebra modeling curriculum was designed and developed to be a separate companion course to support ninth-grade students concurrently taking Algebra I (Olson et al., 2015). Technology provides the opportunity for interaction with dynamic representations of concepts during classroom instruction and can be integrated throughout the curriculum both for teacher and student use. The lessons, built around problems, emphasize the use of models, promote the investigation of open-ended questions, and provide multiple opportunities for students to develop concepts, generalizations, and skills. Students are given opportunities to model, represent, graph, write about, and discuss their strategies for investigating and solving problems as they begin to internalize algebraic ideas and develop an understanding of algebraic techniques.

Using problems selected from the modeling curriculum appealed to the study's middle school teacher as a way to supplement the school's newly adopted program that emphasized procedures and algorithms rather than conceptual understanding. Patterns emerged from preliminary analyses of teacher-adapted worksheets, discussion questions posed, and teacher reflections. The data suggest that while the investigations selected by the teacher were designed to emphasize problem solving and modeling, the teacher provided more guidance, often in the form of added structure, for students to understand problem contexts and to consider specific models. Constraints to keep pace with the required Algebra I textbook, a limited availability and use of technology, and no professional development support for the teacher are factors likely to have contributed to less emphasis on the modeling aspect of the lessons outside the intended use.

THE TEXTBOOK EXPERIENCE: AN ANALYSIS OF CONTEXT EXPOSURE IN CORE-PLUS MATHEMATICS TEXTBOOKS

Laura Willoughby
University of Delaware
LWilloug@udel.edu

Keywords: Curriculum, Curriculum Analysis, High School Education

The Core-Plus Mathematics Project [CPMP] is a National Science Foundation funded reform based curriculum. The CPMP embraces mathematical learning in context and has been shown to have comparable performance results for students in most areas when compared to a traditional high school mathematics sequence (Schoen & Hirsch, 2003). The overview section of the CPMP 2015 edition's teacher's guide, states that "making real-world contexts accessible to students promote[s] greater access and equity in mathematics classrooms." Expanding on the notion that context is important for accessibility, there is a benefit in examining the contexts from that perspective. Macintyre and Hamilton (2010) discovered that students can be aware of disparities and perceive inaccessibility not immediately apparent to the authors of the curriculum.

In an effort to analyze the accessibility of the CPMP curriculum, an analysis using a five-part "No Context," "Factual," "Topic," "Location," and "Character" framework, was conducted on all 804 "On Your Own" problems in Course 1B and Course 2A. The five-part framework was adapted from one used by Sleeter and Grant (2011) in their evaluation of textbooks across different disciplines. The rationale for using this framework was that each dimension has the potential to affect the accessibility of problems from the students' perspectives.

The analysis revealed that on the *context* dimension, 303 (38%), of the problems analyzed were contextually-based problems (CBPs) (i.e. problems placed in a real-world contextual scenario). On the *factual* dimension, 24% of the CBPs included cited references for the information presented. On the *topic* dimension, a wide variety of topics were included. On the *location* dimension, 75 CBPs mentioned the United States, and 40 of them were further categorized by region; 23 CBPs were placed in the Northeast or Midwest while only 6 mentioned the Southwest or Southeast. Finally, on the *character* dimension, the CBPs included more references to students than to professionals. Furthermore, 13 of the 22 CBPs involving individuals where race could be definitively determined, the subjects were Caucasian. In every instance where a historical figure was mentioned by name, the individual was a white male.

In summary, despite the emphasis on context to promote accessibility, the results of the analysis suggests that the features of the contexts used in the CPMP curriculum may not reflect all students' experiences. Gaining awareness of potential disproportionate representations of student experiences, including location and ethnicity, may guide future efforts to improve the accessibility for all students in future iterations of the CPMP curriculum.

BENEFITS OF ANALYZING CONTRASTING INTEGER PROBLEMS: THE CASE OF FOUR SECOND GRADERS

Mahtob Aqazade	Laura Bofferding	Sherri Farmer
Purdue University	Purdue University	Purdue University
maqazade@purdue.edu	lbofferd@purdue.edu	farmer10@purdue.edu

In this study, we explore four, second graders' performances on integer addition problems before and after analyzing contrasting cases involving integers. The students, as part of a larger study, participated in a pretest, small group sessions, one short whole-class lesson on integer addition, and a posttest. Based on their integer mental models and scores on arithmetic and transfer problems, each student progressed, although in different ways. We use these instances and their interactions in their group sessions to describe their progressions.

Keywords: Number Concepts and Operations, Elementary School Education, Instructional Activities and Practices

Students start learning about negative numbers and interpreting integers in real-world situations (e.g. temperature, account balance) in sixth or seventh grade; yet, they learn whole number concepts starting in kindergarten (National Governor's Association Center for Best Practices & Council of Chief State School Officers, 2010). During this large time gap, students solidify ideas about numbers and addition based on whole number experiences, and when they encounter negative numbers, they try to make sense of them using this prior knowledge in various ways (e.g. treating negative numbers as positive numbers or zero) (Bofferding, 2014). Helping students bridge the gap between whole numbers and integers by providing them with helpful instructional experiences is important.

One possible way to bridge the gap is to shorten it by introducing negative integers earlier. There is recent evidence that young children are capable of learning about and using negative numbers even in the first grade (e.g., Bishop, Lamb, Philipp, Schappelle, & Whitacre, 2011; Bofferding, 2014; Behrend & Mohs, 2005/2006). Another possible way is to help students make connections between the two types of numbers. Findings by Gentner (2005) suggest there is evidence that learners, who have opportunities to compare two analogous cases, are more likely to succeed at a "relational transfer" than those who have not compared the cases (p. 252). However, prior investigations in students' learning from contrasting cases have mostly focused on older students (e.g. Rittle-Johnson & Star, 2011).

In a larger study, we explored the potential of having second graders analyze different contrasting cases to see if it could help them learn about negative integer addition. Through case studies of two pairs of students, we aim to address the following research questions:

1. How do four, second graders' integer mental models and performance on integer addition problems change after analyzing contrasting cases of integer addition and participating in one lesson on the topic?
2. In attempting to account for these changes, what will the students notice and describe during the analysis of the contrasting cases?

Theoretical Framework

Integer Mental Models

Bofferding (2014) categorized first graders' order and value mental models into initial, synthetic, and formal, along with two transitional levels, which exhibit parts of both. Students with initial integer mental models ignore negative signs, operate with negative numbers as if they were positive

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

numbers, or order them correctly but treat them as having positive values (Bofferding, 2014). As they transition away from an initial mental model, some students give new meaning to the negative sign and treat it as a minus (transition I mental model). Therefore, they sometimes treat negative numbers as zero (as if the number is subtracted from itself) and sometimes treat them as positive numbers (numbers that have not been taken away yet). This reflects a focus on the binary (or subtraction) meaning of the minus sign (Bofferding, 2014; Vlassis, 2004).

Students with synthetic integer mental models acknowledge that negative numbers are less than zero but consider larger negatives as "more" (Bofferding, 2014). This focus on absolute value may lead them to reverse the order of negatives. Before developing a formal mental model for integers, some students will both consider negative numbers with larger absolute values as greater than smaller ones and treat them as less, depending on the tasks (transition II mental model) (Bofferding, 2014). As students move toward having a formal mental model, they develop a better understanding of the unary meaning of the minus sign (Bofferding, 2014; Vlassis, 2004).

Contrasting Cases

The key differences among the integer schemas described above are the meanings given to the symbols involved (i.e., the negative sign) and the relations established between order and value. One method for students to notice important relations in problems is by analyzing contrasting cases (e.g., Rittle-Johnson & Star, 2011; 2009, 2007). For example, students who analyzed contrasting alternative solutions in algebraic equations showed better improvement in their procedural knowledge than students who analyzed solution methods presented sequentially (Rittle-Johnson & Star, 2007, 2009). In one case focused on algebraic manipulations, three different comparison groups compared equivalent problems, different solution methods, or different types of problems. Students who compared solution methods gained greater procedural flexibility and conceptual knowledge than students in the other two groups (Star & Rittle-Johnson, 2009). Durkin and Rittle-Johnson (2012) also found that providing students with opportunities to compare incorrect and correct answers can help students improve their understanding of new concepts. Further, others found that even students with low performance on a pretest who later compared correct and incorrect examples of equations improved more in conceptual knowledge on a posttest (Lange, Booth, & Newton, 2014). In this study, we investigate second graders' understanding of integer addition before and after they analyze contrasting cases on the topic.

Methods

Participants & Setting

The larger study, from which this data is drawn, took place at two public schools in a rural mid-western district where about 32.2% of students are English-language learners and 75.2% qualify for free or reduced-lunch. Students were recruited from the second grade population, and 109 of the original 110 participants completed all aspects of the study. After a pretest, students were assigned randomly to groups that analyzed different types of contrasts.

For this study, we chose 4 students to investigate more closely. Because students in the larger study made sizeable gains from pretest to posttest, we chose the two initial case study students to exemplify this change. First, we narrowed the pool to students who had gained at least 30% from pretest to posttest. This resulted in 9 students out of 36 from the intuitive contrast group, 13 students out of 35 students in the conflicting contrast group, and 6 students out of 36 students in the same type, sequential group. We chose to look at students in the intuitive and conflicting contrast groups since they had made slightly more gains than those in the sequential group. We then selected one student from each of the remaining two groups who had 60% or above correct on the session

questions and had a consistent partner across the small group sessions. We also included their consistent partners, who had similar pretest scores.

Design and Materials

    Pretest. The pretest included three ordering questions (two involved filling in missing numbers on a number path and number line; we ignored the third because students had trouble interpreting it). Students also solved sixteen temperature comparison questions (eight where they circled the hottest temperature and eight where they circled the coldest) that targeted their understanding of integer values and four directed magnitude questions. For the arithmetic questions, they solved four positive integer addition and subtraction questions and then fourteen integer addition questions. Finally, they solved two types of transfer problems: three integer addition problems with three addends and six missing-addend addition problems. Overall, the highest possible score for the pretest was 50.

    Small group sessions. After students were randomly assigned to contrast group, they participated in 2 small group sessions. During the small group sessions students analyzed sets of contrasting integer addition problems with accompanying illustrations (both solved correctly and incorrectly) and talked about what was similar and different in the problems and pictures. They also talked about why some of the answers were wrong and how they could use the pictures to solve the problems. The illustration contexts involved (a) a gingerbread man moving on a number path, (b) ants going above and below ground next to a vertical number line, (c) positive and negative chips, and (d) a folding number line (see Tsang, Blair, Bofferding, & Schwartz, 2015). For some of the contrasts, students had to write down their thoughts without discussion, and on others, students talked about their answers aloud. The contrasts the two groups analyzed are shown in Table 1. Each intuitive contrast and conflicting contrast group session took about 20 minutes. At the end of each session, students solved 6 related integer addition problems for a total of 12 problems by the end of both sessions.

Table 1: Contrasts that the Students Explored in their Groups

Illustration Context	Intuitive Contrast, Session 1	Conflicting Contrast, Session 1	Intuitive Contrast, Session 2	Conflicting Contrast, Session 2
Gingerbread	3+5 vs. -3+-5	3+5 vs. 3+-5	-2+5 vs. 2+-5	-2+-5 vs. -2+5
Ants	2+7 vs. -2+-7	2+7 vs. 2+-7	-3+6 vs. 3+-6	-3+-6 vs. -3+6
Chips	6+4 vs. -6+-4	6+4 vs. 6+ -4	-5+5 vs. 5+-5	-5+-5 vs. -5+5
Folding number lines	5+3 vs. -5+-3	5+3 vs. 5+-3	-7+2 vs. 7+-2	-7+-2 vs.-7+2

    Whole-class instruction. After all students completed the two sessions, they participated in a 30-minute, whole-class lesson on negative numbers and addition problems with integers. Students learned that adding a positive number to an integer corresponds to moving the gingerbread boy up on the number path, and adding a negative number corresponds to going down on the number path. For example, to solve -2 + 2, the gingerbread boy first moves down 2 (more in the negative direction) and then up 2 (more in the positive direction), ending up at 0, where he started. This led to the introduction of the term "zero pair." Students explored a few more zero pairs on the number path and then played a card game based on zero pairs with a partner. Students had a stack of -1 cards and a stack of +1 cards (much like with positive and negative chips) and a dice with negative and positive

numbers on it to play with. Students rolled the dice and collected the appropriate cards. Using the cards in their hand, their goal was to make zero pairs and be the first person to run out of cards.

Post-test. The posttest contained the same items as the pretest with a couple of additions. We added 3 questions asking students to determine which integer is closest to 10 and 3 more addition problems with 3-addend numbers where it was advantageous to make zero pairs. The highest possible score on the posttest was 56.

Analysis

To analyze the data, we first classified each students' integer mental models on the pretest and posttest based on Bofferding's (2014) framework. We investigated students' answers on the order and value questions and their use of the minus sign on both pretest and posttest. We also referred to explanations they provided in the groups sessions to clarify their mental models.

Then, we transcribed the group sessions for the case study students to identify their contributions to the discussions and identify how each student interpreted negative numbers in the various contrasts and which meaning of the minus sign they used for their interpretations. Finally, we calculated students' gains on the ordering, arithmetic, and transfer questions across the testing situations. We looked across each student's data from the pretest, sessions, and posttest to build a case of their understanding.

Results

Overview

The larger study analysis shows that there were no significant differences between groups (Bofferding, Farmer, Aqazade, & Dickman, 2016); similarly, in our four sampled cases, the students' gains from pretest to posttest were the same regardless of their group. In the intuitive contrast group, X04 started with 22% correct on the pretest overall, which increased to 78% correct on the posttest. On the other hand, W05, her partner, started with 12% correct on the pretest and only increased to 30% correct on the posttest. Students' gains from pretest to posttest in the conflicted contrast group were similar to those in the intuitive contrast group. In the conflicted contrast group, Z08 started with 40% correct on the pretest and went up to 98% correct on the posttest. However, Z10, his partner, started with 30% correct on the pretest and only went improved to 46% correct on the posttest.

Pretest Mental Models

To better distinguish students' performance, we determined their mental models for the order and value questions and then calculated their percent correct for the 14 integer addition problems (with two addends) (see Table 2). Each group had comparable students who made similar high gains in percent correct over the entire set of questions (X04 gained 56% and Z08 gained 58%) or low gains (W05 gained 18% and Z10 gained 16%).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 2: Case Study Students' Integer Mental Models and Arithmetic Scores (Pre & Post)

ID	Group	Gender	Mental models Shift	Pretest	Posttest
X04	Intuitive contrast	F	T1-T2 (shift of 2)	7%	100%
W05	Intuitive contrast	F	I-I (shift of 0, but progress)	0%	29%
Z08	Conflicted contrast	M	S-F (shift of 2)	29%	100%
Z10	Conflicted contrast	F	I-I (shift of 0, but progress)	36%	64%

I = initial mental model; T1 = transition I mental model; S = synthetic mental model; T2 = transition II mental model; F = formal mental mode (see Bofferding, 2014)

W05 and Z10. In both groups, one of the pair started with an initial mental model. Both W05 and Z10 filled in only whole numbers on their empty number path and number line. Further, they determined which temperature was hottest and coldest based on absolute value. The main difference was that W05 answered "none" for some of the comparisons. Although they both started with initial mental models, Z10 got 36% of the arithmetic problems correct on the pretest. Looking at the problems she got correct, Z10 was able to solve the problems when she could use the negative sign as a subtraction sign. Therefore, she got -1 + 8 correct (can be solved as 8-1), 7 + -3, 5 + -2, 9 + -9, and -4 + 6. W05, on the other hand, answered all of the problems by ignoring the negative signs (e.g., 9 + -9 = 18, -6 + -4 = 10).

X04 and Z08. Both groups also had a student who demonstrated some use of the negative signs on the pretest. X04 filled in positive numbers on both sides of zero when filling in the number path (i.e., 11, 10, 9, 8, 7, 6, 5 4, 3, 2, 1, 0, 1, 2, 3, 4, 5). Further, she answered the temperature comparison questions by focusing on absolute value. All of these responses would suggest that she has an initial integer mental model. However, she frequently treated negative numbers as worth zero on the arithmetic problems. For example, she answered -5 + 5 = 5 and 0 + -9 = 0. Explaining how she solved -9 + 2, she said, "Minus nine is zero then plus two, so there would only be two left." Her treatment of the negative sign as attached the particular number and indicating that the number was worth zero, suggested that she had a Transition I integer mental model. Finally, Z08 had some knowledge of negatives on the pretest. He filled in negative numbers on his number path and number line, but also included -0 (e.g., -2, -1, -0, 0, 1, 2). When completing the temperature comparisons, he correctly determined that positive temperatures would be hotter than negative ones; however, when choosing which negative temperature was hotter, he chose the larger negative. Therefore, he demonstrated a synthetic integer mental model on the pretest.

Students' Performance in Small Group Sessions

W05 (initial mental model) and X04 (transition I mental model). The intuitive contrast group investigated addition problems with two positive versus two negative numbers in the first session and then compared adding both a positive to a negative number and a negative to a positive in the second session. Based on their conversation, X04 and W05 both noticed the negative sign across the sessions; however, they used the binary meaning of the minus sign or called it line. When asked about differences between two problems (5+3 = 8 vs.-5+-3 = -8) and their corresponding pictures in a folding number line context, X04 explained, "That one [is] normal (referring to the initial picture) but that one has a one and a minus (referring to the second picture)." W05 later continued, "These all

there have a minus." In general, W05 primarily focused on the minus sign and made more generic comments, such as indicating that the two problems were not the same rather than pointing to what exactly was not the same. On the other hand, X04 frequently talked about more details beyond just the minus signs. She was more likely to talk about all elements in the problems and to come up with reasons why the information in the pictures matched the problems. On the end-of-session questions, W05 got 6 out of 12 (50%) of the questions correct, and X04 got 12 out of 12 (100%) correct.

Z10 (initial mental model) and Z08 (synthetic mental model). The conflicted contrast group investigated addition problems with two positive numbers versus a positive number plus a negative number in the first session and then compared adding a negative number to a negative versus adding a positive number to a negative number in the second session. Their conversations in the sessions showed that they mostly used the unary meaning of the minus sign and sometimes the binary meaning of minus sign when interpreting negatives. Unsurprisingly, Z08 was more dominant in reasoning about negative integers compared to Z10 and sometimes helped Z08. This occurred when they compared -2 + -5 (where a gingerbread man started at 0, hopped to -2 then hopped -5 more to -7) versus -2 + 5 (where a gingerbread man started at 0, hopped to -2, then hopped 5 to 3). Z10 looked at the ending point on the pictures and said, "This one starts at -7, and this one starts at normal 3." Z08 clarified, "That one actually starts at 0." Z10 then saw that the answers to the problems corresponded to the ending points for the gingerbread man. Z10 tended to focus on the minus as meaning subtraction. When thinking about how to solve -5+5=0 with the positive and negative chips, Z10 explained, "This takes this one (referring to a circled group of -1 and 1) and this one takes this one; these are zeros." On the other hand, Z08 correctly identified negative signs and used them to interpret the ant's movement on the number line when explaining why the ant would go down for 2 + -7: "Cause of negative seven." On the end-of-session questions, Z10 got 3 out of 12 (25%) of the questions correct, and Z08 got 11 out of 12 (92%) correct.

Posttest Mental Models

W05 and Z10. On the posttest, W05 and Z10 from the two different groups still had initial mental models, but they had advanced from whole number to absolute value mental models. Both filled in the number path completely. However, they continued to choose hottest and coldest temperatures by their absolute value. In W05's first session she compared adding two positives versus adding two negatives, and she paid attention to the negative signs. On the posttest, instead of providing only positive answers, she answered all problems by adding the absolute values and making the answers negative. By overgeneralizing the rule that negative problems have negative answers, she only correctly solved arithmetic questions where this strategy led to a correct answer (see Table 3). She was also able to correctly answer -2 + __ = -8 from the transfer problems.

Z10's original session focused on adding two positives and adding a negative to a positive, and she continued to treat negative signs as subtraction signs. Therefore, she performed better on solving arithmetic and transfer problems with 3-addend numbers compared to W05. On the pretest, she solved 8 + -3 + 4 as 8 – (3+4) = 1; however, she correctly answered it on the posttest.

Table 3: Case Study Students' Performance on Arithmetic Problems by Strategies

	Add Absolute Value and Make Negative			Use Negative as Subtraction			Count from Negative		
Test Items	-2 + 0; 0 + -9; -6 + -4; -1 + -7			-4 + 6; -5 + 5; -1 + 8; 5 + -2; 7 + -3; 9 + -9			-3 + 1; -9 + 2; 6 + -8; 4 + -5		
	Pre (n=4)	Mid (n=3)	Post (n=4)	Pre (n=6)	Mid (n=4)	Post (n=6)	Pre (n=4)	Mid (n=2)	Post (n=4)
X04	0%	100%	100%	17%	100%	100%	0%	100%	100%
W05	0%	100%	100%	0%	0%	0%	0%	0%	0%
Z08	100%	100%	100%	0%	100%	100%	0%	50%	100%
Z10	0%	0%	25%	83%	0%	100%	0%	0%	50%

X04 and Z08. Both X04 and Z08 shifted two mental model levels up after posttest. Both correctly filled in the number path and could answer all "coldest" comparisons correctly. When asked to select the hottest temperature with only negative number choices (e.g. -6, -2, -3), X04 selected, "none". Therefore, she demonstrated a transition II integer mental model; whereas, Z08, who got all of the comparisons correct demonstrated a formal mental model. Overall, they both were able to build on their understanding of negatives after analyzing the contrasts and solved almost all of the arithmetic and transfer problems correctly (see Table 4) on the posttest.

Table 4: Case Study Students' Performance in Transfer Problems (Pre & Post)

	Addition with 3-addend numbers		Missing numbers	
ID	Pre (n=3)	Post (n=6)	Pre (n=6)	Post (n=6)
X04	33%	100%	17%	83%
W05	0%	0%	0%	17%
Z08	0%	100%	17%	100%
Z10	0%	100%	0%	17%

Conclusions and Further Study

Contrasting cases helped the students focus on relevant details and develop their understanding of negative numbers to varying degrees. By chance, the students with lower scores had been paired with higher performing peers. This pairing throughout the sessions allowed them to share information with their partner. However, they did not seem to benefit equally from the sessions. In line with their lower background knowledge, W05 and Z10 focused on one main idea from their sessions. W05 attended to using negative signs, and she provided negative answers for almost every integer problem on the posttest (instead of only providing positive answers). Her initial session focused on negative problems only having negative answers, which may have contributed to this tendency. Z10 continued to use the negative sign as subtraction. Interestingly, her initial session reinforced the idea that adding a negative is similar to subtraction. Therefore, she might have made more progress if she had made a different comparison first that made her question her interpretation of the minus sign.

Both X04 and Z08 demonstrated that they treated negative numbers different from positive numbers on the pretest, although Z08 was further along in his understanding. They both benefited

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

greatly from their sessions, reasoning in more depth about the problems they were analyzing. Based on these cases, it is not clear if they would have had similar gains if they had been in the opposite group. One of our future goals is to develop cases of all students to determine if there are any trends in students who benefited more from their group versus those who made less progress. This could help teachers determine optimal contrasts for students.

The two students in the conflicting cases group made some gains from the end-of-session questions to the posttest. In the case of Z10, his percent correct on the problems that would be correct if you used the negative as subtraction (e.g., 7 + -3) went down after the sessions and then went back up by the posttest. Z08, made steady progress on the problems that are best solved by counting from negative. These results suggest that especially for that contrast group, the instruction helped them make sense of the problems they had analyzed. Further exploration of the larger dataset will clarify the extent to which this was true for the second graders overall.

ALGEBRA ACHIEVEMENT GAPS: A COMPARATIVE STUDY ACROSS THE STATES OVER THE YEARS

Rachel A. Ayieko	Elif N. Gokbel	Ahmet O. Akcay
Duquesne University	Duquesne University	Duquesne University
ayiekor@duq.edu	karalie@duq.edu	akcaya@duq.edu

The purpose of this study was to examine eighth grade students' algebra achievement scores across various states, over years, and by students' demographics (including ethnicity/race, language spoken at home, SES factors, and academic resources). The questions guiding the study were, (a) What are the differences in eighth grade students' algebra achievement scores across sixteen states between the years 2005 to 2015? (b) Are there significant differences in eighth grade students' algebra achievement scores by student demographics? There were significant differences found in the students' algebra achievement scores based on different students' demographics. Further, the students' mean algebra scale scores continue to rise over the years.

Keywords: Algebra and Algebraic Thinking, Equity and Diversity, Policy Matters, and Middle School Education

Introduction

The move towards "Algebra for All" is based on the notion that success in Science, Technology, Engineering, and Mathematics (STEM) competencies in the 21st century requires fluency in algebraic reasoning and problem solving. Although there is a great need for more students to join the STEM fields, few students pursue these fields in higher education. Scholars have proposed that algebraic thinking should be introduced in the early grades to ease the transition to learning complex algebra (e.g., Blanton & Kaput, 2011; Cai & Knuth, 2011). Indeed, research has shown that it is possible for students in the earlier grades to engage in functional thinking (Warren, Cooper, & Lamb, 2006), and algebraic reasoning (Bjuland, 2012).

The motivation of this study, therefore, is to examine the algebra achievement of eighth- grade students in various states. This comparative study will illuminate the algebra knowledge that students enter high school with as they begin the algebra requirement or their development of early algebraic thinking. Further, it will also illustrate the improvements in early algebra learning over the years. The algebra strand of mathematics is important because of the varying content taught across and within the United States (Kieran, 2007). More importantly, the abstract nature of algebraic reasoning, the language of mathematics using symbols, and structural characteristics associated with learning algebra makes it a challenging strand of mathematics (Rakes, Valentine, McGatha, & Ronau, 2010). Further, considering the adoption of the Common Core State Standards (2010) across the United States, there is the need to examine the influence of this initiative in the algebra achievement of students before they join high school.

The questions guiding this study are, (a) What are the differences in eighth-grade students' algebra achievement scores across sixteen states between the years 2005 to 2015? (b) Are there significant differences in eighth-grade students' algebra achievement scores by ethnicity/race, language spoken at home, socio-economic status (SES) factors, and academic resources? This report contains information on algebra achievement across various states, over the years, and by students' backgrounds. To compare students' algebra scores, we selected states identified as benchmark states in previous cross-national studies (e.g. Trends in Mathematics and Science Studies-2011) and the ten states with available data in the High School Longitudinal Study (HSLS). Using the National Assessment of Educational Progress (NAEP) data from 2005 to 2015, we present the trends in students' achievement in sixteen states.

The findings from this study will be used to inform the next series of studies that will investigate the opportunities to learn algebra related to the differential algebra achievements across the United States. Further, the states in which students' algebra achievement is higher based on students' demographics, and the states that have narrower algebra achievement gaps provide information for policy and practice.

Theoretical Framework

Overall, students' mathematics achievement in the United States has shown a steady improvement over the years in the different grade levels (e.g., Hemphill & Vanneman, 2011; Vanneman, Hamilton, Baldwin Anderson, & Rahman, 2009). However, the variation in mathematics achievement across different groups of students across the United States is prevalent. The studies that focus on mathematics achievement gaps include those that examine gaps across races, socioeconomic status, gender, and factors explaining the gaps that are predominant (e.g., Lubienski, Robinson, Crane & Ganley, 2013; McGraw, Lubienski, & Strutchens, 2006; Lubienski, 2002). Lubienski's (2008) research commentary emphasized the need for more mathematics educators to focus on gap analysis to inform education policy, classroom practices, and research. Additionally, the commentary points to the need to focus on opportunity gaps related to the inequities found in mathematics achievement (Lubienski, 2008). Furthermore, gap analyses inform public opinions and deficit notions when carefully conducted using factors related to the disparities found (Lubienski, 2008). Some suggestions for useful analysis suggested in the commentary include the study of gaps found in different strands of mathematics, intersections of race and socioeconomic status that could include or exclude gender. The literature cited in the present study includes achievements gaps by race, socioeconomic status, and language spoken at home. However, the information from the studies shown is in general mathematics without providing knowledge of particular strands of mathematics.

Racial and Socioeconomic Differences in Mathematics Achievement

Mathematics achievement gaps between races and socioeconomic status have abounded over the years. A study done by Lubienski (2002) that examined achievement gaps by race and socioeconomic status indicated that there were significant achievement gaps by race among students from both high SES and low SES backgrounds. In particular, white students with the lowest SES scored significantly higher or at par when compared to the black students in the highest SES in fourth, eighth and twelfth grade in 1990 and 1996. These findings indicate that racial achievement differences cannot be assumed to be the same as the socioeconomic differences. Indeed, the white students considered as low socioeconomically perform higher than black students from low socioeconomic backgrounds. Similarly, a focus on the SES across races, considering the socioeconomic measure on eligibility for free and reduced lunch, showed that in the fourth and eighth grade, the achievement gaps persisted by race. Specifically, for the fourth- grade students there was a significant achievement gap between those that received reduced price lunch in 2004 and 2007 for the black/white comparison. Further, among the eighth-grade students there were narrower achievement gaps in 2007 for free and reduced lunch, indicating that in this SES level, there was an improvement gain in the black students' mathematics achievement (Vanneman et al., 2009).

A focus on the achievement differences in Hispanics and White students also shows that the achievement gaps are narrowing. In particular, between 1990 and 2009 there was an improvement in Hispanics mathematics achievement. However, across these two years the difference in the achievement gaps was not significant (Hemphill & Vanneman, 2011).

The patterns of achievement gaps in mathematics are not consistent across the United States. Although there was a steady gain in eighth-grade mathematics achievement scores over the years in 41 states, the achievement gaps in Arkansas, Texas, Colorado, and Oklahoma was smaller in 2007, when compared to the gap in 1990. Similarly, the gaps between the black and white students in the

fourth grade were narrower in 2007 than in 1990 in 46 states (Vanneman, et al., 2009). In sum, these findings show that the persistence of these achievement gaps across the grade levels indicate that there could be other factors contributing to these gaps.

Differences in Mathematics Achievement by Language Spoken at Home

Students' language background is related to mathematics achievement. Howie's (2005) study indicated that students who spoke the language of the test (e.g. English) more frequently at home had higher scores on the mathematics test. Additionally, white pupils' mathematics scores were significantly higher than other groups who are not speaking English at home (Howie, 2005). Likewise, Reardon and Galindo (2008) found that fifth-grade students from homes where English is not the predominant language scored lower than students from English-speaking homes. These earlier studies show that there is need to analyze further the mathematics achievement gap comparing students' who use other languages other than English at home and those who do not are changing over the years and across states. In so doing, the results could indicate that the interventions on English language acquisition are influencing mathematics achievement.

Algebra achievement

The algebra content of mathematics is a gatekeeper in the selection of further mathematics and future career of students (Kaput, 2000). Some studies have shown that differences in the algebra achievement are too often associated with demographic and personality variables of students such as ethnicity, socioeconomic status, teacher quality, and student attitudes (e.g., McCoy, 2005) and instructional strategies (e.g., Rakes et al., 2010). Spielhagen (2006) suggested that the reduction of the opportunity gap and improved achievement is possible with the introduction of more algebra courses in the earlier grades. Similarly, other scholars have suggested that learning algebra in the early grades provides a strong baseline for more complex algebraic thinking that students experience in high school and beyond (e.g., Blanton & Kaput, 2011; Carraher & Schliemann, 2007).

In sum, these findings show that the persistence of these achievement gaps across the grade levels suggest that factors contributing to this scenario. One of the factors could be the algebra knowledge that students have acquired before joining secondary school. The level of algebra knowledge which can be either an advantage for learning further algebra content or not succeeding or selecting higher-level algebra-related courses.

Methods

The NAEP Main Assessment

The National Assessment of Educational Progress (NAEP) data provides information across the United States and over the years for possible state-level comparisons. The state assessments of NAEP have been administered across the states in grades 4, 8, and 12 in various subject matters since 1990. This data provides representative samples of students' mathematics achievement in grades four and eight from each state every two years. For example, 136,900 eighth grade students took the assessment throughout the nation in 2015. The NAEP assessment items include a variety of formats, such as multiple-choice and open-ended questions (requiring short constructed-response, and extended-response). The test items were classified by mathematical complexity: low complexity, moderate complexity, and high complexity. Each assessment question was designed to measure one of the five mathematics strands: number properties and operations, measurement, geometry, data analysis/statistics, and algebra. The data used in this study were from the years between 2005-2015 main NAEP mathematics assessments, and the participants that were the focus of this study were the eighth-grade students.

Variables

The NAEP background questionnaire items that were selected for this analysis include: language other than English spoken at home, student-reported mother's education level, the number of books at home, lunch eligibility, and race/ethnicity. Specifically, a description of the independent variables including the categories are: (a) A language other than English spoken at home (never (1), one in a while (2), half of the time (3), and all or most of the time (4); (b) Lunch eligibility (not eligible, reduced price lunch, and free lunch); (c) Academic resources including Mother's education level (did not finish high school, graduated college) and Books at home (less than 10 books, more than 100 books), For the academic resources at home the highest and lowest ordered responses were used; and (d) Race/ethnicity allowing multiple responses (White, Black, and Hispanic).

Analysis

Descriptive statistics were run using the NAEP Data Explorer (NDE) tool to illustrate the gap in eighth-grade students' average algebra scores across contexts, races and SES in selected states and over the years. The NDE is an online data analysis program that provides detailed results' from NAEP's national and state assessments. An independent-samples *t*-test was conducted to analyze differences between average algebra scores of eighth-grade students (a) whose mothers did not finish high school and those whose mothers graduated from college, and (b) who have less than 10 books at home and those having more than 100 books at home. An analysis of variance (ANOVA) was conducted to examine how the average algebra scores differ among (a) three ethnicity groups, (b) lunch eligibility (including "not eligible, reduced price lunch and free lunch"), academic resources and (c) language other than English spoken at home. Other ANOVA tests were also performed to assess the differences in algebra scores by ethnicity, lunch eligibility, academic resources, and a language other than English spoken at home over the years from 2005 to 2015.

Results

The results of this study were from nationally representative samples of eighth grade students from public and private schools. The alpha level (.05) for the quantitative analyses indicated that there was a statistically significant difference between the independent variables. Due to space limitations, for descriptive statistics we only provide Figure 1 presenting average algebra scale scores for eighth graders by ethnicity.

Race/Ethnicity

Figure 1 presents the graphs of the average algebra scores of the students by ethnicity (White, Black, and Hispanic) in each state over the years from 2005 and 2015. At the national level, the achievement gap between White and Black students seemed to be greater than White and Hispanic students. Notably, there is a large achievement gap between White, Black, and Hispanic students over the years. In Minnesota and Ohio, the achievement gap between Hispanic and Black seemed to be closing toward 2015. Interestingly, in Colorado, the Black students' algebra scores appeared to be dramatically increasing between 2007 and 2009 followed by a substantial decrease between 2009 and 2011.

Figure 1. Algebra Achievement (Scores) by Race, 2005-2015.

A one-way ANOVA was conducted for the algebra score differences by race. The mean score for Black students was found to be lower than the mean scores for Hispanic and White students, and the mean score of white students was the highest. There were statistically significant difference in students' algebra scores between ethnicity groups, $F(2, 303) = 592.37$, $p <. 001$. A Post Hoc test result showed that there were significant differences between all race/ethnicity groups. A one-way ANOVA to determine differences in algebra scores by race/ethnicity across the years 2005, 2007, 2009, 2011, 2013, and 2015, was significant, $F(5, 300) = 2.98$, $p = .012$ for race/ethnicity over the years. Follow-up tests were conducted to evaluate differences among the means. The results indicated that the mean score of 2005 was significantly lower than the mean scores in the other assessment years. Additionally, the students' algebra scores were significantly higher in 2013 and 2011 than in the 2005 assessment year. The algebra scores by race/ethnicity increased from 2005 to 2013. However, the mean scores decreased from 2013 to 2015.

Lunch Eligibility
NAEP used student's lunch eligibility as a determinant of family income level. Students are eligible for free lunch if their family income is at or below 130 percent of the poverty level and are eligible for reduced-price lunches if their family income is between 130 percent and 185 percent of the poverty line. The findings show that there was a notable increase in the mean algebra scores for students who are not eligible for National School Lunch Program (NSLP) from 2005 to 2015 and also those eligible for free lunch. Massachusetts had the highest algebra scores in all their categories over the years when compared to the other states.

A one-way ANOVA was conducted to evaluate differences for the students' algebra scores by NSLP eligibility among the 16 states from 2005 to 2015. The dependent variable was lunch eligibility, including "not eligible, reduced price lunch, and free lunch". The ANOVA test was significant, $F(5, 285) = 5.217$, $p < .001$, for the eighth grade algebra scores by lunch eligibility over the years. A follow-up test result showed that the algebra score of 2005 was significantly lower than the score for all the other assessment years. Further, the students' algebra scores were significantly higher in 2015, 2013 and 2011 than in the 2005 assessment year.

The result also shows that the mean score of the students who were eligible for free lunch ($M = 270.06$, $SD = 6.86$) was lower than the mean scores of the students who are eligible for reduced lunch ($M = 280.75$, $SD = 6.84$) and the students who were not eligible ($M = 298.59$, $SD = 6.92$). There were significant differences in the students' assessment scores between groups, $F(2, 288) = 46.899$, $p < .001$.

Academic Resources at Home

Mother's Level of Education. An independent-samples t-test was conducted to evaluate the differences in the students' algebra scores by mother's education level, including two levels: did not finish high school and graduated from college. The test was significant, $t(202) = -29.66$, $p < .001$. The students whose mother graduated from college ($M = 299.12$, $SD = 7.35$) had higher scores than those whose mothers did not finish high school ($M = 270.65$, $SD = 6.32$). The 95% confidence interval for the difference in means was wide, ranging from 30.36 to 26.57. A one-way ANOVA of the algebra scores by mother's level of education showed no significant differences over the years.

Number of Books at Home. An independent-samples t-test was conducted to determine the differences in the students' algebra scores by the number of books at home over the years from 2005 to 2015 at two levels: less than 10 and more than 100. The test was significant, $t(202) = -41.56$, $p < .001$. Students who have more than 100 books at home ($M = 304$, $SD = 7.45$) had higher algebra scores than those have less than 10 books at home ($M = 264.25$, $SD = 6.14$). The 95% confidence interval for the difference in means ranged from 41.60 to 37.82. A one-way ANOVA of the algebra scores by the number of books at home showed no significant difference over the years.

Languages other than English Spoken at Home

A one-way ANOVA was conducted to determine the differences that exist in the eighth graders' algebra scores by languages other than English spoken at home from 2005 to 2015. There was a significant difference in algebra score by language spoken at home over the years, $F(5, 401) = 10.187$, $p < .001$. Particularly, the mean algebra scores increased over the years; the lowest mean score was in 2005, and the highest mean score was in 2015. Follow-up tests showed a significant difference that (a) 2005 eighth graders had a significantly lower score compared to the other assessment years, and (b) 2007 had a significantly lower score compared to 2013 and 2015.

We also compared students' algebra achievement by language spoken at home. The post-hoc test result showed that students who spoke English most of the time at home had a significantly higher algebra score than those who spoke English less often. Similarly, students who spoke English half of the time at home had a significantly higher score to those who rarely spoke English at home.

Discussion

The purpose of this study was to examine the achievement gap among students across the 16 states over the years from 2005 to 2015. There were differences in eighth-grade algebra achievement based on SES, academic resources, race/ethnicity, and languages other than English spoken at home, over the years. An earlier study that examined students' mathematics achievement in different grades had similar findings (Hemphill & Vanneman, 2011; Vanneman, et al., 2009). This present study's results also suggest that the eighth-grade algebra score in 2005 was significantly lower than the

algebra score in all the other assessment years. The improving algebra achievement scores over the years could be related to the adoption of the Common Core State Standards from 2010.

Although the students' average algebra scores continued to rise over the years, some significant differences persist. In particular, algebra scores differed significantly by race/ethnicity, SES, and languages other than English spoken at home. Specifically, the eighth- grade black students consistently posted significantly lower scores over the last ten years. Notably, in the last two years, ten of the selected states showed a drop in the black eighth-grade students' algebra achievement. The Hispanic students' algebra achievement dropped in six of the 16 states studied. In contrast, only five of the selected states showed a drop in the white students' algebra achievement. In general, there was an average drop in students' algebra achievement in the last two years. By highlighting the algebra achievement, it is evident that the Black and Hispanic students join high school with significantly lower algebra achievement scores. Similarly, students from families with lower income, and less academic resources, and those classified as having English as a second language join high school with lower algebra achievement. Indeed, other earlier studies also found that student algebra achievement scores were related to students' demographics, with notable achievement gaps across the different demographic groups (McCoy, 2005; Rakes et al., 2010). Thus, if students require knowledge of early algebra to be successful in further algebraic thinking learned in high school, it is evident that on average Black and Hispanic students could be joining high school with significant gaps needed for a successful transition to more complex algebraic reasoning.

The algebra achievement gaps should be further explored to show the related factors influencing these persistent patterns. Further, the opportunities that students have to learn algebra in high school could provide more information on the effect of these gaps in students' early algebra learning and future course taking patterns. Finally, the findings from this study suggest that early algebra achievement could be a factor related to the small representation of minority students in STEM fields.

MORE AND LESS: LANGUAGE SUPPORTS FOR LEARNING NEGATIVE NUMBERS

Laura Bofferding
Purdue University
lbofferd@purdue.edu

Sherri Farmer
Purdue University
farmer10@purdue.edu

The language that students use with whole numbers can be insufficient when learning integers. This is often the case when children interpret addition as "getting more" or "going higher." In this study, we explore whether instruction on mapping directed magnitudes to operations helps 88 second graders and 70 fourth graders solve addition and subtraction problems with negative numbers. Further we explore to what extent having prior training with directed magnitude language (as opposed to just more and less language, without a direction specified) prepares students to benefit from the instruction. Our data shows that students, regardless of which language training they had, improved, and second graders, even with less initial knowledge, were able to make the same gains as fourth graders, suggesting that having initial exposure to negatives earlier could help students reach proficiency by the time the standards expect it.

Keywords: Number Concepts and Operations, Elementary School Education, Instructional Activities and Practices

Because subjects are usually taught separately in elementary school, there is often a boundary between language and mathematics instruction. Yet the National Council for Teachers of Mathematics (NCTM, 2000) standards call for students to "use the language of mathematics to express mathematical ideas precisely" (p. 60). Precise language can clarify ideas; whereas, vague language can create confusion. Unfortunately, the language that students use with whole numbers can be insufficient when they learn new numbers, such as integers. This is often the case when children interpret addition as "getting more" or "going higher." Consider, for example, the following second grade student (B05) explaining why -1 + 8 = -9: "Because negative one, and then eight *more* is negative nine." The student's statement includes language that highlights the operation (more = addition) and magnitude (8). However, "more" in integer operations has multiple meanings. The problem involves getting *more positive* (counting up the number sequence in the positive direction), an operation with a directed magnitude (adding positive 8), as opposed to getting *more negative*. Therefore, finding ways to help students interpret and apply directed magnitude language to comparisons and operations with negative integers is necessary as they transition from work with whole numbers to integers.

Theoretical Framework

Before the introduction of negative numbers, students learn that "more" corresponds to an increase in magnitude, which corresponds to counting up the number sequence (moving to the right on the number line), and maps onto addition (Case, 1996). With the inclusion of negative numbers, an additional level of specificity is needed. Students need to learn that an increase *in the positive direction* is getting "more positive", which corresponds to moving right on the number line and maps onto adding a positive number. Similarly, *an increase in the negative direction* is getting "more negative", which corresponds to moving left on the number line and maps onto adding a negative number. Similar relations exist for subtraction, except instead of an increase in a direction, there is a decrease in a direction (getting less positive or less negative).

Students' understanding of comparisons with more and less has been explored both from a language perspective and a mathematical perspective. Language studies indicate that, initially, comparisons with positive or unmarked adjectives are easier for students to answer than negative or marked ones. Therefore, determining which object is *higher* is easier than *lower* (Smith, Rattermann,

& Sera, 1988), and determining which set of objects or glass of liquid has *more* is easier than *less* (Palermo, 1973). However, there is still some debate as to whether this happens because positive adjectives are used more or because they are conceptually easier to understand (e.g., Ryalls, 2000).

Studies from a mathematical perspective focus on exploring students' responses to questions about which of two numbers is more. Students tend to categorize numbers as large and small. For positive number comparisons, when two numbers belong to different categories defined by the students (e.g., large and small), young children do better on the comparisons than when both numbers are part of the same category (e.g., two numbers they consider large) (Murray & Mayer, 1988). When comparing two negatives, experienced sixth graders are faster when the two numbers are farther apart than when they are closer. However, there are no differences when they compare a positive and negative number, suggesting they use a rule that positives are more than negatives regardless of how far apart the numbers are (Varma & Schwartz, 2011).

Aside from teaching students the rule that positives are greater than negatives, using questions that include a context could make the desired value or point of comparison more explicit. For example, if integer problems were presented in a golf context, negative numbers would be better than positive numbers; whereas, this would be reversed for many video games or board games, where the goal is to achieve a higher positive score. The desired value is also clearer with temperature (e.g., which temperature is hottest vs. coldest)? To get the same level of obviousness with numbers there would need to be a move away from the magnitude questions (where positive is the assumed reference category) to directed magnitude questions (where we explicitly say which type of value - positive or negative – is the reference category).

Knowing which direction "more" relates to (as opposed to assuming more always means more positive) is especially important when adding and subtracting negative integers. Students who have learned about negatives know that positive numbers are considered more than negative numbers and that the question, "Which is more?" is asked from a positive perspective. Therefore, they might be more receptive to a focus on the language connecting integer addition and subtraction to directed magnitudes. This would also align with the Common Core Standards for Mathematics' recommendation that integers be introduced in the sixth grade (National Governor's Association Center for Best Practices & Council of Chief State School Officers, 2010). On the other hand, students with little experience with negatives often determine which number is more based on absolute value (Bofferding, 2014). Given young students' willingness to consider "large negatives" as more, they might be more receptive to such a focus on language. Further, if current magnitude language, emphasized in whole number instruction, is limiting, it is possible that using directed magnitude language in early elementary would help students build more cohesive conceptions of "more" and "less".

Research Questions
Based on the issues described above, we explore whether instruction on mapping directed magnitudes to operations helps second and fourth graders solve addition and subtraction problems with negative numbers. Further we explore to what extent having prior training with directed magnitude language (as opposed to just *more* and *less* without a direction specified) prepares students for the instruction. Specifically, we investigate the following research question and sub-questions:
How does instruction mapping directed magnitude language to operations with integers affect students' learning of integer comparisons, addition, and subtraction?
  (a) To what extent does having a background understanding of language related to magnitude (e.g., more, lower) versus directed magnitude (e.g., more positive, less negative) influence learning?
  (b) How do gains differ for students in second grade versus fourth grade?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Methods

Participants and Setting

This study took place at two public schools in the same rural Mid-western district. Students were recruited from all of the second and fourth grades, resulting in 88 second-grade, and 70 fourth-grade participants. The district reports 32.2% English-language learners and 75.2% as qualifying for free or reduced-lunch.

Design and Materials

The study involved a pretest, random assignment to language group (magnitude or directed magnitude), three small group sessions, individual language training, whole class instruction, and a posttest. We describe each of these below.

Pretest. Students individually completed a written pretest during a whole class session. Students not in the study had their tests returned to their teacher or shredded. The pretest consisted of filling in the missing numbers on a number path, value comparisons with different language (n=24), feeling-related questions (n=4), and integer addition and subtraction problems (n=13) (see Table 1 for examples).

Table 1: Example Items from the Pretest

Question Type	Examples
Integer Order	Fill in the missing numbers before 4 and after 6. [ ][ ][ ][ ][ ][ ][4][5][6][ ][ ][ ]
Value Comparisons	Circle the temperature that is… …hottest….most hot…least cold. / Circle the temperature that is… …coldest….most cold…least hot. $2\,^oF$ $3\,^oF$ $8\,^oF$ none / $2\,^oF$ $6\,^oF$ $4\,^oF$ none $0\,^oF$ $-6\,^oF$ $-1\,^oF$ none / $-1\,^oF$ $0\,^oF$ $-6\,^oF$ none $-4\,^oF$ $-2\,^oF$ $3\,^oF$ none / $3\,^oF$ $-4\,^oF$ $-2\,^oF$ none $5\,^oF$ $-10\,^oF$ $-8\,^oF$ none / $-8\,^oF$ $5\,^oF$ $-10\,^oF$ none $-6\,^oF$ $-2\,^oF$ $-3\,^oF$ none / $-3\,^oF$ $-6\,^oF$ $-2\,^oF$ none $-5\,^oF$ $-4\,^oF$ $-7\,^oF$ none / $-7\,^oF$ $-5\,^oF$ $-4\,^oF$ none
Feelings Comparisons	Circle the face that is **least sad**. / Draw a face that is **less happy** than this face.
Addition & Subtraction	4 + -5; -1 + 8; -6 + -4 / 1 – 4; -6 – -9; 5 – -3

Students were stratified within each grade level based on their performance on the pretest, and then students from each strata were randomly assigned to one of two language groups: a control group that used traditional magnitude language or an experimental group that used directed magnitude language.

Small group sessions. With 2-3 students from their group, students participated in three, 15-minute sessions. The initial session consisted of three activities. The first activity was a game where

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

students were asked to find matching integers. Cards were arranged in an array, and students turned them over one at a time, seeking the matching value. Researchers asked questions, such as, "How are they (the numbers) the same?" or "How are they different?" in an effort to focus attention on the positive or negative values. During the second activity, students were told that negative numbers are used below zero. Students then explored integer order by filling in spaces on a number path marked only with zero. Using their completed number path as a reference, students played a card game for their third activity. Their goal was to collect and trade integer cards in an effort to get a card hand with three integers in a row (e.g., -2, -1, 0).

The second and third small group sessions both involved playing a game where students moved on a number path labeled -10 to 10. The language of the magnitude group remained consistent with the use of operating with magnitudes. Therefore, they moved "more or less" or "higher or lower" a certain amount; whereas, the directed magnitude group used language consistent with operating with directed magnitudes. They moved "more positive or less positive" and "less negative or more negative" a certain amount.

Training. During their training session, students completed four phrasing-type rounds, with up to twenty-eight comparisons per round. The control group received training on magnitude comparisons (phrasing: Which is more? Which is less? Which is higher? Which is lower?), and the experimental group received training on directed magnitude comparisons (phrasing: Which is more positive? Which is less positive? Which is more negative? Which is less negative?). Students continued only until they got seven consecutively correct for each phrasing type. They were then asked to order a set of non-consecutive integers according to the above-mentioned phrasing (e.g., from most positive to most negative). Both groups then sorted a set of integers into categories three times: high/low, less/more, and positive/negative piles.

Whole-class instruction. In each of the classrooms, two researchers presented a 30-minute lesson to all students using the directed magnitude language. To introduce the idea of moving on a continuum with directed magnitudes, the researchers showed an emotion-continuum of faces from very sad to very happy with a neutral face in the middle. They then read a story about a boy who got more happy, more sad, less happy, and less sad. Students helped show how the boy's mood changed on the emotion-continuum at the front of the room. After this introduction, students were told that addition means moving *more in a particular direction* (either more positive or more negative) and that subtraction means moving *less in a particular direction* (either less positive or less negative). The researchers then did a series of problems with the class to reinforce the mapping of the directed magnitude language onto the operations. Problems were designed as number strings (DiBrienza & Shevell, 1998; Lampert, Beasley, Ghousseini, Kazemi, & Franke, 2010), and students participated using their own number path and sticker to move as they solved the problems. Table 2 lists the typical order of the problems used.

Table 2: Problems Included in the Class Number Strings

1)	4 + 3	4)	2 – 6	7)	-1 – -7
2)	3 + -4	5)	2 – -6		Extra, if time:
3)	-3 + 4	6)	-6 – 2		-7 – -1; -5 + -3; -5 + 3

Posttest. The posttest was largely the same as the pretest, except for a few additions and changes. We only re-asked the most difficult temperature comparison questions from the pretest (n=12). We also changed the feeling comparisons to allow students to pick 1 of 5 faces (very happy, happy, neutral, sad, very sad). Finally, we added a small selection of transfer questions, such as solving for a missing addend, subtrahend, or minuend.

Analysis

We began analysis with a multivariate ANOVA on the difference in temperature comparison scores and the difference in arithmetic scores for grade and condition (including only items present on both pretest and posttest). Then, we conducted a 2 (second grade vs. fourth grade) x 2 (control vs. experimental) x 2 (pretest vs. posttest) x 2 (temperature comparisons vs. arithmetic) repeated measures ANOVA to learn more about potential differences. To better understand students' difficulties with the arithmetic problems, we further analyzed the results by looking at common responses students gave. For each of the arithmetic problems on the pretest and posttest, we calculated the percentage of students who provided a specific numerical response. For example, we looked at the percentage of second and fourth graders who, for -4 + -6, answered 10, -10, 2, -2, or 0. Further analysis of the temperature comparisons can be found elsewhere (Bofferding & Farmer, 2016).

Results

Gains from Pretest to Posttest

The results of the multivariate ANOVA were not significant for condition or grade. Therefore, any gains made were statistically similar for students regardless of whether they had the training with magnitude or directed magnitude language, and regardless of whether they were in second grade or fourth grade. Based on the repeated measures ANOVA, there was a significant interaction between test and item type, $F(1, 154) = 9.11$, $p=.003$. Students did significantly better on the temperature comparisons and arithmetic problems on the posttest than they did on the pretest. Further, on average, performance was significantly higher on the temperature comparisons than the arithmetic problems, $F(1, 154) = 83.27$, $p<.001$. Students had an average gain of 2.15 on the temperature comparisons versus 1.15 on the arithmetic problems. Fourth graders did start out performing significantly higher than second graders on both items, based on an item type by grade interaction, $F(1, 154) = 17.55$, $p<.001$; however, as mentioned previously both fourth and second graders made similar gains (see Table 3).

Table 3: Pretest, Posttest, and Gain Scores for Second and Fourth Graders

Grade	Temperature Comparisons Average Correct (SD)			Integer Arithmetic Problems Average Correct (SD)		
	Pretest n=12	Posttest n=12	Gain	Pretest n=13	Posttest n=13	Gain
2nd (n=88)	2.86 (2.97)	5.38 (3.66)	2.52	2.52 (1.62)	3.61 (2.41)	1.09
4th (n=70)	6.59 (3.54)	8.37 (3.77)	1.78	4.04 (2.06)	5.24 (2.74)	1.20

Although students as a group made significant gains, we investigated the gains further by running analyses for each grade separately. For fourth graders, there was no significant interaction between test and item type, so their gains from pretest to posttest are only significant when averaging over both item types, $F(1, 69) = 39.83$, $p<.001$. Averaging over both tests, they also did significantly better on the temperature comparisons than the arithmetic problems, $F(1, 69) = 66.58$, $p<.001$. For second graders, there was a significant interaction between test and item type, $F(1, 87) = 12.30$, $p=.001$, with performance on both the temperature comparisons and arithmetic problems increasing from the pretest to the posttest. These results suggest that in the overall analysis, the test by item interaction was largely driven by the second graders.

Arithmetic Problems Involving Negatives

Students' performance on the arithmetic problems involving negatives varied widely, and their gains on these items were not as large partly because many students got a problem correct on the pretest without knowing about negative numbers, and then got the same problem incorrect on the posttest because they were paying attention to the negative and trying to use it. For example, when solving -2 - -6 on the pretest, 31% of second graders correctly answered "4" as opposed to 16% of fourth graders. Several second graders who answered "4" also solved -4 - -3 = 1, as if all numbers were positive and 4 - -5 = 1, as if the problem was 5 - 4 = 1. Therefore, they likely got -2 - -6 correct because they solved the problem as 6-2=4. In contrast, on the posttest, B01 (who answered 0 on the pretest), explained why the answer was 4 as follows: "So there's a take away, and it's negative. You had to go farther from the negative because it's in the positive." This student had training with the directed magnitude language and used it to reason about the answer, correctly answering all but one of the arithmetic problems.

Both grade levels had 10%-16% of students gain on solving 1 - 4 and 6 - 8, suggesting they got better at counting into the negatives. However, 29% - 44% of students at each grade level still solved the problems as 4-1 or 8-6 on the posttest. Both grade levels showed a stronger focus on negatives on the posttest than on the pretest, even if they did not get correct answers. Second graders made a large gain on answering -6+-4=-10. On the pretest, 16% of them correctly answered this problem, while 34% of them answered "10", as if the numbers were positive. On the posttest, 38% of them correctly answered the problem, and their most prevalent incorrect response changed to "-2". Fourth graders made the largest gain on solving 5 + -2 = 3 (from 27% correct to 49% correct). On the pretest, 29% of them incorrectly answered "7", but on the posttest, their most common incorrect response was "-7".

Although there were several instances where the fourth graders made larger gains on certain problem types than the second graders, the second graders consistently performed better and made larger gains than fourth graders on problems where they had to subtract a negative number from a positive number (see Table 4). Especially for 5 – -3, students in both grades solved the problem as 5 – 3 = 2 on the pretest. Although the same percent of fourth graders still answered this way on the posttest, a lower percent of second graders did so.

Table 4: Percent of Students Providing Different Answers to Integer Questions

4 – -5	Second		Fourth		Change in %	
Answer	Pretest	Posttest	Pretest	Posttest	2nd Grade	4th Grade
Correct: 9	2%	15%	0%	6%	+13%	+6%
-9	6%	5%	10%	20%	-1%	+10%
1	25%	14%	10%	16%	-15%	+6%
-1	19%	32%	53%	46%	+13%	-7%
0	25%	17%	10%	3%	-8%	-7%
5 – -3	Second		Fourth		Change in %	
Answer	Pretest	Posttest	Pretest	Posttest	2nd Grade	4th Grade
Correct: 8	3%	15%	1%	0%	+12%	+9%
2	59%	47%	49%	49%	-12%	0%
-2	6%	13%	19%	14%	+7%	-5%
0	1%	2%	1%	1%	+1%	0%

Conclusions & Implications

Overall, students in the study benefitted from instruction on mapping the language of directed magnitude onto the operations, regardless of which language they had training on. This suggests that the level of explicitness in the lesson was beneficial. Further, the differences between groups may have been reduced based on this common instruction. Therefore, future work should investigate students' knowledge just prior to the instruction to tease apart how much benefit they received from their training versus the instruction. Additional qualitative analysis will also help illuminate if students' language training played a role in how they answered and reasoned about the arithmetic problems, as was the case for student B01.

The higher performance on the temperature comparisons than the arithmetic problems makes sense given Case's (1996) framework. Based on his theory of number development, students need to understand the relations among number values before they can use this relation to add and subtract numbers. Further analysis of the ordering questions during the training session will clarify to what extent each student was able to map the directed magnitude language onto the integers.

The similar performance between second and fourth graders is interesting. On the one hand, the fourth graders performed higher than the second graders on the pretest. This is unsurprising as they had more time to be exposed to negative numbers and likely had more experience hearing about temperatures. However, second graders, even with less initial knowledge, were able to make the same gains as fourth graders! This suggests that the border established for when we introduce and/or teach negative integers should be reconsidered; second graders can make significant gains even with a relatively short intervention. If grade level doesn't matter, then having initial exposure to negative integers earlier could help students reach proficiency by the time the standards expect it.

Finally, second grade did better than fourth graders on problems, such as 4 - -5, which are traditionally the hardest (Wheeler, Nesher, Bell, & Gattegno, 1981). It is possible that they were more successful at using the language to make sense of the problems; this is an area for further exploration. However, it suggests that younger students might benefit more from earlier exposure to the cognitively conflicting problems like these.

STUDENTS' CONCEPTIONS SUPPORTING THEIR SYMBOLIZATION AND MEANING OF FUNCTION RULES

Nicole L. Fonger	Amy Ellis	Muhammed F. Dogan
University of Wisconsin-Madison	University of Georgia	Dicle University
nfonger@wisc.edu	amyellis@uga.edu	fatih.dogan@dicle.edu.tr

This paper explores the nature of students' quantitative reasoning and conceptions of functions supporting their ability to symbolize quadratic function rules, and the meanings students make of these rules. We analyzed middle school students' problem solving activity during a small group teaching experiment (n=6) emphasizing quadratic growth through covarying quantities. Results indicate four modes of reasoning supportive of students' symbolization of quadratic function rules: (a) correspondence, (b) variation and correspondence, (c) covariation, (d) flexible covariation and correspondence. We discuss implications for research on learning vis-à-vis students' representational fluency, as well as design principles to support quantitative reasoning.

Keywords: Algebra and Algebraic Thinking, Cognition, Middle School Education

Research Issues and Purpose

Students' understanding of functions is central to school algebra in which two perspectives on algebraic thinking are valued: a change and variation perspective, and a structural or symbolic perspective (Cai, Bie, & Moyer, 2010). An oft-cited goal of students' activity in algebra, and functional thinking particular, is to cultivate the ability to create, interpret, and connect numeric, graphic, symbolic, and verbal representations of functions (Kieran, 2007). Indeed, there is a large body of work addressing students' understanding of function vis-à-vis the study of students' abilities to translate between multiple representations, especially from symbolic to graphical representations of function (e.g., Leinhard, Zaslavky, & Stein, 1990). Such research often focuses on students' representational performances (e.g., abilities to connect multiple representations) to the detriment of understanding what representations *mean* to students and how this representational activity is supported or constrained by students' *conceptions* of mathematical ideas (Thompson, 1994b).

In this research we explore the interplay between students' representational abilities and their conceptions and meanings of functions. We focus on students' symbolization of quadratic functions of the form $y=ax^2$, a topic commonly taught using a "method of finite differences," with the meaning of *a* restricted to determining the steepness of the parabola (Ellis & Grinstead, 2008). In contrast to these common approaches, we ground our investigation of students' understandings of quadratic functions in a quantitatively rich context as a source of possible meaning for students' activity (Thompson, 1994a). We address three research questions:

- What is the nature of students' quantitative reasoning about quadratic growth situations?
- What ways of reasoning *support* students' abilities to symbolize quadratic function rules?
- How do students *make sense of* the symbolic quadratic function rules they write?

We first articulate three mutually supportive lenses that guided our interpretations of student thinking: quantitative reasoning, conceptions of function, and representational fluency.

Theoretical Framework and Background

Quantitative Reasoning and Conceptions of Functions

By quantities, we refer to measurable attributes of objects or phenomena (Smith & Thompson, 2007). A quantity is a mental concept, composed of one's conception of an object, a quality of the

object, an appropriate unit or dimension, and a process for assigning a value to the quality (Thompson, 1994a). Examples of attributes that can be conceived as quantities are height, length, and area. Students engage in quantitative reasoning when they operate with quantities and their relationships, conceiving new quantities in relation to one or more already conceived quantities. Comparing quantities multiplicatively is a critical aspect of quantitative reasoning.

A correspondence perspective of function identifies function relationships such as $y = ax^2$ as the fixed correspondence mapping between the members of two sets (Farenga & Ness, 2005; Smith, 2003). From this perspective, pairs of quantities are linked by a multiplicative relationship. Although this static view of function is privileged in school mathematics curricula, some researchers argue that a covariation approach to functional thinking is important in supporting a well-developed understanding of function as a dynamic relationship between quantities (e.g., Confrey & Smith, 1994; Thompson & Carlson, in press).

One stance on covariation involves the examination of a function in terms of coordinated changes of x- and y-values, in which students move operationally from y_m to y_{m+1} coordinating with movement from x_m to x_{m+1} (Confrey & Smith, 1994; Smith, 2003). This perspective requires that students understand quantities as having a sequence of values and relate the values in each sequence additively or multiplicatively. Thompson and Carlson (in press) instead emphasize the importance of helping students envision change through the notion of *continuous variation*. Students who can think about smooth continuous variation can imagine a variable's magnitude increasing in bits while simultaneously anticipating that within each bit, the value varies smoothly. From this stance, students engage in *covariational reasoning* when they can envision the values of two quantities, such as the height and the area of a growing rectangle, varying together (Thompson & Carlson, in press). In this study we will characterize students' reasoning as *covariational* when they attend to coordinated change across two or more quantities. This does not mean the students necessarily thought about continuous variation; in many cases, their understanding of variation was likely chunky, or even discrete. However, we characterize reasoning as covariational when students used language and gestures that suggested images of a rectangle's height values and area values simultaneously varying together.

Representational Fluency and Meaning Making

Zbiek, Heid, Blume, and Dick (2007) define representational fluency as "the ability to translate across representations, the ability to draw meaning about a mathematical entity from different representations of that mathematical entity, and the ability to generalize across different representations" (p. 1192). In this study we focus on both students' translations (i.e., the correct creation and interpretation of quadratic function rules from tables, words, or diagrams), and what these symbolizations *mean* to students. What one is able to "see" in a representation is supported and constrained by what one knows (Piaget, 2001). Thus we adopt a constructivist stance in building second-order models of students' mathematics (Steffe & Olive, 2010), making inferences about students' meaning making as opposed to first-order models of a researcher's meanings of representations.

Methods

Teaching Experiment

We conducted a 15-day videotaped teaching experiment (Steffe & Thompson, 2000) with 6 middle school students in an after school setting. The teacher-researcher (TR, Ellis) taught all teaching sessions, each lasting 1 hour. All sessions were transcribed and pseudonyms were assigned to all participants. One purpose of the small-scale teaching experiment is to gain direct experience with students' mathematical conceptions and the change in those conceptions over time (Simon,

1995). Our aim was to study the factors promoting students' algebraic generalizations as they explored rectangles that grew proportionally by maintaining the same height-to-length ratio. The teaching-experiment setting supported the development and testing of hypotheses about students' understanding in real time while engaging in teaching actions. Thus, the mathematical topics for the entire set of sessions were not pre-determined, but instead we created and revised new tasks on a daily basis in response to hypothesized second-order models of the students' mathematics.

Task design. All tasks were grounded in the growing rectangle context, in which the relationship between the height, h, and the area, A, can be expressed as $A = ah^2$. Students worked with computer simulations of the growing rectangles, drew their own rectangles, created tables representing the heights, lengths, and areas of growing rectangles, and created and justified algebraic rules comparing the rectangles' areas with their heights (Figure 1).

Task a. Here is a table for the height versus the AREA of a rectangle that is growing in proportion:

Height	Area
3	6.75
4	12
5	18.75
6	27
7	36.75
8	48
50	?
h	?

Task b. Here is a table for the height versus the AREA of a rectangle that is growing in proportion:

Height	Area
2	16
4	64
6	144
8	256
10	400
65	?
1/2	?
h	?

Figure 1. Sample far prediction and generalization tasks.

Data Sources and Analysis

Data for this study included video, transcripts, and PDFs of students' written work. We analyzed all student discourse and written work in which a student stated (written or spoken) a correct rule of the form $A = ah^2$. Data analysis focused on identifying the nature of students' quantitative reasoning (RQ1), ways of reasoning supportive of symbolizing function rules (RQ2), and students' meanings for the coefficient a in the function rule $A = ah^2$ (RQ3).

Two coders independently coded half of the data corpus in a first round of coding, then met to discuss findings and clarify questions. In a second round, one coder (Fonger) independently compiled all data from the first round of analysis and named major code categories and subcategories. In a third round of analysis Fonger re-analyzed all compiled data, one (sub)category at a time in a constant comparative fashion (Strauss & Corbin, 1990), referring to the original transcripts as needed. In a fourth round of analysis, Fonger engaged in axial coding (Straus, 1987) to discern relationships among codes. Coding was aimed at identifying how types of quantitative reasoning may have supported students' symbolization of rules and meanings of a. For a given episode it was possible for a student to demonstrate multiple forms of quantitative reasoning; all types were coded where appropriate, except when a student demonstrated evidence of covariation, in which case we did not also code variation. In cases in which students demonstrated flexibility across ways of reasoning, we coded multiple meanings of a.

Results

Students' Quantitative Reasoning

We characterized the nature of students' quantitative reasoning about functional growth situations (RQ1) into four types: (a) *Static Correspondence*, (b) *Variation*, (c) *Uncoordinated Variation*, and (d) *Covariation* (Figure 2).

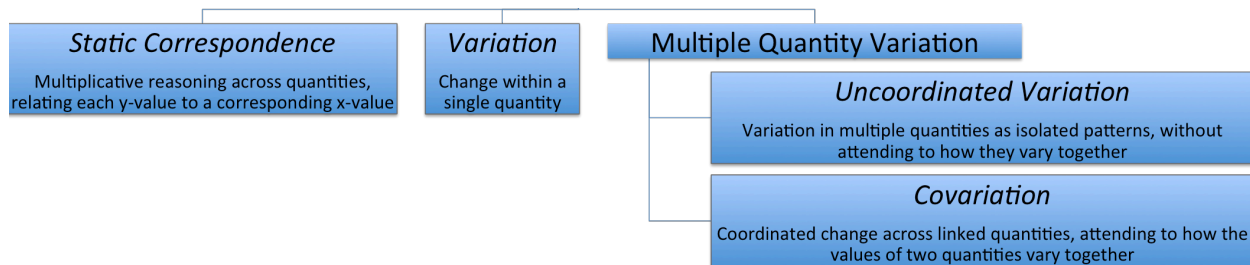
Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.


Figure 2. Quantitative Reasoning about Functional Growth Situations.

For *Static Correspondence*, students demonstrated evidence for reasoning multiplicatively across quantities, directly relating each *y* value to a corresponding *x* value. This includes both multiplicative relationships between height (*x*) and length (y_1) and height (*x*) and area (y_2); the first case was more common. For example, Daeshim said "height times 3 is length" and Bianca noted "length over height" as a static multiplicative relationship across linked quantities.

Students reasoned about *variation* when they reasoned about change within a single quantity, for instance, attending to growth in area without coordinating with growth in height. Typical ways in which students reasoned about *variation* in quantities was through attending to either differences in height or in length of the growing rectangle, but not to both. For example, for the rule $A = .75h^2$ Ally described .75 as "the rate of growth of the length." When students reasoned about variation in more than one quantity we categorized their thinking as either uncoordinated variation or covariation. *Uncoordinated variation* is typified by students' attention to variation in two or more quantities in a manner that does not coordinate simultaneous change, but rather treats the variation as isolated patterns or sequences (Figure 3).
Figure 3. Ally's uncoordinated variation of length and height.

Ally's work in Figure 3 (for Task b) shows how she computed length values for each pair of height and area values. Ally attended to variation in L by computing successive differences in length (which the students called DiL). She also noted a pattern for the difference in height (which the students called DiH), writing, "you can't reduce regularly because it is going up by 2s." Thus Ally attended to DiL and DiH as isolated patterns.

Finally, we characterized students' quantitative reasoning as *covariational* when they attended to a coordinated change across more than one quantity, envisioning both quantities varying together. For example, Jim wrote the rule $A=4.5h^2$ and explained if you grew a rectangle "it would go over 4.5 for every time you go up the height 1."

Conceptual Supports for Students' Ability to Symbolize Function Rules

Students' symbolization of quadratic function rules of the form $A = ah^2$ was supported by four modes of reasoning (RQ2): (a) *Static Correspondence*, (b) *Variation and Static Correspondence* (when ΔH=1), (c) *Covariation*, and (d) *Flexible Covariation and Correspondence*. Each mode of reasoning is exemplified across two task types in Table 2 (save mode D, which combines modes A

and C). See Figure 1 for the two tasks (Tasks a and b), in which $\Delta H=1$ for Task a and $\Delta H=2$ for Task b. The examples in Table 2 are sample student responses to these tasks, and are paraphrased from our analyses of student thinking. These results reflect the relationships observed in students' quantitative reasoning.

Table 1: Conceptions of Functions Supportive of Symbolizing Function Rules

Mode of Reasoning	Example for $\Delta H=1$	Example for $\Delta H>1$
A. Static Correspondence. Student writes a rule by computing a ratio of two quantities, either (a) length to height, or (b) area to height^2.	$A=.75h^2$ because I take the ratio of length to height, 2.25/3, which is .75.	$A=4h^2$ because the ratio of the length to height, 8/2, is 4.
B. Variation <u>and</u> Static Correspondence. Student reasons about the difference in length (DiL), multiplicatively relates height and change in length (L=H*DiL), and writes the rule A=HL as A=H(DiL*H).	$A=.75h^2$ because .75 is the difference in length, so I can write L=.75*H, and A=LH so A=(.75H)(H)	n/a (i.e., mode of reasoning leads to incorrect rule)
C. Covariation. Student understands coordinated variation in two linked quantities and uses this to support writing a correspondence rule of the form $A = ah^2$. This includes change in length, change in height, and rate of growth of area.	$A=.75h^2$ because the length changes by .75 each time (the height changes by 1).	$A=4h^2$ because the length increases by 8 cm for every 2-cm increase in height.

There are two important cases to discuss regarding our results of RQ1 in relation to RQ2. First, in some cases, students' quantitative reasoning was evident in their thinking without necessarily supporting their ability to write a rule. For example, Bianca reflected on the rule $A=4.5h^2$ and questioned "What is the 4.5 that we came up with? What does that have to do with anything? Length over height!" Thus Bianca's reasoning about a correspondence relationship did not inform her writing of the rule (it was a retrospective connection she made). Second, some types of reasoning did not support students' ability to write correspondence rules. Recall Ally's reasoning on Task b (Figure 3). Notice that Ally wrote the rule $h \times 8 \times h = A$, which was informed by her understanding that $A=HL$ and $H=8L$ (mode B, *variation and static correspondence* for $\Delta H>1$). This example illustrates two findings: Ally's *variation and static correspondence* reasoning for $\Delta H>1$ led to an incorrect rule (see Table 2), and Ally's uncoordinated variation of DiL and DiH did not support writing a correct rule. Thus in what follows we focus only on the cases for which students' quantitative reasoning informed their symbolization of function rules. For brevity, we exemplify modes B and D.

In mode B, students coordinated their reasoning about variation in length with reasoning about a static relationship between height and length in order to re-write the area formula $A=HL$ in terms of these quantities. For example, on Task b, Tai found "the rate of growth of the length" to be .75 and explained "height times .75 equals the length … and then you take the length and you times it by the height." Thus Tai attended to variation in L to posit .75 as the rate of growth in the length, then stated a multiplicative correspondence relation between length and height ($H*.75=L$), and used the rule $A=LH$ to write $.75h^2$.

In mode D, students could think both covariationally and in terms of correspondence relations to symbolize function rules. Daeshim, Jim, Bianca, and Tai demonstrated flexibility in their conceptions of functions across the static correspondence view and the covariation view, which supported their abilities to symbolize correspondence rules. For instance, given a table of values in which the height increased by uniform increments of 3 cm, Jim found the rate of growth in length to be 6.75 cm for each 3-cm change in height. He wrote "$2.25h^2 = $ Area" and explained that he divided 6.75 cm by 3 cm "because that's what you're going up by each time." Jim's attention to the coordinated change in height and length supported his symbolization of the function rule. Jim also demonstrated flexibility

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

in leveraging his correspondence thinking to write rules. In one example, he created a table for the height, length and area of a growing rectangle and quickly said "$4.5h^2$ … I just did the first two numbers and that's all I need to do." Jim computed the ratio of the original length to the original height, and thus a static multiplicative relationship informed his writing of the rule.

Students' Meanings of Symbolic Quadratic Function Rules

In light of the finding that students demonstrated great variation in their conceptions supporting their ability to symbolize quadratic function rules, it is not surprising that their meanings for a in the symbolic function rules they wrote of the form $A = ah^2$ varied as well. We discerned five types of meanings of a in students' symbolic rules $A=ah^2$ as shown in the rows of Table 3. We exemplify three themes that emerged across students' meanings next.

Table 2: Students' Meanings of Symbolic Function Rules

Meaning of a in $A = ah^2$	Nature of Quantitative Reasoning
A Quantity	$a = length$ when $height$ is 1
Ratio of Quantities	$a = (original\ length)/(original\ height)$; $a = length/height;$ or $a = area/(height^2)$
Variation in Quantities	$a = DiL;$ or $a = 1/DiH$
Ratio of Variation in a Quantity to Value or Quantity	$a = DiRoG/2$; $a=(DiL)/(original\ height);$ or $a = DiRoG/(2(original\ height)^2)$
Covariation of Quantities	$a =DiL/DiH$; $a = DiL$ when $DiH = 1$; $a = DiL/DiH$ when DiH>1; $a = DiRoG/2 = DiL$, $\Delta height = 1$; or $a = DiRoG/(2*DiH)$

Ratio of Quantities or a Quantity

Students made sense of the coefficient a both as a quantity and as a ratio of two quantities. For instance, Daeshim wrote a general expression nh^2, explaining n as "the length when the height is 1" (Task b). Bianca explained that the coefficient a could also represent "length over height." Students often wrote the static ratio of length to height in the general form, $a = (original\ length)/(original\ height)$. The parameter a could also represent a static ratio of area to height squared. For example, Tai wrote a symbolic rule $4.5h^2$ by computing "the area [288] divided by h squared [8^2=64] equals a number [4.5]". In this case, $a = area/(height^2)$.

Variation and/or Ratio of Variation and Quantity

As a second theme, students reasoned about the variation in length or in the difference in the rate of growth in area (which the students called the *DiRoG*), sometimes also computing a ratio with a fixed quantity. For instance, Ally made sense of a as "the rate of growth of the length" (Task b), or $a = DiL$. Students also attended to the DiRoG in order to determine the value of a. Bianca explained, "I just found the DiRoG and divided it by two and then I knew what number to multiply by," so $a = DiRoG/2$. Other students related variation in quantities to a fixed quantity. For example, Tai explained: "First you figure out the, um, length. And then you find out the rate of growth, and then you divide the rate of growth by the height, and then you put like whatever number, height squared." In this case, $a=(DiL)/(original\ height)$.

Covariation of Quantities

Students also conveyed meanings of a that were firmly grounded in a covariation perspective, both (a) as the ratio of the change in height (DiH) to the change in length (DiL), and (b) as a coordination of the difference in the rate of growth (DiRoG) with either the DiL or the DiH. As an example of the first meaning, Sarah explained, "the height squared times the DiRoG of the length equaled the area [$h^2*DiRoG_L=A$]. And then depending on how much it went up by, you would divide

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

by that number [e.g., $h^2 * DiRoG_L/2 = A$]." In this case, $a = DiL$ when $DiH = 1$ and $a = DiL/DiH$ when $DiH > 1$. In the second case, students coordinated the difference in the rate of growth (DiRoG) with variation in height or length. For example, in one task, students had to relate the parameter a to the DiRoG. Both Joe and Tai made sense of a as the ratio of the difference in the rate of growth in area over 2 which equals the difference in the length. In this case Tai wrote DiRoG/2=DiL thus $a = DiRoG/2 = DiL, \Delta H = 1$. It is notable that in these cases the symbolic equation actually represents a covariational relationship between coordinated variation in the quantities length and height.

Discussion and Conclusion

This study addresses how students' ways of thinking may support their ability to create symbolic rules from numeric tables embedded in a quantitative context, and meaningfully interpret those rules from both the correspondence and covariational perspectives. Our results suggest that if students' function activity is grounded in a continuous quantitative context, such as the growing rectangle, and guided by a purposeful sequence of tasks focused on encouraging covariational reasoning, students may come to see function rules as representations of covariation. Such a stance can encourage a powerful and flexible understanding of function rules and serve as a productive foundation for further exploration in algebra.

Our findings also suggest that students need not necessarily be flexible in moving back and forth between correspondence and covariation views. Instead, students who develop a strong covariation view of functional relationships may come to make sense of algebraic symbolic rules as statements of covariation (e.g., seeing the parameter a as a relationship between two quantities that vary together). For example, recall Jim's reasoning; for him, the coefficient of 2.25 was a ratio of change in length to change in height. This suggests that a correspondence relation between area and height can emerge from attention to covariation in height and length, demonstrating the power of covariational reasoning in writing function rules (cf. Thompson & Carlson, in press).

Finally, when we consider the results of RQ1 and RQ2, an important finding emerges: students' conceptions of uncoordinated variation or variation alone were generally *not* supportive of their ability to symbolize function rules. This finding contributes to the literature on students' ways of thinking that might help explain representational disfluencies (i.e., unsuccessful translations from verbal descriptions or numeric tables to symbolic rules). On the other hand, we hypothesize that students' representational fluency in symbolizing function rules—especially the meanings they developed for the rule $A = ah^2$—seemed to be supported by (a) grounding their activity in a quantitatively rich task situation, (b) designing task sequences to encourage attention to the nature of how quantities change, (c) asking students to consider how quantities are related, and (d) prompting the generalization of those relationships by extending to far cases. Our approach to focus on the interplay between students' conceptions and meaning making from multiple representations of functions grounded in a quantitatively rich setting is a productive stance that warrants further exploration and research.

DEVIN'S CONSTRUCTION OF A MULTIPLICATIVE DOUBLE COUNTING SCHEME: DUAL ANTICIPATION OF START AND STOP

Rachael Risley	Nicola M. Hodkowski	Ron Tzur

risleyrachael@gmail.com	nicola.hodkowski@ucdenver.edu	ron.tzur@ucdenver.edu

In this case study with Devin (pseudonym), which was part of a larger, constructivist teaching experiment with students identified as having learning difficulties in mathematics, we examine how a fourth grader constructed a dual anticipation involved in monitoring when to start and when to stop the simultaneous count of composite units (numbers larger than 1) in multiplicative tasks. We postulate that such a dual anticipation underlies the first, Multiplicative Double Counting (mDC) scheme (Tzur et al., 2013) that marks children's conceptual progress from additive to multiplicative reasoning. Data from three teaching episodes with Devin focus on his anticipation of the start/stop features of his double counting activity. We discuss theoretical implications of these findings in terms of similarity between the dual anticipation in additive and multiplicative reasoning, and practical implications in terms of task design and sequencing.

Keywords: Elementary School Education, Number Concepts and Operations

Introduction

Researchers have developed models for thinking about and promoting children's learning to reason multiplicatively (Park & Nunes, 2001; Sophian & Madrid, 2003; Steffe, 1992, 1994; Steffe & Cobb, 1994; Tzur et al., 2013). By and large, these models are rooted in studies of normally achieving peers' construction of particular multiplicative schemes. Currently, less is understood about how students identified as having learning difficulties (SLDs) construct understandings of multiplicative reasoning (Evans, 2007). To address this lacuna, our study addressed the problem: How may SLDs progress *within* the identified scheme of multiplicative Double Counting—the first in their transition from additive to multiplicative reasoning?

In particular, we examine a possible intermediate stage in SLDs' construction of the mDC scheme, which may be a corollary of the intermediate stage distinction of anticipating starts and stops in the additive operation of counting on (Tzur & Lambert, 2011). Specifically, they found that students who learn to count need to develop an anticipation of both a starting and stopping point for the double count needed. For example, a child who is adding 7+4 would anticipate both a starting point of the number after 7 and the need to double count each item added as being simultaneously a constituent of the sequence of added items (1-2-3-4) and of the total (8-9-10-11). That is, in counting on, the child's counting of the added items serves as a purposeful aid in knowing when to stop her activity. In this paper, we focus on a similar anticipation of knowing where to start and where to stop counting of composite units which can be inferred in SLDs' work.

Conceptual Framework

Our conceptual framework for this study consists of general and content-specific constructs. The general constructs are rooted in a constructivist perspective on knowing and learning (von Glasersfeld, 1995). We view one's transition from not knowing to knowing a new mathematical idea as a mental activity that an observer must infer from observable actions and language of learners. Specifically, we drew on the construct of scheme as a three-part mental structure (von Glasersfeld, 1995). The first part of a scheme is the recognition of a certain situation. Here, a learner uses assimilation to "recognize" the situation based on previously recorded, like experiences. This "recognition template" sets the person's goal. In turn, the goal triggers the second part of the scheme, a mental activity used to accomplish the goal that may or may not be coupled with observable

actions. The third part of the scheme is the result a learner expects to follow the activity based on previous, similar activities.

Building on this three-part notion of scheme and on Piaget's (2001) core notion of reflective abstraction, Simon, Tzur, Heinz and Kinzel (2004) articulated cognitive change as the mental process of reflection on activity-effect relationship. This mental process is postulated to take place as a learner compares between the expected result and actual effect of an activity, and through comparison across instances of similar activity-effect dyads. Learning is marked by a change in the relationship between an activity and newly noticed effects, which turn into a new anticipation that can be linked to different situations.

The content-specific constructs we used are based on Tzur et al.'s (2013) developmental framework of six schemes used by children to reason multiplicatively. They distinguished those schemes based on units and operations a child uses. Specifically, scheme for multiplicative reasoning are thought of in terms of units coordinating activities a child is inferred to be using (Norton, Boyce, Ulrich, & Phillips, 2015; Steffe, 1994; Steffe & Cobb, 1994). In this paper we focused on the first scheme, termed multiplicative Double Counting (mDC).

A child who has constructed the mDC scheme anticipates the effect of coordinating at least two levels of composite units (CU). For example, such a child anticipates that 12 could be composed by coordinating an operation in which, say, 4 units of 1 (e.g., 4 cubes per tower) are distributed over the items of another composite unit (e.g., 3 towers) (Tzur et al., 2013). Consider, for example, a child who is presented with a multiplicative situation such as, "There are six packs of gum, each with 4 pieces of gum; how many pieces of gum are there in all six packs together?" A student who can bring forth and use the mDC scheme might sequentially hold up six fingers while simultaneously distribute four pieces of gum across to each (e.g., the first is 4, the second is 8, etc.), and arrive at the answer of 24 pieces of gum.

Research has suggested several possible reasons that SLDs may not make adequate progress in mathematics, including reliance on counting based strategies longer than normally achieving peers (Geary & Hoard, 2003), memory issues (Raghubar, Barnes, & Hecht, 2010), and SLDs' lack of the developmental requisite of composite unit (Tzur, Xin, Si, Kenny, & Guebert, 2010) to construct multiplicative reasoning. However, it should be noted that different researchers define mathematical disabilities in various ways. In our study we drew on a definition that includes both students who may have "qualified" for specialized support given to those identified as having mathematics learning disability as well as students who are significantly behind in mathematics achievement (Mazzocco, 2007). Throughout the rest of the paper, we will use the term students with learning difficulties (SLD) to refer to students who are significantly behind in mathematics—whether or not they were identified by their school system as such.

Methodology

The case study on which we report in this paper was part of a larger constructivist teaching experiment (Cobb & Steffe, 1983) conducted with four 4th graders in a western US school as part of the first author's doctoral dissertation. The students were sampled for the instructional intervention based on underachievement measured on state mathematics assessments along with their classroom teacher recommendations. The two first authors conducted the video recorded teaching episodes with the group of students or with individual students. We focus in this paper on teaching episodes conducted with one student, Devin (pseudonym), twice a week (30-45 minutes each), from October through December of 2014.

To teach and study Devin's construction of the mDC scheme, in each episode the researcher-teachers engaged him in playing a version of the game, *Please Go and Bring for Me* (PGBM), which Tzur et al. (2013) described in detail. The PGBM game was designed to promote children's reflection on the units used in multiplicative reasoning, by asking them to build towers from a given number of

single cubes. The game is played in pairs (with either a peer or the teacher). The players take turns as either a "Sender" or a "Bringer." The Sender poses the task by asking the bringer to build and bring back several, same-size towers, one tower at a time. For example, the Sender may plan to ask the bringer to bring 3 towers with 5 cubes; she would first ask the bringer to construct and bring one tower of 5, then another tower of 5 cubes, etc. Once the bringer brought all towers to the Sender's satisfaction, the Sender asks the Bringer four questions (in our work – those were written on a poster to promote students' use of full sentences and explicit mention of units): (a) How many towers did you bring (emphasizes number of composite units)? (b) How many cubes are in each tower (emphasizes unit rate – number of 1s in each composite unit)? (c) How many cubes are in all the towers? (d) How did you figure this [total of 1s] out? Similarly, the poster included 'answer-starters' that enabled the bringer to express her answers as full sentences (e.g., "I brought __ towers"). Initially, the teacher constrained the game so Devin could only use particular numbers of cubes per tower (e.g., 2 or 5) and of towers in all (e.g., up to 6 towers). The teacher also asked Devin to use different numbers for each kind of unit (e.g., disallow bringing 5 towers of 5 cubes each).

Our line-by-line retrospective analysis of video records, transcripts, and researcher field notes taken during each episode focused on the third and fifth teaching episodes with Devin. The focus of the analysis was on transitions Devin might make within the multiplicative Double Counting (mDC) scheme, while 'zooming in' on the interplay between his ways of operating and the numbers chosen in each task. The two first authors conducted ongoing analysis following each episode. The entire team of authors then conducted the line-by-line analysis of the three segments presented in the next section.

Results

In this section we present and analyze three excerpts that demonstrate advances in Devin's construction of goal-directed activities of coordinated counting to solve multiplicative tasks in which we used what for him were harder numbers (e.g., 5 towers of 6 cubes each and 7 towers of 6 cubes each, symbolized as 5T6 and 7T6, respectively). We selected these data because, prior to Devin's work on these tasks, to solve PGBM tasks with "easier" numbers he could independently call up an anticipation suitable for figuring out the total of 1s in a compilation of CUs via a coordinated count of the dual accrual of 1s and CUs. However, he was yet to construct and independently use an anticipation of the need to monitor his simultaneous count of composite units to know where to stop the count when "harder" numbers were given.

Excerpt 1 presents how Nina (pseudonym, the teacher/researcher and second author of this paper) began the work with Devin in the typical way PGBM is played, particularly when towers are hidden, namely, asking him to repeat (and firmly establish) the number of towers and the number of cubes per tower. This common practice when playing the game can help eschew a claim that the child's difficulties result from short-term memory issues. Excerpt 1 shows Devin's facility in the anticipation required for the double counts in the accumulation of up to 5 towers, and his inability to anticipate where to stop in the accumulation of the unit rates.

Excerpt 1, keeping track of where to stop when counting the unit rate (student: Devin; task 5T6; date: October 15, 2014).
11:21 *Nina*: How many towers are there, Devin?
11:28 *Devin*: There are s…. There are … how many towers? Five towers.
11:30 *Nina*: How many cubes are in each tower?
11:32 *Devin*: There are six cubes in each tower.
11:34 *Nina*: [Covers the towers with a piece of paper after Devin has confirmed the number of towers and the number of cubes per tower.] How many cubes are there in all?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

11:45 *Devin*: [Under his breath.] Six; twelve; [He presses the thumb and index finger of his right hand on the table to indicate the first two towers, then shifts to counting six 1s with his left hand starting with his thumb.] 13, 14, 15, 16, 17, 18; [He presses the third finger of his right hand on the table and continues to incorrectly count five 1s using the fingers on his left hand.] 19, 20, 21, 22, 23; [He then presses the fourth finger of his right hand and continued to count five more 1s.] 24, 25, 26, 27, 28; [He then presses the fourth finger of his right hand and continues to count six more] 29, 30, 31, 32, 33, 34. [He raises his hand indicating that he has finished and is ready to give his answer.]

Devin's response to the question about how many cubes are there in all indicated an anticipation of the need to coordinate the counts of 1s and CUs. Specifically, he independently initiated a start of the counting from the second multiple of 6, indicating his coordination of the compilation of CUs and the unit rate. That is, with the first two easy (for him) numbers in the sequence of multiples of 6, he seemed to distinguish the number of 1s in each CU from the number of composite units for which he had been accounting so far. As he tracked the accumulation of cubes past these two easy numbers (6, 12), however, he shifted to counting only five (instead of six) items per composite unit while keeping track of six towers (instead of just five). That is, whereas with "easy" numbers the role of each unit in regulating Devin's activity was properly anticipated, with "hard" numbers his effort to focus on accrual of both types of unit took over these roles. In this sense, Devin provided an example of a student for whom a claim that the more difficult (5+n) numbers impact construction of mDC can be demonstrated.

Excerpt 2 provides data from an instructional prompt from Nina designed to capitalize on Devin's work (and errors). In this excerpt, Nina oriented Devin's reflection to the way in which he accurately used his left hand to keep track of six cubes.

Excerpt 2, teacher/researcher supporting tracking the unit rate (student: Devin; task 5T6; date: October 15, 2014).

12:42 *Devin*: There are 34 cubes altogether.

12:57 *Nina*: Now I want you to double check.

13:00 *Devin*: [Uncovers the cubes and starts counting at 12 cubes for two towers (confirming his mDC even when the cubes were available to him). Moves the first two towers and continues counting the rest of the towers by 1s, arriving at 30. Smiles and looks at Nina.] I got it wrong.

13:10 *Nina*: [Orienting Devin on his own tracking methods.] So, Devin; what I saw you doing, which I thought was so good, is this. [Nina holds her left hand over the table and begins to fold each finger down.] You had this hand and were going like this [Holds her left hand over the table and begins to fold each finger down.] Can you tell me what you were doing?

13:24 *Devin*: [Places both hands on the table and moves his right hand.] That [hand] was towers [moves his left hand] and this [hand] was [for] my cubes.

13:26 *Nina*: [Models Devin's error.] And what I saw you doing was something like this. [Folds over each of 5 fingers on her right hand]

13:34 *Devin*: Oh, it was 5 [Indicates possible recognition of his error of counting 5 cubes instead of 6 cubes.]

13:37 *Nina*: So you were doing… almost like… [Gestures at Devin to show his count.] Can you show me?

13:42 *Devin:* Um, oh so 5 towers [presses his right hand on the table] and cubes [presses his left hand on the table] so 6+6 is 12.

13:56 *Nina*: So how many towers is that?

13:57 *Devin*: [Demonstrates his ability to track towers.] Two.

13:58 *Nina*: Ok.

13:59 *Devin*: So my third tower is [presses each finger of his left hand on the table and counts his thumb twice for an accurate 6 count.] 13, 14, 15, 16, 17, 18.

14:06 *Nina*: Ok … [Does not indicate whether the response is correct or incorrect, but encourages him to continue.]

14:08 *Devin*: My fourth tower is: 19, 20, 21, 22, 23, 24.

14:13 *Nina*: Ok …

14:15 *Devin*: My fifth tower is: 25, 26, 27, 28, 29, 30.

14:20 *Nina*: [Compares Devin's answer to another student's response they both heard previously.] So you got 30, too.

Excerpt 2 shows that, with Nina's prompting, Devin appeared to recognize the inconsistency in his previous counting of the unit rate in this task (13:34). Furthermore, he was able to re-orient his attention to systematically monitoring the subsequent stops of each of the unit rate counts at 6. We assert that when Nina oriented Devin's reflection on his own tracking methods, she fostered his monitoring of his own goal-directed activity. Consequently, Devin could begin monitoring a stop at 6 for each tower as he monitored the accrual of the total number of cubes. A crucial point in the shift in Devin's counting activity is that, for each tower, he *first* stated its number in the sequence of accruing CUs and only then interjected the 1s that constituted that CU. This is a subtle but important difference from first counting the 1s and then raising a finger for the CU, in that the count of 1s after stating the CU's ordinal number may indicate distribution of those items into each of the CUs (as shown in the study by Clark and Kamii, 1996).

Excerpt 3 provides data from Devin's work on a task during an episode that took place three teaching episodes after the one presented in Excerpts 1 and 2. In Excerpt 3, Devin still needed prompting to regulate his stoppage of the count of the unit rate when solving mDC tasks with harder numbers. This provides additional evidence of the difficulty of developing the double anticipation (start, stop) required for an mDC when faced with larger numbers. Despite of Devin's acceptance of Nina's suggestion, and his subsequent ability to monitor the stops in the unit rate for 5T6 in Excerpt 2, Devin's anticipation of where to stop counting the unit rate remained inconsistent. This inconsistency suggests that, in the previous episodes, Devin's construction of the coordinated count was at the participatory (prompt-dependent) stage.

In Excerpt 3, Devin first determined the total number of cubes in 7 towers of 6 cubes in each tower (7T6). In this case, we purposely increased the difficulty of the numbers because both—the compilation of CU and the unit rates—exceeded the number of fingers (five) on each of his hands. Devin readily anticipated where to start both counts, but again was unable to regulate where to stop the unit rate count past the second tower.

Excerpt 3, anticipating the stop when tracking the unit rate (student: Devin; task 7T6; date: October 23, 2014).

15:24 *Devin*: [Raises the thumb and index finger of his right hand] So 6+6 is 12; [then] 13, 14, 15, 16, 17, 18 [Raises the middle finger of his right hand and continues counting.] 19, 20, 21, 22, 23, 24 [Raises the ring finger of his right hand and continues counting albeit with 5 counts this time.] 25, 26, 27, 28, 29, [Raises the pinkie finger of his right hand and continues counting 5 counts again.] 30, 31, 32, 33, 34 [He folds all fingers on his right hand and raises his thumb again. At this point, the thumbs of his right hand (towers) and left hand (cubes) are raised.] He counts six counts.] 34, 35, 36 37, 38, 39…. I got 39 but I got 40 before.

Excerpt 3 indicates that, in this task, Devin could independently initiate the coordinated count while beginning from the second (known) multiple of 6, just as he had in Excerpt 2. This independent initiation indicated his anticipated coordination of the compilation of CUs and the unit rate. That is, with the first two "easy" (for him) numbers in the sequence of multiples of 6, he seemed to clearly

distinguish and monitor the number of 1s in each CU and the number of CUs for which he had been accounting so far. As he tracked the accumulation of cubes for the fifth and sixth multiples of 6, however, he shifted to counting only five (instead of six) items per CU. At the seventh multiple, he recounted 34 (the last number he said when incorrectly counting the 6th multiple), and then accurately counted 6 counts of 1s. That is, whereas Devin's prompt-dependent anticipation of when to start/stop each count with "hard" numbers lagged behind his independent, correct use of this anticipation with "easy" numbers.

Discussion

In this paper we examined a difficulty SLDs may face when learning to anticipate both where to start and where to stop in each of the coordinated counts required in mDC. The difficulty to anticipate this dual monitoring illustrates a possible intermediate stage in the development of mDC, particularly by SLDs. mDC requires a coordination of more than one count and each of the coordinated counts requires a dual anticipation of where to start and where to stop. The analysis of Devin's work in this study amounts to suggesting that mDC requires the learner's (and teacher's) attention to both an anticipation of where to shift each count of a CU (unit rate, first anticipation) and of where to stop a count for the compilation of CUs (second anticipation). It is this dual anticipation that makes operating on harder numbers, for example, when CUs and/or 1s exceed the number of fingers on one hand, a challenging feat to overcome. We suggest that this difficult conceptual shift may be rooted in the need to count figural items standing for each type of unit through a 1-to-1 correspondence (e.g., finger and the unit for which it stands).

In addition, Devin was able to recall the number of towers and the number of cubes per tower, but not yet to anticipate the stops when operating on those units. Thus, his case indicated that besides memory issues, other, conceptually born factors may underlie challenges SLDs' face when constructing the mDC for any number. That is, Devin could clearly and independently remember and accurately continue a coordinated count from the 2nd multiple of six. With prompting, he could also distinguish the number of 1s in each CU and the number of CUs for which he had been accounting so far (2T6). However, Devin's action in the subsequent coordinated counts highlighted the ongoing difficulty of anticipating stops within the operation of a double count in the development of mDC. This finding seems consistent with Tzur and Lambert's (2011) identification of two intermediate sub-schemes in children's progress from counting all to counting on in additive situations. Specifically, it suggests a possible extension to include anticipation of the start and stop of two simultaneous counts in multiplicative situations.

To better understand the role that ways of reasoning play in students' success on integer addition and subtraction problems, we examined the relationship between students' flexible use of ways of reasoning and their performance on integers open number sentences. Within groups of students in 3 participant groups—39 2nd and 4th graders who had negative numbers in their numerical domains, 40 7th graders, and 40 successful 11th graders—we found that flexibility and success were positively related. That is, the more flexibly students invoked ways of reasoning, the greater their success. These findings indicate that rather than searching for one particular model or approach to teaching integer operations, teachers should support multiple ways of reasoning and discuss features of problems that might make one way of reasoning more productive than another.

Keywords: Number Concepts and Operations, Cognition, Learning Trajectories (or Progressions)

Students' lack of success operating on negative numbers is well documented in the literature (Kloosterman, 2014; Vlassis, 2002). Understanding students' thinking about integer addition and subtraction is important for teachers to better support students' learning and to promote their transition from arithmetic to algebra (Peled & Carraher, 2008). We see our research on the flexibility of students' ways of reasoning about integers as connecting to the PMENA theme of Questioning Borders in our examining the role of implicit borders among instructional approaches to teaching integers. Existing literature tends to be focused on identifying a single best model or instructional practice for supporting students' understanding of integers, that is, promoting a *border* around a single practice. Our findings indicate that an opening of borders (or promoting more than one way of reasoning) may be more productive for students than a closed-border approach (or reliance on a single way to learn to operate with integers).

Theoretical Framework and Literature Review

We approach our research from a children's mathematical thinking perspective. We consider it important to see mathematics through children's eyes to better understand the sense that they make. This perspective is based on principles that children have existing knowledge and experiences they bring with them into the classroom and upon which they continue to build (e.g., Carpenter et al., 1999). We take this view because our ultimate goal in our research is to find ways to better support children's learning of mathematics, and instruction that builds on students' ideas benefits both teachers and students and supports rich instructional environments (Sowder, 2007; Wilson & Berne, 1999). Moreover, we hope that by studying the variety of ways students reason about integer arithmetic we can broaden existing instructional approaches so that more students can successfully engage with this important mathematical topic.

Literature Related to the Teaching and Learning of Integers

To provide background for this paper, we examine the research on computational fluency, students' understanding of integers, and integer instruction. Much of the research related to students'

understanding of integers is focused on secondary students' difficulties with integer arithmetic (Gallardo, 2002; Kloosterman, 2014; Vlassis, 2008). Students also have difficulties solving algebraic equations, simplifying algebraic expressions, and comparing quantities that include negative integers (Christou & Vosniadou, 2012; Vlassis, 2002). However, researchers have found children to be capable of reasoning about integers in relatively sophisticated ways, even in the lower elementary grades (Behrend & Mohs, 2006; Bishop et al., 2014; Bofferding, 2014). Despite these findings, few researchers have focused on students' ways of reasoning about integers. Instead, in the majority of integer-related studies, researchers developed and tested a variety of approaches to the teaching of integers, using various models, tools, and contexts (see Liebeck, 1990; Linchevski & Williams, 1999; Stephan & Akyuz, 2012). In most articles related to integers instruction, a single model or instructional approach, such as movement on a number line or zero pairs, was proposed. Although some models showed promise in terms of student achievement, no model is perfect, and each one has both affordances and limitations. The lack of compelling results across interventions led us to consider whether multiple approaches might be warranted; thus, we shifted to the literature on flexibility, described in the next section.

Literature Related to Flexibility

Although the research related to integers instruction has been focused on identifying one way to support students, the research on flexibility heightened our curiosity about the role that flexibility might play in relation to students' success in solving integers problems. Star and Newton defined *flexibility* as "knowledge of multiple [strategies] as well as the ability and tendency to selectively choose the most appropriate ones for a given problem and a particular problem-solving goal" (2009, p. 558). In recent years, researchers have identified flexibility as a critical characteristic of one who has attained deep procedural knowledge (Star & Newton, 2009) and as a characteristic shared by expert mathematicians (Dowker, 1992; Star & Newton, 2009). Additionally, many researchers have studied the influence or development of flexibility in different content domains, ranging from 2-digit-addition and -subtraction to estimation, multistep linear equations, and proportional reasoning (e.g., Berk, Taber, Gorowara, & Poetzl, 2009; Blöte, Van der Burg, & Klein, 2001; Dowker, 1992; Star & Newton, 2009).

Given middle-school students' well-documented struggles with integers, we questioned the emphasis in the literature on finding a single, best model to support students' learning. Instead, we sought to determine the degree to which flexible use of ways of reasoning influenced students' performance in solving integer problems. We asked the following research questions: How flexible are students in using ways of reasoning when completing integer open number sentences, and to what degree is students' flexible use of ways of reasoning related to their success in this activity? In reviewing the literature, we did not find any study that systematically sampled students at different grade levels to document the flexibility in their reasoning about integer addition and subtraction. We here provide a cross-grades view of flexibility in students' ways of reasoning about integer addition and subtraction and then relate flexibility to performance. The findings reported here advance the field's understanding of students' flexibility and performance on integer addition and subtraction problems. This study contributes to the efforts of the mathematics education research community to support instruction that enables students to successfully transition from arithmetic to algebra.

Methods

Background and Participants

This study is part of a larger project in which our goal was to understand K–12 students' conceptions of integers and integer arithmetic. In this paper, we focus on flexibility in students' ways of reasoning—an aspect of integer understanding rarely mentioned in the literature yet which we

believe supports students to develop deeper conceptions of integers as well as more efficient computational strategies. Data for this study include clinical interviews with 160 students from 11 schools (3 elementary, 3 middle, 1 K–8, and 4 high schools) in the Western United States. During the 2010–2011 school year, these students participated in individual interviews about integer addition and subtraction. We conducted clinical interviews with students in Grades 2, 4, 7, and 11 (40 children from each grade level). Students in Grades 2 and 4 had yet to receive school-based integer instruction; students in Grade 7 had completed integer instruction; students in Grade 11 were enrolled in a precalculus or calculus course and, because of their course taking, were deemed to be successful high school mathematics students. Because our focus is on understanding students' productive ways of reasoning, we restrict our findings in this paper to students who had some knowledge of negative numbers: *2nd/4th with negatives* ($n = 39$), those 2nd- and 4th-grade students who provided evidence of at least limited knowledge of negative numbers, *7th-grade students*, and *successful 11th-grade students*. The *2nd/4th with negatives* group included 13 Grade 2 students and 26 Grade 4 students who, on the basis of responses to tasks posed at the beginning of the interview, provided evidence of having at least some knowledge of negative numbers.

Clinical Interview

The videotaped 60–90-minute clinical interviews (Ginsburg, 1997) were conducted at the students' school sites. Although we sought to understand and follow the child's thinking during the interviews, the interviews were standardized: All children were posed the same set of 47 tasks, except for those students who did not have negative integers in their numeric domains. The interview had four categories of tasks: introductory questions, open number sentences (e.g., -3 + ☐ = 6 and ☐ + 6 = 4, with unknown location varying), contextualized problems, and comparison problems. Findings shared herein are from responses to the open number sentences.

Coding and Analysis

The interviews were coded at the problem level for both correctness and the underlying way of reasoning the child used. The Ways of Reasoning coding scheme was developed and refined iteratively over a period of 2 years. We identified five broad categories we call *Ways of Reasoning* and a total of 41 subcodes that provide more detail as to the child's specific strategy or strategies. The five ways of reasoning are order-based, analogy-based, computational, formal, and developmental (see Table 1 below for definitions). Each response to the 25 open number sentences was assigned a way-of-reasoning code (some responses involved more than one way of reasoning and, thus, received multiple codes). For example, some students completed -3 + 6 = ☐ by counting up 6 units, by ones, from -3. This solution would be coded as an order-based way of reasoning because counting leverages the ordered and sequential nature of numbers. However, another student might complete the same sentence using analogy-based reasoning, explaining, "It's like I borrowed 3 dollars from my friend. It's like I owe him; that's minus 3. And I give him 3 from the 6 my mom gave me, and now I have 3." We would code this response as analogy-based reasoning because the student solved the problem by comparing negative integers to owing money. Of the 160 interviews 42 (or 26.25%) were double coded, and interrater agreement was 92% at the Ways of Reasoning level and 83% at the subcode level.

Table 1: Ways of Reasoning About Integer Addition and Subtraction

Ways of Reasoning	Definitions
Order-based	In this way of reasoning, one leverages the sequential and ordered nature of numbers to reason about a problem. Strategies include use of the number line with motion as well as counting forward or backward by 1s or another incrementing amount.
Analogy-based	This way of reasoning is characterized by relating numbers and, in particular, signed numbers, to another idea, concept, or object and reasoning about negative numbers on the basis of behaviors observed in this other concept. At times, signed numbers may be related to contexts (e.g., debt or digging holes). Analogy-based reasoning is often tied to ideas about cardinality and understanding a number as having magnitude.
Formal	In this way of reasoning, negative numbers are treated as formal objects that exist in a system and are subject to fundamental mathematical principles that govern behavior. Students may leverage the ideas of structural similarity, well-defined expressions, and fundamental mathematical principles.
Computational	In a computational way of reasoning, one uses a procedure, rule, fundamental mathematical principle, or calculation to arrive at an answer to a problem involving negative numbers either as part of the problem statement or as appearing in the solution set.
Developmental	This category of reasoning often reflects preliminary attempts to compute with signed numbers. An example of this category is a child's overgeneralization that addition always makes larger with the claim that a problem for which the sum is less than one of the addends (e.g., $6 + \square = 4$) has no answer. In this case, the domain of possible solutions appears to be restricted to natural numbers and the effect (or possible effect) of adding a negative number is not considered.

Measuring flexibility. *Flexibility* is a measure of the variety of ways of reasoning students use to solve integer-arithmetic tasks. Flexibility indicates whether a student primarily uses one way of reasoning or chooses different ways of reasoning depending on the affordances of the problem. We calculated a flexibility measure for each student by identifying the number of times each way of reasoning was used across all 25 open number sentences. Note that we did not include the developmental way of reasoning in this calculation because developmental approaches reflected preliminary attempts to compute and typically resulted in incorrect responses. We deemed a student to be proficient with a particular way of reasoning if that student used it three or more times during the interview (that is, used a given way of reasoning on at least 12% of the open number sentences). The number of ways of reasoning with which a student was proficient was our measure of flexibility. For example, if a student used order-based reasoning on 7 open number sentences, analogy-based reasoning on 2 open number sentences, formal reasoning on 3 open number sentences, and computational reasoning on 16 open number sentences, the student would be proficient with 3 ways of reasoning and receive a flexibility score of 3. We used this flexibility score to explore the relationship between flexibility and performance on the 25 open number sentences of students in the participant groups: 2nd/4th with, 7th-grade students, and 11th-grade students. In the next section, we report findings and provide case studies of three students to underpin the quantitative findings.

Findings

We found that flexibility is positively correlated with performance in our data within grades ($r = .347, .523, .429$ for 2/4, 7th, and 11th, respectively, two-tailed, all p-values < .05). In Table 2, we share frequency counts for flexibility scores of 0, 1, 2, 3 and 4 at each grade level. These frequency counts reflect the number of students who were proficient with 0, 1, 2, 3 or 4 ways of reasoning.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

More than half of the 2nd/4th graders with negatives used two ways of reasoning, and almost all (87%) used 1 or 2. The 7th graders had the greatest spread in flexibility; although almost half (45%) used 3 ways of reasoning, one fourth used 2 ways and one fourth used 4 ways of reasoning. Finally, more than half of the 11th graders (55%) used 3 ways of reasoning, and almost all (85%) used either 3 or 4. The findings that 11th graders were both the most flexible in their ways of reasoning and the most accurate indicate that particular ways of reasoning are not necessarily *replaced* by other, more sophisticated, ways of reasoning but, rather, that students who have access to and use multiple ways of reasoning are more successful than those who do not.

Table 2: Frequency Counts for Ways of Reasoning

Flexibility score	Grades 2/4 with negatives ($n = 39$)	Grade 7 ($n = 40$)	Grade 11 ($n = 40$)
0	2 (5%)	0 (0%)	0 (0%)
1	11 (28%)	3 (8%)	4 (10%)
2	23 (59%)	10 (25%)	2 (5%)
3	3 (8%)	18 (45%)	22 (55%)
4	0 (0%)	9 (23%)	12 (30%)

Cases

We provide cases of three 7th-grade students—Hannah, Sofia, and Maria (pseudonyms)—to exemplify the relationship between flexibility and accuracy. Hannah invoked order-based reasoning on more than 80% of all open number sentences, whereas Sofia primarily used a computational way of reasoning. Maria invoked every productive way of reasoning, each on one fourth to one half of the open number sentences.

The case of Hannah. Hannah completed about one third (32%) of the open number sentences correctly and used order-based reasoning almost exclusively. Although she could use this way of reasoning productively at times, more often than not her almost exclusive use of order-based reasoning hindered her success. Hannah tended to be able to productively use order by invoking the strategy *motion on a number line* for problems such as -3 + 6 = ☐ and -9 + ☐ = -4, for which the second addend (or, for subtraction problems, the subtrahend) is positive, correctly completing 73% of these types of number sentences. However, she also used the same order-based way of reasoning for almost every other problem and answered every one of them *incorrectly*. For example, on 6 – -2 = ☐, Hannah placed her pen at 6 on the number line and paused. She then moved her pen to the left 2 units and answered 4, explaining, "You go to positive 6 minus negative 2 equals 4." The interviewer asked for clarification and Hannah added, "I am just a little bit confused by this (points to the open number sentence), so I just looked at this (points to the number line). So then I just minused 2, and I got 4." The discussion continued.

Interviewer: Which part is a little confusing?
Hannah: Because it is a positive 6 minus a negative 2 (she points to the number line). I don't know if you go down here (moves her pen to the negative side of the number line), or, I don't know, but I think it's 4."
Interviewer: Was there something else (another answer) you were considering?
Hannah: Negative 4, but then I was like, "No. Because it [-4] is all the way down here (points to the negative side of the number line)."

Hannah appeared to implicitly recognize that the problem has a structure different from the other problems she had successfully solved, and she shared her confusion about how to adapt her use of motion on the number line when subtracting a negative number. Her second answer of -4 (also incorrect) appeared to reflect her attempt to account for subtracting -2 (rather than +2). Hannah's

almost exclusive use of order-based reasoning limited her options for solving problems. Because she appeared to have no other ways of reasoning to support her completion of the open number sentences, she was often unsuccessful, as were most others who exclusively relied on one way of reasoning. In the next case we describe Sofia, who, like Hannah, tended to rely primarily on one way of reasoning and also had limited success. Unlike Hannah, however, Sofia used primarily computational reasoning.

The case of Sofia. Sofia was more successful than Hannah, inasmuch as she answered about two thirds (64%) of the problems correctly. She used primarily computational reasoning. For example, on the problem $6 + \square = 4$, Sofia correctly answered -2, using a rule. In particular, she used what is often referred to as the *different-signs rule*, such that when adding a negative number and a positive number, one finds the difference of the absolute values of the numbers and appends the sign of the number that has the larger absolute value.

> *Interviewer*: So how come you can put -2?
> *Sofia*: Because [the sum] can still become a 4 if you subtract from a positive and a negative. You can still get a number that is positive because this one (points to 6) is bigger, and then the answer has to be positive. If [the positive number] is a lower number, like if a negative number is higher (points to -2), and this one (points to 6) is like 3, [the sum] becomes a negative."

Sofia solved this problem by applying a rule: She subtracted 2 from 6—what she described as "subtract[ing] from a positive and a negative"—and the difference of 4 takes the sign of the number with the larger absolute value. Her focus on primarily computational approaches likely explains why she also applied the different-signs rule on a problem for which the rule was not applicable. For example, on the problem $-8 - 3 = \square$, Sofia incorrectly answered -5, explaining that she subtracted 3 from 8 and, because the 8 was negative, her answer should also be negative. "When [the absolute value of] a negative number is bigger than a 3, like, a positive number (points to 3), if this one (points again to 3) is lower [than the absolute value of -8], then the answer becomes a negative sign." For this problem, Sofia inappropriately invoked the different-signs rule. Similarly, she invoked a rule for multiplying negative numbers to complete $-5 + -1 = \square$. Sofia explained, "I think it is 6 because if you add both negatives, then it becomes a 6, but if you see the signs negative and a negative, it becomes a positive number, so I say it's a 6." When asked why two negatives become a positive, Sofia responded, "Because when the signs are the same, it becomes a positive. Well, my teacher said that if … it was two negatives, then it [the result] would become a positive."

Like Hannah's exclusive focus on order-based reasoning, Sofia's focus on computational reasoning appeared to hamper her success. Looking across both cases, we see that the particular way of reasoning upon which students focused was less important than the fact that each student appeared to have one way of reasoning on which she relied, and being limited to a single way appeared to negatively influence success.

The case of Maria. In contrast to Hannah and Sofia, Maria completed every open number sentence correctly and used all four productive ways of reasoning. For example, she used order-based reasoning for $-3 + 6 = \square$ by "jumping to" 0. Maria explained her answer of 3 saying, "Half of 6 is 3, so then that would bring it to the 0. And 3 more would bring it to the 3. And that would equal 6." Maria decomposed 6 into 3 and 3 so she could jump to 0 using a partial sum. Her strategy of using a decade number of 0 supported her to count more efficiently than counting by ones. Maria then used analogy-based reasoning on the problem $-5 + -1 = \square$, by comparing negative numbers to "bad guys." For this problem she correctly answered -6, saying, "Since negative numbers are like bad guys, 5 bad guys met up with one more bad guy, so there were 6 bad guys total." In contrast, she correctly completed the number sentence $6 - -2 = \square$ using computational reasoning, explaining, "I changed the signs so it was plus-plus, and 6 + 2 is 8." Finally, Maria used formal reasoning for $6 + \square = 4$.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

She answered, "Negative 2. It's [the unknown] not going to be a positive because the sum is less than 6 and it [the operation] is addition. So it [the missing addend] has to be a negative number. So, -2." This response received a formal code because Maria used deductive reasoning (by noticing that if she added two addends and the sum was less than one of the addends, then the other addend must be a negative number) to determine that the sign of the number had to be negative.

Similar to others who used all the productive ways of reasoning, Maria not only flexibly invoked a wide range of strategies on the problems but also appeared to choose strategies that corresponded with the underlying structure of the problem, indicating that her (perhaps implicit) attention to the underlying structure evoked particular ways of reasoning. This attention appeared to be influential in her choice of strategy and, presumably, in her success.

Discussion

Our unique contribution to the research literature is documenting statistically significant and moderate-to-strong correlations within participant groups between flexibility and performance on integers open number sentences. Additionally, the cases of Hannah, Sofia, and Maria provide insight into how the degree of flexibility played out in relation to students' performance on the open number sentences. Although not causal, these findings indicate a need for students to have several ways of reasoning at their disposal. Further, the finding that 11th graders were both the most flexible in their ways of reasoning and the most accurate indicates that particular ways of reasoning are not necessarily *replaced* by other, more sophisticated, ways of reasoning but, rather, that a mark of expertise in operating with negative numbers is the flexible use of many ways of reasoning. These findings have implications for instruction, which we discuss below.

Implications and Contributions

In other work, we have found that many younger students used more than one productive way of reasoning about integer-related tasks prior to school-based instruction (Bishop et al., 2014). Thus, in any given classroom, teachers across grade levels may have different students approach the same problem in different ways. Teachers should be aware that they can leverage these different ways and that having multiple ways of reasoning appears to promote successful performance on these problems. That is, no single best model or way of reasoning that students successfully use across all problems exists, and attempting to teach students one all-encompassing way may have the unintended consequence of impeding students' success by limiting their flexibility. Rather than teaching any one particular strategy, teachers could instead discuss a variety of ways of reasoning and features of problems (signs of numbers, relative sizes of numbers in the problem, and operation) that might evoke one way of reasoning more than another.

Our findings align with the following famous quote: "I suppose it is tempting, if the only tool you have is a hammer, to treat everything as if it were a nail (Maslow, 1966, pp. 15–16). Those students who relied on a single tool (or way of reasoning) approached every problem with that tool, and they tended to be less successful than those who had a variety of tools from which to choose. This finding is particularly powerful in that the correlations between flexibility and accuracy held for every participant group—the more flexible students were, the more successful they were. Thus, the ways of reasoning may be thought of as a tool belt. We find that, in general, the more tools the better.

DISTINGUISHING BETWEEN SCHEMES OF MATHEMATICAL EQUIVALENCE: JOE'S TRANSITION TO ANTICIPATORY QUANTITATIVE RELATIONAL EQUIVALENCE

Jerry Woodward
Ball State University
jawoodward@bsu.edu

This study examined how a child constructed a scheme (abbreviated QRE) for producing mathematical equivalence via operations on composite units between two multiplicative situations consisting of singletons and composite units. Within the context of a teaching experiment, the work of one child, Joe, was analyzed over the course of 14 teaching episodes. Joe made the conceptual advance from a Relational Equivalence Scheme (RE) and absence of a Quantitative Relational Equivalence Scheme (QRE), through the participatory stage, to an anticipatory stage of a QRE scheme. Joe's progression distinguished between creating equivalence with an RE via operations on singletons and a QRE—a conceptual root for fundamental algebraic concepts such as the distributive property, solving linear equations, and a relational understanding of the equal sign.

Keywords: Learning Trajectories (or Progressions), Algebra and Algebraic Thinking

Introduction

This study examines the schemes of mathematical equivalence a child constructed to create equality between two multiplicative situations. Developing an understanding of mathematical equivalence is a foundational idea for algebra (Blanton et al., 2015; Knuth, Stephen, McNeil, & Alibali, 2006; McNeil, Fyfe, & Dunwiddie, 2015). Algebraic concepts such as solving linear equations and a relational understanding of the equal sign are rooted in children's conceptions of equivalence (Kieran, 1981; Knuth et al., 2006; McNeil et al., 2015). It is also well documented, however, children's struggles solving problems that require an understanding of equivalence (Falkner, Levi, & Carpenter, 1999; Kieran, 1981; Knuth et al., 2006; Stephens et al., 2013). This highlights the critical importance of learning what it means for children to come to understand equivalence and how this process occurs.

This study investigated schemes children construct for creating equivalence between two multiplicative compilations of abstract composite units (CUs) (Steffe & Cobb, 1998) (such as 7 baskets with 4 apples in each basket and 13 baskets with 4 apples in each basket). This requires operating on and coordinating two compilations and the difference between them. There are many ways to solve such tasks without concrete 1s present. For the purposes of this study, I will focus on two specific types of solutions that can occur when the CUs differ between the two compilations, but the unit rates are the same (13 CU of 4 and 7 CU of 4). For one solution the child may first find the total 1s in each compilation via multiplication (7•4=28, 13•4=52), subtract to find the difference in 1s (52-28=24), and then operate with the difference in 1s to create equivalence (52-12=28+12). Alternatively, the child may first produce the difference in CUs between the two compilations (13-7=6), and then operate with the difference in CUs to create equivalence (7+3=10, 13-3=10).

Multiplicative reasoning was chosen as the context for this study for two significant reasons. First, research on mathematical equivalence and children's understanding of the equal sign (Falkner et al., 1999; McNeil et al., 2015) has predominately focused on problems that require additive reasoning (e.g. 8+4=__+5). Results in the domain of additive reasoning have pointed to the possibility young children can develop a relational understanding of the equal sign (Baroody & Ginsburg, 1983; Jacobs, Franke, Carpenter, Levi, & Battey, 2007). However, the schemes of mathematical equivalence children develop have not been identified and it is also not known if equivalence schemes evolve as children's reasoning expands. The second reason the use of

multiplicative situations is so critical is that they allow for differentiation between children's schemes based on the units they operate on and with (Steffe & Cobb, 1988). A child's additive and multiplicative reasoning afford and constrain the algebraic schemes they construct (Steffe, Liss, & Lee, 2014). By including multiplicative situations, how children's constructions of equivalence schemes are afforded and constrained by their current additive and multiplicative reasoning can be studied.

Conceptual Framework

The cognitive foundation for this study was provided by the reflection on activity-effect relationship (*Ref*AER*) framework (Simon, Tzur, Heinz, & Kinzel, 2004; Tzur & Simon, 2004). *Ref*AER* is an elaboration of constructivist scheme theory (Piaget, 1985; von Glasersfeld, 1995) that describes how a learner forms a novel conception through two types of reflections on their mental activity (Simon et al., 2004). *Type-I reflections* are comprised of comparisons between the learner's goal and the effects (as noticed by them) of their mental activity. When newly noticed effects become associated with a particular (mental) activity or activity sequence, the learner can anticipate an effect from that activity and an activity-effect relationship (*AER*) is created. Each time a learner sets a goal, brings forth their mental activity and connects an effect with that activity, a record of experience is formed. *Type-II reflections* consist of comparisons across these records. Through such reflections, a learner can abstract invariants and develop the anticipation of when to call up an *AER*. The stage distinction (Tzur & Simon, 2004) is used to describe the stages that comprise the formation of a new conception. At the participatory stage, a learner has connected a particular mental activity or activity sequence with an effect and has created an *AER*. What they cannot do, until the anticipatory stage, is call up such an *AER* spontaneously and independently when the original activity is not available to them.

The content-specific constructs guiding this study were children's multiplicative reasoning and number schemes. The Explicitly Nested Number Sequence (ENS) (Steffe & Cobb, 1988) and the Generalized Number Sequence (GNS) (Steffe, 1994) were schemes drawn upon to describe children's operating on CUs. In each, the child conceptualizes smaller compilations as embedded within a larger compilation. For example, 7 CUs of 4 (7 baskets of 4 apples) and 6 CUs of 4 (6 baskets of 4 apples) are embedded within 13 CUs of 4 (13 baskets of 4 apples). Additionally, a child with GNS can operate with abstract iterable CUs and can anticipate the multiplicative structure (four 1s distributed over each of the 7 CU) prior to operating with it (Steffe, 1994). The multiplicative schemes included multiplicative double counting (mDC) (Tzur et al., 2013) and Unit Differentiation-and-Selection (UDS) (McClintock, Tzur, Xin, & Si, 2011).

Methodology

This study consisted of 14 teaching episodes taught by the author over 2 months with an 8th grader, Joe. It was conducted as part of a teaching experiment with two pairs of 7th and 8th grade students, designed to develop algebraic reasoning in middle school students. Joe was purposefully selected for this study because he was operating with at least an Explicitly Nested Number Sequence (ENS) (Steffe & Cobb, 1988). McClintock et al. (2011) identified operating with an ENS as key to children's construction of a UDS scheme.

The two primary tasks provided to Joe during the episodes were UDS tasks (McClintock et al., 2011) and QRE tasks. UDS tasks ask the learner to compare two compilations that differ by either the number of CU (3 CU of 5 singletons and 8 CU of 5 singletons) or by the size of the CU (3 CU of 5 singletons and 3 CU of 4 singletons). Once presented with the two compilations, the learner is then asked a succession of questions, "How are these collections similar? How are they different? Who has more cubes and how many more?" (McClintock et al., 2011, p. 166). QRE tasks can follow or be independent of UDS tasks. They also incorporate two compilations that can differ by the quantity or

size of the CU, but the central question asked to the learner is for them to make the two compilations the same. In some cases, the learner is also asked to build the compilations using Unifix cubes (3 CU of 5 = 3 towers with 5 cubes in each tower, designated $3T_5$) and to demonstrate their solution using the cubes.

Data analysis was conducted in two phases: during the planning and evaluations of teaching sessions and retrospective analysis. In the on-going analysis, critical events such as evidence of current conceptions and the stage of these conceptions were identified and discussed. Through this analysis, appropriate tasks and prompts were then selected for the next episode. The purpose of the tasks and prompts was either to foster development of new conceptions or to test the access a child had to their current conceptions. In the retrospective analysis, previously identified critical video segments were transcribed and analyzed. The children's written work was also analyzed. Of particular importance were segments that enabled inferences about Joe's operating and provided evidence of his transition between stages.

Results

In this section, data supporting Joe's initial relational equivalence (RE) scheme and lack of a quantitative relational equivalence (QRE) scheme are first discussed. Next, analysis of data is provided in support of the assertion that Joe progresses to a QRE scheme. Specifically, I claim Joe transitions into the participatory stage and then anticipatory stage of a QRE scheme.

Relational Equivalence Scheme

During our third session together, Joe and another child, Javier, were given a UDS task (McClintock et al., 2011) followed by a QRE task using the same compilations. Joe was given (for pretend) compilations consisting of 7 towers with 8 cubes in each tower ($7T_8$) and 9 towers with 8 cubes in each tower ($9T_8$), respectively. During the UDS portion of the task, he multiplicatively produced the two totals ($7 \cdot 8 = 56$, $9 \cdot 8 = 72$) and then operated on 1s ($72 - 56 = 16$) to find that Javier had 16 more cubes than he did. A QRE task then directly followed which asked Joe to create equality between the two compilations. Excerpt 1 contains his explanation of his solution to the QRE task (T=teacher-researcher, J=Joe).

Excerpt 1 (April 17, 2012)

J: I took eight from him and gave me 8.
T: Okay, you took eight from him and gave you eight. Why were they both equal –because they both equaled what?
J: Um. [Looks at his work for a few seconds and then starts to write.] I don't know.
T: That's okay. You just knew that they were 16 apart.
J: Yeah because if I subtracted it, then I could add it, then [inaudible].
T: Okay, so you don't really have to know what the number is. You just know it's equal.
J: [Writes 56 + 8 vertically and then 64 underneath.] It's 64.

The exchange provided evidence that Joe had an anticipatory RE scheme. Joe's goal was to create equivalent quantities of 1s by reducing the difference in 1s between the two compilations to zero. His activity sequence consisted of: select the CUs and unit rate in each compilation and produce two totals of 1s ($7 \cdot 8 = 56$, $8 \cdot 9 = 72$), subtract the smaller total from the larger total to produce the difference ($72 - 56 = 16$), divide the difference by two to produce half of the difference ($16/2 = 8$), dis-embed an amount of 1s equal to half the difference from the larger total and add it the smaller total. Joe relied on his part-to-whole reasoning and his operations with three levels of units (Steffe, 1994). He used part-to-whole reasoning to create a nested relationship between the two totals of 1s. Joe then operated with three levels of units as he transformed the totals. He operated on the three CUs (the

smaller total, the larger total, and the difference) where the smaller total and difference acted as a second level of units embedded in a third level of units (the larger total). Using his additive operations, he dis-embedded and re-embedded pieces of the difference as he saw fit to bring the two totals into balance.

Evidence of his solution method, designated Halve-the-Difference (HTD), was further supported by his written solution, "To make same u (you) need to take 8 from (Javier) and give them to me." Joe did not need to enact the transformations of the totals to verify that equality had been achieved. He did not produce the 64 until the researcher requested it. Joe anticipated that balance was achieved by his operating (re-distributing the difference to the totals) rather than by the end result of his operating (comparing the two new totals). Joe's RE scheme was at the anticipatory stage. He anticipated creating the embedded structure of 1s and the subsequent operations on 1s to produce equivalence without any prompting in a novel situation.

Fostering Construction of the Participatory Stage of a QRE Scheme

Joe created equivalence, but even when prompted, he did not balance the CUs. I hypothesized he lacked a QRE scheme. To promote Joe's construction of a QRE scheme, he needed to be oriented to operations on CUs. This required Joe to suspend producing the totals multiplicatively in the original compilations and operate with each of them as a collection of CUs. The following three episodes describe how Joe made this transition. In the first episode, our 6th episode together (April 26, 2012), Joe created equivalence via operations on CUs for the first time. The compilations for the task given were Javier scored 4 baskets each game for 5 games and Joe scored 4 baskets each game for 6 games. After finding who scored more baskets and by how many, Joe was given the QRE task, "Can you make them the same?"

Joe enlisted his RE scheme to produce the solution, "Take 2 baskets…" At this point, the teacher-researcher cut Joe off so he did not give the solution away to Javier. Making Joe wait for Javier prompted him to reflect on his operating and produce a second solution. Joe's initial utterance demonstrated he initially created equivalence via the HTD method. He took 2 baskets (half of the difference of 4 baskets) from the total of his compilation (24-2) and added 2 baskets to the total of Javier's compilation (20+2). But after the prompt, he balanced the two compilations and created equivalence by adding one more CU to the CUs in the smaller compilation (5 games with 4 baskets + 1 game with 4 baskets = 6 games with 4 baskets). Evidence of this was provided from his written work that included "6 – 5" and "add 1 game."

Despite Joe's subtraction of 5 from 6, I did not consider him to have purposefully returned to the compilations with the intention to find the difference in CU. Rather, I hypothesized he first reconstituted the difference in 1s as one CU (1 game of 4 baskets) via his segmenting operation (Steffe, 1992). This required Joe to return to the original compilations to retrieve the size of the CUs (4 baskets in each game). It was only after he had produced the CU of 1 game from the 1s in the difference (4 baskets) that he noticed it was the same as the difference in CUs between the original compilations. Joe had abstracted new activity through a Type-I reflection that could be used to produce equivalence, but it was tied to his original goal of operating on the difference as an embedded total of 1s. His current RE scheme still need to be executed before Joe could use CUs to produce equivalence. This indicated Joe still lacked a QRE scheme.

During session 7 on May 8, Joe continued to create equivalence via operating on CUs. I asked Joe to create equality between two compilations: 8 boxes of cookies with 6 cookies in each box (48 cookies) and 7 boxes of cookies with 6 cookies in each box (42 cookies). The purpose of the task was to test the participatory and anticipatory nature of his QRE scheme. If Joe had not moved to the participatory stage of QRE, the task was also designed to foster such a progression by offering him a chance to notice the difference in 1s (6 cookies) was also a difference of 1 CU. Joe produced equivalence by adding 6 to the smaller total of 42 cookies to create totals of 48 cookies. His initial

solution demonstrated that he did not have access to operations on CUs in anticipation and was not in the anticipatory stage of a QRE scheme. I then prompted Joe in two ways to orient him to the difference in the CUs.

I prompted Joe by asking him for an alternate solution. Joe again operated on 1s as he found and balanced the two totals by removing 3 cookies from the larger total and adding them to the smaller total (an HTD method). It was not until a second prompt that Joe operated on CUs. When I asked Javier to explain why Joe's method worked, it served as a prompt for Joe who immediately wrote down, "1 box to me." I hypothesized the prompt had re-focused Joe to the original compilations of the task and the relationship between the individual quantities across the two compilations. Excerpt 2 provides evidence of how Joe re-constituted his solution of adding 6 cookies to adding 1 box of cookies to balance the CUs (8 boxes of cookies per person).

Excerpt 2 (May 8, 2012)

J: You can also give me one more box.
T: What do you mean by, "give you another box"?
J: Well, he has 7 boxes. I have 7 and he has 8 boxes and each box has 6 in it, so it would
    give me one more box.

From his explanation, I inferred Joe was developing a new goal associated with a QRE scheme. Joe reflected on the relationship between the original compilations and the CUs (created through operations on 1s) used to create equivalence. I hypothesized that through a Type-II reflection, Joe was abstracting a new invariant: the embedded nature of the three compilations as collections of CUs. Moreover, Joe was transitioning into the participatory stage of a QRE scheme. My hypothesis was supported during the next task when Joe enlisted a method, designated Distribution-of-Embedded CUs (DECU), which used the embedded structure. The task asked, "Javier buys 7 boxes of cookies with 3 cookies in each box. Joe buys 9 boxes of cookies with 3 cookies in each box. Can you make them the equal?" The left side of Figure 1 shows Joe's initial computations of the totals. At that point, Joe paused for a moment, looked back at the statement of the problem, and then wrote, "add 2 more box(e)s to Javier."

Figure 1. Joe's written work demonstrating his transition to operations on CUs.

Initially calculating the totals served as an internal prompt for his activity associated with operations on CUs. I inferred that a reorganization of Joe's multiplicative and balancing schemes had occurred. Joe's new goal was to produce a difference in CUs and use those CUs to create equivalence. He progressed to a higher level of operating that included operations on CUs, but he could only access this goal through the original context (for him) of two embedded totals of 1s. From Joe's operating, I concluded he was in the participatory stage of a QRE scheme.

Anticipatory Stage of a QRE Scheme

During his 8th session on May 10, I tested Joe's reorganization of his QRE scheme. Joe continued to enlist his HTD method prior to operating on CUs, indicating he was not in the anticipatory stage of a QRE scheme. To help him gain access to his QRE scheme, I re-introduced Unifix cubes to use when he explained his solutions. This gave Joe an opportunity to physically see and mentally reflect on the relationship between the CUs in the original compilations and the

difference. Moreover, Joe could reflect on how balancing the number of CUs also produced equality of the total 1s because the CUs and total 1s were equal in the two compilations.

When solving a novel task at the beginning of the next episode, Joe independently and spontaneously enlisted operations on CU in anticipation. The task was "Javier buys 19 bags of candy with 6 pieces of candy in each bag. Joe buys 15 bags of candy with 6 pieces of candy in each bag. Make them so you have the same amounts." Joe was also given the constraint of written work was not allowed. This constraint created a new task for Joe in the sense that it required his QRE scheme. The size of the quantities coupled with the constraint introduced computational complexity for his RE scheme. Joe brought forth his QRE scheme and took 2 bags of candy away from Javier and added 2 bags of candy to his own collection leaving each compilation with 17 (19-2=17 and 15+2=17) bags of candy. Similar to his previous work with 1s, Joe did not produce the 17 bags of candy for each person. He did not have to because his method, designated Halve-The-Difference-CU (HTD-CU), had created equivalence without it.

Joe had balanced two compilations in a similar fashion with 1s when using his RE scheme. His equivalence scheme, in conjunction with his conceptualization of the difference as a qualifier of the nested relationship between the smaller and larger totals of 1s, enabled him to anticipate an even re-distribution of the difference brought the two compilations to balance. Now, as evidenced by the description of his HTD-CU solution in Excerpt 3, Joe had turned his focus to the CUs (4 bags) in the difference.

Excerpt 3 (May 15, 2012)

T: Yeah. It looked like at first you had plus two and minus two.
J: Yeah, I was thinking about bags.
T: You were thinking about bags.
J: Um-hum.
T: Tell me what you mean when you were thinking about bags. You took two bags from?
J: Javier, and [grabs two towers from his 15 towers of 6 and moves them to Javier's 19 towers of 6] I take these two. And then I give them to me. And then they'd be equal.

Joe enlisted his GNS (Steffe, 1994) as he operated with the four CUs (of size 6 pieces of candy) comprising the difference in a manner similar to his earlier operating with 1s. Joe produced units of units of units as he halved the difference into 2 groups of 2 bags with 6 pieces of candy in each bag. He then operated on the 2 units of units of units by dis-embedding them from the difference and then re-distributing them to the two compilations ($19T_6 - 2T_6$ and $15T_6 + 2T_6$) to create equivalence. His QRE scheme was now recursively being applied to the 2 CUs in the same way he had operated on 1s previously. Joe operated purposefully only on the CUs throughout the process and did not operate on the 1s in the compilations at all. He anticipated the *AER* (Tzur & Simon, 2004), connecting his mental activity of operating on the embedded the compilations as CUs to the effect of creating equivalence via operations on CUs.

In solving the task, Joe independently and spontaneously created equivalence via the activity sequence (a) differentiate the 1s and unit-rate from the CUs (b), select the CUs and operate on them to find their difference (using subtraction), (c) select the difference in CUs and operate on it to halve it (via division by 2), (d) subtract a quantity of CUs equal to half the difference from the CUs in the larger compilation and add the same quantity to the CUs of the smaller compilation. The key to getting Joe to demonstrate he had an anticipatory scheme was to create a need for him to use it in a novel task. The task was successful because of two aspects: the constraint of not allowing written work and the inclusion of large numbers that made mental computation difficult. Joe's solution provided evidence he was operating with an anticipatory QRE scheme.

Discussion

This study provides three contributions. First, this study identifies two schemes for mathematical equivalence. RE and QRE both incorporate additive balancing operations that create equivalence between two multiplicative compilations. When operating with an RE scheme, the learner first multiplicatively produces the totals of 1s from each compilation. They then find the difference in 1s between the totals and create equivalence by operating on the totals with some or all of the 1s in the difference. For a learner with a QRE scheme, operations for creating equivalence with 1s are available, but they instead select CUs for operating. They enlist a method (such as DECU or HTD-CU) that requires operations with three levels of units. The learner produces a difference in CUs between the two compilations and creates equivalence via additive operations on CU. They may re-distribute the CUs in the difference or transform the CU in one of the original compilations to create equivalence. In either case, this study demonstrates how an anticipatory QRE scheme enables a child to relate multiplicative compilations via operations on CUs. Such operations can provide the conceptual roots for fundamental algebraic concepts such as the distributive property of multiplication over addition [$19 \cdot 6 - 15 \cdot 6 = (19-15) \cdot 6$] and solving linear equations ($8 \cdot 5 = \_\_ \cdot 10$).

Second, differentiating between RE and QRE can help teachers address why their students continue to struggle with understanding the equal sign as a relational symbol (Kieran, 1981). When examining children's understanding of mathematical equivalence, research has focused on children's conceptualization of one side of an equation as "the same as" the other side of the equation (Falkner et al., 1999; Knuth et al., 2006; Stephens et al., 2013). Moreover, because it has been shown that children can use their additive operations to make sense of the equivalence of expressions such as 4+5 and 6+3 (Baroody & Ginsburg, 1983; Stephens et al., 2013), researchers have posited that a relational understanding of the equal sign can be developed as early as first grade. However, this study suggests how children understand "same as" changes as their operations evolve. Children who have constructed a QRE scheme can make sense of equivalence in CUs or 1s, while children with an RE scheme need 1s to conceive of equivalence.

Finally, this study demonstrates the transition from a lack of a QRE scheme to the anticipatory stage of a QRE scheme. This transition is rooted in operations on CUs. The operations on 1s contained in the child's RE scheme must be "lifted" to a higher level where they become operations on collections of CUs. Joe solved the tasks with his current schemes, but through reflection, he made two new abstractions. First, when the compilations differ only in the quantity of CUs, he abstracted that the difference, as a number of CUs, could be operated with to create equivalence between the two compilations. His second abstraction was the embedded relationship between the compilations as collections of CUs. The key to the second abstraction made by Joe and his transition to QRE was his GNS allowed him to anticipate the multiplicative structure of each compilation prior to any operating.

STUDENTS' REASONING AROUND THE FUNCTIONAL RELATIONSHIP

Michele Carney   Angela Crawford
Boise State University   Boise State University
michelecarney@boisestate.edu   angelacrawford1@boisestate.edu

Proportional reasoning is related to flexible use of the scalar and functional relationships that exist in proportional situations. More specifically, in regard to the functional relationship, students' understanding of the multiplicative comparison that exists between two quantities in a ratio is a key concept. We conducted student interviews with 12 high performing students to examine their conception of the functional relationship. Analyses provided initial evidence that the majority of students did not conceive of the multiplicative comparison when solving problems designed to press the functional relationship, indicating students' written work that makes use of the functional relationship should not imply understanding of the multiplicative comparison.

Keywords: Algebra and Algebraic Thinking, Cognition, Middle School Education

Introduction and Purpose

Students' ability to understand and apply proportional reasoning is critical to their future success in mathematics and science. Yet, there is evidence students are not developing proportional reasoning during their school experiences (Brahmia, Boudreaux, & Kanim, 2016: Cohen, Anat Ben, & Chayoth, 1999). One way to address this issue is for instruction to focus on developing understandings regarding mathematical relationships present in proportional situations, allowing for connections across topical borders into more sophisticated mathematics (e.g., rate of change, slope, and covariation) and other content areas (e.g., physics and chemistry) (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Teuscher & Reys, 2010).

One important aspect of the development of proportional reasoning is the understanding of the multiplicative comparison relationship that exists between two quantities in a ratio (Lobato, Ellis, & Charles, 2010; Tourniaire, & Pulos, 1985). The research focuses on students' conception(s) of the multiplicative comparison relationship (Lo, Watanabe, & Cai, 2004) and how they articulate their conception(s) of that relationship in a problem solving situation.

Theoretical Framework

We argue it is important for students to demonstrate the ability to flexibly and fluently make use of the scalar and functional relationships to solve problems (mathematics perspective), and at the same time they must possess understandings of these relationships through both a composed unit and multiplicative comparison conception (student cognition perspective).

Mathematics Perspective: Scalar and Functional Proportional Relationships

From a mathematics perspective proportional situations involve an equivalent relationship between ratios, such that $a/b = c/d$. There are two multiplicative relationships that can be found within proportions – scalar and functional (Tourniaire & Pulos, 1985). Imagine the situation "*Callie bought 7 cookies for $3. How many cookies can Callie buy for $12?*" as represented in the first row of Table 1. One can solve this problem by scaling up both elements of the original ratio by a factor of 4 to find 28 cookies for $12. This is referred to as the *scalar relationship* because we can scale up both components of the ratio by a common scale factor to create a new equivalent ratio. Alternatively, imagine the situation "*Callie bought 6 cookies for $2. How many cookies can Callie buy for $13?*" as represented in the second row of Table 1. Rather than scaling the original ratio by a factor of 6.5, one can use a simpler mathematical relationship expressing the number of cookies in

terms of the dollars (cookies are 3 times the dollars). This is the *functional relationship* because one variable is defined as a function of the other.

Table 1: Examples of contexts and student work around the scalar and functional relationships and students' related proportional reasoning conceptions

Mathematical Relationship			Students' Proportional Reasoning Conceptions
Scalar Relationship		Composed Unit	Students view the quantities in the ratio relationship as separate entities requiring coordination in conjunction with one another. For example, *"If I can buy 7 cookies for $3, then if I multiply the number of cookies times 4 to get 28, I have to multiply the number of dollars times 4 and get $12."*
Functional Relationship		Multiplicative Comparison	Students view one quantity in the ratio relationship in terms of the other quantity. For example, *"If I can buy 6 cookies for $2, then my cookies are always 3 times my number of dollars. Therefore, if I have $13, I know my cookies are 3 times more or 39 cookies."*

Missing-value proportion-based problems can be solved using both relationships. How one chooses to solve the problem typically depends on two factors. First, the context and the numbers therein may make the use of one relationship more efficient (Steinthorsdottir & Sriraman, 2009). Second, the choice is influenced by that particular student's proportional reasoning conception.

Student Conception: Composed Unit and Multiplicative Comparison

Students' conceptions of proportional relationships may parallel the scalar and functional relationships, but their use of a relationship does not necessarily mean a particular conception is present. Students may tend to see a given ratio as a *composed unit* involving the joining of two quantities in a ratio relationship (Lobato et al., 2010) which can then be scaled up or down to create equivalent ratios (see first row of table 1). Alternatively, students may tend to see one component of the ratio as a *multiplicative comparison* of the other component (see second row of table 1). Ideally students will possess both conceptions in order to flexibly operate with ratios in different contexts and situations.

Given the parallel nature of these relationships and conceptions, one may expect students to explain solution processes for scalar items through composed unit thinking and functional items through multiplicative comparison thinking. However, researchers have cautioned that students' solution processes that make use of the functional relationship may actually involve a composed unit conception (Lamon, 1993; Simon & Placa, 2012). For example, given the problem *Callie bought 6 cookies for $2. How many cookies can Callie buy for $13?*, a student may divide 6 cookies by $2 with a result of 3. How a student then expresses the meaning of '3' may indicate a focus on the composed unit or multiplicative comparison conception of the ratio relationship.

- Composed unit example: "Well 6 divided by 2 equals 3, so I knew $1 could buy 3 cookies. I had to multiply by the 3 cookies for a dollar by $13 to get $39." In this example, the student expresses the meaning of the '3' as 3 cookies and part of a composed unit, $1 for 3 cookies.
- Multiplicative comparison example: "Well 6 divided by 2 equals 3 that means the cookies are always 3 times the dollars. If I have $13, I multiply this by 3 to get the number of cookies." In this example, the student expresses the meaning of the '3' as a multiplicative comparison between cookies and dollars, 3 times more.

Students need both conceptions to fluently and flexibly proportionally reason. Yet there is little empirical evidence related to how students who make use of the functional relationship express their conception of this relationship. This study addresses the question: how do students articulate their

conception of the functional relationship when presented with problems that press the functional relationship?

Methods

We conducted interviews with 12 grade six students who exhibited high performance on an assessment of proportional reasoning to examine their conceptions of the functional relationship. The individual student interviews were conducted at one school immediately following the administration of the assessment. Three items that pressed the functional relationship were selected. Students were presented with their worked solution strategies for the three problems (bulleted below) and asked to describe their process. The interviews were video recorded and then transcribed for analysis.

- Marta found brownie deal with 3 brownies for $9. How many brownies can she buy with $12?
- Tomas found a hamburger deal with 4 hamburgers for $28. How much will 5 hamburgers cost?
- Mark found a hamburger deal with 8 hamburgers for $32. How much will it cost to buy 5 hamburgers?

Analysis

Thirty solution strategies from 12 students were available for analysis as not all students received all items in the interview process. The first round involved coding the written strategies as explicit, implicit, or indeterminate in regards to written evidence for use of a *composed unit understanding*. We opted to code based on evidence of composed unit understanding due to its relatively high frequency in our cursory examination of the strategies. An explicit code typically was applied to written use of the words 'per' or 'each'. An implicit code involved evidence of adding or multiplicative scaling ratios. All other work was coded as indeterminate. The second round of coding involved examining students' interview responses as confirms, indeterminate, or multiplicative comparison in regards to evidence for composed unit understanding. A code of confirms indicated verbal evidence of use of a composed unit strategy, typically involving the use of the words 'per' or 'each'. The indeterminate response could not be clearly coded as a scalar or functional strategy. The multiplicative comparison code involved evidence of one quantity being defined in terms of the other quantity multiplicatively, using the word 'times'.

Results

Of the 30 solution strategies, 27 were correct. The following categories (and counts) resulted from the coding process for the correct written work: explicit (7), implicit (6), and indeterminate (14) indication of composed unit understanding. We followed this by examining the type of thinking indicated in the interview response. The following categories emerged from the interviews: confirmation of a composed unit conception (23), indeterminate (3), and multiplicative comparison (1).

The number relationships were designed to press students to use multiplicative comparison understanding. While all students made use of the functional relationship, only one response out of 27 provided clear articulation of the multiplicative comparison between the quantities in the ratio and 23 of the 27 responses provided evidence of composed unit thinking. This indicates either the problems did not encourage multiplicative comparison conceptions or that the majority of the students did not possess this understanding. A second finding is written solution strategies often do not provide an explicit indication of whether students used composed unit or multiplicative comparison thinking.

Discussion

The results provide evidence that students' use of the functional relationship in their solution strategy does not indicate an understanding of the multiplicative comparison. Students typically made use of the functional relationship through division to generate a unit rate. These results provide empirical evidence to support previous statements in the literature (Lamon, 2005; Simon & Placa, 2012) regarding students' difficulty in understanding the functional relationship as a multiplicative comparison.

A small sample and the use of a discrete, easy to visualize context and missing value problem types may have impacted the findings. It is possible the context and/or problem type increased students' use of per-one or composed unit thinking; a different one may promote more multiplicative comparison thinking.

The primary implication is the need for intentional intervention to make explicit the functional relationship as a multiplicative comparison. Students' use of the functional relationship to generate a unit rate is often assumed to indicate students' understanding of the functional relationship as a multiplicative comparison. It is imperative that we build teachers' knowledge around these relationships and students' conceptions if we want students to develop a multi-faceted ability to proportionally reason.

LEARNING ARITHMETIC BY PROGRAMMING ROBOTS

Krista Francis   Brent Davis
University of Calgary   University of Calgary
kfrancis@ucalgary.ca   brent.davis@ucalgary.ca

With frequent predictions of upcoming technological and economic difficulties triggered by an impending shortage of information and communications technologies (ICT) professionals, the calls are growing stronger to include computer programming as a core element of school curriculum. These calls are bolstered by the suggestion that programming supports the development of thinking skills – which echoes a longstanding argument for teaching mathematics. Motivated by the parallel, we attempted to investigate some of the common ground between the learning to program and the development of core mathematical concepts. We photographed and video recorded children, aged 9–10, as they learned to build and program Lego Mindstorms^{TM} EV3 robots over four days. Our findings suggest that programming supports children's understandings of arithmetic and decimal numbers.

Keywords: Modeling, Number Concepts and Operations, Technology, Elementary School Education

Introduction

In recent years there has been a growing recognition that information and communications technologies (ICT) are a major contributor to innovation and economic growth. For instance, the Organization for Economic Cooperation and Development (OECD, 2013) considers computer programming a necessity for a highly skilled labour force. Shortages are already felt across the world impacting IT innovations and revenues (see Arellano, 2015; Clendenin, 2014).

Currently, a major push around the world is to include programming as a core part of school curriculum. In response, some educators and educational systems are shifting from teaching "how to use" software programs toward "how to code." These sorts of arguments for teaching computer programming parallel long-standing rationales for teaching mathematics. Similarly, many of the structures and strategies within programming bear strong resemblances to elements of mathematical concepts. We discuss a few of these resemblances in this paper, focusing on arithmetic.

Context

In this study we photographed and video recorded children as they learned to build and program Lego Mindstorms^{TM} EV3 robots over four half days. On Day 1, the children followed the instruction manual to build the robots. Day 2 children were taught to program their robots to "dance" and to trace a regular polygon. On Day 3 they were given the final challenge of building a robot that could find and douse a fire in any of four rooms in a building. Day 4 was the final challenge demonstration/competition.

The study's 22 participants were aged 9–10 in Pakan School at Whitefish Lake 128 First Nation in Northern Alberta. Data included video-recordings, GoPro digital images, field notes, and artifacts. Video analysis consisted of an iterative process for selecting videos and GoPro digital images that exemplified children's embodied spatial actions of mathematical thinking. A narrative developed through an iterative process of rereading the literature, reviewing the video and GoPro data, and rewriting. The instance that we use to focus our discussion was a trio of girls learning to program their robot to move a certain distance into the hallway to illustrate a developing understanding of number.

Findings

Arithmetic Topic 1 – Understanding Number

In the video[1]from Day 3, Krista (author) was helping the pink team program their robot to move into the building. The team members started out with a guess of 0.4 wheel rotations to move the robot into the first corridor of the building. After testing how far the robot moved and observing that the robot needed to move a considerably greater distance, Krista prompted the girls by asking what they should try next. Celina suggested they try 0.5. The small incremental change was still not enough, so Krista suggested they try 2. Two rotations moved the robot too far, which prompted the question, "What is between 0.5 and 2?" Celina responded "5." Krista drew a simple number line on the whiteboard and asked again, "What is between 0.5 and 2?" "Oh!" Celina exclaimed, "1.5." The number Celina chose was close to the number of rotations actually required, which indicated she understood the meaning of 1.5.

Analysis/Interpretation

In the exchange above, we take Celina's immediate and satisfactory response as evidence that invoking the number line appeared to provide an appropriate metaphor for helping Celina understand. Lakoff and Núñez's (2000) have noted that "Mathematical ideas…are often grounded in everyday experiences" (p. 29). For example, understandings of set theory are rooted in a "container" metaphor, which begins to develop as babies put things in their mouths and, later, drop objects into other objects. With regard to the concept of number, Lakoff and Nunez describe four grounding metaphors of arithmetic: *arithmetic as object collection*, *arithmetic as object construction*, the *measuring stick metaphor*, and *arithmetic as object along a path*.

The metaphor of *arithmetic as an object collection* is based on a one-one correspondence of numbers to physical objects. With this metaphor a greater size corresponds to a bigger number. For instance, 5 is *greater* than 3 because it forms a *bigger* collection. The metaphor of *arithmetic as object construction* is based on fitting objects/parts and arithmetic operations. In this instance, 5 is greater than 3 because an object comprising 5 units is larger than one comprising three. The *measuring stick* metaphor maps numbers onto distances, whereby 5 is greater than 3 because it is *longer*. The metaphor of a*rithmetic as an object along the path* is based on arithmetic as motion, by which 5 is greater than 3 because it entails moving further from a common starting point (i.e., zero).

In the following description, we summarize how the task of programming a robot to move into a room calls for all four of Lakoff and Núñez's representations of arithmetic. To begin, the metaphor of *arithmetic as an object collection* is used in most counting situations, whenever the forms being counting are perceived as discrete objects. It is called for in programming complicated actions into discrete steps or instructions. And more obscurely too, such conceptual moves as the discretizing of wheel turns, so that they can be counted and thus used as a tool in programming, might be argued to rely on this metaphor.

The *arithmetic as an object construction* might be encountered when programming a robot to move. Celina wanted a larger wheel rotation than 0.4, so she added an incremental amount of 0.1 wheel rotations to make 0.5 wheel rotations. Contrasted to the previous metaphor, in this instance, wheel turns are not perceived as discrete objects, but as parse-able continuities. Those parsed elements can then be assembled into an appropriate "object" to move the robot a precise distance.

The *measuring stick* metaphor also featured prominently in the children's programming, and was particularly prominent in in the frequent need to interpret wheel turns in terms of actual distances (e.g., when the phrase "1 wheel turn" was deployed not as a description of movement but was a reference to a distance of roughly 12 cm). In this instance, programming the code block requires understanding measurement of approximately 1.5 wheel turns.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Programing the robot to move can draw upon the metaphor of *arithmetic as on object along the path*. In this case, starting place becomes a critical element that occurs where the robot enters the room and recurs in the opposite direction when the robot leaves.

To re-emphasize, each of Lakoff and Núñez's four metaphors of arithmetic are present in programming the robot to move a required distance in the room. The ability to identify to the particular metaphor(s) that a situation is calling for is a critically important teaching competence, as Krista demonstrated in the interaction with Celina. Re-interpreting that brief episode, Krista recognized that Celina was not interpreting number as a distance (i.e., she was not using a *measuring stick* metaphor), and thus reminded her of that metaphor by offering the image of a number line. No explanation other than an image of number that fitted the application at hand was required.

Closing remarks

In the episode reported, the tasks of programming robots required more than parsing complicated actions into singular direction; they entailed flexible engagement conceptual metaphors and mathematical models. Computer programming aligns closely with concepts and structures in mathematics and we suspect that it might provide other powerful instantiations for mathematical concepts that have not yet been noticed. That suggestion is perhaps not surprising, given the mathematical roots of computer programming. However, to our reading, it is not an aspect of programming that has garnered much consideration in either mathematics education or the technology education literature.

Given that likelihood, and in consideration of the fact that mathematics literacy, like competency with programming, is of growing relevance, the realization that engagement with emergent technologies can complement and co-amplify mathematics learning – while, perhaps, contributing to evolving understandings of what "basic" mathematics might be for our era.

With regard to important complementarities between learning mathematics and learning to code, the Lego Mindstorms[TM] EV3 robots and the associated programming language provide a powerful instance of "multiple solutions." They afford tremendous flexibility for accomplishing a range of tasks, from the trivial to the complex. None of the programming tasks set for the children in our study had pregiven or optimal "solutions." Despite that – or perhaps because of that -- the children were able to engage in manners that they could recognize as successful, even when "complete" solutions were not reached. With incremental tasks and iterative refinements, children were able to learn more sophisticated and efficient methods for programming the robot. It is not difficult to imagine a mathematics class with similar standards of success.

The results of this study underscore the importance of developing and implementing a computer programming curriculum in schools. Programming is an emergent literacy that can amplify other critical literacies, while affording access to a diverse range of cultural capitals. The reasons to teach programming go beyond the technical and economic; for us, they are fundamentally ethical.

A FRAMEWORK FOR DESCRIBING CONCEPTIONS OF SLOPE

Courtney R. Nagle	Deborah Moore-Russo	Rafael Martínez-Planell
Penn State Erie	University at Buffalo	University of Puerto Rico
The Behrend College	dam29@buffalo.edu	at Mayagüez
ctr12@psu.edu		rafael.martinez13@upr.edu

This paper builds on the cannon of literature on the concept of slope to introduce a framework for describing conceptions of slope. The framework will allow us to consider how slope is viewed and used. It also provides researchers a way to classify student understanding of slope and educators a guide to help design slope tasks. The framework brings together ideas from APOS theory with research on slope conceptualizations to describe how students may develop an understanding of slope.

Keywords: Advanced Mathematical Thinking, Algebra and Algebraic Thinking

Theoretical Framing

APOS Theory (**A**ction, **P**rocess, **O**bject, **S**chema) is a cognitive theory, based on the ideas of Piaget, that considers how individuals may learn mathematical ideas (Arnon, et al., 2013). APOS is a well-known theory; it is now described briefly. In APOS, an **action** is a transformation of a previously constructed mathematical object that the individual perceives as external. It may be the rigid application of a sequence of steps that are explicitly available or the application of a memorized fact or property. When an action is repeated and reflected upon it may be interiorized into a **process**. A process is perceived as internal, and the individual may imagine, skip steps, and anticipate the result of a process without having to explicitly perform all steps. Processes may be coordinated with other processes and may also be reverted to the actions they came from as needed in a problem situation. As an individual needs to perform actions on a process he/she may gain consciousness of the process as an entity in itself. When the individual is able to apply or imagine applying actions to a process then it is said that the process has been encapsulated into an **object**. An object may be de-encapsulated into the process or processes it came from as needed in a problem situation. A **schema** for a specific mathematical notion is a coherent collection of actions, processes, objects and other schema, which are related to the given notion in the individual's mind. The schema is coherent in the sense that the individual can interrelate its different components and decide when a given problem situation falls within the scope of the schema. The progression from action to process to object often appears more like a dialectical rather than a linear progression. APOS Theory asserts that students' understandings of a particular mathematical concept as an action, a process, or an object influences their approaches in solving diverse mathematical tasks.

How Students Consider Slope: A Framework

How slope is used

In Figure 1, we provide descriptions for three ways students commonly use slope in mathematical classrooms to: (a) describe behavior, (b) measure steepness, and (c) determine relationships. For each of these uses a student may show either an action, process, or object conception of slope. By simultaneously considering how slope is viewed (i.e., as an action, process, or object) and for what purpose slope is used (i.e., to describe behavior, measure steepness, or determine relationships), the framework displayed in Figure 2 provides researchers a way to classify student understanding of slope and educators a guide to use when designing slope tasks. We will now consider how a "generic student" might consider slope as an action, process, or object.

Slope used to...

Describe Behavior	Measure Steepness	Determine Relationships
Example: Slope is used to describe that (and how quickly) the graph of a line or a table of output values increases or decreases.	*Example:* Slope is used as a means to measure the degree of tilt of a line in a real-world context to consider the pitch of a roof.	*Example:* Slope is a means to determine if two given lines are either parallel or perpendicular.

Figure 1. Diagram representing ways students commonly use slope**.**
Figure 2. Diagram for how slope is viewed and used in light of APOS theory.

How slope is viewed

In light of APOS theory, we now look at how students view slope as: (a) a **number** (i.e., a single, calculated quantity); (b) a **ratio** that represents the covariation of two quantities; and (c) an **invariant,** that depends neither on a particular pair of points used for its computation within a given line nor on a particular line within the collection of all lines parallel to the given line. We claim that students who are limited to thinking of slope as a single quantity, a number, have an action conception of slope. We also claim that students who are able to think of slope in terms of covariation of two quantities must have at least a process conception of slope. As is detailed later in this paper, we argue that thinking of slope as an invariant implies that the student has an object conception of slope. In this section, we make reference (in italics) to 11 conceptualizations of slope described in Moore-Russo, Conner & Rugg (2011) and Stanton & Moore-Russo (2012): *physical property*, *algebraic ratio*, *geometric ratio*, *parametric coefficient*, *functional property, trigonometric conception*, *calculus conception*, *real world situation*, *determining property*, *behavior indicator*, and *linear constant*.

Slope is treated as a **number** when it is seen as a value that is calculated or determined either from a formula or by counting. A student who is limited to thinking of slope as a number has an action conception of slope and may falter when solving unfamiliar slope tasks (Nagle, Moore-Russo, Viglietti & Martin, 2013). For example, when given the graph of a line for problems related to measuring steepness, students often count vertically and then horizontally and then divide the two numbers to determine the line's slope without thinking about how the numerator changes with changes in the denominator (*geometric ratio*). It is often the case that students who are limited to this "count up, then count over" sequence struggle when they encounter decreasing lines, and some resort to moving from right to left to keep the "count up, then count over" steps intact. This action conception may also lead to the incorrect slope for a line graphed on a non-homogenous coordinate system where the vertical and horizontal units represent different quantities (Zaslavsky, Sela, &

Leron, 2002) or the incorrect assumption that lines on two non-homogenous coordinate systems are parallel because they appear to have the same slope or tilt (*determining property*). When dealing with the slope-intercept equation of a line, students often recognize that "the number in front of the x" is the line's slope (*parametric coefficient*); however, it also happens that students apply this procedure to all equations and erroneously report that the coefficient of the x is the slope even when a linear equation is written in standard form. Finally, it is also common for students to plug coordinate values either from two given points, or from a table, in the $m = \frac{y_2 - y_1}{x_2 - x_1}$ formula (*algebraic ratio*); although they often "forget if the y's or the x's are on top" since they are plugging into the formula without thought as to what the resulting value represents. In fact, for each of these examples, students may not have any notion of what the number produced for the slope actually means. The number is only the result of applying a formula or following a procedure blindly; hence, it is the result of an action.

When a student is able to move past blindly following procedures and comprehend slope as a **ratio** describing the covariation of two quantities, then that student has at least a process conception of slope. Students with a process conception of slope can move past blindly following procedures so that their engagement is purposeful. They are able to recognize patterns, do calculations with understanding, and think of slope as a ratio that represents the change in the dependent variable in light of the change in the independent variable. Individuals who are able to think of slope as the covariation of two quantities can relate the *geometric ratio* and *algebraic ratio* conceptualizations of slope, as outlined in Nagle and Moore-Russo (2013), by moving flexibly between the symbolic, numeric, and graphical representations as needed to think of slope as a ratio that is independent of representation. Moreover, they can coordinate processes of algebraic manipulation to relate the algebraic ratio, $m = \frac{y - y_1}{x - x_1}$, to $y = m(x - x_1) + y_1$ and then to $y = mx + b$ where $b = y_1 - mx_1$ thus connecting the *algebraic ratio* and *parametric coefficient* conceptualizations of slope. Also, they should be able to convert situations given verbally (e.g., word problems involving slopes of ramps) to other representations in ways that connect a *physical property* conceptualization with either the *geometric ratio* or *algebraic ratio* conceptualizations.

Thinking of slope as an *invariant* means students recognize that the slope of a line is the same regardless of which two points are used to compute it and regardless of which of a set of parallel lines is used to calculate it. It is important to stress that in our definition of *invariant* we require an understanding that goes beyond an action conception, so that these properties are not simply memorized facts but rather are obtained from doing actions on processes of geometric and algebraic ratios, and on a process of similar triangles. Recall that in APOS, doing actions on processes is needed to encapsulate a process into an object. The understanding of slope as a <u>constant</u> rate of change relates to the *linear constant* conceptualization of slope. This understanding of slope being related to the tangent of the angle and that all slope triangles are similar (and hence their corresponding angles are all congruent) ties into the *trigonometric* conception of slope.

Of course, students with a process or object conception may choose to apply an action; for example, they may choose to use the formula $m = \frac{y_2 - y_1}{x_2 - x_1}$ if it happens to be a convenient or efficient means of determining slope. However, those students would not be limited to thinking of slope as a single quantity. For example, a student with a process conception of slope may identify the coefficient 2 in the linear equation $y = 2x + 1$ as the slope of the line, but may also recognize that the slope being equal to 2 means that for each unit of change in the horizontal (or input) value there is a change of 2 units in the vertical (or output) value (*functional property*). Similarly, a student who thinks of slope as an invariant and has an object conception of slope, will also be able to think of slope as a covariation of two quantities or as a single quantity as required by the problem situation, and will be able to apply the notion in different contexts (*real world situation*).

This framework brings together past research on slope with the ideas of APOS theory to provide new insight into students' reasoning about slope. This framework can be used by educators to design varied tasks and by researchers to classify students' conceptions of slope. It advances past research on slope by moving past classifying ways students interpret slope to describing a framework that can account for students' interpretations.

STUDENT REASONING WITH FUNCTIONS: NEGOTIATING VISUAL AND ANALYTIC PRESENTATIONS

Arnulfo Pérez	Bailey Braaten	Anthony Myers
The Ohio State University	The Ohio State University	The Ohio State University
perez.378@osu.edu	braaten.7@osu.edu	myers.1105@osu.edu

This study provides an analysis of twelfth-grade students' reasoning about functions. It focuses on differences in performance and thinking about mathematical tasks depending on how functions are presented (visually or algebraically) and whether a task requires transformations from one mode of presentation to another. Using NAEP mathematics items that focus on functions as well as additional instruments to elicit student reasoning, the study examines the function performance of twelfth-grade students in Algebra 2, Pre-Calculus, and Calculus courses at a midwestern high school. Results are contextualized in relation to national data on function performance drawn from the Grade-12 mathematics NAEP. Findings offer insights into students' function concept and highlight opportunities to better support their efforts to navigate a range of function representations.

Keywords: Algebra and Algebraic Thinking, Curriculum, Assessment and Evaluation

Introduction

Although functions have long been presented most explicitly in algebra courses, the high school *Common Core State Standards for Mathematics* (CCSSM) (National Governors Association Center for Best Practices, Council of Chief State School Officers [NGA & CCSSO], 2010) present functions as their own conceptual category. (The other CCSSM categories are number and quantity, algebra, modeling, geometry, and statistics and probability.) This shift reflects the fact that functions are a dynamic concept that intersects with numerous other mathematical ideas, cutting across content traditionally divided into separate courses. For example, functions play an important role in statistics (e.g., linear regression) and geometry (e.g., area of a square as a function of the length of its side), and they are also prominent in real-world applications (e.g., the modeling of growth, decay, and motion).

Another important dimension of functions is that they can be represented in a number of ways (e.g., graphical, algebraic, tabular). The most significant and frequently discussed challenge presented by functions is this diversity of representations and the difficulty of moving between one form of representation to another (Eisenberg, 1991). Because functions have historically been stressed primarily in the context of algebra, students may have a limited concept image of functions. That is, the set of mental representations that they associate with functions does not reflect the range of representations of functions that they may encounter through their mathematical learning trajectory (Vinner & Dreyfus, 1989). This study examines students' performance on function items and their thinking about functions and their representations. These findings will help direct efforts in teacher professional development and pre-service teacher programs to maximize students' understanding of this crucial concept.

Background

For the Grade 12 math assessment, the National Assessment of Educational Progress (NAEP) reports overall results to represent nationwide math achievement. NAEP also offers results broken down by content strand (number and operation; geometry and measurement; algebra; and data analysis, probability, and statistics). NAEP does not, however, break these strands down into further subcategories or provide information about skills or concepts that extend over several content strands. This study builds on the researchers' past work to identify those NAEP items related to functions (across several content strands) and to analyze this nationally representative data (Pérez,

2014). The findings from that study provide context in the present study regarding what U.S. students know about functions in general as well as how they perform differently on items that elicit a visual or an analytic approach to handling functions.

Study Design

The study examines the function concept of a sample of twelfth-grade students from Algebra II, Pre-Calculus and Calculus courses at a midwestern high school. These students will respond to 6 function-related problems drawn from the 2005 and 2009 Grade 12 NAEP math assessments, a problem set that includes multiple-choice and short-answer questions. 6 function items will be selected from a body of items blind coded by math education professionals into three categories: (1) those items that engage analytic processing of information (e.g., the problem includes formulas and/or verbal description), (2) those items that engage visual processing (graphs and/or tables) of information, and (3) those items that require both visual and analytic processing to arrive at a solution. Table 1-3 below are examples in which the question presents a function analytic, visually, and both.

Table 1: Items 1 (Analytic)

Yvonne has studied the cost of tickets over time for her favorite sports team. She has created a model to predict the cost of a ticket in the future. Let C represent the cost of a ticket in dollars and y represent the number of years in the future. Her model is as follows: $C = 2.50\,y + 13$. Based on this model, how much will the cost of a ticket <u>increase</u> in two years?

    (A) $5 (B) $8 (C) $13 (D) $18 (E) $26

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

After completing the assessment, students will answer follow-up questions designed to elicit information about their reasoning, and selected students will be interviewed about their problem-solving process. Analysis of items and of interview responses will focus on identifying particular areas of challenge for students, whether in the presentation (visual versus analytic) or in the function concept that the item draws upon. The analysis will also examine the degree to which students' content knowledge parallels or differs from that of the nation's secondary students (as reported by NAEP).

Expected Findings

While the study is still in progress, for the presentation we will report concrete data on student performance and illustrate their thinking using brief excerpts from the assessment and related interviews. Preliminary findings from NAEP suggest that secondary students do relatively well on items that present functions algebraically and also offer algebraic solution choices. Similarly, they perform well on items that graphically present functions and offer graphical solution choices. By contrast, performance decreases significantly on those items that require students to engage both visual and analytic representations of a function to arrive at a correct solution. These outcomes are in line with previous research that has demonstrated a persistent gulf between students' visual concept images of functions and their analytic characterizations of functions (Eisenberg, 1991). Based on the NAEP results on function items, a similar pattern of performance is expected in the results from the local student sample. Nevertheless, the study also seeks to identify possible relationships between current course-taking (Algebra 2, Pre-Cal, or Calculus) and student thinking about functions.

The interviews in the study provide opportunities to better understand students' approach to the problems. Particular attention will be paid to the degree to which students express awareness of the interrelations between visual and analytic presentations of functions. This information will lead to insight on the areas in which students need additional support to develop the depth of understanding that will then allow them to successfully engage with mathematics as an integrated discipline.

Presentation Overview

Presenters will provide tables that describe: (a) nationwide NAEP student performance on analytic and visual function items as well as those that engage both representations and (b) local twelfth-grade students' performance on the same items (analyzed by course level). A brief discussion of the patterns in performance follows, and vignettes from interviews will illustrate observations about student reasoning with regard to functions. Implications of the pilot study for future research in student reasoning will be briefly discussed.

ADDITIVE INVERSES: SECOND GRADERS' USE OF "ZERO PAIRS"

Questioning boundaries between mathematics topics can illuminate ways to support students' developing mathematical knowledge. For example, algebra and negative integers intersect around the concept of additive inverses: $a + -a = 0$, which we call zero pairs. Two popular conceptual models can illustrate additive inverses (Wessman-Enzinger & Mooney, 2014). Movements along a number line draw on a translation conceptual model, where zero can be a relative position. The chip model, where positive chips (1) cancel out negative chips (-1), typifies a counterbalance conceptual model because although the quantities cancel out, they still remain; zero in this model results from having an equivalent number of positives and negatives. We explore the following questions:

1. How do second graders perform on zero pair problems before and after instruction?
2. What characteristics of zero pair problems do they notice?

This study involved 109 second graders and employed a pre-test, random assignment to condition, group sessions with test questions, instruction, post-test design. As part of their two group sessions, students analyzed problem contrasts involving a zero pair problem, illustrated using pictures of positive and negative chips with zero pairs circled. Following the group work, students learned about using a translation conceptual model to move up (+ positive) or down (+ negative) on a number path. The last few "zero pair" problems (e.g., $-2 + 2$), resulted in zero. Then, students played a card game involving a cancellation conceptual model where they had to make zero pairs to discard.

During small group sessions, students noticed that for $5 + -5 = 0$ and $5 + -4 = 1$, the chips not circled (or cancelled) were the answer. When looking at the work for $-5 + -5 = -10$ and $-5 + 5 = 0$, one student clarified, "This time they started on a -5, so on the number line you start on negative five, so $-5 + 5$, you get to zero." After the first part of the lesson, students came up with many zero pairs, such as "$4 + -4$" and "$-45 + 45 = 0$." When playing the card game, many students paired single -1 cards with +1 cards, and others paired multiple cards (e.g., paired -2 and 2).

When solving zero pair problems (e.g., $-5 + 5$, $9 + -9$), students averaged 15% correct on the pretest, 33% at the end of sessions, and 59% on the post-test after instruction. They also used this knowledge to solve the transfer problems on the posttest ($4 + -4 + 3$, $-5 + -1 + 6$, and $-2 + 5 + 2$). On average, students got 40% of these correct. Overall, students made reference to a translation and cancellation conceptual model, suggesting that the use of both conceptual models could be helpful in reaching more children. Analyzing contrasting cases proved to be a useful experience.

LEVERAGING CONTRASTING CASES: INTEGER ADDITION WITH SECOND GRADERS

Laura Bofferding
Purdue University

Having students analyze contrasting cases can help them pay attention to similarities and differences in problems (e.g., Rittle-Johnson & Star, 2011). One area where this would be beneficial is with negative numbers, as students often treat them as positive (Bofferding, 2014). Therefore, we investigate to what extent second graders can improve their integer knowledge from analyzing varied contrasting cases and participating in short instruction.

The analysis focuses on 107 second graders. After a pretest, students were randomly assigned to one of three groups: one compared problems of the *same type* (e.g., 2+3 vs. 3+3 then -2+-3 vs. -3+-3); the other two either started with an *intuitive* contrast (e.g., 2+3 vs. -2+-3) or a *conflicting* contrast (e.g., 2+3 vs. 2+-3). After two comparing sessions and one lesson, the students took a posttest. The tests targeted students' understanding of integer order and values, integer addition (e.g., -5+5), and transfer problems with three addends or a missing addend.

During their 2 small-group sessions (20-40 minutes each), students discussed and wrote about how the contrasting problems were similar and different, why some answers were incorrect, and how to use the pictures to solve the problems. After each session they solved midtest items (problems similar to those they analyzed). Students also participated in a whole class 30-minute session where they learned that adding a positive corresponds to moving up on a number path and adding a negative corresponds to moving down and played a card game about making additive inverses.

A repeated measures ANOVA on the common items across testing times (-9+2, 9+-9, -1+-7) was not significant for the interaction between test and group. However, there was a significant effect for test, $F(2, 199) = 69.412$, $p = .001$; students did significantly better on the midtest questions compared to the pretest and on the posttest compared to the midtest questions. The repeated measures analysis for the items on pretest and posttest was also only significant for test, $F(1, 104) = 112.69$, $p = .000$, $\eta^2 = .520$. On the pretest, students got an average of 14% correct (range: 4%-24%); on the posttest, they averaged 32% correct (range: 14%-50%). As a whole, the second graders benefitted from analyzing contrasts, regardless of type. They then gained even more after explicit instruction and playing a game. The ease with which these diverse students made gains suggests we rethink the boundary of when integers and integer addition are introduced.

COMPARING STUDENTS' COMPETENCE AND CONFIDENCE FOR THE CONCEPT OF SLOPE

Yanqing Ding
University of Central Missouri
Yqd668@hotmail.com

Deborah Moore-Russo
University at Buffalo
dam29@buffalo.edu

Keywords: Algebra and Algebra Thinking, Assessment and Evaluation, Gender, Measurement

Confidence assessment evaluates students' confidence about their answers to items. It can be used to explore the strength of mathematical misconceptions. Hasan, Bagayoko and Kelley (1999) claimed that low confidence in a correct answer indicates guessing, which implies a lack of understanding. High confidence on a wrong answer indicates a misunderstanding. There have existed large arguments about gender difference in mathematics confidence (e.g. Hyde, 2005).

The slope of a line is a fundamental underpinning concept for students to understand mathematics (Carlson, Oehrtman, & Engelke, 2010). In precalculus, slope plays a key role in understanding the most basic rate of change of a function. In the calculus sequence, slope is used for the definition of a derivative and can be used to explain directional derivatives (McGee & Moore-Russo, 2015). Due to its diverse representations and conceptualizations in many different contexts, students' difficulties in slope have been observed in the literature throughout school math learning. Their difficulties in slope set up a barrier to their college-level math learning. To measure college students' slope competence and confidence, Ding (forthcoming) developed a 3-tier 27-item instrument on the slope of linear function (person reliability: 0.84 & 0.95; item reliability: 0.86 & 0.96 respectively). Along this line of research, this study is guided by two research questions: (1) How confident are college students about their slope understanding? (2) Is there any difference between females and males in confidence in slope understanding?

By the Rasch rating scale model, this study analyzed the self-reported responses of college students (n=93) in a 4-year pubic college on a 5-point scale (from *not confident* to *very confident)* 27-item slope confidence assessment instrument (Ding, forthcoming). The study found 33% of the sampled students were *very confident* in their slope understanding, while 25% of them were *not confident*. The items associated with low confidence indicated that students lacked competence in connecting multiple concepts. Students' slope competence and confidence were moderately related ($r = 0.55$). There was no significant difference between female and male students although females were slightly less confident than males ($p = 0.09$). The findings have implications for college mathematics and developmental mathematics teaching and learning.

PRELIMINARY FINDINGS OF FIRST GRADE STUDENTS' DEVELOPMENT OF REVERSIBILITY

Beth L. MacDonald	Melissa J. Ashby	Kristy Litster
Utah State University	Utah State University	Utah State University
beth.macdonald@usu.edu	cagirlmja@gmail.com	chemile@hotmail.com

We define *reversibility* as an individual's ability to rely on both inversion and compensation when solving problems. *Inversion* of an operation undoes the previous to return to the original. In contrast, *compensation* of an operation is a return to an equivalent state (Hackenberg, 2010). Hackenberg argues that an individual simply reversing one's scheme (inversion) without being aware of the need to coordinate operational structures (inversion and compensation) may not be engaging in reversibility. In this study, we focus on an analysis of preliminary qualitative data that suggest first grade students' engagement with piloted tasks may promote reversibility.

Methodology

Four, first grade children (Francis & Callie, Allen & Becka) from the northwestern United States were chosen as participants due to their below average Test of Early Mathematics Ability 3 (TEMA-3) score (Ginsberg & Baroody, 1983). Two teaching experiments (Steffe & Ulrich, 2014) were used to investigate students' cognitive reorganization when engaging with reversibility tasks. The 12 teaching experiment sessions included inversion and compensation tasks with counters to assess students' ability to count and group visual material.

Results/Conclusion

Callie struggled with the inversion and compensation tasks when concrete material was absent, but Francis could re-imagine patterned orientations and elicit her understanding of "doubles" providing her success when finding missing addends and compensating problems between tasks (e.g., $4 + 2 = 3 + 1 + 1$). Francis' reliance on patterned orientations also limited her ability to engage flexibly with groups. Francis cognitively reorganized her grouping thinking structures when tasks elicited "doubles" or "near doubles" (e.g., $4 + 4 = 5 + 3$). Allen and Becka solved the compensation tasks (e.g., $4 + 1 = 3 + ?$) in very different ways. Allen matched the counters on each side and then moved them to align with the original problem. Becka imagined the same subgroups on each mat with the same number and then described extra counters.

Preliminary analysis of these data suggest that students' abstract and flexible development of their grouping thinking structures provides effective engagement with inversion and compensation tasks. Implications of these findings provide educators with more insight as to intervene when promoting more sophisticated reasoning associated with reversibility.

A crucial conceptual leap for students is to transition from grounded arithmetic problems to a more abstract world of algebra problems with variables (Heffernan & Koedinger, 1998). Students with prior misconceptions of mathematics solve fewer equations correctly and have difficulty learning new procedures and problems (Booth & Koedinger, 2008). It is therefore important to identify the type and source of common errors at a large scale. In the current study, 48 middle school students transformed and solved 15 linear equations with one variable using a new dynamic technology, Graspable Math (GM) (Ottmar & Landy, 2015) and then were asked to manually write their answers into the system. We found that, while many students were able to successfully use procedures to manipulate the symbols to arrive at the correct answer using GM, many students would then type in incorrect answers. In this study, we used error analysis to identify the most common error patterns and mal-rules that occurred after successful symbol manipulation. 4 categories of student errors emerged (Table 1). These errors can be used to inform future instructional interventions that target algebra readiness and student difficulties.

Table 1: Four Categories of Errors

Equation vs. Expression - When simplifying expressions with two unlike terms, students turned it into an equation, set the expression equal to zero, and then solved for x (ex. $2x-6 \rightarrow 0=2x-6 \rightarrow 6=2x \rightarrow x=3$)	**Everything to the Right -** Students moved everything to the right of the equals sign until a 0 was on the left and then simplified the right. Their answer was everything to the right of the equals sign (ex. $6=4x \rightarrow 0=4x-6$).
Combining Un-like Terms -Students simplified an equation resulting in two unlike terms (ex. $x=2t+10$). They then added together the 2 and 10, and entered $x=12t$.	**Hidden Negatives** - If there was a negative sign next to a term or number on the left, students would often ignore negative signs (ex. $-x=6 \rightarrow x=6$)

PRECONCEPTIONS OF NEGATIVE NUMBER PRODUCTS AND QUOTIENTS

Julie Nurnberger-Haag
Kent State University
jnurnber@kent.edu

Despite the regularity of rules for integer products and quotients, on a standardized test only about half of eighth-grade students accurately answered such problems (Ryan & Williams, 2007, p. 218). Ignoring negative signs or treating them as subtraction signs are typical student errors in integer arithmetic (Ryan & Williams, 2007; Vlassis, 2008). Although integer multiplication and division are difficult, with the exception of Sfard (2007), student thinking about this has been largely ignored as a research focus. Thus, to help future students improve learning outcomes, it behooves us to understand how students make sense of products with negative numbers prior to instruction (i.e., preconceptions). The term *Intelligent Overgeneralization* (*IG*, Ryan & Williams, 2007, p. 23) is used here to acknowledge inaccuracy of overgeneralization, yet recognize the intelligence of student sense-making from prior experience with non-negative numbers. This report seeks to contribute to student-centered views of transfer (Lobato, 2006) with the question: In what ways might conceptions students express when making sense of integer multiplication and division prior to instruction be IGs from prior instruction with non-negative numbers?

Fifth grade students from two schools (n=107) participated. Students were primarily European-American, 45% of whom were eligible for free or reduced lunch. Data come from two measures: (a) a written task in which students were asked to explain and draw what the problem "means" (e.g., ˉ2 × ˉ8) and (b) interview tasks with a subset of students. Analysis consisted of three phases with all coders confirming presence of each preconception. I report three of these preconceptions here. *Negative Sign is Like a Unit* revealed the idea that the negative sign is like other unit symbols that can be ignored while calculating, such as a dollar sign. *Synthesized Meanings of Opposites* refers to students who treated negative numbers both as opposite of positive and the inverse of multiplying. Students who *Coordinated Multiple Operations* saw a negative sign as a subtraction sign and used the order of operations to first multiply then subtract.

These results detail ways students may generalize from non-negative number instruction. Framing these preconceptions as IGs honors students' interpretations of structures in mathematics that common instructional practices may foster. The poster describes how each preconception relates to prior non-negative number instruction from which students could have intelligently overgeneralized and how such an IG might impact future learning.

TEACHERS' COVARIATIONAL REASONING IN CONTEXT: RESPONSES TO A GRAPHING TASK

Cody L. Patterson
University of Texas at San Antonio
cody.patterson@utsa.edu

Rebecca McGraw
University of Arizona
rmcgraw@math.arizona.edu

Keywords: Algebra and Algebraic Thinking, Mathematical Knowledge for Teaching

In order to build and interpret graphs of functions, students must learn to coordinate changes in an independent variable with corresponding changes in a dependent variable. Covariational reasoning describes a hierarchy of mental actions involved in coordinating changes in two related variables (Carlson et al., 2002). Carlson et al. studied calculus students' responses to a graphing task in which the independent variable can be viewed as a proxy for a time variable. However, relatively little is currently known about how learners think covariationally about relationships in which neither variable changes linearly with time.

In Summer 2015, the authors taught a professional development course to middle and high school mathematics teachers in the Southwestern United States. Teachers spent class time working on activities meant to highlight key ideas in middle grades and secondary mathematics. During this course, teachers were asked to work individually on the following task:

> Arun gets on a Ferris wheel from a platform several meters above the ground. The Ferris wheel rotates and Arun makes several laps around it. A power line runs just above the Ferris wheel. Sketch a graph of the relationship between Arun's distance from the ground and his distance from the power line while he is on the Ferris wheel. Label and explain any key points or features in your graph.

Our data consisted of teachers' written work on this task. Approximately half of the teachers created graphs showing a non-linear relationship between the variables; most of these teachers drew either graphs of sinusoidal functions or graphs of functions that increased toward a maximum and then decreased, or vice versa. Approximately one fourth of the teachers drew graphs of decreasing linear functions, with most of these teachers appearing not to attend closely to the placement of endpoints. Of the remaining respondents, several sketched graphs that we categorized as "ambiguously linear": the graphs did not show visible variations in the rate of change of one variable with respect to the other, but also did not show clear evidence that the respondents understood that the function is linear. These responses suggest that the context of the problem, in which both variables change non-linearly with time, created resistance to recognizing the relationship between the two variables as linear.

Further investigation is needed to illuminate the types of reasoning by which learners arrive at the correct graph of the relationship between the two distances, and how the non-linear variation in each distance with time interferes with recognizing this relationship as linear. We hope to improve the quality of data by capturing video of teachers working on this and related tasks and asking them to explain the shapes of the graphs they create.

INTEGRATION OF MATHEMATICS AND PROGRAMMING: EMPOWERING TEACHERS TO BRING COMPUTING INTO THE ALGEBRA CLASSROOM

Azin Sanjari	Arnulfo Pérez
The Ohio State University	The Ohio State University
Sanjaripirmahaleh.1@osu.edu	perez.378@osu.edu

Computational thinking should have a central role in today's mathematics classrooms because this thinking is central to many growing fields such as computer science and bio-informatics (Next Generation Science Standards Lead States (NGSS), 2013). The reciprocal relationship between computational learning and mathematics understanding is an additional motivator for introducing computational thinking into mathematics classrooms (Weintrop et al., 2016). The potential of computational thinking to enhance mathematical reasoning makes integrating this twenty-first-century skill into algebra contexts especially compelling.

As part of a larger NSF-funded project on the integration of computer programming in a mathematics classroom, this study seeks (1) to enhance teachers' pedagogical content knowledge of functions and their computational thinking and (2) to support them in incorporating computer science in their teaching of functions. Success in algebra has been strongly linked to college access and attainment, and a deep understanding of functions—which are central to algebra and prominent across the mathematics curricula—has proven elusive for many students (Dubinsky & Wilson, 2013).

Twenty participant teachers from a medium-sized city in the Midwest will engage in a 10-day training to explore a unit that deepens function knowledge through computer modeling and programming. Observations of teachers' engagement with the training tasks will enable the team to position their programming knowledge on a spectrum running from novice to proficient and expert. For example, we ask teachers how proficient they are with designing function related problems. We anticipate that most participating algebra teachers will be at the novice level; to enable them to introduce their students to the modeling and programming experiences, we seek to move them to the level of "proficient." In addition to technical skill, the training seeks to increase teachers' self-efficacy in computational thinking to increase the teachers' motivation to implement the new approaches in their classrooms (Graham & Weiner, 1996). Based on an assessment after the training and analysis of the teachers' engagement in the training experiences, we will evaluate the degree to which it has shifted teachers' proficiency with computational thinking and teachers' self-efficacy.

EL ESTUDIO DE LAS FUNCIONES LINEALES COMO UNA INTRODUCCIÓN DEL ÁLGEBRA EN EDUCACIÓN SECUNDARIA

THE STUDY OF LINEAR FUNCTIONS AS AN INTRODUCTION TO ALGEBRA AT GRADE 7

Palabras clave: Álgebra y Pensamiento Algebraico, Modelación, Educación Secundaria

Respecto a los procesos de transición hacia el pensamiento algebraico, la investigación ha demostrado que la ruta de introducción determina las concepciones que se desarrollan en el estudio del álgebra. Específicamente, la introducción del álgebra vía el estudio de las funciones requiere el desarrollo de la noción de variable y de sus diferentes representaciones, mediante tablas, gráficas cartesianas y las expresiones algebraicas correspondientes (Sutherland, 2004). Si bien los resultados reportados de la implementación de propuestas didácticas con enfoque funcional son prometedores, se ha encontrado que la integración de las diferentes representaciones de las funciones es un asunto que requiere mayor investigación (Kieran, 2006).

El estudio que presentamos se centró en las dificultades y los avances de estudiantes de primer grado de secundaria al seguir una secuencia de problemas y actividades que, a partir del estudio de las funciones lineales, introdujo la simbolización algebraica como una más de las formas de representación de la variación, junto con la gráfica cartesiana y las tablas de valores (Sadovksy, 2005).

La secuencia fue tomada y adaptada del trabajo presentado por Bravo-Barletta y Matos (2005). En esta secuencia, los alumnos deben interpretar la información que surge de una lectura directa de las gráficas, así como obtener datos que requieren un análisis más profundo (de intervalos de crecimiento, máximos, mínimos, etc.). Se incluye además un trabajo de construcción de gráficas para modelar situaciones en contextos específicos.

Nuestra investigación se centró en problemas de fenómenos lineales, lo cual nos permitió establecer continuidades y contrastes entre el trabajo con las relaciones de proporcionalidad (estudiadas desde el nivel de primaria, en aritmética) y el trabajo con las funciones lineales (que en México se estudian en secundaria, con las herramientas del álgebra). Las expresiones algebraicas se introdujeron como una forma de representación que permite sintetizar el comportamiento de las relaciones relevantes del problema y hacer anticipaciones sobre ellas.

Esta secuencia se implementó con un grupo de 36 alumnos, de un poblado semi-rural de las afueras de la Ciudad de México. La secuencia consta de 12 problemas que se distribuyeron en 20 sesiones (de 50 minutos cada una). Se usó el video para registrar el trabajo colectivo, las intervenciones del profesor y sus interacciones con los estudiantes. El profesor a cargo de estas clases fue uno de los investigadores del equipo.

En el análisis se buscó estudiar la manera en que los estudiantes se apropian de las herramientas algebraicas para el estudio de las funciones lineales a través de esta secuencia específica. Entre los resultados encontrados están la construcción de representaciones "híbridas" por parte de los estudiantes, así como diversas dificultades en la coordinación de las distintas formas de representación de la variación, en particular al relacionar el "factor constante de proporcionalidad", la "pendiente de la recta" y la "razón de cambio constante".

Keywords: Algebra and Algebraic Thinking, Modeling, Middle School Education

Regarding the transition processes toward algebraic thinking, research has shown that the choice of the introductory route determines the conceptions that are being developed during the study of algebra. Specifically, the introduction of algebra through the study of functions requires the development of the notion of variable and its different representations, using tables, Cartesian graphs, and the corresponding algebraic expressions (Sutherland, 2004). Although reported results on the implementation of didactic proposals with a functional approach are promising, it has been found that the integration of the different representations of functions is a matter of further research (Kieran, 2006).

The research we are presenting was centered on the secondary First Grade (equivalent to Grade 7 in US and Canada) students' difficulties and advances while engaging in a sequence of problems and activities that, based on the study of linear functions, introduced algebraic symbolization as another form of representation of variation, joint with Cartesian graphs and charts (Sadovksy, 2005).

The implemented sequence was adapted from the work presented by Bravo-Barletta and Matos (2005). In this sequence students are requested to both interpret the information from a direct reading of the graphs and infer data that require a deeper analysis (such as growing intervals, and maximums and minimums values). Additionally, the sequence includes graph construction to model specific contexts.

Our research focused on lineal phenomena problems, allowing us to establish continuities and contrasts between the work with proportional relationships (studied at the elementary level, in arithmetic) and the work with linear functions (that in Mexico are studied at secondary level with the algebraic tools). The algebraic expressions were introduced as a type of representation that allows both synthetizing the significant relationships of the problems and making predictions about them.

This sequence was implemented in a 36-student classroom, from a semi-rural town in the surroundings of Mexico City. The sequence comprises 12 problems, distributed in 20 sessions (50 minutes each). Video was used to record the collective work, teacher's interventions and her interactions with the students. The teacher was a member of the research team.

During data analysis we sought to study the way students appropriate the algebraic tools for the study of linear functions through this specific sequence of tasks. Among the results we have found, there are the "hybrid" representations constructed by students and diverse difficulties in coordinating the several representation of the functional variation; particularly in relating the "proportional constant factor," the "slope of the straight line" and the "constant rate of change."

ELEMENTARY STUDENTS' UNDERSTANDING OF EQUIVALENCE AND MULTIPLICATIVE REASONING

Rashmi Singh
Kent State University
rsingh9@kent.edu

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Key Words: Elementary School Education, Number Concepts and Operations

Children with a relational (1+2 *is the same as* 3), as opposed to an operational (1+2 *makes* 3), conception of equivalence are more able to engage in algebraic tasks in later grades (Knuth et. al, 2006 etc.). Children's multiplicative reasoning (MR) also facilitates the development of algebraic reasoning in later grades (Hackenberg, 2013). However, there is little to no research available which examines how children's MR relates to their conceptions of equivalence. Therefore, this study examines whether elementary students' multiplicative unit coordination affects their scores on a conception of equivalence assessment.

Data came from a larger study on mathematical argumentation collected in May 2015 and includes 168 second and third grade students. Participants completed an assessment on equivalence (adapted from Rittle-Johnson et al, 2011) and MR via students' unit coordination (Kosko & Singh, in review). We used the MR assessment scores to categorize students as demonstrating one level of unit coordination (Tier-0, or pre-multiplicative), two levels of unit coordination (Tier-1, which includes skip-counting), and initial three levels of unit coordination (Tier-2, where students demonstrate disembedding by 1s). We used one-way ANOVA to examine if children at each level had different equivalence scores. The initial ANOVA violated the assumption of homogeneity of variance and normality. Therefore, we used Welch's ANOVA to account for this violation (Lix et al., 1996). The Welch's ANOVA test on levels of MR and equivalence test scores found statistically significant results, *Welch's F* $(2, 60.88) = 27.45$, $p=.000$. Post-hoc analysis found statistically significant differences between Tier-0 and 2 ($p=.000$) and Tier-1 and 2 ($p =.005$), but not between Tier-0 and 1 ($p = .318$).

These findings indicate that students at Tier 2 are significantly more likely to have a relational conception of equivalence than students at Tiers 0 or 1. One likely explanation is that students at MR Tier 2 can disembed with units (e.g., understanding 5x8 = 5x3+5x5), and this might be applied via the comparative strategies of students with relational conceptions. For example, solving 12+17 = 18+11, a student may disembed tens and ones on both sides to identify each expression as the same as 20 + 9 (or 29). Yet, this must be explored and confirmed by further study.

Keywords: Algebra and Algebraic Thinking, Classroom Discourse

Although generalizing is "intrinsic to mathematical activity and thinking" (Kaput, 1999, p. 137), students struggle to generalize, often make weak generalizations, and rarely justify their generalizations. Supporting generalizing in the mathematics classroom requires a better understanding of the source of students' generalizing. What are the mechanisms that encourage students' generalizing? This question is central to our research, which seeks to understand the nature of the discourse that supports students' generalizing. This study explored the ways in which a fourth grade class generalized and justified their generalizations about even and odd numbers during a lesson.

We conducted a multi-level analysis of the classroom discourse, identifying shifts and instances of re-centering. Based on the inferred goal of the speaker, each utterance was coded for purpose and technique for fulfilling that purpose (Gonzalez & DeJarnette, 2012). Additionally, we recorded generalizations (Ellis, 2011), and situated these generalizations in the discourse in order to describe the discursive moves that contributed to and resulted from the generalizations.

Two important shifts in the discourse occurred during the lesson. First, the mode of representation shifted from an array to a number expression—a shift in representation that indicates a shift in discourse. Second, after establishing "cubes and left over cubes" as a shared way to describe even and odd number generalizations, students shifted from using "left over/leftover" as a modifier or adjective to using it as a noun, an indication of an evolving understanding of the shared idea. Although five generalizations occurred during the lesson, they all occurred during the second half of the lesson, subsequent to the shifts in discourse. Thus, the results suggest that the shifts in discourse may function as generalizing-promoting actions (Ellis, 2011). We also identified particular discursive techniques, and suggest that future research might focus on these aspects of discourse to further explore generalizing-promoting actions.

A TEACHER'S BOARD WORK AS A REFLECTION OF NOT ATTENDING TO STUDENT THINKING

Gabriel Tarr
Arizona State University
GTarr@ASU.edu

Derek Reading
Arizona State University
DJReadin@ASU.edu

The content on the board (symbols, alphanumeric characters, and pictures) can provide evidence of the discourse, culture, and beliefs of the classroom participants to an outside observer (Stigler & Hiebert, 1998). Since the board is evidence of the classroom discourse, culture, and beliefs, it is our belief that we can study the work displayed on the board to analyze (in part) the type of teaching taking place in the classroom. In this study, we will analyze a middle school mathematics teacher's scheme for partitioning fractions on the board. Furthermore, we will examine the following questions: *How does the teacher's board work reflect the level of attention that she pays to student thinking, and how might this potentially influence student thinking about fractions*?

Data Sources and Methods

The data we collected for this study was gathered through the efforts of a large-scale professional development and research project focused on Arizona middle school teachers. The project focused on promoting the mathematical and pedagogical development of its participants.

Our subject, Ellie, is a 6th grade mathematics teacher. At the time of this study Ellie taught at a middle school that aligns with Common Core State Standards (National Governors Association, 2010). Ellie volunteered to have one of her class periods observed and filmed one to three times per week during her first year. These are the specific data in this study. These data were analyzed using a grounded theory approach (Corbin & Strauss, 2008) approach.

Conclusion

Based on her board work, Ellie didn't express attention to how students may have thought about fractions. There did not seem to be an explicit effort on her part to relate what students might have be thinking to what she presented at the board.

Ellie's board work consistently displayed fractions as merely procedures to engage in and commands to compute. While it is possible that Ellie might have held some productive meaning for fractions, her board work did not convey these meanings. Thus, we believe that she conveyed unproductive meanings for fractions to her students.

Palabras clave: Álgebra y Pensamiento Algebraico, Cognición, Actividades y Prácticas De Enseñanza

La aproximación a la enseñanza del algebra lineal es frecuentemente formal, Dorier (2000) lo que hace que muchos de los conceptos de ella sean interpretados sólo desde sus definiciones, lo que obscurece las relaciones entre la expresión algebraica y la gráfica.

En este trabajo pretendemos proponer a los estudiantes de bachillerato y licenciatura actividades que les permitan observar las representaciones gráficas asociadas a las trasformaciones que dan origen las matrices en 2D de manera que articulen los registros de representación algebraico y gráfico, Duval (2006) usando como base de esta inspección ciertas matrices que tienen ceros en alguna de las diagonales.

En un primer momento trataríamos a las matrices de la siguiente manera:

Tabla 1: Tratamiento de las matrices de esta propuesta

Matriz como transformación lineal	Usando las propiedades de la linealidad	Matrices con diagonales cero como bases del espacio
$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} x \\ -y \end{bmatrix}$	$\alpha\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \alpha x \\ -\alpha y \end{bmatrix}$	$\alpha\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} + \beta\begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$
Reflexión sobre el eje x	Contracción o dilatación de la matriz cuando α<0, 0≤α ≤1, α>1	Estas matrices son linealmente independientes, para α=β=0

A continuación, mostraríamos la forma cómo estos arreglos de vectores posibilitan expresar a todo punto del plano como un vector, es decir son una base para el espacio 2D. Esta aproximación no cubre todas las necesidades de explicación de cualquier tipo de matriz en 2D sobre puntos del plano, sin embargo permite imaginar que sucede cuando las matrices son usadas para conformar una base de este, incluso mostrar que el espacio puede ser generado por distintas bases, esto es, como distintos arreglos de vectores linealmente independientes.

Keywords: Algebra and Algebraic thinking, Cognition, Instructional Activities and Practices

The common teaching approach to Linear Algebra is frequently formal, Dorier (2000), this causes that many concepts are interpreted based only on their definitions and murking the relationship between the graphical and the algebraic expressions.

In this work we want suggest high school and college students some activities that will allow them to link the graphical representations associated with the transformations that lead (give rise) to the 2D matrices, so that they can articulate the registers of graphical and algebraic representations, Duval (2006), using as a base for this inspection matrices with zeros in one of the diagonals.

As a first step we would treat the matrices in the following way:

Table 1: Treatment of matrices with this proposal

Matrix as linear transformation	Using the properties of linearity	Matrices with zero diagonals as space bases.
$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} x \\ -y \end{bmatrix}$	$\alpha \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \alpha x \\ -\alpha y \end{bmatrix}$	$\alpha \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} + \beta \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$
Reflection in the x-axis	Contraction or Dilation of the matrix when α<0, 0≤α≤1, α>1	These matrices are linearly independent, for α=β=0

Afterwards, we would show how these arrays of vectors make possible to express every point of the plane as a (single) vector, in other words, in fact these matrices are a base for the 2D space. This approximation does not include the explanation for every type of 2D matrix of the plane, however it allows us to imagine what happens when these matrices are used to make up a base of the plane even to show that the same space can be made up from different bases, that is to say, as different arrays of vectors linearly independent.

USING STUDENTS' FUNDS OF KNOWLEDGE TO TEACH ALGEBRA

Candace Walkington
Southern Methodist University
cwalkington@smu.edu

Algebra is a gatekeeper to higher-level mathematics, with significant implications for equity in education and students' economic attainment (Moses & Cobb, 2001). Concepts from algebra are often not seen as being connected to students' worlds, including their home and community activities (Chazan, 1999). However, all students bring to the classroom mathematical funds of knowledge (Civil, 2007), ways of reasoning quantitatively from their home and community lives. In previous work, I found that students draw upon rich algebraic ways of reasoning when pursuing their out-of-school interests in areas like sports and video games (Walkington, Sherman, & Howell, 2014).

In the present studies, students author their own personalized "algebra stories." Here, *personalization* refers to the instructional approach of making connections between students' interests in topics like shopping, music, and social networking, and instructional content they will be learning in school. My overarching research question is: What are the affordances and constraints of personalized problem-posing as a scaffold for students' deep understanding of algebraic principles? I draw upon data from three studies where students pose, solve, and share personalized algebra problems related to their interests: single session interviews with pairs of 7th and 8th grade students; an extended teaching experiment of Algebra I students; and a large-scale intervention in intact 8th grade classrooms. These studies all took place at a high-poverty urban school with a significant proportion of students who spoke English as a second language.

Through a thematic analysis of videos, transcripts, and student work in these three research contexts, several key affordances and constraints were identified. First, personalized problem-posing sometimes involved compromising the *mathematical goals* of the lesson or activity. Specifically, when students' experiences did not fit well into the domain of linear functions, or when students had the tendency to fall back on more familiar everyday use of arithmetic, it was difficult to keep the activity focused on meeting grade-level standards. Second, the personalized problem-posing sometimes involved compromising the students' *funds of knowledge* of their interest area. Specifically, students would sometimes have to warp or misrepresent how they actually used quantities and change while pursuing their interests, in order to better fit into canonical school algebra norms. Despite these limitations, as a whole I found considerable and surprising affordances of students using their interests as a vehicle for understanding linear functions. Students generated a wide range of interest-based, mathematically-valid, content related to linear functions, and with practice found useful ways to draw upon their funds of knowledge as a resource in the mathematics classroom. In all three contexts, there was evidence of students' growth in their understanding of foundational ideas in algebra.

VISUALIZACIÓN Y ANÁLISIS DE REPRESENTACIONES GEOMÉTRICAS

VISUALIZATION AND ANALYSIS OF GEOMETRIC REPRESENTATIONS

César Briseño-Miranda   José Guzmán-Hernández
Cinvestav IPN   Cinvestav IPN
cbriseno@cinvestav.mx   jguzman@cinvestav.mx

En este artículo reportamos los resultados obtenidos al implementar actividades, cuyo foco es la visualización de representaciones geométricas, en ambientes de papel-y-lápiz y tecnológico con estudiantes[1] de grado 11. Esta investigación es de tipo cualitativo, y está apoyada en la teoría de representaciones y en la visualización de objetos geométricos con ayuda tecnológica. Discutimos cómo el uso de la tecnología favorece el aprendizaje de conceptos matemáticos a través del análisis de figuras geométricas estáticas y dinámicas. Nuestros resultados muestran que la tecnología favoreció la visualización de representaciones geométricas, durante la resolución de actividades, sin embargo, el papel-y-lápiz es fundamental para que emerjan conjeturas sobre el significado de conceptos abstractos relacionados con tales representaciones.

Palabras clave: Geometría y Pensamiento Geométrico y Espacial, Medición, Tecnología, Educación Secundaria.

Antecedentes y problema de investigación

Desde hace algunos años, la visualización matemática ha sido investigada como recurso para lograr el aprendizaje de conceptos matemáticos (e.g., Arcavi, 2003; Duval, 2003, 2006; Phillips, Norris, & Macnab, 2010; Presmeg, 2006; Zimmermann & Cunningham, 1991; entre otros). Los estudios de estos autores –sobre la visualización– han tenido el propósito de explorar distintas formas de "mirar" objetos matemáticos abstractos en ambientes de papel-y-lápiz y tecnológico, los cuales apoyan y median el surgimiento y desarrollo de conceptos matemáticos. Debido a las numerosas representaciones geométricas surgidas en la resolución de tareas de esta disciplina, al usar papel-y-lápiz y tecnología, se vuelve necesario identificar características y propiedades de éstas. En este artículo pretendemos responder la pregunta: ¿cómo influye la visualización en el aprendizaje de conceptos matemáticos en los ambientes de papel-y-lápiz y tecnológico?

Marco Conceptual

Esta investigación tiene como marco conceptual el relacionado con las aportaciones teóricas sobre la visualización matemática (e.g., Duval, 2003, 2006; Arcavi, 2003; Phillips et al., 2010; Zimmermann & Cunningham, 1991; entre otros). De acuerdo con el Diccionario de la Real Academia Española, el verbo "visualizar" puede ser entendido como sinónimo de "visualización" y se refiere a "formar en la mente una imagen visual de un concepto abstracto" (RAE, 2014). Diversas investigaciones en educación matemática han contribuido puntualmente respecto a lo que debe ser entendido por "visualización". He aquí tres de ellas: (i) "la visualización es la capacidad del individuo de producir una representación que, en ausencia de toda percepción visual de los objetos representados, por medio de la cual permite observarlos como si estuvieran realmente delante de los ojos" (Duval, 2003, p. 48); (ii) "la visualización es la capacidad, el proceso y el producto de la creación, la interpretación, el uso y la reflexión sobre figuras, imágenes, diagramas, en nuestra mente o sobre el papel con el propósito de representar y comunicar información, pensar y desarrollar ideas y avanzar en su comprensión" (Arcavi, 2003, p. 215); (iii) "la visualización matemática es el proceso de formación de imágenes mentales, usando papel-y-lápiz, o bien tecnología, y la utilización eficaz de dichas imágenes para el descubrimiento matemático y la comprensión de los objetos en estudio" (Zimmermann & Cunningham, 1991, p. 3). En estas y otras contribuciones sobre el significado de la

visualización matemática es patente el carácter cognitivo de ésta. A continuación, se describen algunos conceptos involucrados durante la visualización de representaciones geométricas en los ambientes de papel-y-lápiz y tecnológico.

Visualización en ambiente de papel-y-lápiz

La representación de objetos matemáticos involucra su análisis; el cual permite a los estudiantes acercarse a su significado institucional. Si las representaciones son figuras geométricas, entonces se debe identificar características de ellas, empleando el sentido de la vista. Sin embargo, independientemente de las concepciones, de la naturaleza y de la existencia de los conceptos matemáticos –de quienes aprenden o enseñan–, diversos autores (e.g., Arcavi, 2003; Duval, 2003, 2006; Phillips et al., 2010, entre otros) afirman que esa manera de construir conocimiento, a través de la visualización, debe efectuarse mediante la visión, la imaginación y la inteligencia. La visualización desencadena procesos automáticos no conscientes del sujeto; que dependen de todo eso que ha podido ser guardado en su memoria, los cuales permiten discriminar e identificar en menos de una décima de segundo los diversos elementos del campo de visión y sus relaciones (Duval, 2003).

Por medio de la visualización de representaciones, el individuo puede acceder a las propiedades, características y dar sentido al objeto matemático analizado (Phillips et al., 2010). La visualización matemática –en ocasiones– se emplea para describir representaciones; en otras, se usa para determinar cómo funciona cierta representación específica en la comprensión o resolución de problemas matemáticos; o bien, para definir la actividad cognitiva del sujeto cuando hace uso de representaciones. Las ideas surgidas de la visualización en matemáticas permite –a los estudiantes– enriquecer contenidos, cuya utilización resulta provechosa, tanto en las tareas de representación como en el manejo de conceptos de esta disciplina. De acuerdo con Phillips et al. (2010, p. 26), en la visualización se distinguen: (a) *objetos físicos* percibidos mediante el sentido de la vista (e.g., ilustraciones, animaciones, pantallas generadas por la computadora, etc.); (b) *objetos mentales* almacenados y procesados en la mente en forma de esquemas mentales, imágenes mentales, construcciones y representaciones mentales; (c) *funciones cognitivas* manifestadas en la percepción visual, la manipulación y transformación de las representaciones visuales en la mente, concretando los modos abstractos de pensamiento e imaginando hechos.

Phillips et al. (2010) enfatizan que estas distinciones son importantes para entender el contexto de la visualización y poder establecer aplicaciones eficaces de ésta en el salón de clase. Para que los estudiantes comprendan y utilicen formas pertinentes de representaciones geométricas, deben entender el significado de las rectas, puntas de flecha, marcadores de ángulos, números y variables, entre otras. Debido a que las representaciones no son fáciles de ser empleadas en la resolución de tareas, es necesario que los alumnos tengan conocimiento considerable de los símbolos y convenciones de ellas de modo que esas representaciones adquieran sentido para ellos (Phillips et al., 2010). La visualización involucra actividad cognitiva, como la interpretación y la abstracción de aquello que el objeto matemático representa (Duval, 2003; Arcavi, 2003; Hitt, 1995; Zimmermann & Cunningham, 1991; entre otros). Sin embargo, la imposibilidad de un acceso directo a los objetos matemáticos, fuera de toda representación, provoca en los estudiantes confusiones casi inevitables (Duval, 2003).

Visualización en ambiente tecnológico

En la actualidad, existe una gran cantidad de programas informáticos (e.g., GeoGebra, Maple, Mathematica, Cabri-Geometry, Matlab, entre otros) utilizados en la enseñanza de las matemáticas. Este tipo de herramientas favorece la visualización de representaciones de conceptos matemáticos, y se vuelve trascendental en educación matemática; en particular, el uso de algún Software de Geometría Dinámica (SGD) facilita la incorporación de la visualización en la enseñanza de conceptos de la geometría, ya que se cuenta con imágenes dinámicas, las cuales a través de las herramientas propias de los SGD se pueden medir, agregar trazos auxiliares o simplemente explorar

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

alguna figura geométrica. Al hacer uso de representaciones dinámicas en la resolución de problemas geométricos, mediante la visualización, se facilita la manipulación, trazado o construcción de las figuras utilizadas y es posible modificarlas –si es necesario– en tiempo real (Hitt, 1995). Un atributo importante del SGD es su versatilidad de uso, el cual estimula el interés y la participación de los estudiantes cuando resuelven problemas geométricos. Diversos autores (e.g., Arcavi, 2003; Hitt, 1995; Phillips et al., 2010; Zimmermann & Cunningham, 1991, entre otros) mencionan que la visualización, empleando modelos dinámicos permite a los alumnos comprender conceptos o significados extraídos de las representaciones, y juega un rol importante en el desarrollo de su pensamiento analítico que, con frecuencia, no sucede en ambiente de papel-y-lápiz.

Metodología

El estudio es de tipo cualitativo. En él participaron 12 estudiantes mexicanos [grado 11], agrupados en parejas (seis Equipos). El trabajo estuvo dividido en dos fases: la primera se enfocó en la visualización de figuras geométricas usando papel-y-lápiz, con la finalidad de extraer las propiedades que, de acuerdo con el conocimiento previo de los alumnos, estaban implícitas en la figura; la segunda incluyó el análisis visual de la figura en ambiente dinámico (tecnológico). Mediante el uso del SGD (GeoGebra) los participantes debían validar las propiedades de las figuras visualizadas en papel-y-lápiz. Durante la resolución de las actividades en este ambiente, se buscó que los estudiantes conjeturaran el comportamiento general de las figuras cuando cambiaban algún parámetro de la misma, descubrieran invariantes, si los había, describieran y explicaran los objetos matemáticos visualizados.

La primera actividad fue retomada del artículo *A cognitive analysis of problems of comprehension in learning of mathematics* (Duval, 2006, p. 117). En esta actividad, el autor propone a los alumnos que a partir del esbozo de la gráfica (véase Figura 1) hallen la longitud del segmento $\overline{ED}$, tomando como datos fijos la longitud de los segmentos $\overline{AB} = \overline{DC} = 4$ cm y $\overline{BC} = 7$ cm. El autor reporta tres tipos de respuesta: 9% da 3 cm (repuesta matemática), 39.6% da 3.5 cm (medida directa del segmento) y 24.4% da otras respuestas, incluyendo la ausencia de ellas. Los resultados de los estudiantes tuvieron como referente el ambiente de papel-y-lápiz.
Figura 1. Cálculo de la longitud del segmento $\overline{ED}$, usando papel-y-lápiz.

La segunda actividad fue adaptada del libro *Plane and Solid Geometry* (Wentworth & Smith, 1913, p. 33). En nuestro estudio se propuso a los participantes un triángulo rectángulo ABC, que de acuerdo con sus características, permitiera a los alumnos identificar sus propiedades (implícitas y explícitas) con la finalidad de calcular su área. En la actividad, se pretende que los estudiantes identifiquen si existe alguna relación proporcional entre las áreas de los triángulos *ABC* y *XYZ*, este último formado a partir de los puntos medios del Δ*ABC* (véase Figura 2). Para determinar si existe (o no) cierta relación entre las áreas de los triángulos *ABC* y *XYZ*, se pidió a los alumnos que calcularan sus áreas; si existía alguna relación entre éstas, entonces los estudiantes debían explicar si tal relación podía (o no) mantenerse para cualquier triángulo independientemente de su tamaño o forma.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figura 2. Identificación de la relación de áreas de triángulos, usando papel-y-lápiz.

El acopio de datos fue mediante el registro escrito de las respuestas de los estudiantes al resolver las actividades, las cuales fueron video-grabadas, además de preguntas del investigador –a los participantes– durante la implementación de éstas. Las actividades propuestas a los participantes debían ser abordadas usando papel-y-lápiz y tecnología (GeoGebra). En las mismas actividades se les solicitó que validaran sus resultados obtenidos en ambos ambientes.

Análisis de datos y discusión de resultados
El análisis de los datos recabados se basó en la interpretación y en el número de incidencias comunes, por parte de los alumnos, de sus soluciones en ambos ambientes, tomando en cuenta las video-grabaciones –de las discusiones [estudiante-estudiante y estudiante-profesor] durante la experimentación– y los registros escritos, una vez solucionado el problema. A continuación, analizamos y discutimos los resultados de las actividades implementadas.

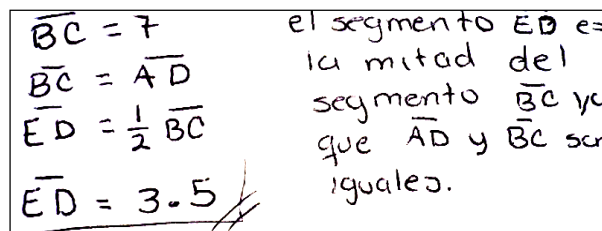
Primera actividad
En la primera actividad –en ambiente de papel-y-lápiz– se obtuvieron los siguientes resultados: cinco equipos percibieron que el valor del segmento $\overline{ED}$ es 3.5 cm y sólo un equipo consideró las propiedades de la circunferencia, al darse cuenta de que el valor real del segmento $\overline{ED}$ es de 3 cm. De acuerdo con los resultados obtenidos, podemos afirmar que la manera de visualizar –por parte de los estudiantes– esta figura geométrica tiende a adquirir la forma de mayor simpleza (Duval, 2003), es decir, ellos perciben que los segmentos $\overline{AE}$ y $\overline{ED}$ son iguales. Esta afirmación está basada en que –la mayoría de ellos– identificó que el punto E (intersección de la circunferencia con el segmento $\overline{AB}$) se localizaba en el punto medio del segmento $\overline{AB}$. Un ejemplo de esta forma de visualización es la efectuada por el Equipo 1 (véase Figura 3), en la cual se muestra que la dificultad para visualizar de forma correcta radica en la manera de articular la información implícita y explícita dada (Arcavi, 2003; Duval, 2003, 2006). A partir de los resultados obtenidos, podemos asegurar que la visualización de la figura, por parte de los alumnos –en ambiente de papel-y-lápiz–, generó dificultades de percepción que impidieron lograr la visualización correcta del objeto geométrico mostrado (Duval, 2003, 2006).


Figura 3. Influencia de la percepción visual en el cálculo de la longitud del segmento $\overline{ED}$, usando papel-y-lápiz.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

En la segunda parte de esta actividad (ambiente tecnológico), los participantes reprodujeron la Figura 1 empleando el SGD (GeoGebra) y, usando esta herramienta, calcularon la longitud del segmento $\overline{ED}$. Una vez resuelto el problema, usando el SGD, compararon el resultado obtenido con el software respecto del conseguido con papel-y-lápiz. Al hacer uso del software GeoGebra, el total de los equipos concluyó que la longitud del segmento $\overline{ED}$ es de 3 cm, debido a que E no está localizado en el punto medio del segmento $\overline{AD}$ (véase Figura 4).
Figura 4. Influencia de la percepción visual en el cálculo de la longitud del segmento $\overline{ED}$, usando ambiente tecnológico.

A continuación, analizamos y discutimos un extracto de lo expuesto por el Equipo 4[2] (Estudiantes 4A y 4B) al contrastar los resultados surgidos en papel-y-lápiz, respecto de lo obtenido con ambiente tecnológico:

[1] *Profesor*: De acuerdo con la Figura 1 [*ambiente de papel-y-lápiz*] ¿cuál es la longitud del segmento $\overline{ED}$?

[2] *Estudiante 4A*: Como el segmento $\overline{BC}$ y el segmento $\overline{AD}$ son iguales. Entonces, si éste [punto E] está al centro [*punto medio del segmento $\overline{AB}$*] vale la mitad [3.5 cm].

[3] *Profesor*: Usando el software [*ambiente tecnológico*] ¿el resultado cambió o es el mismo?

[4] *Estudiante 4A*: Nos dimos cuenta de que el radio de la circunferencia es 4 cm y el   radio en todas las partes de la circunferencia siempre es el mismo, entonces mide 4 cm, aunque [*visualmente en la figura en papel-y-lápiz*] sea la mitad de $\overline{AD}$.

[5] *Profesor*: Finalmente, ¿cuál sería el valor [*la longitud*] de $\overline{ED}$?

[6] *Estudiante 4A*: Tres, ya que la distancia de $\overline{AE}$ es 4 cm y el segmento $\overline{AD}$ es 7 cm.

[7] *Profesor*: ¿De qué forma les ayudó el software en la visualización de la figura?

[8] *Estudiante 4A*: A simple vista se ve como si fuera la mitad [*ambiente de papel-y-lápiz*] y al ponerlo en la computadora [*GeoGebra*] se ven bien definidas las unidades de la figura [*perciben las propiedades del objeto matemático*].

[9] *Profesor*: ¿Qué pueden decir de la figura impresa [*ambiente de papel-y-lápiz*]?

[10] *Estudiante 4A*: Se tiene una figura que no es proporcional [*según sus características*].

Segunda actividad

En la segunda actividad (en ambiente de papel-y-lápiz), se pidió a los participantes que identificaran si existía alguna relación proporcional entre las áreas de los triángulos *ABC* y *XYZ*. Sólo el Equipo 6 tuvo dificultades en el cálculo de las áreas de los triángulos; ellos calcularon de manera errónea la altura del Δ*XYZ* (considerando la medida del segmento $\overline{YZ}$ como 2 cm), y concluyeron que las áreas de los triángulos *ABC* y *XYZ* eran distintas y no tenían relación alguna.

Cuando se preguntó a los demás estudiantes si la relación encontrada (de haberla obtenido) podía o no mantenerse para cualquier triángulo [rectángulo o no], dijeron lo siguiente: (a) Equipo 4: la relación no se mantiene "porque los ángulos no siempre son los mismos"; (b) Equipos 2, 3 y 5: la

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

relación puede mantenerse "podría mantenerse [*esta relación*] siempre y cuando se cumpla la regla del punto medio en cada segmento o lado del triángulo" [*se refieren al ΔABC*] (Equipo 5); (c) Equipo 1: "se mantiene la relación porque los puntos que dividen a los lados del ΔABC son puntos medios"; (d) Equipo 6: "no existe relación alguna entre [las áreas de] los triángulos"; no argumentaron porqué.

En la segunda parte de esta actividad (ambiente tecnológico), los alumnos usaron el software GeoGebra para buscar las relaciones entre las áreas de los triángulos. Todos los equipos concluyeron que las áreas de los ΔXYZ, ΔAXY, ΔYZC y ΔXBZ eran iguales y que el área del ΔXYZ es la cuarta parte del área del ΔABC. En seguida, se les pidió a los participantes desplazar los puntos *A*, *B* y *C* (vértices del ΔABC), usando las herramientas del software con la finalidad de obtener nuevos triángulos, cuya longitud de sus lados fuera diferente entre sí e identificaran el porqué esta relación puede o no mantenerse para cualquier triángulo. He aquí un extracto de lo expuesto por el Equipo 5 (Estudiantes 5A y 5B):

[11] *Profesor:* Al desplazar los puntos *A*, *B* y *C*, ¿la relación [*se refiere a que el área del ΔXYZ es la cuarta parte de la del ΔABC*] se mantiene para cualquier triángulo?

[12] *Estudiante 5A*: Siempre que se respete el punto medio de cada uno de sus lados va a tener [*ΔABC*] cuatro triángulos inscritos con la misma forma del triángulo mayor y cada uno de ellos va a ser siempre la cuarta parte del área total (Figura 5).

[13] *Profesor*: ¿En qué momento se podría perder esta relación?

[14] *Estudiante 5A*: Cuando los puntos ya no sean los puntos medios [*se refiere a los puntos X, Y, Z*], ya que nos dimos cuenta [de] que al mover los puntos [*se refiere a los vértices A, B y C*] las áreas [*de los triángulos interiores*] seguían siendo iguales y que la suma nos daba la mayor [*área del ΔABC*] debido a que los puntos medios hacían esta proporción, pero sólo lo pudimos ver cuando hicimos diferentes casos con el programa.

Al hacer uso del software, todos los equipos lograron generalizar la relación de las áreas de los triángulos formados por puntos medios de cada lado para cualquier triángulo.
Figura 5. Generalización de la relación de áreas, usando tecnología.

Conclusiones

Respuesta a la pregunta planteada (c.f., p. 1 de este documento): ¿cómo influye la visualización en el aprendizaje de conceptos matemáticos cuando intervienen en ésta los ambientes de papel-y-lápiz y tecnológico? De acuerdo con las evidencias surgidas en la implementación de las actividades, podemos decir que la interpretación por parte de los estudiantes de la representación de los objetos geométricos, ya sea en el ambiente de papel-y-lápiz o en el tecnológico, depende de sus conocimientos previos y del contexto (trabajo en papel-y-lápiz o con tecnología; tipos de actividades; discusiones: estudiante-estudiante, estudiante-profesor), los cuales son fundamentales y les permiten interpretar y dar sentido a las representaciones, y por ende comprender al objeto matemático en cuestión.

A partir del reconocimiento de las propiedades vinculadas con las representaciones de figuras geométricas, los participantes lograron plantear conjeturas que, finalmente, les dieron pautas para definir conceptos ligados con la percepción visual del objeto matemático. La representación geométrica –en el ambiente de papel-y-lápiz– dio a los alumnos poca información sobre el objeto a visualizar, pues no lo pudieron manipular, ya que se trata de una figura estática. En cambio, al utilizar el software GeoGebra los participantes adquirieron recursos de apoyo, que les permitieron identificar propiedades de esos objetos (e.g., parte de la solución de la segunda actividad). Como resultado de la interacción con el software, los estudiantes descubrieron propiedades de las figuras geométricas y lograron formular conjeturas apoyados en sus observaciones mediante la manipulación de las representaciones figurales de los objetos geométricos. Estos recursos les permitieron establecer *puentes* entre la representación del objeto matemático y sus propiedades; así generaron conceptualizaciones del objeto geométrico en cuestión.

Podemos conjeturar, finalmente, que cuando se emplean representaciones geométricas, su visualización involucra siempre dos operaciones visuales que tienden a asimilarse dentro de un mismo acto por parte del sujeto: (i) distinguir varias formas dentro de una figura, y (ii) identificar estas formas o su configuración representada, usando información previa plenamente reconocida. En nuestro trabajo, resaltamos el hecho de que el uso de la tecnología en la resolución de las actividades propuestas permitió a los estudiantes distinguir propiedades geométricas de los triángulos, en términos de sus áreas, dentro de una figura (triángulo, segunda actividad). Nuestros resultados –en ambiente de papel-y-lápiz– concuerdan con lo expuesto por Duval (2003), quien afirma que las personas no especialistas en visualización, con frecuencia, no toman en cuenta características de la representación, o bien, interpretan erróneamente las representaciones y crean contenidos con significado personal, que no se parecen en lo absoluto a las representaciones matemáticas institucionales (e.g., parte de la solución de la primera actividad). Es cierto que el SGD favorece el aprendizaje de conceptos geométricos, pero no es sólo este ambiente que debemos tomar en cuenta como herramienta de enseñanza, sino que es crucial también el uso de papel-y-lápiz, pues ellos se complementan con la finalidad de lograr un éxito (parcial) en la visualización de objetos matemáticos, además de que favorece en la generación de conjeturas de conceptos abstractos surgidos de tales representaciones. Este trabajo permite apuntar el rumbo de nuevas investigaciones, en las cuales se pretende responder la pregunta de investigación ¿qué tipo de figuras u objetos, analizados a partir de su visualización, promueven la abstracción matemática? Esta y otras preguntas pretenden responderse en el futuro.

Notas finales

[1] Estudiantes, alumnos y participantes son tomados como sinónimos en este artículo.
[2] Esta es la traducción de la discusión original, la cual se efectuó en español.

In this paper we report the results obtained when implementing Activities related to the visualization of geometric representations in paper-and-pencil and technological environments with students[1] grade 11. This is a qualitative research supported by both the representation theory and the visualization of mathematical objects using technological aid. We discuss how the use of technology promotes learning mathematical concepts through the analysis of static and dynamic geometric figures. Our results show that the technological tool contributes to the visualization of geometric representations arisen from working with Activities; however, paper-and-pencil as a working tool becomes necessary to give rise to conjectures about the meaning of abstract concepts linked to these representations.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Background and research problem

For some years, mathematical visualization has been researched as a resource to achieve learning mathematical concepts (e.g., Arcavi, 2003; Duval, 2003, 2006; Phillips, Norris, & Macnab, 2010; Presmeg, 2006; Zimmermann & Cunningham, 1991, among others). These authors have developed numerous studies with the objective of exploring different ways of "visualizing" abstract mathematical objects in paper-and-pencil and technological environments, which support and mediate the emergence and development of mathematical concepts. Due to the large number of geometric representations found in different media –paper-and-pencil and technological–, there is the need (in the student) to identify the characteristics and properties they have. In this article we seek to provide an answer to the following question: how does visualization influence the learning of mathematical concepts when the paper-and-pencil and technological environments intervene?

Conceptual framework

The conceptual framework used in this research is supported by the contributions about visualization in mathematics (e.g., Duval, 2003, 2006; Arcavi, 2003; Phillips et al., 2010; Zimmermann & Cunningham, 1991; among others). Accordance with the Dictionary of the Royal Spanish Academy, the word "seeing" can be understood as synonymous with "visualization" and means "to form in the mind a visual image of an abstract concept" (RAE, 2014). Several researchers in mathematics education have contributed to what should be understood by "visualization". Here are three of them: (i) "Visualization is the individual's ability to produce a representation that, in the absence of any visual perception of the objects represented, through which allow observe as if they were really in front of the eyes" (Duval, 2003, p. 48); (ii) "visualization is the ability, the process and the product of creation, interpretation, use of and reflection upon pictures, images, diagrams, in our minds, on paper or with technological tools, with the purpose of depicting and communicating information, thinking about and developing previously unknown ideas and advancing understandings (Arcavi, 2003, p. 217); (iii) visualization is the process of creating mental images either using paper-and-pencil or technology as well as the effective use of such images in mathematical discovery and understanding of the objects under study (Zimmermann & Cunningham, 1991, p. 3). These and other contributions on the meaning of mathematical visualization demonstrate cognitive character of this concept. We will now describe some concepts involved in the visualization of geometric representations both in paper-and-pencil and in technological environments.

Visualization in paper-and-pencil environment

The representation of mathematical objects involves analysis of their institutional meaning. If the object is a geometric figure, its characteristics must be identified; besides, a treatment of the object with the sense of sight must also be done. Nonetheless, regardless of the conceptions, the nature and the existence of mathematical concepts - of those who learn or those who teach-, many mathematicians (e.g., Arcavi, 2003; Duval, 2003, 2006; Phillips et al., 2010; among others) consider that this way of constructing knowledge consists of "seeing", and such visualization must be done by the senses, the imagination and the intelligence (Duval, 2006). Due to the fact that visualization triggers non-conscious automatic processes in the subject which depend on anything that might be kept in his or her memory, visual learning is direct. This allows learners to discriminate and identify in less than a tenth of a second the various elements of sight and relationships (Duval, 2003).

Through the visualization of representations, the individual can access the properties, characteristics and give meaning to the mathematical object analyzed (Phillips et al., 2010). Sometimes, visualization is used to describe visual representations; on other occasions, it is used to

determine how a certain specific representation works in the understanding of or solving of mathematical problems; it might also be used to define the cognitive activity of the subject when using visual representations. The ideas that emerge from visualization in mathematics lead (students) to enrich visual contents whose use is beneficial both in representation tasks and in handling concepts of this discipline. According to Phillips et al. (2010), in visualization one may distinguish: (a) physical objects perceived by the sense of sight (e.g. illustrations, animations, computer-generated displays, etc.); (b) mental objects collected and processed in the mind in the form of mental schemes, mental imagery, constructions and mental representations; (c) cognitive functions expressed in visual perception, manipulation and transformation of visual representations in the mind, making concrete the abstract ways of thinking and imagining facts.

Phillips et al. (2010) point out that these distinctions are relevant to understand the context of the visualizations and to establish effective visualization applications in the classroom. In order for the student to understand and use geometric representations in an adequate manner, he or she must first understand the meaning of straight lines, arrowheads, angle markers, numbers, and variables (Phillips et al., 2010). Since visual representations are not necessarily clear to the students, they must have a considerable knowledge of symbols and representation conventions so that they have meaning. Visualization involves cognitive activities like interpretation and abstraction of that which the mathematical object represents (Duval, 2003; Arcavi, 2003; Hitt, 1995; Zimmermann & Cunningham, 1991, among others). However, the impossibility of direct access to mathematical objects, outside any representation, inevitably causes confusion in students (Duval, 2003).

Visualization in technological environment

Nowadays there are a vast number of computer programs (e.g., GeoGebra, Maple, Mathematica, Cabri-Geometry, Matlab, among others) used in mathematics teaching. This type of tool promotes visualization as a way of teaching mathematical concepts, and becomes a key factor in mathematical education; particularly, the use of any Software of Dynamic Geometric (SDG) makes the inclusion of visualization in teaching geometric concepts an easy thing because any SDG has dynamic images which allow measurement or the addition of auxiliary lines using the tools available in the software; one may even simply explore a geometric figure. When using dynamic representations to solve geometry problems through visualization, handling is facilitated, sketching or construction of the figures used becomes easier and it is possible to modify them in real time if needed (Hitt, 1995). A relevant feature of SDG is its versatility in terms of use which stimulates the interest and participation of the students when solving geometry problems. Different authors (e.g., Arcavi, 2003; Hitt, 1995; Phillips et al., 2010; Zimmermann & Cunningham, 1991, among others) agree that visualization using dynamic models allows students to understand the concepts or the meanings that may be extracted from representations; therefore, it plays an important role in the students' development of analytical thought, something that does not often happen in a paper-and-pencil environment.

Method

The study is qualitative. The participants were 12 Mexican high-school students [grade 11] paired in six teams. The study was divided in two phases: the first one focuses on visualizing geometric figures using a static environment (paper-and-pencil) in order to extract the properties which, according to the student's knowledge, are implicit in the figure; the second one includes the visual analysis of the figure in a dynamic environment (technological). Using SDG (GeoGebra), the student validates the properties of the figures visualized in paper-and-pencil. During the work with the activities in this environment, we seek for the students to conjecture about the general behavior of the figures when any parameter of the figures changes, to find invariants –if there are any, and to describe and explain the mathematical objects visualized.

The first activity was taken from the article *A cognitive analysis of problems of comprehension in learning of mathematics* by Duval (2006, p.117). In this activity the author proposes that, from a sketch of the graph (see *Figure 1*), students find the length of segment $\overline{ED}$, taking as fixed data the length of the segments $\overline{AB} = \overline{DC} = 4$ *cm* and $\overline{BC} = 7$ *cm*. The author reported three types of answers: 9% answer 3 *cm* (mathematical answer), 39.6% answer 3.5 *cm* (direct measure of the segment) while 24.4% provide other answers, including no answer. The students' results had the paper-and-pencil environment as a referent.
Figure 1. Calculate the length of segment $\overline{ED}$, using paper-and-pencil environment.

The second activity was adapted from the book *Plane and Solid Geometry* (Wentworth & Smith, 1913, p. 33). In our study, the students were presented with a right triangle ABC which according to their characteristics, allow students to identify its properties (implicit and explicit) in order to calculate its area. In the activity, we seek for the students to identify whether there exists a proportional relationship between the area of the triangles *ABC* and *XYZ*, the latter formed from the midpoints of $\triangle ABC$ (see *Figure 2*). To determine if there exists (or not) a relationship between the areas, the students are asked to calculate the areas of the triangles mentioned; if there is any relationship, the student must explain if such relationship may (or may not) be maintained for any triangle regardless its size or shape
Figure 2. Identifying the characteristics of a triangle, using paper-and-pencil environment.

Data collection included the written record of student responses to the activities, which were video-recorded, in addition to students' responses to questions asked by the researcher during the activities. The activities presented to participants were to be addressed using paper-and-pencil and technology (GeoGebra). At the same activities they were asked to validate the results obtained in both environments. They were asked to validate their results in the same Activities using technological (GeoGebra) and paper-and-pencil environment by confronting them.

Data analysis and result discussion

The analysis of the collected data was based on the students' interpretation and on the number of common events and their solution in both environments, taking into account videos of the discussions (student-student and student-teacher) during the activity and the written record once the problem was solved. In the next section, the results of the implemented activities are analyzed.

First Activity

In the first activity, during the work in paper-and-pencil environment, the following results were obtained: five teams detected that the value of the segment $\overline{ED}$ was 3.5 *cm*, while only one team considered the properties of the circle after they realized that the real value of the segment $\overline{ED}$ was 3 *cm*. According to the results obtained, we may state that the visualization of this geometric figure produced by the students tends to acquire a simpler form (Duval, 2003); this way of "seeing" makes the students perceive the segments $\overline{AE}$ and $\overline{ED}$ as equal. This statement is based on the fact that most of the students identified that point E (intersection of the circle with segment $\overline{AB}$) was located at the midpoint of segment $\overline{AB}$. An example of this way of visualizing is evident in the work of Team 1 (see *Figure 3*) in which it is shown that a difficulty to visualize correctly lies in the manner of articulating the implicit and explicit information given (Arcavi, 2003; Duval, 2003, 2006). From the results obtained, we can state that the way in which the students saw the figure (in a paper-and-pencil environment) generated an impression at first sight that prevented them from reaching the correct visualization of the geometric object shown (Duval, 2003, 2006).

(a)

$\overline{BC} = 7$

$\overline{BC} = \overline{AD}$

$\overline{ED} = \dfrac{1}{2}\overline{BC}$

$\overline{ED} = 3.5$

the segment $\overline{ED}$ is half of the segment $\overline{BC}$ since $\overline{AD}$ and $\overline{BC}$ are equal.

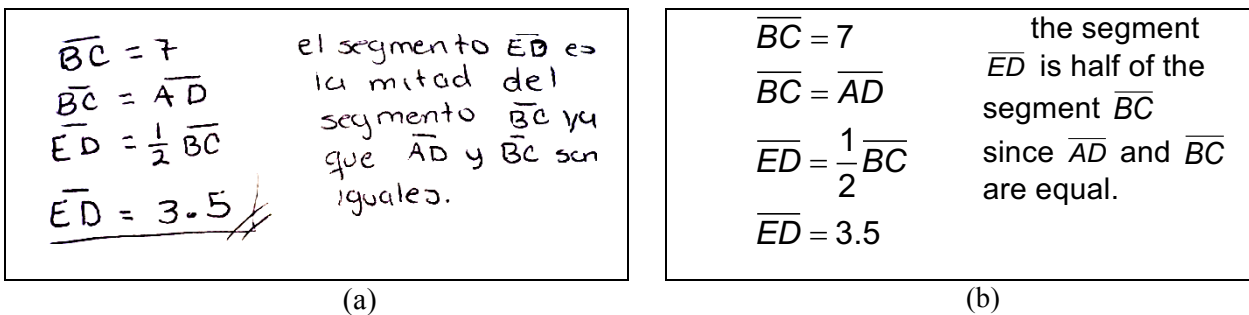
(b)


Figure 3. (a) Influence of visual perception when calculating the length of segment $\overline{ED}$, using paper-and-pencil environment. (b) Transcription of the answer provided in (a).

In the second part of this activity (technological environment), the students reproduced *Figure 1* with SDG (GeoGebra) and using its tools calculated the length of segment $\overline{ED}$. Once the problem was solved with SDG, they compared the result obtained with the software to that obtained with paper-and-pencil. When using GeoGebra, all of the teams concluded that the length of segment $\overline{ED}$ was 3 *cm* because point E is not located at the midpoint of segment $\overline{AD}$ (see *Figure 4*).
Figure 4. The students realize that point E is not located in the midpoint of segment $\overline{AD}$, using the technological environment.

Next, we discuss an excerpt of what was presented by Team 4[2] (students 4A and 4B) when they contrasted the results obtained in paper-and-pencil with those obtained in the technological environment:

[1] *Teacher:* According to *Figure 1* [*paper-and-pencil environment*], what is the length of segment $\overline{ED}$?

[2] *Student 4A*: Since segment $\overline{BC}$ and segment $\overline{AD}$ are equal. Then, if this [*point E*] is at the center [*midpoint of segment $\overline{AB}$*], it is equal to the half [*3.5 cm*].

[3] *Teacher*: Using the software [*technological environment*], did the result change or remain the same?

[4] *Student 4A*: We realized that the radius of the circumference is 4 *cm* and the radius in all the parts of the circumference is always the same, so it measures 4 *cm* although [*visually in the figure in paper-and-pencil*] it is half of $\overline{AD}$.

[5] *Teacher*: Finally, what would be the value of [*the length of*] $\overline{ED}$?

[6] *Student 4A*: Three, because the distance of $\overline{AE}$ is 4 *cm* and segment $\overline{AD}$ is 7 *cm*.

[7] *Teacher*: In which way did the software help you to visualize the figure?

[8] *Student 4A*: At first sight, it looks as if it were half [*paper-and-pencil environment*] and when we put it in the computer [*GeoGebra*] the units of the figure look well-defined [*they notice the properties of the mathematical object*].

[9] *Teacher*: What can you say about the printed figure [*paper-and-pencil environment*]?

[10] *Student 4A*: There is a figure that is not proportional [*according to its characteristics*].

Second Activity

During the second Activity (in a paper-and-pencil environment), the students were asked to identify whether there is a proportional relation between the area of triangles *ABC* and *XYZ*. Only Team 6 had difficulties calculating the areas; they identified the height of triangle Δ*XYZ* incorrectly (they considered the measure of the segment $\overline{YZ}$ as 2 cm), and concluded that the areas of triangles *ABC* and *XYZ* were different and therefore, they did not find any relationship.

When the rest of the students were asked whether the relation found (if they had found any) could or could not be maintained for any triangle [right or not], they said: (a) Team 4: the relation is not maintained "because the angles are not always the same"; (b) Teams 2, 3, and 5: the relation "could be maintained as long as the midpoint rule is obeyed in each segment or side of the triangle" [*they mean triangle* Δ*ABC*] (Team 5); (c) Team 1: "the relation is maintained because the points that divide the sides of the triangle *ABC* are midpoints"; (d) Team 6: "there is no relation between [the areas of] the triangles"; they do not provide arguments as to why.

In the second part of this activity (technological environment), the students used GeoGebra to look for the relations between the areas of the triangles. All the teams concluded that the areas of the triangles Δ*XYZ*, Δ*AXY*, Δ*YZC* and Δ*XBZ* were equal and that the area of triangle *XYZ* is a fourth of the area of the triangle *ABC*. Afterwards, the students were asked to move points *A*, *B* and *C* (vertices of Δ*ABC*) with the software tools in order to obtain new triangles whose side lengths were different from one another. They were also asked to identify why this relationship can or cannot be maintained for any triangle. Here is an excerpt of what Team 5 (students 5A and 5B) presented:

[11] *Teacher*: When moving points *A*, *B* and *C*, is the relation [*he means that the area of* Δ*XYZ is a fourth of* Δ*ABC*] maintained for any triangle?

[12] *Student 5A*: As long as the midpoint of every side is respected, there will be [Δ*ABC*] four triangles inscribed with the same shape as the largest triangle and each of them will always be a fourth of the total area (*Figure 5*).

[13] *Teacher*: When might this relationship be lost?

[14] *Student 5A*: When the points are no longer midpoints [*he means points X, Y, and Z*] because we realized [*that*] when moving the points [*he means vertices A, B, and C*], the areas [*of the interior triangles*] were still equal and that the sum was equal to the largest [*area of* Δ*ABC*]

because the midpoints made that proportion; but we were only able to see that when we did different cases with the software.

Using the software, all the teams managed to generalize the relation of the areas of the triangles formed by the midpoints of every side of any triangle.
Figura 5. Generalization of the relation of the areas, using technological environment.

Conclusions

Answer to this question (c.f., p 1 of this document.) how does visualization influence the learning of mathematical concepts when the paper-and-pencil and technological environments intervene in it? According to the evidence arising in the implementation of activities, we can say that the interpretation by students of the representation of geometric objects, either in paper-and-pencil or in technological environments, depends on the student's previous knowledge and the context (work on paper-and-pencil or technology, types of activities, discussions: student-student, student-teacher), which are essential and allow students to interpret and make sense of the representations, and thus understand the mathematical object.

Starting from the recognition of the properties linked to the representation of geometric figures, the students were able to propose conjectures that ultimately provided them with the guidelines to define concepts related to visual representation. When working with paper-and-pencil, the geometrical representation offers the student little view [information] about the object because it cannot be manipulated, since it is a static figure. On the other hand, when using the software GeoGebra, the participants gained support resources that allowed them to identify properties of these objects (e.g., part of the solution of the second activity). As a result of interaction with the software, students discovered properties of geometric figures and managed to formulate conjectures supported by observations made while manipulating dynamic representations of geometric objects. These resources helped students to create bridges between the representation of the mathematical object and its properties which lead (the students) to generate conceptualizations of the geometric object in question.

When geometric representations are used, their visualization always involves two visual operations that tend to be assimilated in a single act by the subject: (i) distinguishing several shapes inside a figure, and (ii) identifying those shapes or their represented configuration using previous information widely known. In our paper, we highlight the fact that the use of technology in solving the proposed activities allowed students to distinguish geometric properties of triangles, in terms of their areas, within a figure (triangle, second activity). Our results [paper-and-pencil environment] are in accordance with what Duval (2003) explains when he says that people who are not specialists in visualization simply overlook characteristics of the representation, or they may incorrectly interpret the representation, or make up representations of contents with a personal meaning even if they are not similar at all to the institutional mathematical representations (e.g, part of the solution of the first activity). It is true that the SDG promotes learning geometric concepts, but this is not the only

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

environment we should take into account as a teaching tool. The use of paper-and-pencil is a key factor as well since the two environments complement each other to achieve a (partial) success in the visualization of mathematical objects, besides it favors the creation of conjectures on abstract concepts that arise from such representations. This work points to directions for further research, which may seek to answer the research question: what kind of figures or mathematical objects, analyzed through visualization, promote mathematical abstraction? This and other questions are intended to be answered in the future.

In this study we investigated eighth grade students' informal justification for the circle area formula to expand accounts of the measurement knowledge for middle-school age students. Data were collected during three paired interviews of a three-year teaching experiment. Here we describe schemes students exhibited as they operated on measurement tasks at a level we have described as "conceptual area measurer"; the tasks prompted the use of square units to quantify a figure that is not rectilinear. We found students could follow and rehearse a rationale for the validity of the circle area formula with substantive opportunities for movement and figural operations with units, or with decompositions from unit images that coordinated circle and rectangle images.

Keywords: Measurement, Learning Trajectories (or Progressions), Geometry and Geometrical and Spatial Thinking

Area measurement is an important part of elementary and middle school mathematics; unfortunately, many students do not have an adequate understanding of area measurement concepts (Outhred & Mitchelemore, 2000). Many elementary students can remember standard formulas for shapes such as rectangles; however, area measurement is still problematic (Lehrer, 2003). This could be because students are taught the area formula through rote memorization (Simon & Blume, 1994). "Rather than memorize particular formulas for certain shapes, they need to understand why the formulas work" (Strutchens, Martin, & Kenny, 2003). The Common Core State Standards for 7th grade recommends students be able to give an informal justification for the circle area formula (National Governors Association Center for Best Practices, & Council of Chief State School Officers, 2010). In this paper we set out to explore 8th grade students' understanding of the area formula for a circle, including their ability to apply and reason about area formulas for circles.

We expect that asking students to justify the use of the area formula for circles provides an effective context for assessing advances in students' area measurement knowledge. The purpose of this study is to describe and analyze students' thinking as they found the area of circles and developed an informal justification for the circle area formula by coordinating with the area of a triangle, and by tiling with squares. We also hoped to extend a hypothetical learning trajectory (HTL) on area measurement by addressing measures of non-rectilinear shapes.

Research Question
How do eighth grade students develop an informal justification for the circle area formula?

Theoretical Framework

To investigate students' development of understanding for area measurement, we needed a tool to identify varying levels of understanding of area. Thus, we used a hypothetical learning trajectory (HLT) for area measurement developed by Barrett et al. (in press) that describes levels of sophistication. An HLT has three parts: an instructional goal, developmental progressions to characterize mental schemes and actions pertaining to the knowledge goal, and instructional activities to help students progress along the progression (Clements & Sarama, 2014). The instructional goals and activities follow from particular schemes and certain mental actions on objects characteristic of successive levels in the trajectory. An HLT on area measurement has guided the development of our tasks.

The following area HLT levels (Barrett et al., in press) are relevant for the present study because the tasks were designed to scaffold the students to a more sophisticated level. These three levels of thinking address the degree to which children may integrate and coordinate figural images and internal, conceptual images by analyzing parts of figures. By re-organizing a figure into essentially the same collection of components, yet within a different overall shape, children may accomplish the first, least sophisticated of these levels (ARCS). The more sophisticated levels are achieved as children abstract the measures of regions to define area measures as constructions that are products of other linear measures, measures which refer to highly indexed, linear collections of units arranged along a second, orthogonal dimension in arrays. The highest level indicates the most flexible, algebraic grasp of products from linear quantities, taken as inputs to a functional account of the area measurement.

- *Area row and Column Structurer* (ARCS): children at this level can decompose and recompose partial units to create whole units
- *Array Structurer* (AS): children at this level have an abstract understanding of the area formula for rectangles
- *Conceptual Area Measurer* (CAM): children at this level have an abstract and generalizable understanding of the rectangle area formula, they are able to restructure regions to find area, and can provide a justification for the restructuring of the shape.

In the interview sequence reported on here, we prompted students to connect the measure of circles to that of rectangles as a consequence of our reading of the mental actions on objects most likely to be enacted at the Conceptual Area Measurer level of the HLT and because we had found the students expressing related schemes of decomposition and recomposition of area measures.

Methodology

As part of a three-year longitudinal teaching experiment (Steffe & Thompson, 2000) on children's thinking and learning about length, area, and volume, we investigated four children's thinking on area of circles. The students were in eighth grade at a public school in the Midwest. For this report, we used data from three 25- to 30-minute semi-structured interviews with four students (Kari, Lindsey, Joey, and Tanner). We interviewed students in pairs, with Kari and Lindsey as partners and Joey and Tanner as partners. The interviews were videotaped and transcribed and the researchers then analyzed the data. The interviews took place during November and December of 2015.

For the first task, we asked students to find the area of a circle and tell us if they could explain why the circle area formula worked. We used this as an opportunity to see the prior knowledge the students had about area of circles. In the second task, we asked students to compare the area of a square radius to the area of a circle. We created a display with two orthogonal radii serving as adjacent sides of a square, having an area of one radius squared. In this approach, the interviewers

encouraged the students to tile over the circle with cutout squares radii. We saw this activity as an opportunity for students to make a connection to the circle area formula (i.e., $A = \pi r^2$). We hoped students would either: (a) estimate that it would take between three and four square radii to match the area of the circle, or (b) use the formula to assert that approximately 3.14 square radii will always cover the circular region.

Next, students watched a video of a circle and its interior being transformed into a triangle (see Figure 1). We designed this video to help students relate the area of the circle to the area of the triangle. We expected to activate their scheme for decomposing and recomposing space.
Figure 1. Circle Transformed to a Triangle.

For the third task, the students were asked to reflect on the transformation in the video and to find the area of a circle through relating the area of the circle to the area of a triangle. When they expressed the area of the triangle with an invented expression, we asked them to apply their invented expression to state the area of the circle without relying directly on the standard formula. In the fourth task, we asked students to provide an informal justification of the circle area formula, both by reviewing their prior work and by synthesizing what they had observed in the prior tasks.

Results and Discussion

Next we present descriptions of the students' work and responses for each of the four tasks. Following that, we sketch a generalized account of the reasoning we observed and the knowledge that was within their grasp given this set of tasks, and we comment on the relation of such knowledge to an existing framework characterizing relevant levels of sophistication for students' knowledge about area measurement.

Task 1: Find the area of this circle. If you use a formula, explain how you know that it will give you the correct area or where it comes from.

All four students correctly calculated the area of the circle using the standard area formula $A = \pi r^2$ during the first interview on this topic. Despite knowing the formula and how to compute the area, none of the four students gave an explanation about why the formula makes sense or its relation to that of a rectangle. One student, Lindsey, attempted to develop an explanation of the formula. She split the shape using a diameter and said the formula may have something to do with the height and the base.

Although all of the students successfully found the area of the circle using the standard formula, they did not explain any part of the formula besides telling us the formula and that π was 3.14. This

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

could be an indication that students were taught the formula through memorization alone. Students' responses to this task lead us to claim they were not yet operating at a Conceptual Area Measurer (CAM) level of the HLT for area measurement. We make this claim because they used the standard formula for area of a circle but did not demonstrate an abstract understanding of that formula, which is characteristic of the CAM level.

Task 2: Compare the area of the square radius to the area of the circle.

Kari and Lindsey made a guess that it would take four square radii to fill the circle. When they compared the area of the square radii with the area of the circle algebraically, they found the difference, not the ratio, which did not help them interpret how many square radii it takes to fill the circle. Later, using cut out square radii, they determined that it would take about two or three squares. When they were prompted to reflect back on the formula, Lindsey said, "oh π is 3.14 and so it would be 3 or a little bit more that would fit in the circle." Although this may have helped Kari and Lindsey interpret the formula, they still reported that they could not justify why the formula worked.

In the third interview, Kari and Lindsey were asked this question again. They were able to say it takes 3.14 square radii to fill the circle but they may not have taken the square as an object that occupied "radius square units" of the circle area. Instead, Lindsey dragged her finger along two sides of the square and said each showed a length of a radius. Students operating conceptually with area often use a sweeping motion within or across the area being discussed, (Dougherty, 2008). In contrast, Lindsey's gestures may indicate she was treating the sides operationally, as factors that would be used to feed into a calculation for a product of "radius squared". Later, Lindsey labeled another square shape with edge length of "radius" by writing "radius squared" on the interior, indicating an advance beyond the operational approach.

In the first interview Joey and Tanner concluded it would take three square radii to fill the circle. They did not relate the square radii to the standard formula. At the beginning of the third interview they went back to this task. The interviewer asked how many squares it would take to fill the circle? Joey said, "3 point something." The interviewer then asked them if the formula helps them answer that question? Tanner said, "3.14 because the radius square times π is the area of the circle." The interviewer explained to the students this was the beginning to understanding the standard formula for area of a circle but was not yet a justification for the formula.

Based on this interview, we claim Kari and Lindsey were able to interpret the formula as a statement of the number of square radii it would take to fill a circle but struggled to justify why. Joey and Tanner did not articulate a connection between the square radii and π at the end of the first interview, but at the end of the third interview they described the relationship clearly. Apparently this task allowed these students to develop an understanding of the circle area formula as an approximate value, in relation to the number of square radii units needed to cover the circle. Still, it did not help them justify why the formula specifies π square radius units.

Task 3: Finding the area of a circle by transforming it into a triangle

After watching the video of a circle being transformed into a triangle, Kari and Lindsey were given a page that had the circle and triangle shown in the video. They told the interviewer the triangle had the same area as the circle. They labeled the height of the triangle r because they could see the height of the triangle was concurrent with the segment showing a radius of the circle. However, they would not label the base of the triangle circumference, but the were willing to label it C. Lindsey said, "[we can] label it circumference of a circle, but not really because it is not circular." Kari agreed and said, "but if we rolled the circle out it would go to here" as she pointed to the end of the triangle. They agreed they could label it C. We think Lindsey and Kari did not view circumference as a measure but only as a name of part of a circle. They found the area of the triangle by first measuring the length of the base and height of the triangle and then multiplying the base (circumference), height

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

(radius), and $\frac{1}{2}$. They checked to see if the triangle had the same area as the circle by using the standard area formula for a circle and found their calculation was about one square centimeter different. With the help of the interviewers they concluded the circle had the same area as the triangle; they found a difference between area measures of 18.75 and 19.63 but they needed to account for measurement error. They concluded they could find the area of the circle using the formula $A = Cr\frac{1}{2}$ (see Figure 2).
Figure 2. Kari and Lindsey's work for Task 3 on the picture of the circle to triangle transformation page given to them.

In the second interview, Kari and Lindsey, were given another circle and asked to calculate the area without using the standard formula. They drew a triangle that had an altitude the same as the radius of the circle and a base the same as the circumference. They used their invented formula $a = Cr\frac{1}{2}$ to find the area of the circle. After they found the area using their invented formula, they checked their answer with the standard formula (i.e., $a = \pi r^2$) and found the answer to be the same. This suggests a conceptual advance in that they expressed the area of a circle in terms of a related expression involving a triangle that was a reconstituted collection of parts of that circle.

Similarly, after Joey and Tanner watched the video of the circle being transformed into a triangle they found the area of the circle from the video (same page was given as Figure 2), by working with the triangle and using $a = bh\frac{1}{2}$. Joey and Tanner were then given a different circle and asked to find the area without using the standard formula. As we had hoped, their strategy was to try to create a triangle that would have the same area as the given circle. They knew the height of the triangle would be the radius, which they measured correctly. They were not sure how to calculate or measure the circumference of the circle, which they recognized would be the other side length needed for the triangle. With some prompting from the interviewer, they used a wikki-stix to find the distance around the circle. Once they found the measure of the circumference they found the area of the circle by find the area of their created triangle using the triangle area formula. Next, with guidance from the interviewer, Joey and Tanner wrote $\frac{rc}{2} = \frac{bh}{2} = r^2\pi$ on their paper. They then checked their answer by finding the area of the circle using the standard circle area formula. They had a difference in their answers by one square centimeter but concluded the difference was due to a measurement mistake.

We found evidence that students could follow our guidance and logic to interpret a more tangible formula for the area of a circle. Kari and Lindsey seemed to be able to complete the transformation of the circle into a triangle without guidance from the interviewer because they knew how to find the circumference of the circle. Joey and Tanner were able to complete this task with the help of the interviewer giving them a wikki-stix and later the interviewer told them the formula for finding the circumference of a circle.

Task 4: Justifying the circle area formula

   Kari and Lindsey began their informal justification for the circle area formula by drawing a circle and a radius. Lindsey said, "So the circumference is the circle and if you lay that out it would be this, which is the base of the triangle, which we are calling C, cause it is like the circumference of the circle. Then the height is like the radius. And to get the area of the triangle you do base times height which is like C times r … times a half." Kari said that the triangle had same area as the circle. They then set πr^2 equal to $Cr\frac{1}{2}$. They substituted $d\pi$ in for C, followed by $2r$ for d and simplified (see Figure 3).

Figure 3. Kari and Lindsey's work on Task 4.

Figure 4. Tanner and Joey's work on Task 4.

   In the third interview with Joey and Tanner, they were asked to justify the circle area formula. To reply, they revisited previous work and recalled this equation: $\frac{rc}{2} = \frac{bh}{2}$. They substituted $2\pi r$ for the circumference leaving them with $A = \frac{r2\pi r}{2}$. They simplified this equation and were left with the standard circle area formula. This algebra was not easy for them and it took them some time to decide if $r \times r$ was $2r$ or r^2 (see Figure 4).

   All four students took for granted the equivalence of the circle and the triangle and used it in their defense for the informal justification of the formula for area of a circle. At first they all wanted to use the standard formula they knew for area of a circle to justify their invented formula. The students were able to restructure the circle into a triangle and relate the shape to the area of a triangle and provide justification for the transformation and the circle area formula. We note here that the operation used in the video display of representing the circle and the triangle with an identical set of strips, and reorganizing to show the transition between the two figures involves an over-simplification, but we believe it was productive. This scenario disregards the contortion of the inner

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

and outer edges of these unitary strips. However, as we approach the limiting case for the width of the strips this distortion becomes negligible. Thus, our imagined conservation of a collection of strips serves as a thought experiment more than a comprehensive argument. Nonetheless, it is conceptually sound, as the knowledge can be expected to mature when a student gains a sophistication level suited to learning the principles of the calculus, later in their academic career. We note too, that others have experimented with similar spatial morphing, which children may see as space conserving (e.g., Lehrer, Jenkins, & Osana, 1998; Kara, 2013).

Conclusion and Implications

Prior to the interviews, the students were not able to explain the standard circle area formula and at the end of the interview they were able to produce an informal justification for the circle area formula. We claim, these tasks supported students' development of a more meaningful understanding of finding the area of a circle. With scaffolding, the four students were preforming at the CAM level because they were able to restructure a circle into a triangle to find an area measure using algebraic expressions and operations. As well, they were able to provide an informal justification of this transformation and defend the circle area formula.

After the first task we found the students were able to compute the area, but they were not able to explain or interpret the formula. Our findings from this task support those of Outhred and Mitchelemore (2000) that elementary and middle school students do not have a sufficient understanding of measurement and those of Lehrer (2003) that students can remember standard formulas but not have a understanding of the formula or area measurement.

To our surprise, these students used the standard formula to justify their invented formula instead of using their invented formula to justify the standard formula. This could be because they had been taught the standard formula and did not learn about the formula as measurement from units and unit iteration for covering such an object. We conjecture that if they were to invent their own formula first, they could use their formula to develop the standard formula, which would drastically alter their conception of the standard formula. They may have conceived of the standard formula as an arbitrary construction that the teacher was merely relaying to them, and moreover, assumed it did not have a practical basis in physical measures with units of area. Students often accept statements like this as valid statements (theorems in action) for practical use without testing or challenging them. Setting measurement activities as empirical tasks is unusual, especially the measure of the circle, given that a formulaic computation is available, requiring only the measure of a radius. By problematizing the formula for measuring area, we found that students in 8th grade were capable of taking a novel unit square, the unit with a side length of one circle radius, and using it to measure both the circle and the triangle for area. By relating a circle to a triangle through a physical transformation we were able to relate the area formula for a circle to the area formula for a triangle. By working with the imagistic and the symbolic representations at the same time we claim students were able to recognize an informal argument to justify the formula for measuring the area of a circle.

Thus, we found that students in Grade 8 are able to recognize the validity and figural veracity of the standard formula for computing the measurement of the area of a circle in terms of its radius. This finding informs and allows us to adapt the row of the area HLT for Conceptual Area Measurer, indicating that students at a conceptual understanding of area measuring in terms of arbitrary square units should also be expected to recognize extensive algebraic manipulation of the area formula to relate it to the formula for finding the area of a triangle and add the four tasks to the HLT. Future research will be completed with these students to see they are able to describe and complete an informal justification for the circle area formula on their own.

HIGH SCHOOL STUDENTS' FORMING 3D OBJECTS USING TECHNOLOGICAL AND NON-TECHNOLOGICAL TOOLS

Samet Okumus

sokumus@ncsu.edu

Karen Hollebrands
North Carolina State University
karen_hollebrands@ncsu.edu

We analyzed the ways in which two high school students formed 3D objects from the rotation of 2D figures. The students participated in a task-based interview using paper-and-pencil, manipulatives, and Cabri 3D. The results indicated that they had difficulty using paper-and-pencil to rotate 2D figures to form 3D objects. Their difficulty stemmed from thinking of the rotation in a 2D context. Although the use of manipulatives helped them reason about 3D problems, they still had difficulty representing 3D objects correctly. However, the students were able to relate the rotations applied to the 2D figure to the resultant 3D object using Cabri 3D.

Keywords: Geometry and Geometrical and Spatial Thinking, Technology

Introduction

Forming 3D objects from the rotations of 2D figures (e.g., forming a cone from the rotation of a right triangle about one of its legs) is important for the study of calculus (Baartmans & Sorby, 1996) and for developing students' visualization skills. Nevertheless, there is little research about students' forming 3D objects by rotating 2D figures and how different tools might influence those processes. Although *Common Core State Standards for Mathematics* (National Governors Association Center for Best Practices, Council of Chief State School Officers [NGA & CCSSO], 2010) states that students should be able to "identify the shapes of two-dimensional cross-sections of three-dimensional objects and identify three-dimensional objects generated by rotations of two-dimensional objects" (HSG.GMD.B.4) there is little guidance about how teachers can assist students in learning this important skill and the tools that may be useful. Research is needed to understand how students reason about 3D objects generated by rotations of 2D objects using different tools. The purpose of this research study is to understand how high school students' form 3D objects using two different types of tools: non-technological tools that consist of paper-and-pencil and physical manipulatives, and the technological tool Cabri 3D. Our research question is "How do high school students form 3D objects using different learning tools?"

Theoretical Framework

According to Duval (2006), changing one semiotic system into another system (e.g., statement to equation; figure to statement) using denotations, and coordinating these systems are essential for acquiring mathematical knowledge. Duval refers to *semiotic registers* that allows for representing mathematical objects, making transformations within the same semiotic system (e.g., figure to figure), and creating an equivalent representation in another semiotic system. Two types of transformations of semiotic representations are characterized: *treatment* and *conversion*. Treatments are transformations within the same register (e.g., rotating a triangle 360 degrees). Conversions involve transformations from one register to another one (e.g., finding an algebraic equation for a given graph). Treatments and conversions are given through *discursive* and *non-discursive* representations/apprehensions. Discursive representations are given through speech (articulation of thoughts) using mathematical properties, symbols, definitions, etc. (Duval, 1995).

Students who recognize shapes utilizing *perceptual* apprehension perceive geometric shapes by "figural organization laws, and pictorial clues" (Duval, 1995, p.145). Therefore, students are likely to be misled by perceptual characteristics of geometric shapes. Students who utilize *operative* apprehension make physical or mental manipulations of a geometrical shape such as dividing it into

sub-figures, changing the orientation of it, shrinking-enlarging it, etc. (Duval, 1995). For example, in Figure 1, a student may state that the points are collinear if he or she uses perceptual apprehension. On the other hand, the student who utilizes operative apprehension notices the partial line segments are on different surfaces of the cube and/or changes his or her orientation toward the cube.
On the cube, point B is located on $\overline{XY}$, point C is located on $\overline{YZ}$. Are points A, B, C, D collinear? Why/why not?

Figure 1. A task related to apprehension of 3D objects.

Gorgorió's (1998) research indicated that students with low spatial abilities had difficulty describing the movements of rotations mentally and providing enough spatial information about 3D objects. Students may not think that they are to spin 2D figures to form 3D objects when they are given tasks in a paper and pencil environment. Especially students who use perceptual apprehension; they may consider this rotation in a 2D context. Under this circumstance, students may have difficulty making a conversion from one semiotic system to another one. There may be certain features of a task that prompt the student for particular actions. For example, the teacher may provide additional cues on the paper-based task such as including a spiral arrow in the question to suggest a rotation about a particular axis. Using manipulatives, students may be better able to see the different locations of the 2D object as it rotates that are not possible to see and difficult to draw in 2D. However, in both cases the learner is still responsible to bring the pieces together, and imagine the final 3D object because "most physical actions on physical manipulatives do not leave a trace sufficiently complete to reconstitute the actions that produced them" (Kaput, 1995, p.167). With the availability of dynamic geometry software (DGS), students can drag points, objects etc., observe the path of motion by activating the trace tool of DGS without being required to remember all of its locations and consider what is formed (Schumann & Green, 1997). With the help of the trace tool, technology allows students to observe and interpret the outcomes of fixed properties under different circumstances (Hollebrands & Dove, 2011).

In the current research study, we examine high school students' formation of 3D objects from the rotation of 2D objects. This study will investigate how students use manipulatives, and technology to form 3D objects.

Methods

The participants were selected among 29 students (18 females, 11 males) from a rural high school enrolled in a second year mathematics class. Students were given a spatial ability test. We selected six students (two above average, two average, two below average) to participate in one 90-minute clinical interview during 2013-2014 spring academic semester. In this report, results from two students, Andrea (female) and Pete (male), will be reported. After consulting their mathematics teacher and considering their test scores, we identified Pete as having low spatial abilities and Andrea as having high spatial abilities. The mathematics teacher of the participants reported that it had been over a year since they looked at 3D geometry, and all they would have done would be finding volume of different shapes. At the beginning of 2013-2014 spring academic semester they studied 2D transformations. None of the participants used Cabri 3D or any other DGS.

The interviewees were given five tasks. The tasks were sequenced beginning with paper and pencil. Afterwards, the participants solved the same tasks using manipulatives and then Cabri 3D. Square-centimeter grid paper was used for presenting the paper and pencil tasks, and students had

access to a ruler and compass. In this report, results from the first two tasks are presented. In the first task, students rotated a rectangle about a line that passed through one of the longer sides. In the second task (Figure 2), students were asked to rotate a rectangle 2 cm away from the axis of rotation. In these tasks, the student needs to match the statement (e.g., intersects the plane perpendicularly, rotate the rectangle 360 degrees about line *KL*) with the figure given in the task (Figure 2) utilizing operative apprehension. In other words, a conversion from statement to figure (or vice versa) is needed. Also, a treatment from figure to figure that involves spinning the rectangle 360 degrees in a continuous motion is required.

> Task 2: Suppose the line in the figure (Figure 2) intersects the plane perpendicularly. In the figure, rectangle *ABCD* is 2 cm away from line *KL*. Draw the three-dimensional object that is formed if you rotate the rectangle 360 degrees about line *KL*.
Figure 2. The figure given in Task 2.

A video camera, audio recorder, and a program that recorded the computer screen only when students used Cabri 3D were used to capture the participants' work. Because the participants were not familiar with Cabri 3D, the interviewer spent the first ten minutes teaching them the basic features of the program using some preliminary activities. The interviewees learned how to rotate objects and examine them from different perspectives, mark, label and trace points using Cabri 3D menu tools.

After the interviews, the researchers constructed verbatim transcripts. We identified the interviewees' apprehensions and production of registers within a semiotic system, by focusing on how the participants rotated 2D figures, what types of 3D objects they formed, and if they related the given lengths of 2D figures with the 3D objects (height, radius, etc.). We illustrated the participants' interpretation and constructions within and across the learning tools they used by comparing and contrasting the participants' representations and reasoning with regard to each tool they used.

Results

Results from the Participants' Uses of Paper and Pencil

In the first section of the interviews, the interviewees used paper and pencil to work on the tasks. Andrea and Pete stated that after rotating the rectangle 360 degrees it would arrive at its original location. Andrea summarized her thinking by saying: "basically, you take this figure and you rotate it 360 degrees by the line *AD*. So, that would just be the same figure cause you're rotating it 360 degrees just puts it back where it is." The interviewer asked her to describe how she rotated the rectangle 360 degrees. Andrea denoted the rotation step-by-step by rotating the rectangle 90 degrees each time separately.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Andrea described the rotation as flipping although her rotation method involved rotating the rectangle about its centroid. After rotating the rectangle, she produced a semiotic representation in 2D. Andrea stated that it would be impossible to get a 3D object. She explained her thinking as follows: "if you start with a 2-dimensional object, I don't really think that you can turn into a 3-dimensional object." In the rest of the tasks, Andrea was consisted with her thinking and refused to produce a semiotic representation in 3D geometry, and said: "no matter what you do to it, it's still going to be the same flat shape it is. It's gonna stay 2-dimensional."

Pete conducted the 360-degree rotation by rotating each corner of the rectangle (Figure 3a) and $\overline{AD}$ (one of the sides of the rectangle) to exemplify how he rotated the rectangle. Similar to Andrea, Pete rotated the line segments 90 degrees each time separately, and stated that the rectangle would be back to its original location. Afterwards, he showed the rotation using an eraser as shown in Figure 3(b), he rotated the rectangle about its centroid. Then, he drew a rectangular prism and said: "most rectangles that one puts in a 3D perspective, it's gonna be a rectangular prism." After Pete had denoted the edge lengths, the researcher pointed at the height of the rectangular prism, and asked how he identified the length of it (Figure 3c). Pete said that he was looking at the object from the top view, and added:

It states that 2 cm is right here (points at one of the short sides of the rectangle), 5 (cm) is here (points at one of the long sides of the rectangle). So, it never tells you the height but it does tell you the 5 cm on this line segment. So, I kinda took that as if possibly it could be saying that how tall it is. It is on a grid, it's not 3D, it could have that (inaudible) this is how tall it is…

(a)   **(b)**   **(c)**
Figure 3. (a) Pete's illustration of the rotation, (b) Pete's illustration of the rotation using an eraser, and (c) Pete's illustration drawing for the first task.

In the second task, Pete rotated the rectangle similar to the first task (90-degree rotation each time separately) and associated the lengths of the rectangle with the edges of the rectangular prism he drew by saying: "if it is telling you to rotate it at, the rectangle 360 degrees about line *KL*, so you'd probably- rotate it towards *KL* that 2 cm could be telling us the height of the object like I said the height on the side." In his semiotic representations, Pete rotated the rectangles 360 degrees through their centroids and put them back in their original positions. He produced a semiotic representation in 3D geometry converting 2D figures into polyhedrons by matching one of the lengths he observed in the tasks.

Results from the Participants' Uses of Manipulatives

In the second session of the interviews, the interviewees solved the same tasks using manipulatives. The use of manipulatives helped Andrea and Pete utilize operative apprehension to reason about the problems since they had rotated the rectangles through the centroid of them in a 2D system using paper and pencil. They made sense of the crucial statements given in the tasks. Namely, the rotation line was perpendicular to the plane and rotating the rectangles about the line implied

spinning objects. They noticed that the statement meant to spin the rectangles. However, Pete said that the same object would be formed although he was aware of the blind spots of the rotation. He demonstrated the rotation using the eraser (Figure 4(a)) and said: "when I am doing it this way, it's rotating, I am rotating it as towards me so it'd look like straight line (when the rectangle is rotated 90 degrees, it looked like a straight line) kind of but a 3-dimensional object."

| (a) | (b) | (c) |
Figure 4. (a) Pete's illustration of spinning using an eraser, (b) Pete's use of manipulatives for the second task, and (c) Pete's modified drawing for the second task.

When Pete was reasoning about the second task using manipulatives (Figure 4(b)), he changed the height of the rectangular prism from 2 cm to 4 cm by adding *KD* and *CD* together by saying: "the 2 cm is here and here but also we added to the 2 cm that it is away. And, if you add them together so that it maybe 4 cm as the height of it from the ground now that I am looking at like this" (Figure 4(c)). Although Pete was doing a right treatment demonstrating how the rotation took place, he had difficulty coordinating the representations in the treatment. He focused on the outcome of the rotation and made little connection between his 3D drawings (e.g., Figure 4(c)) and how the rectangles were rotated.

On the other hand, Andrea held the same belief that one cannot form a 3D object by rotating a plane figure by saying:" it just goes around, stays the same. No matter what you do, if you flip 360 this way and go back to where it was...But no matter what you do if you spin it this way, this way, flip it upside down, it stays the same." She had difficulty thinking of the rotation in a continuous motion. However, using manipulatives, Andrea was able to notice the circular motion of the rotation. She described the previous rotation as flipping, and the new rotation using manipulatives as spinning. While Andrea was solving the third task in which she rotated a semi-circle, she highlighted that it would look like a sphere if one spins it fast enough by saying: "I assume the figure, if you're looking at it when you're spinning fast enough it will look as if it a whole sphere but it still won't be a sphere."

| (a) | (b) | (c) |
Figure 5. (a) Manipulatives designed for the first task, (b) Andrea's drawing for the first task, and (c) Andrea's drawing for the second task.

Afterwards, the researcher asked what she would form by rotating a rectangle fast enough. Andrea thought it would form a rectangular prism. However, soon after she rotated the rectangle using manipulatives (Figure 5(a)), she noticed that it would form a cylinder by saying:

If you spin it fast enough it would look like all the edges are coming up. Oh, actually, probably look more circular instead of actually rectangular. It would look like a flat, like a cylinder instead of a rectangular prism if you're spinning it so it could be a cylinder instead of a square thing (rectangular prism). Cause if you're spinning it'd look circular on the edges but look flat on the top.

Although Andrea figured out the correctly formed 3D objects after rotations, she mislabeled the radii of circles in her both drawings. Also, she misrepresented the location of line *AD* by drawing it at the left edge of the cylinders instead of in the center of them. The third task in which a semi-circle was rotated 360 degrees helped Andrea revise the radii lengths of cylinders and the location of line *AD*. While identifying the object after she rotated a semi-circle, Andrea highlighted that a sphere would be formed by saying: "yeah, like that makes a sphere. Because half of the line is kind of going down the middle of it. This is a semi-circle on this side, and if you're spinning fast enough, you can kinda see a sphere form out of it." Afterwards, the interviewer showed that she drew the line in the middle when she formed a sphere, while the line was at the edge of the cylinders in the previous tasks. With the prompt of the interviewer, Andrea modified her drawing as shown in Figure 5(b) and Figure 5(c).

Results from the Participants' Uses of Cabri 3D

In the third session of the interviews, the interviewees used Cabri 3D and the *Trajectory* tool. Because Andrea reasoned about the tasks correctly using manipulatives, she did not modify her drawings; instead she verified her drawings and restated her thinking. For example, in the second task, she looked at the object from the top view to indicate the inner cylinder as shown in Figure 6(a) by saying:

Andrea: You can see there is a cylinder in the middle and a cylinder on the outside (Figure 6(a)). So, you see both of the shapes and stuff.
Interviewer: So, why did we get a hole in it?
Andrea: Because the lines are going outwards, they make it, right there, they made it so where it would have a space between this cylinder and this line and the outward cylinder.

| (a) | (b) | (c) |
Figure 6. (a) The rectangle in the second task traced out by Andrea, (b) The rectangle in the first task traced out by Pete, and (c) The rectangle in the second task traced out by Pete.

Andrea appreciated Cabri 3D by saying: "this one (Cabri 3D) helped a lot more because you can actually show everything that was going on..." On the other hand, Pete changed his reasoning by observing the objects formed in Cabri 3D. After he rotated the rectangle (Figure 6(b)), he said "I observe that it made a cylinder" and added "because you are dragging around 360-degree motion that it's tracing the whole time you go around. It's tracing the object during it went." The interviewer asked him to compare and contrast what he was thinking before and what he observed. He explained his previous thinking by saying "I was thinking before that it wanted to know the 3-dimensional shape of the object after you rotated it. So, I was thinking that the object that it wanted to know was

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Tucson, AZ: The University of Arizona.

what the shape would be after you rotated it, not the rotation would look like - the shape that rotation made." Using Cabri 3D, he made a connection between how the rectangles were rotated and the resulting 3D objects. Similarly, in the second task, Pete interpreted what he observed (Figure 6(c)) as follows:

> A cylinder but it's hollow in the middle… Because of the fact that it's 2cm away, and instead of like I was thinking, what I was thinking telling you the height of it, of the object. Instead of that, it's telling you that's how far away the rotation going around the object was.

While using Cabri 3D, he observed the rotations from different perspectives to articulate his thinking. The interviewer asked Pete to explain how he considered the tasks using three different learning tools. Pete explained his thinking as follows:

> I was thinking on this one (manipulatives) just like I was on this one (paper and pencil) that it was wanting to know what the 3-dimensional object was, and not what the actual rotation of the object would make if you were to trace it all the way around.

Discussion and Implications

In this research study, we analyzed Andrea and Pete's formation of 3D objects by rotating 2D figures using paper and pencil, manipulatives and Cabri 3D. They were reasoning about the problems primarily affected by perceptual apprehension because they made treatments rotating objects in a 2D semiotic system. They had difficulty understanding how they were asked to rotate the rectangles about the axes of rotations. In other words, they had difficulty making a conversion from the figures to the statements given in the tasks (or vice versa). As a consequence, Andrea was unable to produce a representation in a 3D semiotic system. Pete produced representations matching one of the lengths he observed in the tasks to denote the height of 3D objects. In Pete's drawings, there was little connection between the rotations and the resulting 3D objects. He had difficulty associating the rotation of 2D figures with the resultant 3D objects. Similarly, Gorgorió's (1998) research indicated students with low spatial abilities had difficulty describing the movements of rotations. Pete viewed prisms as a 3D form of 2D figures (e.g., rectangle $\rightarrow$ rectangular prism). These findings suggest a need to conduct research to examine how students can make connections between extruding (e.g. forming a cylinder translating a circle in a linear and continuous motion) and spinning 2D figures (e.g., forming a cylinder spinning a rectangle about one of its sides).

When Andrea and Pete were given manipulatives to solve the tasks, they observed the circular motion of the rotation utilizing operative apprehension. Pete focused on the outcome of the rotations, and provided a similar semiotic representation drawing rectangular prisms. On the other hand, Andrea, at first, held the same belief that one cannot form a 3D object by rotating a 2D figure until she rotated a semi-circle. Then, she identified the correct formed objects although she mislabeled the measures of the cylinders. After using manipulatives, the description of the rotation that Andrea used shifted from flipping to spinning. However, she needed to go beyond to identify the resultant objects because as Kaput (1995) emphasized manipulatives do not always provide sufficient information. She managed to form the objects associating the statements given in the tasks with the semiotic representations she produced. However, Pete who had low spatial abilities could not identify the objects. Schumann and Green (1997) emphasized that imagining a point's continuous motion in mind and conceive its path to look for mathematical relationships is closely related to students' visual imagination capabilities.

When Pete used Cabri 3D, he was aware of the continuous curricular motion of the 2D figures. Based on his observation of the objects formed in Cabri 3D, he attended to the properties of the formed objects. He compared and contrasted the representations in Cabri 3D with his previous drawings. With the feedback of Cabri 3D, Pete considered the rotation as a continuous process

different from his previous methods that focused on outcomes of the rotations. As Hollebrands and Dove (2011) state, technology allows students to observe and interpret the outcomes of fixed properties under different circumstances with the help of the trace tool. On the other hand, Andrea verified her reasoning based on the feedback DGS provided, and supported her previous thinking.

Using manipulatives, the interviewees observed different locations of 2D figures as they helped them to think about the problems in a 3D context. However, the interviewees had difficulty imagining the resulting 3D objects. Manipulatives that give a concrete evidence about forming 3D objects as shown in Figure 7 can be given to students. Future research can examine short- or long-term influences of using different learning tools. Also, we had students use Cabri 3D for comparing and contrasting their previous thinking. New research is needed to indicate how students form 3D objects by the rotations of 2D figures.

YOUNG CHILDREN UNDERSTANDING CONGRUENCE OF TRIANGLES WITHIN A DYNAMIC MULTI-TOUCH GEOMETRY ENVIRONMENT

Yenny Otálora
University of Massachusetts Dartmouth; Universidad del Valle
yotalorasevilla@umassd.edu

This study examined how small groups of second-grade children developed understandings of the concept of congruence while collaboratively exploring and solving problems with dynamic representations of triangles using Sketchpad on the iPad. One case study is presented to illustrate how young learners can infer geometrical relationships between congruent triangles and co-construct mathematical strategies to create congruent triangles using these technologies.

Keywords: Geometry and Geometrical and Spatial Thinking, Technology, Problem Solving

Introduction

Congruence is an important mathematical idea for humans to understand the structure of their environment. Congruence is embedded in young children's everyday experiences that allow them to develop intuitive senses of this geometric relationship. Understanding the concept of congruence provides strong foundations for learning more advanced mathematical processes such as area and volume measurement (Huang & Witz, 2011; Wu, 2005). However, prior research has revealed a variety of students' difficulties in learning congruence at both the elementary and secondary grades (Clements & Sarama, 2014; Wu, 2005). Wu (2005) claims that the teaching of this concept is focused on the static informal definition "congruence is same size and same shape" (p. 5), which does not relate congruence to planar transformations, while the precise mathematical definition of the concept is based on rotations, translations and reflections. Wu notes that middle-school students have difficulties in understanding the precise mathematical definition of congruence and fail to grasp how it underlays other mathematical processes. Clements and Sarama (2014) state that the natural development of congruence also represents critical challenges for young children because they tend to analyze only parts of the shapes (e.g. length of one side) but not the relationships between these parts (e.g. lengths of all the sides) and privilege aspects of the shapes that are salient perceptually (e.g. orientation) rather than aspects that are mathematically relevant (e.g. number of sides). Thus, young children fail when one of the two figures is rotated or flipped or when the figures are unusual for them (e.g. long and thin triangles, scalene triangles, hexagons). The authors suggest that traditional teaching of geometry in early grades is implemented in rigid ways, which means that children are exposed to only prototypical shapes and have little experience with non-examples or variants of shapes. Students' difficulties can endure until adolescence if not well addressed educationally, limiting their access to formal mathematics in higher grades (Clements & Sarama, 2014). Furthermore, although learning congruence is important for the growth of advanced mathematical thinking, its teaching has been traditionally relegated to middle school (Huang & Witz, 2011; Wu, 2005). However, prior research has shown that from birth to 7-8 years of age, children spontaneously develop Euclidean geometry knowledge about two-dimensional shapes including triangles (Shustermann, Lee & Spelke, 2008) as well as intuitive ideas of congruence (Clements & Sarama, 2014). This suggests that second-grade children could engage in informal reasoning about congruence and benefit from the early implementation of the concept as groundings for its future formal learning.

Researchers have stressed that utilizing digital interactive technologies in early childhood education can promote new ways of mathematical thinking in young learners (Clements & Sarama, 2014; Hegedus, 2013; Sinclair & Moss, 2012). The use of dynamic geometry software such as

Geometer's Sketchpad® (Jackwic, 2009, hereon Sketchpad) could support young children's reasoning on properties of two-dimensional shapes and facilitate their access to more complex concepts (Sinclair, deFreitas & Ferrara, 2013; Ng & Sinclair, 2015). The addition of multi-touch devices could foster direct interaction with the mathematical configurations and collaborative behaviors that, in turn, could support the co-construction of shared mathematical meanings (Hegedus, 2013). This study posits that combining *Sketchpad* with the iPad through the application *Sketchpad®Explorer*, could enhance young children's learning experiences of congruence by helping them grasp in a dynamic way what means 'same shape and same size', so that they can link these properties to continuous geometric motions and to a variety of triangles. Moreover, children could work in small groups manipulating the dynamic shapes directly and simultaneously on the iPad, to also benefit from gestural expressivity and social interaction. Such an environment could help students overcome some of the learning challenges stated above. However, research on early learning of congruence is scarce. Furthermore, little is known about how the use of these digital multimodal technologies in small groups could benefit young children's development of foundations on congruence. This study aimed to design and implement a sequence of exploratory and problem-solving activities using *Sketchpad* on the iPad in order to examine the ways in which small groups of young learners reason about and understand congruence ideas while collaboratively working with dynamic representations of triangles. The question was: *How do small groups of second-grade children make sense of the concept of congruence within a collaborative Dynamic Multi-touch Geometry Environment?*

Theoretical Framework

This study is grounded on sociocultural theories of situated learning that see human activity as an integral part of the process of knowing that is mediated by both social interaction and cultural artifacts, such as digital interactive technologies. The theoretical framework of *semiotic mediation* related to the use of dynamic geometry environments and haptic technologies for the development of children's mathematical reasoning (Moreno-Armella, Hegedus, & Kaput, 2008; Hegedus, 2013; Sinclair & Moss, 2012) guided the research. The construct of *semiotic mediation* is central to understand how the use of multimodal technologies can nurture young children's co-construction of understandings about congruence. *Sketchpad* is a computer micro-world that enables users to continuously manipulate and transform, into a drawing-like space, a variety of geometrical objects that are pre-defined mathematically (Sinclair & Moss, 2012). Students can utilize the function tool *dragging* and, after any dynamic transformation, these objects preserve their defining mathematical properties, even if other characteristics vary. These affordances can mediate children's access to a variety of representations of mathematical objects and ways of thinking about the underlying properties (Hegedus, 2013; Sinclair & Moss, 2012). In this study, the dragging tool could mediate children's access to multiple representations of congruent triangles and the discovery of the underlying congruence relationship. Multi-touch horizontal tablets allow for physicality of learning, multiple inputs and co-location of students, facilitating small-group collaboration and haptic representations (Dillenbourg & Evans, 2011; Hegedus, 2013). Mediation of visual dynamic feedback and multi-touch input could foster young children's mathematical inquiry entailing reasoning and discovery, as they are able to conjecture and generalize while interacting with peers and the technology, as well as richer mathematical discourse, gestural expressivity, and understanding of geometric concepts such as congruence.

Methodology

The study entailed the design and implementation of an educational intervention strategy based on collaborative inquiry and problem solving within a dynamic multi-touch geometry environment (hereon DMGE). A sequence of seven activities was implemented in small groups of students for the

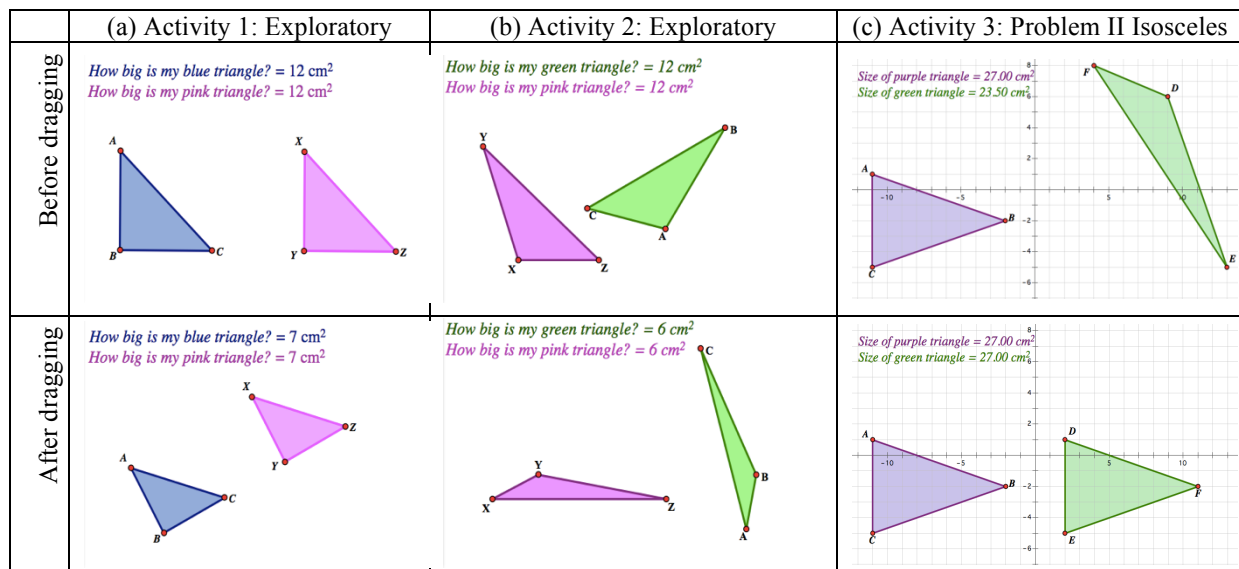
early learning of congruence and similarity. Thirteen children (7-8 year olds) from five second-grade classrooms of a middle-SES public elementary school from Massachusetts, U.S., participated in the study. Children included girls and boys from various cultural backgrounds and were organized into five groups –two groups of two students and three of three students. This educational strategy was implemented as part of the afterschool program. A qualitative multiple-case study research approach was the method of inquiry to analyze small-group work on the tasks. This paper focuses on the three first activities of the sequence, designed to promote informal understandings of congruent triangles from a dynamic and multimodal perspective: Two exploratory activities (one task each one) and one problem-solving activity (three tasks). In Activity 1 and Activity 2, children were shown two congruent triangles of contrasting colors, and were asked to drag one of them and describe what happened with the other triangle. In Activity 1, both triangles could be continuously rotated, resized, and translated by dragging one of them, adopting different positions on the screen, but after any dynamic transformation the triangles always remained congruent (Figures 1a). In Activity 2, both triangles could be continuously transformed by dragging one of them, adopting different orientations and positions between them, but they always remained congruent (Figures 1b). In Activity 3, children were shown a referent triangle and a non-congruent triangle over a grid, and were asked to make the non-congruent triangle identical to the referent triangle (Figures 1c). This activity had three tasks with increasing degree of complexity based on the type of triangle (e.g. right, scalene). All the activities showed the area of each triangle at the top, which was called the Size Marker tool.


Figure 1. Sequence of exploratory and problem-solving activities for congruence.

The task-based interview with a semi-structured interview protocol was the primary data collection method. Each small group of children had one iPad with the activities developed in the DMGE and was observed and interviewed while solving each activity. The entire sequence of learning took place during four 1-hour sessions, once a week during four consecutive weeks, which were fully videotaped, transcribed and codified for analysis. Discourse analysis of children's interactions within each group was the data analysis method (Wells, 1999). The analytical framework included: (a) Children's ways of thinking about congruence (e.g. one or two relationships between attributes, discovering congruence invariance, measurement, representation of attributes), (b) Collaborative patterns, and (c) Uses of the technology. These aspects were analyzed from children's discourse -utterances, actions, gestures-. Coding consisted of a stepwise iterative process of seeking redundancy, using a first cycle-process coding method and a second cycle-pattern coding method.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Results

Partial results from this study are presented in three sections regarding three emergent themes. These results are illustrated with excerpts from one case study correspondent to the analysis of Nathan and Kevin's discussions while interacting with each other, the researcher and the DMGE, in Activities 1 and 3. This group was selected because children planned the strategy in Activity 3 before using it, different to other groups. Actions are presented between braces, gestures underlined between brackets, and utterances are presented in normal format (between quotes only within the narrative).

Dynamism Mediated the Discovery of Congruence Relationships between Triangles

The first relevant finding of the study is that *dynamism* mediated young children's discovery of geometric relationships related to congruence of triangles within the DMGE. In Activity 1, I asked Kevin and Nathan: "I would like for you to drag the blue triangle (hereon BT) and tell me what happens with the pink triangle (hereon PT)". Initially, children showed an explorative use of the dragging function, systematically examining different continuous motions of BT such as turning around it, resizing it and, sliding it up and down, and observing the PT's behavior. When Kevin dragged BT up and down several times he began identifying *one relationship between attributes* of both dynamic triangles referred to their same movements as he said "Oh! Now when I move the triangle, if you move it up and down *{drags BT up-and-down}*, that one moves just up and down *{shows PT} [moves right hand back-and-forth]"*. Kevin' statement implied dynamism as he talked about the up-and-down motion of the triangles. Nathan began dragging BT, turning around several times and stretching it until the triangles got increasingly bigger or turning around and shrinking it until the triangles got increasingly smaller, while Kevin observed the screen. I had asked them to explore more, when the following discussion took place.

> **Excerpt 1.** *Case Kevin and Nathan, Activity 1 (BT: Blue Triangle; PT: Pink Triangle).*
>
> 1 *Kevin*: Ok! *{Drags BT stretching and shrinking the triangles two times}* Oh! May be, I think when you move the blue triangle that makes the blue triangle bigger and then also that makes the pink triangle bigger and it also moves?
> 2 *Researcher*: Yeah? What do you think Nathan?
> 3 *Nathan*: Whenever you make the blue triangle bigger *{drags BT stretching the triangles}* or smaller *{drags BT shrinking the triangles}*, they both are always equal, the same size *{drags BT turning around several times}*
> 4 *Researcher*: Yes? Can you show me that?
> 5 *Nathan*: *{Drags BT stretching the triangles, shrinking the triangles, turning around the triangles, stretching the triangles, shrinking the triangles, translating the triangles}*
> 6 *Researcher*: What do you think Kevin about what Nathan says?
> 7 *Kevin*: Um, well like *{observes what Nathan does on the screen}*, they're, yeah, they're always like the same size *{shows the triangles}* and they're, they both have the same lengths of edges *[extends two hands as horizontal parallel lines]*
> 8 *Researcher*: Can you show me that? I want to see
> 9 *Kevin*: Like they both, they both have the same lengths on the sides *{shows one side in PT; then shows the correspondent side in BT; then shows another side in PT and the correspondent side in BT; then shows the last side in PT and the correspondent side in BT}*

The Excerpt 1 shows that both children began inferring *two relationships between attributes* of the dynamic triangles such as same change of size and same type of movement, for instance when Kevin said "Oh! May be I think when you move the blue triangle that makes the blue triangle bigger and then also that makes the pink triangle bigger and it also moves?". They also discovered *two invariant relationships between attributes* of the dynamic triangles such as same change of size and same size,

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

for instance when Nathan said "Whenever you make the blue triangle bigger or smaller, they both are always equal, the same size"; or same size and same lengths of the edges as when Kevin said "they're always like the same size and they're, them both have the same lengths of edges". Kevin and Nathan' statements implied dynamism as they talked about the triangles' movements or about their changes of size, which are attributes of dynamic triangles. This dynamism mediated the discovery of the invariant relationship related to "same size", which was evidenced in the use of words such as "whenever", "always" or "also", along with the words "same" and "equal" to make explicit the condition that the triangles are always equal because of the same size, independently of the type of movement. Although they did not say "same shape", Kevin talked about the "same length of edges" as another attribute different from size. Moreover, further on Kevin was able to specify which were the equal edges by showing them by pairs of congruent sides in both triangles. The children found out what was invariance in the activity and were able to formulate these relationships in their own words as a permanent rule of the two triangles. The Excerpt 1 also shows that the use of the technology evolved from exploratory to demonstrative. The children accompanied their statements with actions of dragging and gestures (e.g. pointing out) intentionally directed to demonstrate to each other and me, as the interviewer, what they were thinking. A collaborative behavior was seen when Kevin built on and extended Nathan's idea about "same size" (Line 7).

Gestures Mediated the Co-Planning of Strategies to Create Congruent Triangles

The second relevant finding is that gestural expressivity mediated young children's collective planning of strategies to create congruent triangles within the DMGE. Children used gestures on the iPad to represent a congruent triangle and properties of congruent triangles. The Excerpt 2 is a discussion from Activity 3, Task 2 (Level II: Isosceles) in which Kevin and Nathan planned a strategy to make the green triangle (GT) identical to the purple triangle (PT, see Figure 1c).

Excerpt 2. *Case Kevin and Nathan, Activity 3a (PT: Purple Triangle; GT: Green Triangle)*

1 *Nathan*: (To Kevin) We can move the F down *[points out from GT's point F towards a place down on the grid in front of PT's point A]* and then the D, the E over here *[points out from GT's point E towards a place down on the grid in front of PT's point B]* and then the D over here *[points out from GT's point D towards a place down on the grid in front of PT's point C]*.

2 *Kevin*: We have to equal up as there *{shows that the Size Marker of the referent triangle PT is 27 cm.}* so, that one *{shows PT}* is 27 centimeters *{shows PT' Size marker}*, and that one…

3 *Nathan*: Yeah! 27, so we try to make it 27 *[nods]*

4 *Kevin*: That one is a little thinner so *{shows GT}* (Inaudible)

5 *Researcher*: How do you say Kevin?

6 *Kevin*: The purple triangle *{shows PT' Size Marker}* is like 27 centimeters *[extends 2 fingers on PT's area making a big space between fingers]* and that one is only 23.50 centimeters *[extends 2 fingers on GT's area making a smaller space between fingers]* and this one is a little skinnier *[extends 2 fingers on GT's area making a smaller space between fingers]*

7 *Researcher*: Yeah?

8 *Kevin*: Like it is skinnier *[extends two fingers on a thin area of a GT's angle leaving little space between fingers]* and then is a little fatter at the top *[extends two fingers on a wide area of a GT's angle leaving a wide space between fingers]* and then gets skinnier *[extends two fingers on another thin area of a GT's angle leaving little space between fingers]* and that one is a little fatter *[extends two fingers on a wide area of a PT's angle leaving a wide space between fingers]* than that one *[extends two fingers on a thin area of a PT's angle leaving little space between fingers]*.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

9 *Nathan*: It is skinnier over here *[extends two fingers on a thin area of a PT's angle leaving little space between fingers]* and fatter here, and then gets fatter *[extends two fingers on a wide area of another PT's angle leaving a wide space between fingers]*

10 *Kevin*: That one gets skinnier *[extends two fingers on an thin area of a GT's angle leaving little space between fingers]* and then gets skinnier again *[extends two fingers on another thin area of a GT's angle leaving little space between fingers]*. I just think that it's a little fatter *{shows PT}* than that one *{shows GT}*. We have to make it *{shows GT}* the same lengths *{shows 2 sides of PT}* and everything.

11 *Nathan*: Yeah! *[Nods]*

The Excerpt 2 shows how Nathan and Kevin explicitly discussed a strategy to create a congruent triangle before implementing it. The pre-planned strategy consisted of relocating the points of the GT and aligning them with the points of the PT (referent). Nathan used hand gestures to represent the trajectories of the three GT's points to become a congruent triangle as well as their new location on the grid just in front of the PT, displaying what I call an 'imagined' spatial representation of the new triangle. This representation implies dynamism, as it involves imagined trajectories of the points. It is also embodied, as Nathan used his fingers to show to Kevin the new positions of the points. It also implies informal processes of measuring, specifically, the estimation of distances among the points of the imagined triangle, and the alignment of the points of the two triangles. As a result, the imagined triangle had an approximate shape and size to the PT's shape and size. Kevin and Nathan also talked about another informal measuring component, equaling up the size of the two triangles through the use of tools such as the Size Markers of both triangles (Lines 2 & 3). When Kevin began talking softly about the triangles' attributes, I asked him to repeat what he said and he elaborated on his idea to explain it (Lines 4 & 5). The children began making explicit attributes of the referent and the non-congruent triangles by comparing them informally; for example, they compared their shapes using words such as "thinner", "skinnier" and "fatter". Simultaneously, they utilized hand gestures featured by the use of two fingers on the triangles and intended variation of the space between fingers, to represent the triangles' areas or the areas of their angles and to plan equaling up their sides' lengths (Lines 6, 8, 9 & 10). This process of co-planning the strategy revealed how children were aware of the relationships between attributes of the two triangles such as equal sizes and equal shapes. Uses of the technology were characterized by children's utilization of special tools to solve problems, for instance the grid to imagine the new triangle (Line 1), or the Size Markers to compare sizes (Lines 2, 3 & 6). Children were less explorative than in Activity 1; the use of their fingers was mainly demonstrative so that even without dragging they could represent both trajectories and properties of the triangles as discussed above. The Excerpt 2 also shows the emergence of a collaborative pattern to co-construct strategies. First, children proposed new ideas to each other, discussed actions of their strategy, and explained and justified their ideas demonstrating them to others through gestures (Lines 1, 6, 8, 9 & 10). Second, children built on each other's ideas. For instance, Kevin proposed an idea and Nathan adopted and extended it (Line 3 & 9), or Kevin expanded a Nathan's explanation and made a conclusion (Line10).

Informal Measuring as Mathematical Focus of the Co-Creation of Congruent Triangles

The third relevant finding is that young children used emergent informal ways of measuring as the mathematical focus to assure that two triangles had the same shape and size during the collective creation of congruent triangles. The Excerpt 3 presents a discussion from the process of implementation of Kevin and Nathan' strategy during Activity 3.

Excerpt 3. *Case Kevin and Nathan, Activity 3b (PT: Purple Triangle; GT: Green Triangle)*

1 *Nathan*: *{Re-locates GT's point F on the grid in front of PT's point A, slides GT's points D and E towards left, slides back them towards right and closes the space between them}*

2 *Kevin*: *{Looks at Size Markers}* No! Try to make them both fit *{shows Size Markers; then makes GT taller, opening space between points D and E}* (Triangle is tall but thin)

3 *Nathan*: Ok! *{Makes GT fatter opening space between point F and points E and D; then makes GT taller opening space between D and F}* (…)

4 *Kevin*: (…) We have to align all with that (to Nathan) *{shows the points in PT}*

5 *Nathan*: I'm trying to *{makes GT taller, opening space between points D and E}*

6 *Kevin*: Let's make it bigger *{shows GT}* (GT is on the top-right while PT is on the bottom-left)

7 *Nathan*: I'm doing it bigger *{smoothly slides point E up-and-down on the grid many times}*

8 *Kevin*: Move, move this one *{shows point D}*

9 *Nathan*: You can't move the D. It's a thing!

10 *Kevin*: *{Slides points F and D towards left on the grid}*

11 *Nathan*: 26 *{looks at GT, looks at Size Markers}* (PT or referent is 27 cm.)

12 *Kevin*: *{Slides points F and D back towards right}* I will move D *{Keeps sliding point D}*

13 *Nathan*: 28 *{looks at GT, looks at Size Markers, shows Size Markers}* You cannot move D!

14 *Researcher*: What are you trying to do?

15 *Kevin*: We are trying, we are trying to make it equal, so is like the same *{drags GT }*

16 *Nathan*: One more time *{superposes GT's point D on PT's point A, GT's point E on PT's point C, and GT's point F on PT's point B}*. Then I will move this one over here *{slides GT's point F on the same line of PT's point B locating F in front of B; slides GT's point D on the same line of PT's point A locating D in front of A}*

17 *Kevin*: That one, there it goes! *{Looks at Nathan moving D}* You wanna make it exactly the same?

18 *Nathan*: Yes! *{Slides GT's point E on the same line that PT's point C locating E in front of C. With finger verifies that C and E are aligned measuring distance among them, and adjusts E}*

19 *Kevin*: Yeah! *{Looks at GT and looks at Size Markers, shows Size Markers}* Not, not, move! Ok!

20 *Nathan*: *{Adjusts point F one square on the grid}* Yeah! (GT has the same shape)

21 *Kevin*: 27 centimeters! *{Looks at Size Markers}* Ok! (Size Markers show triangles are 27 cm.)

The Excerpt 3 shows that children implemented and enhanced the strategy they had planned. Their first attempt consisted of relocating the points of PT on the grid one by one. However, they aligned just one of the GT's points with one of the PT's points, using it as the only spatial reference to locate the other points (Line 1). Then they adjusted the sides while checking permanently the Size Markers (Lines 2-13). The triangles were approximate but not exact in shape and size. The first informal way of measuring emerged when Kevin proposed to align all the points of both triangles (Line 4), but children did not reach an agreement (Lines 6, 7, 8 & 9). When I asked them what they were trying to do (Line 14), Kevin had clear their goal as he said "we are trying to make it equal, so is like the same". Nathan also restarted the task suggesting that he was aware that their strategy did not assure that the triangles get the same shape and size (Line 16). Further on, three informal methods of measuring emerged. First, Nathan superposed all the points of GT onto the points of PT, which produced a congruent triangle (Line 16). Second, he dragged each point of GT towards right, one by one, using the x-axis of the grid to align the points of both triangles on the same grid lines (Lines 16 & 18). Third, he adjusted the sides, measuring with his finger the distances between the points of both triangles (Lines 18 & 20). Superposition of two triangles, alignment of the points of two triangles using the x-axis and estimation of distances with fingers between the points aligned are informal ways of measuring that allowed him to correctly equal up the length of all the sides. Kevin

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

was aware of the value of aligning, so he helped giving ideas and controlling the Size Markers (Lines 17, 19 & 21). The use of informal measuring and the regular monitoring of the Size Markers helped children construct a congruent triangle. The role of the technology was focused on the constructive use of the dragging tool and other tools provided to solve the task (e.g. Size Markers, grid, x-and-y axes). The collaborative pattern consisted of distributing and coordinating two functions: Nathan superposed, aligned, verified distances amongst and adjusted the points of GT while Kevin monitored the sizes of the two triangles in the Size Markers until they had equal shape and size. They also exchanged relevant information, suggesting ideas and building on each other's ideas.

Conclusions

This paper illustrated an educational strategy envisioned to cross borders among ages/grade levels for allowing young children in early childhood education (k-2) to access to complex concepts, such as congruence, that are traditionally taught at middle grades. The implementation of the strategy involving children's participation in activities designed in a DMGE, showed three relevant findings: (a) mediation of dynamism for discovering invariant geometric relationships between congruent triangles, (b) mediation of gestural expressivity for co-planning strategies to create congruent triangles, and (c) emergence of informal ways of measuring to assure that two triangles have the same shape and size. Children's collaborative patterns included the use of varied modes for conveying ideas (e.g. dragging actions, gestures), building on each other's ideas and distribution of tasks related to the exploration and the solution of the problems. Uses of the dragging tool had three functions: explorative, demonstrative and constructive. Children also used others tools such as the Size Markers and the grid. The implementation of DMGEs has critical implications for the learning of geometric concepts in both schools and informal settings such as afterschool programs.

FROM PROBLEM SOLVING TO LEARNING THEORIES: UNPACKING A THREE-STAGE PROGRESSION OF UNIT AREA ITERATION

Pingping Zhang
Winona State University
pzhang@winona.edu

Azita Manouchehri
The Ohio State University
manouchehri.1@osu.edu

Based on the findings of a larger study on middle school students' problem solving behaviors, we identified three sub-components for understanding the iteration of unit area in this paper: the mechanism of iteration, an identical unit, and the specificity of the identical unit. A three-stage progression on the acquisition of these components is elaborated through the analysis of the students' work.

Keywords: Learning Trajectories (or Progressions), Geometry and Geometrical and Spatial Thinking, Problem Solving

Background

The research community's knowledge on how individuals learn/understand mathematical concepts serves as an important resource when investigating problem solving processes. The findings of mathematical problem solving studies, in return, could serve as a foundational resource for developing learning theories. In our previous study on middle school students' problem solving behaviors, which was designed to reveal students' ways of knowing and thinking by unpacking the relationship among mathematical concepts, cognitive behaviors, and metacognitive behaviors (Zhang, 2010), we proposed a concept development framework for areas based on Vygotsky's (1962) concept formation theory, Berger's (2004) appropriation theory, and Battista's (2012) Cognition-Based Assessment (CBA) levels. The framework served as a platform for designing and analyzing problem solving interviews. One of the findings of the study suggested that the concept development framework of areas could be further refined to characterize sub-components to be more explicit as a guideline for teaching and studying this particular concept. This paper elaborates on a three-stage progression of the iteration of unit area based on the findings.

Theoretical Framework

Vygotsky's concept formation theory and Berger's appropriation theory were used as the structure of the proposed framework, while Battista's CBA levels served as a key reference for the specific stages along with the corresponding cognitive behaviors in the framework.

Vygotsky's theory proposes a framework for an individual's concept development within a social environment, while Berger's theory proposes an interpretation of Vygotsky's theory in the domain of mathematics by adjusting certain stages. Both theories break down any concept development into three phases: heap, complex, and concept. In the heap phase, the learner associates a sign with another because of physical context or circumstance instead of any inherent or mathematical property of the signs. In the complex phase, objects are united in an individual's mind not only by his or her impressions, but also by concrete and factual bonds between them. In the concept phase, the bonds between objects are abstract and logical.

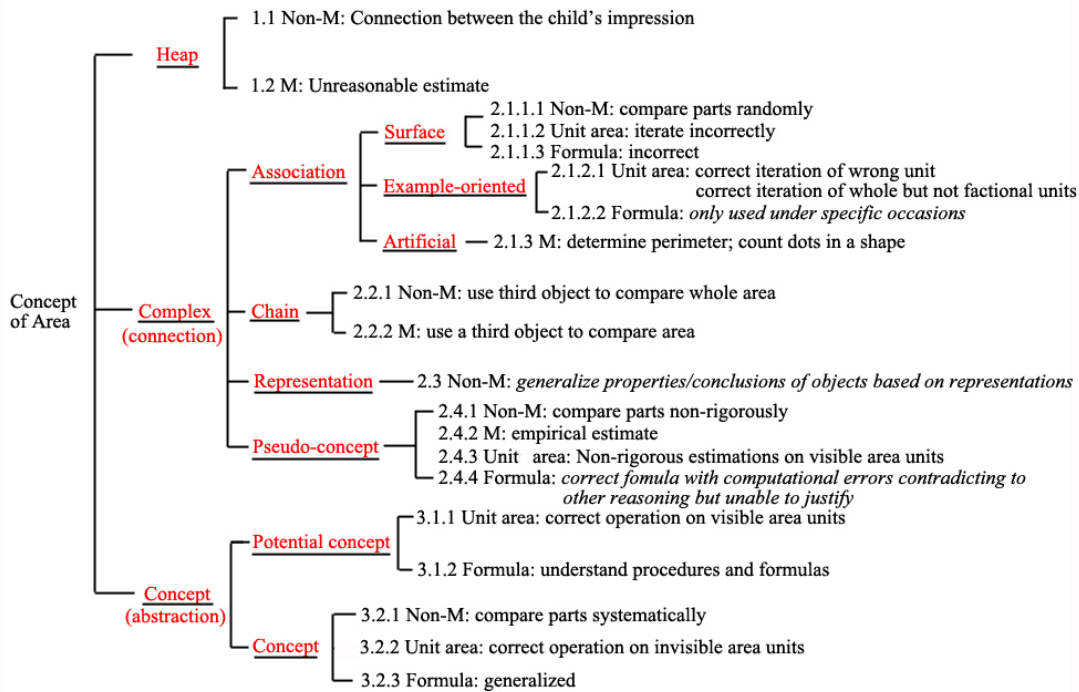
The formation stages for the target concept of study (the concept of area), guided by the two theories described above, are illustrated in Figure 1. The developmental stages were refined based on the pretest responses from 44 middle school students and guided the selection of the interview tasks as well as the analysis of the relationship among mathematical concepts, cognitive behaviors, and metacognitive behaviors emerged from the interview results.


Figure 1. Developmental stages of the concept of area.

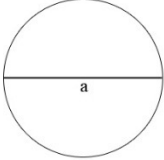
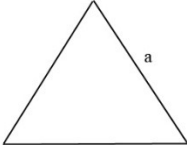
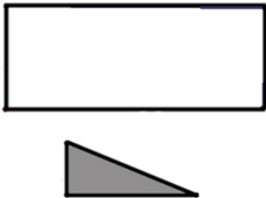
In the concept framework, there are three major components under the concept of area: non-measurement reasoning, unit area, and formula; this paper focuses on the unit area component. The specific stages involved in the progression of unit area iteration include: 2.1.1.2. Surface Association Complex – Unit area (iterate incorrectly), 2.1.2.1. Example-oriented Association Complex – Unit area (correct iteration of wrong unit and correct iteration of whole but not fractional units), 3.1.1. Potential concept – Unit area (correct operation on visible area units), and 3.2.2. Concept – Unit area (correct operation on invisible area units).

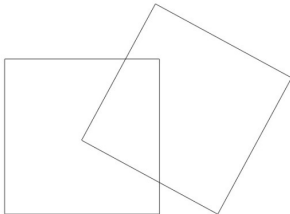
Methods

Participants

Five individuals from a population of 44 sixth grade students were selected to participate in interviews. A pretest was administered to the 44 students and each individual's developmental status revealed in the responses was categorized as "overall low" (all responses were rated as Heap and non-Pseudo-concept Complex stages), "varied" (responses were rated across Heap to Concept stages), and "overall high" (responses were rated as Pseudo-concept Complex and Concept stages). Among the five participants, one exhibited a low status, one exhibited a high status, and three exhibited varied statuses.








Instrument and Data collection

The five participants were interviewed individually. Each interview consisted of two parts. During the background interview part, the participants' mathematics background information, their beliefs about mathematics, and their views on the value of mathematics for their lives were elicited. During the second part, problem solving interviews, the participants worked on specific mathematical tasks, while interviewer interventions were limited to eliciting clarifications, explanations, or justifications when needed.

Five problems were used during the interviews. All problems were related to the concept of area and allowed the participants to tackle the tasks from different stages of concept development. The problems were designed to potentially cover a wide range of concept stages. The process and rationale of instrument design was reported in a previous paper (Zhang, Manouchehri, & Tague, 2015).

The students' working examples referred in this paper are from three out of the five interview questions, which are illustrated in Table 1.

Table 1: Interview problems

| **Compare areas problem** |
| Which of the regions shown below has the largest area? How would you order them? |

| **Shaded Triangle problem** |
| How many of the shaded triangles shown below are needed to exactly cover the surface of the rectangle? Please explain your answer. |

| **Intersected Area problem** |
| Two squares, each *s* on a side, are placed such that the corner on one square lies on the center of the other. Describe, in terms of *s*, the range of possible areas representing the intersections of the two squares. |

In the Shaded triangle problem, the measurement of the rectangle and the triangle was deliberately removed to test how the participants may solve the problem under this condition. The participants had been expected to determine or question the relationship (2:1 ratio) between the measures of the rectangle and the triangle.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Data analysis

Data analysis consisted of three aspects: concept stages, cognitive behaviors, and metacognitive behaviors. First, each participant's key cognitive behaviors during each problem solving episode were documented. Second, a summary of observed concept stages and metacognitive behaviors during the episode were catalogued and noted. Finally, a cross analysis of the observed concept stages, metacognitive behaviors, and the relationship between them concluded the analysis phase. This process was followed for each of the five tasks used.

Results

One of the findings indicated that the progression of the iteration of unit area included three components: *the mechanism of iteration, an identical unit,* and *the specificity of the identical unit.* The data suggested a specific order of stages for the acquisition of these components.

Stage 1 – understanding the mechanism of iteration

When an individual understands the *mechanism of iteration* yet is not able to visualize a given shape as the unit, s/he is at 2.1.1.2. Surface Association Complex – Unit area stage and would iterate different units (e.g. triangles of different shapes and sizes).

The findings suggested that an individual could have different visualization abilities for different shapes. For example, when solving the Shaded Triangle problem, a participant who was not able to visualize the given triangle as a unit, iterated 10 triangles with varied shapes and sizes to cover the entire rectangle (Figure 2). Being asked whether she could use a different approach to solve the problem, she rotated the triangle and formed a small rectangle as a unit, then she was able to correctly iterate the small rectangle as a unit to cover the entire rectangle (Figure 3).
Figure 2. Incorrect visualization of a triangle as a unit.
Figure 3. Correct visualization of a rectangle as a unit.

Stage 2 – understanding the mechanism of iteration and an identical unit

When an individual understands the *mechanism of iteration* and the *identical unit*, s/he is at 2.1.2.1. Example-oriented Association Complex – Unit area stage and could correctly iterate an identical (but not the given) unit.

When solving the Shaded Triangle problem, a participant who correctly iterated eight triangles in the rectangle (Figure 4) claimed that one could iterate differently as long as the total number of triangles was eight (as in Figure 5).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Tucson, AZ: The University of Arizona.
Figure 4. An individual's correct visualization of unit rectangles.

Figure 5. The same individual's Example-oriented Association Complex – Unit area reasoning.

This participant was not aware of the specificity of the identical unit, but he was able to justify the validity of the answer "eight triangles" and abandoned the numerical answer obtained by the correct formula which was 7.57 (the number was incorrect due to inaccurate measures). His Example-oriented Association Complex – Unit area level of understanding was not revealed until the end of the interview. It was triggered by the prompt of "can there be two answers to a problem?" which was intended to elicit his evaluation on the two different answers obtained from visual and formulaic approaches.

Stage 3 – understanding the mechanism of iteration, an identical unit, and specificity of the identical unit

When an individual understands the *mechanism of iteration*, an *identical unit*, and the *specificity of the identical unit*, s/he is at 3.1.1. Potential Concept – Unit area stage or 3.2.2. Concept – Unit area stage.

At the Potential Concept – Unit area stage, an individual is not required to (flexibly) define the area unit prior to the processes of decomposing (e.g. assigning proportional relation between partial squares and whole squares) and reconstructing (e.g. converting partial squares to whole squares) but relying on standard visible area units. For example, when solving the Compare Areas problem, a participant drew unit squares on the circle to find its area (Figure 6) since he forgot the area formula for circles.
Figure 6. A Potential Concept – Unit area reasoning.

While at the Concept – Unit area stage, an individual takes full control over the area units in terms of their shapes, sizes, orientations, and other properties during the restructuring. For example, when solving the Intersected Area problem, the participant defined the overlapping area (a quadrilateral) as her unit, iterated it three times to cover the entire square (Figure 7), and reached the conclusion that the intersected area is a quarter of the whole square.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 7. A Concept – Unit area reasoning.

Conclusion

Among the three components under the concept of area (non-measurement reasoning, unit area, and formula), we identified three sub-components for understanding the iteration of unit area: the mechanism of iteration, an identical unit, and the specificity of the identical unit. A specific order of the acquisition of these components was outlined through the analysis of the participants' work as the three stages in the previous section. Each stage corresponds to one or two stages in the concept framework.

Comparing to the four stages in the concept framework (Figure 1) and the progression of area-unit iteration outlined in CBA levels (Table 2), the proposed three-stage progression provides a more explicit conceptual breakdown of the iteration of unit area. In this way, more accurate assessments of students' knowledge can be developed and used, both in research and in the classroom.

Table 2: CBA levels for unit area iteration

Level	Sub-level	Description
M0		Student uses numbers in ways unconnected to appropriate area-unit iteration.
M1		Student incorrectly iterates area-units.
	M1.1	Student iterates single area units incorrectly.
	M1.2	Student decomposes shapes into parts incorrectly.
	M1.3	Student iterates area-units incorrectly, but eliminates double-counting errors.
M2		Student correctly iterates all area units one by one.
	M2.1	Student correctly iterates whole units, but not fractional units.
	M2.2	Student correctly iterates whole units and simple fractional units.
M3		Student correctly operates on composites of visible area-units.

Both concept development theories and learning progressions emphasize the non-hierarchical nature of their stages and levels, i.e., individuals may jump around the stages/levels without

following a specific order (Smith et al., 2006). Whether the three sub-components can be acquired in different orders remains to be examined by future studies.

TEACHERS' RECOGNITION OF THE DIAGRAMMATIC REGISTER AND ITS RELATIONSHIP WITH THEIR MATHEMATICAL KNOWLEDGE FOR TEACHING

Nicolas Boileau	Justin Dimmel	Patricio Herbst
University of Michigan	University of Maine	University of Michigan
nboilea@umich.edu	justin.dimmel@maine.edu	pgherbst@umich.edu

We examine responses from a national sample of high school mathematics teachers to a questionnaire, which had been developed to study teachers' recognition of a system of hypothesized norms that stipulate that geometry proof problems are to be posed using a diagrammatic register. We report on the psychometric properties of the questionnaire, as well as the relationship between these mathematics teachers' mathematical knowledge for teaching geometry (MKT-G) and their stances on breaching those norms. Although Herbst et al. (2013) hypothesized that the system consisted of five distinguishable sub-norms, the factor structure of the questionnaire suggested that two of those norms might not truly be distinguishable. We also found a positive and significant relationship between teachers' MKT-G and their stances on breaching two of the determined components of the system of norms.

Keywords: Geometry and Geometrical and Spatial Thinking, High School Education, Reasoning and Proof, Measurement

Behavior in social situations involves participants negotiating their way around norms-- ways of behaving in a given social situation that are routine and tacitly expected by those familiar with that situation. Norms are unremarkable when complied with, but elicit comment when breached (Garfinkel, 1963). Our group has been working on bringing these ideas to scale by using visual representations of instructional situations in the context of online questionnaires. This paper reports on a piece of such work, following earlier investigations of the diagrammatic register in geometry proofs (Herbst, Kosko, & Dimmel, 2013).

The present study tests the psychometric properties of Herbst et al.'s (2013) DRN (a.k.a., N3) instrument. We conjectured that teachers with higher MKT-Geometry scores (see Herbst & Kosko, 2014) might be more likely to strategically breach a norm of the diagrammatic register. We examined covariation between the DRN data and data collected with the MKT-G instrument. This work is significant as any efforts to improve mathematical practices in classrooms must come to terms with the norms that undergird ordinary practice (Cobb, Zhao, & Dean, 2009) and because the results suggest that increasing mathematical knowledge for teaching geometry might provide resources for teachers to depart from the norms of ordinary practice.

Theoretical Framework

Our work builds theory to describe the work of teaching. We assume that describing the work of teaching mathematics requires attention to the specificity of the subject matter transactions between students and teacher. To operationalize such specificity we model the transactions between particular items of subject matter knowledge and the tasks in which students can lay claim to them. *Instructional situations* (e.g., doing proofs, solving equations; Herbst, 2006) are modeled by articulating sets of norms that describe what teacher and students are expected to do in those tasks and what knowledge and skills the accomplishment of the task counts toward. The diagrammatic register norm states that proof problems are presented in a diagrammatic register. Herbst et al. (2013) decomposed it into five sub-norms: (SN1) Properties: The statement of the problem does not make explicit properties of betweenness, intersection, separation, collinearity, or concurrency, which are left for the diagram to communicate; (SN2) Diagram: The teacher provides a diagram for students to use while doing the proof; (SN3) Labels: The teacher assigns a proof problem with an

accompanying diagram where all the points needed in the proof are labeled (but not necessarily all points); (SN4) Statement: The proof problem is stated using symbols and labels for elements of a diagram; (SN5) Accuracy: When a teacher provides a diagram accompanying a proof problem, the diagram is accurate.

These norms describe the defaults for setting up problems in the situation of doing proofs, they do not necessarily describe what would be optimal for student learning. Arguably, it would enrich the mathematical experience of students if they could be expected to do themselves what ordinarily would be done by the teacher. Various questions can be asked that contribute to this theory: To what extent do teachers consider adherence to the various aspects of this norm to be appropriate (in comparison with alternatives that might also be compelling)? And: To what extent is mathematical knowledge for teaching geometry related to a teacher's disposition to deviate from these norms?

Methods

Data

As described by Herbst et al. (2013), the DRN instrument (a.k.a., the N3 instrument) contains 30 items that target the 5 sub-constructs of the diagrammatic register norm. Each item asks participants to compare the appropriateness (using a 6-point Likert-like closed response format) of two possible ways of setting up a proof problem: one that we conjecture to be normative and another one that breaches one of the sub-norms (but is otherwise normative). Eight items were designed to measure SN1, five to measure SN2, five to measure SN3, five to measure SN4, and seven to measure SN5. The MKT-G instrument has been described at length by Herbst and Kosko (2014).

The DRN and MKT instruments, as well as a background survey that included a question about participants' years of experience teaching geometry, were administered as part of a larger study to a nationally-distributed sample of high school mathematics teachers, using the Lesson*Sketch* online platform. Participants were randomly sampled from more than 10,000 public secondary schools in the United States, identified using the NCES 2012-2013 School Universe data set. The effective sample of those who completed the background survey, the DRN, and the MKT-G instruments was 300 high school mathematics teachers. The minimum number of years of experience teaching high school geometry that any teacher in the sample had was 1, the maximum was 35, the mean was 6.75, and the standard deviation was 5.96.

Measures

Diagrammatic register norm endorsement. To determine whether the items that are in the DRN instrument measured five distinguishable sub-norms, we conducted an exploratory factor analysis (EFA), after recoding certain items so that high values in the scale of each item indicated departures from the norm. We split the sample into two random sub-samples, then conducted an EFA using the first and a CFA using the second (for more information on this approach, see Duffy, et al., 2012). Once we had determined the factor structure of the items, we created factor scores by taking the mean of each participant's rating of the items that loaded onto each factor. We also created a DRN total score by taking the mean of a participant's ratings of all 30 items. Finally, we calculated alpha scores and average inter-item correlations (IIC) to determine the internal consistency of the set of items in each factor.

Mathematical knowledge for teaching geometry (MKT-G) scores. We used a two-parameter Item Response Theory (IRT) model to create MKT-G scores, after removing four items that the Item Characteristic Curves (ICC) suggested would not discriminate well between individuals. The minimum MKT IRT score was -2.20, the maximum was 2.17, the mean was -0.0000043, and the standard deviation was 0.902.

Analysis

An Ordinary Least Squares (OLS) regression model was then created, in which the DRN total score was regressed on the MKT IRT score and participants' years of experience teaching geometry. After finding that the relationship between the MKT-G score and DRN total score was statistically significant, even when controlling for years of experience teaching geometry, we decided to create four other similar stepwise OLS regression models, each of which used one of the DRN factor scores, rather than DRN total score, as the outcome variable. This was done in order to understand whether participants' stance on breaching the DRN was dependent on which of the sub-norms was breached.

Results

In terms of the EFA, we considered both the criterion of retaining factors with eigenvalues larger than 1 (Kaiser, 1960) and the criterion of retaining components above the point of inflection on a scree plot (Cattell, 1966), as well as factor loadings and fit statistics. Together, these suggested that four factors undergird the DRN instrument. The CFA confirmed that structure to the extent that no standardized item loading was less than 0.3 in the CFA and the fit statistics were reasonable - RMSEA: 0.066, CFI=0.853, TLI=0.841, SRMR=0.091, just short of the typical cut-points of RMSEA<=0.05, CFI>=0.95, TLI>=0.95 and SRMR<=0.6 (Hu and Bentler, 1999). According to that model, the items that were designed to target SN1, SN3, and SN5 loaded onto three factors, in the way that they were expected to. However, the items designed to target SN2 and SN4 loaded onto the same factor. We will hereafter refer to those factors as S1:PRO, S3:LAB, S5:ACC, and S2S4:DNS, respectively.

The means of the DRN total score, SI:PRO, S2S2:DNS, S3: LAB, and S5:ACC scores (described earlier) were 2.86, 3.32, 2.56, 3.38, and 2.42, respectively. The standard deviations of those scores, in the same order, were 0.54, 0.94, 0.89, 0.56, and 0.78. Cronbach's alpha for the DRN total score and each of the factor scores ranged from 0.6909 and 0.8522, and their average inter-item correlations (IIC) ranged from 0.1723 to 0.4344, both of which suggest that the entire set of items as well as the set of items that loaded onto each factor had good internal consistency (Clark & Watson, 1995).

The main take-away from the regression models is that there is a significant, positive association between teachers' comfort with breaches of the DRN and their MKT-G, which seemed to be due to the also significant and positive association between their MKT-G and comfort with breaches of the S2S4:DNS and S3:LAB components of that norm, independent of their years of experience teaching geometry. When the DRN total score was regressed on MKT and years of experience teaching geometry, the MKT regression coefficient and associated standard error were 0.14 and 0.04. When the S2S4:DNS score was used instead they were 0.36 and 0.06. When S3:LAB score was used, they were 0.08 and 0.04.

Discussion

A main finding of this study is the discovery of the somewhat unexpected, but nonetheless comprehensible, factor structure of the DRN instrument. Another is the discovery of relationship between teachers' endorsement of the diagrammatic register norm (as well as two of its subnorms) and their level of MKT. Upon reflection, we imagine that SN2 and SN4 items loaded onto the same factor because all of our proof problems that complied with SN4 (the expectation that the proof problem will be stated using symbols and labels for elements of a diagram) included a diagram and, therefore, complied with SN2 (the expectation that the teacher will provide a diagram for students to use while doing the proof).

In terms of MKT being a significant predictor of S2S4:DNS and S3:LAB, but not S1:PRO or S5:ACC, we would argue that understanding this result also requires careful consideration of each of the 5 subnorms. For example, we would expect that the Accuracy subnorm (SN5) was fairly easy to

recognize, regardless of one's MKT, as there is a sense among teachers that even accurate diagrams can be misleading, and so providing inaccurate diagrams could make something that is to be regarded with suspicion even more problematic. SN1 (properties) deals with subtle issues of positioning. On the other hand, SN2 and SN4 are arguably more directly related to the kind of mathematical knowledge teachers readily have.

LONGITUDINAL PREDICTIONS OF SIXTH-GRADE GEOMETRY KNOWLEDGE

Emily R. Fyfe   Bethany Rittle-Johnson
University of Wisconsin-Madison   Vanderbilt University
efyfe@wisc.edu   bethany.rittle-johnson@vanderbilt.edu

In the current study, we examined the contributions of shape and pattern knowledge at four early time points to formal geometry knowledge in sixth grade within a longitudinal sample of over 500 low-income children. Shape knowledge at the beginning of pre-k predicted geometry in sixth grade, over and above general math and cognitive skills. However, at the end of pre-k, kindergarten and first grade, pattern knowledge was a unique predictor of later geometry, and shape knowledge was not. Results highlight the important roles of two important, but understudied components of math knowledge – early shape and pattern skills – and their contributions to the development of formal geometry knowledge.

Keywords: Geometry and Geometrical and Spatial Thinking, Learning Trajectories, Standards

Introduction

Mathematics knowledge begins to develop at a young age, and this early math knowledge matters. General math skill in pre-k and kindergarten predicts math achievement across primary and secondary school (Watts, Duncan, Siegler, & Davis-Kean, 2014). Research is now needed to identify *specific* early math skills that help predict and improve later achievement in specific math areas. Many theories of mathematics focus on the development of numeracy knowledge, that is, skills necessary for understanding numbers and number relations (see Sarama & Clements, 2004). However, math knowledge extends beyond numeracy knowledge. The goal of this research is to focus on two important, but understudied, components of math – early shape and pattern knowledge – and test their contributions to formal geometry achievement in middle school.

Exploring shapes and patterns is a common mathematical activity for young children (Ginsburg, Lin, Ness, & Seo, 2003) and may be an important contributor to general math development. Knowledge of shapes and their properties is considered foundational to later geometric thinking (National Research Council, 2009) and is included in the Common Core State Standards for Mathematics as early as kindergarten (CCSSM; National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA & CCSSO], 2010). Children first learn to classify typical shapes and then to describe the definitional features of both two- and three-dimensional shapes. According to the learning trajectory theory, these shape skills form the building blocks for later geometry achievement (Clements, Wilson, & Sarama, 2004). However, no evidence to date links early shape knowledge to later math outcomes, including knowledge of geometry.

Pattern knowledge includes the ability to identify, extend, and describe predictable sequences in objects or numbers, and it has been recognized by math education researchers as a core skill for mathematical thinking (Papic, Mulligan, & Mitchelmore, 2011; Warren & Cooper, 2007). The first type of pattern young children engage with are repeating patterns, such as the colors red-blue-red-blue-red-blue. Children's knowledge of repeating patterns becomes systematically more sophisticated from pre-k to kindergarten (Rittle-Johnson, Fyfe, Loehr, & Miller, 2015), and several school-based interventions have shown that instruction on repeating patterns supports general math achievement at the end of the school year (e.g., Kidd et al., 2014). However, patterns are not included in the Common Core State Standards at any grade level, and thus receive little attention.

Method

Participants were drawn from a longitudinal study. The sample included 513 low-income children originally recruited at the beginning of their pre-kindergarten year in the U.S. (56% female,

80% black). Children were initially assessed at four early time points: beginning of pre-k (*M* age = 4.4 years), end of pre-k (*M* age = 5.0 years), end of kindergarten (*M* age = 6.1 years), and end of first grade (*M* age = 7.0 years). These children were re-assessed five years later when most students were near the end of sixth grade (*M* age = 12.1 years, 17% had been retained a grade and were in fifth grade). Students were distributed across 51 middle schools.

The outcome measure of interest (administered in sixth grade) was the *Geometry* subtest from the KeyMath 3 Diagnostic Assessment (Connolly, 2007), a standardized math test. The geometry subtest measures a student's spatial reasoning as well as his ability to analyze, describe, compare, and classify two- and three-dimensional shapes.

For early math predictors (administered in pre-k, kindergarten, and first grade), we assessed children's early *shape and pattern knowledge*, which were measured using items from the Research-based Early Math Assessment (Clements, Sarama, & Liu, 2008). Table 1 provides example items. Shape items (*n* = 14 – 23 depending on time point) focused on identifying, creating, and defining shapes. Pattern items (*n* = 4 – 7) focused on copying, extending, or identifying patterns made out of colored shapes or cubes. We also assessed children's general math achievement using the *quantitative concepts* and *applied problems* subtests from the Woodcock Johnson Achievement Battery III (Woodcock, McGrew, & Mather, 2001). Quantitative concepts assesses the knowledge of basic math concepts, symbols, and vocabulary. Applied problems assesses the ability to analyze and solve various math problems.

Table 1: Example items from the early shape and pattern knowledge subscales

Knowledge Subscale	REMA Item #	Item Description
Shape Knowledge	N05	Given a mat with 26 different shapes on it, the child is asked, "Can you point to all the triangles?"
	NG6	"Is this shape a square? How do you know?"
Pattern Knowledge	G04	The child is shown an ABA_AB pattern and asked, "Can you find the missing piece in this pattern?"
	G30	The child is shown an ABBABB shape pattern. "Make the same kind of pattern here, using these blocks."

We also assessed four non-math predictors to control for general cognitive and academic skills. These included a measure of early *reading* skill (The Woodcock Johnson Letter-Word Identification), a measure of *narrative recall* that varied by time point (the Renfrew Bus Story or the Woodcock Johnson Story Recall), and teacher ratings of *work-related skills* (Cooper-Farran Behavioral Rating Scale;), and *self-regulation* (using the Instrumental Competence Scale).

Results

Reflective of the disadvantaged nature of the sample, age- and grade-equivalent scores on the KeyMath geometry assessment indicated that students were approximately two years behind in geometry. Recall, the assessment was administered near the end of sixth grade when students were an average of 12.1 years old. However, the average grade-equivalent score in this sample was 4.8 (*SD* = 2.1) and the average age-equivalent score was 9.5 (*SD* = 2.0).

In the early years, children's shape and pattern knowledge increased from pre-k to first grade. For example, at the beginning of pre-k, children solved an average of 3.3 shape items and 0.6 pattern items correctly. By the end of first grade, children solved an average of 9.4 shape items and 3.7 pattern items correctly. At each of the four early time points, scores on the shape and pattern

subscales were moderately correlated with geometry knowledge in sixth grade (for shape scores, rs = .34 – .45, ps < .001; for pattern scores, rs = .25 – .49, ps < .001).

The primary goal was to test whether shape and pattern knowledge at early time points predicted formal geometry knowledge in sixth grade, after controlling for other general math and non-math skills. We ran multi-level regression models at each early time point with students nested in their sixth-grade schools. The results are presented in Table 2.

Table 2: Longitudinal predictions of geometry knowledge in sixth grade

	Predicting Geometry in Sixth Grade From Four Early Time Points			
	Beginning of Pre-K	**End of Pre-K**	**End of Kindergarten**	**End of First Grade**
Math Predictors

Control Variables	Included	Included	Included	Included

Note. All models include these control variables: age in sixth grade, current grade level, gender, ELL status in pre-k, ethnicity, pre-k school type (public or Head Start), and socio-economic status (respondent's education level and income level). *p < .05. **p < .01. ***p < .001.

First, we showed that past findings on the importance of early math to later achievement generalize to later geometry. Specifically, across all early time points, children's scores on the quantitative concepts and applied problems tests predicted their sixth-grade geometry knowledge (βs = .13 – .30). Second, the contributions of general math knowledge to sixth-grade geometry were often substantially stronger than the contributions of general cognitive/academic skills, including reading, narrative recall, work-related skills, and self-regulation.

Third, the contributions of early shape and pattern knowledge differed. At the beginning of pre-k, shape knowledge was a significant predictor of sixth-grade geometry knowledge (β = .16, SE = .05, p < .05). However, at the three remaining time points (end of pre-k, end of kindergarten, and end of first grade), pattern knowledge was a significant predictor (βs = .11 – .25), and shape knowledge was not. For example, at the end of pre-k, a one standard deviation increase in pattern knowledge was associated with a quarter of a standard deviation increase in sixth-grade geometry knowledge (β = .25, SE = .05, p < .05), over and above controls. As a note, if we excluded patterning from the model, shape was still not a significant predictor at the end of pre-k or kindergarten, but it was a significant predictor in first grade (β = .13, SE = .04, p < .05).

Conclusion

We evaluated the role of two non-numeracy math skills – shape and pattern knowledge – in the development of geometry achievement. We found that shape knowledge was only predictive prior to formal schooling (at the beginning of pre-k). However, early pattern knowledge from the end of pre-k to first grade consistently predicted middle school geometry knowledge over and above

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

general math and cognitive skills. These results are consistent with recent research foregrounding the importance of early patterning skills, including intervention work that found a preschool patterning intervention led to greater numeracy knowledge at the end of kindergarten than typical preschool instruction (Papic et al., 2011).

These findings provide some limited support for the learning trajectory theory that suggests early shape knowledge is foundational to later geometry knowledge (Clements et al., 2004). However, they also suggest a more prominent role for patterning. Indeed, the current Common Core State Standards include shape knowledge as a key component as early as kindergarten, yet fail to include pattern knowledge at any grade level. Contrary to these recommendations, the current results suggest that math standards should include repeating pattern knowledge in kindergarten and first grade (i.e., copying, extending, and identifying predictable sequences), and that more research is needed on the importance of shape knowledge.

COMMON CORE GEOMETRY TEXTBOOKS: OPPORTUNITIES FOR REASONING AND PROVING

Jenifer Hummer
University of Delaware
jhummer@udel.edu

Reform efforts in the U.S. have placed an emphasis on reasoning and proving. Yet, previous geometry textbook analyses have found limited opportunities for reasoning and proving and lack of opportunities to engage students in high levels of rigor. This analysis investigated how purported Common Core aligned textbooks address standards about proving geometric theorems. Like previous studies conducted with pre-Common Core textbooks, the findings for opportunities to construct proofs and engage students in high levels of rigor were less than expected. These findings suggest that publishers and practitioners need to ensure that students are given adequate opportunities to construct proofs and gain conceptual understanding.

Keywords: Curriculum Analysis, Reasoning and Proof, High School Education, Standards

Engaging in proving is essential to the practice of mathematicians (Herbst & Brach, 2006; Otten, Gilbertson, Males, Clark, 2014), and mathematics educators have suggested that reasoning and proof should play a role throughout all of mathematics curriculum (Herbst & Brach, 2006; Thompson, Senk, & Johnson, 2012; Sears & Chávez, 2014). Despite these recommendations, proof is predominately found in high school geometry courses and textbooks (Otten et.al., 2014). Teachers observed using conventional geometry textbooks, "adhered to the pedagogical suggestions and implemented proof tasks as presented in the teacher's edition of the textbook" (Sears & Chávez, 2014, p. 774). Yet some teachers have claimed that geometry textbooks may impede the instruction of proofs (Cirillo, 2009). This is important because some research has suggested that textbooks may have more impact in mathematics classrooms than in other content areas (Remillard, 2005). Thus analysis of high school geometry textbooks may provide insight to the extent proof is included within secondary classrooms.

Commenting across a set of studies, Cai and Cirillo (2014) noted that mathematics textbooks are lacking in opportunities for students to engage in reasoning and proving. In an analysis of six U.S. secondary geometry textbooks, less than 10% of the student exercises required students to construct proofs, and most were about "particular mathematical statements rather than general statements" (Otten, et.al., 2014, p.71). In two conventional high school geometry textbooks, Sears and Chávez (2014) found that 128 out of 977 and 79 out of 1066 tasks were proof tasks; of the proof tasks 15% and 13% respectively required "higher level demands (doing mathematics)" (p. 774). These findings are troubling given the expectation for students to learn proof in geometry. The Common Core State Standards for Mathematics (CCSSM) (National Governors Association Center for Best Practices & Council of Chief State School Officers [NGAC & CCSSO], 2010) sustain the emphasis on proof, and require higher cognitive reasoning skills (Porter, McMaken, Hwang, & Yang, 2011). Here the analysis sought to answer the following research questions: 1. To what extent do purported CCSSM-aligned geometry textbooks provide reasoning and proving opportunities as suggested by CCSSM geometry standards about "proving geometric theorems?" 2. To what extent do CCSSM-aligned geometry textbooks provide opportunities for high levels of rigor as required by CCSSM shifts?

Method

Two textbooks were analyzed for this study. Engage New York Geometry (Engage NY) was developed by educators in New York State after the CCSSM were developed. The Pearson Common Core Geometry Edition (Pearson) is a conventional textbook which was adapted to the CCSSM.

These two books were chosen due to limited curriculum analysis on CCSSM textbooks—Engage NY has not been included in the above studies. Additionally, both of these textbooks have the potential to reach a wide audience throughout the United States.

Eleven lessons from Engage NY and 15 lessons from Pearson were coded for topics in CCSSM about proving, reasoning and proving, and level of rigor. These lessons were selected based on the publishers' assignment of the standards "Prove Geometric Theorems": HSG.CO.C.9-11(NGAC & CCSSO, 2010) to particular sections. These particular standards require students to prove theorems about lines, angles, triangles, and parallelograms. Focusing on lessons that address standards about proving may provide insight into how CCSSM textbooks are providing activities that engage students in proof construction. Specifically, items within the exposition and student exercises were analyzed—including items intended to be read or completed by the student within sections (lessons) of a chapter. Chapter introductions, mid-chapter reviews, end of chapter reviews, and assessments were excluded.

Analytical Framework

The analytic framework had three dimensions. The methodology and framework was inspired by the Surveys of Enacted Curriculum (SEC) Methodology in which curricula is measured for CCSSM alignment based on content match, expectations for student performance, and instructional content (Martone & Sireci, 2009).

The first dimension of the framework determined how much of the text directly addressed content in Common Core Standards HSG.CO.C.9-11 by identifying items that may give opportunities to engage in activities related to lines and angles, triangles, and parallelograms.

The second dimension adapted from Otten et.al. (2014) investigated ways in which the standards items may provide opportunities for reasoning and proving, hereby denoted as the hyphenated reasoning-and-proving. Types of statements—general, particular, or general with particular instantiation, were analyzed. The exposition was analyzed for types of justifications—deductive arguments, examples, or left to the students. The student exercises were analyzed for types of reasoning-and-proving activities such as developing a proof, developing non-proof arguments, determining truth values, and conjecturing.

Additionally, in order to account for recommendations of Common Core, the third dimension indicated levels of rigor. The development of this dimension drew from three sources: Educators Evaluating the Quality of Instructional Products (About EQuIP, 2012) rubric, SEC criteria for cognitive demand (SEC, 2015), and Smith and Stein (1998) levels of cognitive demand.

<div align="center">Results</div>

Dimension 1 Analysis: Addressing Topics in the Standards

Individual exercises may have received individual codes at the statements level. Thus most of the data analysis refers to "statements." As expected, the findings indicated that most student exercises addressed topics within the chosen CCSSM—99.5% in Engage NY and 94.5% in Pearson. In both textbooks most of the statements addressed topics in theorems about lines and angles or parallel lines and transversals and had less emphasis on theorems about triangles and parallelograms. Additionally, Pearson had several statements that addressed theorems about triangles and parallelograms that were not specified within the standards. The uneven distribution and focus of topics may indicate a lack of alignment to the standards.

Dimension 2 Analysis: Reasoning-and-Proving Opportunities

Given the focus of this analysis on lessons about proving geometric theorems, opportunities for engaging in reasoning-and-proving seemed relatively low-- 48.47 % and 48.8% of statements in Engage NY and Pearson, respectively, addressed reasoning-and-proving.

Reasoning-and-Proving in the Student Exercises. Four types of reasoning-and-proving activities were most common in both textbooks, construct a proof, develop a rationale, investigate a statement (truth of claim), and make a conjecture. However, the distribution of activities contrasted greatly within both textbooks. For example, the highest percentage, 23.39%, of the activities in Pearson focused on developing a rationale or non-proof arguments. Whereas Engage NY had the highest percentages in making conjectures (including filling in the blanks of conjectures), 21.74%, followed closely with 19.75% of the activities focused on constructing proofs. Table 1 indicates the most frequent statement and activity types in both textbooks.

Table 1: Reasoning-and-Proving in the Exercises--Types of RP Activities

Textbook	Statements	RP Statements	RP Statements (%)	Construct a Proof (%)	Develop a Rationale (%)	Investigate a Statement (%)	Make a Conjecture (%)
Engage NY	253	125	49.41	19.76	5.93	0.40	21.74
Pearson	838	392	46.78	6.09	23.39	7.40	5.73

Opportunities for Constructing Proofs. Despite expectations for these lessons to focus on proof, this analysis had similar findings as Otten et. al. (2014). This investigation found that most of the proofs in the student exercises required students to construct proofs about particular statements. Pearson's construct a proof statements consisted of only 6.09% total; 4.65% of those statements required students to construct proofs about particular statements. Engage NY provided more opportunities for students to construct proofs 19.76%, but 14.62% of them were about particular statements, rather than general statements.

Dimension 3 Analysis: Levels of Rigor

The third dimension identified which exercises and statements fell into four levels of rigor: memorization (first level), procedural skill and fluency (second level), conceptual understanding (third level), and application (fourth level). (See Table 2)

Table 2: Levels of Rigor—Percentage of Statements

Textbook	Memorization		Procedural Skill and Fluency		Conceptual Understanding		Application	
	All	Proof	All	Proof	All	Proof	All	Proof
Engage NY	15.65	0	42.75	10	37.40	86	1.91	6
Pearson	42.27	0	63.90	5.9	18.32	94.10	0.21	0

Most of the statements in both textbooks were determined to be procedural skill and fluency. Many of the exercises required computational procedures, following procedures, or completing problems that were similar to worked examples. The majority of statements in Engage NY received procedural skill and fluency and conceptual understanding codes—42.75% and 37.40% respectively. Pearson's statements were mainly assigned to memorization or procedural skill and fluency—42.27% and 63.90% respectively. Neither textbook emphasized the highest level, application activities—such as conjecturing and constructing proofs of general statements.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

The findings for reasoning-and-proving opportunities indicated that each lesson contained less than five problems that required students to engage in constructing proofs. This may be sufficient to develop deep understanding. However most proof writing problems were determined to provide conceptual understanding versus application level of rigor. Within construct a proof activities, 86% of Engage NY and 94.1% of Pearson's statements were assigned to conceptual understanding. Only 6% of Engage NY construct a proof statements were application level and none of Pearson's construct a proof statements.

Conclusion

The findings in this study indicate that CCSSM textbooks follow the trend found in earlier textbooks of limited reasoning-and-proving opportunities, and may not be providing a level of rigor that will develop deep understanding. Curriculum developers need to consider several elements when writing standards based curriculum. Simply adapting textbooks to new standards does not ensure standard alignment. School leaders and teachers may need to supplement CCSSM textbooks with tasks that give students more reasoning-and-proving opportunities at high levels of rigor. If curriculum developers and textbook companies do not adhere to recommendations of standards, reform efforts may not have their intended impact.

Additionally, the analytical framework developed in this study contributes to consistency within curriculum analysis about reasoning-and-proving by adapting a previously used framework. The additional dimensions for standard alignment and level or rigor provide a holistic approach to analyzing Common Core textbooks—making this a valuable framework that may be applied to additional lessons and Common Core geometry textbooks. That is adapting dimension one would allow for investigations of other standards about proving. Research about enacted curriculum in classrooms using these textbooks could investigate the impact that reform efforts are having within the classroom (Remillard, 2005).

JUST GO STRAIGHT: REASONING WITHIN SPATIAL FRAMES OF REFERENCE

Hwa Young Lee
University of Georgia
hylee00@uga.edu

In this report, I present differences in two ninth grade students' reasoning within frames of reference in spatial contexts and their coordination of measurements in organizing two- or three-dimensional space.

Keywords: Geometry and Geometrical and Spatial Thinking, Cognition, High School Education

Although coordinate systems are often considered representational tools for reasoning about quantities, little focus is given to students' construction of coordinate systems or their ways of reasoning within frames of reference. Joshua, Musgrave, Hatfield, and Thompson (2015) pointed to the lack of literature conceptualizing frame of reference and discussed the mental actions that are involved in coordinating or combining multiple frames of reference in terms of quantitative reasoning (Thompson, 2011). I distinguish between the construction of coordinate systems to fulfill either of two goals: 1) *spatial organization*, which is to re-present space by establishing a frame of reference and locating points within the space using coordinated measurements; or 2) *quantitative coordination*, which is to coordinate sets of quantities by establishing a frame of reference and obtaining a representational space using geometrical objects. This report presents data from a teaching experiment with ninth grade students to illustrate differences in students' reasoning within frames of reference in their spatial organization. More specifically, I discuss how the students' spatial frames of reference were coordinated to define directionality and used to coordinate measurements in organizing space.

Theoretical Orientation and Constructs

Finding it important to attend to how students construct their mathematical knowledge, I orient my work in modeling students' constructive activities with a focus on schemes and operations (von Glasersfeld, 1995). In discussing the construction of coordinate systems I use Piaget and Inhelder's (1967) distinction between perceptual space and representational space: Perceptual space is constructed in a figurative sense through sensorimotor and perceptual activity on elements of raw material; representational space is constructed through the interiorization of perceptual space entailing a symbolic function in which the individual could regulate spatial behavior in a systematic way. I also adopt Saldanha and Thompson's (1998) notion of a "*tight coupling*" of two quantities which enables one to track "either quantity's value with the immediate, explicit, and persistent realization that, at every moment, the other quantity also has a value" (p. 299); hence, resulting in a multiplicative object of two quantities co-varying.

Methodology

A two-year teaching experiment (Steffe & Thompson, 2000) was conducted at a rural high school in the southeastern US with two pairs of ninth grade students. In this report I discuss two students, Kaylee and Morgan, and their engagement in two tasks from this teaching experiment to present how they each constructed frames of reference and coordinated measurements in locating points or defining the motion of one point to another in two- or three-dimensional spaces. Kaylee and Morgan were selected and paired together based on their initial interviews, which I conducted to specify the levels of units they could coordinate and utilize in reasoning (Lee, 2015, April). The two tasks I discuss were developed to engage students in locating points in two- or three-dimensional space. In the North Pole Task, I asked the students to imagine being in a helicopter hovering over the North

Pole region holding a map showing the one road to the North Pole, the North Pole point (P), and a missing person's location (A) (see Figure 1-(a)). The students' goal was to provide instructions to a rescuer on the ground holding another map so that he could find point A in the region. In the Fish Tank Task, given a cylindrical fish tank, which consisted of fish models submerged in semi-transparent gelatin (see Figure 1-(b)), the students were asked to locate all four fish and to give instructions for Fish 1 to swim to Fish 2. The shapes of the map and tank were selected so that they would not suggest perceptual guidance in students' locating activities.

(a)   (b)
Figure 1. North Pole Task and Fish Tank Task Materials.

Video recordings and student work were collected from the teaching episodes, each lasting for 20–25 minutes. Both on-going and retrospective analyses were conducted (Steffe & Thompson, 2000) based on inferences from observable activities—visual illustrations, verbal descriptions, and physical gestures—the students carried out.

Analysis and Findings

North Pole Task: Locating a point in two-dimensional space

In the North Pole Task, the students demonstrated a difference in their coordination of perspectives and construction of frames of reference in two-dimensional space. Kaylee located point A in reference to point P by defining the direction of the rescuer's movement from P to A in two different ways. First, Kaylee established a frame of reference consisting of an initial ray anchored onto the rescuer's line of sight, a vertex at point P, and a terminal ray through point A. Second, Kaylee established a frame of reference consisting of horizontal and vertical lines with the intersection of the lines anchored at point P. Utilizing these frames of reference, Kaylee coordinated measurements of angle measure and distance to locate point A and to describe the rescuers motion to find the missing person. Kaylee consistently coordinated an environment-centered frame of reference taking her above-the-ground perspective and a viewer-centered frame of reference taking an imaginary on-the-ground rescuer's perspective (Carlson-Radvansky & Irwin, 1993) in developing instructions for the rescuer. Kaylee utilized decentering, unitizing, and coordinating perspectives which allowed her to anticipate results of movements of the rescuer even when the physical movements of the rescuer were not in her perceptual field.

On the other hand, Morgan tended to take a more temporal approach in that she wanted to give in-the-moment instructions to the rescuer or the missing person from the helicopter. Also, in developing instructions for the rescuer, her language was based on her perspective and did not account for the rescuer's line of sight. For example, after Kaylee shared her strategy in using a protractor to locate point A in reference to point P, I asked the students what they would do if they were only given rulers. Morgan connected points P and A with her ruler suggesting that she intended to tell the rescuer to go straight from P to A for a certain distance. Such tendencies highlighted Morgan's focus on attending to an environment-centered frame of reference (Carlson-Radvansky &

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Irwin, 1993) taking her above-the-ground perspective. As a result, her notion of going straight was not coordinated with the perspective of the rescuer. Moreover, her instructions would have required Morgan to make adjustments based on perceptual imagery of the rescuer's movement.

Fish Tank Task: Locating a point in three-dimensional space

    In contrast to the North Pole Task, Morgan demonstrated a coordination of different perspectives. As shown in Figure 2-(a), Morgan first identified the fish in vertical layers of the tank, taking the side view, and then superimposed a grid on the top of the tank, taking the top view of the tank. In thinking about Fish 1 swimming to Fish 2, both students agreed on coordinating these two perspectives. However, they came to a disagreement in how to coordinate them to describe the movement of Fish 1 to Fish 2. Morgan explained that "he [Fish 1] will go up two and then he'll have to go over however many this is [Figure 2-(a)]." Morgan elaborated that "[y]ou only need two straight lines" because "they're already in line. Then he could *just go straight to him*, instead of moving two times." In short, similar to how she wanted to connect point P and A with the ruler in the North Pole Task, Morgan wanted to tell Fish 1 to "go straight" to Fish 2 once they were on the same layer. On the other hand, using her diagram in Figure 2-(b), Kaylee explained that after going up two layers, "let's say they're on the top now. So, he has to go this way and then this way, that's three units, three different measurements."

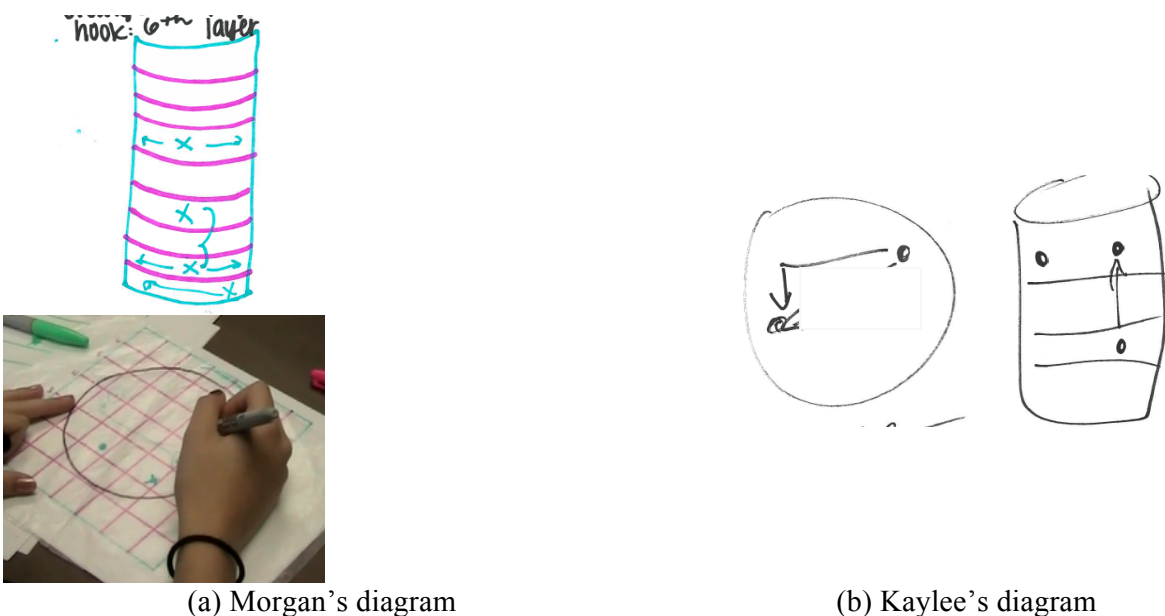
(a) Morgan's diagram   (b) Kaylee's diagram


Figure 2. Students' diagrams explaining the movement of Fish 1 to Fish 2 in the fish tank.

    Although both students coordinated the two perspectives (side view and top view of the tank), Kaylee's coordination of the two perspectives was simultaneous whereas Morgan's coordination was sequential. Through disembedding, Kaylee held her frame of reference of the first perspective as a unit structure, translated and inserted her second frame of reference into the first frame of reference. Still aware of each frame of reference as unitized structures, Kaylee was able to track the location of a given point along one spatial dimension with the realization that the point had a specific location along the other two spatial dimensions. Therefore, I claim that the *position* of each point for Kaylee was a multiplicative object (Saldanha & Thompson, 1998) and that her coordinated system of measurements was a multiplicative structure. This allowed Kaylee to define directionality in three-dimensional space by decomposing the spatial movement of Fish 1 to Fish 2 into three spatial

dimensional movements (to which she referred as length, width, and height). On the other hand, Morgan first considered the vertical movement along the layers in a two-dimensional frame of reference anchored to the side view of tank; then, she considered a second movement along a second two-dimensional frame of reference anchored to the top view of tank. As such, Morgan's coordination of the two different perspectives was sequential and thus the position of each point along each spatial dimension was not tightly coupled (Saldanha & Thompson, 1998). Morgan's instructions of telling Fish 1 to "go straight" to Fish 2 would end in different results based on the perspective that Fish 1 is taking in the moment. Therefore, I claim that Morgan reasoned compatibly with Kaylee to the extent that she could coordinate measurements along three spatial dimensions in activity.

Discussion and Implications

A coordination of different perspectives and a simultaneous coordination of frames of reference were found to be crucial in the students' organization of two- or three-dimensional space. Mental operations such as decentering, unitizing, disembedding, translating, and inserting were utilized in this process. Considering that high school students are expected to use coordinate systems for reasoning throughout school mathematics both in algebraic and geometric domains, lack of ways of reasoning within frames of references could become a border for students developing powerful mathematical concepts. The findings of this study can contribute to the understanding of students' ways of reasoning within frames of references and their coordination of measurements in organizing space. Additional research is needed to investigate connections between students' ways of reasoning for spatial organization and quantitative coordination.

cmayo@cinvestav.mx

José Guzmán-Hernández
Cinvestav-IPN
jguzman@cinvestav.mx

Este artículo reporta cómo la tecnología (Geogebra), el diseño de actividades y el trabajo en parejas –considerado como recurso (Gueudet & Trouche, 2009) – potencian la reflexión de profesores en pre-servicio cuando resuelven problemas de contenido geométrico y algebraico. El estudio está apoyado en dos marcos conceptuales: reflexión-en-acción (Schön, 1983, 1987) y la Aproximación Documental de lo Didáctico (Gueudet & Trouche, 2009, 2010, 2012). El estudio es de tipo cualitativo. Nuestros resultados muestran que el uso de estos recursos, potencia la reflexión de los profesores en pre-servicio durante la resolución de los problemas.

Palabras clave: Conocimiento Matemático para la Enseñanza, Resolución de Problemas, Tecnología, Maestros en Formación

Introducción

Una de las líneas de investigación en educación matemática ha estado enfocada, desde hace algunos años, en el impacto que tiene la falta de conocimiento matemático de los profesores en pre-servicio, en su práctica futura (Ball, Thames, & Phelps, 2008). Esa falta de conocimiento conlleva procesos limitados de enseñanza cuando ellos se integran en sus prácticas escolares. Atendiendo a esta problemática, diversos investigadores (e.g., MacPhail, Tannehill, & Karp, 2013; Tatto & Senk, 2011; entre otros) señalan que debe dársele mayor atención a la formación matemática de los futuros profesores, debido a que su conocimiento matemático es el recurso esencial que utilizará en su práctica futura. Al respecto, Schön (1983) y Freudenthal (1981) mencionan que una manera de contribuir en la reconstrucción del conocimiento –de quienes aprenden– es a través de la reflexión que los propios sujetos hagan sobre los recursos (e.g., Adler, 2000; Gueudet & Trouche, 2009; entre otros) que usan y las acciones que efectúan durante una determinada actividad. En este sentido, la tecnología y el trabajo en grupo deben entenderse como recursos mediadores de la actividad y de la reflexión para quien resuelve problemas (Gueudet & Trouche, 2012; Drijvers, 2013; Gerárd, 2012, entre otros). En este artículo pretendemos responder la siguiente pregunta ¿cómo el diseño de actividades en ambientes de lápiz-y-papel y tecnológico e implementadas en parejas potencia la reflexión de los profesores en pre-servicio cuando resuelven problemas?

Marco Conceptual

Nuestra investigación está apoyada en dos enfoques teóricos: *la reflexión-en-acción* (Schön, 1983, 1987) y la *Aproximación Documental de lo Didáctico* (Gueudet & Trouche, 2009, 2010, 2012). En el enfoque documental los recursos pueden ser de dos tipos: físicos y no físicos. Los recursos tienen origen social y son construidos con el fin de resolver tareas. Durante este proceso documental, el usuario de los recursos construye sus propios *esquemas de utilización* sobre dichos recursos, mientras interacciona con él. La reflexión durante la interacción de los recursos juega un papel importante en la construcción de esquemas. Los esquemas son la parte no observable; es decir, es el conocimiento implícito del sujeto, los cuales guían su acción (Schön, 1983; Vergnaud, 1990).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Metodología

En la investigación participaron seis futuros profesores (entre 22 y 26 años de edad) de educación secundaria [grados 7, 8 y 9]. Para recolectar los datos se implementaron tres actividades en parejas. Cada una de ellas consiste en resolver un problema de contenido geométrico y algebraico en dos etapas. Primero, se les pidió resolver el problema con papel-y-lápiz y una calculadora *CASIO fx-82MS*; segundo, resolver el mismo problema, pero ahora apoyados de la exploración del problema con Geogebra. La implementación de las actividades fue dirigida por uno de los autores de este artículo, mediante entrevistas semi-estructuradas. Las sesiones de trabajo para cada actividad tuvieron una duración, aproximada, de una hora y media. Éstas fueron video-grabadas.

Análisis de Datos y Discusión de Resultados

Debido a limitaciones de espacio, en este artículo sólo reportamos los resultados de la actividad I, implementada a una pareja de estudiantes. En adelante, los integrantes de esta pareja son nombrados como: E1 y E2 y para referirnos al Investigador se usa IN. Las entrevistas fueron transcritas y evaluadas para cada actividad, tomando en cuenta el marco conceptual.

Actividad I. Papel-y-lápiz

Al principio de esta actividad se les pide a los estudiantes que resuelvan el problema 1 (Figura 1), sólo utilizando papel-y-lápiz y una calculadora [proporcionada por el investigador] para fines prácticos de cálculos matemáticos.

Problema 1

Ambiente de papel-y-lápiz: El cuadrado y sus triángulos

En el cuadrado de vértices *ABCD* de lado 1 *cm* (como se muestra en la Figura 1), la diagonal *BD* se divide en cuatro partes iguales. ¿Cuál es el área del triángulo *DFC*? Ahora divide la diagonal *BD* en cinco partes iguales y luego en 6 partes iguales, ¿cuál es el área del triángulo *DFC* que se forma con la quinta y sexta parte de la diagonal *BD*?

Figura 1. Problema 1, papel-y-lápiz, (tomado y modificado de Mason y Stacey, 1989).

Episodio I

L1 *E1*: Creo que hay cinco formas de calcular el área de un triángulo. La más común es base por altura sobre dos, pero no tenemos la altura. ¡No recuerdo la del semi-perímetro! […]. Ahora, si lo hacemos por ángulos […].
Figura 2. El cuadrado y sus triángulos.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

L2 *E1*: ¡Ah! ¡Aunque podría ser! A ver, sí, el concepto de bisectriz […]. Es que no recuerdo ¿es el de mediatriz o el de bisectriz?

L3 *E2*: Porque de nada sirve que se prolongue [*prolonga el segmento CF con el lápiz*] ¿o sí?

L4 *E1*: Es que si prolongamos [*remarca la línea que trazó E2*]. [*Guarda silencio*] ¡Ah¡ Vamos a hacer lo siguiente […]. Entonces se supone que éste [*señala el triángulo DFC*] sería dos sobre cuatro que esto es igual a […] ¿No son cuatro?

L5 *E2*: No, sería igual a un cuarto […] Porque sería 1 por 1.

En este episodio se observa el uso de recursos previos para comenzar con el planteamiento del problema, la interacción entre estudiantes misma que provoca reflexión entre ellos.

Actividad I. Exploración en Geogebra

Las siguiente parte de la actividad consiste en resolver el mismo problema, pero ahora haciendo uso de la exploración en Geogebra.

Figura 3. Actividad I, exploración en Geogebra.

A continuación, se muestra el diálogo de los estudiantes durante la resolución del problema usando Geogebra.

Episodio IT

L6 *IN*: ¿Es similar lo que encontraron en papel-y-lápiz con lo que observan en Geogebra?

L7 *E1*: Sí, es básicamente lo mismo, sólo que lo que hicimos con papel-y-lápiz lo basamos todo en torno al cuadrado y ahorita si lo basamos sólo al triángulo sería exactamente lo mismo, el área.

L8 *E1*: […] N es igual al número de divisiones [*lo escribe*], el área del triángulo DFC es igual a uno entre N por un medio [*lo escribe*] […].

L9 *IN*: Con el cursor presiona dentro de la pantalla donde dice segmento uno.

L10 *E1*: ¡Sí! ¡Es lo que había dicho! Que todos los triángulos comparten la misma altura.

L11 *IN*: Ahora, presiona el segmento dos con el cursor.

L12 *E1*: ¡Ah! ¡Ya sé que es esto! Se supone que esto está en proporción de esto [*señala los segmentos DG y BE*] y esto está […] DC está en proporción de EC y FE está en proporción de BC y FC está en proporción de BD […] ¡sí ahí está, es el teorema de los catetos! [*Se refiere al Teorema de Pitágoras*.]

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figura 4. Segmento I y II.

L13 *IN*: ¿Ven alguna relación entre el segmento GD y el triángulo DFC?

L14 *E1*: FD es la hipotenusa del triángulo DGF y al mismo tiempo este DGF debería de estar en proporción [interrumpe E2].

L15 *E2*: […] GD es la altura del triángulo rectángulo DFC. Entonces, para sacar el área es base por altura. Sabemos que la base es uno y la altura es un cuarto de uno, punto veinte y cinco […] y así se puede sacar el área […].

La pregunta del investigador en este extracto de la entrevista se observa que influye para que los estudiantes ´puedan ver otra manera de resolver el problema.

Conclusiones

Los datos surgidos de la actividad I y su posterior análisis nos permiten dar respuesta parcial a la pregunta de investigación. Durante la implementación de la actividad detectamos intenciones secundarias, de los estudiantes, para resolver el problema. Estas intenciones conllevan hacer uso de recursos previos [conocimientos], no sólo para el reconocimiento del problema, sino para el planteamiento de ideas que los motivaron a efectuar acciones que podrían conducirlos a la solución o a encontrar nuevos recursos. Durante la resolución del problema, observamos estados de sorpresa sobre el uso de recursos; los cuales, desde el punto de vista de Schön (1983) conducen a procesos reflexivos. Dichos procesos llevaron a generar nuevas intenciones y cambios de acción instrumentada. La participación del compañero de trabajo muestra, en algunos episodios de la entrevista, cómo conduce a la reflexión, la cual se ve reflejada en los cambios de acciones instrumentadas de su pareja La exploración del problema en Geogebra, permitió comparar las soluciones efectuadas en papel-y-lápiz; pero también generó el surgimiento de sorpresas y reflexiones que los condujeron a efectuar nuevos planteamientos y acciones instrumentadas sobre el uso de recursos.

This article reports how technology (Geogebra), activity design and work in pairs –considered as a resource (Gueudet & Trouche, 2009) – enhance reflection in pre-service teachers when solving geometry and algebra problems. The study is supported by two conceptual frameworks: reflection-in-action (Schön, 1983, 1987) and the Documentary Approach of Didactics (Gueudet & Trouche, 2009, 2010, 2012). This is a qualitative study and its results show that the use of these resources enhances the reflection in pre-service teachers during problem solving.

Introduction

For some years, one of the research lines in mathematics education has been focused on the impact that the lack of mathematics knowledge among pre-service teachers has on their future practice (Ball, Thames, & Phelps, 2008). This lack of knowledge leads to limited teaching processes

---

once the teachers start their school practice. Addressing this issue, several researchers (e.g., MacPhail, Tannehill & Karp, 2013; Tatto & Senk, 2011, among others) point out that mathematics training for future teachers should be given a greater deal of attention, since mathematics knowledge is the fundamental resource they will use in their future practice. In this regard, Schön (1983) and Freudenthal (1981) state that one way of contributing to the reconstruction of knowledge—of those who learn—is by means of the subjects' reflection on the resources they use (e.g., Adler, 2000; Gueudet & Trouche, 2009, among others) and the actions they take during a certain activity. Therefore, technology and group work must be understood as mediating resources of the activity and the reflection for those who solve problems (Gueudet & Trouche, 2012; Drijvers, 2013; Gerárd, 2012, among others). In this article we seek to answer the following question: How does activity design in paper-and-pencil and technology environments implemented in pairs enhances reflection in the pre-service teacher when solving a problem?

Conceptual Framework

Our research is supported by two theoretical approaches: *reflection-in-action* (Schön, 1983, 1987) and the *Documentary Approach of Didactics* (Gueudet & Trouche, 2009, 2010, 2012). In the documentary approach, there can be two types of resources: physical and non-physical. Resources have a social origin and are constructed in order to solve tasks. During this process, the user builds his / her own schemes of *utilization* of the resources, while interacting with them. Reflection during the interaction with resources plays a fundamental role in scheme construction. Schemes are non-observable part; that is, they are the implicit knowledge of the subject, which guides your actions nonetheless (Schön, 1983, Vergnaud, 1990).

Methodology

The participants of the research were six future teachers (ages between 22 and 26) of secondary school [grades 7, 8, and 9]. In order to collect the data, three activities in pairs were implemented. Each of the activities consisted in solving a geometry and algebra problem in two stages. First, the participants were asked to solve the problem using paper-and-pencil and a CASIO fx-82MS calculator. Then, they were asked to solve the same problem supported by the exploration of the problem using Geogebra. The implementation of the activities was conducted by one of the authors of the article through semi-structured interviews. The work sessions for each activity had an approximate duration of one hour and 30 minutes. The sessions were video-recorded.

Data analysis and result discussion

Due to space limitations, in this article we only report the results obtained from activity I, given to a pair of students to whom we will refer as S1 and S2 while the researcher will be RE. The interviews were transcribed and evaluated for each activity, taking into account the conceptual framework.

Activity I. Paper-and-pencil

At the beginning of this activity, the students are asked to solve problem 1 (Figure 1), using only paper-and-pencil and a calculator [provided by the researcher] to be used for mathematics calculations.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figure 1. Problem 1, paper-and-pencil (taken and modified from Mason and Stacey, 1989).

Episode I

L1 *S1*: I think there are five ways of calculating the area of a triangle. The most common one is multiplying base by height, and then divide by 2, but we don't have the height. I don't remember the one of the semi-perimeter! […] Now, if we do it by angles […].
Figure 2. The square and triangles.

L2 *S1*: Oh! It might be, though! Let's see, yes; the concept of bisector […] I just don't remember, is it perpendicular bisector or angle bisector

L3 *S2*: Because extending it is useless [extends the segment CF using the pencil] isn't it?

L4 *S1*: It's just that if we extend [retraces the line originally traced by S2]. [Remains silent] Oh, let's do this […]. It is assumed that this [points at triangle DFC] would be two divided by four which is equals to […] isn't that four?

L5 *S2*: No, it would be equals to a quarter […] because it would be one times one.

In this episode, we see the use of previous resources to start with the problem statement. The interaction between students proved to be a fundamental resource to promote reflection among them.

Activity I. Exploration in Geogebra

The next part of the activity involves solving the same problem, only this time using exploration in GeoGebra. Below, we show the dialog between students while they solved the problem using GeoGebra.

Figure 3. Activity I, exploration in Geogebra.

Episode IT

L6 *RE*: Is what you found in paper-and-pencil similar to what you see in Geogebra?

L7 *S1*: Yes, it is basically the same; it's just that we based everything we did using paper-and-pencil on the square and now, if we base it only on the triangle, it would be exactly the same, the area.

L8 *S1*: […] N is equals to the number of divisions [writes it down], the area of the triangle DFC is equals to one by N times one half [writes it down] […].

L9 *RE*: Using the pointer, click where it says 'segment one' on the screen.

L10 *S1*: Yes! That's what I'd said! That all the triangles share the same height.

L11 *RE*: Now, click on 'segment two' with the pointer.

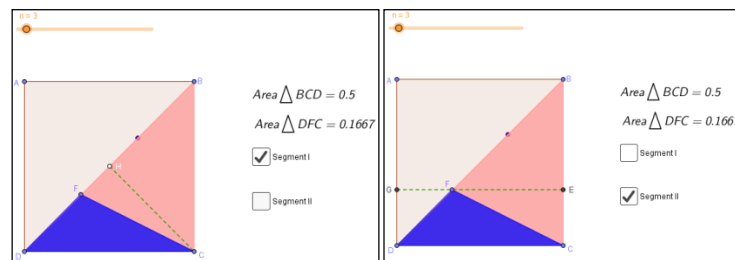
L12 *S1*: Oh! I know what this is! It is assumed that this in proportion to this [points at segments DG and BE] and this is […] DC is in proportion of EC and FE is in proportion of BD […] Yes, it's there! It is the theorem of the legs of the triangle! [S1 means the Pythagorean Theorem].


Figure 4. Segments I and II.

L13 *RE*: Do you see any relation between the segment GD and the triangle DFC?

L14 *S1*: FD is the hypotenuse of the triangle DGF and, at the same time, this DGF should be in proportion [E2 interrupts].

L15 *S2*: […] GD is the height of the right-angled triangle DFC. Then, it is base times height to get the area. We know that the base is one and the height is a quarter of one, point twenty-five […], so we can get the area […].

The question asked by the researcher in this excerpt of the interview helps the students to see a different way of solving the problem.

Conclusions

The data obtained from activity I and their subsequent analysis allow us to provide a partial answer to the research question. During the implementation of the activity we detected that the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

students held secondary intentions to solve the problem. These intentions led them to use previous resources [knowledge], not only to recognize the problem but also to lay out ideas which motivated the students to take actions. Such actions might lead them to solve the problem or to find new resources. During problem solving, we observed states of surprise regarding the use of resources. According to Schön (1983), these states lead to reflective processes; the processes generated new intentions and changes of instrumented action. In some parts of the interview, the participation of the peer promotes reflection, visible in the changes of instrumented actions made by the partner. The exploration of the problem in Geogebra allowed the participants to compare the solutions found in paper-and-pencil and generated surprise and reflection. These led the subjects to lay out new approaches and instrumented actions on the use of resources.

PRE-SERVICE TEACHERS' WAYS OF THINKING ABOUT AREA AND FORMULAS

Rebecca McGraw   Alexis-Jane Torre
University of Arizona   University of Arizona
rmcgraw@math.arizona.edu   alexisjanetorre@email.arizona.edu

In this study, we examine students' understanding of area across three groups – elementary PSTs, secondary PSTs, and non-PST mathematics majors/minors. Analysis of students' solutions to the given tasks did not reveal major differences across these groups; however, further investigation is needed to determine the robustness of these findings.

Keywords: Measurement, Geometry and Geometrical and Spatial Thinking, Teacher Education-Preservice

Introduction

The concept of area and associated formulas are found throughout the K-12 mathematics curriculum. In order to teach these topics meaningfully, teachers must be able to (1) relate formulas to the properties of shapes, (2) use discrete and continuous ways of thinking about area and its relation to linear measurements, (3) understand principles such as area conservation, and (4) recognize equivalent expressions of formulas and how one formula can be derived from another. This list is not intended to be exhaustive, but rather to highlight key aspects of content knowledge essential for teaching area. In this paper, we report on a preliminary study conducted with elementary pre-service teachers (PSTs) and mathematics majors/minors (including secondary PSTs) intended to elicit students' ways of thinking about area and area formulas.

Often, studies of PSTs focus upon only the elementary or secondary level. By administering a task to both groups, we are able to discern productive ways of thinking that cut across these populations, and question some of the assumptions about deficits in mathematical knowledge too often assigned to non-math majors (e.g., elementary-focused PSTs). Further, we administered tasks to mathematics majors/minors including both PSTs and non-PSTs, which allows us to compare the thinking of these two groups.

Related Literature

Beginning in the 1980s, the van Hiele levels have been widely used as a framework within which to classify stages of development of geometric thinking (van Hiele, 1986). In the intervening years, researchers have extended and reformulated the framework. For the purpose of our study, we use the work Clements and Battista (2001) as a construct with which to analyze tasks. These researchers propose that van Hiele levels develop at different rates and in tandem, and that reasoning based on what is visible (visual reasoning) gradually gives way to analysis of properties of classes of shapes (descriptive/analytic reasoning), and then to abstract reasoning based on relations across classes of shapes (abstract-relational reasoning).

Meaningful use of formulas for area depends upon understanding relationships among length measurements, and the coordination of this understanding with the "building up" of an area. However, "many students' measurement reasoning is superficial, with poorly understood procedures or formulas substituting for deep understanding" (Battista, 2007, p. 893). Further, "given the pervasiveness of measure in geometric and graphical contexts, poor understanding of measure might be a major cause of learning problems for numerous advanced mathematical concepts" (p. 902). With respect to PSTs, researchers have documented the challenges students experience in coordinating length measurement, multiplication, and area (e.g., Simon & Blume, 1994). Researchers have also found that the many calculus students have difficulty identifying the correct units for solutions to

area and volume tasks, and that these students lack knowledge of arrays and dimensionality (Dorko & Speer, 2015).

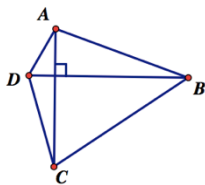
An additional component of geometric thinking necessary for understanding area formulas is conservation of area. In a study of high school and university students, researchers found that a key intuitive notion affecting students' responses to conservation of area tasks was the belief that area equivalence implied congruence (Kospentaris, Spyrou, & Lappas, 2011). These researchers also found that students tended to assume properties and relationships based on the appearance of figures in drawings, which led to erroneous conclusions.

Overall, research suggests that coordinating measurement, area, and area formulas is cognitively complex and students may reach the post-secondary level with an incomplete and superficial understanding of this knowledge domain. Relatively few studies have been conducted at the post-secondary level, and none, that we were able to find, focused on development and justification of non-standard formulas. Thus, our preliminary study of university students' understanding of area concepts and formulas focuses on the following questions:

1. What ways of thinking do PSTs and non-PSTs employ to determine area? To generate and make sense of area formulas?
2. What differences, if any, exist among the 3 populations, elementary PSTs, secondary PSTs, and non-PST mathematics majors?

Study Population and Design

The study population consisted of 39 students enrolled in a large, public university in the U.S. Southwest. Twenty-four of these students were elementary education majors enrolled in one of two required mathematics content courses. The remaining 15 students were all enrolled in a junior level geometry course, and included nine secondary PST mathematics majors, and six non-PST mathematics majors or minors. We note here that we were not able to collect data for all 39 students for any of the tasks administered. This was due in part do to the fact that we administered some tasks at the beginning of the semester when students were still adding and dropping courses, and partly due to general issues of absenteeism.

We selected mathematics tasks in an effort to elicit thinking about area concepts (e.g., measurement, conservation of area) and area formulas, and tasks were administered during the classes described above. Tasks were given across multiple class periods and the time provided for these tasks varied. In this paper, we focus on three tasks out of this set (see Figure 1).


Task A: Why is the formula for the area of a triangle $\frac{1}{2}bh$? (b is the base, h is the height)

Task B: Quadrilateral ABCD is drawn at right. The length of AC is 8cm and the length of DB is 12cm. AC and DB are perpendicular.
 	
 Circle the answer you believe is correct below and explain your choice:
    I do not have enough information to find the area of ABCD.
    I have enough information to find the area of ABCD.

Task C: In Triangle Land, instead of graphing on square graph paper, everything is graphed on equilateral triangle graph paper (in which all the angles are 60 degrees). One triangle on the graph is one unit of area. [*We gave students triangular graph paper.*] Find the formula for the area of a parallelogram in terms of triangular units.

Figure 1. Area concept tasks.

All students worked individually on the tasks. One of the tasks (Task A) was administered to both elementary PSTs and mathematics majors/minors (PSTs and non-PSTs). The second and third tasks (Tasks B and C) were administered only to the mathematics majors/minors.

Analysis of student written work on these tasks consisted of looking for patterns in the data and using the patterns to create and describe initial categories. The data set was coded using the categories, and we created new categories as appropriate. Our methodology utilized aspects of Grounded Theory (Glaser & Strauss, 1967), but we departed from the theory in that our analysis was informed by our reading of related literature.

Findings

Triangle Area Formula

Task A was administered to 19 elementary PSTs, 9 secondary PSTs, and 3 non-PST mathematics majors/minors. Of these 31 students, two students (both secondary PSTs) provided what we considered to be a complete justification. Each of them demonstrated that it was possible to "build" a quadrilateral around *any* triangle, and that the quadrilateral would have twice the area of the triangle. Most students (13 elem. PSTs, 6 sec. PSTs, and 3 non-PSTs) related the area of the triangle to the area of a rectangle and/or parallelogram, but provided an incomplete justification. Some of these students' arguments assumed that all triangles could be formed by dividing a square or rectangle in half. For example: "Because the area of a square is b x h and a triangle is half of a square, so dividing the b x h of a triangle would make sense" (elem. PST). We posit that these students' self-created drawings interacted with their analysis. For example, a student may have begun by drawing a square, and then reasoned visually from the drawing, or a student might have thought "b x h is the area of a square [or rectangle] and then I take ½ of it" and then created a drawing to illustrate this thought. In either case, students' thinking may fall across all three levels of Clements and Battista's (2001) levels – visual reasoning, descriptive/analytic, and abstract-relational. Of the remaining seven students, two (both elem. PSTs) showed evidence of relating the formula to the perimeter of the triangle (e.g., "the area is ½ bh because you only take one side of each . . . instead of multiplying both bases and both heights so you would only need ½"), which is type of thinking well-documented in the literature (Battista, 2007).

Quadrilateral Area Problem

Task B was administered to 5 secondary mathematics major PSTs and 5 non-PST mathematics majors/minors, and we found both similarities and differences in students' approaches to this problem across these two groups. One student in each group believed that they did not have enough information to determine the area because they did not know where AC intersected DB. Both students' explanations indicated that they focused on decomposing the given figure into triangles, finding the areas of the triangles, and then recomposing the shapes. Of the remaining four PSTs, three surrounded the figure with a rectangle, argued that each of the four right triangles in the original figure would be half of its corresponding rectangle, and concluded that the area of ABCD must therefore be one-half that of the surrounding rectangle. The other PST used variables to represent the lengths (i.e., dividing the 12cm length into x and 12-x), decomposed ABCD into triangles, substituted the variables into the formula for the areas of the triangles, and concluded that the area of ABCD was 48cm^2. This method was also employed by one non-PST. Two non-PSTs determined the area by surrounding the figure with a rectangle, but neither student provided an explanation beyond drawing a rectangle around the figure and writing the equation representing the calculation (e.g., multiplying the lengths AB and DC and dividing by 2), The other non-PST deformed ABCD into a rhombus by sliding one diagonal and then the other, found the area, and then argued that both areas would be the same. Overall, 8 of 10 students demonstrated understanding of

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

conservation of area in terms of decomposing and composing, with some students showing a preference for the use of variables and equations, and other students showing a preference for surrounding and subtracting.

Non-Standard Area Formula

Task C was administered to 8 sec. PSTs and 4 non-PSTs. Three PSTs and 1 non-PST wrote that the formula would be A = 2bh (or equivalent), where b is the base length in triangular units and h is the height measured at a 60° angle with the base. One of these students (a PST) wrote that the sides of the parallelogram must have a 60° or 120° angle between them, but crossed this statement out, likely indicating that this caveat had been rejected. Three PSTs and 2 non-PSTs included drawings indicating that they may believe that the formula A = 2bh would only apply to 60-degree angle parallelograms. If true, this would be similar to believing that measuring the height perpendicular to the base applies only to rectangles. The remaining three students (2 PSTs and 1 non-PST) all found the correct formula for 60° angle parallelograms; however, the 2 PSTs reverted to a perpendicular measure of height for other parallelograms, and the non-PST multiplied two of the parallel sides for non-60° angle parallelograms. Based on our data from this problem, it appears that in the face of non-standard units, students tended to exhibit visual reasoning (Clements & Battista, 2001).

Discussion

The findings from this preliminary study are in no way intended to be conclusive. Data from these problems will be used to refine tasks, select additional tasks, and plan task-based interviews. What we can say is that for these problems, and with these sets of students, we did not find evidence of *major* differences in mathematical thinking across the three student groups, although the confusion between area and perimeter exhibited by two elementary PSTs bears further investigation. Most elementary PSTs provided solutions to the Triangle Area Formula task that were similar to those provided by secondary PSTs and non-PSTs. With respect to the other two tasks, secondary PSTs and non-PSTs were very similar except in one regard – when prompted for an explanation in Task 2, PSTs were much more likely provide a written argument supporting their conclusions. This could be due to any number of reasons (including an anomaly due to the small sample size) but we look forward to further investigating this phenomenon.

AREA UNITS WITHOUT BORDERS: ALTERNATIVES TO TILING FOR DETERMINING AREA CHANGE IN DYNAMIC FIGURES

Brandon K. Singleton   Amy Ellis
University of Wisconsin-Madison   University of Georgia
bksingleton@wisc.edu   amyellis@uga.edu

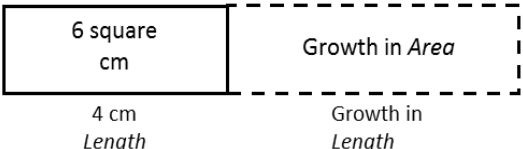
We report on thirteen clinical interviews with middle school students regarding their conceptions of area growth. The tasks involved coordinating length and area for dynamic geometric figures. Students appealed to tiling conceptions as well as a "distributed" conception of area in which the amount is spread evenly throughout the figure based on a unit with no pre-determined boundary or shape. The distributed conception supplements the tiling conception and supports students in reasoning about area units and quantitative change.

Keywords: Geometry and Geometric and Spatial Thinking, Measurement

A frequent outcome of typical instruction in area is that students become proficient with standard area calculations (e.g., the length times width formula for rectangles) but do not demonstrate well-structured conceptions of area units and space (Izsák, 2005; Lehrer, 2003; Simon & Blume, 1994). Student understanding improves during interventions that emphasize area units as two-dimensional entities, focus on coordinating length units with area units, support students' multiplicative grouping of tiles (e.g., as row-column arrays), encourage partitioning and rearranging geometric shapes, and develop pre-multiplicative and multiplicative reasoning (Clements, Battista, Sarama, & Swaminathan, 1997; Kobiela, Lehrer, & VandeWater, 2010; Lehrer, 2003; Simon & Blume, 1994; Zacharos, 2006). Even so, developing area reasoning is an extended and complex process.

This study examines student reasoning about area *change* in dynamically growing geometric figures. We address the following research question: "What area conceptions and strategies are available to middle schoolers as they reason about linear change between length and area in dynamic figures?"

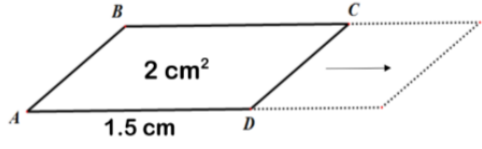
Literature Review

Lehrer (2003) articulated a number of general properties of measurement that can be applied specifically to area. First, the defined unit must relate to the empirical attribute of area. A physical object might be used as a unit, such as an index card. The unit can relate to area indirectly—for instance, a can of spray paint could serve as the unit to measure the area of a collection of walls, or two perpendicular length units could imply a square unit of area. Once the unit is defined, area is measured by iterating the unit to tile the object, with every unit identical to every other. Standard area units are square tiles by convention. Additional properties of measurement, such as proportionality and additivity, enable shapes to be measured in flexible ways, such as converting between measurements based on a known multiplicative relation between different units.


Research has shown that students can experience difficulty mentally structuring tiled regions as row-column arrays, especially in the absence of perceptual cues, and they do not connect arrays to the multiplicative structure of the area formula (Battista et al., 1998; Simon & Blume, 1994). There are recent efforts to rethink the relationship between area, multiplication, and geometric transformations. One effort is to imagine area being produced through "sweeping" one length through another (Kobiela et al., 2010; Smith, 2013). A related effort is to understand area multiplicatively as a composition of two lengths rather than as the additive combination of multiple row-units into an array (Simon & Blume, 1994; Smith, 2013). A third effort is to consider area through transformational reasoning with dynamic figures, attending to change and covariation (Johnson, 2013; see also Simon, 1996).

Method

This study was part of a larger project investigating students' generalizing activity. We conducted thirteen semi-structured interviews with seven boys and six girls in middle school (grades 6-8). Each interview lasted about an hour. We presented the participants with the task sheets shown in Figure 1. The interviews were videotaped and transcribed and we use pseudonyms for all participants. We coded and analyzed the transcripts for variations in student thinking related to area conceptions and strategies.

Task 1—Rectangle


The rectangle below grows along the dotted path as shown in the figure.

6 square cm

Growth in *Area*

4 cm
Length

Growth in *Length*

When the length grows by _____, the area grows by _____.

Task 2—Parallelogram

The figure **ABCD** below is a *parallelogram*. The parallelogram is growing along the dotted lines as shown by the arrow.

2 cm²

1.5 cm

If I increase the length of segment **AD** by _____, then the area grows by _____.

Figure 1. Interview task sheets.

Results

The students employed seven unique strategies. Table 1 lists each strategy, its definition, and a generic example based on Task 1. The counting strategy was infrequent given the form of the tasks and the students' ages. The area formula was used frequently, but not by all students, and not for every question for any one student. Students used the additive strategies, which are inappropriate for these tasks, alongside early multiplicative strategies. Students varied in whether they used one or many strategies as well as in their sophistication and ability to justify their choices.

As students justified their strategies, they sometimes appealed to a tiling or distributed conception of area. First we discuss the tiling conception. Anya was a sixth grader who gave a correct justification of the area formula on the rectangle:

Interviewer: How do you know that the area is the length times the width?
Anya: Because there would be one and a half I guess like kind of rows that way (gestures horizontally) and 4 rows that way (gestures vertically) and that creates sort of like squares or rectangles within the rectangle and there's 4 rows of 1.5 so that would be like 4 times 1.5 so that's how we figure out how many, or how the area would be.

Anya was also able to justify her formula on the parallelogram task by transforming it into a rectangle. Other students could not justify this extension.

Some students circumvented the need for explicit unit tiles by viewing area as an amount that was distributed evenly throughout the shape. In the distributed view, 6 cm^2 can be understood as an expression of the relative magnitude of a region (smaller than 7 cm^2, twice as large as 3 cm^2, etc.) according to a common scale with an implicit unit. The unit has no pre-determined shape; it is a unit without borders.

Table 1: Observed Strategies for Determining Area

Strategy (*n of 13 students who used it at least once*)		Definition	Generic example on Task 1 (a growing rectangle with area 6 cm^2 and length 4 *cm*)
Counting (1)		Fill a region with unit tiles and count the tiles.	Draw an array to produce 6 tiles. If length grows to 8, extend the array to fill the area and count 12 tiles individually.
Formula (8)		Apply a known area formula, e.g. $A = l \cdot w$.	Solve $6 = 4 \cdot w$ for $w = 1.5$. If a new length is 8, solve $A = 8 \cdot 1.5 = 12$.
Additive coordination: Area and length are coordinated through additive comparisons.	*Between measures* (2)	Compare the difference between area and length and preserve that difference after change.	The area of 6 is two more than its length of 4, so a length of 8 would imply an area of 8+2, or 10.
	Within measures (4)	Identify additively the change in one quantity and replicate the change in the second quantity.	If the length increases by 3 from 4 to 7, then the area must also increase by 3 and so 6+3 is 9.
Multiplicative coordination: Area and length are coordinated through multiplicative comparisons.	*Formal proportion* (2)	See the task as proportional and solve formally, e.g. using the cross multiply algorithm.	If the length becomes 8, then the algorithm might be filled in as 4/6=8/x and then solved for x.
	Between measures (3)	Compare the length and area values to one another multiplicatively and preserve that ratio after change.	The area of 6 is 3/2 the length of 4, so a length of 8 means the area is 3/2 of 8, or 12.
	Within measures (12)	Identify multiplicatively the change in one quantity and replicate the change in the second quantity.	If length doubles from 4 to 8, then the area must also double from 6 to 12.

A few students were asked of the given rectangle's area, "Where's the six?" Rather than drawing 6 discrete tiles or units, they indicated the whole region by gesturing, circling, or shading it. When pressed to explicitly show the amount, Robin and Olivia partitioned the region into two rows of three, decoupling the row-column array structure from the perimeter's units of length (Figure 2). Robin also partitioned an adjacent region of growth, 5 cm^2 in size, into 5 columns that did not mesh with his prior array.
Figure 2. Olivia's and Robin's partitions.

The distributed conception appeared to underlie some students' use of the multiplicative strategy within-measures. For example, Willow was a 6th grade girl who began the rectangle task using exclusively additive reasoning. Then she suddenly made an unprompted shift in strategy that seemed to appeal to a dynamic image of the rectangle's growing path. Willow justified how the quantities of length and area accumulate together in a coordinated fashion without having to explicitly articulate the structure of the unit of measure (Figure 3):

> Unless it will start at 0 because if you start at 0…if you start it from 0 to find out the actual growth then say this is like the first they grew, and this kind of, so this grew by 4 first (gesture A)

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

and then this grew by 6 (gesture B) so this could grow by 4 again (gesture C) and this could grow by 6 again (gesture D).
Figure 3. Willow's finger gestures.

There were a couple of advantages to this strategy. The first was that students who reasoned about area growth in this way could engage in meaningful multiplicative reasoning, including forming a composed length-area ratio pair, iterating and partitioning that ratio, finding the unit ratio, and generalizing from the unit ratio to the arbitrary case. The second advantage was that the same reasoning used for the rectangle extended smoothly to the parallelogram with no need to rearrange its parts or recall a formula.

Conclusion

The distributed conception of area is a promising supplement to the tiling conception for making sense of area change. In our study, several students were able to invent strategies to quantify area change and coordinate it with changes in length by drawing on a distributed conception of area and strong multiplicative reasoning.

RATIONAL RULERS: A TEACHING EXPERIMENT ON FRACTION MAGNITUDE

Claudia Bertolone-Smith
University of Nevada, Reno
claudia.bs@charter.net

Keywords: Rational Number, Measurement, Design Experiments

Utilizing the Measurement Construct of Fractions

A curriculum unit was created and tested with the intent of having fourth grade students understand magnitude in a new way. Students folded and labeled rulers as part of their job working for the Rational Ruler Company. Students were given the total length of the ruler such as 4 units or 2 units as illustrated in figure 1. Students' mathematical discourse focused on arguing and justifying what to label the parts. A common argument among the class was the difference between a part/whole perspective and a measurement perspective of ruler labeling. If students perceived each section of the ruler as part of the whole ruler, they would label each section of an 8 section ruler 1/8. This study found that often children did not pay attention to the indication of 1 unit and incorrectly labeled the ruler (see figure 1). However, over time, the students improved their ability to treat each unit within the ruler as a whole, when partitioned into 4ths, it represented a ¼ of one unit (see figure 2). One finding of this study is that creating the rulers in this fashion provided scaffolding for the transition into decomposing fractions into smaller fractions, fraction addition, and fraction multiplication by a whole number. Additionally, it was confirmed that working with the measurement construct of fractions avoided common fraction misconceptions such as seeing a fraction as two whole numbers which can lead to incorrect assessment of fraction magnitude.

CURRICULUM AS A NAVIGATOR: CROSSING BORDERS TO HIGHER LEVELS OF GEOMETRIC REASONING

Stephanie Capen
University of Hawaiʻi at Mānoa
capens@hawaii.edu

lhirashi@hawaii.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Curriculum, High School Education

The van Hiele model for geometric reasoning has been a useful model to describe students' concept development in geometry and provides a framework for curriculum and instruction. This model, conceived as sequential and hierarchical, suggests that school curriculum and instruction match students' level of geometric reasoning. However, prior studies have indicated that the level of instruction in a traditional geometry course often does not match the level of geometric reasoning with which students begin the course (Senk, 1989; Shaughnessy & Burger, 1985). In this paper, we share a study of how a transformation-based curriculum, designed to address the van Hiele levels, contributes to students' reasoning about a similarity task.

Using the van Hiele model as a framework, this case study explores the geometric thinking of 12 ninth grade geometry students, who were from the same high school course and represented a range of developmental levels. Released items from the 1996 twelfth grade National Assessment of Educational Progress (NAEP) related to similarity and congruence were used as the basis for the protocol to assess students' thinking. Students took the written assessment and a smaller representative sample of students were then asked to explain their responses in an interview. The geometry course in which the students were enrolled used a transformations-based curriculum. We describe the curriculum as transformations-based because the curriculum begins by developing student understanding of geometric transformations in a 2-dimensional plane. All other geometric concepts are then developed from transformations. For example, the concept of similarity is developed from students' work with non-congruence motions, such as dilation.

Findings suggest that when pressed to explain their thinking geometric tasks, students shifted to explanations at lower van Hiele levels. That is, while their initial justification could be characterized at van Hiele Levels 1 or 2, when pressed to extend their explanations, students seemed to draw on reasoning characteristic of van Hiele Levels 0 or 1, respectively. We believe that by using discourse from the lower levels in their responses, students had developed what can be described as a meta-discourse (Wang, 2016), where their thinking reflected what was previously practiced and therefore encompassed in their evolved discourse. We believe that when students are provided with rich content experiences at lower levels, they develop reasoning capabilities. Without experiences at the lower levels, students may be without cognitive tools to articulate, justify, or provide alternate methods. We believe this validates the importance of geometry curricula that provide sufficient experiences at lower van Hiele levels, as such experiences enable the development of higher-level geometric reasoning.

DESIGNING CONFIGURE: A MICROWORLD FOR LEARNING QUALITATIVE GEOMETRY

Steven Greenstein, Ph.D.
Montclair State University
greensteins@montclair.edu

Keywords: Technology, Design Experiments, Geometry and Geometrical Spatial Thinking

Piaget's investigation of the child's representational thinking about the nature of space provided evidence that young children possess early and intuitive topological ideas (Piaget & Inhelder, 1956). As I set out to conduct a teaching experiment (Steffe & Thompson, 2000) in order to construct models (Thompson, 1982) of these ideas with two children, "Amanda" (age 6) and "Eva" (age 7), I realized I needed a tool that could make these ideas visible. I explored a variety of existing dynamic geometry environments, but none proved suitable for the exploration of topological ideas. So in seeking to answer the following research question, I initiated a design-based approach (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) to develop one: *How can a software environment be designed and developed in ways that support fundamental topological representations and transformations such that learners' reasoning about topological ideas are made visible and are able to further develop?*

The poster I am proposing illustrates the iterative design and development process by which a dynamic geometry environment called *Configure* (Greenstein & Remmler, 2009) came to be. *Configure* affords users opportunities for a form of reasoning that resonates with the "rubber sheet" conception of topology. However, so as to remain open to findings of children's conceptions without giving in to a felt need to classify them as topological or not, I gave the name "qualitative geometry" to those forms of reasoning.

In my analysis of the experiments with Amanda and Eva (Greenstein, 2014), I determined that the qualitative equivalence schemes they constructed had come about as a result of interactive mathematical activity mediated by *Configure*. The structural character of their property-based distinctions was evident in names like "cherries," "worms," and "blocks," which they had assigned to equivalence classes they had constructed. Importantly, these properties were determined in relation to imagined, mental operations of possible transformations and not by the shapes themselves. Accordingly, I concluded that it is indeed the case that *Configure* had been developed in ways that support fundamental topological representations and transformations such that learners' reasoning about topological ideas were made visible and were seen to further develop. Three mutually informing considerations were integral in its development: 1) the content of topology, 2) Piaget's model of conceptual development (1970), and 3) the software's usability by children who would and did use it.

TOWARD THE SAME OPENNESS: RESULTS FROM A TEACHING EXPERIMENT IN ANGLE MEASURE

Hamilton L. Hardison
University of Georgia
Ham42@uga.edu

Keywords: Geometry and Geometrical and Spatial Thinking, High School Education, Cognition

While researchers have examined students' angle concepts at the elementary, middle, and undergraduate levels (Lehrer, Jenkins, & Osana, 1998; Mitchelmore & White, 2000; Moore, 2013), little research has explored high school students' understandings of angle concepts. I present data and findings from an eight-month teaching experiment (Steffe & Thompson, 2000) which investigated high school students' understandings of angle and angle measure. I focus on one ninth-grade participant, Hillary, and her activities during the first three teaching sessions of the study. During the first teaching session, Hillary manipulated two hinged pairs of chopsticks—one long pair and one short pair—that served as physical models for angles. While Hillary was able to set the short pair of chopsticks to be both more open and less open than the long pair of chopsticks, Hillary explained that it was not possible to set the short pair to have the same openness as the long pair because they were not the same size. From Hillary's inability to set the pairs to the same openness, I inferred that openness and length were not independent attributes for Hillary (cf. Lehrer, Jenkins, & Osana, 1998).

For the second and third teaching sessions, I designed activities with the intention of engendering changes in Hillary's conception of openness. In these sessions, Hillary engaged in activities that involved placing a laser beam at the vertex of the hinged chopsticks and sweeping the beam from one side to the other. In addition to enacting this sweeping action physically, Hillary enacted the sweeping action in a virtual environment with a dynamic geometry software. In the virtual environment, the sweeping beam left a trace as it swept from one side to the other. By the end of the third teaching session, Hillary set the short pair of chopsticks to have the same openness as the long pair of chopsticks. I argue that three factors were critical for engendering Hillary's progress during these teaching sessions: (1) Hillary associated the sweeping action with openness and could carry out this action independently of length; (2) Hillary could visually compare traces of the sweeping action in the virtual environment for two different pairs of chopsticks; and (3) the traces of the sweeping action in the virtual environment engendered Hillary to develop a superimposition scheme for determining whether or not two pairs of chopsticks had the same openness, regardless of the lengths of the chopsticks.

HIGH SCHOOL STUDENTS' DRAWINGS OF ANGLES FROM HAPTIC PERCEPTIONS

Hamilton L. Hardison
University of Georgia
Ham42@uga.edu

Keywords: Geometry and Geometrical and Spatial Thinking, High School Education, Cognition

In this session, I present data and findings from one task in a teaching experiment (Steffe & Thompson, 2000) focusing on high school students' understandings of angle and angle measure. While researchers have examined students' angle concepts at the elementary, middle, and undergraduate levels (Lehrer, Jenkins, & Osana, 1998; Mitchelmore & White, 2000; Moore, 2013), research focusing on high school students' understandings of angle concepts is scarce. Additionally, investigations of students' angle concepts are critical as researchers have shown that incoherent or limited conceptions of angle measure constitute a cognitive border for the study of trigonometry (Akkoc, 2008; Moore, 2013).

This session focuses on a task in which four, sighted, ninth-grade students were asked to draw objects that they felt with their hands. The objects were hidden from each student's visual field at all times by virtue of a screen. The purpose of the task was to examine how students organized haptic perceptions to form an element in representational space (Piaget & Inhelder, 1967). Each student handled four objects, which were angle models cut from plastic: one model was right; two were acute; one model was obtuse. In the teaching session, the teacher-researcher referred to the models as "objects" and never used the term "angle." Students drew one object before moving onto the next and were not permitted to return to previous objects or drawings. To analyze students' drawings, I superimposed each angular model on the corresponding drawing and measured angular discrepancies. The students' right-angle drawings were essentially indistinguishable from the right-angle models. In the acute cases, I found modest deviations across drawings and models. I observed stark differences between models and drawings across all four students in the obtuse case. For the obtuse models, all students underestimated the openness of the models in their drawings, with two of the four students producing acute drawings for the obtuse models. In this poster, I discuss students' words and actions as they engaged in the task in order to support hypotheses for why the obtuse case resulted in the largest discrepancies.

UNITS COORDINATING AND SPATIAL REASONING IN THREE DIMENSIONS

Hwa Young Lee
University of Georgia
hylee00@uga.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Cognition, High School Education

Students' units coordinating activities have been linked with their understandings of various mathematical concepts and reasoning, such as fractional knowledge (Steffe & Olive, 2010), multiplicative relationships (Hackenberg, 2010), combinatorial reasoning (Tillema, 2012), and proportional reasoning (Steffe, Liss, & Lee, 2014). The levels of units that students are able to coordinate and hold together mentally in one structure are associated with different mental operations that a student can utilize in reasoning; as such, students' levels of units coordination can be viewed as an operational border in mathematical learning across multiple domains. This poster shares partial data and results from a teaching experiment (Steffe & Thompson, 2000) with two ninth-graders, Kaylee and Morgan, to explicate their spatial reasoning in three dimensions in relation to the levels of units and the mental operations they used when reasoning.

In this poster, I present an analysis of Kaylee and Morgan's engagement in two tasks from this teaching experiment. In the first task, students were asked to locate four fish or describe the motion of one fish to another in a cubic fish tank. In the second task, the students were asked to reason with cubic blocks of various sizes. For example, they were asked to find the total number of unit cubes in each cubic block and the number of unit cubes that would be painted if the exterior of the block was painted. In the first task, Kaylee utilized mental operations which produced three levels of units to construct frames of reference and coordinated the frames of reference to locate the fish in the three-dimensional space. In the second task, Kaylee utilized her frames of reference to partition the cubic blocks, producing multiple three levels of units structures. Her coordination of frames of reference allowed her to mentally decompose, re-present, and anticipate (Piaget & Inhelder, 1967) the interior of the cubic blocks in the absence of their perceptual availability. In the poster, I compare Morgan's activities with Kaylee's in the tasks and propose that the mental operations that produce three levels of units are necessary for powerful spatial reasoning in three dimensions. Additionally, I consider implications for secondary students and propose future research directions.

SPATIAL COORDINATION AS A PRECURSOR FOR QUANTITATIVE COORDINATION: USING ONE POINT TO REPRESENT TWO POINTS

Hwa Young Lee
University of Georgia
hylee00@uga.edu

Hamilton L. Hardison
University of Georgia
Ham42@uga.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Cognition, High School Education

Saldanha and Thompson (1998) explained thinking covariationally as "holding in mind a sustained image of two quantities' values (magnitudes) simultaneously" (p. 1). Often, Cartesian coordinate systems are used as static representations of the mental covariation outlined by Saldanha and Thompson. We distinguish between two uses of coordinate systems: 1) *spatial coordination*—to re-present space by establishing frames of reference to locate points within the space; and 2) *quantitative coordination*—to coordinate sets of established quantities in a representational space. In this poster, we argue that spatial coordinations are necessary (i.e, border) if Cartesian coordinate systems are to be productive tools for students' quantitative coordination and subsequent covariational reasoning.

We conducted a two-year teaching experiment (Steffe & Thompson, 2000) with two ninth-grade students, Kaylee and Morgan, to investigate their constructions of coordinate systems (Lee, 2015, April). The first author served as the primary teacher-researcher and the second author served as the witness for the teaching experiment. In this poster, we present one task, the Ant Farm Task, in which Kaylee and Morgan were asked to describe the location of two points moving along two different line segments using a single point. Students worked within a dynamic geometry environment. In the environment, the screen was imagined to be the floor of a room on which two ant farms—long, thin rectangles that could be rotated and repositioned within the dynamic environment—were resting. Each ant farm contained an ant—a point that moved haphazardly along the longest segment connecting midpoints of opposite sides of each rectangle. Students were asked to find a way to locate both ants using a single point. Students were presented with the spatial situation absent of any quantitative values (e.g., an ant's distance from the end of the tube). Although we expected this task to be trivial for both students due to their experiences using the Cartesian plane, we found that the spatial coordination was not immediate for either student. In this poster, we present an analysis of Kaylee's and Morgan's strategies in the Ant Farm Task. Additionally, we consider implications for secondary students. In particular, we hypothesize that students must develop spatial coordinations, as in the Ant Farm Task, prior to engaging substantively in quantitative coordination and covariational reasoning involving two-dimensional Cartesian coordinate systems.

OPPORTUNITIES TO INTERACT WITH QUADRILATERALS AND THEIR DEFINITIONS IN ELEMENTARY EDUCATION TEACHER TEXTBOOKS

sglove20@students.kennesaw.edu

Keywords: Teacher Education-Preservice, Curriculum Analysis, Geometry and Geometrical and Spatial Thinking

Rationale

Despite the importance of developing geometry skills at an early age, many students do not receive high cognitive demand geometry tasks during elementary or middle school (Battista, 2007). If we expect future elementary school teachers to cross the border from their own perhaps underdeveloped past experiences to becoming effective geometry teachers it is especially important to ensure that pre-service teacher preparation programs provide opportunities to learn about and fully understand the geometric content covered in elementary school. This study examines the opportunities to interact with quadrilaterals and their geometric definitions found in nine mathematics content books intended for elementary education majors.

Methods

A collection of nine popular text books were selected via a series of searches on textbook sales websites. Sample problems were collected from the end of chapters which introduced definitions of quadrilaterals and examined according to a coding scheme based on Bloom's taxonomy (Sosniak, 1994), with consideration for relations to the van Hiele levels (Burger & Shaughnessy, 1986) and the Common Core State Standards (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). The codes included; recognition, describe, classify, relationships/hierarchy, and create. Problems were also coded to identify those related to teaching contexts rather than exclusively content knowledge.

Results and Implications

Results revealed a reasonable variety of problems across all the text books examined, but that most individual text books contained limited variation. These results imply the need for instructors of pre-service teachers to examine their selected text and supplement their instruction with additional problem types as needed. The results also identify appropriate textbooks to reference when locating examples of each problem type. Similar analyses could be done for other subject areas as the elementary content standards continue to evolve over time.

TEACHERS' USE OF DYNAMIC GEOMETRY ENVIRONMENT IN PROVING THE INSCRIBED ANGLE THEOREM

Gili Gal Nagar
UMass Dartmouth
gnagar@umassd.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Reasoning and Proof, Technology

Purpose and Background

Despite the emergence of new types of digital technologies and the importance of proofs and proving in teaching and learning of mathematics (Tall et al., 2012), only little research is focused on teachers' proving process in Dynamic Geometry Environment (DGE) (de Villiers, 2004). The current study uses Geometer's Sketchpad® (Jackiw, 1991, 2009) to examine: (a) what conjectures do two high school teachers formulate using DGE to explore the Inscribed Angle Theorem (IAT)? And (b) what are the ways that these teachers prove their conjectures? One way to describe the IAT is that the measure of an inscribed angle is half of that of the intercepted arc.

Framework & Methods

Mathematical proving process consists of: (a) formulation of a conjecture and (b) construction of mathematical proof (Sinclair & Robutti, 2013). Becky and Jill (pseudonyms) were certified high school geometry teachers. Data were collected from a 90-minute videotaped clinical interview. All recordings were transcribed and then analyzed using two cycles coding. First cycle includes descriptive coding. In second cycle, I used pattern coding to identify patterns. Task 1 was designed to examine the relationship between the inscribed angle C, the arc AB, and the central angle O. Task 2 was designed to explore the relationships of two inscribed angles that intercept the same arc or alternate arcs (when dragging point D on minor arc AB). The participants could drag points on the circle and measure different properties.

Results

Becky and Jill formulated five conjectures related to similar ideas but focused on different components. For instance, both Becky and Jill formulated the IAT conjecture but Becky discussed the relationship between the inscribed and the central angles and Jill described the relationship between the inscribed angle and the arc that it intercepts. The different formulations impact their proving process. Additionally, three mathematical proofs constructed by Jill and one proof constructed by Becky used only DGE and were verbal. This is important because that the narratives in these proofs were mainly based on theory. Becky and Jill's formulation of the IAT conjecture and relying on previous result (assuming that the IAT has been proven true) seemed to play an important role in their attempt to prove other conjectures.

YOUNG CHILDREN USING ANALOGICAL REASONING TO UNDERSTAND SIMILARITY IN A DYNAMIC MULTI-TOUCH GEOMETRY ENVIRONMENT

Yenny Otálora

University of Massachusetts Dartmouth; Universidad del Valle

yotalorasevilla@umass.edu

Geometrical similarity is a critical concept for the development of advanced mathematical thinking; however, it is a difficult idea for young children to grasp (Lehrer, Strom, & Confrey, 2002). This study investigated second-grade children's ways of reasoning while working in small groups on similarity activities created in a dynamic multi-touch geometry environment (hereon DMGE). The DMGE combines *Sketchpad*, offering visual dynamic feedback, and the iPad offering multi-touch experiences. The study is part of a larger research involving the design and implementation of an educational strategy to nurture in early childhood education (k-2) intuitive senses of congruence and similarity within the collaborative DMGE. The study was implemented with five small groups in the context of the afterschool program of a public elementary school of Massachusetts, U.S., and included thirteen second-grade students (7-8 year olds). The strategy entailed a sequence of seven exploratory and problem-solving activities for congruence and similarity. The poster focuses on the fourth activity, designed to explore two dynamic similar triangles. A qualitative multiple-case study based on task-based interviews and artifacts was the method of inquiry. Discourse analysis was the data analysis method for the small group work. Theories of *semiotic mediation* related to the use of digital interactive technologies guided the whole research (Moreno-Armella, Hegedus, & Kaput, 2008; Sinclair & Moss, 2012).

One main finding was that the young children used analogical reasoning to make sense of the similarity task. Dynamism of the multiple representations of the similar triangles and gestures mediated this form of reasoning. One case study illustrates how children's analogies emerged as a genuine way to 'mathematize' both the activity and their world. The students intuitively used prior everyday experiences to understand the new situation and find out invariant mathematical relationships, even if they did not explain them formally. They inferred that both similar triangles always have the same shape and same type of movement but different sizes, and identified 'objects' in their world that have, in a certain way, the same mathematical structure. The role of the DMGE was critical, as children utilized the dragging tool with their fingers to transform the triangles and the continuous motion of these multiple representations helped them infer the geometrical relationships. Moreover, children in the small group built on each other's ideas to understand these relationships. Implications for early childhood education are discussed.

DEVELOPING STUDENTS' THINKING OF DYNAMIC MEASUREMENT

Nicole Panorkou
Montclair State University
panorkoun@montclair.edu

Keywords: Measurement, Learning Trajectories (or Progressions), Design Experiments, Technology

Although much research has been conducted on the teaching and learning of geometric measurement, what is available shows students' difficulty in understanding area and volume (Clements and Sarama 2014). Moving from an additive reasoning of adding square tiles to a multiplicative reasoning of combining two dimensions in an area formula is extremely difficult, especially if students only understand multiplication as repeated addition. As Piaget et al. (1960) states, "the child thinks of the area as a space bounded by a line, that is why he cannot understand how lines produce areas" (p. 350). This project aims to explore measurement in a *dynamic* way in order to resolve those difficulties and assist students in developing a conceptual understanding of area. An intuitive way for students to visualize a meaning for area in a dynamic way is to view it as a 'sweep' of a line segment of length *a* over a distance of *b* to produce a rectangle of area *ab* (Confrey et al. 2012). For instance, one can imagine taking a paint roller of length *a* and rolling it a distance of *b* to produce a rectangle of area *ab* (Figure 1).
Figure 1. Area as 'sweeping" (reproduction from Confrey et al. 2012).

Our conceptualization of the area formula involves students considering both length (e.g. of the roller) and width (e.g. the distance of rolling) simultaneously as attributes that define the area (e.g. the space generated). In this poster we present a) the type of dynamic tasks and tools that we used for developing students' DYME reasoning, b) the forms of DYME reasoning developed as a result of students' systemic engagement in these dynamic tasks, and c) how DYME experiences assisted students' development of the area formula.

BUILDING A CONCEPTUAL UNDERSTANDING OF FRACTIONS THROUGH A SIX-WEEK INTERVENTION IN EARLY ELEMENTARY

Trena L. Wilkerson	Dittika Gupta	Keith Kerschen
Baylor University	Midwestern State University	Baylor University
Trena_Wilkerson@baylor.edu	dittika.gupta@mwsu.edu	Keith_Kerschen@baylor.edu

Students struggle to change from additive to multiplicative thinking (Moss, 2005) that can be attributed to curricular emphasis on procedures rather than development of important fractional understanding (Bezuk & Cramer, 1989; Behr & Post, 1992; Cwikla, 2014). This study was developed as a partnership between a university and local elementary school for content support and to enhance student achievement and understanding of fractions. Research questions included 1) What do students understand about fractional concepts at kindergarten and third grade? and 2) Are these understandings impacted by a research-based sequence of lessons taught over a six-week period at each grade level? The study seeks to foster conversations about fraction curriculum in light of mathematics standards and examine the need for cross grade curricula discussions to remove borders and barriers in early elementary grades.

Methodology

The intervention was a sequence of six grade-level appropriate lessons that focused on developing fraction concepts using an exploratory approach with a variety of models. Each 30-45 minute lesson designed using research literature, was taught by pre-service teachers once a week for 6 weeks in a small group setting. The results presented in this proposal are for 116 Kindergartens and 115 3rd graders that were part of a larger study conducted from 2007 to 2013 with students in grades K-3 in an urban elementary school in Central Texas, USA with majority African American and Hispanic population and 83% low socioeconomic status.

Pre-and post-assessments were developed by the research team utilizing a variety of sources such as: *Iowa Test of Basic Skills* (ITBS), *California Achievement Test* (CAT), *Texas Assessment of Knowledge and Skills* (TAKS) tests and Lamon's (2005) work on student fractional understanding. Data analysis using a one-tailed t-test was conducted to determine the impact of implementing a sequence of research-based lessons on key fractional concepts to students at K and 3rd grades.

Results

In Kindergarten all means increased from pre to post with 16 of the 27 questions statistically significant ($p < .05$). In 3rd grade while the means increased on 19 of the 24 questions only 8 showed statistically significant increase ($p < .05$). Findings and implications will be shared.

MATHEMATICS TEACHERS' PERSPECTIVES ON FACTORS AFFECTING THE IMPLEMENTATION OF HIGH COGNITIVE DEMAND TASKS

Amber G. Candela
University of Missouri – St. Louis
candelaa@umsl.edu

While there are instructional practices researchers claim teachers should be engaging in, (e.g., use of technology, implementing high cognitive demand tasks) often times teachers are either not engaging in these practices or not successful with implementation (Henningsen & Stein, 1997). I conducted a research study from the perspective of three middle school mathematics engaged in professional development around the implementation of high cognitive demand tasks (Smith & Stein, 2011) and whether or not they could identify when the demand of task was lowered and maintained and what factors contributed to either instance. This report details the teachers' perspectives and hopes to contribute to the body of knowledge around those providing professional development to teachers and how to use teachers' perspectives to shape the professional development to support teachers' use of instructional practices.

Keywords: Teacher Education –Inservice/Professional Development

Smith, Bill, and Hughes (2008) stated, "mathematical tasks that give students the opportunity to use reasoning skills while thinking are the most difficult for teachers to implement well" (p. 132). Teachers should be able to select tasks appropriately and implement those tasks while maintaining demand in order to support students' mathematical thinking (Henningsen & Stein, 1997). These assertions are based from research on teachers' implementation of high cognitive demand tasks that occurred from the researchers point of view (e.g., Henningsen & Stein, 1997; Stein, Grover, & Henningsen, 1996). My goal was to understand from the perspective of middle school mathematics teachers what they cited as impacting the demand when implementing high cognitive demand tasks. In doing so, I was hoping to break down the barrier between teacher and researcher by talking with the teacher and understanding what they claimed made the implementation of a high cognitive demand task difficult and they cited as supporting their efforts to maintain demand. Prior work has solely been from the point of view from the researcher and I wanted to see if teachers could identify the factors that either led to the decline of demand or helped maintain the demand of a task and do more than just provide the account of the lesson from my point of view. If teachers could identify those instances, I maintain that someone working with the teacher would then be able to help a teacher build upon their strengths in maintaining demand and support the teacher around what was lowering the demand of a task. By offering the teachers' perspectives, those working with teachers can anticipate possible roadblocks and provide the necessary support needed when implementing any new instructional practice being learned. The research questions that guided my study included: What are teachers' perspectives of their classroom practices as they implement high cognitive demand tasks? What factors do teachers identify as affecting the implementation of high cognitive demand tasks?

High Cognitive Demand Tasks

Cognitive demand refers to the amount of effort a student needs to expend to think about a problem, and mathematical tasks are categorized in two levels, low and high cognitive demand. Smith and Stein (2011) outlined and characterized four different sublevels of the demands of tasks: memorization tasks, procedures without connections tasks, procedures with connections tasks, and doing mathematics tasks. Memorization and procedures without connections are low cognitive demand tasks while procedures with connections and doing mathematics are high cognitive demand

tasks. This study focuses on teachers implementing high cognitive demand tasks. Research on high cognitive demand tasks to date has focused on whether teachers could identify high cognitive demand tasks and if teachers maintained the level of demand during implementation as determined from the researchers point of view (Henningsen & Stein, 1997; Stein et al., 1996). Stein and colleagues (1996) wanted to observe and portray the nature of the mathematical task as implemented by teachers and found the teachers had success selecting and setting up high cognitive demand tasks but were not as successful in maintaining the intended level of cognitive demand throughout the lesson. Stein and colleagues characterized factors related to the maintenance or decline of cognitive demand during task implementation, but these observations were entirely from the perspective of the researchers. In a follow-up study Henningsen and Stein (1997) looked more closely at the classroom factors associated with the implementation of high cognitive demand tasks, specifically tasks classified as *doing mathematics*. The researchers looked at how tasks at that level affected student engagement and found many factors associated with both the maintenance and decline of demand. Although the researchers described and characterized factors associated with the implementation of high cognitive demand tasks, they used archival data and therefore were unable to include the teachers' perspectives on what happened during task implementation. In these studies, the researchers were unable to converse with teachers to gain their perspectives on whether they realized they lowered demand and if so, their reasons for lowering demand.

Teachers' Perspectives

Research on teachers' perspectives seeks to give voice to teachers. Some research studies on gaining teachers' perspectives involved the researchers understanding topics that have been documented as being beneficial to student learning (eg. technology in the classroom, teaching thematic units) but lack the teachers' perspectives of the reality of implementing such structures in the classroom (Handal & Bobis, 2004; Wachira & Keengwe, 2010). Both Wachira and Keengwe (2010) and Handal and Bobis (2004) wanted to identify barriers that kept teachers from implementing different aspects of instructional practices that research has shown to positively influence students' learning of mathematics. Wachira and Keengwe wanted to gain urban teachers' perspectives on integrating technology in their mathematics classrooms to see if urban teachers' perspectives aligned with research on the benefits of using technology in the mathematics classroom, giving their purpose as follows:

> While the use of technology has been found to be an effective means to produce growth in students' understanding of mathematics content, research findings indicate that few teachers integrate technology into their teaching to enhance student learning. This study sought to explore urban teachers' perspectives on barriers that hinder technology integration in their mathematics classroom. (p. 18)

Handal and Bobis (2004) wanted to capture teachers' perspectives on teaching mathematics around a central theme instead of content and understand what barriers were preventing teachers from teaching thematic units, even though a thematic approach can motivate students and deepen their conceptual understanding of mathematical topics. Barriers teachers cited as preventing them from implementing new instructional practices included no access to technology, unreliability of technology, lack of technology support, lack of time, lack of knowledge, lack of confidence, lack of curricular coherence, and a mismatch from the content being taught and the content on the end of year state test (Handal & Bobis, 2004; Wachira & Keengwe, 2010). Proposed actions to help teachers overcome perceived barriers included strengthening teacher support and building learning communities of teachers.

Theoretical Framework

The theoretical framework guiding my study was the task implementation framework, as shown in Figure 1, developed by Stein and colleagues (1996).
Figure 1. Task Implementation Framework (Stein et al, 1996, p. 459).

I chose to situate my study within this framework because it highlights factors that affect the implementation of high cognitive demand tasks. The task implementation framework "proposes a set of differentiated task-related variables as leading toward student learning and proposes sets of factors that may influence how the task variables relate to one another" (Stein et al, 1996, p. 458). The purpose was to identify factors that changed the task as it was implemented. While a task may start out at one level, during implementation the level may change due to the factors listed in the framework. The level of the task can change between successive phases of implementation: between the task as represented and the task as set up by the teacher or between the task as set up by the teacher and the task as implemented by students. I used the task implementation framework to identify factors affecting implementation when the participants in my study enacted high cognitive demand tasks.

Settings and Participants

I worked with the seventh grade mathematics team at a middle school in the Southeastern United States with approximately 700 students. The participants reported that 75% of the students were eligible to receive free and reduced lunch with 4% of the population being English language learners. The population of the school consisted of 60% African-American, 25% White, 7% Latina/o, 4% Asian, and 4% multi-racial. The three teachers in my study, Mr. Cone, Mrs. O'Neill, and Mr. Fielder all had less than five years experience. Mr. Cone in his 5th year of teaching and taught both mathematics and social studies. His bachelor's degree was in history and decided to get a master's in middle school education where he added a concentration in mathematics. Mrs. O'Neill was in her third year of teaching after being a stay at home mother for 25 years and only taught mathematics. Mrs. O'Neill went through a state certification program where she needed to pass the state certifying exam and be employed by a school. She was hired by the school and earned her certification in a year taking classes online and after school. Mr. Fielder taught mathematics and was in his first year of teaching after completing his bachelor's in middle school education with concentrations in social studies and mathematics. Mr. Fielder was in his second year and he was a student teacher in Mr. Cone's classroom the year before.

Data Collection and Analysis

I collected data through classroom observations and interviews. I provided professional development before school started on high cognitive demand tasks and then initially observed each teacher during one of their class periods for the first two and one-half weeks of school. I then observed each teacher multiple times throughout the semester. I planned with the teachers for the specific implementation of two high cognitive demand tasks, the Figure S Task and the Border Problem (see Figure 2) and made sure to observe and interview the teacher after each of those lessons.

Figure 2. Figure S Task, (adapted from Smith, Hillen, & Catania, 2007, p. 41) and Border Problem (adapted from Boaler & Humphreys, 2005).

During classrooms observations I took field notes and audio recorded and transcribed the interviews. I interviewed each teacher three times with a semi-structured (Patton, 2002) interview that lasted between 40 and 60 minutes. The interviews included questions on conceptions of high cognitive demand tasks, if they thought they maintained or lowered the demand of tasks, when they thought instances of maintaining or lowering demand occurred, and factors that affected the implementation of high cognitive demand tasks.

The goal for data analysis was to gain teachers' perspectives of factors that affected the implementation of high cognitive demand task. The data I used included observations and individual interviews. I went through each teacher's interview line-by-line and found instances where the teacher made a comment about a factor that affected the use or implementation of high cognitive demand tasks. I created narratives separating the data into instances where the teacher cited factors that led to the decline of demand and instances where the teacher cited factors that maintained the demand of the task. Once I had each teacher's narrative, I went through and coded using the factors from the task implementation framework. I coded each teacher's narrative individually first and then looked for common themes across all cases, making note of where the teachers had common factors.

Because I was comparing my perspectives to the teachers, I included a member check in my data analysis that involved checking back with participants to determine whether the analysis accurately represented their experiences. I wanted, to give the participants the opportunity to examine my work and offer advice if they saw a different interpretation (Lincoln & Guba, 1986). I provided each teacher with a copy of my analysis of his/her implementation of tasks in response to the first research question and my analysis of all the teachers in response to the second research question to get their input. Specifically, I wanted to find out if they agreed with the factors I identified as influencing the implementation of high cognitive demand tasks in their classrooms and whether I had omitted any important factors. I emailed each teacher the summary of my analysis telling each to read over the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

analysis and then get back with me on a time so I could meet with each teacher separately. Mr. Fielder responded quickly to the email saying he agreed with my analysis and it was not necessary to meet. I met with both Mr. Cone and Mrs. O'Neill on separate occasions and after discussion the analysis was kept intact.

Teacher Identified Factors Influencing Implementation

Teachers' Instructional Dispositions

Each teacher's instructional disposition was a factor influencing implementation. Stein and colleague's (1996) defined teachers' instructional dispositions as the "features of [teachers] pedagogical … behaviors that tend to influence how they approach classroom events" (p. 461). Examples of teachers' instructional dispositions include the extent to which a teacher is willing to let a student struggle with a difficult problem and the of assistance that teachers typically provide students during that struggle (Stein et al, 1996). All of the teachers said they often guided students to the right answer. They gave different reasons as to why they led students, but each had the tendency not to allow students to productively struggle with the task. Mr. Cone was not apt to let students struggle with the problem but was working on being able to question students instead of just giving them the answer. Mr. Fielder lowered the demand during the Border Problem when the students struggled with finding the border of any size square. He had not intended to lead, but when students could not come up with an expression for any size square, Mr. Fielder showed them how to take each of the numerical expressions and turn it into an algebraic expression rather than asking questions or offering hints to help them find the expression themselves. Mr. Fielder recognized this behavior saying:

> The only struggles I had were in those classes where I had to give it away. It was frustrating because I know that theoretically we are supposed to allow students to develop these ideas themselves, just kind of point them in the right direction. To have to tell someone about this idea and them not get it, that is frustrating because they can't get it on their own and then you try to tell them about it and then they get more confused so then it's almost like you have no idea, and that's the frustrating part.

Mrs. O'Neill also acknowledged that she struggled with leading students too much. During the implementation of the Figure S task, she said she explicitly helped students who were stuck because she was afraid the students would shut down without her help. She said she led students too much during the Border Problem when they were getting an incorrect answer. She initially told a group of students they were getting the wrong answer because they were double counting the corners, but when she realized that she was being too directive, she adjusted her questioning to help the other groups of students arrive at that conclusion without her doing it for them. She said she initially was guiding her students through tasks because she wanted to make sure she had enough time to accomplish her goals. Thus, instead of letting students struggle, she gave them the information needed to solve the problem.

Teachers' instructional dispositions positively influenced students' implementation when the teachers held back and allowed students to productively struggle with the task. Examples of teachers holding back included using questioning techniques or referring students to work with each other instead of relying on the teacher for ideas. Both Mr. Cone and Mr. Fielder pointed to questioning students and not giving away answers as reason for maintaining the demand of tasks. The teachers recognized both instances of maintaining demand due to questioning but also lowering demand due to giving away the information too soon. Mr. Fielder said he had success with the Border Problem because he maintained demand with his on-level students by pulling back and not leading students to the answer. He said he realized the students were getting it on their own, and he could lead less and

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

watch the students come up with the ideas of generalizing any size square on their own. Mr. Fielder said he was becoming okay with allowing students to struggle with the mathematics and if they could not finish the task in one day, he would allow them to take two days to struggle with the task. By engaging with the task for two days, they may flail but not give up entirely. Mr. Cone said that he was getting better at using questions, and his goal was to focus students' attention on the mathematical concepts with questions rather than statements. He said he had to make a conscious effort not to give away pieces of information during implementation and he was getting better at letting students "carry more of the cognitive burden" because he tried to answer the students' questions less frequently and encouraged the students to engage with their peers more.

Task Conditions

The task condition related to class time affected the implementation of the task because often there was not enough time in class for students to grapple with the task, thus lowering demand. Mr. Cone attributed class time as a reason for not maintaining the demand saying he did not think the students discussed how to generalize for either problem. Mr. Cone described the implementation of the Figure S task by saying; "I am leaning towards failure because we didn't have a lot of time in class to do it. Students worked on it, but they weren't able to share their thinking. I didn't have a chance to continue that discussion." Mr. Cone claimed he altered tasks because he did not have the time for students to grapple with the mathematics so he would often make the connections for his students instead of letting them try to figure it out. Mrs. O'Neill identified lack of class time as a reason for lowering demand, saying she often gave the answer away because that would save her time in class to be able to get to each part of the lesson.

The task conditions helped the teachers maintain demand related to students abilities of building on prior knowledge. The teachers commented on the task conditions as a reason for the success of the lessons. Mr. Fielder said the Figure S task was successful because the students did not need a lot of prior knowledge to engage with that task. He had the same sentiment with the Border Problem and explained that the task was both easy to set up and implement because the students could engage with the task. He noted that the Figure S task built on itself in a way that students did not need much support from the teacher. He also said the Border Problem had an easy set up in that all he needed to do was give simple instructions, and the students were able to access the task. Mr. Fielder posed the tasks as challenges or problems for the students to solve because he said lessons were successful when he found tasks that he could set up as challenges and have students engage in without realizing they were doing mathematics. Mr. Cone attributed the success of the Border Problem to it having a low entry floor while also allowing students the option of being creative. Mrs. O'Neill spoke of the nature of the Border Problem and noted that all levels of students could access the task; saying, "The kids that were more advanced, they were looking for different, more complex strategies for solving it, so it was a puzzle for your weakest learner as opposed to the one that is more advanced." As an extension, she had her accelerated group create their own patterns to give other students to come up with the generalization for the pattern.

Students' Learning Dispositions

The teachers explained that high student engagement in the class as well as the ability to have a discussion around the task contributed to maintaining the cognitive demand during successful implementations. Mrs. O'Neill said she was successful with task implementation when she was able to have a discussion around the mathematics with the students sharing multiple solution methods because she enjoyed hearing multiple ways the students had solved the task which was different from the beginning of the year when the students just wanted to know how to get the answer. Mr. Cone said success with tasks implemented in his classroom was due to high student engagement. He said that through the implementation of tasks he had become more reflective about his practice of

interacting with students, thinking about how he can clarify, extend, or prompt students' thinking based on what the student says, which he had not thought of before. Mrs. O'Neill claimed students' learning dispositions lowered the demand of the task saying students relied on her or other adults in the room for the answer and would not productively struggle with the task. She wanted students to work by themselves or ask a neighbor if, but often they wanted her to give them the answer. She said that it just took time for the students to get to know each other to feel comfortable talking with their neighbor.

Discussion

The teachers recognized factors that affected the demand of tasks during implementation. Each of the teachers attributed giving away information to lowering the demand and not giving information away to maintaining the demand. According to the task implementation framework this relates to the teachers' instructional dispositions and their inclination as to when to allow students to struggle with the task. The teachers often did not allow students to grapple with the problem. Instead, they intervened to help students find the answer. The teachers realized they were lowering the demand and provided justification for leading students, claiming that if they did not give the information or help the student, the student would have disengaged with the problem out of frustration. From the perspective of the teachers, lowering the demand was acceptable if it kept a student engaged. The teachers attributed task conditions, students' learning dispositions, and teachers' instructional dispositions as relating to maintaining the demand of tasks. The teachers explained that the tasks having multiple solution methods and multiple entry points allowed students to engage successfully with the task. The teachers noted that students at all levels engaged with the high cognitive demand tasks, which was not always common in their classes. The teachers also attributed their instructional dispositions to helping maintain the demand of the task when they intentionally did not provide students with answers or lead them to solution methods.

The teachers were often able to identify the factors that helped to maintain or lead to the decline of demand. This was encouraging because in the future when they implement high cognitive demand tasks hopefully when there is an instance where they start to lower demand, such as giving a leading answer, they may be able to recognize and correct themselves to ask a question or not provide the student with the answer but still give support. The teachers being able to pinpoint when the demand was lowered can help those providing professional development to then provide support around those areas. Because the teachers all realized they lowered demand when giving students the answers when they struggled, I should have taken that information and then provided more targeted support on how to scaffold in such a way that supports student thinking, but does not explicitly give the student the answer.

Overall, there were many factors identified by Stein et al. (1996) that the teachers identified as contributing factors affecting the demand and illuminate the complexity around implementing high cognitive demand tasks. The teachers' ability to identify these factors illustrates teachers can identify when they maintain and lower demand. Each teacher was able to identify what led to the decline of demand and if I had a chance to continue working with the teachers, I would strive to help each with areas that needed improvement such as helping not give information away to students, or helping to plan a task that fit into the allotted class time. I argue those who work in a professional development capacity with teachers need to break down possible barriers between researcher and participant by listening to teachers' perspectives. Researchers can ascertain what interventions will benefit teachers and will fit within the confines of teachers' many responsibilities and abilities. Listening to teachers can help individualize professional development plans and provide targeted support for each teacher. While I initially implemented one professional development session with all three teachers, when analyzing the data from interviews and observations, it became apparent that each teacher needed different interventions and support to help him/her implement high cognitive demand tasks as related

to what each claimed lowered or maintained demand. Researchers can use teachers' perspectives to provide the support necessary to help teachers become successful when implementing new instructional practices in their classroom.

REPRESENTING VIDEO CLIPS OF STUDENTS' THINKING IN A MATHEMATICS CLASSROOM AS ANIMATIONS

Video clips and animations have been used to encourage discussions of teaching in professional development. While both representations are useful for teacher noticing of students' thinking, animations may be more viable for sharing with a wider audience. We describe a process for representing a video clip of students' thinking as an animation which preserves the focus on students' actions by using the cK¢ framework and video clip selection criteria. We found two types of clips, explaining clips and working clips. We address challenges with explaining clips where students did not provide enough verbal evidence of their thinking, and challenges with working clips where students worked on different conceptions at the same time. This study is relevant for designers of professional development who wish to increase the uses of a classroom video clip and broaden the set of resources available for promoting teacher learning.

Keywords: Design Experiments, Teacher Education-Inservice/Professional Development, Technology

Introduction

Teacher professional development has used both discussions of videos and animations to help teachers notice students' thinking (e.g. Chieu, Herbst, & Weiss, 2011; van Es & Sherin, 2010). When teachers study videos from their own classrooms with other teachers, they can develop a better understanding of their own practices (Borko et al., 2008). However, using video clips recorded in the classroom of a practicing teacher can create challenges because it is important to maintain a stance of critical inquiry while also supporting teachers (Lord, 1994). In addition, compliance with protocols that require protecting the identity of study participants can limit the availability of video to a wider audience, especially when scaling up a professional development intervention, While animations have been used in the past as a way to design stories of classroom instruction (Herbst, Nachlieli, & Chazan, 2011), they also have potential to allow professional developers to show examples of actual students' thinking using a different representation than a video clip. Representing a video clip as an animation could allow professional developers to show the representation to a wider audience and provoke teacher noticing of student thinking differently. In this paper, we describe a process we used to represent video clips of students' thinking as animations while attempting to preserve the nature of the original video clip, and how we addressed challenges with the differences in the representations.

Using Video and Animations in Professional Development

Video Clips

Video clips of actual mathematics classroom instruction are a popular tool in teacher professional development (e.g. Borko et al., 2008; Coles, 2013; Sherin & van Es, 2005). One use of video clips is a video club (Sherin & Han, 2004), where teachers gather to watch a video clip of students' work in one of their own classrooms and identify and discuss the students' thinking. In a typical video club, the focus is on using evidence found in the video clip to identify what the student was thinking (van Es & Sherin, 2010). Video clubs have been shown to encourage teacher growth in focusing on student thinking over teacher moves (Sherin & Han, 2004), interpreting rather than evaluating students' actions (Sherin & van Es, 2005), and using evidence to back claims about students' thinking

(Sherin & van Es, 2005). The video clip is typically around five minutes in length (Sherin & van Es, 2005), and can be of whole class discussion (e.g. Sherin & van Es, 2005), group work (e.g. Borko et al., 2008), or students' work at the board (van Es, 2009). It is important that the video must highlight something mathematically interesting in the class (van Es, 2009).

Animations

Animations have also been used to encourage teachers' discussions in professional development. One example of the use of animations is the ThEMaT project (Herbst & Chazan, 2003), which uses animations to provoke teachers' discussions of what is typical in mathematics instruction by showing interactions that deviate from the norm. Outside of mathematics education, animations have also been used to promote character education (Bailey, Tettegah, & Bradley, 2006) and teach classroom management to pre-service teachers (Smith, McLaughlin, & Brown, 2012). While a goal of the use of animations is to encourage teacher learning (Chieu, Herbst, & Weiss, 2011; Nachlieli, 2011; Smith, McLaughlin, & Brown, 2012), a contrast with video clips is that animations can be designed to showcase specific aspects of teaching (Herbst & Chazan, 2006). Researchers have described additional benefits of animations as the ability to abstract a case so that teachers could identify with it as their own classroom and students by removing distinctive physical features from the classroom and animated characters (Chazan & Herbst, 2012; Herbst & Chazan, 2006). Overall, animations allow for the intentional design of specific cases of instruction in a way that can be presented to teachers in a generalized setting.

Comparing Videos and Animations

Researchers have found that teachers are able to discuss and analyze classroom interactions across multiple representations of teaching (Herbst & Chazan, 2006; Smith, McLaughlin, & Brown, 2006). When pre-service teachers were shown either a 3-D computer animation or a live action video of a classroom management scenario, there was no difference found in teachers' analysis (Smith, McLaughlin, & Brown, 2006). Herbst and Chazan (2006) found that, though teachers did remark on differences in the temporality of events when shown stories of teaching as animations, comic books, and slide shows, they still were able to discuss the stories as if they were real episodes from a classroom. In addition, while they found differences in the types of statements made, Herbst and Kosko (2014) found that animations and video were equally useful for eliciting teacher evaluations. Research comparing teacher reactions to video clips and animations suggests that animations are a valid representation of students' thinking when using video clips is not viable.

Research Questions

Because teachers have the ability to notice similarly when analyzing video clips and animations (Herbst, Aaron, & Erickson, 2013), and animations make it feasible to share video clips with a wider audience as previously described, we designed a process for representing video clips of students' thinking as animations and addressing challenges that we encountered during that process. Specifically, we wish to address the following questions:

1. How can a video clip be made into an animated vignette while preserving the nature of the original representation?
2. What challenges arise when creating an animated vignette from a video clip of students' thinking?

Because the animations we created were slides with voice-recorded dialogue, we could not create an exact replica of the original video clip with animated characters. However, we wanted the experience of watching the animations to be as close as possible to the experience of watching the original video clips. The first question addresses how we created a process that would allow us to

represent video clips as animations with slides and dialogue while maintaining the same criteria of the video clip that caused us to identify it as worthwhile. However, we found challenges in the process both with how to represent entire clips and with individual aspects of the clips. The second question discusses what challenges we encountered and how we addressed those challenges.

Theoretical Frameworks

cK¢ Framework

We used the cK¢ framework (Balacheff, 2013) to understand how students were thinking during the video clips. The cK¢ framework examines students thinking in terms of conceptions, which are composed of a problem which a student attempts to solve with a series of operations, using a set of semiotic resources, and verifying with a control structure (Balacheff, 2013). The cK¢ framework was useful for the analysis of the video clips because identifying the students' conceptions was a key purpose of viewing and discussing the original video clips. By analyzing the clips with a focus on each student's conceptions, we could ensure we represented the video clip as an animation in a way that preserved each of the original conceptions.

Criteria for Criticizing Video Clips

After we identified the students' conceptions using the cK¢ framework, we used the criteria of *window*, *depth*, and *clarity* defined by Sherin, Linsenmeier, and van Es (2009) to analyze how to represent the video clips as animations. The first criteria, *window*, refers to how well the clip affords the viewer an opportunity to determine what the student is thinking, while *depth* refers to how substantive the student's ideas are, and *clarity* refers to how well one can determine the student's thinking from the video clip (Sherin, Linsenmeier, & van Es, 2009). Because the depth of the students' ideas was dependent on the actual student operations, and not how they were represented, we did not consider the depth of the student idea when deciding how to represent the video as an animation. However, understanding the window into students' thinking for each conception and the clarity of the conception provided a framework for preserving the nature of each video clip when representing it as an animation.

Methods

Data for the project comes from video recorded in the classrooms of five Geometry teachers in high-needs schools that participated in a two-year professional development study group funded by the National Science Foundation, focusing on noticing and using students' prior knowledge. Video clips used in this paper were recorded only during the first year of the professional development, and were used for video club discussions during the professional development study group sessions. The animations to be created were a series of still frames of students working at a small group, with scripted audio. Because the original video clips were determined to be worthwhile examples of student thinking by the framework of window, depth, and clarity described by Sherin, Linsenmeier, and van Es (2009), and we desire to compare the video and animated representations of the classroom interaction, our goal was to maintain the nature of the original video clip as much as possible.

In order to design the animations, we first developed a template, using the students' conceptions framework by identifying the operations that students performed and semiotic resources used (Balacheff, 2013) in the video. We viewed the video in order from start to finish, coding each conception with corresponding operations and semiotic resources. To address the need to create both audio and visual slides for the animations, we described in the template what visual and verbal evidence demonstrated the students' operations for each conception. We then used the operations,

semiotic resources, and evidence to decide what should be included in the animated version of the video clip. We will discuss this process further to answer the first research question.

Results

Designing a Process to Preserve the Nature of the Original Video Clip

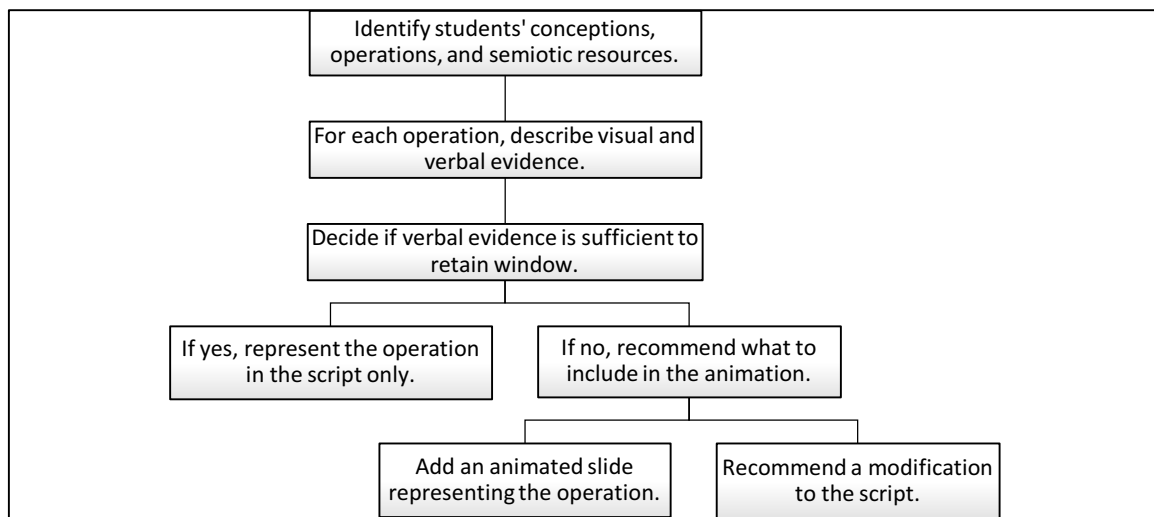
When using the template to recommend how to represent the video clips as animations, the central question we asked for each student operation was how to represent that operation to retain the window into students' thinking while not affecting the clarity. In order to do so, we examined the verbal and visual evidence shown by the student for each operation. Then, we asked if the window into students' thinking changed without the visual evidence. If it did not, we did not need to make a new slide for that operation, and relied on the script to represent the student's idea. If it did, we decided what needed to be added to the animation. Our guidelines were to preserve the script if possible, and write a recommendation for a slide to show the visual evidence. Figure 1 shows a flow chart of our process.


Figure 1. Flow chart of the video to animation process.

As an example of the video clip to animation process, Table 1 shows the template for a video clip of students working on a problem about dilation in the context of one-point perspective. The students are given a diagram with a vanishing point, two houses drawn to be the same size in one-point perspective on the right, and two trees drawn to be different sizes in one-point perspective on the left. In this specific video clip, the students are examining the figure in order to determine which tree is larger.

Table 1: Example of the video to animation template

Student	Description	What is visible at the beginning of the conception	Time Code Video	Operations	Semiotic Resources	Verbal evidence	Visual evidence	Is visual evidence needed?	Necessary evidence to retain window	Recommended modification
Stephanie	The front house is missing a line.	Students' worksheets with answers for question 1	0:40	Describe that she doesn't like the missing line.	Worksheet, pencil as pointing device	She says she doesn't like that there's a line missing	Pointing (missing line)	Yes	Where is the missing line	Slide: Show the paper with Stephanie pointing to the missing line.
Cassie	Use appearance to decide the larger tree	Same as before	0:58	Use appearance to determine the front tree is larger.	Worksheet, finger as pointing device	"But this tree does seem bigger than this one."	Pointing (trees)	Yes	Which tree looks bigger	Script: Replace "this tree" with "the front tree"
Stephanie	Use where the perspective line crosses the tree to decide which is larger.	Same as before	1:00	Examine where the perspective line crosses each tree.	Worksheet, finger as pointing device	"But if you look at it where this line crosses and it crosses right there it gets smaller."	Pointing (intersection of perspective lines and trees)	Yes	What intersections she is examining	Slide: Stephanie pointing to the perspective line crossing the larger tree.
				Determine the trees are the same size because of how the line crosses.		"I am saying yes because they are on the same vanishing point thing."	None	No	None	
				Write her answer on her paper.		None	None	No	None	
Stephanie	Determine what to call the lines.	Same as before	1:30	Ask what to call something on her paper.	Worksheet, pencil as pointing device	"What would you call this? Because that is the vanishing point."	Points to the vanishing point	Yes	What is she determining the name of	Slide: Stephanie pointing to the vanishing point.
				Explain that the point already there is the vanishing point.		"Because that is the vanishing point."	None	No	None	
				Decide to call it "perspective lines".		"Yea let's just call it that."	None	No	None	
Donell	The trees are the same size, and look different because of how far you are from them.	Same as before, with more written explanation in the answers to the questions.	1:50	Decide the trees are the same size because you are closer to the front one.	Worksheet	"I said yes because the closer you are to it the bigger things look. "	None	No	None	
				The second tree and house look smaller because they're further away.		"But the only reason why the second tree and house look smaller is because they are further away."	None	No	None	

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

First, we used what was visible at the beginning of the clip to determine what the initial slide in the animation would be. At the beginning of the clip, Stephanie is addressing the figure of the houses, one of which has a line missing that she remarks about. Her visual evidence to support this conclusion is pointing at the line. While she verbally claimed that a line was missing, the visual evidence of which line is necessary to retain the window into Stephanie's thinking. This required a new slide showing Stephanie pointing to this line. Then, when Cassie uses appearance to determine the larger tree, she claims, "But this tree does seem bigger than this one." Again, the window into her thinking decreases if we do not know which tree she is referring to. However, because there was a slide added directly before and after this comment, we chose to modify the script to retain the window, replacing "this tree" with "the front tree". In the next operation, Stephanie again points to indicate which line she is referring to, so we recommended a slide showing her pointing to the lines she was referring to. Stephanie does not show visual evidence in the next two operations, so no modifications were necessary to retain the window of those operations. However, in the next operation, she asks what to call the vanishing point by referring to it as "this" and pointing, so we added a slide of her pointing at the vanishing point. In the next two operations, she explicitly describes her thinking, and the script is sufficient to provide a window into her thinking. The final conception of the video, from Donell, is a case where the script does not provide a clear window into his thinking when he says, "I said yes because the closer you are to it the bigger things look." However, in the video, Donell does not show any visual evidence of what "it" is, so adding a modification to the slides or script would provide a greater window into his thinking than was shown in the original clip. The same is true with his final comment. As a result, no slides were added to show Donell's thinking.

Challenges in the Process of Representing Videos as Animations

Explaining clips vs. working clips. During the process of representing video clips as animations, we encountered two main types of challenges, challenges with the clip as a whole and challenges with individual operations. In terms of the clip as a whole, we found two main categories of clip, explaining clips and working clips. Explaining clips were those where the students were explaining their thinking to each other, such as the example above, whereas working clips were those where the students were working on new ideas. Some clips included both explaining and working.

Challenges with explaining clips. In general, explaining clips went smoothly using the process we previously described. These clips showed one student describing one conception with one set of visual evidence at a time, and students typically provided verbal evidence to describe their thinking. Most of the modifications we made involved adding slides or making small changes to the script in order to retain the window when students used vague language like "it" or "this one". The main challenges with explaining clips were difficulties representing certain individual operations in the animation.

In an explaining clip, it was difficult to represent when a student showed their work to another student, rather than specifically describing the actions they performed. In these cases, we chose to create a slide showing the student's work. We chose not to add a verbal description to the script because a verbal description would provide a higher window into students' thinking than the exclusively visual evidence provided in the original video clip. A second challenge was when students referred to multiple quantities in the video clip, but were either not specific about the quantities or specified by pointing. In this case, we had two options; to either add a visual slide showing the student pointing, or change the script to add a verbal description. We considered which modification would least affect the window and clarity of the original clip. For example, in Stephanie's first conception above, she is referring to a specific line on the paper, but there was no easily identifiable name for the line and it was the first new slide in the animation, so we chose to create a slide showing her pointing at the line. On the other hand, in Cassie's first conception, she is

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

referring to one of two trees and adding the word "front" to clarify which tree she referred to only modified one word of the script.

Challenges with working clips. Working clips were more challenging to represent as animations because of the nature of the entire clip, rather than challenges with individual operations. Working clips typically showed students independently working on different conceptions simultaneously, students spoke less, and each student showed different visual evidence for their own conception. One adaptation we made to the process for a working clip was to analyze the clip one student at a time, rather than analyzing the conceptions sequentially. This allowed us to remain consistent with the template by examining one conception at a time. After analyzing each individual student, we integrated slides showing the progression of all three students' conceptions back together as close to the original clip as possible.

One challenge in working clips was when a student did mathematical work without explicitly describing it. In some cases, the same clip showed students explaining their operations later. In these cases, we chose to include the explanation of the operations in the animation rather than the student working silently. This allowed the students' thinking to be shown in the video without repeating the same conception, while also retaining the clarity from the original video clip. If the student did not describe the work later, we showed visual slides representing the work without modifying the script. This remained consistent with the original video, where viewers needed to watch the student work on the problem without verbal evidence of what was being done.

Conclusion

Videos and animations have both been used to elicit teacher noticing of students' thinking (Chieu, Herbst, & Weiss, 2011; van Es & Sherin, 2010). Because researchers have found that teachers are able to notice similarly across different representations of students' thinking (Herbst & Kosko, 2014), and due to the ability of animations to reach a wider audience and represent a more general classroom (Chazan & Herbst, 2012), we designed a process to represent video clips we showed in a video club as animations. We found two types of video clips: explaining clips and working clips. While we were typically able to represent an explaining clip as an animation by following the process we designed, we addressed challenges with individual student operations that did not provide enough evidence to retain the window or clarity of students' thinking by making small changes to the script or adding slides to show visual evidence. Working clips were more challenging to represent as animations due to the lack of verbal evidence given by students while working. However, we were able to adapt the process of representing video clips as animations by examining each student individually, making recommendations for what visual evidence would be necessary to retain the window into students' thinking, and integrating the students' conceptions together as slides. Overall, using the dimensions of window and clarity allowed us to both consistently choose whether and when to adapt the script or create visual slides while also ensuring we avoided providing too much evidence in the animation and reducing the ability for teachers to notice student thinking themselves. Further work could compare teachers' reactions to video clips and animations of the same interaction. We believe this work is useful to researchers and designers of professional development as a process for creating animations from video clips in order to increase the number of uses of video clips, create animations that are as realistic to the original video clip as possible, and widen the audience for sharing examples of students' thinking.

NEGOTIATING MEANING: A CASE OF TEACHERS DISCUSSING MATHEMATICAL ABSTRACTION IN THE BLOGOSPHERE

Judy Larsen
Simon Fraser University
ajlarsen@sfu.ca

Many mathematics teachers engage in the practice of blogging. Although they are separated geographically, they are able to discuss teaching-related issues. In an effort to better understand the nature of these discussions, this paper presents an analysis of one particular episode of such a discussion. Wenger's theoretical framework of communities of practice informs the analysis by providing a tool to explain the negotiation of meaning in the episode. Results indicate that the blogging medium supports continuity of discussions and can allow for the negotiation of meaning, but that a more nuanced treatment of the construct is necessary.

Keywords: Teacher Education-Inservice/Professional Development, Technology, Learning Theory, Informal Education

Introduction

> I've been throwing around the term "pyramid of abstraction" recently, and there was some great pushback on Twitter this evening. This post is my attempt to clarify what I mean, and why I think it is a useful perspective to building students' knowledge. (Kane July 31, 2015)

Mathematics teacher Dylan Kane wrote the passage quoted above in a blog post after a series of Twitter interactions with mathematics teacher bloggers Dan Meyer and Michael Pershan. The series of interactions were prompted by Dylan's original blog post in which he explained ideas about a metaphor for mathematical abstraction as pertaining to his teaching practice. The discussion that resulted from this formulation presents an instance of a negotiation of meaning around a metaphor related to the teaching and learning of mathematics. Most importantly, it provides an example of how mathematics teachers are engaging in the practice of blogging, which is the focus of this paper. It should be noted, however, that this paper is not concerned with teacher knowledge (Ball, Thames, & Phelps, 2008; Shulman, 1986), but rather with the social interaction among mathematics teachers that the blogging practice affords.

Mathematics Teacher Blogging

Mathematics teachers around the world are choosing out of their own will to create, organize, and manage their own personal blog pages. On these publicly visible virtual pages, they make relatively regular posts, which are most often related to their work as mathematics teachers. These posts can include written and/or media enhanced recounts from their teaching experiences, links to interesting resources, and responses to posts that other bloggers have made.

Since blog pages are individually managed and no universal blogging platform exists, finding like-minded bloggers may at times be difficult. To mitigate this issue, many bloggers extend their practice through Twitter, a universal micro-blogging platform that allows users to create searchable profiles. There are currently 431 profile listings on the Math Twitter Blogosphere directory, most of whom have both a Twitter handle and a blog page listed on their profile. Although micro-blogging on Twitter is slightly different in nature than blogging due to the 140 character limit on each post, which forces users to communicate ideas more concisely, it is still considered a form of blogging (Ebner, 2013). Blog pages allow users to explore ideas deeply, but Twitter makes it easier for like-minded bloggers to connect. Mathematics teacher bloggers often use both mediums to express ideas, linking between the two when necessary. For instance, some bloggers include snips of Twitter conversations

in their blog posts, and other bloggers link to their blog posts within their Twitter posts. In this way, teachers are communicating with peers across the world.

This sort of collegial interaction is unusual for teachers because teaching is generally an isolated profession (Flinders, 1988; Lortie, 1975). Mathematics teachers' typical contact with other mathematics teachers is limited to that of department meetings and teacher lunchrooms, where teachers usually plan lessons and grade papers individually (Arbaugh, 2003). Sparse one-time professional development initiatives are not generally found to be effective in stimulating teacher collaboration (Ball, 2002), and they don't often extend into more regular professional development opportunities because they require time, funding, and facilitation.

However, there are hundreds of mathematics teacher bloggers who seem to be overcoming these constraints. It is evident that they spend hours writing publicly about their daily practice, posting resources, and sharing their dilemmas with no compensation and no mandate. This unprompted, unfunded, and unevaluated teacher activity is a rich phenomenon of interest that deserves attention. Ironically, this phenomenon is largely unstudied. Empirical investigations related to blogs in mathematics education are limited to studies on the utility of blogging as a pedagogical tool within either a mathematics course (Nehme, 2011) or a mathematics education course (Silverman & Clay, 2010; Stein, 2009). These studies do not account for the autonomous and self-driven nature of the blogosphere and there is no clear work in mathematics education exploring the activities of these teachers.

Research Question

As such, this study is guided by the overall research question of what the mathematics teacher blogosphere affords for teachers who engage in blogging in relation to their practice. To this end, in this paper I pursue an investigation of one episode that exemplifies the type of interaction that is possible within the mathematics teacher blogosphere.

Theoretical Framework

Since blogging is an individual practice that is made public (Efimova, 2009), a mid-level theory that accounts for situated participation is desirable. C*ommunities of practice* (Wenger, 1998) is one such theory: it is a social theory of learning where learning is considered as increasing *participation* in the pursuit of valued enterprises that are meaningful in a particular social context. *Practice* is at the heart of Wenger's (1998) *communities of practice*, and a key aspect of *practice* is the ability to motivate the social production of *meaning*. The continuous production of *meaning* is termed as the *negotiation of meaning*, and is further defined by the duality between *participation* and *reification*. For Wenger (1998), *participation* is "a process of taking part [as well as] the relations with others that reflect this process" (p. 55), and *reification* is "the process of giving form to our experience by producing objects that congeal this experience into 'thingness'" (p. 58). Both *participation* and *reification* shape the participant and the community in which they participate in an ongoing manner.

According to Wenger (1998), *participation* and *reification* imply each other, require and enable each other, and interact with each other. Wenger (1998) notes that the benefit to viewing the *negotiation of meaning* as a dual process is that it allows one to question how the production of meaning is distributed. He notes that there is "a unity in their duality, [because] to understand one, it is necessary to understand the other, [and] to enable one, it is necessary to enable the other" (Wenger, 1998, p. 62). Various combinations of the two will produce different experiences of *meaning*, and together they can create dynamism and richness in meaning if a particular balance is struck.

Wenger (1998) notes that "when too much reliance is placed on one at the expense of the other, the continuity of meaning is likely to become problematic in practice" (p. 65). If *participation* dominates, and "most of what matters is left unreified, then there may not be enough material to anchor the specificities of coordination and to uncover diverging assumptions" (p. 65). However, if

reification dominates, and "everything is reified, but with little opportunity for shared experience and interactive negotiation, then there may not be enough overlap in participation to recover a coordinated, relevant, or generative meaning" (p. 65). In essence, *participation* allows for re-negotiation of *meaning*, and *reification* creates the conditions for new *meanings*. In this interwoven relationship, the two aspects work together to drive the process of *negotiation of meaning*.

The interplay between *participation* and *reification* is different in each unique social situation, contributing to a different experience of *meaning* for participants of that *practice*. What is of interest in this paper is how mathematics teacher bloggers experience the social production of *meaning* within the blogging *practice*.

Method

In order to be able to view mathematics teacher blogger conversations on Twitter, I have spent over a year collecting subscriptions. Every user sees different posts based on who they subscribe to, and it is important to note that my pervasively subjective position influences what I can notice in this ultra-personalized and dense virtual environment.

Initially, my position was predominantly that of a 'lurker' in that I had not made significant contributions to the blogosphere. This position changed slightly after my attendance to the MTBoS conference 'Twitter Math Camp 2015' (TMC15). Physically meeting many of these bloggers connected me to them more than before. As my subscription list grew, I was also able to view more of their conversations. It was during this time after my return from TMC15 that I encountered a particular conversation between Dylan, Michael, and Dan that I flagged as interesting based on my theoretical framework and for its power to illustrate a possible mode of interaction in the blogosphere.

After the conversation took place, I used *storify.com*[1] to identify all tweets related to the conversation from the feeds of each of the participants (Dylan, Michael, and Dan), and rearranged them chronologically. I copied the written content of each post, the name of the participant, and the time stamp, and pasted it into an offline spreadsheet document. I also included the written content of any blog post that was linked to in the Twitter posts within this document. This reconstructed conversation made of Twitter and blog posts comprises the data set for this paper.

This data set was then coded according to Wenger's (1998) *negotiation of meaning* so that conclusions could be drawn about participant experiences of the social production of *meaning*, as embedded within the *practice* of teachers in the blogosphere. As part of the analysis, moments of *participation* and *reification* were coded and labelled at each instance. In general, *participation* was considered to be any action that a blogger took as part of the blogging *practice*, and *reification* was considered to be any trace that was left from a *participation*. The interplay between these aspects was then considered in relation to the data, and conclusions were drawn about the nature of the *negotiation of meaning* as exemplified in this case of mathematics teacher blogging.

In what follows, a reduced version of the reconstructed conversation is presented in the results section, and is then reviewed in terms of Wenger's (1998) *negotiation of meaning* construct in the analysis and discussion section.

Results

On June 25, 2015, Dylan writes a blog post about his ideas regarding how teachers can help students deal with solving difficult mathematical problems by helping them become better equipped to transfer prior knowledge to new contexts in mathematics. He refers to the popular 'ladder of abstraction' metaphor, and claims that it is incomplete.

> I often hear references to the "ladder of abstraction" — the idea that students' understanding begins with the concrete, and climbs a metaphorical ladder as it becomes more and more abstract. I think this is a useful metaphor, but is also incomplete. (Kane June 25, 2015)

Dylan then suggests an alternative to the metaphor that would make it more useful in classroom practice and more reflective of how he has experienced students learning mathematics.

> I think the metaphor of a ladder of abstraction would be better replaced by a pyramid of abstraction . . . I worry that the ladder of abstraction metaphor leads me to believe that, once a student understands one concrete example of a function, they are ready for a more abstract example. While some students may be, I want to focus on building a broad base first, and then moving up the pyramid after we have spent time analyzing the connections between the examples and the underlying structure. (Kane June 25, 2015)

A month later, on July 17th, Dylan writes a reflection about his experiences at PCMI, a three-week summer mathematics institute. In this post, he discusses the importance of letting students engage in productive struggle within mathematical problem solving, without oversimplifying. Just after making this point, he uses a hyperlink (italicized below) to refer back to the June 25th blog post in which he had introduced the idea of a 'pyramid of abstraction.'

> This gets at something I wrote about recently that I called the *pyramid of abstraction* – that students build abstract ideas from looking at connections between a wide variety of examples, rather than simply jumping from concrete to abstract. (Kane July 17, 2015)

Just as for his June 25th post, Dylan publishes a link to his July 17th post on Twitter (Figure 1).

Figure 1: Dylan's Twitter post linking to his blog post.

Shortly after publishing the link to his July 17th blog post on Twitter, Michael Pershan responds in agreement with Dylan's reference to the 'pyramid of abstraction' metaphor (Figure 2).
Figure 2: Michael's response to Dylan's post.

Fifteen days later on July 31st, Dan Meyer challenges Dylan and Michael on Twitter by asking about the meaning of the apex of the 'pyramid of abstraction' (Figure 3).
Figure 3: Dan's question to Dylan and Michael.

This is followed by a series of interactions on Twitter between Dan, Michael, and Dylan that occurs over the course of a few hours. This series of interactions is presented in transcript form below. Some comments have been removed for brevity.

> *3:55 Dan:* Q: What does the apex represent?

4:13 Michael: Like, the uber-apex? Or the apex for a skill family?

4:23 Dylan: an abstract principle that can be transferred among multiple contexts-think of all math as nested pyramids of abstraction

4:24 Michael: And at the very tippy tippy top something like "do math," I guess.

4:28 Dan: I'm asking about the significance of the pyramid's tippy-top in this newfangled metaphor.

4:29 Dan: I don't think Dylan's explanation works. I can always abstract the "abstract principle" he puts at the top.

4:30 Dan: Abstraction has no end. Seems to me you guys are in a jam.

4:31 Dylan: maybe abstract isn't the best word. Heart of this for me is knowledge that will transfer to a new context

4:35 Dan: Pyramid of something-other-than-abstraction then? Curious what it is you're trying to describe.

4:38 Dylan: I'm defining abstract as knowledge that transfers. I want to stick with that, but it's worth defining more carefully

4:39 Michael: I'm staying away from such a tough problem as trying to define "abstract"!

4:40 Michael: When I am interested in pyramids of abstraction, it's an attempt to describe mathematical thinking.

4:40 Michael: There are strategies that we use that often represent bundles of strategies, and so on.

4:55 Dylan: my premise is that students need many representations to abstract from, hence a pyramid.

5:07 Dan: But abstraction requires multiple instances /by definition/.

5:08 Dan: Just saying this pyramid thing complicates an already complicated concept.

A few hours later, at 9:28PM on July 31st, Dylan publishes a blog post in response to this conversation, starting with the post initially quoted in the introduction of this paper, and proceeding to explain how he has defined 'abstraction.'

> I'm defining abstraction very specifically. A student abstracts a concept, or builds abstract knowledge, if they can apply that knowledge in multiple contexts. (Kane July 31, 2015)

He then discusses why he thinks a 'pyramid of abstraction' is useful in teaching mathematics and why this metaphor matters to him as a teacher.

> There are a set of teacher actions we can take to facilitate *transfer* — that moment when a student applies a concept they understand to a context they haven't seen before. That's what I'm chasing. (Kane July 31, 2015)

In the last section of his blog post, he lists issues he still has with the metaphor, acknowledging that it is possible the metaphor obfuscates the concept he wants it to represent, and asking the reader if it makes sense to them. He also concedes that there may be no end to abstraction, but that he personally doesn't believe this is true.

> If points in the coordinate plane are an abstract concept, and linear relationships are another abstract concept, and functions are another abstract concept, do we end up in an infinite pyramid of abstraction? I don't think so. I think each of those ideas can then be a building block for broader mathematical concepts. (Kane July 31, 2015)

Finally, he admits he is integrating knowledge transfer and abstraction into one idea, and implicates that this may be a result of his own understanding of 'abstraction.'

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Do I Actually Understand Abstraction? I'm redefining abstraction a bit, and I'm also lumping knowledge transfer as one giant idea, which it might not be. (Kane July 31, 2015)

Analysis and Discussion

Initially, Dylan *participates* in thinking about his past formulations about problem solving and writes these ideas in the blog post that he publishes on June 25th. Within this process of *participation,* Dylan engages in a process of *reification* when formulating his 'pyramid of abstraction' metaphor. He also produces a public trace of this process, which can be seen as the product of his *reification*. This trace is made even more public than a blog post because Dylan also links to it on Twitter.

On July 27th, Dylan *participates* again in this same manner by posting a blog post and linking to it on Twitter, but this time with a focus on recapturing his experiences from a professional development encounter. In this process of *participation*, he uses a hyperlink to reference a *reification* he made on June 25th regarding his formulation of the 'pyramid of abstraction' metaphor. In this way, the June 25th *reification* has prompted further *participation* around this topic on July 27th, resulting in a new *reification*, and a *re-negotiation* of meaning. The concept now has a rich history, and is traceable through the use of hyperlinks.

When Michael publicly agrees on Twitter with Dylan's metaphor, a *participation* and *reification* in itself, it makes Dylan's 'pyramid of abstraction' *reification* even more public, and catches the attention of Dan fifteen days later, who then challenges the metaphor. The power of Dan's *reification* (3:55) is that it is pervasively public. Dan currently has 46,324 followers, Michael has 4,761, and Dylan has 1190. The nature of Twitter is that if one member tags another in a post, only those who follow both members see the post in their feed. Since Dan, Michael, and Dylan share followers as mathematics teacher bloggers, the number of people who see such a post is large.

This now very visible *reification* prompts a series of *participations* and *reifications* from all three of these members as well as from any 'lurkers' who may be reading. In particular, Dan's question about the apex of the pyramid (3:55) is a *reification* that prompts *participation* from both Dylan and Michael, who *reify* their interpretations of the 'pyramid of abstraction' metaphor. Dylan *reifies* his focus on knowledge transfer as the implication of the pyramid metaphor (4:23), and Michael *reifies* his vision of the pyramid metaphor as a skill family (4:13) that ultimately comprises mathematics (4:24). In this way, the *meaning* of the metaphor is being *negotiated*.

Dan subsequently *participates* by posting that he does not think Dylan's explanation works (4:29) and that there can be no 'top' to abstraction (4:30). This *reification* stimulates a *re-negotiation* of the term 'abstraction.' Dylan *participates* further by *reifying* his focus on knowledge transfer (4:38) while Michael *participates* by *reifying* that the focus should not be on defining abstraction, but rather on how students bundle strategies in mathematics (4:39-4:40). This shifts the *negotiation of meaning* to a focus on the applicability of this metaphor to mathematical learning, and Dylan *reifies* that his intent with the metaphor is to explain that students need multiple representations of a concept in order to be able to abstract mathematical meaning (4:55). Dylan then restates his impressions of the conversation and refines his concept of the 'pyramid of abstraction' metaphor in the blog post he publicizes a few hours later. This post may be seen as a reflective form of *participation* in which Dylan *reifies* a heightened level of awareness regarding the 'pyramid of abstraction' metaphor. Perhaps the most powerful *reification* Dylan makes in this blog post is that 'abstraction' is not ubiquitously defined. This ultimately reflects Dylan's experience of *meaning* in this context.

Wenger (1998) states that "having a tool to perform an activity changes the nature of that activity" (p. 60). It is clear that the blogging tool has done just that for these mathematics teachers because unlike in a face to face discussion, the practice of blogging results in *participations* that directly produce permanent, public, and traceable *reifications*, making them prime contenders for prompting *participation* and holding participants accountable for their statements. As such, the

continuity of *meaning* within this medium clearly does not suffer as Wenger (1998) warns can happen if too much emphasis is placed on either *participation* or *reification*.

Further, the asynchronicity of the medium allows participants to take time between responses, which may imply various degrees of *participation* in the practice, and in turn, various degrees of *reification*. Unfortunately, Wenger's (1998) construct does not provide a mechanism for such differentiation. He defines each component broadly, including a wide variety of interactions, most of which would occur in a face to face setting. However, in the case of blogging, *participations* include not only writing posts, but also restating, questioning, and devising examples, while *reifications* include not only publicized posts, but also ideas that have now attained a state of 'thingness' in the community, which here is most prominently the 'pyramid of abstraction' metaphor.

Conclusions

I have illustrated that the blogging medium changes the nature of mathematics teacher discussions because its design allows for *participation* and *reification* to be closely intertwined in a way that their co-evolving and co-implicated relationship drives the *negotiation of meaning* among participants, ensuring continuity of *negotiation*. Such continuity is an important affordance of the mathematics teacher blogosphere experience, and it can be attributed to three important features: asynchronicity, permanency, and publicity. Asynchronicity allows users to *participate* and *reify* to different degrees depending on how long they take to respond, permanency allows *reifications* to prompt further *participation* even days or months later, and publicity allows *reifications* of *participations* to be visible by many 'lurkers,' whose presence makes *participants* accountable for their *reifications*.

I have also revealed that a more nuanced treatment of *participation* and *reification* is needed for mathematics teacher blogging in particular. Some *participations* are quick and spontaneous tweets, while others are prolonged and accompanied by reflective activity. Some *reifications* are mere traces, while others are concepts such as a 'pyramid of abstraction.' Heightened levels of awareness resulting from a prolonged *negotiation of meaning* can also be considered *reifications*. There is currently no terminology within Wenger's (1998) construct to refer to such higher order *participations* and *reifications*.

Finally, the construct of *negotiation of meaning* also has the power to expose *what* is being negotiated. In this case, teachers found it valuable to invest time into engaging in *negotiating the meaning* of 'abstraction' and the metaphor of a 'pyramid of abstraction' as opposed to a 'ladder of abstraction.' Looking for more of these instances may help identify teaching-related issues of interest to mathematics teachers. Most evidently, the development of ideas can be traced within the blogging medium. Each idea has a history and a future. The history is traceable, and the future is quickly unfolding.

Endnotes

[1] *Storify.com* is an online service that allows users to curate content from various social media sources, and arrange it in any order, with narration if desired. It also makes it possible to automatically arrange content chronologically.

FROM THE UNIVERSITY TO THE CLASSROOM: PROSPECTIVE ELEMENTARY MATHEMATICS SPECIALISTS' PEDAGOGICAL SHIFTS

Kayla D. Myers	Susan L. Swars	Stephanie Z. Smith
Georgia State University	Georgia State University	Georgia State University
kmyers@gsu.edu	sswars@gsu.edu	szsmith@gsu.edu

This project focuses on the development of prospective Elementary Mathematics Specialists (EMSs) in a K-5 Mathematics Endorsement Program. Program courses emphasized elementary mathematics content and pedagogy while providing opportunities for participants to evidence their learning through classroom teaching practice, all in an attempt to facilitate pedagogical shifts toward more standards-based instruction and dialogic discourse. Data presented include scored observation rubrics of classroom practices, professional portfolio reflections on implementation of new teaching practices, and semi-structured, individual interviews.

Keywords: Teacher Knowledge, Teacher Education-Inservice/Professional Development, Problem Solving

Purpose

Many in the field of mathematics education are proponents of Elementary Mathematics Specialists (EMSs) and the critical role they have in elementary schools of supporting effective mathematics instruction. The recent unified position of several prominent mathematics education organizations, including the Association of Mathematics Teacher Educators (AMTE, 2013), asserts every elementary school in the U.S. should have access to an EMS and that advanced specialist certification should be offered via intensive preparation programs. One salient challenge associated with EMSs' preparation is their development of new ways of teaching in elementary classrooms.

Adopted by most states in the U.S., the Standards for Mathematical Practice in the *Common Core State Standards for Mathematics* (CCSS-M; National Governors Association Center for Best Practices [NGACBP] & Council of Chief State School Officers [CCSSO], 2010) and the National Council of Teachers of Mathematics' *Principles to Actions* (NCTM, 2014) both strongly depict *standards-based learning environments* (SBLE) that foster dialogic discourse and conceptual understandings of mathematics. In such learning environments, students make conjectures about their mathematical ideas and explain their thinking and reasoning while teachers value students' multiple perspectives and carefully craft mathematical discussions by using their ideas to bring the classroom to shared mathematical understandings. This pedagogical approach requires thoughtful planning and questioning on the part of the teacher and is a key shift away from traditional classroom instruction. An important goal of EMS preparation is the development of these pedagogical competencies.

Our university is located in one of the limited number of states in the U.S. offering EMS certification (i.e., a K-5 Mathematics Endorsement [K-5 ME]). Key goals for participants in the K-5 ME program are pedagogical shifts toward alignment with a SBLE, development of the *specialized content knowledge* (SCK) necessary for teaching mathematics, and changes in mathematical beliefs. Research in general on EMS preparation is limited, and our previous research on this particular program shows teachers had significant: increases in SCK, changes in pedagogical beliefs toward a cognitive orientation, and increases in mathematics teaching efficacy (Swars, Smith, Smith, Carothers, & Myers, 2016). This study in particular extends the existing inquiry on the program by focusing more so on the translation of learning in the K-5 ME courses into instructional practices. It was guided by the following research questions: What pedagogical shifts do prospective EMSs experience as they complete a K-5 ME program? How do prospective EMSs describe their pedagogical shifts during a K-5 ME program?

Literature Review

EMSs are generally considered to be teachers, teacher leaders, or coaches with the expertise to support effective elementary mathematics instruction and student learning in the classroom, school, or other levels (AMTE, 2013). Over time, the roles of EMSs have mostly been considered in two ways, including EMSs who work with students and EMSs who work with teachers (AMTE, 2013; Reys & Fennell, 2003). In general, the specific roles and responsibilities of EMSs vary according to the contextual needs and plans of schools and school systems, with an increasing number of schools utilizing EMSs in some manner (Gerretson, Bosnick, & Schofield, 2008). The extant studies on EMSs have focused on improving instructional practices, designing coaching programs, and improving student achievement, with overall results showing positive impacts of EMSs on teacher development and student learning (Campbell & Malkus, 2011; McGee, Polly, & Wang, 2013).

A body of research shows that classroom pedagogy has more influence on improving student learning than the use of particular curriculum materials (Brown, Pitvorec, Ditto, & Kelso, 2009; Remillard, 2005; Tarr et al., 2008). The *Principles and Standards for School Mathematics* (NCTM, 2000) and the CCSS-M recommend the intersection of mathematical content and process standards requiring a pedagogical approach different from the traditional direct instruction in computational skills still found in many U.S. classrooms. Many of these suggestions are grounded in constructivist compatible instruction, where teachers: engage students in real-life contexts; provide students with original, non-routine problems; and develop a classroom community grounded in dialogic discourse intended to develop students' individual and shared understandings of mathematical concepts and practices in ways that nurture their abilities to problem solve, reason, and communicate mathematically (Charalambous & Hill, 2012; Cobb & Jackson, 2011; Tarr et al., 2008). Teachers are creating SBLEs and ensuring their instructional tasks hold high levels of cognitive demand (Porter, 2002; Stein, Smith, Henningsen, & Silver, 2009). According to the Tarr et al. (2008) study, improved student learning and achievement was connected to the extent of enactment of such a SBLE.

Methodology

This inquiry used a descriptive, holistic case study design. The case was the described experience of implementation by a group of elementary teachers in an EMS preparation program. We focused on their efforts to enact instructional practices in their classrooms drawn from their learning in the program. Collected data were both qualitative and quantitative in nature.

Participants and Setting

Participants were 13 elementary teachers enrolled in a graduate level K-5 ME program at a large, urban university in the southeastern U.S. The teachers worked at one urban, elementary school recently converted to a charter school. They held varying teaching positions at the school, including those of classroom teacher, small group resource teacher, and instructional coach, but all worked with the primary grades.

A foremost goal of the program was the development of a deep and broad understanding of elementary mathematical content, including the *specialized content knowledge* (SCK) for teaching elementary mathematics (i.e., the "mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students" [Ball, Thames, & Phelps, 2008, p. 399]). The program also focused on high-leverage teaching capabilities in the elementary classroom, including: (a) selection and implementation of mathematical tasks with high levels of cognitive demand, (b) use of multiple mathematical representations, (c) use of mathematical tools, (d) promotion of mathematical dialogic discourse, explanation and justification, problem solving, and connections and applications typical of a SBLE, and (e) use of children's thinking and understandings to guide instruction. Learning during course sessions occurred via: (a) active inquiry and analysis of the mathematics in the elementary curriculum, specifically the CCSS-M, (b) study of children's thinking and learning by way of video

clips and teaching cases, (c) examination of examples of classroom practice through video clips and teaching cases, and (d) scrutiny of the research base related to mathematics teaching and learning in the elementary grades.

The program was two semesters in duration and included four 3-semester-hour mathematics content courses for elementary teachers that integrate pedagogy, plus one 3-semester-hour practicum course providing an authentic residency. The four courses were: Number & Operations, Algebra, Data Analysis & Probability, and Geometry & Measurement. Each course was offered for 7 weeks, meeting 1 evening per week for 5.5 hours at the elementary school. The Number & Operations course had a significant focus on Cognitively Guided Instruction (CGI). Key program assignments included: clinical-style interviews of children's mathematical understandings; selection, adaptation, or generation and analyses of worthwhile mathematical tasks; an in-depth data design, collection, and analysis project; and critical examination and presentation of extant research on elementary mathematics education via synthesis papers. The participants also completed a 3-semester hour practicum course during the second semester of the program that provides an authentic residency enacting the synthesis of content knowledge and problem-based pedagogy emphasized in the program. Practicum assignments included the creation of a portfolio demonstrating expertise in teaching elementary mathematics, analyzing impact on diverse student learning, and technology integration. Successful completion of the practicum and all four of the content/pedagogy courses led to recommendation for the K-5 ME.

Data Collection and Analysis

Quantitative data were collected using scored observations of classroom teaching practices with what we have called the Standards-based Learning Environment Observation Protocol (SBLEOP), which documents the degree to which the teacher facilitates and the students experience a SBLE (Tarr et al., 2008). This observation protocol was adapted from an observation tool in the Wisconsin Longitudinal Study (Romberg & Shafer, 2003) and slightly modified for the K-5 ME program. It consists of a rubric assessing the extent to which specific mathematics classroom learning events are apparent during an observed lesson, using a scale of 1 to 3, with a higher score indicating more alignment with a SBLE. Five of the classroom events were included as data in this study.

Qualitative data include professional portfolios with teacher reflections, as well as six individual interviews. The professional portfolios with teacher reflections and two classroom observations, conducted by the university supervisor, were completed as part of the authentic residency course in the second semester of the program, and provided the opportunity to document: the degree to which classroom instruction included worthwhile mathematical tasks and evidence of a SBLE; analysis of diverse student work and achievement using formative assessments and remediation; technology integration; and personal reflections on teaching practices. This documentation experience served as a cumulative reflection for the participants and a summative evaluation for the university supervisor. Portfolios were required to have at least ten enacted lesson plans with at least one lesson from each of the four mathematical domains of the program's courses. Given the participants' consistent focus on the Number and Operations domain for the classroom observations, as well as the majority of the additional six chosen lessons included in the portfolios, teacher reflections were drawn from the Number and Operations section of the professional portfolio for analysis. The semi-structured, individual interviews were conducted with six randomly selected participants within two weeks of completion of the program, exploring their experiences with implementation and documentation (i.e., the portfolio, classroom observations, reflections, etc.) during the program.

The qualitative and quantitative data were intended to reciprocally illuminate and extend the findings, particularly in the drawing of conclusions. The interview and teacher reflection data were analyzed using line-by-line open coding that generated numerous meaning units (i.e., embedded coherent and distinct meanings), which were then documented in a coding manual. These meaning

units were then compared across cases and as consensus was reached between the researchers, coded meaning units were collapsed and renamed until final shared themes were determined. Descriptive statistics were used for analysis of the items on the SBLEOP.

Results

Quantitative Findings

The SBLEOP from the authentic residency course in the final semester of the program provided categorical data for five classroom events from two classroom observations. We used the same approach as Tarr et al. (2008) to convert these data to numerical data. We summed the individual scores (1, 2, 3) from the two observations, then determined whether each event for each participant should be rated as high (5-6), medium (3-4), or low (2). These categorical codes were then assigned numerical values of 2 (high), 1 (medium), or 0 (low). These numerical values were then summed across the five classroom events to find a composite score for each participant ranging from 0-10, which indicate teachers' enactment of a SBLE. Table 1 shows the percentages of participants who were rated as low, medium, or high by classroom event and the percentages of participants in each range of composite scores. The composite scores show that 85% of these teachers enacted a SBLE at a high level (7-10), and the remaining 15% enacted a SBLE at a medium level with a composite score of 6 out of 10.

Table 1: Percentage of Participants by Score for SBLEOP and Composite Score

Classroom Event	Scores with Numerical Codes of 0, 1, 2		
	Low (0)	*Med (1)*	*High (2)*
CE1 Making Conjectures	31%	62%	8%
CE2 Conceptual Understanding	0%	8%	92%
CE5 Explaining Strategies	0%	15%	85%
CE6 Multiple Perspectives	0%	0%	100%
CE7 Using Student Statements	0%	54%	46%
	Sum of Event Scores (0-10)		
	Low (0-2)	*Med (3-6)*	*High (7-10)*
Composite Scores	0%	15%	85%

Qualitative Findings

The analysis of the interview and reflection data revealed several commonalities across participants' experiences with classroom implementation. These themes tell a story of movement through shifting beliefs and practice across the program. Participants began in a place of *skepticism*, troubling this new way of teaching and learning mathematics, with resistance that came from doubt and uncertainty. It was not until participants *tried it on*, by putting pieces into practice and experimenting in the classroom, that they began to see things differently. This move to the classroom was often credited to the implementation assignments and documentation requirements (i.e., classroom observations and creation of the portfolio) from their authentic residency course, which served as *shifters,* or impetuses for change in their practices and beliefs about teaching and learning mathematics. Ultimately, though, we found that participants *need more support* in their classroom endeavors. The changes they were making were challenging and significant in scale, and the feedback and support needed to maintain these new practices were acknowledged.

Skepticism. When these participants started the endorsement courses, they were coming from a place of skepticism. This community of teachers was immersed into a very rigorous program of study, and the initial reaction was resistance. Participants were holding on to well-entrenched habits and customary practices, which provided a level of comfort and safety. These long standing teaching

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

practices were troubled in the endorsement courses. Their first course, Number & Operations, introduced them to CGI, including the problem types, solution strategies, and the power of a problem-based pedagogical approach when implemented with rich dialogic discourse in the classroom. Participants watched videos in the course of CGI implementation and voiced skepticism because they thought: (a) it took too much time to develop such a pedagogical routine, (b) their own students were not capable like those from the videos, and (c) the expectations for classrooms were unrealistic.

Participants initially believed that incorporating CGI would be too difficult because it would take a long time to develop an aligned pedagogical routine with students. This assumption came from a place of skepticism about the capabilities of students' thinking and learning in their own classrooms. When reflecting on watching the videos in class, one interviewee said, "I was still wondering, ok, how long had they been exposed? It just was really scary especially um with me teaching the kids who are struggling in math… will they be able, you know, to do this?" However, that same interviewee came to think about her students in a new and promising way: "I'm thinking, like, these kids aren't, you know, as LOW as people think…"

The biggest place of skepticism was in this disbelief about what children can do mathematically and how they can learn: "I was a non-believer at first… I'm like, word problems are the hardest things that kids have to do in math. They struggle with that the most, and to just see it is unbelievable." This skepticism about their own students quickly diminished as they began to witness firsthand their learning in the classroom, as one participant asserted, "I think for me the biggest a-ha was my mindset about what I thought kids could do… so for me, it's just planning it out and knowing that kids can." Participants started to see their students "can do more than we give them credit for", and "they can surprise you with what they know".

Trying it on. In the authentic residency course experience, participants were required to complete two passing classroom observations of their mathematics instruction. The observation rubric was highly conducive for a CGI lesson, so nearly everyone chose to try that on. In this trying on, this implementation of CGI, participants felt anxious about their execution, wondering if they were "doing it right". They also felt uncomfortable in not knowing if it would work. In trying it on, though, and engaging in it for themselves, they grew in confidence about the effects of CGI and also their impact as mathematics teachers. They were valuing the mathematics, the thinking involved, the conceptual understanding and problem solving skills, the multiplicity of strategies, and the explanations their students were using. Said one participant, "Kids that can't even read word problems necessarily work them out and have the strategies and the conceptual understanding… it's just that powerful."

The mathematics that participants noticed was another focus in their stories of implementation. They spoke of "witnessing a shift in their [students'] mathematical thinking," and their students "feeling successful in their ability to solve problems" and "going from procedural to conceptual understanding". The discourse that participants facilitated in their classrooms also led to important shifts in their thinking about how children learn mathematics. Finding (for themselves and from their students) that there are multiple ways to solve problems, many ways to think about the same mathematics, and numerous perspectives on the same story problem. Most importantly, participants began to value discourse, this opportunity for the class to hear and learn from each other, as a way for students to explain and justify their thinking. One participant asserted, "I think [CGI] has been the best thing I have learned in math as a teacher thus far, hands down. Nothing compares to it… I think that's the most important thing I have learned in math thus far." Additionally, they found it built a stronger classroom community.

Having 13 prospective EMSs as participants in the same school, working on the same coursework and implementing the same practices, built a strong community of teachers as learners as well. This support system provided a push to ask questions, to try new things, and to persevere. This

parallel, between what CGI did for their mathematics classroom community and what a collective implementation did for the school community, is noteworthy.

Shifters. In connecting their learning of theory, methods, and content from the courses to enactment in the classroom setting, there are many factors that contributed to shifts in instructional practices and beliefs. These factors, or "shifters", include: receiving and using critical feedback, program coursework (e.g., clinical interviews and worthwhile mathematical task collections), implementation of and reflection on classroom observations, documentation in the professional portfolio, listening to children's mathematical thinking, trying on new and different instructional practices, and deepening their own mathematical understanding, to name a few. In particular, interviewees spoke specifically about the value of the implementation (classroom observations) and the documentation (portfolio), in their shifts: "I think I would've continued to do it the way I was doing it and probably would've kept getting frustrated with not getting the results that I was looking for. So I think that really helped me, having [the university supervisor] come in here."

Facilitating this buy-in and meaningfully shifting the prospective EMSs' instructional practices and beliefs was not easy. These salient experiences, these "shifters", generated a change that pushes beyond imagination into reality: "There's no way that I would have ever bought in to this had I not had the practicum experience." By taking their course learning and having a space as a community to implement and document over time as they tried on these new teaching practices in their own elementary classrooms, participants began to notice their beliefs shifting, their practices shifting, and their attitudes toward mathematics shifting. Said one participant, "The mantra that I have lived by every year, I want to reinvent myself, and I will say that every year. I say it and then [in] the summer I'm like, did I reinvent myself? I don't think I did. But I think if I reflect THIS time I can say I reinvented myself."

Need more support. Across the data, there was an emphatic call for further support and feedback. Each participant made note of their appreciation for the feedback they received; however, two evaluative classroom visits provided limited time and support from the university supervisor. One participant in particular recommended some sort of follow-up as they tried on new practices: "just come back and check on us". Another participant, one of several, mentioned the need for non-evaluative spaces for feedback and support. For their two observations, participants would choose lessons that they felt confident implementing; but, in their struggles and changing instructional practices and beliefs, they often had questions and a need for support apart from their evaluation: "It would be great for us to kind of still have mentors, somebody to come and check in on us."

Another consistent desire voiced by the teachers was sustainability. Participants recognized that they learned a lot in one year, and they voiced an aspiration to make sure they continue to implement these new teaching strategies. Some ideas for this sustainability were to implement ongoing professional development, to have more classes over the summer, and to have more opportunities to bring university supervisors or mentors into their classrooms.

Discussion

EMSs provide crucial and needed mathematics expertise in elementary schools. However, there is limited research on how to best prepare EMSs and in particular support the difficult process of pedagogical shifts in classrooms. This case study explored the experiences of one group of prospective EMSs as they sought to connect their learning of theory, teaching methods, and content knowledge in program courses with their classroom instructional practices.

The quantitative and qualitative data revealed the prospective EMSs were facilitating instruction mostly aligned with a SBLE. The SBLEOP showed the largest gain across the two observed lessons was the classroom event of enacting lessons that foster development of conceptual understanding. Prospective EMSs were encouraging and valuing students' multiple strategies and perspectives and creating learning opportunities grounded in dialogic discourse as they valued students' mathematical

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

statements and used them to build discussion or develop shared understanding, and students were explaining their mental reasoning and problem-solving strategies. However, they struggled to provide frequent opportunities for their students to make conjectures (i.e., informal generalizations) about mathematical concepts and processes in the context of problem-based learning. From our own experiences, overcoming this difficulty requires more time for classroom discourse, deeper understandings of the mathematical connections to and within the content by both teachers and students, and higher expectations that young children can make important connections and generalizations.

These teaching practices evidenced on the SBLEOP did not come easily for the participants. Skepticism and disbelief marked their perceptions of their own students' mathematical capabilities. When viewing videos of children's mathematical reasoning and explanation during the course sessions, the teachers were highly dubious that such could occur in their own classroom realities, due to students' inabilities and time constraints of a pedagogical routine grounded in problems. However, experimentation with what they were learning in the courses, particularly a problem-based pedagogy aligned with CGI, made them believers. Trying it on and seeing the benefits for and capabilities of their own students were instrumental in the prospective EMSs changing their practices and beliefs about teaching and learning mathematics.

The qualitative data revealed the key supports for trying on new instructional practices, including the authentic residency course assignments. Shifters, like supervisor feedback, clinical interviews and worthwhile mathematical tasks assignments, classroom observations, and the creation of the professional portfolio, pushed participants to make these pedagogical changes. Many participants began the program from a place of skepticism, but after implementation (trying on new teaching practices) and documentation (portfolio assignments and reflections), changed their practices and beliefs. Participants identified the importance and profound impact of implementing a SBLE in their classrooms, notably the use of CGI as a guide for instruction. However, the prospective EMSs voiced the need for more support. They wanted help and feedback beyond the two enacted lessons in the program and also after program completion. Participants wanted opportunities for non-evaluative classroom observations with reflection and feedback.

In sum, it is vital that the efficacy of EMS preparation programs, such as the one in this study, be carefully studied in order to determine their impact. Based on our findings, the participants in this program connected their learning in the courses with their classroom teaching practices. Even more importantly, the participants found immense value in that connection and desire continued support in maintaining these new practices. It seems the implementation and documentation expectations during the authentic residency course supported this very difficult translation, facilitating the ultimate goal of the program of pedagogical shifts.

There has been limited attention to early career teachers' (ECTs) understandings and practices related to language in teaching and learning mathematics. In this qualitative case study, we drew upon frameworks for teacher noticing to study the language practices of six early career elementary and middle school mathematics teachers. We describe multiple themes that cut across teachers' noticing related to language and language learners, and discuss one theme (i.e., Perspectives on multiple languages) in more detail, including evidence of specific forms of noticing. Implications for teacher education and professional development are discussed.

Keywords: Elementary School Education, Teacher Education-Inservice, Instructional Activities and Practices, Equity and Diversity

Various calls have been issued to better prepare teachers to address the mathematics learning needs of a growing multilingual student population (Diversity in Mathematics Education Center for Learning and Teaching [DiME]; 2007; Grossman, Schoenfeld, & Lee, 2005; National Council of Teachers of Mathematics [NCTM], 2014). However, despite a sociopolitical turn in teacher education (Gutiérrez, 2013), serious attention to equity has been slow to gain hold. Mathematics teacher educators have argued that a key component of equitable mathematics instruction is drawing on the diverse experiences and understandings that children bring to the classroom, including children's mathematical thinking and children's linguistic and cultural funds of knowledge, or what we refer to as children's multiple mathematical knowledge bases (Turner et al., 2012). Prior research has documented preservice elementary teachers' learning related to children's multiple mathematical knowledge bases in the context of mathematics methods courses (Turner et al., 2012). Yet few studies have investigated how preservice teachers take up these practices in early career teaching. In particular, there has been limited attention to early career teachers' (ECTs) understandings and practices related to *language and language learners* in teaching and learning mathematics (Janzen, 2008). Given the increasing linguistic diversity among public school students (National Center for Education Statistics, 2014) and the fact that as many as 88% of teachers work with English learners (Karabenick & Noda, 2004), increased attention to teachers' language practices is critical.

Noticing includes attending to classroom actions and interactions, as well as reflecting, reasoning, and responding (Hand, 2012; Jacobs, Lamb, & Philipp, 2010; Mason, 2011; van Es, 2011). In this study, we drew on Jacobs et al.'s (2010) and Jacobs, Lamb, Philipp, and Schappelle (2011) three components of noticing (attending, interpreting, and deciding to respond), to investigate early career teachers' understandings and practices related to language and language learners. While Jacobs et al. (2010, 2011) focused on teachers' noticing of children's mathematical thinking, in this

study, we extended the noticing framework to explore teachers' noticing related to language. Specifically, we investigated the following research question: How do ECTs notice language in planning, enacting, and reflecting on mathematics lessons?

Literature Review and Analytical Framework

Mathematics Teachers' Practices with Language

Several emerging areas of research relate to teachers' practices and understandings about language and language learners in mathematics. For example, McLeman, Fernandes and McNulty (2012) studied preservice teachers' beliefs, and found that opportunities to learn about English learners supported non-deficit oriented views. In addition, broader sociopolitical forces have been found to shape teachers' understandings of language in mathematics teaching. Barwell (2014) documented consequences of institutional mandates to use English as the sole language of instruction. Barwell found that in mathematics classrooms taught by monolingual English speaking teachers, linguistically diverse students' use of language was painstakingly monitored for grammatical accuracy. Researchers have also investigated the impact of professional development (PD) on mathematics teachers' understandings and practices with language. For example, Ross (2014) found that PD specifically focused on working with English learners in mathematics classrooms correlated with teachers' increased self-efficacy. Additionally, Takeuchi and Esmonde (2011) found that participation in an inquiry-based PD program positively changed mathematics teachers' discourse about linguistically diverse students and families. Teacher participants initially described language as a barrier for English learners when learning mathematics. During the project, teachers' discourse began to shift and teachers ultimately focused on the importance of making their students' linguistic diversity more visible in their classrooms (Takeuchi & Esmond, 2011). Similarly, Chval, Pinnow, and Thomas' (2014) found that focused PD supported a third grade teacher in understanding that language could be used to build students' mathematical knowledge and, conversely, mathematical instruction could support language development. This led to the teacher providing more explicit language instruction during her mathematics lessons for all of her students.

In summary, prior studies have focused on the role of teacher beliefs and PD experiences in shaping teachers' practices related to language in mathematics. In this study we draw on frameworks of noticing to make sense of how teachers notice language in planning, enacting, and reflecting on mathematics lessons. Noticing frameworks are particularly well-suited for understanding how teachers make sense of complex situations in classrooms (Sherin, Jacobs, & Phillips, 2011), such as teaching and learning mathematics with students of diverse linguistic backgrounds. Moreover, given that what teachers notice and how teachers interpret what they notice impacts what teachers do in the classroom (van Es & Sherin, 2008), a focus on teacher noticing is warranted.

Teacher Noticing in Mathematics

In framing our study, we found that Jacobs and colleagues' definition of *professional noticing of children's mathematics thinking* provided a useful foundation from which to build (Jacobs et al., 2010; Jacobs et al., 2011). Noticing consists of a set of three interrelated skills. First, *attending* to children's strategies includes focusing on "noteworthy aspects of complex situations" and discerning patterns in children's mathematical strategies and understandings (Jacobs et al., 2010, p. 172). Second, *interpreting* children's mathematical understandings involves teachers reasoning about children's strategies and how they construct a picture of children's understanding based on details of a child's work and research on children's mathematical thinking. Finally, *deciding how to respond* on the basis of children's understandings reflects the decisions teachers make for instruction and whether these decisions draw on specifics of children's thinking as well as research on children's learning and development (Jacobs et al., 2010, 2011).

Noticing skills develop over time, and much of the existing research has focused on teachers' development of noticing through teacher education or PD programs (McDuffie et al., 2014a, 2014b; Star & Strickland, 2008; van Es, 2011). For this study we take a different approach in three ways. First, instead of looking for changes in teachers' noticing over time, our aim was to understand what and how teachers notice during their first years of teaching to investigate noticing skills as teachers begin their career. In other words, our intent was to map the noticing terrain for early career teachers (ECTs) so that we might better understand what is possible for those new to teaching and also glean what areas will need support for teachers' professional development across their career. Second, instead of focusing on teachers' noticing of children's mathematical thinking, we shift the object of noticing to *language* in mathematics teaching and learning. Although we view language as tightly linked to children's mathematical thinking, our intent was to bring language to the foreground of study. Third, unlike Jacobs et al.'s (2010, 2011) focus on interviewing teachers to examine how they notice children's mathematical thinking, we extended our data collection to include classroom observations, and correspondingly, we studied both teachers' decisions for responding and their actions resulting from in-the-moment decisions during lesson enactments.

Methods

We used a qualitative case study design (Creswell, 2013; Stake, 1995), to study the practices of six early career elementary and middle school mathematics teachers. The ECTs were part of a larger study (Aguirre et al., 2012; Turner et al., 2012; McDuffie et al., 2014a, 2014b) that followed participants across math methods courses, student teaching, and into their first or second year of teaching. The ECTs attended one of two universities located in different regions of the U.S.

Participants

Table 1 outlines the background and teaching context of each ECT participant.

Table 1: Participating Teachers

Teacher	Grade	Teachers' Linguistic and Ethnic Background	Students' linguistic background	Linguistic Context of Instruction
Evelyn	Y1 & Y2: 7th	English and some Spanish; Mexican American	Some bilingual (Spanish L1); All English proficient[2]	English; non ELD[3] classroom
Estelle	Y1 & Y2: 2nd	English; European American	Many students bilingual (Spanish, L1); All English proficient	English; non-ELD classroom
Padma	Y1: 4th Y2: 3rd	English; Indian American	All students bilingual (Spanish, L1); Range of English proficiency	ELD classroom
Kara	Y1: 5th	English; some Spanish; European American	All but one bilingual; All English proficient	English; Spanish encouraged
Natalie	Y1: K	English; some Spanish; European American	Many bilingual (Spanish or dual L1); All English proficient	English; Spanish encouraged
Elena	Y1: 1st	Bilingual (Spanish/ English); Mexican American	All bilingual (Spanish L1)	Bilingual 90/10 Spanish/English

[1]All teacher and district names are pseudonyms.
[2]English proficient as determined by district language assessment and placement policies.
[3]ELD refers to English Language Development classrooms for English learners.

Data Sources

Data sources included classroom observations of mathematics lessons, coupled with pre and post observation interviews. Observations were clustered so that we observed a sequence of mathematics lessons on two or three consecutive days. We observed 8-12 mathematics lessons per year in each ECTs' classroom. We recorded detailed field notes for each lesson, and collected lesson artifacts including student work samples. We conducted pre-observation interviews prior to each set of observed lessons, and post observation debriefs for the first and final lesson observed. These interviews probed ECTs' perspectives and reasoning, and provided opportunities for ECTs to recount, interpret and respond to key moments from lessons. We conducted interviews at the beginning, middle and end of the year to capture reflections about teaching and learning across the year (not just at the level of the lesson), and information about their teaching contexts (e.g., leadership, PD, curriculum, assessment, policies.) Interviews lasted approximately one hour, and were recorded and transcribed for analysis.

Data Analysis and Analytical Framework

Through multiple and iterative cycles of analysis, we conducted within-case analysis and cross-case analysis for these cases of teaching (Creswell, 2013; Stake, 1995). As part of the larger project, we conducted preliminary analysis with first-cycle coding to summarize segments of data and identify themes relative to our research foci (Miles, Huberman, & Saldaña, 2014). This initial phase resulted in a code book including the following codes that were relevant to the study reported here: context and background; language; connections to students; connections to family/community; equitable participation. When creating the code book, we developed decision rules for the coding process and descriptions for each code. For example, we defined a *stanza* (Miles, Huberman, & Saldaña, 2013) of text as including both the question and the participant's response, as well as additional text needed for context.

During the second phase of data analysis we used the code book to code all transcripts in the qualitative data analysis software HyperResearch (Researchware, 2011). During this phase we sorted the data by topic and continued generating themes. For example, themes related to language such as: acquiring vocabulary; multiple meanings of words; mathematical discourse; multiple languages. To achieve *interpretive convergence* (Miles, Huberman, & Saldaña, 2013) and ensure consistency in coding data so that all data on a topic were identified with appropriate codes, two researchers independently coded approximately one third of the transcripts, and then met to discuss and resolve any discrepancies.

For a third phase of analysis, we focused on our six ECT cases. For each participant, we generated a *narrative compilation* (Creswell, 2013) of practices related to language. These compilations included representative and compelling examples, along with non-examples, from all data sources to test emerging themes (confirming, refuting, or investigating further). These three phases of analysis, along with research and theory in the field, led us to teachers' noticing skills regarding language in their practice.

In the fourth phase of analysis, we adapted Jacobs et al.'s (2010, 2011) definitions for each of the three components of noticing (*attending*, *interpreting*, and *deciding to respond*) to include language as an object of noticing. We expanded *deciding to respond* to include decisions evidence in lesson enactments. We identified noticing patterns for each participant based on coding data over these two dimensions (language and noticing) and created an analytic memo for each ECT's language-related practices. Finally, we looked across ECTs for larger patterns to build our cross case analysis.

Findings

We found that ECTs demonstrated all three forms of noticing language as they planned, enacted, and reflected on mathematics lessons. More specifically, we identified themes that cut across various

teachers' noticing related to language. Given space constraints, we only briefly describe each theme below, discuss the final theme in more detail, and evidence how specific forms of noticing were evidenced.

Sense-making of Mathematical Terms by Eliciting Students' Ideas

One strategy that ECTs used to promote student sense-making of mathematical vocabulary was asking students to discuss and generate their own definitions for key mathematical terms. ECTs noticed that when they repeatedly elicited students' ideas about key vocabulary, students moved beyond memorized definitions to deeper understandings. A related pattern was that ECTs tended to introduce vocabulary as a way to help students describe and name their experiences with mathematics concepts.

Connections Among Language, Concepts, and Everyday Contexts

ECTs often began mathematics lessons with connections among language, mathematical concepts, and everyday contexts. ECTs explained that they aimed to engage students' interests and leverage students' experiential knowledge to support students in making sense of both the mathematical concepts and the associated terminology.

Multiple Opportunities for Students to Hear, Say and Use Key Mathematical Vocabulary

ECTs attended closely to students' needs to hear and say new terms repeatedly throughout a lesson. ECTs highlighted key vocabulary through voice inflection, encouraged the use of terms in classroom talk between students and with the teacher, and provided multiple prompts for students to use new vocabulary (e.g., choral response, talk to a partner and say the term, sentence frames).

Emphasis on Precise Use of Mathematical Vocabulary

ECTs often held students accountable for precise use of language, and stopped to question students when mathematics terms were missing or not used correctly. ECTs displayed mathematical vocabulary in the classroom, and reminded students to be precise with the use of these words during small and whole group discussions, and in written descriptions of solutions.

Expectations for Justifying Reasoning and Explaining Thinking

Most ECTs evidenced a consistent emphasis on mathematical discussion, and expected students to justify solutions and explain their strategies to others. ECTs viewed mathematical discussions as a key component of students' mathematical learning, and as a context for students to practice using and making sense of mathematical vocabulary.

Perspectives on Multiple Languages

Most ECTs evidenced noticing that reflected a resource orientation towards students' home languages. That is, ECTs interpreted inclusion of home languages, and students' spontaneous use of multiple language during lessons as supportive of student learning. Notably, ECTs held this perspective despite the fact that three of six ECTs were teaching in contexts that mandated English as the language of instruction. Beyond this commonality, ECTs evidenced more variation in their perspectives and practices towards the use of multiple languages than was evident in the other themes. Three of the ECTs attended closely to challenges with mathematical language that some English learners in their classrooms faced. For example, when Evelyn noticed students using Spanish as they worked on mathematics, even though she was not able to fully understand their conversation, she positioned Spanish as a resource to support student learning and encouraged students to continue talking and thinking with Spanish. In one instance, a student started talking through one of the lesson tasks in Spanish, and then looked at Evelyn and remarked "I'm sorry, I can't do that." Evelyn responded by encouraging the student to continue (Year 1, Post observation interview).

While ECTs in general supported connections to students' home languages in mathematics instruction, their reasons for doing so varied. For example, Elena maintained that teaching mathematics in the home language of students allowed students to focus on the concepts and deepen their understanding. This stance was consistent with the bilingual education model at her school, and Elena taught mathematics instruction almost exclusively in Spanish. Elena's primary goal was to ensure student understanding, and she used (and encouraged students to use) both Spanish and English to support learning. For example, when mathematics worksheets were only available in English, Elena translated the directions and problem text into Spanish, so that students had access to both languages to support their sense-making (Post Observation Interview). For Estelle, occasional connections to students' home language were aimed at increasing student interest and engagement, and "helping students feel proud" of their bilingualism. She explained that when she asked students to contribute Spanish translations of key words in her lessons, "they had this big smile on their face like, 'Wow! I have something that Ms. Estelle doesn't have!'" (Y1, Middle of the year interview). As noted above, Evelyn also used connections to students' first language to support mathematical understanding, but responses were also aimed at honoring students' identities. Evelyn was aware of the struggles and lack of support her mother experienced as a bilingual student learning mathematics in an all-English instructional environment, and was determined to offer a different experience for her students (Year 2, End of year interview).

Two of the six ECTs evidenced noticing related to multiple languages that in some instances reflected a mixed (deficit/resource) orientation toward language other than English. The deficit-based ideas included perspectives such as: a lack of English caused student confusion, a lack of English proficiency in parents served as a barrier to students, and when students use only English in math class this evidences progress/understanding. For example, on one hand Padma expressed strong support for students' bilingualism and consistently praised families for supporting students Spanish language development. But on the other hand, she did not view attending to multiple languages as part of her role as a mathematics teacher. She positioned English as the (only) language of school mathematics and did not invite the use of Spanish as a resource to support students' learning. She explained:

> The problem is, I don't know enough [Spanish]. The only one [term in Spanish] I remember was during my student teaching, when we were doing polygons, so like, septagon, seventh grade in Spanish is *septimo*, so that's what I used last year [when I taught the names of polygons] (Year 2, post observation interview).

Padma framed her own lack of proficiency in Spanish and her school language policy as shaping her noticing and responses related to multiple languages. Specifically, Padma explained that the school's philosophy regarding speaking any language other than English was that "it can't happen," because "we're here to teach the students English" (Year 2, post observation interview).

Finally, in some cases a mismatch existed among what teachers attended to related to multiple languages, what teachers planned for instruction, and what they actually enacted. Three of the ECTs claimed to welcome multiple languages in instruction, and described plans for using multiple languages, but the teachers' descriptions did not always match what we observed. For example, Kara explained that she attempted to use cognates whenever possible to support student understanding. She noted:

> Well I try and use as many cognates as I can. I don't know a lot, but I try and sometimes I make them up and I shouldn't because they're not what they're supposed to [be]. And then so I make sure I run them by my bilingual teachers first (Year 1, beginning of the year interview).

She explained she "welcomes" students to speak Spanish during math ("my kids are always welcome to use Spanish when they're learning math. I never limit them to English, ever"). However,

connections to languages other than English were not evident during the lessons observed, either by Kara or her students. It is possible that Kara connected to multiple languages in lessons that were not observed, but it is also likely that Kara's noticing of multiple languages was limited to attending in her plans and reflections, and that she did not evidence responding to multiple languages in her lesson enactments. This mismatch between some ECTs' *vision* for noticing language and their *enacted practices* related to language may have reflected tensions between school contexts that on one hand encouraged the use of Spanish in instruction, and on the other hand emphasized students' acquiring academic language in English.

Significance

Patterns in ECTs' practices indicate that beginning teachers *can* engage in complex work of noticing and drawing on language in teaching and learning mathematics. We also identified key supports and challenges that have implications for teacher education. Extended experiences in classrooms with multi-lingual students might support learning ECTs in attending to the role of language in teaching and learning mathematics and in learning about diverse students and families. Similarly, on-going prompts to consider ways to draw on language in instruction might sharpen teachers' noticing of students' resources. These findings deepen our understanding of how to support equitable instructional practices that meet the learning needs of a culturally and linguistically diverse student population.

As teacher educators, we are challenged to design professional development materials that build a perspective on problem solving as an avenue to achievement of content objectives. This qualitative study examines the impact of the intentional design of school-based Lesson Study as a follow-up to a content institute. Data analysis identified four barriers to the critical transformation of practicing teacher mindset about implementing high cognitive demand tasks: time, expectation of student mastery, perception of student readiness, and proficiency in orchestrating productive discussions. Identifying ways in which teacher educators can close gaps in teachers' problem solving perspectives is essential to changing the perceptions of problem solving from an activity to a content-driven learning experience.

Keywords: Teacher Education-Inservice/Professional Development, Problem Solving, Teacher Beliefs, Teacher Knowledge

After an eight-week content institute, mathematics teachers in grades 3-8 from 37 schools collaborated to implement strategies for productive mathematical classroom discourse in the form of Lesson Study (LS). Many of the teachers discussed how pivotal the professional development (PD) sessions were in envisioning problem solving in their classrooms. However, their beliefs did not translate to practice. As university facilitators, we studied the evolving relationship between participants' beliefs and actions as they transferred knowledge from the content institute to LS planning, implementation and reflection.

Theoretical Framework

Classroom implementation of rich mathematical tasks is challenging for many teachers, as problem solving standards are at times foreign and inconsistent with previous beliefs. Engagement in rich mathematics in PD can help teachers to view problem solving as an exploration of connected ideas instead of as an isolated activity (Schifter & Riddle, 2004). It is important to address teachers' pedagogical beliefs in concert with content-focused PD to foster a growth mindset (Boaler, 2011; Dweck, 2006) toward mathematics teaching and learning. While engagement with content can support teachers in shifting their instructional practices, innovative ideas are not always accepted nor sustained (Foss & Kleinsasser, 2001). LS provides an opportunity for continued PD (Garet, Porter, Desimone, Birman, & Yoon, 2001) through interaction, collaboration and collective professional "noticings" (Jacobs, Lamb, & Phillip, 2010; Mason, 2011). Therefore, we designed a tailored LS protocol to provide multiple iterations of a specific lesson for this collective and organic noticing to take place (Murata, 2011) and to improve the potential for these innovative strategies to be maintained in practice.

Research Context

University facilitators, including the authors, modeled mathematical inquiry in the development of computational fluency and proportional reasoning as they highlighted strategies for a problem

solving mindset in the classroom. An adapted protocol (Smith, Bill, & Hughes, 2008) provided a framework for developing lessons of high cognitive demand, and *Orchestrating Discussions* (Smith, Hughes, Engle, & Stein, 2009) defined five practices to support teachers in using student responses to explore content objectives. After the content institute, facilitators supported vertical teams as they designed and implemented an iterative LS protocol that included three phases: 1) One teacher piloted the lesson and shared the results; 2) A second teacher enacted a formal LS in which all members observed the classroom lesson; and 3) The remaining members individually enacted the lesson with contextual modifications based on the LS reflection and their students' learning needs.

In the following sections, we present the analysis of two LS groups focused on proportional reasoning. The first group, The Patriots, consisted of three general educators and one Spanish immersion teacher. They enacted "The Fencing Problem" adapted from the problem "Surrounded and Covered" (Noyce Foundation, 2013) in which students calculated perimeter with the goal of maximizing area. The second group, Mason's Pride, consisted of eight teachers, five general educators, two special educators, and one mathematics specialist. They enacted "The Pizza Problem" (Erickson, 2015) in which students each received a part of the problem, and collaboration was essential to identify the required proportions.

Method

Purposeful sampling was utilized as the nature of the teachers' interactions in theses groups warranted further exploration (Patton, 2002). Data for this research included coursework from the content institute, formal lesson plans, video-recorded and transcribed conversations from LS debriefs, participant written reflections, and field notes. As data was collected we shared insights and reflections with one another in weekly meetings and captured our thoughts in researcher memos. We identified relevant information through the use of open coding (Merriam, 2009). We collaborated to categorize codes after we examined documents individually. Upon completion of the analyses, categories were grouped and labeled with a theme. The reduction of these categories led to the emergence of a select few themes. Incorporating multiple sources into the research design was a purposeful decision that provided validation for our findings and helped to achieve construct validity (Maxwell, 2005).

Findings

Teachers did not demonstrate the anticipated growth in viewing problem solving as a content-driven learning experience and expressed views of problem solving as an isolated activity. For the two LS groups we examined, data suggested that there were four barriers to the critical transformation of teacher mindset.

Time

The greatest lesson learned from both groups piloting the lesson was the amount of classroom time required to implement the task. After the first lesson iteration, both groups highlighted a need to extend the allotted time to allow students more opportunity to productively struggle before providing the additional guidance. As a result, they extended the time for problem solving during the formal LS. However, as teachers implemented the third iteration of the lesson in their own classrooms, many expressed a lack of confidence in the students' ability to productively struggle with the problem and an uncertainty in how to manage the timing of the lesson. Teachers expected the lesson to take only one math block and were frustrated when the lesson was not finished in the allotted time.

Expectation of Student Mastery

Teachers in both groups valued the idea of students persevering on tasks, yet they were challenged by the student frustration they perceived. The tendency to guide and control the lesson

was difficult for some teachers to resist as many of the teachers felt driven by the needs of their students to arrive at a correct response. One host teacher expected mastery of the content objectives within the one lesson and was disillusioned when some students never arrived at the answer. "The children in my classroom started to learn the process of how to have rich math discussions with their peers, but fell short of mastering it" (Erin, Mason's Pride, individual lesson reflection). The expectation of student mastery during initial experience was mirrored when group members implemented the lessons in their own classrooms.

Perception of Student Readiness

Based on their perceptions of student readiness, teachers implemented their lessons in ways that decreased the cognitive demand of the task. Many teachers did not believe their students capable of accessing the problem and over-accommodated to ensure student success. Kate, a math interventionist and member of The Patriots, did not offer the problem to her students the problem as she believed it was too challenging for the large percentage (90%) of English Language Learners in her classroom. Instead, she scaffolded the problem to provide step-by-step guidance. Melissa, a special education teacher, engaged her students in similar problem solving, but at a "more basic level to give them the experience they need."

Orchestrating Productive Discussions

Each LS group defined objectives for their task based on mathematical content and process standards and purposefully planned how they would approach the group discussion at the end of the lesson. The lesson template prompted teachers to preplan the higher-level questions that would support a productive discussion. However, while all participants were able to implement aspects of their purposefully planned discussion, the challenge that many faced was orchestrating a productive discussion that supported exploration and achievement of the lesson content goals.

Many teachers were unable to connect student problem solving with standards-based objectives due to novelty of the experience. They shared that not knowing what to expect caused them to take more time than expected evaluating students during the problem solving process. As a result they felt rushed sequencing the discussion to support student learning. Both the novelty of the experience and lack of time heightened the disconnect between individual perception of problem solving as an activity and the institute goal of implementing problem solving as a content-driven learning experience. "I am struggling to see the practicality of the lesson...it is too much effort that goes into one lesson that makes it very difficult for teachers to use on a daily basis" (Carlos, The Patriots, individual lesson reflection).

Implications

Even though participants attended our institute and had the opportunity to engage in deep mathematical thinking, many teachers still viewed problem solving as an activity separate from developing mathematical proficiency. Teachers are challenged by leading student-centered discussions and require additional support in developing their ability to use problem solving to achieve a mathematical content objective and to impact student learning.

Identifying ways in which teacher educators can not only facilitate highlighting content connections during problem solving but also relate problems back to the mathematical objectives will foster productive teachable moments. Analysis of LS provides important evidence of teacher thinking and informs our development of future PD opportunities. Lessons learned will assist mathematics teacher educators in breaking down the barriers in teacher beliefs about problem solving that relegate opportunities for engagement with rich mathematical tasks to extra time in the curriculum pacing.

La investigación enfocada en mejorar la práctica docente de las matemáticas ha creado y perpetuado un discurso de experto/novato. Estas dicotomías crean una división—por consiguiente una frontera—al generar conocimiento que crece entre investigadores relativamente más que entre maestras y maestros. Posterior a una breve crítica de estas metodologías, proponemos una metodología que reconoce la complejidad de los diferentes contextos que le dan vida a la enseñanza de las matemáticas. Compartimos ejemplos de un proyecto de investigación que muestran las transformaciones colectivas de la enseñanza mediante la multivocalidad de maestras/os, estudiantes, padres e investigadores.

Palabras clave: Métodologías de Investigación, Capacitación Docente / Desarrollo Profesional

Los estudios enfocados a transformar la enseñanza de las matemáticas tienen un lado que genera ideas y otro que las inhibe. Tomemos como ejemplos las investigaciones que enfatizan "*best practices*" (Ball, 2000), o la profesionalización de la enseñanza basada en interpretaciones del marco teórico de Goodwin (1994), o la reciente acumulación de estudios sobre "*teacher noticing*" (Sherin, Jacobs, & Philipp, 2011). El lado generador de ideas mueve a los investigadores a refinar ideas y constructos. El lado que las inhibe—no tan evidente como el lado generador—surge al observar críticamente las metodologías empleadas en estos estudios, las cuales separan el proceso de enseñanza de los contextos complejos en los cuales existe. Estas metodologías asumen que la práctica docente se puede descomponer con propósitos de análisis (Jacobs & Empson, 2015), y asignan un grado mayor de responsabilidad a un solo agente: el/la maestro/a. El resultado es una serie de propuestas que promueven jerarquías e incluso trayectorias de lo que el/la maestro/a debe saber, practicar, y notar. Estamos conscientes que todo enfoque implica un desenfoque, lo que nos lleva a refleccionar en la seriedad de este desenfoque.

El análisis de una realidad que ha sido fracturada perpetúa el discurso expero/novato de acuerdo al cual el/la maestro/a posee o carece de ciertos conocimientos. Lo que nos preocupa acerca de estas dicotomías es que surgen de una visión tácita que supone que la enseñanza es un fenómeno estable que se puede analizar y categorizar de tal manera. Estas dicotomías a la vez crean una división—por consiguiente una frontera—misma que no ha sido suficientemente interrogada. Nuestra interrogación es la siguiente: Aunque estos enfoques de investigación sofistifican el conocimiento del investigador, dicho conocimiento aún no logra traducirse a una transformación de la práctica docente, al impedir que los/las maestros/as logren percibirse en la realidad fracturada que ocupa nuestro estudio. Cuando esto sucede, la posibilidad de transformar la práctica docente se debilita. Nuestro enfoque es diferente, ya que busca la transformación colectiva, la que emerge y se observa a través de procesos participatorios colectivos que incluyen a estudiantes, maestras/os, padres de familia, e investigadores.

Perspectiva teórica

Para explorar la complejidad inherente a la transformación de la práctica docente es indispensable no reducirla con propósitos de análisis. Para ello nos adherimos a las ideas de Davis y Simmt (2003) acerca de cómo estudiar la trascendencia de un colectivo:

Complexity is not just another category of phenomena, but an acknowledgement that some phenomena are not deterministic and cannot be understood strictly through means of analysis (i.e., literally, by taking apart or cutting up). A different attitude is required for their study, one that makes it possible to attend to their ever-shifting characters and that enables researchers to regard such systems, all at once, as coherent unities, as collections of coherent unities, and (likely) as agents within grander unities (p. 140).

Para estudiar las transformaciones en la enseñanza de maestras con estudiantes que provienen de comunidades vulnerables, nos enfocamos en la multivocalidad de maestras, estudiantes, padres, e investigadores de educación matemática. Aunque presentamos estas voces en espacios separados, la resonancia de estas voces es la que crea un colectivo coherente con una gran agentividad y una diversidad interna que es auto regulada por los mismos participantes (Davis & Sumara, 2006). Alineados al principio de la investigación cualitativa de *mostrar* en lugar de *dictar* (Tracy, 2010), proporcionamos ejemplos de transformaciones ocurridas en un proyecto de investigación en diferentes aulas de matemáticas a través del tiempo. En estos ejemplos vemos a los participantes en medio de transformaciones, experimentando tropiezos, retos, y logros situados en una colectividad compleja. Nuestro propósito es ilustrar los senderos de enseñanza que las maestras recorren y que, lejos de ser aislados, se entrelazan y comunican con las realidades igualmente complejas de los estudiantes, padres, e investigadores. A lo largo de estos senderos, las maestras no experimentan un conocimiento individualizado del tipo que se propone en muchos estudios, sino que ellas con los demás participantes hacen camino al andar.

Transformaciones colectivas desde la perspectiva del investigador

Durante el primer año de un proyecto de investigación enfocado en la reciprocidad como proceso generador de transformaciones colectivas, empecé a notar cómo al llegar a observar la clase de matemáticas, por lo general había un estudiante excluído de la instrucción (*time out*) por mal comportamiento. Estos estudiantes tendían a ser los mismos semana tras semana. Decidí acercarme a ellos para indagar los motivos de su exclusión. Sus faltas eran mínimas: inatención, hablar fuera de turno, ponerse se pie sin permiso, interrumpir a un compañero, no compartir materiales. Uno de estos estudiantes era Ray, un niño afroamericano, el más alto de su clase de segundo grado. Ray era inquieto, curioso, y le gustaba ir a observar lo que otros grupos hacían. Su curiosidad era tal que muy fácilmente se distraía con todo lo que él notaba en el aula. Esto lo metía en problemas y como castigo casi todas las semanas era excluído de la instrucción. Al acercarme a Ray en su aislamiento físico de los demás, ambos comenzamos a discutir los mismos problemas de matemáticas que su maestra discutía con el resto del grupo. Al usar preguntas abiertas encaminadas al significado de los problemas, empecé a notar que las ideas de Ray diferían de las que los dos escuchábamos de sus compañeros/as—a distancia, desde nuestra esquina en el aula. Por ejemplo, el sentido numérico de Ray era evidente. Un día su maestra mostró a los estudiantes un grupo de objetos y les pidió que contaran cuántos objetos había. Una niña contó 16 en lugar de 15. Al preguntarle a Ray si era correcto, me explicó que en realidad eran 15 porque "*there is 10 and 5 more makes 15, because 15 is 5 more than 10.*" Cada semana seguí escuchando de Ray ideas sobre importantes relaciones numéricas. Un día decidí pedirle a su maestra traer de regreso a Ray durante la discusión final de grupo. Habiendo hallado un espacio físico e intelectual para Ray en la discusión de grupo, Ray compartió con sus compañeros sus ideas matemáticas, subrayando cómo él notaba importantes relaciones numéricas en los problemas. Al día siguiente del regreso de Ray a su participación en grupo, Ray me tomó del brazo y, con un sentido de urgencia, insistió en que me sentara cerca de él. Tal parecía como si yo me hubiera convertido en su pasaporte de participación, en su presentador, en alguien que él necesitaba para lograr entrar a un espacio que se le había negado. Poco a poco, y sobre

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

todo después de mi acercamiento a Ray. el cual hice evidente ante su maestra, dejé de encontrar a Ray en su acostumbrado sitio de *time out*.

Transformaciones colectivas desde la perspectiva de los estudiantes

A veces solo se necesita una sola oportunidad para que los estudiantes nos ayuden a transformar la instrucción matemática. Este fue el caso de un grupo de estudiantes latinos/as de tercer grado durante una unidad de estimación. Después de una primera semana de instrucción enfocada en la técnica de redondeo, la maestra no lograba entender por qué los estudiantes parecían no entender la técnica: "*I don't know why they're not getting something that seems so easy, you know?*" Ambos decidimos entrevistar a los estudiantes para entender sus perspectivas, para que nos dijeran lo que ellos notaban en los problemas de estimación. Lo que a simple vista parecía una aplicación errática o inconsistente del método de redondeo tenía, de hecho una lógica compleja. Por ejemplo, los niños nos informaron que algunos ejemplos incluían números tan simples que no era necesario estimar. También hallaban un conflicto linguístico: al leer las palabras *estimar* y *total*, esto activaba dos procesos distintos: total significaba para ellos un cálculo exacto, mientras que la palabra estimar algunos la entendían y otros simplemente no sabían su significado, lo cual los hacía a veces estimar y otras veces calcular. Estas perspectivas llevaron a la maestra a revisar los problemas de manera que reflejaran la perspectiva de los estudiantes. Empezamos a usar palabras como más o menos, casi, y aproximadamente, en lugar de estimar. Revisamos los números incluídos en estos problemas, así como los contextos para hacerlos más relevantes y con un cierto propósito. La transformación fue tal, que la maestra comenzó a enseñar la estimación no como una técnica que se debe memorizar, sino como una herramienta útil a través de todo el currículo de matemáticas.

Transformaciones colectivas desde la perspectiva de los padres de familia

Como preámbulo a una unidad de medición de tercer grado en un aula bilingüe, la maestra decidió invitar a un grupo de padres y madres de familia para que platicaran con sus estudiantes acerca del uso de la medición en sus trabajos. Al llegar, tomaron asiento en la parte de atrás del aula de clase. La maestra y el investigador los invitamos a pasar al frente a manera de un panel. Estos adultos hablaron y demostraron el papel de la medición en trabajos tan variados como la limpieza (cuánto líquido limpiador se deben mezclar con cuánta agua), el arreglo de mobiliario en un cuarto (incluyendo los muebles del aula de clases), las compras del supermecado (pesar dos kilos de frijol), y el corte de metales mediante rayo laser (para la construcción de muebles de metal). Esta plática despertó la curiosidad de los estudiantes, llenando el aula de preguntas que los padres contestaron. La visita de los padres generó transformaciones multiples del espacio físico-intelectual en esta aula de matemáticas. Por un lado, los estudiantes desarrollaron un reconocimiento de las conecciones entre las matemáticas escolares y las de la vida diaria. Así mismo, en entrevistas subsecuentes expresaron respeto hacia los conocimientos de sus propios padres y la relevancia de este conocimiento en el contexto escolar. La maestra por su parte rediseñó los problemas de medición con ejemplos que los padres habían mencionado durante su vista. Y aún después de varios años, esta maestra sigue enseñando medición con un enfoque que coloca al estudiante como centro desde el cual toda noción de medición deriva su significado. Por ejemplo, el largo de un brazo, el tamaño de una mano, o el marco de una puerta no son mediciones al azar sino que existe una interconneccíon que los estudiantes exploran, alteran, reinventan, analizan, y refleccionan a fondo antes de formalizar el tema.

Transformaciones colectivas desde la perspectiva de las maestras

La coplaneación de unidades que las maestras eligen por ser difíciles de enseñar y aprender ha servido para que estas maestras creen transformaciones a nivel colectivo. Por ejemplo, una maestra y yo planeamos una unidad de medición del tiempo. La planeación ocurrió a dos niveles: primero al

nivel de las ideas más trascendentales, y día a día estas ideas las complementábamos con lo que apredíamos de los estudiantes. Durante la unidad de estudio, los estudiantes lograron reinventar importantes conecciones entre mediciones lineales y mediciones del tiempo, lo cuál les permitió aprender el concepto con comprensión. Al año siguiente, una maestra de segundo grado del mismo proyecto, amiga y colega de la maestra de cuarto grado, solicitó nuestra colaboración porque había escuchado todo lo que los estudiantes habían aprendido. En este caso, la maestra y yo usamos ideas similares pero para segundo grado. Este tipo de transformaciones se asemeja a las descritas por Davis y Sumara (1997) quienes describen cómo "It was not long before we became aware that the complex weave of classroom activity had spilled into other communities through what appeared to be a mix of deliberate communication, casual conversation, and unconscious imitation" (p. 115). Estas transformaciones no son efectuadas solo por las maestras, sino que pertenecen al colectivo de maestras, alumnos, e investigador. Por ejemplo, al final de una de estas unidades de estudio, una maestra escribió la siguiente reflección: "*When the child takes a new or different direction than we expect, we have the potential for new common resources*."

Nuestras consideraciones colectivas

Los ejemplos presentados sugieren que las transformaciones observadas se dan como parte de esfuerzos colectivos. Esta colectividad—particularmente su diversidad interna, su auto regulación, y el efecto cascada del conocimiento emergente que desarrolla—nos obliga a no romper la naturaleza compleja de estas transformaciones. Parecido al proceso de una cámara fotográfica, nuestro interés es ampliar el enfoque utilizado para así analizar la formación y el desarrollo de una transformación. Creemos que una de las características más importantes observada en los ejemplos anteriores es la auto sustentabilidad del cambio (Franke, Carpenter, Levi, & Fennema, 2001). Así mismo, el cambio no recae en un solo individuo, sino que se construye a partir de la diversidad interna de grupos. Para comunicar nuestra diversidad interna como investigadores, ofrecemos nuestras perspectivas de cómo entendemos las transformaciones que hemos ilustrado. Higinio: El cambio y su sustentabilidad en las aulas de matemáticas va mucho más allá de las acciones individuales de las maestras. Me interesa estudiar cómo un aula es en realidad un sistema complejo que aprende, que se auto regula, y que está en continua generación de conocimiento. Luz: Con frecuencia me pregunto cómo podríamos construir un puente entre las investigaciones y la complejidad de lo que ocurre en un aula de clase. Esta complejidad require más de una voz y muy a menudo, son las maestras las que tienen mucho que aprender de los estudiantes, padres y comunidades. Carlos: Las transformaciones colectivas de la práctica docente presentan una esperanza y un desafío. La esperanza está en que, como facilitador/a, la responsabilidad de una transformación de este tipo no es solo mía. El desafío parte de mi rol como docente o investigador/a, al trabajar con otras personas para propiciar—o no—un proceso generativo complejo que permita que el pensamiento, planeación, y acción colectiva sucedan.

El lado generador de ideas del que hablábamos al principio nos ha permitido desarrolar un conocimiento muy importante que no deseamos ignorar. Más bien, lo que queremos es descubrir formas de situar este conocimiento dentro de la complejidad del proceso de enseñanza. Nuestras experiencias en colaboraciones con comunidades diversas nos llevan a cuestionar el discurso de experto/novato porque quienes efectúan estas transformaciones son grupos complejos. Lo aprendido de estas experiencias nos anima a proponer que es posible re-enfocar nuestras investigaciones de manera que nos ayuden a entender la transformación de la enseñanza matemática como un proceso complejo que requiere asumir una responsabilidad de grupo.

Research focused on improving the teaching of matemathics has created and perpetuated an expert/novice discourse. These dichotomies create a divide—therefore a borderline—by generating knowledge that grows relatively more among researchers than teachers. Following a brief

methodological critique, our methodology recognizes the complexity of the contexts in which mathematics teaching lives. We share examples from a research project to show collective transformations of teaching through multivocality of teachers, students, parents, and researcher.

Keywords: Research Methods, Teacher Education-Inservice/Professional Development

Most studies that focus on transforming the teaching of mathematics have an aspect that generates ideas and another aspect that inhibits them. Let us take as examples the research that emphasizes "best practices" (Ball, 2000), or the professionalization of teaching based on interpretations of Goodwin's theoretical framework (1994), or the more recent studies on teacher noticing (Sherin, Jacobs, & Philipp, 2011; Jacobs, Lamb, & Philipp, 2010). The generative aspect of this research moves researchers to refine ideas and constructs. The inhibiting aspect—perhaps not as evident as the generative aspect—emerges from a critical consideration of the methodologies that these studies employ and that separate teaching from the complex contexts in which it exists. These methodologies assume that the teaching practice can be decomposed for analysis (Jacobs & Empson, 2015), and assign a great deal of responsibility to one single agent: the teacher. The result is a series of claims that promote hierarchies and even trajectories of what teacher know, believe, practice and notice. We are aware that every focus implies a defocus. Our intention is to invite participants into a reflection regarding the seriousness of this defocus.

The analysis of a fractured reality perpetuates an expert/novice discourse according to which teachers possess or lack certain knowledge. These dichotomies emerge from the assumtion that teaching is a stable phenomenon that can be analyzed and categorized accordingly. These dichotomies create a divide—therefore a borderline—which has not been interrogated enough. Our interrogation is this: Although these research approaches add sophistication to our researcher knowledge, such knowledge resists translation into transformative teaching practice, as teachers may not be able to see themselves in the fractured reality we study. When this happens, the possibility for transforming the teaching practice weakens. Our approach is different, since it is focused on the collective transfromation, the kind that emerges and can be observed through collective participatory processes that include students, teachers, parents, and researchers.

Theoretical Perspective

To recognize the complexity inherent to the process of transforming the teaching practice requires not reducing it for analytical purposes. To achieve this we adhere to Davis and Simmt's (2003) ideas about how to study complex phenomena:

> Complexity is not just another category of phenomena, but an acknowledgement that some phenomena are not deterministic and cannot be understood strictly through means of analysis (i.e., literally, by taking apart or cutting up). A different attitude is required for their study, one that makes it possible to attend to their ever-shifting characters and that enables researchers to regard such systems, all at once, as coherent unities, as collections of coherent unities, and (likely) as agents within grander unities (p. 140).

To study the teaching transformations in classrooms with students from non-dominant communities, we focus on the multivocality of teachers, students, parents, and math education researchers. Although we present these voices in separate spaces, their resonace is what creates a coherent collective with internal diversity that is self-regulated (Davis & Sumara, 2006). Aligned with the principle of qualitative inquiry of *showing* rather than *telling* (Tracy, 2010), we share moments of transformations observed in one research project in different classrooms across time. We showcase participants in these transformations as they experience stumbles, challenges, and achievements situated in a complex collectivity. Our purpose is to illustrate the teaching pathways

that teachers walk through that, far from being isolated, intertwine and enter into dialogues with the equally complex realities of students, parents, and investigators. Along these pathways, the teachers do not experience an individualized knowledge of the kind proposed in many studies, but rather participants *hacen camino al andar* [form paths by walking].

Collective Transformations from the Reseacher's Perspective

During the first year of a research project focused on reciprocity as a process for collective transformations, I began to notice that upon arriving to do my classroom observations, often there were students excluded from instruction (*time out*) due to bad bahavior. These students tended to be the same week after week. I decided to join them instead of the whole group to find out the reasons for their exclusion. Their mishaps were minor: inattention, speaking out of turn, standing up without permission, interrupting a peer, not sharing materials. One of these students, Ray, was an Afroamerican child, the tallest of his second grade class. Ray was hyperactive and curious. He liked to observe what others were doing. His curiosity was such that he was easily distracted with everything that he was noticing in the classroom. This often got him in trouble and as a punishment he was excluded from instruction almost every week. When approaching Ray in his physical isolation, he and I began to discuss the same math problems that his teacher was discussing with the rest of the group. By using open-ended questions focused on the meaning of problems, I began to notice that Ray's ideas differed from those that he and I were listening from his peers—at a distance, from our corner in the classroom. For example, Ray's number sense was evident. One day his teacher showed the class a set of objects, asking them to count them. A girl counted 16 instead of 15. When I asked Ray if that was correct, he explained that it was actually 15 because "*there is 10 and 5 more makes 15, because 15 is 5 more than 10.*" Every week I continued hearing ideas from Ray about important numerical relationships. One day I decided to ask his teacher to bring Ray back into the final whole group discussion. Having found a physical and intellectual space for Ray in the group discussion, Ray shared with his classmates his mathematical ideas, emphasizing how he was noticing important numerical relationships in the problems. The day after Ray returned to his group participation, Ray took me by the arm and, with a sense of urgency, insisted that I sit next to him. It was as if I had become his passport to participation, his presenter, someone that he needed to be able to enter a space that had been denied to him. Little by little, and especially after my working closely with Ray, which I made evident to his teacher, I stopped finding Ray in his habitual time out corner.

Collective Transformations from the Students' Perspectives

Sometimes all it takes is one single opportunity for students to help us transform mathematics instruction. This was the case in a group of third grade Latino/a students during an estimation unit. After the first week of instruction focused on the rouding technique, the teacher could not understand why students seemed not to understand the technique: "*I don't know why they're not getting something that seems so easy, you know?*" The teacher and I decided to interview the students to understand their perspectives, so they could tell us what they were noticing in the estimation problems. What at first sight looked like an erratic or inconsistent application of the estimation method had, in fact, strong sense making. For instance, students informed us that the numbers in some examples were so easy that estimation seemed unnessesary. They also found a linguistic conflict: in reading the words *estimar* and *total*, two distinct processes were activated: total meant for them an exact calculation, whereas the word estimate some understand but others simply did not know its meaning, which led them to sometimes estimate and other times calculate. This student noticing led the teacher to revise the problems to reflect the students' perspectives. We began using words such as *más o menos*, *casi*, and *aproximadamente*, instead of estimate. We revised the numbers in the problems, as well as the contexts to make them more relevant and purposeful. The

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

transformation was such that the teacher began teaching estimation not as a technique to be memorized, but as a useful tool across the mathematics curriculum.

Collective Transformations from the Parents' Perspectives

As a preamble to a third grade measurement unit in a bilingual classroom, the teacher decided to invite a group of parents to talk with students about the use of measurement in their jobs. The parents initially sat in the back of the room. The teacher and researcher invited them to move to the front as a panel. These adults demonstrated the role of measurement in jobs as varied as cleaning (how much cleaning solution to mix with water), furniture arrangement (including the classroom furniture), grocery shopping (weighing two kilograms of beans), and laser cutting metalwork (for metal furniture). This conversation awoke students' curiosity, filling the room with questions that parents answered. Their visit generated multiple transformations of the physical-intellectual space in the classroom. On the one hand, students recognized connections between school math and everyday math. On the other hand, in subsequent interviews they expressed respect for their parents' knowledge and the relevance of this knowledge in the school context. The teacher, in turn, redesigned the measurement problems using the examples the parents had mentioned. Even after several years of this transformation, the teacher continues teaching measurement with a focus that positions students at the center from where every measurement notion derives its meaning. For example, the length of an arm, the size of a hand, or the height of a door frame are not random measures but there exists a connection that students explore, alter, reinvent, analyze, and deeply reflect upon before formalizing the topic.

Collective Transformations from the Teachers' Perspectives

The coplanning of units that teachers find difficult to teach and learn has helped teachers to create collective transformations. For example, a foruth-grade teacher and I co-planned a unit on measuring time. The planning occurred at two levels: first, at the big ideas level, and then these big ideas were shaped by the students' own ideas on a day-by-day basis. During this unit, students were able to reinvent important connections between linear and time measurement, which allowed them to learn the concept with meaning. The following year, a second-grade teacher in the same project, who was a friend and colleague of the fourth-grade teacher, asked for our help because she had heard about how much the fourth-grade students had learned. This teacher and I used similar ideas but adapted for second grade. These kinds of transformations resemble those described by Davis and Sumara (1997): "It was not long before we became aware that the complex weave of classroom activity had spilled into other communities through what appeared to be a mix of deliberate communication, casual conversation, and unconscious imitation" (p. 115). These transformations are created not by the teachers alone, but they belong to the collective of teachers, students, parents, and researcher. For example, at the end of one of these units of study, one teacher wrote the following reflection: "*When the child takes a new or different direction than we expect, we have the potential for new common resources*."

Our Collective Considerations

The above examples suggest that transformations occurred as collective efforts. This collectivity—particularly its internal diversity, self-regulation, and the cascade effect of the emerging knowledge—urges us not to break the complex nature of these transformations. Similar to the process of a photographic camera, we are interested in amplifying its focus so we can analyze the formation and development of a transformation. We believe that an important characteristic observed in the examples provided is the self-sustainability of change (Franke, Carpenter, Levi, & Fennema, 2001). Similarly, change is not in the hands of one individual, but it is constructed from and within the group's internal diversity. To communicate our internal diversity as researchers, we now offer

our perspectives of how we understand the illustrated transformations. Higinio: Change and its sustainability in math classrooms extend beyond teachers' individual actions. I am interested in studying how a classroom is in fact a complex system that learns, that self-regulates, and that it continuously generates new knowledge. Luz: I often wonder how to build a bridge between research findings and the complexity of what happens in a classroom. This complexity requires more than one voice and, quite often, the teachers are the ones who have much to learn from students, parents, and communities. Carlos: Collective transformations present a hope and a challenge. The hope is that the responsibility for a transformation of this kind is not exclusively mine. The challenge is how as a collaborator working with others, I can occasion a generative process by which complex thinking, planning and acting can occur.

The generative aspect of the research reviewed has allowed us develop knowledge that we do not wish to ignore. Rather, we want to find ways to situate this knowledge within the complexity of the teaching process. Our experiences collaborating with diverse communities lead us to question the expert/novice discourse because those who learn how to create transformations are complex groups. What we have learned from and with these groups encourage us to think that it is possible and desirable to refocus our research so it can help us understand the transformative teaching practices as a complex process that requires assuming a group responsibility.

EXAMINING THE RELATIONSHIP BETWEEN CERTIFICATION PATH AND TEACHING SELF-EFFICACY

Erik Jacobson
Indiana University
erdajaco@indiana.edu

Rebecca Borowski
Indiana University
Rborowsk@indiana.edu

In this paper we explore the relationship between certification path and teaching self-efficacy for teachers of K-12 mathematics. We focused on teaching self-efficacy for a content area that spans the K-12 curriculum: fractions, ratios, and proportions. Initial findings indicated that alternate certification is significantly correlated to teaching self-efficacy. However, in multiple regression analysis of certification after including other variables that predicted teaching self-efficacy, the relationship between certification path and teaching self-efficacy was no longer statistically significant. Findings suggest that the apparent relationship between alternate certification and teaching self-efficacy is likely due to other factors (age, highest grade taught, MKT) that differentiate alternately certified and traditional teachers.

Keywords: Teacher Beliefs, Teacher Education-Preservice, Teacher Knowledge

In this paper, we question a border within mathematics teacher education: the path to certification. In order to understand the relationship between certification path and teacher beliefs, we compare teachers who were certified after a traditional 4-year undergraduate degree in education with those who took an alternate path. Paths to teacher certification are part of an ongoing policy debate which continues to rage in the wake of the Every Student Succeeds Act becoming law (Sawchuk, 2015). Alternate certification is often promoted as a way to bring people with high levels of knowledge into classrooms. In this study, we focused on a different consequential teacher characteristic that might describe those who pursue different paths: teaching self-efficacy: a belief in one's ability to help students learn.

Studies have shown that higher teaching self-efficacy has an impact on student learning (Chang, 2015; Fox, 2014). Thus self-efficacy for teaching is important for mathematics teachers. Because K-12 math teachers teach different topics, we focused on a central idea: teaching self-efficacy for fractions, ratios, and proportions. The purpose of this study was to answer the following research question: *Do teachers who achieve certification through an alternate path have higher teaching self-efficacy for teaching fractions, ratios, and proportions?*

Theoretical Framework

Teaching self-efficacy (TSE) beliefs are a teacher's own judgments about her capability to teach and her confidence that her instruction will affect student learning (Bandura, 1986; Pajares, 1992). The construct of TSE has been used extensively for several decades and several measures of TSE exist (see review, Tschannen-Moran & Hoy, 2001). Under Bandura's (1986) social-cognitive theory, TSE beliefs determine teachers' "persistence when things do not go smoothly and their resilience in the face of setbacks" (Tschannen-Moran & Hoy, 2001, p. 784), and thus is clearly related to the productive disposition for teaching. Self-efficacy to teach may vary with the content taught. Bandura (1986) wrote that self-efficacy as such was too broad to be useful for research without narrowing one's attention to self-efficacy beliefs that are relevant to the specific situation or activity being researched.

What factors contribute to teachers' self-efficacy? One factor may be the path by which they become certified. Another may be a teachers' academic achievement prior to college. As people age, they tend to be more self-assured, so it is possible that a teacher's age contributes to their self-efficacy In education, there is a general perception that higher grade levels teach more difficult math,

so it's possible that having taught at a higher grade level (regardless of their present grade) may make teachers more confident in their teaching of particular content. Finally, mathematical knowledge for teaching (MKT) may also be related to teaching self-efficacy.

In the last decade, large-scale studies using more sharply focused instruments have found evidence of the expected relationships between teacher knowledge and student achievement. These new instruments share a focus on the content knowledge that teachers' arguably use in practice. Ball, Thames, and Phelps (2008) proposed a framework for content knowledge for teaching "subject-matter-specific professional knowledge," (p. 389). Mathematical knowledge for teaching (MKT) includes pure content knowledge as well as specialized content knowledge (SCK), which is a kind of mathematical knowledge that teachers but few other adults possess.

Methods

Data for this study was collected from a variety of sources. Participants' certification path, age, and highest grade taught was provided from official records for teachers completing the Texas Teacher Training Survey (TTTS). This survey was conducted by the National Research Council in association with the Texas Education Authority and collected data on a representative sample of Texas teachers certified between 2006 and 2010. University selectivity using ratings for undergraduate institution selectivity (Barron, 2001) and was based on self-reports. TSE and MKT data came from a follow up survey of TTTS participants (Jacobson, 2013).

The instrument for TSE was adapted from measures for prospective science teachers (Enochs & Riggs, 1990; Roberts & Henson, 2000). The items measuring TSE were modified to address the domain of multiplicative reasoning by replacing the word "science" with the phrase "topics involving fractions, ratios, and proportions." For example, the question, "I usually do a poor job teaching science" became, "I usually do a poor job teaching topics involving fractions, ratio, and proportion." Overall TSE scores were obtained using a rating scale IRT model.

The MKT instrument was composed of 25 items selected from the Measures of Effective Teaching project (Bill & Melinda Gates Foundation, 2010) that focused on fractions, ratios, and proportions. The items explicitly addressed two kinds of MKT: understanding and evaluating students' mathematical thinking (18 items) and selecting and using tasks and representations (7 items). The selected items could be cross-classified by three topics that make up the domain of multiplicative reasoning: fraction multiplication and division (8 items), fraction and ratio comparison (10 items), and proportional reasoning (7 items). Both TSE and MKT instruments had high internal consistency (Cronbach's α > .9). All items had point-biserial correlations greater than or equal to .2, and all item parameters were acceptable (Crocker & Algina, 1986).

Results

In order to answer our research question, we began with descriptive statistics. We then ran correlations to understand the relationships between pairs of variables. After that, we ran a multiple regression model to predict teaching self-efficacy from the other variables.

An analysis of correlations (see Table 1) shows that for all but one explanatory variable (university selectivity), there was a statistically significant linear relationship between it and the outcome variable. This indicates that these variables may indeed be related to teachers' self-efficacy for teaching fractions, ratios, and proportions. However, there were also significant correlations between several of the explanatory variables.

Our findings seem to indicate that teachers who undergo alternate paths to certification have higher teaching self-efficacy for teaching fractions, decimals, and percentages than those who receive their certificate after completing a traditional undergraduate education program. However, because of significant correlations between our explanatory variables, it is possible that teachers with higher teaching self-efficacy also have other characteristics in common which may be responsible for this

correlation. Thus, we decided to run a multiple regression of certification on the other variables to further understand these relationships.

Table 1: Correlations among teacher variables [A]

	1	2	3	4	5
1. Teaching self-efficacy (TSE)					
2. Traditional Certification Path	-.181*				
3. University selectivity	.049	-.136 *			
4. Math Knowledge for Teaching (MKT)	.284 *	-.106	.252 *		
5. Age	.202 *	-.230 *	.038	.031	
6. Highest grade taught	.310 *	-.217 *	.089	.327 *	.042

[A] N is between 362 (MKT & Age) and 443 (TSE & Age); * $p < .01$

A standard regression model was tested in which teachers' self-efficacy for teaching fractions, ratios, and proportions was predicted from certification path, university selectivity, MKT, age, and highest grade taught. Overall, the model was significant, $F(5, 303) = 11.67$, $p < .001$, and accounted for 14.8% of the variance in efficacy scores, $R2 = .148$. Standard error of regression coefficients are reported in Table 2.

Table 2: Predictions of self-efficacy for teaching fractions, ratios, and proportions

	Self-efficacy for teaching fractions, ratios, and proportions		
	B	SE	Significance level
Constant	-.794	.278	.005
Traditional Certification	-.189	.107	.079
MKT	.259	.069	<.001
University selectivity	-.008	.037	.838
Highest grade taught	.049	.016	.002
Age	.015	.005	.001

Coefficients for three of the explanatory variables – MKT, highest grade taught, and age - were significant ($p < .01$). As the MKT score increases, the predicted self-efficacy also increases. In other words, the more a teacher knows about math knowledge for teaching, the higher self-efficacy they have. As the highest grade taught increases, so does the predicted self-efficacy. Finally, as a teacher's age increases, so does the predicted self-efficacy. After controlling for other variables in the model, the coefficient for certification path was not statistically significant ($p = .079$), and neither was the coefficient for university selectivity ($p = .838$).

Conclusions

With this study, we sought to determine the relationship between certification path and teachers' self-efficacy for teaching fractions, ratios, and proportions after taking into account other information about teachers including the selectivity of undergraduate college/university, MKT, age, and highest grade taught. The regression model indicates that yes, these explanatory variables do account for some of the variance (15% of it) in teachers' self-efficacy for teaching fractions, ratios, and proportions. One limitation of this study may be that the R^2 is not large, different variables than the ones we selected may be required to understand teaching self-efficacy. However, the significance of the model indicates there is definitely a relationship between the predictors we chose and the teaching self-efficacy outcome variable.

We were most interested in certification path because few studies have examined the relationship between certification path and teaching self-efficacy, an established predictor of student

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

achievement. The correlation we found between certification path and teaching self-efficacy was very interesting in this regard, and we hypothesized that there would be a statistically significant regression coefficient for this variable when predicting teaching self-efficacy. However, there was not: when other factors including age, MKT, and highest grade taught were included in the model, certification path was still negative but was no longer statistically significant ($p = .08$). These results seem to indicate that neither certification path – alternate or traditional - predicts higher teacher self-efficacy than the other. Instead it is other differences between teacher characteristics that account for the apparent relationship between teaching self-efficacy and certification path. We conclude that teaching self-efficacy may not be a meaningful difference between teachers who follow different paths to certification.

In this paper, we show how one teacher used software, curriculum and new teaching moves to advance student argumentation and promote equity in discourse. The professional development (PD) she engaged in, Bridging PD, focuses on assisting teachers in diverse urban school communities to infuse argumentation into their practices so that all students actively engage in mathematical argumentation. Bridging PD integrates technology-based curriculum and dynamically-linked representations in the PD and then teachers use these in their classrooms.

Keywords: Teacher Education-Inservice/Professional Development; Equity and Diversity

Literature Review

As demonstrated in recent studies (Knudsen, Shechtman, & Kim, 2012; Choppin, 2014; Cirillo et al., 2014), strengthening the alignment between mathematical communication and argumentation is consistent with current mathematics curriculum policy documents (National Council of Teachers of Mathematics, 2000; the National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). The Common Core State Standards for Mathematics (CCSSM) Standards for Mathematical Practice 3 includes constructing and critiquing mathematical arguments (Cirillo et al., 2014). Several researchers (Herbel-Eisenmann, Choppin, & Pimm, 2012) have also observed that there is a need to increase access for students of color and the poor to "participation in dominant mathematically-based discourse practices, such as argumentation" (p. ix). Further, fostering student involvement in classroom discussions enhances the view that students hold of themselves as mathematics learners and doers (Walshaw & Anthony, 2008, p. 536).

A number of researchers (Hicks, 1998; Walshaw & Anthony, 2008) have also reported that for many teachers, it is a major challenge to include classroom discourse as an integral part of their teaching. In their comprehensive and critical review of the literature on mathematical discourse, Walshaw and Anthony (2008) identified what teachers can do to promote discourse that allows all students to achieve. Among these practices are revoicing to achieve clarity, using students own ideas as a springboard for developing new knowledge, supporting students in making their own conjectures and pressing for justification. The authors observed that when talking about mathematics became acceptable in the classroom, mathematical discussion, explanation and defense of ideas became defining features of a quality mathematical experience (Walshaw & Anthony, 2008).

Bridging PD

A multifaceted professional development (PD) program, Bridging PD prepares teachers to address the challenge of bringing argumentation to diverse urban classrooms. One important part of Bridging PD is providing teachers with curriculum that supports argumentation. Through teaching games, they develop teaching moves to use in this context as well as in their own lessons. The technology allowed the participants to generate different cases, and to test and justify their conjectures. In the 7th-grade unit focused on in this paper, students learn about linear functions within the context of motion, so the student software presents a motion represented as an equation, as a graph and in a simulation of vehicles traveling (Figure 1). In the first lesson of the unit, the

onscreen prompts ask students to create a story to correspond to a graph, check their story with the simulation, create new graphs and stories, and make conjectures about the graphs.

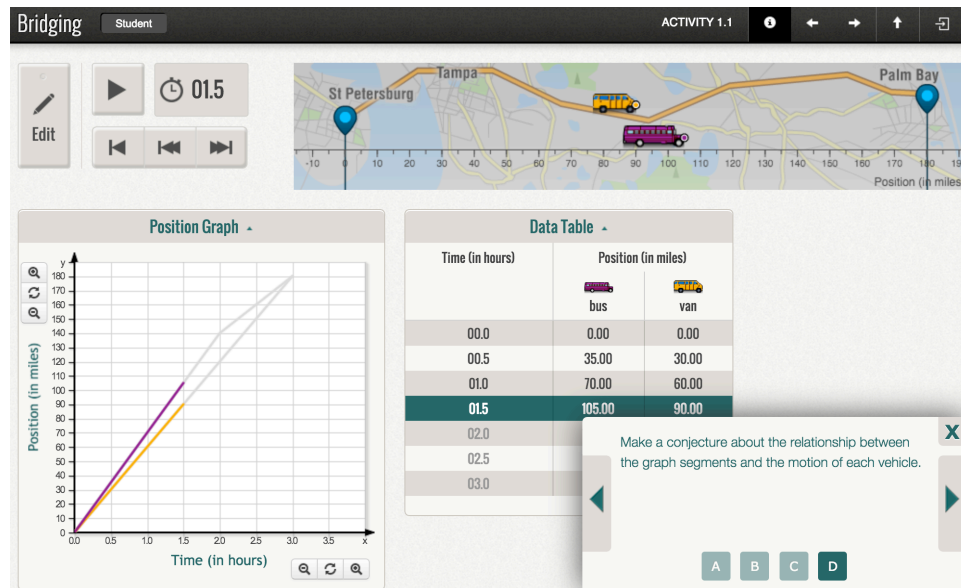

Figure 1. Dynamically linked representations with onscreen prompts.

Methods

Our study has a quasi-experimental design complemented by in-depth case studies for a subset of teachers. One of the case study teachers is Ms. Norris, a 7th-grade teacher with less than three years experience in the classroom. She works in an urban school with about 70% Black, 10% White and 15% Hispanic students. Roughly 50% of the students receive free or reduced-price lunch. The following analysis is based on two observations of her classroom in spring 2015 and two post-PD observations in fall 2015. Notes were created during the observation and cross checked with the videos, using an observation protocol developed to capture teaching practices and classroom norms that support mathematical argumentation. Then, argumentation episodes were parsed out for further analysis for teaching moves and students' responses.

Analysis

In pre-PD observations, Ms. Norris's practice was identified as having "little to no argumentation." She demonstrated how to solve a problem step-by-step to the whole class, students worked on problems individually under her supervision, and selected students shared their work with the whole class.

In November, Ms. Norris's classroom was observed when she was using the 7th grade unit. In the first lesson, students were assigned to make a conjecture about the relationship between motions and graphs. As she circulated among small groups of students working with the software, she visited a pair of students who were working together with an animation, which showed a van and a bus moving at different speeds, and its corresponding graph.

The following excerpt illustrates the teacher's moves for supporting conjecturing:

Ms. Norris: Do you almost have a conjecture?
Kyanna: A conjecture?
Ms. Norris: Yeah, down here okay. So skip this editing again. See if you can jump to how is the graph and the animation related? Like what makes you say about like which bus, like how can you make the bus win, how can you make the van win based on the graph, okay?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Kyanna: So, we can say if the bus moves further [Bree interrupts]
Bree: No, if you make the van closer to the finish line, the uh
Kyanna: Then the van will win.
Bree: yeah, but if [Ms. Norris interrupts]
Ms. Norris: What do you mean?
Kyanna: If you make the van go the finish line [Bree interrupts]
Bree: No, if you make, if you place the van closer, ahead, ahead of the bus [Ms. Norris interrupts]
Ms. Norris: The start?
Bree: Yeah.
Ms. Norris: It has to win?
Bree: Yeah
Ms. Norris: Try that and see if that works.

The teacher initiated the conversation by prompting for a conjecture about the relationship between the graph and the motion. She then followed up with questions prompting students to clarify their conjecture and to generate a case to confirm it. Generating cases is a structure used explicitly in the Bridging curriculum to support students in finding patterns by exploring various cases, come up with a conjecture from the patterns and use later as evidence to support their conjecture. Clarifying, a move developed in the PD, is important in conjecturing because it leads students to use more precise language and to refine their ideas so that they establish shared understanding about the conjecture and can critique the conjecture with reasons that are not rooted in simple confusion (Thompson & Schultz-Ferrell, 2008). This interaction was brief, but it led students to come up with an extreme case that excited them. Later, Ms. Norris came back to the pair as they called on her.

Ms. Norris: It just shrank. That's okay. Oh, Wow! [Bree and Kyanna giggle] Cool. What that, what does that graph look like? That's a, so making kind of crazy situations like that are actually really helpful for making conjectures because if you notice, what's crazy about this situation? [Ms. Norris points to the representation of the motion] It's like where you were just talking to me about like "Wow." Why did you say that?
Bree & Kyanna: Because it went so fast.
Ms. Norris: Which one went so fast? What's true about its picture? its graph?
Kyanna: [indiscernible]
Ms. Norris: How, that's, you can just use that to make a conjecture. You said, "wow it's going so fast." What's- [Bree points to y-axis on graph on computer]
Kyanna: [Indiscernible]
Bree: Oh, oh, look in the graph. It's 80 and 0. on the [Bree starts writing in her notebook]
Teacher: There you go. [Teacher leaves the pair]

The pair continued their conversation. One of them played the animation again.

In this conversation, the teacher addressed the role of extreme cases in making a conjecture. First, she shared the excitement with the students about their finding of an interesting case, where a van moved really fast while a bus moved slowly. She noted the unusualness of the case students found by labeling it as "crazy." Also, she probed further for the mathematical aspects of their findings by building on what students said—using teaching moves to seek for, clarify and use student ideas as a springboard for introducing new knowledge are effective for promoting student discourse (Walshaw & Anthony, 2008). She pressed students to say more than what they simply noticed about motions and to think about "what is true" about the relationship between the motion and the graph, which later became their conjecture: "If the van/bus is close to the origin, the line closer to the y-axis will be faster." Ms. Norris further clarified with them that they meant the y-axis instead of the origin.

Conclusion

These selections show that this teacher, working in a diverse urban school classroom, is learning to support her students in argumentation, specifically in generating cases that lead to conjectures, with the support of online curriculum. She used students' engagement with what they saw on the computer screen to lead them to more sophisticated conjectures. Starting with students' own ideas, she helped students clarify their thinking and supported them in talking to each other, formulating conjectures, and asking and responding to questions—all practices aligned with the literature on enhancing math discourse. She was, indeed, providing the kind of access to high-level disciplinary practices that have been lacking in many such classrooms. This finding is also consistent with other results from prior Bridging PD studies (Knudsen, Shechtman, & Kim, 2012).

EPISTEMOLOGIES AND COALITIONS *SIN FRONTERAS* IN MATHEMATICS EDUCATION

Acknowledging our position as outsiders and researchers in the work with specific communities of students of color and their teachers, we examine our epistemological paradigms through the lens of Latina/o Critical Theory. Analysis of our testimonios revealed that our experiences have influenced our perspectives as mathematics educators and researchers. Findings describe our necessity to "straddle the borderlands" of different epistemologies to responsively and more explicitly address issues of equity, specifically race, in our coalitions with school communities.

Keywords: Equity and Diversity, Teacher Education-Inservice/Professional Development

As researchers and mathematics educators concerned with issues of equity in mathematics education, we believe that forming coalitions—across racial, gender, cultural, and geographical borders—may support the combined work of "allies" when aiming at engaging in actions and goals *sin fronteras*. An ally is a person who helps, supports, or acts in solidarity with another in a particular effort. Through ally work, we aspire to disrupt systems of privilege and oppression in mathematics education. Drawing on ally perspectives, we accept that our knowledge, goals, and values as math educators are influenced and bounded by mainstream mathematics education perspectives. Consequently, we intentionally contrast our stances with borderline epistemologies of a minoritized group, specifically a Latina/o Critical (LatCrit) framework to reflect on our stances in these possible coalitions. The LatCrit perspective aims "to move researchers and educators into spaces of moral and critical practice" (Delgado Bernal, 2002, p. 393).

Theoretical Perspective

We adopted the LatCrit perspective to critically examine our emerging understanding of what it means to be an ally. The five tenets of this framework (Delgado Bernal, 2002) include:

1. *Centrality of race and racism and their intersectionality with other forms of subordination.* Historically, racism has been associated with other forms of oppression such as class, gender, language, and immigration status and among others. LatCrit maintains that at this intersection some answers to theoretical, conceptual, and methodological questions might be found.
2. *Challenge dominant ideologies*. LatCrit values culturally specific ways of teaching and learning as ways of knowing that extend beyond the formal. This stance defies traditional educational deficit frameworks that privilege dominant groups' ideas such as objectivity, meritocracy, color-blindness, race neutrality, and equal opportunity.
3. *Commitment to social justice*. LatCrit epistemologies seek structural and personal political and social change by dismantling structural subordination that empower minoritized groups.
4. *Centrality of experiential knowledge*. LatCrit views experiential knowledge of people of color as a strength. Methods such as storytelling, family history, biographies, *testimonios*, and oral histories, etc. are utilized as processes to learn about these students' unique experiences.

5. *Call for transdisciplinary perspectives*. LatCrit challenges unidisciplinary in research and education and instead encourages the merging of various research methods to examine race and racism in education in historical and contemporary contexts.

Methods and Data Sources

This study involved the participation of fourteen project team members from eight U.S. public universities. Members included nine faculty members (six white females, one white male, one African American male, and one Latino male), four doctoral students (one white female, two Asian females, and one African American male), and one postdoctoral researcher (African American male). Participants engaged in life history and background interviews to document the incoming epistemologies informing this work. Two rounds of interviews were conducted either via phone conference, online, and/or face to face by two white faculty members of the team. The semi-formal interviews included open-ended questions that explored the participants' stance, perspectives, knowledge, experiences, and personal definitions regarding issues of privilege and oppression as well as features of equitable mathematics teaching and learning including *access* and *agency* (Gutiérrez, 2012), and *allies*. All interviews were audiotaped and transcribed. We viewed the interview data as testimonios related to awareness on issues that affect minoritized students. *Testimonio* is a verbal description of a journey that reveals the injustices suffered by marginalized people with the goal of promoting healing, empowerment, and advocacy for similar current and future populations (Pérez Huber, 2010).

To address the research question – *In what ways do the project team members' epistemologies align (or not) with the basic tenets of LatCrit?* – a content analysis of the interviews was developed by two faculty members (Latino and white female) and doctoral students (African American male and Asian female). Content analysis is a "technique for making inferences by objectively and systematically identifying specified characteristics of messages" (Holsti, 1969, p. 14). Guided by LatCrit epistemology and critical race grounded theory, themes emerged from data through critical lens that explicitly addressed issues of equity (Pérez Huber, 2010). Three stages of data analysis were implemented: preliminary, collaborative, and final. In the preliminary phase, themes in the data were identified through initial coding strategies (Charmaz, 2006). The themes were shared and discussed with the team until reaching consensus. This process served as an opportunity to member-check as well as to further reflect on our epistemological stances and provide richer understanding of our work (Kruger, 1988). Results are described through four contrasting and yet complementary examples that help present the major themes from the analysis.

Results

Initial themes were collapsed into three explanatory themes: (a) the recognition of one's power and privilege when working for social justice at the social and personal levels in mathematics education, (b) the acknowledgement that the assessment of our relationships across roles (such as students, mathematics teachers, and mathematics teacher educators) is crucial when considering the development of purposeful coalitions and actions as allies that support agency and access across these roles, and (c) a need for more explicit focus on race, language, and immigration as forms of subordination to promote equitable changes for diverse learners.

Experiential knowledge framing stances about power and privilege

Similarly to other analyses using LatCrit, the members' testimonios overwhelmingly identified experiential knowledge as a source of their perspectives and understandings of issues of equity. For example, Liz described some of her research interests linked to her school experience: "My interest in voice and authority has to do with my own silencing as a math student." Liz's silencing informed her need to further explore a key aspect in mathematics instruction, the relationship between

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

students' voices and teachers' authority construed in classroom interactions. Likewise, Frida made use of her experiences as a teacher to support the work of teachers. She shared, "My experiences in the classroom, enlisting the support of parents, that's all about teachers in the service of the children because parents can support the work of teachers reaching into the community and so on." As a teacher, Frida realized the powerful changes that students experience through the combination of understanding the interactions between mathematics and their communities. Both of these previous stances represent an approach towards equitably addressing issues of student diversity.

Moreover, members' *testimonios* revealed that participants have learned that, with teachers and students, equitable work starts with equitable stances, which comprise the acknowledgment of one's own privilege. For example, Liz stated, "In terms of trying to be an ally, you almost have to learn to see the world in a different way and step outside of your own privilege to understand and be genuine in those relationships." Similarly, Tracy shared, "Every time you see injustice, you have to interrupt it. You should be the one. If you have the privilege of power, say something." According to Liz's and Tracy's *testimonios*, awareness of one's privilege is a necessary condition for supporting equity. Simultaneously, this awareness confers a responsibility of knowing when to "use it" and when to "step outside of it" in order to support equitable community work and productive alliances, something that leads to the next theme.

Assessment of relationships and roles yielding tensions in coalitions for change

Social change is a major goal addressed by the tenet of *commitment to social justice*. The *testimonios* highlighted the relevance of coalitions to achieve this goal. Mathematics educators may play a role as allies in this process, but *testimonios* presented an evolving definition of this role. Most participants agreed with Liz "being an ally is something you have to live." Thus, ally work requires purposeful action. Liz used a simile of allies being like 'brokers.'

> People who are brokers, who can sort of exist between teachers and […] (they) exist sort of between spaces can do and say things that people who live in those spaces can't do and say. For example, I can go to the principal and say things and do things on behalf of the teachers without them asking me to and create opportunities for them, without repercussions for me.

Liz's account of a broker represents the role of an ally for teachers because s/he can work at a different level than the teacher community. Thus, people with powerful positions have more opportunity to exert their agency to implement changes, to be allies. As Frida described, however, an ally alone cannot promote the intended change. "I worked sometimes at schools with teachers who really didn't want to work with math professional developers. They weren't interested in the district or school's goals. […] If teachers set their own goals, then they're more likely to work with someone else."

The power of alliances resides in the development of coalitions that are mutually developed and embraced by all parties involved. Contrastingly, other *testimonios* raised concerns about the feasibility of coalitions. For example, Tracy questioned, "Who wants allies and who doesn't? Do you want me, as a white person, as an ally? Are there some people of color who have written that white people can't be allies for people of color? Like, stop calling yourself an ally!" A tension in the role of an ally occurs at the border of a patronizing or a colonizing approach. LatCrit supports critical coalitions among Latinas/os and nonLatinas/os to dismantle structures of oppression (Valdes, 1999), raising the question, not of "if," but "how" and "on what" coalitions can develop.

Focus on the intersectionality of identity to promote equitable changes for diverse learners

Analysis of the *testimonios* yielded recurrent concerns about class, gender, and ability as forms of subordination. Katy, for example, argued:

> My family really influenced the way that I think about the world. I remember most clearly my parents talking to me about gender equality. […(and)] less explicit talk about race. My dad married a black woman so obviously that would have been a huge influence on the way that I thought about race. Still I don't remember explicit discussions as much as on gender.

While identifying experiential knowledge as an epistemological source, Katy described how her context did not include race as a central issue to consider. Consequently, topics such as race, language, and immigration were less prevalent in the *testimonios*. LatCrit, however, identifies race as intersecting with other issues, but yet it places race at the center of analyzing forms of subordination. This recurring theme is a critical call to our team to epistemologically expand towards and more explicitly consider language, immigration, and especially race as forms of subordination to be examined and dismantled in mathematics education (e.g., Foote & Bartell, 2012; Martin, 2009; Moschkovich, 2010; Nasir, Hand, & Taylor, 2008).

Scholarly Significance

The juxtaposition of our epistemological stances identified our *frontera,* our challenge of taking a more explicit stance on issues of race in mathematics education, and not only on other intersecting issues, latter issues which are more evident to the majority of our team. Paying more attention to issues of race in mathematics education would be fruitful not only in relation to inform our stance as allies, but also—as LatCrit sustains—it is at this location where answers to structural subordinating forces might be found. As researchers and mathematics educators, we understand our need to "*straddle the borderlands*" (Anzaldúa, 1987) by embracing the issue that our lived experiences do not match those of diverse students. Thus, our aimed ally-stance in our coalitions with diverse teacher and student communities demands from us to learn to listen, notice and address explicitly, *sin fronteras,* issues of race in mathematics education and research.

THE SMARTNESS DILEMMA: A CHALLENGE TO TEACHING MATHEMATICS FOR EQUITY

Nicole L. Louie
The University of Texas at El Paso
nllouie@utep.edu

Abstract: Research on teachers frequently illustrates the persistence of beliefs about students and mathematics that reproduce inequity. The prevalence of these beliefs suggests that they not only belong to individual teachers but also are part and parcel of culturally dominant discourses concerning the nature of mathematical ability. In this paper, I show how these discourses interfere with equity-oriented reforms, focusing on a teacher who was deeply engaged in redefining what counts as "smart in math," dismantling the borders between "smart" and "not smart." In spite of her efforts, the teacher continued to see students' deficits and, more significantly, she constantly doubted the legitimacy of the "smartnesses" she worked hard to see. I call this phenomenon the Smartness Dilemma. Understanding how it functions is important for understanding how to support teachers to disrupt hierarchies of perceived ability.

Keywords: Teacher Beliefs, Equity and Diversity

Introduction

The dominant "ideology of intelligence" in the United States holds that intellectual ability is innate, fixed, and quantifiable on a linear scale, so that some people plainly appear to have more than others (Oakes, Wells, Jones, & Datnow, 1997). Although there is growing recognition that intelligence is not fixed but developed through learning and effort, boundaries between intelligent and unintelligent students remain deeply inscribed in schools, as evidenced by the persistence of classifications such as "gifted," "average," and "remedial."

Amanda Pepper (a pseudonym), the high school mathematics teacher at the center of this paper, consistently strove to erode these boundaries and support all of her students to see themselves as intelligent and capable—an especially ambitious goal because most of her students had histories of struggle in school, particularly with mathematics. Despite their protests, she routinely insisted that they rely on each other to solve complex problems, refusing to step in herself to explain how to reach a solution or to adjudicate a disagreement about content. In doing so, she enacted confidence in her students and gave them meaningful opportunities to learn that they could succeed without her. Redefining mathematical intelligence even more explicitly, Amanda labeled her students and a wide variety of their skills "smart," challenging schools' traditional emphasis on accurate and efficient computation. Near the end of class one August day, for example, she asked students to write about how they were "smart today in math," noting that she had seen them recognize patterns; make predictions; use multiple representations (e.g., tables, graphs, and equations); use technology to help solve problems; persist and continue to try when stuck; ask questions; and communicate their thinking clearly.

Yet even in the midst of naming a multitude of ways that her students were smart, Amanda sometimes found herself stuck in "a deficit mindset." Research spanning several decades has analyzed such mindsets in terms of individual teachers' beliefs about students (e.g., Garmon, 2004; Gomez, 1993; Jackson, Gibbons, & Dunlap, in press). Here, I question boundaries between good and bad teachers as owners of good or bad beliefs. I focus instead on social ideologies of intelligence. I find that dominant ideologies of intelligence create a quandary that I call the Smartness Dilemma: although teachers may strive to see each of their students as smart, the lens of hierarchical ideologies

of intelligence remains before them, bringing borders between "smart" and "not smart" into focus and making many strengths invisible.

Theoretical and Empirical Background

Seeing is a social practice. What teachers notice and how they make sense of it comes not only from their individual knowledge and beliefs but also from social and historical ways of seeing and making sense (Vygotsky, 1986; Wenger, 1998). Hierarchical ideologies of intelligence are deeply engrained in American education, pushing teachers (and others) to see more intelligence in some and less in others. Apparent differences are reified with increasing concreteness. For example, standardized testing produces categories like Advanced, Proficient, Basic, Below Basic, and Far Below Basic (as the proficiency bands are called in California). While these labels are meant to designate only performances, in practice, they "acquire" children (McDermott, 1996), so that it becomes sensible for educators to talk about "my FBBs [far below basics]" and "the bubble kids" (those on the cusp of proficiency).

"Metaphors of hierarchy" are especially salient in mathematics, a discipline that is often assumed to proceed along a "linear path" from the basic to the sophisticated (Parks, 2010). As Parks describes, a linear hierarchy is inscribed throughout mathematics education discourse, shaping everything from casual teacher talk to mathematics textbooks to policy documents. Its ubiquity creates a context in which it is natural to locate students on the path as either on track, ahead, or behind—and unnatural to see intelligence as multidimensional or all students as smart.

Of course, no matter how dominant an ideology is, meanings are never cemented but always in negotiation (Wenger, 1998). Still, as I show here, asserting alternatives to dominant ideologies of intelligence is not merely an issue of changing individual teachers' beliefs.

Methods

This paper draws on data from a study that involved 18 mathematics teachers in two diverse urban high schools. I focus here on Amanda Pepper. Amanda is a White woman who was in her third year teaching at the time of the study. She was an active participant in a district-sponsored professional development (PD) program based on a pedagogical approach called Complex Instruction (CI; see Nasir, Cabana, Shreve, Woodbury, & Louie, 2014). CI asserts that *all* students are not only capable of learning but also already "smart." The PD was designed to support teachers to broaden their views of what counts as mathematically smart and to accordingly transform their instruction. Amanda attended workshops and received sporadic CI coaching. She was held up as a leader and a model in the local CI community.

I conducted observations in CI PD sessions, in Amanda's classroom (n = 8), and in routine meetings of the mathematics teachers at Amanda's school (n = 8) for one school year. I also interviewed Amanda informally throughout the year and once in a semi-structured format at the end. I collected these kinds of data for a total of six teachers in the study but elected to focus on Amanda for the present analysis because she was uniquely clear in articulating a dilemma that is not commonly addressed in the literature on teaching mathematics for equity.

My analysis focused on Amanda's own descriptions of her goals and of the obstacles she encountered as she worked toward those goals. I also drew on transcripts from classroom observations and teacher meetings in cases where they were directly related. I used open coding (Emerson, Fretz, & Shaw, 1995) to develop the themes described below.

Findings

Amanda expressed two broad kinds of challenges: ideological and structural. The structural difficulties she described are likely familiar to many who have worked in under-resourced schools.

They included lack of time, lack of access to expertise, and lack of support for professional learning, as well as high mobility amongst students, teachers, and school leaders.

More central to this paper are the ideological challenges—manifestations of the Smartness Dilemma—that Amanda faced. Specifically, she described continuing to see her students' deficits and doubting the legitimacy of the "smartnesses" that she worked hard to see.

Seeing deficits instead of strengths

At times, Amanda caught herself "in a deficit mindset, where I'm like, [my students] can't do all of these things instead of [focusing on] what they can do." She noted that they rarely came to class "prepared and having studied" and that they weren't "willing to work hard." Yessica was "so lost" because, as a newcomer from Mexico, she spoke very little English and was also frequently absent. Keshia would "probably never be able to manipulate an equation."

These ways of thinking and talking about students draw on dominant ideologies that not only highlight certain types of knowledge and motivation but also link deficits in these areas to particular groups, such as students of color, students from low-income households, English learners, and students with learning disabilities. These ideologies found their way into Amanda's thinking, even when she intended to look for her students' strengths. They presented her with one facet of the Smartness Dilemma: whether or not to trust her own perceptions, and if not, what to do with these apparent "facts" about her students' capabilities.

Doubting the legitimacy of nontraditional "smartnesses"

Although she sometimes dwelled on students' deficits, Amanda was skilled at noticing and publicly acknowledging ways of being smart that are not typically recognized in American schools or society (a capacity that she had successfully been supported to cultivate, unlike many teachers). Even when she focused on strengths, however, Amanda was plagued by doubt—a second facet of the Smartness Dilemma. She described own education in "a very White, one-way school," saying that there was "this traditional view of what smart looks like … I think I still have it in my head." This view made her question whether "I'm out of reality, by wanting to believe that [my students] are so smart in different ways."

The "traditional" voices in Amanda's head were amplified by a number of her colleagues, who vocally reasserted traditional views of mathematics and mathematical intelligence. For example, in a department discussion of how to teach factoring in their Advanced Algebra classes, Amanda advocated for a multi-modal approach using area models as well as algebraic manipulation. Rob, who taught the department's most advanced courses, insisted on a purely symbolic procedure that "shows algebraically what's happening to the factors." Larry interjected that he would ideally like to teach students both methods, but given time constraints, he preferred Rob's way because "it's just like, this method is what math looks like." These teachers' reluctance to embrace CI and their confidence in traditional views came up repeatedly in my conversations with Amanda. They shook her trust in her students, in her own content knowledge, and her own intelligence, leading her to ask questions like: "Do I need to be thinking more critically about it? Am I really, are [my students] really smart? Or am I just trying to compensate?" Even when she felt empowered to push back and ask Rob how his students felt about themselves and mathematics, Amanda described wondering if she was being "soft" and experiencing "this awful twist in my head again of just, constant questions and doubt."

Discussion and Conclusion

In much the same way that Amanda worked to challenge boundaries between "smart" and "not smart" students, her case challenges boundaries between "good" and "bad" teachers. She was successful in noticing a wide variety of "smartnesses," and many in her district viewed her as a

highly skilled and deeply committed CI teacher. Yet dominant ideologies of intelligence were ever present for her, highlighting students' deficits and making her question the validity of the different strengths she saw. This shows that even teachers who are unusually committed to expansive ideas about what counts as mathematically smart are deeply affected by dominant ideologies. Future research should explore the range of these effects for different teachers, taking ideology as an analytic focus. Such a focus can challenge the deficit views of teachers that beliefs-focused research often implies. It can also help the field to better understand the diverse kinds of support that teachers may need to navigate the Smartness Dilemma and other challenges associated with resisting the narrow and hierarchical ideologies that currently dominate American society. We may find that resources like community support and ongoing validation, for example, are just as if not more important than resources for developing technical and other kinds of expertise.

Research has shown the importance of teachers' participation in professional communities for supporting instructional change. However, recent studies indicate the potential of online communities for supporting engagement in productive and generative instructional practices that are transferable to teachers' classrooms. This study aimed to better understand the nature of 28 mathematics teachers' participation in an emerging online community. Results indicate a relationship between the extent of teachers' persistence in project activities and their beliefs about their relationship with the community. This study has implications both for the design of professional development programs and the ongoing support provided during such programs for increasing the likelihood of teachers' persistent involvement.

Keywords: Teacher Education-Inservice/Professional Development

Introduction

Research-based instructional practices such as student-centered instruction, the use of cognitively demanding tasks and orchestrating productive mathematical discussions have been shown to be conducive for improved student achievement (Jackson, Garrison, Wilson, Gibbons, & Shahan, 2013). Such instructional practices, however, are difficult for teachers to enact, especially when local institutions are not supportive of such practices (Gamoran et al., 2003; Kazemi & Franke, 2004). In our work, we seek to capitalize on the structure and support of professional communities to facilitate teachers' instructional change (Vescio, Ross, & Adams, 2008). Specifically, we focus on the potential of online communities that lie outside specific classrooms, schools or districts to support teachers development and implementation of high quality instructional practices — even those that may run counter to the norms and practices that are accepted within teachers' local settings. More generally, our work focuses on supporting the emergence of online communities for teachers that provide a context for meaningful and generative professional development (PD) and support emergence of research-based instructional practices. This paper reports on our current efforts to better understand the nature of teachers' participation in this online community and the potential impacts of their participation.

Theoretical framework and related research

To frame our work of cultivating online teacher communities, we draw on Wenger's (1998) notion of communities of practice. Participating in a community of practice involves sharing a history of learning with others. Involved in this history of negotiating meaning and common experiences, participants in a community develop shared practices, common beliefs and a repertoire of tools (Wenger, 1998). Such involvement, however, results in discontinuities between practices of "those who have been participating and those who have not" (Wenger, 1998, p. 103). Thus, boundaries form and communities' practices diverge.

Boundary encounters can be designed to support the crossing of boundaries. Encounters can include one community visiting another and immersing themselves within the host community's

practice. This exposes the visiting community to the host's practices and provides contexts for the intersection, negotiation and coordination of practices. Prolonged engagement in negotiating meaning and shared experiences at the boundary can result in the emergence of boundary practices and, consequently, the emergence of a new community of practice (Wenger, 1998).

Our work in the Emerging Communities for Mathematical Practices and Assessment project (EnCoMPASS) drew from this theoretical perspective and aimed to purposefully design a boundary encounter between a group of mathematics teachers and an existing online community of practice, the Math Forum, consisting of experienced mathematics teachers and teacher educators whose practices and beliefs are aligned with research-based instructional practices (Shumar, 2009). EnCoMPASS began with a face-to-face experience but continued (and currently continues) with online PD activities that focused on analyzing, organizing, and annotating student work and developing feedback for students in a technologically mediated environment (Shumar, 2009). Activities were designed to support teachers' engagement in the existing practices of the Math Forum, an online community that recently celebrated its 20th year supporting online mathematics education. These activities, which were designed to function at the boundary of the EnCoMPASS teachers and the Math Forum, are conjectured to facilitate the emergence of boundary practices and consequently the emergence of a professional community for teachers that is both "their own" and, at the same time, in alignment with the research-based instructional practices that guide the Math Forum's work.

Methods

To better understand teachers' participation and the emergence of community, we documented teachers' engagement in these boundary encounters quantitatively and conducted more in depth qualitative analysis of teachers' use of discourse in project activities. The question we explore in this brief research report is: What is the relationship between participants' participation in the community (investment over time) and their beliefs about the community and their relationship to and with it?

Project data included 28 participants' interactions during two one-week, face-to-face workshops (summers of the first and second years of the project) as well as 7 shorter face-to-face workshops and 20 online classes/workshops from the first three years of the project. Quantitative analysis was conducted using basic social network analytic methods, including counts of participation and engagement in project activities. Qualitative analysis was conducted using a modified grounded theory approach (Corbin & Strauss, 1998), where segments of discourse identified as significant were subjected to theoretical interpretation, resulting in a set of codes that represented similar moments. We report on the connections between participation and one set of codes from this analysis.

Results

This study uncovered a relationship between teachers' participation in project activities and their beliefs about their relationship with the community. First, teachers' overall participation in project activities could be sorted roughly into three categories – those with high, medium and low levels of participation (Table 1). The validity of these categories was further elaborated using more detailed social network methods and reported elsewhere (Matranga & Koku, 2015).

Table 1: Levels of Investment

Level	Participants	Number of activities involved
High	14	6-13
Medium	12	3-5
Low	2	0-2

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Qualitative analysis of participants' utterances and interactions revealed a distinction between teachers in the three levels of participation and, in particular, differences in the ways that they talked about their relationship and future engagement with the project.

Personal Connection and Community-based Language

Teachers characterized as having a personal connection with the community used community-based language to describe their future engagement. As part of these descriptions teachers showed affect towards the group, specifically referenced their involvement in a "community," or used pronouns such as "we," "us" and "our" to discuss their involvement. The following excerpts are examples of such community-based language:

- "EnCoMPASS has been near and dear to my heart … So, I'm so grateful and thankful for being part of EnCoMPASS and meeting this wonderful group of people. I'm most thankful for the interactions I've had with you, and hopefully we will continue to work together" *(FA, W1)*.
- "And continuing the communication with others, because, you know, I'm learning so much, and I really hope that, as I've said, I'm able to take this back home and really continue working with it and continue being part of this community" *(LA, W2)*.

Egocentric, Outsider Language

Teachers characterized as egocentric discussed their future work by using outsider language. Teachers characterized in this way focused on what "I" want to do, or the ways in which the project can be used as a resource for their own future work. Examples include:

- "Novel approaches are interesting to me, when I look at student work I want to see something that I didn't think of yet, that is what is interesting to me" *(NK, W1)*
- "I am very intrigued on how to incorporate [problem solving] into my instruction. I've never done that, unlike several of you … I have very little exposure to it, so I am interested in pursuing it further" *(LH, W2)*.

Mixed Language

The third way in which teachers talked about their future work related to the project mixed both outsider and community-based language. Teachers characterized in this way tended to discuss what "I" wanted to do but also appeared to be in transition to using community-based language as they referenced specific individuals that they would like to work with in the future.

- "One thing I definitely want to do is be more consistent with my use of [problem solving] in my classroom. I will be lucky enough to have 60 extra classes this year. Instead of 180 we have 240 classes, so I know I can carve a lot of time out, at least 30 extra days of problem-solving in there, so that's really good… I hope to also use [the software] a little bit- Jerry L and Maggie S and I talked about this- to give a task to students, have them submit responses, and we can comment on each other's feedback and support each other … and I'm sure we'll do [Google] Hangouts together as well" *(JA, W2)*

Discussion

Research indicates the importance of community for supporting teachers' instructional change. The goal of the EnCoMPASS project is to facilitate boundary encounters that support the emergence of a self-sustaining and generative online community of mathematics educators. The research reported in this paper aimed to better understand the nature of a group of mathematics teachers' experiences in such encounters. This study suggests that there is a relationship between participants'

persistent involvement in PD activities and the extent to which they used community-based language and illustrated a personal connection to the community.

This finding has two implications. First, this emerging typology can frame additional analysis of participants within each level of investment to better understand why they continued to engage in the project and whether particular activities led to their use of these different types of discourse. One conjecture we have is that specific "community-building" activities or unscheduled work time allotted during face-to-face workshops could be factors that influence the development of relationships and a resulting personal connection to the community.

Second, this typology develops a continuum that relates characteristics of teachers' discourse to their likelihood to continue to engage in community-based PD. Professional developers could leverage this continuum to support the emergence of teacher communities. For example, they could support teachers who are identified as egocentric to foster their valuing of the importance of a support network for implementing high quality instructional practices. In addition, as different discourses emerge, they could purposefully group participants to be more involved with those that use community-based language and appear to value communal relationships.

In our ongoing work, we are collecting and analyzing additional data that can further verify and refine the results reported in this paper. This process includes a chronological analysis of project activities to understand the changing and evolving nature of teachers' beliefs about their relationship with the community and how this is related to engagement with particular project activities/participants. Moreover, we are investigating the content of teachers' interactions to relate teachers' experienced norms and practices to their investment and communal relationships.

In addition, the results reported in this paper, coupled with social network analysis reported elsewhere (Matranga & Koku, 2015) will allow us to make predictions regarding leaders and other individuals that can influence the persistence of the community.

CROSSING THE UNIVERSITY BORDER: SUPPORTING ELEMENTARY MATHEMATICS SPECIALISTS SHIFTING PEDAGOGY DURING AN AUTHENTIC RESIDENCY COURSE

Kayla D. Myers	Susan L. Swars	Stephanie Z. Smith
Georgia State University	Georgia State University	Georgia State University
kmyers@gsu.edu	sswars@gsu.edu	szsmith@gsu.edu

This innovative project supports the development of Elementary Mathematics Specialists (EMSs) during their final authentic residency course required for a K-5 Mathematics Endorsement. This coursework provides the opportunity for participants to evidence their learning from their mathematics content courses through classroom teaching practice, with the ultimate goal of pedagogical shifts toward more standards-based instruction and dialogic discourse. This project provides and examines additional coaching sessions focused on classroom discourse, peer collaboration, and mentor feedback. Data collection includes scored observation rubrics of classroom practice, Portfolio Key Assessments, belief surveys, content knowledge assessments, supervisor and participant reflections of coaching sessions, and individual interviews.

Keywords: Teacher Knowledge, Teacher Beliefs, Classroom Discourse, Elementary School Education

Purpose

As the mathematics standards in the U.S. for grades K-12 increase in rigor, so does the need for highly qualified teachers. Teachers require a deep and broad mathematical knowledge to draw from during instruction (Hill, 2010), especially to create *standards-based learning environments* (SBLEs) that encourage dialogic discourse and foster conceptual understandings of mathematics (Tarr et al., 2008). Developing learning environments that prompt students to make conjectures about mathematical ideas and explain their thinking requires thoughtful planning and questioning on the part of the teacher. Teachers must value multiple student perspectives and carefully build whole class discussions using students' statements in an effort to help the class reach shared mathematical understandings. These skills are not common in today's elementary classrooms, even with the widespread adoption in the U.S. of the *Common Core State Standards for Mathematics* (CCSS-M, NGACBP & CCSSO, 2010) that include mathematical practices depicting such a pedagogical emphasis.

With the new mathematical content and practice standards set forth by the CCSS-M, along with the accompanying high-stakes standardized assessments, teachers feel added pressure to change their instructional practices to align with the increased expectations and emphases for student learning. This has contributed to the focused discussion on the important role of elementary mathematics specialists (EMSs), who are mostly considered to be teachers, teacher leaders, and/or coaches with the established expertise to support effective elementary mathematics instruction along with student learning in the classroom, school, or other levels (Association of Mathematics Teacher Educators, 2013). Our university offers an EMS preparation program (i.e., a K-5 Mathematics Endorsement [K-5 ME] program) that contains 15 semester hours of courses, including 12 mathematics content course hours and a 3-hour authentic residency course. Our K-5 ME program aims to develop EMSs that can effectively orchestrate classroom discourse, create and employ a SBLE, meet and exceed the expectations of the National Council of Teachers of Mathematics' *Principles to Actions* (2014), all while supporting fellow teachers. The purpose of this project is to provide increased support during the authentic residency course experience with the aim of supporting EMSs' pedagogical shifts in classrooms and to study the outcomes of these additional supports.

Related Perspectives

Elementary teachers' beliefs about mathematics teaching and learning are often shaped during education programs, but enacting these shifting beliefs can prove difficult for teachers as they rely on past experiences and comfortable practices (Charalambous, Panaoura, & Philippou, 2009; Connor, Edenfield, Gleason, & Ersoz, 2011). "Teacher preparation coursework and professional development offerings must address both mathematical content and pedagogy in ways that advance teachers' subject matter understanding and their understanding of students' emerging conceptions of mathematics while also fostering effective instructional skills and practices" (Campbell et al., 2014, p. 453). When considering EMS preparation programs, practicum experiences serve as the opportunity to implement new pedagogy and demonstrate specialized content knowledge. However, when too little attention is paid to this implementation during and after program completion, teachers often fall back on traditional instructional practices (Fennema et al., 1996; Philipp, 2007). Polly and Hannafin (2011) found that teachers' espoused beliefs did not always match their enacted classroom practices, but that scaffolding and ongoing support can aid this connection.

An additional means of supporting the connection between changing beliefs and enacted practices is through the use of mentorship. For example, Halai (1998) worked as a mentor with teachers as they learned new ways of teaching mathematics and found that a trusting relationship with a mentor supported growth and pedagogical shifts. These findings lend credence to the importance of the practicum phase of an EMS preparation program, with attention focusing on teachers' implementation and pedagogical shifts.

K-5 ME Program Experiences

Our K-5 ME program strives to shape and create EMSs as mathematics teacher leaders. This innovative program produces specialists in the field of elementary mathematics, filling leadership roles in their schools and modeling the impact of advanced specialist certification. The K-5 ME program aims to develop EMSs who can effectively orchestrate classroom discourse, establish and utilize a SBLE, implement the expectations of the CCSS-M, and support their peers in doing so. The participants in this project have completed the first half of the K-5 ME mathematics content/pedagogy course requirements and are working to complete the final half while enrolled in a practicum/authentic residency course. This authentic residency provides them the opportunity to implement what they have learned and document their enacted classroom practices, serving as their final evaluative piece toward obtaining the K-5 ME.

The learning goals for the authentic residency course include that prospective EMSs should: (1) demonstrate the knowledge, skills, and dispositions gained during program coursework via effective classroom practices; (2) apply information gained from feedback to their classroom practices; and (3) apply reflective thinking to their classroom instructional practices. Course assignments include planning, implementing, and reflecting upon at least ten mathematics lessons modeling the content knowledge and pedagogy learned throughout the program's four mathematics courses. Two of these lessons are observed by a university supervisor, using a rubric specifically designed for observing elementary mathematics instruction and the extent to which it is aligned with a SBLE and providing evaluative feedback on the observed teaching practices. Using the Portfolio Key Assessment, an assignment adapted from the state proposed K-5 Mathematics Endorsement Program Portfolio Guidelines, participants submit a portfolio evidencing their content knowledge and pedagogical skills acquired in the four mathematics courses and authentic residency course.

In previous semesters, the authentic residency course provided minimal feedback to the participants due to the evaluative nature of the course assignments, limited time spent with the university supervisor and colleagues, and lack of collaborative mentorship opportunities. Previous research on the program has shown participants need more critical and constructive feedback, more guidance as they implement new teaching practices, and more coaching from their university

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

supervisor as well as peers, teacher leaders, and mentors in their schools. This project is an effort to provide that support to endorsement candidates during their authentic residency experience. Ultimately, this project shifts the role of the supervisor, aiming to provide support as a coach and mentor to the participants rather than an evaluator. This allows for more direct and practical feedback, collaboration between participants and their mentor, and a model for future effective teacher leaders.

As part of this innovation, participants engage in monthly coaching sessions aimed at providing support and guidance for K-5 ME candidates as they complete their authentic residency. These coaching sessions maintain a heavy focus on residency course assignments, implementation of new teaching practices, reflection on these implementation experiences, and collaboration with fellow teachers within a safe and supportive environment. Coaching session topics focus on facilitating classroom discourse as a lens to provoke conversation and questions. Further, participants engage in a book club with their mentor. The book, *5 Practices for Orchestrating Productive Mathematics Discussions* (Smith & Stein, 2011), highlights the focus of classroom discourse and provides an extension of participants' content knowledge and pedagogical skills learned through the program's mathematics courses. Sections include: the 5 practices for facilitating effective inquiry-oriented classrooms, anticipating what strategies students will use in solving a problem, monitoring their work as they approach the problem, selecting students whose strategies will enhance discussion and meet the lesson objectives, sequencing those students' presentations to maximize their potential to increase students' learning, and connecting the strategies and ideas in a way that helps students deepen their understanding of the mathematics. Drawing from participants' learned mathematics and venturing into the art of orchestrating discourse can bridge the gap between understanding the content and implementing effective instruction. As many K-5 ME participants have expressed in the past, asking questions and orchestrating discourse are often the most difficult skills to master. By reading together and crafting those skills, participants can build confidence as a teacher leader. Furthermore, in order to extend this practice of collaboration and coaching, participants can video-record their teaching practice. This offers an added opportunity for participants to critically reflect on their own practice while the mentor is able to speak directly to the lesson and provide specific feedback. Celebrating successes together and providing constructive feedback to those that need help are essential practices of teacher leaders.

Data Collection and Preliminary Analysis

Data continues to be collected via observation rubrics of classroom practice, Portfolio Key Assessments, pre- and post-surveys for pedagogical and teaching efficacy beliefs, content knowledge assessments, supervisor notes and participant reflections of coaching sessions and feedback provided, and participants' evaluations of the innovation through individual interviews following their authentic residency course.

Data collection and analysis is ongoing, and preliminary evaluation of this new authentic residency course support already reveals an increase in participants' confidence in putting their learning into action, shifting pedagogical practices, practicing discourse in the mathematics classroom, refining questioning strategies, and completing their required course assignments. Participants' classroom observations show more thorough and thoughtful planning, and portfolios are much more detailed and robust. The relationships that the university mentor has been able to create with participants allow for more collaboration and engagement in new teaching practices. These coaching sessions are opening up the experiences of the authentic residency course into more of an opportunity than a requirement, feeling more supportive than evaluative. It is expected that continued data collection followed by a thorough data analysis will show evidence of participants' strengthened abilities to implement a SBLE, carefully build classroom mathematics discussions, and find value in multiple solution methods and perspectives, allowing these prospective EMSs to become more

effective at orchestrating discourse and implementing the CCSS-M. Further, preliminary data analysis shows the beginnings of pedagogical shifts for these prospective EMSs. Therefore, it is expected that a final analysis of the complete data collection will exhibit participants' pedagogical shifts in their teaching practice, grounded in their changing beliefs about how children learn mathematics, how they teach mathematics, and how to build a classroom environment conducive for both. As this project is designed to better support those shifts in pedagogy, we anticipate it will create a longer-lasting, more effective change for these prospective EMSs.

THE LANGUAGE OF PROFESSIONAL DEVELOPMENT LEADERS

Andrew Riffel   Kathleen Melhuish   Eva Thanheiser

riffle@pdx.edu   kmelhuish@teachersdg.org   evat@pdx.edu

Leaders in professional development (PD) initiatives (such as facilitators, principals, coaches) hold a great deal of power in their language, carrying the ability to manage meaning and frame experiences. Rather than working from interview data, this report addresses a gap in leadership research by examining the words used by leaders in their on-the-job interactions. We present an initial framework for capturing leadership language qualities at the macro level (framing the PD's purpose) and micro level (rhetorical crafting in terms of metaphor usage, pronoun choice, and other language selections). Our data come from a larger project evaluating the efficacy of a large-scale sustained PD. Through developing a lens for analyzing leadership, we hope to build a tool to eventually connect leadership with other related PD measures including teacher buy-in, fidelity of implementation, and ultimately outcomes in schools.

Leaders in professional development (PD) initiatives (such as facilitators, principals, and coaches) hold a great deal of power in their language. Their words carry the ability to inspire participants to buy into initiatives, establish themselves as credible leaders, and build positive learning communities. Communication is more than the transmission of information, as language acts to bring meaning to ideas and frame experiences.

In this report, we share a preliminary analysis of leader interactions with careful attention to rhetoric and framing choices of leaders within schools and the PD program. Our data comes from a quasi-experimental study evaluating the efficacy of a mathematics PD program in a midsized, urban school district. We use detailed field notes and video-taped PD sessions to compare language across various leaders. Despite a well coordinated PD, we found consistent differences in framing and rhetoric across leaders at various sites.

On Framing and Language

Fairhurst and Sarr (1996) describe "reality [as] a social construct, and language is its primary vehicle" (p. 19). They go on to explain that leaders' discourse can serve to build frames to explain purposes of innovation, gain interest, to inspire, and to promote a sense of community. Individuals' experiences are shaped by the discursive choices of those around them. We use the lens of *framing* and *rhetorical crafting* to analyze the language of leaders. We use these constructs in a way consistent with Conger (1991) where framing is the defining of major concepts and purpose, and rhetorical crafting is at a finer-grained level. Conger defines framing as "the process of defining the purpose of an organization in a meaningful way" (Conger, 1991, p. 32). We generalized this construct to capture framing of major ideas including, but not limited to, the purpose of our PD. Conger discusses rhetorical crafting as using symbolic language, focusing on emotional power in his writing, to package a message. He goes on to use the analogy of a gift's wrapping paper being "as impactful as the gift itself" (p. 32). For our analysis, we adapt this notion to analyze language choices across leadership interactions.

Leaders in PD

Leadership is essential for positive change in schools (Leithwood, Harris, & Hopkins, 2008). The role of several types of leaders has been explored within PD including principals (e.g. Youngs & King, 2002), PD facilitators (e.g. Linder, 2011), and teacher leaders (e.g. Darling-Hammond, Bullmaster, & Cobb, 1995). Leadership literature varies from describing types of effective leaders (often relying heavily on interview data), to leadership roles, and leadership actions. We aim to build on leadership work by addressing *leadership interactions* directly. That is, our primary source of data are videos and notes from PD sessions where various leaders interact with participants.

Methods

Context of the Study

We are currently conducting a large quasi-experimental study evaluating the efficacy of a studio model PD in a midsized urban school district. We have all grades 3-5 teachers at 25 elementary schools participating in either (a) 3-day summer sessions only or (b) 3-day summer sessions and five 2-day cycles of PD (studio model) throughout the year. The PD focuses on creating mathematically productive classrooms through Best Practices in teaching that promote students developing mathematical habits such as justifying and generalizing (Foreman, 2013). For the schools participating in the studio model, the two-day cycle is split into a leadership coaching day and studio day. During the studio day, one teacher at each school (the studio teacher) opens his or her classroom for a commonly planned and subsequently observed lesson. All teachers at the school work together to plan, refine, and debrief the lessons. This day is preceded by a day of leadership coaching with the principal and math coach, as well as planning with the studio teacher. The PD facilitators work with the principal and coach at each school to (a) help the principal understand the goals of the PD, (b) plan the principal introduction for the next day during which the principal frames the PD, (c) observe in the grades 3-5 math classrooms and connect these observations to teacher implementation of the PD, and (d) plan on how to increase buy-in and sustain the PD between cycles.

Data Collection and Analyzing Leadership

We collected data on two case study schools, School 1 (year 1, 2, and 3 data; 603 students in 2012-2013 with 83.5% receiving free/reduced lunch, 53.3% of 5th graders meeting standards in math) and School 2 (year 1 data only; 358 students in 2012-2013 with 38.5% receiving free/reduced lunch, 75% of 5th graders meeting standards in math). For each PD session, both days were video-recorded and at least one member of the research team took detailed field notes. The field notes were first processed by identifying instances of *leadership interactions.* We used leadership interactions to capture any interaction between participants where (a) one of the participants was in a leadership role; and (b) the communication was substantive. We then analyzed the leadership interactions across three midyear sessions each of which had a different PD facilitator and principal. Initially, we open-coded the leadership interactions to look for trends across discourse. After this initial exploration, we developed categories of rhetorical crafting and identified instances of framing related to the PD. We then returned to the video to assure our categories accurately reflected the conversations.

Preliminary Results

Through our initial analysis, we found that leaders varied in how they framed important aspects of our work and in their discourse choices in a variety of ways such as pronoun choice and usage of metaphors.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Framing

We analyzed leadership interactions based on the framing of the purpose and nature of the PD, the roles and expectations around teachers, and the nature of mathematical classrooms. Consider the following contrasting principal framing of the PD work from their opening statements to teachers.

Principal S: Some of those, what that looks like is short answers to a question, it could be restating facts or statements, showing procedures, and we got to be getting out of that and instead challenging our students more, bumping up the rigor. A big piece of our work this year is aligning our actions and being really purposeful about this is what we want to see: we want students to be making sense, we want students to be justifying, we want students to be generalizing, making connections to the work, making representations of the work.

Principal A: The group is also flexible, so that when it comes to our homework assignments and that type of thing, I think we can make them more genuinely confirming for the work we're going to be building. Yesterday when we were walking around, I saw a couple, well more than a couple of great things and I want to encourage you guys to keep trying to do these things. They're new and learning to do anything new is the hardest part. I think we're over a big hump in terms of effort and the work in terms of conferences. The hard part's done, we just have to focus in on the gift of the work.

Principal S frames the PD work in terms that are a.) consistent with the focus of the PD such as having students justify and generalize, and b.) as purposeful for benefiting students. In contrast, Principal A frames the PD work in terms that are a.) not specific to any of the PD's focus, and b.) pleasing an external source, "the group", through completion of "homework". The choice of the word "homework" alludes to the PD work being prescribed and perhaps undesirably necessary.

Rhetoric

We also found a number of differences in leaders' rhetorical crafting. We present two example differences: pronoun choice and imagery. Table 1 includes additional categories of rhetoric themes.

Table 1: Sample Themes in Leadership Rhetoric

Sample Rhetorical Crafting Category	Description
Inclusiveness of language	Pronoun choice such as *I* and *you/they* vs. *we*
Orientation towards school/participants	Strengths-based or deficit-based language
Level of specificity	Specific examples or broad statements
Level of personalization	Personalized or generic messages
Use of imagery	Figures of speech (i.e. metaphor) in language

Within our first theme, inclusiveness of language, we present excerpts from two leaders with contrasting crafting. The first tended to favor "I" and "you" statements such as, "The survey is a gift you give yourself. I know how busy you are and how fast you are running." In contrast, the second leader used "we" statements such as, "We're going to work hard to see what we can do so students are engaging with these." This may situate leaders as either part of the group of teachers or external to them.

Leaders also use imagery to manage meaning. In one episode the leader begins the day by saying, "We're going to put on roller skates this morning." This conjures up an image of the leader and

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

attention, compared the struggle to "herding cats". This image brings a sense of chaos to the situation where the leader is separate from the participants, trying to manage them.

Conclusion and Discussion

Our examination of leaders' use of framing and rhetorical crafting revealed patterns and themes in their language choice, which could reveal how they establish themselves as leaders, create buy-in amongst their teachers, and develop a positive learning community. This is true both in global framing of ideas and in subtle language choices. For instance, Fiol, Harris, and House (1999) found that charismatic leaders more frequently used inclusive referents such as "we" rather than "I" and "you". Similarly, the use of metaphor has been associated with leadership rhetorical selections where images can either help bring positive meaning to ideas or potentially confuse or skew a message (Fairhurst & Sarr, 1996).

Through analyzing the language of PD leaders, we are beginning to unravel some potential causes for differences in buy-in and enactment of this initiative (Thanheiser, Melhuish, Shaughnessy, & Foreman, 2015). A leader's language choices can serve as a motivating factor, but could also serve to exclude or alienate participants. Our initial framework provides a tool for analyzing rhetoric and future analysis will test the generalizability of the work. Furthermore, we look to connect leadership language with other constructs such as fidelity of implementation and outcome changes such as teaching quality and student achievement.

EXPERIENCIAS NARRATIVAS DE PROFESORES DE EDUCACIÓN BÁSICA CON LA ANSIEDAD MATEMÁTICA

IN-SERVICE TEACHERS NARRATIVE EXPERIENCES OF MATHEMATICS ANXIETY

Bernardita Peñafiel	Kathleen Jablon Stoehr	Salomé Martínez
University of Chile	Santa Clara University	University of Chile
bpenafiel@dim.uchile.cl	kstoehr@scu.edu	samartin@dim.uchile.cl

El propósito de este estudio fue aportar a la comprensión acerca de la ansiedad al enseñar matemática de profesoras de Educación Básica a través de conversaciones guiadas. Estas conversaciones giraron en torno a las experiencias de los participantes con la matemática como estudiantes y como profesores. La narrativa generada en esta experiencia, provee un discurso poderoso que da cuenta del grado en que la ansiedad matemática que sienten los profesores moldea sus actitudes y sus posibilidades de éxito al impartir la asignatura. El foco de análisis para este estudio fue la comunidad de profesores de Educación Básica, específicamente profesoras que han sufrido ansiedad en el proceso de aprender y enseñar matemática.

Palabras clave: Capacitación Docente / Desarrollo Profesional, Creencias de los Maestros

Antecedentes y Objetivos

La ansiedad matemática en profesoras de Educación Básica es un tópico que ha capturado el interés de investigadores en educación matemática. Las experiencias de ansiedad vividas por profesoras de Educación Básica en sus propios procesos de aprendizaje, puede impactar en cómo ellas se aproximan a la enseñanza de la matemática y en cómo imparten la asignatura en sus salas de clases (Ball, 1988; Bursal & Paznokas, 2006; Stoehr, 2015). Estudios previos relacionados con la ansiedad matemática padecida por profesoras de Educación Básica investigaron si profesoras que la experimentaban podían ser exitosas en la enseñanza de esta disciplina (Beilock, Gunderson, Ramirez, & Levine, 2010; Bursal & Paznokas, 2006). También ha habido preocupación respecto a si profesoras con ansiedad matemática pueden traspasarla a sus estudiantes (Beilock et al., 2010; Sloan, 2010). Actualmente hay acuerdo respecto a que una profesora de matemática segura y competente es vital y necesaria en la clase de matemática (Beilock et al., 2010; Oswald, 2008).

Recientemente académicos han estudiado la ansiedad y seguridad relacionada con la matemática desde un enfoque narrativo, ellos sugieren que la conversación colaborativa entre mujeres es una herramienta muy significativa por la cual las mujeres que participan en ellas pueden expresar ideas y sentimientos, propios o de otros, desde su punto de vista (Stoehr, 2013). Reunir a mujeres en torno a conversaciones guiadas de temas relevantes de estudio, permite que en dicha experiencia afloren tópicos y conclusiones que no se podrían lograr de otra manera (Belenky, Clinchy, Goldenberger, & Tarule, 1986). Involucrar a profesores en conversaciones basadas en la metodología narrativa *Conversations that Matter* (Stoehr, 2013) es una manera de guiar a profesores en un trabajo complejo, intelectual y moral, de pensarse como un profesor (Griffin, 1988).

El objetivo de este estudio es reportar los resultados de un estudio narrativo enfocado en entender la ansiedad matemática vivenciada por profesoras chilenas en servicio a través de un instrumento narrativo basado en *Conversations that Matters* (Stoehr, 2013). Estas conversaciones guiadas giran en torno a las experiencias relacionadas con la matemática de profesores en servicio de Educación Básica, tanto como estudiantes como profesores.

Perspectiva/Marco de trabajo

Perspectiva 1: Mujeres y Ansiedad Matemática

La ansiedad matemática es más que solo no tener afinidad o gusto por la matemática (Vinson, 2001). "Ansiedad matemática se refiere a un estado de respuestas poco saludables que ocurre en algunos estudiantes cuando se enfrentan a problemas matemáticos, manifestándose a través de sentir pánico, tener dificultades para concentrarse, estados depresivos y desesperanzados, nervios e inseguridad" (Luo, Wang, & Luo, 2009, pp. 12-13). También se pueden producir reacciones fisiológicas como manos sudorosas, puños apretados, sensación de enfermedad, sequedad labial, palidez facial, produciendo que los estudiantes pierdan no solo su interés por la matemática sino también su seguridad por aprenderla (Luo et al., 2009).

Profesores que están ansiosos con la matemática frecuentemente traspasan su propia ansiedad a sus estudiantes, lo que puede generar una perpetuación del problema (Beilock et al., 2010; Sloan, 2010; Vinson, 2001). En efecto, Beilock et al. (2010) reporta que profesoras de Educación Básica que padecen ansiedad matemática, repercuten negativamente en el logro matemático de sus estudiantes mujeres. El estudio revela que mientras mayor sea la ansiedad con la matemática de la profesora, mayor es la probabilidad de que las estudiantes crean que los hombres son mejores para la matemática que las mujeres. Dejar de lado este "carga de matemático" es crítico para los profesores (Brown, Mcnamara, Hanley, & Jones, 1999).

Perspectiva 2: Investigación narrativa en profesores como un medio para crear *Conversations that Matters* en torno a la matemática.

Académicos han utilizado de manera exitosa la narrativa en el campo de la educación, esta provee un foco claro de cómo los profesores le dan sentido al proceso de enseñar, incluyendo la relación con su propia experiencia escolar. (Clandinin & Connelly, 2000; Carter, 1993; Doyle & Carter, 2003). La indagación narrativa genera un espacio para que los profesores hablen y escriban sobre sus historias de vida, conectándolas a sus experiencias de enseñanza y dándole sentido (Carter, 1993; Clandinin & Connelly, 2000). Con el fin de lograr una comprensión más profunda del rol y las consecuencias que tiene la ansiedad matemática en los profesores de Educación Básica, Stoehr (2013) desarrolló un programa de investigación narrativa para estudiar los procesos cognitivos y los significados personales que profesores le dan a la matemática a través de "conversar" respecto a su experiencias con la matemática, como estudiantes y como profesores. El uso de narrativas, oral y escrito, es un método de investigación poderoso que puede ser utilizado para desarrollar una nueva concepción de la ansiedad matemática en profesoras de Educación Básica. Para este trabajo se utilizó el instrumento narrativo de conversación colaborativa *Conversations that Matter* diseñado por Stoehr (2013).

Fuente de los Datos

Este estudio es parte de una línea de trabajo de una prestigiosa universidad en Chile, como parte de sus esfuerzos por desarrollar y fortalecer las capacidades disciplinares y pedagógicas para enseñar matemática, en establecimientos educacionales públicos del país. Este estudio se enfoca en aproximadamente 54 profesores de escuelas básicas, la gran mayoría mujeres, que estaban participando en un taller de desarrollo profesional enfocado en Ansiedad Matemática. Los participantes eran todos chilenos de entre 25 a 60 años de edad, promedio de edad 40 años y el promedio de años de servicio era de 10 años.

Método y Contexto

Los participantes de este estudio fueron ordenados en grupos de 10 profesores con un investigador que facilitaba el trabajo en cada grupo. Luego se le pedía a cada participante que de

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

manera individual respondiera 4 frases del instrumento *Conversations that Matter* relacionadas con el proceso de aprender y enseñar matemática. Estas frases eran: En matemática soy bueno para…; Cuando era estudiante, una de mis experiencias más desafiantes con la matemática fue…; Para mi enseñar matemática es…; Pienso que la ansiedad o poca seguridad en matemática es causada por…

Luego de completar cada frase, los participantes compartían sus respuestas unos con otros. Ellos comentaban similitudes que veían entre las respuestas de unos con otros, como también comentaban cómo la respuesta de uno los llevaba a pensar algo que ellos consideraban que era interesante compartir. A su vez, conversaron de los diferentes aprendizajes y conclusiones que llegaban al comentar cada frase. La narrativa recogida en las conversaciones generadas por el instrumento *Conversations that Matter* fueron grabadas y duraron una hora aproximadamente.

Durante el análisis, la narrativa de las *Conversations that Matter* fueron revisadas y analizadas de manera cuidadosa en orden de demarcar e identificar elementos analíticos de la narrativa relacionados con la ansiedad matemática. Utilizando técnicas temáticas e iterativas propias del análisis cualitativo, incluyendo métodos de comparación constante de los análisis (Bogdan and Biklen, 2006), la atención fue puesta entonces en los detalles temáticos documentados en el proceso de recolección de datos.

Resultados

Los hallazgos centrales del análisis de las narrativas y sus implicancias se muestran a continuación.

Resultado 1: Yo soy bueno para algo en matemática

Todos los participantes reportan ser exitosos de alguna manera en matemática. Algunos profesores hablaron de tener competencias en la capacidad de cálculo, otros compartieron ser buenos para la resolución de problemas, para razonar, resolver problemas de lógica, y para estimar. Otros participantes reportaron ser competentes en temáticas específicas como geometría y álgebra. Un participante dijo: "Soy bueno para motivar a mis estudiantes para trabajar en problemas matemáticos y yo soy bueno para hacer cálculo mental".

Resultado 2: Experiencias desafiantes en el aprendizaje de la matemática

Los profesores comparten una diversidad de experiencias al momento de recordar el proceso de aprender matemática en su época de estudiantes escolar y universitaria. Una temática que se repite de manera constante es la mala base o la falta de conocimientos sobre la matemática elemental, la cual era causal de dificultades en niveles superiores. Otros participantes declararon que se sentían incapaces de entender contenidos específicos de la matemática como el álgebra, geometría, cálculo, mientras otros reportaron que tenían dificultades porque no encontraban la matemática una asignatura relevante para sus vidas. Algunos profesores recalcan haber tenido experiencias de presión y ansiedad para completar tareas matemáticas al frente de sus compañeros. Por ejemplo un participante reportó: "ir a la pizarra a resolver un problema me ponía muy nerviosa".

Resultado 3: Perspectiva enseñando matemática

La mayoría de los participantes en el estudio reportaron que el enseñar matemática en Educación Básica era una experiencia desafiante. Un participante compartió que para ella era desafiante porque cada vez que debía enseñar un contenido, tenía que primero reaprenderlo y luego buscar maneras para enseñarlo a sus estudiantes. Algunos declararon que tenían poco manejo de la matemática, otros sentir angustia al momento de enseñarla. Sin embargo, otros participantes compartieron que se sentían desafiados al enseñar matemática ya que tenían la oportunidad de desarrollar habilidades matemáticas en sus estudiantes. Otros participantes reportaron que enseñar matemática para ellos era

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

importante porque era una disciplina necesaria para la vida diaria, por lo que lograr que sus estudiantes aprendieran y se sintieran seguros con sus conocimientos matemáticos era un desafío.

Resultado 4: ¿Dónde nace la poca seguridad y la ansiedad en matemática?

Las respuestas de los profesores respecto al origen de la ansiedad o poca seguridad en matemática se relaciona principalmente con las propias experiencias de los docentes al aprender matemática. Sus respuestas incluyen los siguientes ejes temáticos: (1) Sentimientos de vergüenza al momento de aprender matemática; (2) miedo a fracasar al momento de "hacer matemática"; (3) falta de conocimiento matemático; y (4) sentirse siempre "tonto" para la matemática. Más específicamente, algunos participantes hablaron del miedo y vergüenza al momento de equivocarse o cometer errores. Otros participantes declararon que la reacción negativa de la profesora y la falta de apoyo a los estudiantes con dificultades podía generar ansiedad matemática. Algunos participantes creían que los métodos tradicionales de enseñanza para enseñar matemática podían generar en algunos estudiantes sentimientos de ansiedad.

Significancia académica del estudio

Nuestro estudio sugiere que hay mucho por aprender sobre la ansiedad al enseñar matemática que sienten las profesoras de Educación Básica. La metodología *Conversations that Matter* abre una ventana para que investigadores en matemática puedan observar cómo se genera la ansiedad matemática, sus consecuencias y puedan trabajar en estrategias para redirigir la ansiedad que algunas profesoras de Educación Básica viven. Este estudio revela que la ansiedad matemática puede ser un tema que puede afectar a profesoras de Educación Básica y que puede perpetuarse durante décadas. De hecho, puede ser que algunos individuos nunca dejen de sentir ansiedad al realizar actividades matemáticas. Futuras investigaciones deberían buscar estrategias para que los formadores de profesores en matemática pudieran dirigir y trabajar con las historias y experiencias de ansiedad matemática de los profesores, teniendo en cuenta que probablemente dichos esfuerzos al menos en su etapa inicial solo van a hacer consiente a la población de la existencia de esta problemática por sobre prevenir la aparición de la ansiedad matemática. Además, futuras investigaciones pueden proporcionar a los formadores de profesores en matemática una visión más profunda de lo penetrante que es la ansiedad matemática para algunas profesoras de Educación Básica.

The purpose of this study was to gain a better understanding of the issues that surround Chilean women in-service elementary teachers' mathematics anxieties through Conversations that Matter. These conversations revolved around the participants' mathematics experiences as students and practicing teachers. These narrative writings provide a powerful voice for the degree to which mathematics anxiety shapes teachers' attitudes in this subject area as well as their ability to be successful in mathematics. The focused analysis for this paper was directed to impact the elementary mathematics education community with a specific focus on women who have had anxiety in learning and teaching mathematics.

Keywords: Teacher Education-Inservice/Professional Development, Teacher Beliefs

Background and Purpose

Mathematical anxiety in women elementary teachers is a subject that has captured the interest of mathematics educators. Women's experiences of mathematics anxiety in their own student learning days can impact how they approach mathematics instruction in their own classroom (Ball, 1988; Bursal & Paznokas, 2006; Stoehr, 2015). Previous research in mathematics anxiety in women elementary teachers question if teachers who experience mathematics anxiety can be successful in teaching mathematics (Beilock, Gunderson, Ramirez, & Levine, 2010; Bursal & Paznokas, 2006). Moreover, there is concern that teachers who have mathematics anxiety may pass their anxiety onto their students (Beilock et al., 2010; Sloan, 2010). There is agreement that a confident and competent mathematics teacher is a vital necessity in the classroom (Beilock et al., 2010; Oswald, 2008).

Recently scholars have examined anxiety and confidence in mathematics from a narrative perspective. Research on narrative work suggests that collaborative conversations among women can be a powerful means by which women can reflect on issues that are not only important to them but told from their point of view (Stoehr, 2013). Engaging women in conversations of specific topics of study affords opportunities for themes to emerge that can either move them forward or propel them backwards (Belenky, Clinchy, Goldberger, & Tarule, 1986). Engaging teachers in narrative based Conversations That Matter (Stoehr, 2013) offers a means by which to engage students in the intellectual, moral, and complex work of *thinking like a teacher* (Griffin, 1988).

The specific objective in this paper is to report findings from a narrative-based study aimed at understanding Chilean women in-service teachers' issues of mathematics anxieties through a researched based and instructionally focused Conversations That Matter narrative tool (Stoehr, 2013). These conversations revolved around in-service teachers' own mathematics experiences as students as well as their experiences of teaching mathematics.

Perspectives/Frameworks

Perspective 1: Women and Mathematics Anxiety

Mathematical anxiety is more than just not liking mathematics (Vinson, 2001). "Mathematics anxiety refers to such unhealthy mood responses which occur when some students come upon mathematics problems and manifest themselves as being panicky and losing one's head, depressed and helpless, nervous and fearful, and so on" (Luo, Wang, & Luo, 2009, pp. 12-13). Physiological reactions such as sweaty palms, tight fists, feeling sick, having dry lips, and a pale face can also occur which can result in students losing not only their interest in mathematics but in their confidence to learn mathematics (Luo et al., 2009).

Teachers who are anxious about mathematics often pass their own anxieties to their students, which can result in a perpetuation of the problem (Beilock et al., 2010; Sloan, 2010; Vinson, 2001). Indeed, Beilock et al. (2010) reported that mathematically anxious women elementary teachers often impact the mathematics achievements of the girls in their class. The study revealed that the more anxious the teacher was about mathematics, the more likely the girls in the class were to believe boys were better at mathematics than girls. Discarding this "mathematical baggage" is critical for teachers (Brown, Mcnamara, Hanley, & Jones, 1999).

Perspective 2: Narrative Research in Teacher Education as a Means to Create Mathematical Conversations That Matter

Scholars have successfully used narratives in the field of education as a research framework to provide a clear focus of how new teachers make sense of teaching, including how it relates to their own school experiences (Clandinin & Connelly, 2000; Carter, 1993; Doyle & Carter, 2003). Narrative inquiry creates a means for teachers to talk and write about their storied lives while making connections to teaching (Carter, 1993; Clandinin & Connelly, 2000). In order to move forward

toward a productive and meaningful understanding regarding the role mathematics anxiety plays in women elementary teachers, a narrative research agenda was developed by (Stoehr, 2013) to examine the cognitive understandings and personal-sense making strategies used by the participants to "converse" about their mathematical experiences, as students and teachers. The use of narratives, both oral and written, is a powerful research tool that can be used to develop new understandings of mathematical anxiety in women who are elementary teachers. For this work, (Stoehr, 2013) has termed this narrative based collaborative discussion as *Conversations That Matter.*

Data Sources

This study is part of a larger, multi-year and on-going effort at a large University in Chile aimed at strengthening and developing disciplinary and pedagogical capacities for teaching and learning mathematics in public schools. This paper focuses on approximately 54 urban public school teachers who were predominantly women and who were participating in a professional development workshop on mathematics anxiety. The participants were all Chilean between the ages of 25 - 60, with an average age of 40 years old. The average years of teaching were 10.

Methods and Context

Participants in this study were arranged in groups of ten teachers with one researcher facilitating each group. Each participant was then asked to respond individually to four Conversations that Matter prompts that were related to learning and teaching. These prompts were as follows: In math I am good at…; One of my most challenging experiences learning mathematics as a student was…; For me teaching mathematics is…I think anxiety and/or low confidence in mathematics is caused by….

After completing each prompt, the participants shared their responses with each other. They commented on the similarities they saw in each other's responses or how one person's responses prompted them to think of something else they found relevant to share. They also talked about the themes they shared with one another. The Conversations that Matter narrative data collection activity was video recorded and lasted under one hour.

During analysis, the Conversations that Matter narratives were reviewed and carefully analyzed in order to demarcate and identify analytical narrative elements related to mathematics anxiety. Using iterative and thematic qualitative analysis techniques, including constant comparison methods (Bogdan and Biklen, 2006), attention was then turned to a detailed documentation of thematic elements that were revealed during the data collection process.

Findings

This brief research paper reports on the narrative experiences of in-service teachers' mathematics anxiety as students and as teachers. Central findings from the analysis of the narratives and their implications are shared below.

Finding 1: I Am Good at Something in Mathematics

All participants reported being successful in some way in mathematics. Some in-service teachers spoke of having competent computation skills. Others shared they were good at problem solving, logic and reasoning, estimation. Some participants reported they were able to do well in specific content areas such as algebra and geometry. One participant stated, "I'm good for motivating my students to work on math problems, and I´m good for doing mental calculus."

Finding 2: Challenging Experiences Learning Mathematics

The teachers shared a variety of different types of challenging experience of learning mathematics as a student. One major theme included participants reporting a lack of a strong foundational mathematics background that made higher levels of mathematics difficult. Other

participants stated they felt unable to understand specific content areas such as algebra, geometry, and calculus, and while others reported that they struggled to find mathematics as being relevant in their lives. Some teachers recalled experiencing pressure and anxiety to complete mathematics tasks in front of their classmates. For example, one participant reported that "going to the board for solving problems made me very nervous."

Finding 3: Perspectives on Teaching Mathematics

The majority of the participants in the study reported that they found teaching elementary level mathematics to be challenging. One participant shared how each time she taught a content area she had to try and first relearn the content herself and then worried how she would teach it to her students. Some shared that they lacked expertise in mathematics content while others stated they felt distress when teaching this content area. However, other participants stated that despite feeling challenged in teaching mathematics, they were dedicated to creating mathematics understanding for their students. Some participants reported that teaching mathematics was an important content area for their students to learn and feel secure in, as mathematics is needed in everyday life.

Finding 4: Where Does Mathematics Anxiety and Low Confidence Come From?

The teachers' responses regarding the sources of mathematics anxiety and lack of confidence in this content area were derived mainly from their own experiences of learning mathematics. These responses included the following themes: (1) strong feelings of embarrassment while learning mathematics; (2) failure to be able to "do math"; (3) lack of mathematical understanding; and (4) always feeling mathematically dumb. More specifically, some participants spoke of the fear and shame that can accompany being wrong or making mistakes. Other participants stated that teachers' negative reactions or lack of support for students struggling in mathematics could create mathematics anxiety in students. Some participants believed that traditional methods of teaching mathematics (such as direct instruction) and the lack of opportunities to work with peers in the mathematics classrooms can lead to some students feeling anxious about mathematics.

Scholarly Significance of the Study

Our study suggests that much that there is much to be learned about women elementary teachers' mathematics anxiety. Conversations That Matter opens a window for mathematics researchers to peer inside of the issues that create mathematical anxiety for teachers as well as ways to address mathematics anxiety that some women elementary teachers experience. This study reveals that mathematics anxiety may be an issue or concern for women elementary teachers that may recur for decades. In fact, it may be that some individuals may never stop experiencing mathematics anxiety. Future research might address how mathematics educators can work with teachers' histories of experiences with mathematics anxiety, keeping in mind that their efforts might primarily serve to raise awareness and provide options rather than to prevent mathematics anxiety. In addition, future research may provide mathematics teacher educators with a more in-depth view of how pervasive mathematics anxiety is for some women elementary teachers.

Using design research as a method of inquiry, we immersed twenty-four elementary teachers in mathematical modeling (MM) during a professional development institute and Lesson Study to co-design lessons and collaborate in collecting evidence of student learning. Results reveal that the design of the professional development and Lesson Study offered opportunities for teachers to become inspired by what their students were capable of doing as young mathematical modelers. Despite encountering challenges as they transformed their teaching approach to focus more on the cyclical process of MM, teachers found ways to rethink their mathematics instructional practices in order to promote higher ordered thinking skills in their elementary students.

Keywords: Teacher Education-Inservice/Professional Development, Modeling, Instructional Activities and Practices

Introduction

In the spirit of *Questioning Borders in Mathematics Education,* we attempt to identify the barriers that exists when teachers take up reform practice. Typically, reform in mathematics involves teachers moving from traditional approaches to teaching that is more problem-based in nature. The purpose of our study was to examine the challenges and support teachers needed as they implemented mathematical modeling in the elementary grades. We situated the professional learning in schools and classroom contexts through Lesson Study to provide the authentic classroom setting in which to consider the impact on student learning (Putnam & Borko, 2000). In addition, the mathematics educators worked with teachers in a *community of practices*, as teachers assumed the role of co-designers and implementers of this novel instructional approach in elementary grades.

Research Literature on Mathematical Modeling

Mathematical modeling (MM) is seen as a powerful tool for advancing students understanding of mathematics and for developing an appreciation of mathematics as a tool for analyzing critical issues in the real-world, that is, the world outside of the mathematics classroom (Greer & Mukhopadhyay, 2012). Traditionally, MM has been implemented primarily in secondary schools, but recent research examines using this approach with elementary students to promote their problem solving and problem-posing abilities (e.g. English, 2010). As students create and modify mathematical models to understand and solve real-world problems, they engage in a cyclical process of generating and validating their model and results. The teacher must be able to: (a) provide opportunities for students to acquire mathematical competencies and make connections between the real world and mathematics; (b) maintain the high cognitive demand of the MM process; and (c) provide classroom management that is learner-centered (Blum & Ferri, 2009). MM can be difficult for teachers to implement as they must be able to merge mathematical content and real-world applications while teaching in a more open-ended and less predictable way (Blum & Ferri, 2009).

Method of Inquiry

Using design research as a method of inquiry, we immersed twenty-four elementary teachers in mathematical modeling during a professional development institute so they would experience first hand the cycle of mathematical modeling before implementing MM through follow-up Lesson Study in their own classrooms. Through our professional development and research design, we wanted to understand and document how teachers developed and grew over time in their practice as they implemented mathematical modeling in the elementary grades. Specifically, we asked: (RQ1) What challenges do teachers face when implementing mathematics modeling in the elementary grades? (RQ2) What were some affordances of mathematical modeling that motivated teachers to continue to pursue it in their classrooms? (RQ3) What kinds of support do teachers need in order to implement mathematical modeling in the elementary grades?

To begin analyzing the themes, we used the document analysis technique using teachers' individual reflections, video transcripts of the Lesson Study debriefs, symposium presentations and researcher memos. We systematically analyzed the data by developing initial codes and used the method of axial coding to find categories in such a way that drew emerging themes (Miles & Huberman, 1994).

Results

In the results section, we present our analysis of the challenges teachers encountered when implementing MM, the affordances that inspired them to persist in using MM, and the supports needed as they continue to use MM in their classrooms (See Figure 1). The Mathematical Modeling Lesson Study tasks included planning a school fundraiser, designing and budgeting a butterfly garden, fighting hunger in their community, and being a smart consumer of goods. This analysis reflects the qualitative observations and data collected during the Lesson Study process that the teachers were engaged in.

Teacher Challenges

For the first research question we examined the challenges teachers face when implementing mathematics modeling in the elementary grades. The challenges that emerged from the data analysis included a) completing the modeling process, b) managing discourse, and c) school constraints. When implementing MM in the classrooms for the first time, teachers found that is was difficult to move students through the full process of creating and validating their mathematical models. For example, teachers commented that it was hard "…getting students to transition from collecting information to making a model", and "the students struggled moving past those assumptions because they wanted an answer to everything." As they implemented MM in their classrooms, teachers struggled with what type of support to provide to students during the MM process; they were unsure of when to intervene and when to allow students to productively struggle. Teachers "struggled answering and providing them with guidance" and noted that it was important, "not to give too many suggestions or impose too much control". During the debriefing of the Lesson Study, the participants acknowledged that MM takes time to implement in the classroom and that additional class time to implement these tasks would be helpful.

Affordances of Mathematical Modeling

For the second research question we examined the affordances of mathematical modeling that motivated teachers to continue to teach mathematics using this new method. The main affordances our teacher-researchers mentioned in our data emerged from mathematical modeling providing the a) opportunity for content to be covered without direct instruction, b) its interdisciplinary nature, and how MM provided c) mathematical relevance, and d) student engagement. When teachers implemented MM in their classrooms for the first time they were amazed at the amount of content

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

that could be covered without direct instruction. By having students go through the process of creating and validating their model, teachers commented, "it was amazing to see them just automatically asking for this math. They were asking you to teach them this math until they could figure it out and they could solve this problem. I think that this was the coolest part of this math model." Another positive take-away from implementing MM in these teachers' classrooms for the first time was how MM created a space where content covered was interdisciplinary. During lesson study a host teacher noted, "our math modeling on choosing a school fundraiser was cross curricular. One of the biggest things in third grade is economics where you're talking about opportunity cost is what you have to give up when you choose something". Like this host teacher experienced, multiple lesson studies seamlessly incorporated economics, technology, geography, and science into their lessons and mathematics was used to solve problems and make decisions.

Support Teachers Need

For the third research question we examined the kinds of support teachers need in order to implement mathematics modeling in their classrooms. The three main areas of support that emerged from our teacher-researchers were access to a) MM resources and pictures of practice, b) time constraints and c) collaboration with like-minded teachers.

Teachers expressed a desire to see examples of "successful MM tasks" across various grade levels. Teachers indicated that these supports would be helpful as they continued to implement MM in their classrooms. During the debriefing part of the Lesson Study, a number of teachers expressed the need for more time to work through and become comfortable with implementing the modeling process in their classrooms. Teachers noted that it was only in working through multiple MM cycles that they felt comfortable with the process and felt that their students were able to understand the whole MM process. A number of teachers had implemented several MM tasks in their classrooms since the beginning of the year and they discussed the benefit of doing multiple MM tasks as a way to familiarize students with the MM process. Finally, teachers indicated a desire to continue to work with a cohort to build MM lessons as well as to collaborate with and observe other teachers implement MM in their classrooms. They expressed the desire to work alongside a colleague who valued MM and with whom they could share ideas.

Figure 1. Bridging the barriers of implementing Mathematical Modeling in elementary grades during Lesson Study.

Conclusion

Reform practice in mathematics is a complex endeavor because there are many levels of support needed for change and many stakeholders who need to embrace the reform practices. In addition, teaching is a cultural activity that has many sociocultural norms. In order for reform practices, such as MM, to be taken up, teachers need to "relearn" mathematics through the reform practices so that they can understand how students will engage in that practice. Initially, our teachers were uncertain of their success with mathematical modeling with elementary students. It was after they were immersed as "mathematical modelers" and then co-designed and implemented a mathematical modeling lesson that the teachers gained more confidence about their ability to facilitate a

mathematical modeling lesson. Moreover, it was after seeing students engaged in the learning that teachers had the "proof of concept" needed for them to embrace this reform oriented teaching practices. Despite initial concerns about the time it would take to use MM in the classroom, the teachers learned that the modeling process provided a return on their investment of time because more content was covered meaningfully in the classroom using MM.

OVERCOMING RURAL TEACHER ISOLATION AND PROMOTING CHANGE IN SECONDARY MATHEMATICS CLASSROOMS THROUGH VIDEO CLUBS

Abraham Wallin
University of Idaho
wallin@uidaho.edu

Julie Amador
University of Idaho
jamador@uidaho.edu

The topic of rural mathematics education and the experiences of teachers working in these schools is one that has not been fully discussed within the literature. The relative isolation imposed by their circumstances create specific challenges, such as lack of resources, which is especially true for secondary teachers. This paper reports the results of a yearlong professional development project based on teacher noticing of student thinking involving the use of video club meetings at one rural school district. Findings show that while the project teachers developed deeper understanding of student thinking and task development/implementation they also changed their view of collaboration with their fellow teachers.

Keywords: Instructional Practices, Teacher Education-Inservice/Professional Development, Teacher Knowledge

Introduction

One of the largest shifts required for enacting the *Common Core State Standards for Mathematics* (CCSSM) (National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA & CCSSO], 2010) is the pedagogical considerations necessary for developing a new framework of classroom expectations (National Council of Supervisors of Mathematics [NCSM], 2014). Changes in the mathematical landscape motivate the need to analyze current pedagogical strategies and the implementation of available curricular resources (Lloyd, Remillard, & Herbel-Eisenmann, 2009). At the same time, the available literature on rural education topics, and more specifically mathematics education, is limited (Howley, 2008) despite these contexts representing more than 27% of schools in the United States (National Center for Education Statistics [NCES], 2015). In this paper we describe findings from a single-case study which examined the lived experience of three rural secondary mathematics teachers from one school district engaged in a video club based on *Teacher Noticing of Student Thinking*.

Background

Teachers who engage in conscious decision making regarding the impact of their own teaching have a greater chance of anticipating how students may respond to the tasks posed in the classroom (Sherin & Star, 2011). Through the process of planning lessons with several possible strategies in mind, and with set questions for each of these strategies at hand, teachers can be better prepared for addressing situations which arise (Smith & Stein, 2011). Reviewing teaching episodes provides teachers a necessary lens for analyzing student thinking and understanding opportunities the educator can draw on in the future. This was particularly important for the participants in this study, representing the secondary mathematics faculty at a rural, western school district, as they teach only one section of each class in a given day and do not have a means of clarifying content as the day progresses, as would secondary teachers in larger schools where individuals may have multiple sections of a single course.

This project assumed teacher noticing was a skill which could be learned (Jacobs, Lamb, & Philipp, 2010; Sherin & Star, 2011) and collaboration was an essential part of understanding one's own practice in the field of mathematics education (NCSM, 2014). The use of video clubs created a means for reviewing practice among groups of teachers and this reflection, when specifically focused on mathematical tasks and the instruction of those tasks, created a deeper capacity within the teachers

for analyzing instruction and planning for future lessons (Smith & Stein, 2011). Ideally the result would then be that teachers could develop better tasks, and these tasks would produce opportunities for students to learn content in meaningful ways.

Two primary research questions were created to address the problem of shifting teacher practice. These were (a) How does teacher noticing affect decision making around selecting and implementing classroom tasks? and (b) How does engaging in video club meetings focused on teacher noticing affect rural teachers' ability to identify and utilize pedagogical strategies which promote student thinking? Because of the nature of these questions, qualitative methodologies were used to collect and analyze data.

Methodology

Setting & Participants

The participants were three teachers representing all of the mathematical instruction from sixth through twelfth grade in one rural school district. Their teaching experience ranged from 15 ½ years to 23 years in the classroom and between 11 and 18 years in the particular district selected. Because of the small size of the district, none of the teachers taught the same course in a given day and all taught classes outside of the field of mathematics. The fact that no teacher taught the same course as their peer meant collaborative planning seldom occurred and each individual was responsible for preparing six different classes each day.

Data Collection

In line with creating a trustworthy study, multiple sources of data were collected throughout this project (Yin, 2009). Teaching observations were made on days when teachers conducted tasks that were filmed and later viewed during the video club (task days) and also on days when teachers were taught without being video recorded (non-task days). In addition, an initial and summative interview was conducted with each participant. These were semi-structured and served to create a deeper understanding of teacher thinking. Teachers also participated in five video club meetings. These meetings represented a type of group interview where participants would view clips of each member's teaching, reflect on their own pedagogy, and then discuss aspects of instruction and task selection; these meetings were recorded and transcribed for analysis. Several impromptu interviews occurred during the study as well and were video recorded. These were individual meetings, informally structured, and mostly focused as a discussion of instruction which had just occurred in the classroom. Finally, all observation notes, email exchanges between participants and the researcher or other teachers, teacher reflections, and classroom artifacts were also collected.

Data Analyses

Using a two-cycle coding method (Miles, Huberman, & Saldaña, 2014), data were first organized in clusters, which typified categories. These data were further refined using a system of pattern coding which sought to describe the clusters found during the initial cycle of coding and to better define the case as a whole. These were later condensed into categories, which represented commonalities in the coding focused on the researcher questions guiding this study. The three categories which emerged were: (a) beliefs about effective teaching, (b) role of classroom tasks, and (c) development and enactment of tasks. In addition, van Es' (2011) *Learning to Notice* framework (p. 139) was used to determine "what" teachers noticed and "how" the teachers noticed (van Es, 2011, p. 139). Determining the teachers' level of noticing provided a tangible means of evaluating the impact of the project on their beliefs about teaching, but equally important were the individual interview data as it allowed for deeper examination of views regarding the collaboration process.

Results

Teacher Noticing of Student Thinking

Following examinations of the video club meeting data, it became clear that teachers developed modified views of student thinking. Using van Es' (2011) *Learning to Notice* framework (p. 139), all three teachers advanced one level in both "what" they noticed and also in "how" they notice over the course of the study. None of the teachers were at the same initial level in either category, so therefore they ended the project with various depths of noticing. Data from the second and fifth video club illustrate these shifts (see Table 1).

Table 1: Noticing Levels Based on Learning to Notice Framework (van Es, 2011)

Teacher	Second Video Club		Fifth Video Club	
	What Teacher Noticed	How Teacher Noticed	What Teacher Noticed	How Teacher Noticed
Dean	Level 1–Baseline	Level 1–Baseline	Level 2–Mixed	Level 2-Mixed
Wilson	Level 2–Mixed	Level 2–Mixed	Level 3–Focused	Level 3-Focused
Larson	Level 3–Focused	Level 3-Focused	Level 4–Extended	Level 4-Extended

Curriculum Usage

As the teachers developed a deeper understanding of the role student thinking played in the learning process, their views of the curriculum, specifically regarding textbooks, began to shift.(See Figure 1.) Initially all three teachers were at various degrees of the offloading stage, which meant they used the curriculum materials and scope and sequence as intended by the curriculum developers. By the end of the project they all reflected different levels within the adapting stage where the teacher continues to use the textbook as a reference, but feels the freedom to make adjustments to content and sequencing. Mrs. Larson most closely approached the improvising stage, in which the teacher takes on authority for planning instruction and the curriculum is referenced periodically. All three teachers continued to use the curriculum, but they discussed how conversations with their peers began to have more significance.
Figure 1: Teacher Curriculum Usage using Brown's (2009) Framework.

The teachers recognized shifts in perceptions regarding the power of tasks and the needs of students when this type of instruction was used. Collectively they began to notice the power of requiring students to discuss their mathematical thinking, which had not been a significant aspect of instruction prior to the beginning of the project. In the initial interview, Mrs. Dean described tasks as something fun for student to do, but in the summative interview she stated:

> Now that we have been together and done tasks together, I now see when I can tweak those things and where you get more out of them. It's one thing to do an application thing. It's another thing to squeeze out all of the thinking skills you want to get out there.

Throughout the project the teachers continually attempted practices they observed their peers using in the videos. The power of seeing these strategies applied locally increased the teachers' willingness to

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

apply them while working with their own students. The video club meetings presented a forum for teachers to learn from each other and affect instructional changes.

Conclusion

Video clubs based on teacher noticing present an opportunity for teacher to grow in their own practice while removing barriers between colleagues who do not teach the same content. The use of this kind of professional development within rural contexts presents a valuable format for working with those who may otherwise feel isolated from their peers and complements the limited research on rural mathematics education (Howley, 2008). Further, the video club structure provided a context for the teachers to develop their noticing (van Es, 2011) and provided a system for the teachers to reflect on and make conscious decisions about their teaching in relation to students' mathematical thinking and the tasks posed in the classroom (Sherin & Starr, 2011). Although this research is limited to a case study for three practicing rural teachers, these data provide evidence of the importance of video clubs on developing teachers' abilities to notice and pay attention to students' mathematical reasoning. In this case, the data offer insight into how the teachers were implementing the CCSSM through tasks, while also emphasizing the students' mathematical strategies. Despite the fact that more research is needed, the findings of this project provide a resource for those working with rural educators.

SUPPPORT SYSTEMS OF EARLY CAREER SECONDARY MATHEMATICS TEACHERS AND THEIR AFFECTS ON TEACHER RETENTION

Lisa Amick	James Martinez	Megan W. Taylor
University of Kentucky	CSU Channel Islands	Sonoma State University
lisa.amick@uky.edu	james.martinez@csuci.edu	megan.taylor@sonoma.edu

Significance/Purpose of Study

In partnership with the Mathematics Teacher Education Partnership (MTE-P), this study's main goal is to gather preliminary data on the nature and quality of professional support for early career teachers over time. Addressing the math teaching crisis meaningfully will require building a more cohesive system of teacher preparation, support, and development (Mehta, Theisen-Homer, Braslow, & Lopatin 2015).These data are part of the work of the *Secondary Teacher Retention and Induction in Diverse Educational Settings* (STRIDES) Research Action Cluster (RAC) of the MTE-P, toward efforts to increase the number of years that early career secondary mathematics teachers remain in the field and ultimately, increase their effectiveness at facilitating student learning.

Methodology/ Survey Details

The research question guiding this work is: *What is the perceived scope, nature and impact of professional support for early career math teachers, and how does this (a) change as teachers progress in their teaching career and (b) relate to how likely it is a teacher will remain teaching?*

The current data collection tool is a 20-item survey asking participants – secondary mathematics teachers in their first, second, or third year of teaching – to reflect on the degree to which the professional learning activities and communities they participate in (e.g., working with a mentor, attending a professional conference, being a Noyce Scholar) increases their enthusiasm for teaching mathematics and influences their ability to facilitate student learning. Additionally, participants are asked to describe the role of administrators, universities, and school structures (e.g., teaching load) on these self-reports, and their satisfaction with teaching and likelihood to continue teaching.

In order to better understand the degree to which early-career mathematics teachers are being supported by: 1) professional development, 2) professional learning communities and 3) administrators, the MTE-P STRIDES survey allows participants to specify activities that have helped them grow professionally, and the degree to which these activities were worthwhile to them. Additionally, since the survey is longitudinal, responses can be measured over time, allowing the researchers to understand how these teachers are supported throughout their early service (pre-service, 1st, 2nd, or 3rd) years. The survey ends with an estimation of: 1) their overall level of satisfaction in their teaching, 2) whether they would choose the profession again knowing what they have learned so far, and 3) how long they plan to remain in the teaching profession.

Possible Implementations of the Findings

The STRIDES RAC goal is to assure that, by July 1, 2022 at least 85% of the program's early-service teachers employed in partner districts begin a third year of employment as math educators.

We position the learning of mathematics as participation within a community, specifically, a mathematical system. In order to learn, one needs *access* to the community, in other words, they need the resources (tangible and otherwise) and practices that enable people to participate in ways that are viewed by other members in the mathematical systems as competent. *Agency*, for those within the community, is the ability to use such resources and practices both within and on the mathematical system. Finally, those co-invested in negotiating what equity means within the community are *allies*. These are the mathematics teachers, students, community members, mathematics teacher educators, administrators, etc. who help, support, or act in solidarity toward what has been negotiated as an equitable mathematical system. We seek to negotiate and work toward an equitable mathematics system by designing, facilitating, and studying professional development based around the principles of access, agency and allies. Within this poster we will illustrate the design around five strands: (a) rich mathematical (Horn, 2012) tasks and social justice (Gutstein, 2003) mathematical tasks; (b) discourse practices (Herbel-Eisenmann, Steele, & Cirillo, 2013), (c) cultural connections (Civil, 2007; Aguirre et al., 2013), (d) action research (Zeichner & Noffke, 2001), and (e) privilege and oppression (McIntosh, 1989). We will present our planned progression of these five strands across a two week teacher institute and describe activities designed to connect the strands to each other and to *access*, *agency*, and *allies*.

SUPPORTING CULTURALLY RESPONSIVE TEACHING: WHEN MEETING TEACHERS WHERE THEY ARE MAY PERPETUATE THE STATUS QUO

Keywords: Equity and Diversity, Teacher Education, Inservice/Professional Development

An enduring challenge in mathematics education is supporting teachers in meeting the needs of diverse students. One promising practice to meet this challenge is culturally relevant pedagogy (Ladson- Billings, 1995). With this in mind, we designed a course to support secondary mathematics teachers in building their knowledge to more effectively teach diverse students.

An issue we confronted from the inception of the course was how to bring the ideas of culturally relevant pedagogy into our particular context. We characterize our context by the large presence of Whiteness (of teachers and administrators) accompanied by the heterogeneous nature of the student population. In this poster, we explore our reflections on one instructional dilemma: how to include in the course a focus on critical consciousness (e.g., discussions of power and privilege) while also addressing a central tenet of culturally relevant pedagogy to meet students (in this case, teachers) where they are so as to engage them in learning. This dilemma troubles us because a tension seemed to exist between two recommended pedagogical strategies for culturally responsive teaching: meeting our teachers where they are and explicitly grappling with teachers on issues of power and privilege.

Following the work of Toll, Nierstheimer, Lenski & Kolloff (2004), we take a narrative research approach. First, we each wrote a response to the prompt "Can you appropriately/ authentically port culturally responsive pedagogy to our context?" as a way to identify some of the dilemmas we faced as mathematics teacher educators in this particular context. These initial narratives became the foundation of our research. Next, each of us read the three narratives and wrote a response to each other's stories (one response per author). Our data sources, then, included our initial stories and our responses to those stories. Data analysis consisted of open coding of the stories (Miles & Huberman, 1994) for recurring themes.

Our poster will share verbatim text from our stories that describe how we perceived what it meant to meet teachers where they are and whether or not this resulted in teachers developing an understanding of power and privilege. It will also highlight key questions that remain, such as questions about empathy for and empowerment of teachers, the potential for indoctrination and the use of power, and the role of our Whiteness in this project.

Like Toll et al, "we seesaw between exerting our power to shape teachers and withholding our power to make space for teachers' own exertion of power, and the result is our confusion and guilt" (p. 173). Our dilemma addresses important, unsolved issues in how to design and implement professional development for secondary mathematics teachers, in contexts such as ours, which result in more equitable mathematics education.

EXPLORING CONDITIONS OF VIDEO-BASED PROFESSIONAL DEVELOPMENT: TEACHERS' CONVERSATIONS ABOUT AND REFLECTIONS ON INSTRUCTION

Mary Beisiegel	Rebecca Mitchell
Oregon State University	Pine Manor College
beisiegm@oregonstate.edu	mitchell@pmc.edu
Johanna Barmore	Samantha Booth
Harvard Graduate School of Education	Harvard Graduate School of Education
jmb349@mail.harvard.edu	samantha_booth@gse.harvard.edu

The use of video clips of mathematics instruction for professional development purposes continues to grow. While exploring the research literature on video-based professional development (VB-PD), we mainly found studies in which groups of teachers experienced either facilitator- *or* teacher-directed sessions, and studies that used video clips from teacher participants *or* from unknown teachers. We found only one study that compared the type of facilitation (van Es & Sherin, 2006) and two studies comparing the type of video (Seidel, Sturmer, Blomberg, Kobarg, & Schwindt, 2011; Zhang, Lundeberg, Koehler & Eberhardt, 2011). Due to these findings, we aimed to answer the question: what is the optimal type of facilitation and the best type of video for mathematics VB-PD?

We designed a VB-PD program that would cross the conditions to create four types of professional development: (a) facilitator-led, stock-video, (b) facilitator-led, own-video, (c) teacher-led, stock video, and (4) teacher-led, own video. Twelve groups of teachers were assigned to these types of VB-PD and received the same training to use the *Mathematical Quality of Instruction* (MQI) instrument as a lens for watching videos. The MQI was also used to ensure that teachers had a common language for discussing mathematics instruction. Teachers then had ten professional development sessions in which they viewed, scored, and discussed video clips. In facilitator-led groups, facilitators directed teachers to focus on evidence from the video clip and use language from the MQI. In teacher-led groups, teachers were asked to lead the conversation about the clips. All groups viewed the same stock video clips for four weeks, then teachers in the own-video groups shared clips from their classrooms.

To answer our research questions, we audio recorded the groups' conversations, collected teachers' reflections on their own lessons, and developed coding schemes for the two sets of data. Based on our analysis, we found no significant difference in the quality of conversations in the comparison of facilitator- and teacher-led groups. In the comparison of own- versus stock-video conversations, we found teachers in the own-video groups more likely to come to consensus about MQI scores on their peers' clips, with more willingness to agree-to-disagree about the clips in the stock-video groups. With regard to their reflections, teachers in the teacher-led, own video groups were more likely to utilize the MQI when reflecting on their teaching.

THE IMPACT OF PROFESSIONAL DEVELOPMENT ON HIGH SCHOOL ALGEBRA TEACHERS' KNOWLEDGE AND PRACTICES

Babette M. Benken	Anne Cawley
California State University, Long Beach	University of Michigan, Ann Arbor
babette.benken@csulb.edu	acawley@umich.edu

Keywords: Teacher Knowledge, Teacher Education-Inservice/Professional Development

Algebra is a gatekeeper to advanced study in mathematics, yet many students do not successfully complete algebra and achievement gaps are large. A grant-supported professional development (PD) program worked to increase high school students' algebra achievement in a large, urban district (CA Dept. of Education, #10-703). The district, UC, is large (~80,000 students) and only 13% of students were considered proficient in algebra in 2009. In 2010, at least 24% of the algebra teachers were teaching outside their credentialed areas. The PD (3 years, ~250 hours) included: (a) intensive, week-long Summer Institutes (SI), (b) on-site monthly workshops, and (c) within classroom on-going coaching and support. Professional Learning Communities were developed to support teachers' learning and on-going communication and collaboration. The PD intentionally provided experiences that would assist teachers in learning new ways of thinking about mathematical content and the teaching of that content (Zwiep & Benken, 2013), specifically as it related to the new algebra standards required by the state (CCSS-M). Participants included 42 teachers at 6 UC high schools separated into two cohorts (experimental group, EG=26 teachers; control group, CG=16 teachers, ~40% of PD).

What impact did the PD have on teachers' algebra content knowledge and pedagogical practices? Analysis of survey content questions showed an overall increase by both groups ($p < 0.05$). Teachers in the EG made larger gains than teachers in the CG; these gains were statistically significant in years 2 and 3 ($p < 0.05$). Growth was most notable within strands addressing function content and on generated items based on SIs. Participants indicated that PD experiences allowed them to both enhance their understandings of relevant algebraic topics (e.g., solving equations) and improve their ability to communicate these conceptions. Following each SI, participants enhanced their capacity to problem solve both individually and in small groups, including developing multiple solutions/ways to conceptualize a given problem.

Analysis of practice questions on surveys, classroom observations, and PD evaluations support that participants in the EG statistically significantly developed their practice as follows: (1) increasing the use of different methods for students to perform mathematical tasks ($p=0.0321$), (2) integrating problems that have multiple approaches and answers ($p=0.0406$), (3) adapting content to differing learning and language levels ($p=0.0001$), and (4) facilitating more interaction within the classroom ($p=0.0091$). Thus, the EG showed significant gains in many areas; although the CG showed increases after their first 6 months in the PD, this growth was not yet statistically significant.

Results suggest that when teachers experience and are modeled strong long-term PD that is focused on integrating content-rich activities with pedagogical practices grounded on data and district need, they can expand their knowledge, which can then translate to changes in practice.

MIDDLE GRADE TEACHERS' PERCEPTIONS ON COMMON CORE CURRICULUMS: EFFECTS ON TEACHING AND STUDENT LEARNING

Brian Bowen
West Chester University
bbowen@wcupa.edu

The launch of the Common Core State Standards (CCSS) in 2009 has influenced many aspects of K-12 mathematics education in the United States including areas such as content, pedagogy, curriculum, and assessment. School districts have looked to support these changes in varied ways, including the adoption of curriculum materials whose content is intended to align with these newly formed standards. However, adoption of standards and use of appropriate curriculum materials is only one step in the successful implementation of educational reform. The fidelity of implementation of mathematics curriculum reforms is strongly dependent on the way the standards and accompanied materials are implemented and interpreted by the teacher in the classroom (e.g., Hill and Ball, 2004; Roehrig and Kruse, 2005).

The objective of this study was to contribute to the understanding of role and influence of the current CCSS focused curriculum materials on teacher instruction, specifically on the middle grades level. Our focus on this level was driven largely by the increasing emphasis to move traditional high school level content to younger grades, thus adding to the complexity of integrating curriculum reforms in the middle grades. In gathering our data a mixed-method approach was used, which included interviews (n=18) and surveys (n=36) that used a Likert Scale. Questions from the two instruments focused on the ways in which in-service teachers perceived the impact of their CCSS curriculum materials on their own teaching strategies, classroom structure, use of technology, and content focus. The study also looked at the ways in which middle grades mathematics teachers perceived the adoption of these programs impacting student learning in their classrooms.

The results of the study indicate that the majority of teachers supported the use of a unified form of mathematics standards. However, the teachers in the study suggested that the implementation of the CCSS curriculum materials and associated assessments have widened the achievement gap for students. Participants found they are highly dependent on the mathematics curriculum materials for their planning and instruction, and they do not have ample opportunity for creativity and differentiation. Participants also discussed that they found the rigor of the step-by-step instruction detrimental to the students because it did not allow them to master certain skills before moving on to different concepts. There were areas of praise for the adoption of the CCSS curriculum materials including higher level thinking and integrating multiple modes of learning. Implications for professional development emerged from the analysis.

cnt_tran@fullerton.edu	kahartmann@fullerton.edu	tcadwall@fullerton.edu

Keywords: Gender, Equity and Diversity, Teacher Beliefs

Supplemental Instruction (SI) programs, based on the model pioneered at the University of Missouri – Kansas City, have long been shown to be beneficial to student participants. In this model, peer leaders conduct informal seminars in which students review notes, work together to solve problems, and learn study skills. However, evidence that SI programs also benefit the peer leaders of the SI workshops has been largely anecdotal.

One recent quantitative study (Malm, Bryngfors, and Morner, 2012) was conducted in an engineering program at a Swedish university. This study found that the peer leaders of the SI program benefitted from the program with improved communication, interpersonal, and leadership skills, as well as improved self-confidence and a deeper understanding of course content.

Our study is a similar quantitative study, conducted at a large public university in southern California, and largely confirms the study by Malm, et al. (2012). However, we also examine the difference in responses based on gender and under-represented minority (URM) status. Our study consisted of ten Likert-scale items sent to 153 SI leaders, of which 88 responded. The vast majority of respondents led SI sessions in STEM disciplines. Table 1 shows demographic information that we used in our study.

Using the Mann-Whitney U-test, we found that men were significantly ($p < 0.05$) more likely than women to report that leading an SI session helped them to be more effective when communicating with professors and students. We also found that URM students were significantly ($p < 0.05$) more likely than non-URM students to report that leading an SI session has had a strong influence on their career choice, helped them to become more aware of campus resources, and to deal with student conflict.

Our results show that it is important to encourage female SI leaders, in particular, to take advantage of leading an SI workshop to develop their communication skills with professors and students, especially in STEM fields, where under-representation of women is a long-standing problem.

Table 1: Demographic Information

Female	Male	Declined to State
44	43	1
URM	Non-URM	Declined to State
26	50	12

USING THE INSTRUCTIONAL QUALITY ASSESSMENT OBSERVATION TOOL IN A PROFESSIONAL DEVELOPMENT CAPACITY WITH TEACHERS

Amber G. Candela
University of Missouri – St. Louis
candelaa@umsl.edu

Research on teachers' use of high cognitive demand tasks (HCDTs) has included providing professional development (PD) on HCDTs and whether or not the PD impacted teachers' use of HCDTs (e.g., Stein, Grover, & Henningsen, 1996). Boston (2012) developed an observation instrument used to rate teachers' implementation of HCDTs, the Instructional Quality Assessment (IQA). In a previous study I used the IQA to rate teachers' implementation of HCDTs and after completion, I wanted to know if using the IQA in a PD capacity would give mathematics teachers a better frame to plan and implement HCDTs. I recently conducted a yearlong PD with 11 participants with the following question framing the study: *Does PD using the IQA as a frame for planning and implementing, impact teachers' use of HCDTs from their perspective and the perspective of the researcher?*

The IQA consists of six rubrics and is based on the premise that in order for students to engage in rigorous mathematics, they must have access to the type of problems that will allow such engagement (Boston, 2012). The rubrics of the IQA are based on the task implementation framework developed by Stein and colleagues (1996). Boston created the rubrics to comprise of four dimensions critical to assessing students' opportunities to learn mathematics with understanding. These four dimensions include potential of the task, implementation of the task, student discussion following the task, and the academic rigor of the teachers' expectations. When using the IQA, at least two raters observe a lesson and rate each aspect of the lesson with the given rubric.

The participants included 10 teachers in grades 3-8 and the mathematics coach from a charter school in a large Midwestern city. There were two teachers from each grade level to provide each with a collaborative partner, and the mathematics coach so there could be continued support. The PD included two half-day sessions before the start of the school year, six 2.5-hour sessions during the school year, and a concluding session at the end of the PD. Each session was based on different topics from the IQA (e.g., potential of the task, student discussions, teacher questioning) and how those topics related to maintaining demand of HCDTs. Data collection included video recorded pre and post observations of each teacher using the IQA to rate the lessons, one audio recorded individual interview, video of each PD session, and recordings of the teachers watching and rating each other using the IQA and their reflections of that process. The poster will share initial data analysis on the teachers' perspectives of the PD and how the IQA impacted their use of HCDTs and the researchers' perspective of how the PD and IQA impacted their practice.

DEVELOPING MATHEMATICS TEACHER LEADERS THROUGH A PARTNERSHIP ENHANCEMENT PROJECT

Merryn Cole
University of Kentucky
merryn.cole@uky.edu

Jennifer Wilhelm
University of Kentucky
jennifer.wilhelm@uky.edu

Keywords: Teacher Education-Inservice/Professional Development, Algebra and Algebraic Thinking

We describe a school district (Wren) involved in a partnership enhancement project (PEP), where school districts received micro-investments for professional development (PD) programs designed to provide support for locally identified and developed mathematics and science education projects. Kirschenbaum (2001) found school partnerships with universities were most effective when there was effective leadership and stakeholder involvement at the school level. A traditional top-down approach often fails because teachers do not implement innovations in the way intended by designers (van Driel, Beijaard, & Verloop, 2001). This qualitative study examined PEP challenges, outcomes, and collaborations in Wren. Data collection consisted of project proposals, midpoint conference presentations, and final project reports. The data were "analyzed to identify the recurring patterns or common themes" (Merriam, 2002, p. 6). This study addresses the research questions: How did participating in a partnership enhancement project enable the development of mathematics teacher-leaders? What evidence exists for the likelihood of sustaining partnerships and teacher leaders?

Prior to participating in the PEP, less than 50% of Wren students met mathematics benchmark scores for their age group on standardized assessments. Wren set goals to identify and address gaps in curriculum and in teacher and student content understandings. They planned to include all algebra teachers (grades 6-12) and to partner with instructional coaches and higher education. Wren held district-wide PD in year one for secondary mathematics teachers. Thirty-nine teachers participated in PD focusing on formative assessment, instructional and intervention strategies, and progression of Algebra skills. In year two, 22 middle school mathematics teachers attended PD along with 5 high school algebra teachers who acted as mentor teachers. Mentor teachers attended PD alongside the middle school teachers, providing support and instruction.

The PEP allowed teachers to take an active role in the improvement of district-wide algebra education, participating in planning and implementing professional development. Some teachers emerged as leaders who became mentor teachers and helped to build relationships between schools in addition to providing support for middle school mathematics teachers. The PEP was originally designed as a one-year project. When given the opportunity for a second year, Wren focused on bringing in sixth grade teachers, as they realized early preparation for algebra success was needed. This commitment to continually identifying factors in student algebra success in addition to finding time and funding for teachers to meet and plan suggests that the partnerships and teacher-leaders developed through the PEP will continue.

TEACHER NOTICING OF STUDENT THINKING DURING VIDEO CLUB DISCUSSION OF A PROBLEM ABOUT PERPENDICULAR BISECTORS

Gloriana González	Lisa Skultety
Univ. of Illinois at Urbana-Champaign	Univ. of Illinois at Urbana-Champaign
ggonzlz@illinois.edu	dobson2@illinois.edu
Gabriela E. Vargas	Jason T. Deal
Univ. of Illinois at Urbana-Champaign	Univ. of Illinois at Urbana-Champaign
gvargas2@illinois.edu	jdeal2@illinois.edu

This study examines the effects of combining video clubs (Sherin & Han, 2004) and Lesson Study (Fernandez, 2002) to promote teacher noticing of students' prior knowledge in a professional development program funded by the National Science Foundation. Similar to the notion of noticing proposed by Jacobs, Lamb, and Philipp (2010), teacher noticing of students' prior knowledge requires teachers' attention to students' prior knowledge, interpretation of that prior knowledge, and anticipation of how to use that prior knowledge in instruction. The teachers planned and taught a problem-based lesson situated in the context of finding a fair location on a map to place a new building. We ask: *what notions of "fairness" do teachers notice during the video club discussions about student problem-solving strategies?* We investigate whether attention to students' problem solving strategies promoted a better understanding of the relationship between students' solutions and their prior knowledge.

We analyzed data from four video club sessions following the Toulmin model (1958). The lesson focused on the theorem: *If a point is on the perpendicular bisector of a segment, then it is equidistant from the endpoints of the segment*. The problem was situated within the context of finding three possible "fair" locations for building a sports complex between two schools. When planning the lesson, the participants had little discussion about connections between students' prior knowledge and their work on the problem.

During the video club, the participants noticed five notions of fairness. We labeled these notions of fairness as: (1) equidistant, (2) area of two intersecting circles, (3) symmetry, (4) close cluster, and (5) nearness. The first three notions of fairness are related to students' mathematical prior knowledge of equidistance, area, and symmetry. The other two notions of fairness are related to students' prior knowledge of the problem's context. There was a case where teachers did not notice a notion of fairness that we had hypothesized was evident in a video. The construct of noticing students' prior knowledge enables us to examine whether teachers pay attention to other sources of knowledge besides their mathematical knowledge.

The Instrument

The purpose of this study was to validate a Spanish version of the Secondary Mathematics Teachers TPACK survey developed by Zelkowski, Gleason, Cox, and Bismarck (2013). This new survey was named *Encuesta para Maestros de Matemática de Escuela Secundaria: Conocimiento Tecnológico, Pedagógico, Matemático (hereafter EMMES-CTPM).* The participants in the study were all Spanish speakers, Spanish being their mother tongue. For that reason there was a need for the original survey to be translated into Spanish. The survey needed to be validated given that participants in the study were (1) Spanish speakers, and (2) in-service teachers whereas Zelkowski et al. (2013) used preservice teachers as participants. The survey was administered in person to forty-nine secondary mathematics in-service teachers at the University of Puerto Rico at Mayaguez.

Findings

Although *a priori* information from Zelkowski et al. (2013) suggested there might be four factors (TK, CK, PK, and TPACK), the validated survey consists of three factors (TK, CK, and TPACK). The internal structure and the internal validity of the EMMES-CTPM survey was verified through an exploratory factor analysis using principal axial factoring (PAF) as the extraction method. Cronbach's alphas for the TK, CK, and TPACK constructs were .87, .91, and .95 respectively. Each factor has 5 or more strongly loading items (items loading is more than 0.50 each), and item communalities are within the recommended boundaries to be considered acceptable (between .40 and .70). The validated survey consisted of a total of 18 items, five within the TK construct, five within the CK construct, and eight within the TPACK construct.

The existence of a new instrument translated to the Spanish language and validated to be used with secondary in-service mathematics teachers provides researcher within the field with a new tool to measure teachers' self-perceptions of their TK, CK, and TPACK. Having a validated instrument offers researchers in countries where Spanish is the main language the opportunity to obtain reliable measures of teachers' self-perceptions of their TK, CK and TPACK since the items in the instrument are written in a language teachers can comprehend.

Acknowledgments

REFRAMING MATHEMATICAL UNDERPARTICIPATORS: WHAT TEACHERS NOTICE IN STUDENTS' SMALL GROUP INTERACTIONS

Maggie Hackett
University of Arizona
mhackett@email.arizona.edu

Keywords: Elementary School Education, Teacher Education – Inservice/Professional Development

Noticing is defined to consist of attending to significant events, reasoning about events using knowledge from one's context, and making decisions based on connections between events and broader principles of teaching and learning (van Es, 2011; van Es & Sherin, 2008). Noticing is considered a skill of the expert teacher (van Es, 2011), however it is a skill that might need further development (van Es & Sherin, 2008). Status and its effect on student learning is one such construct that teachers might need further development to notice. Cohen (1994) defined status as a social ranking where it is better to be ranked high. Students of low social or academic status can lack self-confidence and become underparticipators in the classroom. Teachers cannot notice status issues occurring until they recognize that status exists within their classroom culture. Once a teacher has acknowledged that status does exist, they can begin to analyze how it affects everybody's access to the mathematical learning.

I adapted van Es's (2011) framework on learning to notice, shifting the focus from student mathematical thinking to noticing students' participation in small group interactions. The framework was used to code the annotations of what eight elementary teachers noticed when they observed small group interactions, the strategies teachers used to analyze what they observed, and the level of detail at which teachers discussed their observations of small group interactions in a Complex Instruction structured setting. For this poster, I focus on one teacher's annotations of one 8-minute video clip of a group of students working on a mathematical task.

On a scale of one to four the level of *what* the teacher noticed in terms of students' participation in small group interactions rated fairly high, meaning the teacher was a focused noticer. In the course of the 8-minute video-clip, the teacher's fourteen annotations could be coded as a Level 3: Focused, meaning the teacher attended to particular students' mathematical participation, or a Level 4: Extended, meaning the teacher attended to the relationship between particular students' mathematical participation. The level of *how* the teacher noticed in terms of students' participation in small group interactions rated low. All but one of the teacher's annotations was coded as a Level 1: Baseline, or a Level 2: Mixed. The teacher formed general impressions or highlighted noteworthy events, provided primarily descriptive and evaluative comments with some interpretive comments, and provided little or no evidence to support analysis. Further time in a notice-focused setting might continue to develop the teacher's ability of *how* they notice, and provide an opportunity to suggest pedagogical strategies to disrupt the issues of status which interfere with all students' learning experiences.

DESIGNING AND DELIVERING A STANDARDS-BASED PROGRAM TO AUTHORIZE ELEMENTARY MATHEMATICS SPECIALISTS

Rachel A. Harrington
Western Oregon University
harringr@wou.edu

Cheryl Beaver
Western Oregon University
beaverc@wou.edu

Keywords: Teacher Education-Inservice/Professional Development, Elementary School Education, Instructional Activities and Practices

The purpose of this poster is to detail the development and implementation of an Elementary Mathematics Instructional Leader graduate program at Western Oregon University. In 2013, the Association of Mathematics Teacher Educators adopted the Standards for Elementary Mathematics Specialists (AMTE, 2013). Using the Standards as a framework, the State of Oregon authorized the development of the Elementary Mathematics Instructional Leader Specialization to be added to current teaching licenses. This specialization includes three components: three years of successful teaching at the elementary level, a passing score on the NES Multiple Subjects Examination, and demonstrated competency of the Standards for Elementary Mathematics Specialists (SEMS). The graduate program outlined in this study was the first approved program in the state and the first to recommend teachers for the specialization.

In November 2014, the university in this study was awarded a Oregon Department of Education grant to fund the development of up to 60 teachers through the program. The grant includes funds for graduate coursework, monthly webinars, and summer institutes. This poster will report the findings of the first two years of the program including program design, participant experiences, and initial assessment data.

Initial findings indicate some attrition, mostly due to the perceived difficulty of the mathematics coursework. Data indicate the students appreciate the structure of the program, support of the faculty, and the program activities that connect to their current teaching role in the schools. As leaders see their roles changing and growing, the project partners search for ways to advocate for and support the leaders after they finish the program.

THE IMPORTANCE OF A LEADER IN PROFESSIONAL LEARNING GROUPS

Jennifer Holm
University of Alberta
jdholm@ualberta.ca

Ann Kajander
Lakehead University
ann.kajander@lakeheadu.ca

The Ontario Ministry, for one, has called for the use of professional learning groups to support teachers in developing new and effective practices for teaching (Ontario Ministry of Education, 2007). Personal experience and past research (e.g. Kajander & Mason, 2007) have shown professional learning groups in mathematics can have a varied effect on the teachers in the groups. Other research has suggested that the importance of having a shared and supportive leadership (Hord & Sommers, 2008) in order for the groups to be productive and meaningful.

This research focuses on the results of a three-year, narrative case study of a mathematics professional learning group of upper elementary (grades 6 to 8) and early secondary (grades 9 and 10) in northwestern Ontario, Canada (Holm, 2014). Over the three years, field notes, meeting recordings, and interviews comprised the data collection for the study. The current report focuses on data related to one aspect of these observations, that of the role of the leader.

The teachers included in the professional learning group varied in their knowledge of mathematics, their beliefs about teaching, and their understanding of teaching mathematics. Within the group there was a strong dichotomy between the secondary teachers who believed that mathematics was about teaching better rules and procedures, and the elementary teachers who supported the need for discussions and explorations within mathematics. In a number of observed instances, various members of the group were vocal about leading the group in non-productive directions or back towards a focus on only teaching rules and procedures earlier. Different stimuli were observed to steer the group back to a position of growth. At times these were another member of the group, or even several members. At other times it was a piece of literature, visiting presenter, or other external source that was used as a focusing piece for the group. What appears important based on this case study is that the leader has a strong knowledge of appropriate mathematics and supports a belief in using reform-based strategies within mathematics teaching.

In the end, we found that the various instances of this fluid idea of the leader seemed important to allow the group studied here to move forward in making reform-oriented changes. We saw the leader (in its various forms) as continually expanding the reach of the group and encouraging the ongoing growth of the group. This focus allowed for the direction of the group to be on strategies that were expanding the knowledge of the teachers instead of maintaining the status quo.

TEACHERS' ACTIVE ENGAGEMENT IN SOCIAL MEDIA: ANALYZING THE QUALITY OF MATHEMATICAL PRACTICES WITHIN PINTEREST

Sihua Hu
Michigan State University
husihua@msu.edu

Kaitlin T. Torphy
Michigan State University
torphyka@msu.edu

Keywords: Teacher Knowledge, Technology, Teacher Education-Inservice/Professional Development

In a digital age, social media has become part of teachers' daily routines. In this paper, we focus on a photo-based personalized media platform that allows teachers to demonstrate their conceptualization of mathematics instruction through the act of pinning resources and ideas in visual forms.

Theoretical Framework

This work focuses on the potential of the written tasks that attract ECTs' attention, motivate them to conceptualize mathematics teaching, and construct knowledge of practices (Cochran-Smith & Lytle, 1999). The cognitive process levels the task requires of students are determined using one dimension of the Revised Bloom's Taxonomy (Anderson & Krathwohl, 2001) and its interpretation in the mathematics context. The six hierarchical cognitive process levels are 1) Remembering; 2) Understanding3) Applying; 4) Analyzing; 5) Evaluating; and 6) Creating.

Method

Using a sample of 19 Early Career Teachers (ECTs) in the 2014-2015 school year, identified through a larger study on planning and enactment of elementary mathematics, we use the above framework to code for the primary task embedded in ECTs' mathematical pins. For example, a pin features a poster with the Think Math activity that reads: "The answer is 9 penguins, what is the problem?" We coded this pin with a primary task *at Level 6: Creating*, because the task is about to ask students to *create* a word problem with the answer 9 penguins. It is an open-ended question, and students need to understand different operations and their meaning in order to create a meaningful word problem.

Results

Out of the 1,123 mathematical pins examined, 396 of them are content resources with a conglomerate of tasks, whose cognitive process cannot be determined because the primary nature of the task is not definite. For the remaining 727 pins with mutually exclusive mathematical tasks, the majority are at the level of *Level 2: Understanding* (n=315), followed by *Level 1: Remembering* (n=302). Also, ECTs within this sample present few mathematical pins requiring a higher cognitive process demand for their students.

Acknowledgments

EMERGING LEADERSHIP ACTIONS OF ELEMENTARY TEACHERS
IN AN URBAN MATHEMATICS EDUCATION GRADUATE PROGRAM

DeAnn Huinker
University of Wisconsin-Milwaukee
huinker@uwm.edu

Melissa Hedges
University of Wisconsin-Milwaukee
mhedges@uwm.edu

Educational improvement at the level of daily mathematics instruction necessitates leadership by teachers (Neumerski, 2013). This requires teachers to open up their own instruction to scrutiny, while navigating and building relationships and trust within school cultures (Lumpkin, Claxton, & Wilson, 2014). In addition, teachers must be seen as credible in regards to their mathematical knowledge for teaching at the intended grade levels (Manno & Firestone, 2008).

This study examined the effects of a three-year graduate program on the mathematics leadership actions that teachers pursued in their schools. Participants studied mathematical knowledge for teaching, examined equitable and high-leverage teaching practices, and developed coaching and facilitation skills. The research questions guiding this study were:

- What aspects of the program encouraged teachers to move beyond their own classroom instruction to support and influence the professional practice of others?
- What informal and formal opportunities did teachers recognize or generate to provide mathematics leadership at their school site?

We examined the evolution of 26 elementary and middle school teachers as they progressed through a graduate program in urban mathematics education. Periodically participants prepared written summaries and reflections of ways in which they provided leadership for mathematics within their schools and districts. Additional data sources included course assignments, online discussions, and verbal and email conversations. Qualitative data coding using constant comparison for both cross-case and within-case analyses surfaced several themes. Some of the major emerging themes among the emerging teacher leaders included the following:

- Teachers grew in their confidence as capable of providing leadership for peers.
- Teachers became initiators of leadership actions in prompting learning of colleagues.
- Powerful "sites" of leadership included informal (e.g., bulletin boards, lunch) and structured interactions (e.g., grade-level meetings, staff development, committees).
- Teachers lead on the content studied in the graduate program (e.g., equality, discourse, representations, unit fraction instruction, number talks, growth mindsets, role of mistakes).
- Several teachers were on a "mission" to improve the mathematics teaching and learning throughout their schools or across their school districts.

Keywords: Teacher Education-Inservice/Professional Development, Reasoning and Proof

Research demonstrates the way students are engaged in mathematics tasks determines what they learn from the experience (Stein, Smith, Henningsen, & Silver, 2000). Evidence points to an increase in achievement when students are asked to explain their thinking on complex problems (Boaler & Staples, 2008). Teachers must not only present mathematics tasks to students, but also engage them in productive interactions that include opportunities to explain their thinking and participate in discussions of their peers' thinking (Stein et al., 2000). Making Mathematical Reasoning Explicit (MMRE) is a five-year NSF MSP professional development (PD) project focused on helping teachers increase their students' instances of justifying. This study reports how one teacher's questions changed over time as she elicited student justifications.

As we examined the ways in which Pam (a pseudonym) engaged her students in justifying, we collected and analyzed research notes and video recordings focused on Pam's classroom interactions with her math students over the course of five years. We found there was a clear difference in her questioning strategies before and after she engaged in PD activities.

Pam showed an affinity for engaging students in sense making during mathematics classes prior to her involvement with MMRE. Her desire to have students explain their thinking was evident throughout her involvement with MMRE. However, early on, Pam posed questions like "what did you do?" that led to students stating or describing a procedure. Over time, the type of questions Pam asked students shifted focus, and she began to ask questions such as "why did you choose to solve the problem this way?" These types of questions align with assertions from Stein et al. (2000) that teachers can maintain a high level of cognitive engagement by a sustained press for justification, which was demonstrated in student responses in Pam's classes.

As we reflect on the experiences Pam was offered throughout the PD, it is apparent that the PD activities had an impact on her ability to engage students in high level thinking. She showed clear changes in her ability to engage students in explaining their mathematical reasoning over time. However, the fact that Pam demonstrated this evolution over the span of five years serves in stark contrast to the perhaps too frequently accepted notion that sustainable educational change can and should occur quickly. We urge teacher educators and others associated with implementing teacher change to be patient as they work with teachers to alter practice.

While teaching has been considered as highly complex, recent reform-oriented principles and standards (e.g. CCSSI, 2010; NCTM, 2000) suggest teaching should be student-centered or responsive to student thinking. This new teaching practice makes teaching more complicated, uncertain, and dependent on teachers' ability to improvise as they encounter and respond to students' novel ideas during teaching. Thus it is critical for teachers to learn how to plan in ways that lead to being more prepared for the uncertainty and improvisation that accompanies teaching (Heaton, 2000). This study investigates how elementary teachers become more intentional and reflective in their lesson planning in the context of content-focused coaching, called *Math Studio*. The Math Studio, one model of teacher professional development with a coach and other members of a school community including a principal and classroom teachers, consists of three phases in a cycle: (1) lesson planning; (2) lesson implementation; and (3) lesson reflection. There are three to five cycles, across a year. This is a kind of job-embedded professional development for in-service teachers that has been happening for the last 4 years in an urban school district in Nebraska. In this article, we focused on three elementary teachers who were studio teachers in the during the 2014 - 2015 school year. Audio-recordings of each teacher's planning sessions over the school year were transcribed and analyzed using quantified qualitative methods. The analytical framework was developed building on an instructional triangle (Cohen, Raudenbush, & Ball, 2002; Lampert, 2001) consisting of three aspects, *teaching*, *student thinking and learning,* and *mathematical content.* In order to capture the patterns of teachers' deeper understanding of each aspect and how they became more intentional, planful, and reflective revealed in teacher-coach interactions, different levels of depth (level 1 – level 4) corresponded to each code. The full analytical framework will be presented on our poster in more details.

Preliminary analysis of multiple planning sessions across a year illustrates different paths of teachers' learning. Patterns of discourse revealed various and different levels of depth, with all teachers' discourse moving from lower to higher levels. Findings describe how individual teachers make more sense of student mathematical thinking and learning, more intentionally use and create lesson materials, and attend more to their own teaching practice with connections to student learning, particularly in their lesson planning. Detailed diagrams of results and examples will be described on the poster. This research adds to our understanding of how teachers learn and of the process through which teachers have opportunities to advance their understanding on the details and substance of student mathematical thinking and to intentionally choose the lesson materials. Our work has implications for curriculum developers and designers of professional development how to best support teachers to become more responsive to student thinking.

rlarochelle89@gmail.com	snickerson@mail.sdsu.edu	Lisa.Lamb@sdsu.edu

Keywords: Teacher Education-Inservice/Professional Development, Algebra and Algebraic Thinking

Professional noticing of children's mathematical thinking (PNCMT) requires expertise consisting of three interrelated component-skills: (a) attending to the details of a child's strategy, (b) interpreting a child's understanding, and (c) deciding how to respond on the basis of this understanding (Jacobs, Lamb, & Philipp, 2010). Jacobs et al. described this expertise as a part of a teacher's in-the-moment response to a student's explanation, and thus is a fundamental component of instruction that builds on student thinking. Hence, investigating the nature and development of teachers' noticing of children's mathematical thinking is important.

Many studies on PNCMT focus on preservice teachers (e.g. Sanchez-Matamoros, Fernandez, & Llinarez, 2014). Few studies have investigated K-12 practicing teachers' PNCMT and even fewer have focused on secondary teachers. Notably, Jacobs et al. (2010) found in their cross-sectional study that practicing K-3 teachers tended to demonstrate robust evidence of deciding how to respond on the basis of children's mathematical thinking only after completing *four or more years* of professional development (PD) around children's mathematical thinking. For many K-3 teachers, two years of PD did not fully support their development of this expertise.

In our longitudinal study we investigated the noticing expertise of 16 secondary mathematics teachers who we are supporting in a 5-year PD to improve their practice and become leaders of their teaching communities. Due to the rigorous selection process for the PD, we claim these teachers all (a) exhibit effective teaching practices, and (b) have a positive stance toward learning. Activities from the PD have included interviewing students, analyzing students' written work, working on challenging mathematical tasks, and collaboratively planning lessons.

We collected data on teachers' noticing expertise twice: prior to the PD, and two years into the PD. We collected and analyzed data using similar prompts and coding procedures as Jacobs et al. (2010). Both times, teachers watched and then responded to noticing prompts about an eight-minute video of middle school students working on a generalizing patterns task. Our findings indicated that initially our participants were able to attend to key details of students' strategies. However, they shared little evidence of interpreting students' understandings or deciding how to respond on the basis of those understandings. In our poster we will share the degree to which this expertise changed over the first two years of the professional development.

Acknowledgments

The MQI is a research-based instrument developed by Learning Mathematics for Teaching Project and designed to assess the quality of mathematics instruction by evaluating several dimensions of instruction (Hill et al., 2008). In this study we used the dimensions of the MQI instrument as a lens to investigate the effects of PD program on elementary teachers' instructional practices in the case of four 4th grade elementary mathematics teachers. Specifically, we focused on answering the following research questions: (1) what changes do teachers demonstrate in terms of their teaching practice before and after the PD? and (2) how does the PD influence teachers' quality of mathematical teaching?

In this study, we used pre-and post- teaching videos as the main data sources along with materials used in workshops. At the beginning of PD, all four teachers were asked to video-record their mathematics lessons. These videos were used as the pre-teaching video. After a year-long PD, we asked teachers to plan a lesson and teach the lesson in their classroom, which happened almost the end of the PD. Teachers collaborated with a researcher to plan a math lesson and implement the lesson through the end of the PD. We used these videos as our post-teaching videos.

Two pairs of researchers who had completed a training to use the MQI instrument, analysed each teacher's 40 minute-teaching video after choosing an 8-minute video clip that is the densest with mathematical activity. After the initial analysis, the researchers reconciled their results, and then created a detailed summary about each teacher's teaching practice. Based on the summary of each teacher, we examined overall tendency of each major dimension from four teachers' teaching videos.

In the pre-teaching videos, the average of the four teachers' MQI scores was 36.25 but in the post-teaching videos, the average increased to 47.5. Every teacher showed the increase of MQI scores from 5 to 19. Teacher A demonstrated the most significant change and Teacher B showed a small amount of change. In terms of the five major dimensions, teachers showed the biggest improvement in the aspect of "richness of mathematics" and followed by "working with students and mathematics" Also, teachers demonstrated pretty small improvement in the aspect of "student participation in meaning-making and reasoning." Moreover, teachers showed the smallest change in "errors and imprecision" aspect because they tended to show high scores in both pre-and post-teaching videos.

The findings of this study shed light on the importance of PD programs integrating strategies that can be used to promote students' participation in meaning-making and reasoning. To do so effectively, it may require to establish socio-mathematical norms which include mathematical discourse, unpacking mathematical problems and evaluating different solution strategies.

Palabras clave: Educación Informal, Capacitación Docente / Desarrollo Profesional, Conocimiento del Profesor

Existen múltiples investigaciones que reportan aspectos del desarrollo profesional del profesor de matemáticas, su relevancia y resultados de diversas experiencias formativas (Even & Ball, 2009; Paquay, Altet, & Charlier, 2012; Wood, 2008), pero es reducida la información sobre la actividad de desarrollo profesional del profesor de matemáticas en escenarios informales. La colaboración entre personas y grupos de personas empleando Internet, se transforma no sólo porque los participantes se encuentran geográficamente en lugares y contextos distintos, sino porque dicha interacción le cambia su naturaleza; es multimodal, pues permite interactuar combinando múltiples formatos que la potencian (voz, texto, música, video, fotografía) (Borba, Clarkson, & Gadanidis, 2013). El trabajo previo con profesores de matemáticas en modalidad a distancia, nos ha llevado a la construcción de una red social *DocenMat*, en una plataforma en línea, la que ha permitido experimentar diferentes tipos de interacciones entre sus miembros: profesores de matemáticas de distintos niveles educativos, estudiantes de posgrado, formadores de profesores e investigadores de la Matemática Educativa, tanto en México como de América Latina. Es este espacio se pone al servicio de los profesores, buscando que éstos reconozcan en la Matemática Educativa el campo de saber de referencia del profesor de matemáticas, así como a una comunidad de pares que ejercen la profesión y promueve su desarrollo profesional, haciéndole accesibles herramientas que lo pueden ayudar para mejorar su práctica docente. Además encuentran a una comunidad que investiga y que produce conocimiento para el profesor. En *DocenMat* los profesores pueden interactuar de múltiples maneras, grupos de trabajo especializados, diálogos académicos en foros, actividades que le permiten reflexionar sistemáticamente su quehacer. Hasta ahora no se cuenta con un protocolo que evalúe efectos en el desempeño profesional de los profesores a partir de su participación en la Red, se producen cotidianamente en la red, evidencias de sus entradas y acciones en ella. Esto se convierte en material de análisis. Así mismo se mantienen contactos periódicos con varios profesores y grupos de trabajo que nos permiten conocer y valorar el impacto de su adhesión a DocenMat. Tenemos evidencias para afirmar que *DocenMat* (http://www.docenciaenmatematicas.ning.com/) constituye un espacio de desarrollo profesional informal -libre, comunitario, basado en intereses específicos de los participantes- y proveedor de conocimientos formales de un campo de saber.

Keywords: Informal Educational, Teacher Education-Inservice/Professional Development, Teacher Knowledge

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Multiple research studies have reported on aspects of professional development for mathematics teachers, as well as the importance and the results of different learning experiences (Even & Ball, 2009; Paquay, Altet, & Charlier, 2012; Wood, 2008), but there is little information about professional development with mathematics teachers in informal settings. With the internet, collaboration among people and groups of people changes not only because the participants are located in different geographical places and contexts, but because the nature of the interaction changes; it is multimodal, using a variety of formats that boost interaction (voice, text, music, video, photographs. (Borba, Clarkson, & Gadanidis, 2013). Previous work conducted with mathematics teachers in distance learning formats, has led us to create a social network in an online platform called *DocenMat,* which has allowed different types of interactions among the members including mathematics teachers of different educational levels, graduate students, teacher educators and researchers of mathematics education, from Mexico and Latin America. The aim of this online tool is to help teachers recognize the knowledge of mathematics teachers in the field of mathematics education, as well as to support a community of peers practicing the same profession, and to promote professional development by making tools accessible to help teachers in their daily teaching practice. The tool also provides a community that researches and produces knowledge for teachers. Through *DocenMat* teachers are able to interact in many ways, such as in specialized working group, academic discussion forums, and systemic reflection activities related to the work of teaching. So far there is not a protocol to assess the effects of participation in online professional networks on teacher performance, although evidence of participation and actions in online networks are produced daily. This material becomes data for analysis. This also allows maintaining regular contact with various teachers and working groups to understand and assess the impact of participation in DocenMat. We have evidence to establish that DocenMat (http://www.docenciaenmatematicas.ning.com/) is an informal professional development space - free, communal, based on specific interests of participants- and a provider of formal knowledge in specific fields.

MEASURING FIDELITY OF IMPLEMENTATION IN A LARGE-SCALE PROFESSIONAL DEVELOPMENT EFFICACY STUDY

Kathleen Melhuish

ros8@pdx.edu

Keywords: Teacher Education-Inservice/Professional Development

Fidelity of implementation is the essential link between professional development (PD) experiences and changes in outcomes. Yet, as a field we have few measures available to directly look at implementation. In this poster, we present our preliminary work measuring teachers' implementation of a research-based PD.

Background

We are currently conducting a large study evaluating the efficacy of a studio model professional development (Foreman, 2013) in a mid-sized urban school district working with 3rd-5th grade teachers. The PD focuses on a set of mathematical habits for students and teachers that promote high-level reasoning and productive discourse in mathematics classrooms. In order to measure teacher fidelity of implementation, we identified these habits along with cognitive demand (Stein & Smith, 1998) and connection to learning target as the *critical components* (O'Donnell, 2008) of the PD.

The Measures of Implementation

In order to measure implementation, we developed a classroom observation tool aligned with the critical components discussed in the previous section. We triangulated this measure with both PD facilitator ratings, and teacher self-reports. We piloted the tool in 22 teacher classrooms. We found that the observation tool implementation scores were consistent with facilitator ratings, but diverged from teacher self-reports.

We also looked at outside measures: Mathematical Quality of Instruction (MQI) (Hill, 2010) and student achievement on the Smarter Balanced assessment. We found that teachers who scored high on implementation observation tool had higher overall MQI scores and higher percentages of students passing the standardized assessment than medium and low implementers.

Discussion

In this poster session, we share a model for measuring fidelity of implementation. We explore the development of a tool targeting implementation, the triangulation with other measures, and the correspondence with outside variables. We hope to contribute a process that can be leveraged by other researchers evaluating the impact of PDs.

UNDERSTANDING THE WAYS GTAS APPROPRIATE AND TRANSFORM PROFESSIONAL DEVELOPMENT

Hayley Milbourne
San Diego State University
Haley.milbourne@gmail.com

Susan Nickerson
San Diego State University
snickerson@mail.sdsu.edu

Keywords: Teacher Education-Inservice/Professional Development, Post-Secondary Education

Students' experiences in Calculus I are a main contributing factor to students' decisions to leave the STEM (Science, Technology, Engineering, and Mathematics) disciplines (Seymour & Hewitt, 1997). One way departments have been working to address this is to offer professional development to the Graduate Teaching Assistants (GTAs) and to reorganize the structure of the GTA program. Research has been done on the varieties of professional development available for GTAs across the nation (e.g., Belnap & Allred, 2009), as well as on particular structures at specific universities (e.g. Burr, 2016). However, little research has been done on how the GTAs are appropriating and transforming the professional development activities.

In our study, the GTA program around Calculus I and II has been restructured into a lead TA format. In this, there is a GTA designated as the lead who observes the other GTAs and provides feedback on their teaching. Furthermore, the lead TA becomes the main point of contact for the other GTAs; they assist the coordinators of the courses in setting up weekly meetings. Additionally, the GTAs at this university participate in formal professional development (PD) with mathematics education faculty. Hence, GTAs engage with various forms of professional development: weekly meetings with the coordinator, supervision of the lead TA, and formal PD.

Since there are goals in the minds of the professional development leaders for the teaching done by the GTAs, we are interested in how exactly GTAs are appropriating the professional development in which they are engaged. Specifically, how do the GTAs appropriate the professional development as they participate in the meetings and how are they transforming it to support their own needs? Additionally, what role does the lead TA play in publicizing and the conventionalization of the professional development activities?

We are collecting and analyzing data for Calculus I TAs from the weekly meetings with the coordinator, their classrooms, the professional development sessions, and the debriefings conducted by the lead TA. Through the use of a framework known as the Vygotsky Space, we will be looking for ways in which the professional development topics are appropriated and transformed by the GTAs over time. The Vygotsky Space framework is used to describe the ways the individual appropriates ideas from the social plane into their individual plane, transform these ideas, and then makes the ideas public again to the social plane (Harré, 1983). In our poster, we will discuss the initial findings from our study using the Vygotsky Space framework.

Keywords: Curriculum, Teacher Education-Inservice/Professional Development, Teacher Beliefs

There is evidence that one way to improve the quality of mathematical instruction is to improve the curriculum decisions of teachers at varying scales, such as how to respond to a student's question during a lesson or the selection and sequence of tasks. Studies of how teachers read and plan with curriculum materials highlight the need for useful conceptual tools for making sense of the content of mathematics curriculum (e.g., Remillard, 1999). Teachers need multiple ways to analyze their curriculum beyond just attention to individual tasks and directions. One way to conceptualize how mathematical ideas unfold in a classroom is to interpret a math lesson as a story (Dietiker, 2015). Similar to a literary story, a *mathematical story* is the ordered sequence of connected mathematical events connecting a beginning with its end. Examining curriculum through the lens of the mathematical story framework enables teachers to see how the posing and resolution of mathematics tasks and mathematical questions over time could shape the experience of the learner.

As part of a three-day professional development in Summer 2015, teachers learned about the mathematical story framework and how it could be used to interpret their curriculum. We collected statements during the professional development and during the following year that captured how they were and were not using the story framework to frame their thinking around curriculum. These statements were analyzed for patterns that reveal how teachers make sense of the story framework and how it informs their practice. In particular, this poster reports our findings regarding how the narrative elements of this framework supported these teachers in thinking about the development of mathematical ideas and curricular goals. In addition, the poster presents examples of mathematical stories the teachers created. Our findings indicate that this framework supports the curricular insight of teachers into how even minor curriculum adaptations can potentially enhance student learning and engagement. Themes of teachers as authors of mathematical stories and the importance of sequence emerged. Several teachers also connected student motivation with mathematical story. One teacher noted that when the mathematical story can grip a student's attention, it "gives [the student] a reason to do the math."

PROGRAMMING EXPERIENCES IN AN ALGEBRA CONTEXT: TEACHERS CROSSING BORDERS BETWEEN MATHEMATICS AND COMPUTING

Arnulfo Pérez	Anthony Myers	Julie Maynard
The Ohio State University	The Ohio State University	The Ohio State University
perez.378@osu.edu	myers.1105@osu.edu	maynard.238@osu.edu

How do we engage a broader swath of U.S. students in STEM and computer science fields, especially for minorities and low-income students who have traditionally been underrepresented in STEM and computer science? This study is part of an NSF-funded STEM+Computing project to pilot a secondary algebra unit that integrates project-based learning, engineering, and computer science into an exploration of linear functions. The study examines the impact of a strategic professional development on algebra teachers' pedagogical content knowledge of functions, competency in basic computer modeling and programming, and engagement in computational thinking.

The professional development piloted in the study involves computational concepts, computational practices, and computational perspectives. The study's approach reflects the benefits of context-based experiences with mathematics (Heid, 1995) and incorporates project-based learning (PBL) as well as the *Guided Inquiry and Modeling Instructional Framework* (EIMA) proposed by Schwarz and Gwekwerere (2006).

The study: 1) employs design-based research methods that deliberately intertwine the design of innovative learning environments and the development of a theory of learning (The Design Based Research Collective, 2003); and 2) uses progressive refinement to revise both the learning environment and the theory of learning through cycles of design, implementation, analysis, and revision (Cobb, 2001). At the core of this process is a 10-day professional development designed to engage teachers as learners through an engineering-focused exploration of linear functions in a project-based unit utilizing computer modeling, programming, and problem-solving.

A brief intake survey will identify teachers' current level of programming knowledge and ability using a spectrum that runs from novice to advanced beginner, to competent, proficient, and expert. By complementing core exercises with collaborative problem-solving and mini-lessons that highlight characteristics of expert practice, the training aims to move teachers to the stage of advanced beginner or competent programmer. Tables will highlight findings from teachers' pre- and post-tests. Numerical data will be complemented by brief analysis of short video clips to illustrate changing engagement with computational thinking and programming approaches to teaching functions.

ACCEPTED STUDENTS' ANSWERS TO HIGHER ORDER QUESTIONS AND CONCEPTUAL UNDERSTANDING

Gorjana Popovic	Susie Morrissey
Illinois Institute of Technology	Illinois Institute of Technology
popogor@iit.edu	gmorriss@hawk.iit.edu

Keywords: Teacher Education-Inservice/Professional Development, Classroom Discourse

Principles to Actions include Posing Purposeful Questions as one of the Mathematics Teaching Practices, allowing teachers "to assess and advance students' reasoning and sense making about mathematical ideas and relationships" (NCTM, 2014, p. 10). However, as Walsh and Sattes (2005) point out, teachers, when faced with incorrect or incomplete answers, rarely use prompts and questioning to guide students' reasoning to help them give correct answers.

Over the past two years we have provided professional development (PD) to mathematics teachers from three all-boys charter high schools in an urban area (98% African-American, 84% low-income households.) PD focused on the concepts from their curricula and Mathematics Teaching Practices (NCTM, 2014). Teachers solved tasks that allowed multiple entry points and solution strategies, promoted reasoning and problem solving, shared with each other, used manipulatives, worked in cooperative groups, and reflected on their experience, as recommended by Desimone (2011). We then observed teachers and provided feedback that included specific examples from their instruction to point out how they could use questioning to extend student understanding beyond procedural mastery.

To analyze our observation notes, we used a framework described in Principles to Actions (NCTM, 2014) for four types of questions: *gathering questions* ask students to recall facts, definitions, and/or procedures; *probing questions* require students to explain, elaborate, or clarify their thinking and communicate the steps in solution approaches or the completion of a task; *making the mathematics visible* questions ask students to discuss mathematical structures and make connections among mathematical ideas and relationships; and *reflection* questions encourage students to reflect on their reasoning and actions, and provide valid arguments for their work. Similarly to Walsh and Sattes (2005), we noticed that, although the teachers asked questions perceived to require higher order thinking, teachers accepted student answers at a lower cognitive level, such as recalling facts, definitions, and/or procedures. Our poster presents three examples of how students' answers and/or explanations to higher order questions accepted by their teachers as appropriate could hinder student conceptual understanding of the content.

We concluded that experiences and support we provided thus far in our PD were not sufficient for teachers to realize that asking a higher level question is not enough – they must also demand an appropriate higher cognitive level response from their students in order to gauge their students' conceptual understanding. Future PD will address this disconnection.

OPPORTUNITES AND CHALLENGES AS TEACHERS PROBLEM-SOLVE

Priya V. Prasad	Cinthia Rodriguez	Emily P. Bonner

Keywords: Problem Solving, Teacher Education-Inservice/Professional Development, Teacher Knowledge

Current reform practices in mathematics hold problem solving processes at the core of teaching and learning. However, bridging the gap between intentions and implementation of problem solving methods in the classroom remains a challenge. Enhancing teachers' content and pedagogical knowledge through professional development (PD) opportunities is critical to on-going teacher excellence, as those experiences can provide teachers with valuable dialogue that develops personal mathematical understandings and restructures instructional beliefs and practices (Crespo & Featherstone, 2006). Providing teachers with rich problem solving experiences has the potential to "help teachers reflect on their identities as mathematics learners and to understand their role in the development of their students' mathematical identities" (McCulloch, Marshall, DeCuir-Gunby, & Caldwell, 2013, p.1).

The purpose of this study was to immerse middle-school teachers in the problem solving process and examine their experiences as learners and teachers. The analysis addresses the following questions: (1) What opportunities and challenges do teachers experience as problem solvers and (2) what are their attitudes and beliefs about problem solving and how do they develop, if at all? Researchers investigated fifteen middle-school teachers who participated in a grant-based summer PD program about problem solving. The study analyzed data collected from (1) teachers' reflections during the PD, (2) artifacts from the PD, (3) researchers' field notes taken during the PD, (4) the PD facilitators' reflections, (5) videos of teachers' model-lessons during the PD, and (6) observations from teachers' classrooms. Data was analyzed using a phenomenological approach as it aligned with the study's intention of examining a group's shared experience: middle-school teachers' interactions with problem solving.

This poster focuses on an analysis of teachers' reflections in the context of the other data sources. Findings show that teachers experienced a range of opportunities and challenges in their interaction with problem solving in the PD. Teachers' comments fell under two overarching themes: their experiences as problem solvers and their potential implementations of problem solving in their own classrooms. Teachers revealed a variety of orientations towards problem solving, many of which changed over the course of the PD and were heavily influenced by teachers' knowledge of and beliefs about their students. Even as teachers worked through problems themselves as learners (employing a "learner lens"), they did not abandon their "teaching lens," which revealed contrasting perspectives about implementing such problems in their classrooms.

Keywords: Teacher Education-Inservice/Professional Development, Elementary School Education

School-based collaborative inquiry groups are increasingly recommended as a key feature of teacher professional development as they allow teachers to enhance their expertise through the investigation of and reflection on their own practice. In this study we explored how teachers in grades 3-5 worked together in self-facilitated, school-based collaborative inquiry (CI) groups to develop the practice of noticing children's mathematical thinking (Jacobs, Lamb, & Philipp, 2010) of fractions. The teachers were participants in a larger study of professional development and were expected to complete a total of 12 CI sessions over three years. Prior to each session, teachers posed a fraction story problem to their class and collected students' written work to bring to the session for discussion. Each CI session involved two teachers, and their conversation was supported by an online protocol that prompted teachers to discuss what they noticed about individual students' strategies.

Data was collected from three groups engaged in their ninth CI session during their third year of professional development. The teachers agreed to audio record their discussion using their own devices, copy the written student work, and mail the recording and images to the off-site researchers. To explore their collaboration, we considered two aspects: the form and the content of these discussions. Form was analyzed using Mercer's *ways of talk* (Mercer, 2000). Content was analyzed in terms of teachers' noticing of children's mathematical thinking, which was defined as the interrelated skills of (a) attending to a child's strategy details, (b) interpreting what the child understands, and (c) deciding how to respond based on that understanding.

Building on Mercer's work, we identified two ways teachers exchanged ideas*: show-and-tell* and *back-and-forth*. Most often teachers used *show-and-tell,* that is one teacher presented what he or she noticed about a student's thinking while the partner teacher listened to and acknowledged the speaker. During these exchanges teachers mostly either attended to the details of the strategy or interpreted the understandings, seldom making connections between the two. In contrast, teachers sometimes used a *back-and-forth* exchange in which they both shared details of what they noticed by building on or challenging one another. We found that in these exchanges teachers more explicitly made connections among attending, interpreting, and deciding how to respond. This exploratory study suggests the importance of looking at not only the content but also the forms of interactions to support teachers' engagement in all three skills of noticing. Further study with a larger sample is needed to confirm and extend these findings.

DEVELOPING LEADERSHIP CAPACITY: THE IMPACT OF AN ELEMENTARY MATHEMATICS SPECIALISTS PROGRAM

Juliana Utley
Oklahoma State University
juliana.utley@okstate.edu

Stacy Reeder
University of Oklahoma
reeder@ou.edu

In response to a newly developed Elementary Mathematics Specialist (EMS) certification program in our state, we collaboratively developed six graduate courses to satisfy the EMS program and emphasized 1) mathematics content knowledge, 2) instructional and assessment strategies, and 3) leadership skills. There is a scarcity of evidence detailing the impact of this type of program on teachers and on their students and as such, the guiding research question for this study was: What is the impact of the EMS program on teachers' leadership capacity?

Desimone (2009) proposed a conceptual framework for exploring the impact of professional development on teachers and students. This model illustrates the interactive connections between "the *critical features* of professional development, teacher knowledge and beliefs, classroom practice, and student outcomes" (p. 184). EMS graduate coursework can be considered on-going targeted professional development. Program participants tend to apply what they are learning to their current classrooms and share those experiences during class time. This qualitative study involved 16 elementary teachers who completed pre-post short answer questions and semi-structured interviews that included questions focused on teachers' leadership activities and program aspects that had impacted them most. Initially, researchers independently analyzed data through an open-coding process. Once themes were determined, the data were analyzed again and coded in an effort to determine the impact of the program on teacher leadership capacity.

Results indicate several themes related to the impact of the EMS program on teachers' leadership: *increased empowerment*, *collaboration/networking*, *professional development*, and *increased content and pedagogical knowledge*. Several teachers indicated that they have an increased sense of *empowerment* as a teacher and their confidence in what they do and why they do it was impacted by their work in the EMS program. The importance of their collaboration and new teacher networks seemed to be prevalent in the teachers' beliefs about the impact of the program. Teachers pointed to their increased comfort level to share their newfound knowledge by conducting workshops and facilitating book studies. The teachers in this study overwhelmingly cited an increase in their content and pedagogical knowledge from their participation in the EMS program as a catalyst and support for their leadership activities.

"A growing body of research makes it clear poverty and ethnicity are not the primary causal variables related to student achievement … leadership, teaching and adult actions matter. Adult variables, including the professional practices of teachers and the decision leaders make can be more important than demographic variables" (Reeves, 2006, p. xxiii). The results of this study reveal that the experiences and coursework as part of the elementary mathematics specialist program have an impact on teachers' leadership skills, abilities, and activities.

PERFORMANCES ON "TEST OF LOGICAL THINKING" AND "COGNITIVE REFLECTION TEST": PILOT RESEARCH WITH MATHEMATICS TEACHERS

Josip Slisko Ignjatov	Adrián Corona Cruz	Honorina Ruiz Estrada
Univ. Autónoma de Puebla	Univ. Autónoma de Puebla	Univ. Autónoma de Puebla
josipslisko47@gmail.com	acorona@fcfm.buap.mx	hruizestrada@gmail.com

Keywords: Cognition, Metacognition, Teacher Knowledge

The Cognitive Reflection Test (CRT), designed by Frederick (2005), became a popular instrument for exploring the factors that influence decision taking and elementary economic behavior. The CRT consists of three well-known mathematical puzzles on which many people give erroneous answer, using "fast thinking" (Kahneman, 2011). It turns out that persons, who perform poorly on the CRT (no correct answer to any of three puzzles), also take erroneous economic and business decisions.

In this pilot research, 21 in-service Mexican mathematics teachers answered the CRT and the Test of Logical Thinking (TOLT). Spanish version of the CRT was formulated by López Puga (2012), while Acevedo and Oliva Martínez (1995) elaborated and validated the Spanish version of the TOLT. The TOLT has 10 items and measures, beside control of variables, four reasoning modes (proportional, probabilistic, correlational and combinatorial).

Research questions were: Are mathematics teachers better at solving mathematical puzzles than university students? Is there a relationship between the results on the TOLT and the CRT?

Average teachers' score on the CRT was *1.52*. Ten teachers (5 with no correct answer and 5 with 1 correct answer) were below, and 11 teachers (6 with 2 and 5 with 3 correct answers) were above that average score. Percentages of teachers with a particular score were: No correct answer (24%), 1 correct answer (24%), 2 correct answers (28%) and 3 correct answers (24%). Data for 3,428 university students, collected by Frederick (2005), are very similar. The average score is *1.24* and percentages of particular scores are: no correct answer (33%), 1 correct answer (28%), 2 correct answers (23%) and 3 correct answers (17%). So, mathematics teachers involved in this research are only slightly better than university students at solving well-known mathematical puzzles. This result calls for more presence of CRT-like puzzles in mathematics teaching

Teachers' average score on the TOLT was *8.38*. Eight teachers (scores 5, 6 and 7) were below and 13 teachers (scores 9 and 10) were above that average score.

Although the number of teachers was rather small, it seems that someone with good results on the TOLT is likely to have good results on the CRT, too. Namely, the teachers with 10 points on the TOLT got on average *2.11* points on the CRT, while those with 5, 6 and 7 points had average CRT result of only *1.25* points. Nevertheless, the fact that some teachers with 10 points on the TOLT get zero or one point on the CRT indicates that good performances on the CRT (3 correct answers) do not depend only on logical thinking, but on other cognitive variables, too.

Keywords: Teacher Education-Inservice/Professional Development, Instructional Activities and Practices, Learning Trajectories (or Progressions), Algebra and Algebraic Thinking

Using a coach-facilitated PD model, we used Lesson Study to focus on the teaching and learning of algebra in the transitions grades guided by these research questions: 1) How did the focus on the learning trajectories of algebra across the transition grades help teachers go beyond the borders of their grade level standards and their traditional instructional practices? 2) What were the affordances of using the coach-facilitated and school-based PD model?

Results from the analysis of teacher reflections, video analysis, and lesson study debriefs revealed that the design of the coach-facilitated professional development and Lesson Study offered opportunities for coaches and teachers to mutually develop in their content knowledge and pedagogy while deepening their understanding of students' learning progressions in algebraic thinking. School-based professional development and Lesson Study created a community of practice that provided opportunity for educators not only to co-design lessons but to bring together all their expertise and strength. This collective knowledge yielded more than the sum of their individual knowledge and provided opportunities for school teams to develop collective teaching agency. The coach facilitated PD provided teachers with the immediate trust in the work they were doing because they came with the school-based coach. Knowing that their coach endorsed the instructional practices and the problem-based approach validated our methods and gave them more impetus to put forth effort in their professional learning. Teachers with the various expertise were able to mutually offer and benefit from the vertical articulation and in essence provided a collaborative coaching environment. An added strength of a learning trajectories approach was that it emphasizes why each teacher, at each grade level along the way, had a "critical role to play in each student's mathematical development" (Confrey, 2012, p. 3). As we continue our work, we will continue to explore how coach-facilitated PD and Lesson Study can help sustain the PD efforts and make best practices "stick" with teachers.

Within schools, how teachers interact shape what and how they learn (Coburn, 2001; Spillane, 1999). Teacher professional communities happen both within and beyond school boundaries, with many exchanging resources or ideas, often informally, across virtual platforms including social media. These professional relationships may inform teachers' informal learning (Schugurensky, 2000) how one conceptualizes teaching, instruction, or their subject matter. This work examines teachers' conceptualization of mathematics instruction as evidenced by social media engagement.

Method
Pinterest, a widely used social media photo based platform, is a personalized virtual scrapbook of resources and interests. Using a sample of 19 Early Career Teachers (ECTs) in the 2014-2015 school year, identified through a larger study on planning and enactment of elementary mathematics, we identify and analyze teaching and mathematical pins. Relying on a process of retroduction (Ragin, 1994), existing frameworks for mathematics instruction, and mathematics education literature, we create a schema of mutually exclusive mathematical categories to represent the primary nature of ECTs' mathematical pins.

Results
Findings indicate ECTs vary in their use of Pinterest, pinning more content related to general teaching than mathematics. Among ECTs' mathematical pins, we find ECTs predominately pin resources related to visual mathematical representations, standard algorithm, and conglomerated content resources. Within Pinterest, ECTs most frequently conceptualize mathematics with less emphasis on problem solving or contextual mathematical tasks. This work contributes to an effort to understand the types of mathematical resources pinned and shared within a virtual network. Future work examines cognitive process rigor of mathematical tasks embedded in the pins.

Mathematics has been a gatekeeper especially for diverse students (Martin, Gholson & Leonard, 2010). The implications of an increasingly diverse school population calls for the development of culturally and linguistically responsive materials, including support materials for mathematics in Spanish. Teachers of mathematics in the United States have limited resources available to them in Spanish to support bridging mathematics content and practices for English Learners (Moschkovich, 2013). The CCSS-M requires deep conceptual understanding in order for students to be successful in their formal K-12 education. Students, whose home language is other than English, need support and opportunities to success in mathematics classrooms. According to Wright (2010), a practice that could support these students is to learn new conceptual ideas in one's native language and then in English. Also, literature indicates the need of rich contexts to support learning content reducing cognitive demands due to language (Khisty, 1995). Educational games/animations could provide context for mathematics learning.

Math Snacks has created computer-based materials in Spanish to support mathematics learning. These free products, created initially in English, have been implemented in schools showing positive impact in students' learning. Due to the growing number of Spanish speakers in the school system, Spanish materials were created. Twenty mathematics teachers (3rd -7th grade), who had Spanish speakers in their classrooms, were invited to participate in a professional development session to learn about these materials. After the session, teachers were required to utilize Spanish materials (one animation and one game) in their classrooms. Then, teachers completed a survey regarding their experiences during the implementation.

In this poster we will share teachers' perceptions of these materials in their classrooms. Content analysis methodologies were utilized. Six themes emerged from this analysis. We found that teachers perceived that the materials (1) were helpful in understanding the mathematics concepts, (2) supported collaboration and communication among students, (3) enhanced Spanish speaker students engagement, (4) supported language development, (5) provided a visual representation that enhanced understanding, and (6) were played at home with family members. Our poster will include quotes from teachers' responses and more about data analysis.

A significant problem in mathematics education is the separation between what researchers know about the learning and teaching of mathematics and the instructional practices used by teachers. We report on our efforts to tap existing grade level team (GLT) structures to engage teachers in developing topic-specific knowledge for teaching mathematics across multiple schools, blurring the lines between researcher and practitioner. We see the GLT as an underutilized resource; while GLTs are currently present at many schools, they often do not attend to problems of instructional practice (Vescio, Ross, & Adams, 2008), and even if knowledge is developed, GLTs are isolated and lack structures for sharing across schools. Our project provides structure in which teachers use technological tools to collaborate with peers to investigate common problems of instruction.

In the project, we examined the implementation of two prototype modules with 17 third grade teachers in four elementary schools. For each module, each teacher administered the same equal sharing task in her class. The student strategies for these tasks were recorded using a screencast application on tablet devices. Then each teacher selected two or three recordings to share with the GLT, using a secure website to post and annotate the selected recordings. At face-to-face meetings, facilitators led discussions of selected screencasts, and each school collectively selected one or two annotated screencasts to share with all teachers in the project.

The initial analysis of the data revealed that teachers within the same school showed substantial variation in what they noticed and inferred when examining the same student work. Student screencasts stimulated rich discussions about student thinking within GLTs, and over time teachers showed increased attention to the details of students' solution strategies. Perhaps more importantly, this process resulted in set of rich examples of student thinking tagged with teachers' insights about the important mathematical ideas that were revealed at particular points in each recording. These artifacts can be preserved, shared with other GLTs, and refined in future iterations of the modules. In this way, teachers are not positioned merely as consumers of knowledge; they actively refine and update it as they work through the modules. We see this project as a first step towards the creation of a robust set of learning experiences for GLTs as well as the development of a repository of artifacts of teaching that can be improved by practitioners over time (Morris & Hiebert, 2011).

HOW MIDDLE LEVEL INSERVICE MATHEMATICS AND SCIENCE TEACHERS VISUALIZE MOTION, SPACE, AND SCALE

Jennifer Wilhelm
University of Kentucky
jennifer.wilhlem@uky.edu

Merryn Cole
University of Kentucky
merryn.cole@uky.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Teacher Education-Inservice/Professional Development

This research focused on the alternative understandings that middle level teachers hold about spatial-scientific, lunar-related concepts. These alternative understandings were influenced by teachers' sense of scale and proportion, 3-Dimensional (3D) visualization skills, and mental rotation abilities. The term "alternative understandings" refers to the explanations learners construct that are different than the accepted scientific explanation (Danaia & McKinnon, 2008). The questions guiding this research were: (a) What spatial sense do middle level teachers possess with regard to mental rotation and visualization of 3D systems? (b) What alternative conceptions do middle level teachers hold concerning the scale and proportion of the Earth/Moon/Sun system and the cause of lunar phases? Results from investigating these questions can aid professional development educators in constructing the appropriate experiences and instruction to help teachers overcome their alternative beliefs and formulate accurate understandings of spatial-scientific concepts. Creating these instructional opportunities for teachers will strengthen their spatial-scientific identity and will help to prevent them from passing along their alternative conceptions to their current and future students.

This research study included 24 middle level mathematics and science teachers participating in a Professional Development (PD) workshop aimed to enhance teachers' spatial and content knowledge and to create a project-based instructional experience with an Earth-space unit for teachers as learners. For this study, we used pre-tests to determine teachers' pre-understandings of lunar-related concepts and spatial skills. Survey assessments included a Lunar Phases Concept Inventory (LPCI; Lindell & Olsen, 2002) and the Purdue Spatial Visualization-Rotation Test (PSVT-Rot) which assisted with diagnosing the level of teachers' mental rotation reasoning (Bodner & Guay, 1997).

Individual scores ranged from 20 – 95% correct on the overall LPCI and from 10 – 90% on the PSVT-Rot. Item analysis of LPCI results showed teachers displaying alternative conceptions concerning the cause of lunar phases. Alternative conceptions included a "blocking" notion, the Sun's shadow explanation, and the Earth's shadow explanation. One-third of the teachers showed a scientifically accurate explanation (phase due to the Moon's position relative to the Earth), 41.7% held the Earth's shadow explanation, 12.5% displayed the Sun's shadow explanation, and 12.5% chose an object-blocking notion. In terms of the LPCI spatial domains, teachers performed best on test items concerning periodicity (orbital, phases, etc.) with an average percent correct of 69.2%. The most difficult items for teachers were those items concerning cardinal direction with an average percent correct of 36.7%. Analysis of the LPCI test items displayed that not only did teachers not understand the cause of lunar phases, but they also had limited understanding of the apparent daily lunar motion (as a result of the Earth's spinning on its axis) where the Moon rises in the East and sets in the West.

THE INFLUENCE OF MINDSET ON AN ELEMENTARY TEACHER'S ENACTMENTS OF MATHEMATICS PROFESSIONAL DEVELOPMENT

James C. Willingham
James Madison University
willinjc@jmu.edu

Introduction and Research Question

An essential border exists in the translation of a teacher's professional development experiences into classroom practices. Although the influence of teachers' beliefs on their practices has been widely examined, there is little empirical research into the role of mindset as a mediator of classroom practice (Rattan, Good, & Dweck, 2012). Therefore, this study examined the research question: How do characteristics of the growth mindset influence an elementary mathematics teacher's enactments of her professional development experiences, if at all?

Theoretical Framework

Dweck and Leggett (1988) described a framework of implicit conceptions of the nature of ability that have come to be known as mindset. This research base and its connections to self-regulation theory (Burnette, Boyle, VanEpps, Pollack, & Finkel, 2013) formed the theoretical framework in which this study was founded. Additionally, contextual elements of the change environment posited in The Interconnected Model of Teacher Professional Growth (Clarke & Hollingsworth, 2002) offered a lens through which to consider the operationalization of mindset.

Methodology

To examine the role of mindset in professional development, I used a holistic, exploratory case study methodology (Yin, 2014) to examine the critical case of a teacher with strong characteristics of the growth mindset whose beliefs and practices regarding the teaching of mathematics were in transition. I performed a simple time series analysis (Yin, 2014) across four stages of data collection: participant selection, baseline classroom observations, a demonstration lesson, and the enactment of the demonstration lesson in the classroom.

Results

The preliminary results of this study indicated that a strong alignment exists between the tenets of self-regulation theory and operationalized characteristics of the growth mindset. Additionally, mindset appeared to act as a pathway for both enactment and reflection in the change networks predicted by the Interconnected Model of Teacher Professional Growth.

In this exploratory study we considered how one teacher's understanding of proportional reasoning related to his teaching. We used Epistemic Network Analysis to consider the teachers' knowledge organization and connections between knowledge resources as a way to make sense of his understanding. Then, we examined how his understanding was reflected in his teaching. From our analysis, we found key aspects of the teacher's proportional reasoning from two interviews related to his lesson. We concluded that this teacher's knowledge organization influenced his ability to teach lessons in coherent ways. This has implications for professional development.

Keywords: Teacher Knowledge, Rational Numbers, Mathematical Knowledge for Teaching

Purpose and Background

Research in mathematics education is beginning to show that the ways in which teachers understand mathematics matter (e.g., Baumert et al., 2010; Hill, Rowan, & Ball, 2005). How teachers understand their content is associated with what they are able to do when they teach (Ma, 1999; Silverman & Thompson, 2008; Thompson, Carlson & Silverman, 2007; Thompson, 2015; Wilson & Berne, 1999), and how that content knowledge is organized shapes their ability to teach coherently (Thompson et al., 2007). Drawing from cognitive psychology, we could frame the mathematics education findings as contributing to research on the development of expertise. Thus, in this paper, we cross the borders between cognitive psychology and mathematics education research. We also cross the borders between research on how teachers understand proportional reasoning and what that knowledge means to their practice.

We have chosen to focus on proportional reasoning because it is a salient domain of middle school mathematics and teachers are expected to support students in developing deep understanding in this domain. Proportional reasoning has become a prominent area, being treated as its own content domain in the Common Core State Standards for Mathematics (National Governors Association & Council of Chief State School Officers, 2010). Interestingly, despite the importance and its role as foundational knowledge for advanced topics in mathematics (Lamon, 2007; Lobato & Ellis, 2010), little is known about how teachers understand proportional reasoning (Lamon, 2007). The limited research suggests that, like students, teachers struggle with proportional reasoning (e.g., Akar, 2010; Harel & Behr, 1995; Orrill & Brown, 2012; Orrill & Kittleson, 2015; Post, Harel, Behr, & Lesh, 1988; Riley, 2010).

Teacher struggle may be related to the dominance of rote algorithms, such as cross multiplication, to solve proportion tasks instead of focusing on the multiplicative nature of proportional relationships (Berk, Taber, Gorowara & Poetzl, 2009; Lobato, Orrill, Druken, & Jacobson, 2011; Modestou & Gagatsis, 2010; Orrill & Burke, 2013). Studies have also suggested that teachers hold naïve conceptions about proportions (Canada, Gilbert, & Adolphson, 2008; Lobato et al., 2011). For example, Canada et al. (2008) found that only 28 pre-service teachers out of a sample of 75 were able to reasonably interpret a unit rate (e.g., amount per dollar) as useful for determining which package was a better buy when comparing two different size packages of ice cream. Teachers'

proportional reasoning should include the understanding that a ratio represents a multiplicative comparison and not an additive comparison (Lamon, 2007; Lobato & Ellis, 2010; Sowder, Philipp, Armstrong, & Schappelle, 1998). This is a crucial understanding, as teachers need to be able to discern whether students are using additive or multiplicative reasoning (Sowder et al., 1998).

In this exploratory study, we examined how one teacher's understanding of proportional reasoning is related to his enactment of a lesson associated with proportional reasoning.

Framework

Knowledge in Pieces and Expertise

We rely on the knowledge in pieces theory (KiP; diSessa, 2006) to make sense of teachers' understandings. KiP asserts that our understandings are organized as fine-grained knowledge resources that can be drawn upon in a variety of combinations for a given situation. Learning occurs through perturbations that promote the development of new resources and the refinement of existing ones. Learning also includes developing connections between knowledge resources so they can be more readily drawn upon on in a variety of situations. KiP offers a unique lens for exploring the development of expertise, which is dependent, in part, on the extent of the *coherency of knowledge* (Orrill & Burke, 2013). We see coherency as meaning multiple knowledge resources connected in robust ways allowing for *in situ* access. Coherence, combined with a robust set of knowledge resources, allows teachers to deal with complex situations in more efficient ways. This is consistent with cognitive psychology research on expertise that shows that experts have both more knowledge than novices in their area of expertise and that their knowledge is organized differently than that of novices (e.g., Bédard & Chi, 1992). We also see our idea of coherency among knowledge resources as being consistent with Ma's (1999) concept of profound understandings of fundamental mathematics. We hypothesize that as a teacher's knowledge becomes more coherent (i.e., more knowledge resources are inter-connected), the teacher will be more flexible in supporting student learning of mathematics.

Epistemic Network

Epistemic Network Analysis (ENA; Shaffer et al., 2009) provides an analytical lens for identifying the connections between resources that a participant uses. We use ENA to focus on the connections participants make between knowledge resources, which are predefined using a coding scheme. Analysis is binary—thus each utterance either does or does not exhibit the presence of each pre-specified knowledge resource. ENA visually shows the relationships between the knowledge resources present (See Figure 1 for an example of a representation of an ENA equiload graph) in that it draws lines between those resources that co-occurred in a given utterance. We have interpreted these connections as being a way of determining connections between the resources. In this way, ENA provides a new alternative for measuring complex thinking and problem solving (Shaffer et al., 2009).
Figure 1. Matt's ENA equiload graph.

Methods and Data Sources

Data were collected as part of a larger project focused on teachers' proportional reasoning. Matt (pseudonym) was a certified 7th grade teacher with seven years of teaching experience. His classroom was in a K-8 school in an urban district in the United States.

Data were collected from two interviews and one classroom lesson. One interview relied on a paper-based protocol with 23 think-aloud prompts. Matt completed the protocol using a LiveScribe pen that recorded his voice as well as his written work. The second interview was a 90-minute videotaped clinical interview that included 18 items. The interview tasks were intended to elicit different aspects of reasoning about proportional relationships. The context of many items was in the work of teachers, asking participants to make sense of reasoning or work created by others. Both interviews were transcribed verbatim. The third data source was a video recording of Matt's 7th grade class during a single 90-minute lesson. We used two cameras: one focused on the primary speaker(s) and one directed on written work, when students were working in multiple groups a camera followed the teacher to document all teacher-student interactions.

We analyzed Matt's response to each interview task using a predefined code set for proportional reasoning knowledge resources (Table 1 shows all knowledge resources present in Matt's interview). We then created an ENA equiload graph for Matt's responses to all interview prompts (see Figure 1). In an ENA equiload graph, knowledge resources serve as vertices and the lines indicate those knowledge resources that co-occurred in the same response (see Table 1). The line thickness indicates the relative frequency of each co-occurrence across the interviews.

We relied on the same coding scheme to identify knowledge resources present in the classroom lesson. For the lesson, we coded knowledge resources present in each turn of Matt's talk. We then relied on qualitative analysis to compare Matt's understanding as portrayed in the ENA equiload graph to his understanding presented in the enacted lesson. (Note that we were unable to conduct an ENA-based analysis of the single class session due to mathematical limitations of ENA.)

Table 1: Knowledge resources present in Matt's interviews

Code	Description
Covariance	Recognizes that as one quantity varies in a rational number the other quantity must covary to maintain a constant relationship.
Ratio as Measure	Identifies an abstractable quantity created from the combination of the two quantities (e.g., flavor or speed) or discusses the effect of changing one attribute in terms of its effect on the ratio.
Unit Rate	Uses the relationship between the two quantities to develop sharing-like relationships such as amount-per-one or amount-per-x.
Scaling Up/Down	Uses multiplication to scale both quantities to get from one ratio in an equivalence class to another.
Relative Thinking	Demonstrates multiplicative reasoning about the change in a quantity relative to itself or another quantity. This includes re-norming.
Proportional Situation	Recognizes that a situation involves proportional reasoning.
Distortion	Describes "that things need to not get distorted" in similarity contexts.
Rules	Shares a verbal or written rule (e.g., blue = red + 2) stated in a way that conveys a generalizable relationship.
Anticipates or Builds from Others' Thinking	Talks about or builds from the mathematical thinking of others.
Contextualizing	Introduces a context for a relationship or anticipates impact of a context for students' reasoning.
Problem solving with Representation	Uses representation to support reasoning about the problem.
Justify or Communicate with Rep.	Justify or clarify a position already developed using the representation.
Introduce New Representation	Introduces a representation not implied or requested by task.

Results

In our analysis we found key aspects of Matt's proportional reasoning from interviews related to his lesson. Because of space limitations, our findings focus on Matt's knowledge organization and the ways it was reflected in his teaching.

Matt's Knowledge Organization

Matt's ENA equiload graph (Figure 1) showed strong connections between several pairs of knowledge resources. Strong connections indicate that Matt used those resources together in addressing particular tasks. We assert that co-occurrences of knowledge resources serve as indicators that the knowledge is linked in some way for the participant. Thus, we infer that connected knowledge resources indicate ideas that are conceptually tied together for the participant.

An example emphasizing strong connections is from the paper-based interview, in which Matt was asked to determine which was the better buy: a 16 oz box of Bites that costs $3.36 or a 12 oz box of Bits that costs $2.64. To solve this, he introduced a ratio table as a new representation (Figure 2) and used it to find a common multiple (link between *Introduce New Representation - Scaling Up/Down)*. Then, Matt communicated the idea that using ratio tables helps in "keeping it balanced and proportioned" (*Introduce New Representation – Justify or Communicate with Representation)*. Further, Matt emphasized that a ratio table helps to show how the proportion is maintained

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

(*Introduce New Representation - Proportional Situation*). In his solution, we see the 1s used by Matt to add 3.36 twice to get to 10.08 in his ratio table as opposed to him using multiplicative reasoning to solve the problem.

Matt was not limited to his own ratio table reasoning. He offered that students might try to solve Bits and Bites with long division and suggested that scaling is more efficient for them (*Scaling Up/Down -Anticipates or Builds from Others' Thinking*). He also explained that this task could be solved using unit rate (*Unit Rate*) when he said: "I could've also got down to unit rate—how much per ounce." Matt had access to this knowledge resource, but chose not to use it often in solving tasks. He explicitly talked about how unit rate can be difficult for students to use because of division. We assert that this special attention to *Unit Rate* is consistent with Matt's ENA equiload graph, which shows *Unit Rate* only weakly linked to *Scaling Up/Down* for Matt. This suggests Matt considers *Unit Rate* as an approach for only specific tasks.

Figure 2. Matt's written work for the Bits and Bites problem.

Matt's Classroom

Matt's pattern of knowledge resource use was echoed in his teaching. Matt described the concept of proportion in his lesson the same way he had in his interview. He emphasized the importance of keeping the equivalence by *adding* the same amounts. This way of describing how to maintain a proportion suggested additive reasoning rather than multiplicative reasoning.

In Matt's lesson he posed a task similar to Bits and Bites. Students were asked to compare two deals on pencils. Matt set a clear objective "students will be able to determine the better deal using proportional reasoning and ratio table". This parallels the strong connection between *Introduce New Representation* and *Scaling Up/Down* consistent with his own problem-solving approach.

In the whole class discussion, Matt emphasized the use of ratio tables to solve the pencils problem by recognizing that the situation involved proportional reasoning. This was consistent with the approach we saw him take in Bits and Bites. However, Matt was able to make sense of students' different representations and solution strategies as well as how they communicated their solutions. For example, one student suggested another strategy using the common multiple of 120. Matt took a paper and pencil and tried it out himself by representing the pencil deals in ratio tables and scaling up both packs to 120 to solve the problem (this parallels his pattern of connecting *Introduce New Representation - Scaling Up/Down*). Matt also used students' work in his instruction, for example he used some students' work to discuss scaling using a ratio table versus long division (*Scaling Up/Down -Anticipates or Builds from Others' Thinking*).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 3. Student's work – using one ratio table to scale the 12-pack of pencils.

Consistent with his approach in the interviews, Matt did not rely on *Unit Rate* in his teaching. As students worked in small groups, they used ratio tables in different ways. Some built one ratio table (Figure 3) to scale only one pack of pencils and some used two ratio tables to scale both packs (Figure 4). And when students did attempt unit rate, Matt tried to steer them away. For instance, Matt approached one student who tried to use unit rate and asked if "there is a reason to get to one?" He then guided the student to think about getting to 60 instead. Further, when one group presented the solution using unit rate to the class (Figure 4), Matt said that finding unit rate is an efficient strategy "if the question asks you for the price per pencil". Matt seemed to prefer *Scaling Up/Down* using ratio tables in his teaching as well as in his problem solving. This was consistent with his interviews in which he mentioned that he worried about students relying on unit rate because it required strong division skills that his students often did not have.
Figure 4. Student's work – using ratio tables to scale both packs of pencils to 1.

Conclusions

The knowledge resources and connections Matt used to solve problems about proportions were consistent with the ways in which Matt used the same resources and connections to guide his lesson. This aligns with the assertion that a teacher's relative level of coherence will shape their ability to teach lessons in coherent ways (Thompson, et al., 2007). We note that Matt's views of *Unit Rate*, his

definition of proportion, and his reliance on ratio tables were factors that shaped his interaction with his students. Additionally, his use of additive language as opposed to multiplicative language when describing a proportion was used with his students and in his interviews. Matt understood unit rate and had taught his students unit rate; but he reinforced other approaches for problem solving in his classroom. One important take-away from this study is that despite showing evidence of having particular knowledge resources, Matt did not draw on them in his teaching. Thus, demonstrating particular measurable knowledge may not be a sufficient measure for teacher knowledge as they may have access to an array of knowledge that is not used in their classroom teaching. This raises questions about how best to measure or research teacher knowledge as it relates to opportunities for student learning.

Scholarly Significance

This study explores what it means for a teacher to have coherent knowledge. While many researchers assert that mathematics teachers need a deep understanding of the mathematics they teach (e.g. Ma, 1999; Thompson et al., 2007), little work has been done to understand what this means and what difference it makes to students' opportunities to learn. This study contributes to research on teacher understanding by stepping away from focusing on quantifying the amount of knowledge a teacher exhibits to instead focus on how the organization of that knowledge was used to drive the enactment of a single lesson. Studying how teachers understand and use the mathematics they teach has practical implications on the design of teacher preparation and professional development programs.

The teacher, in our study, demonstrated a variety of knowledge resources about proportional reasoning and strong connections between some of those resources. Based on our experience watching teachers implement proportional reasoning lessons, we hypothesize that not all teachers have the same kinds of connections between their own understanding and their teaching. We will be conducting additional analyses to determine whether the similarities between personal knowledge and enacted knowledge are maintained.

HOW TEACHERS IN CHINA AND U.S. RESPOND TO STUDENT ERRORS IN SOLVING QUADRATIC EQUATIONS

Qintong Hu	Ji-Won Son	Lynn Hodge
Columbia College	University at Buffalo, SUNY	The University of Tennessee
qintong.hu@gmail.com	jiwonson@buffalo.edu	lhodge4@utk.edu

To improve mathematics achievement, students' errors should be treated as a source to stimulate their understanding of the conceptual and procedural basis of their errors. The study investigated 20 Chinese and 20 U.S. high school teachers' interpretations and responses to a student's errors in solving a quadratic equation. The teachers' responses were analyzed quantitatively and qualitatively. Analysis results show that the Chinese teachers provided more negative evaluations toward students' errors and identified more students' errors than the U.S. teachers did. Responding to students' errors, the two groups of teachers highlighted conceptual explanations targeting students' mistakes. The U.S. teachers were more likely to provide general knowledge guidance while the Chinese teachers tended to go back to basic knowledge.

Keywords: Algebra and Algebraic Thinking, Teacher Knowledge, High School Education

Introduction

Algebra has long been regarded as a critical bridge to high school mathematics. National Council of Teachers of Mathematics (NCTM, 2000) highlighted the importance of algebra to all students. The content in school algebra mainly covers two major themes: equations and functions (NCTM, 2000; Drijvers, Goddijn, & Kindt, 2010). Quadratic equations take on an important role in the high school Algebra I curriculum. From straight lines to curves it is an essential transition that requires students' conceptual understanding and computational proficiency. Prior research reveals that many students are challenged with solving quadratic equations (Vaiyavutjamai, Ellerton, & Clements, 2005; Zaslavsky, 1997). For example, Didiş, Baş, and Erbaş (2011) found that 10th graders lacked conceptual understanding of the null factor law in solving quadratic equations. Additionally, when asked to solve a quadratic equation in the form $(x - a)(x - b) = 0$, many students who correctly found the solutions mistakenly held the concept that x in $(x - a)$ was equal to a, and simultaneously the x in $(x - b)$ was equal to b.

Helping students develop mathematical understanding, NCTM (2000) indicated that teachers should recognize and respond to students' errors appropriately. Students who figured out the misunderstandings under their mistakes can learn what they did not know and what they thought they knew. Rather than avoiding discussing students' errors, teachers are being called to use such errors as catalyst for stimulating reflection and exploration (Ashlock, 2006; Borasi, 1994). Taking good advantage of students' errors initiates the path of developing students' understanding of the conceptual and procedural basis of their errors.

The 2011 Trends in International Mathematics and Science Study (TIMSS) reported that both Chinese 4th graders and 8th graders outperformed their U.S. counterparts in mathematics remarkably (Provasnik et al., 2012). Teachers' knowledge has a long history of being identified as an essential factor that affects students' achievement (Ma, 1999; Hill, Rowan, & Ball, 2005). In this study, we investigated Chinese and U.S. high school algebra teachers' knowledge of interpreting and responding to students' errors in solving quadratic equations. The research questions that guided are: (1) How do Chinese and U.S. teachers interpret students' errors in solving quadratic equations?; (2) How do Chinese and U.S. teachers respond to students' errors in solving quadratic equations?; and (3) What are the similarities and differences between Chinese and U.S. teachers' knowledge of interpreting and responding to students' errors?

Theoretical Framework

Students' Conceptual Obstacles in Solving Quadratic Equations
The methods of solving quadratic equations are introduced through factorization, the quadratic formula, and completing the square by using symbolic algorithms. Of these techniques, Didiş et al. (2011) argued that students prefer factorization since it is much faster than the other two methods. This result aligns with that from Eraslan's (2005) study. However, while applying factorization to solve quadratic equations students tended to follow the procedural rules without paying attention to the structure and conceptual meaning (Sönnerhed, 2009). As a result, they tended to make some common errors. Didiş and his colleagues (2011) summarized that when attempting to solve quadratic equations presented in a factored form, students tended to expand the parentheses to get the standard form and then re-factorize. Also, students lacked conceptual understandings of the zero-product property that they used to miss the root $x = 0$ by doing simplification. Additionally, students mistakenly tried to transfer the zero-product property into a new context, for example, to solve $(x - a)(x + b) = 12$, they simply let $x - a = 3$ and $x + b = 4$. Moreover, students used "and" rather than "or" to combine two solutions of a quadratic equation. This finding aligns with those from Ellerton and Clements (2011) that 79% of the 328 preservice middle school teachers in the study did not know that $x^2 + 6 = 0$ has no real-number solutions and many of them thought two x's in $(x - 2)(x + 3) = 0$ hold different values.

Analytical Framework
Tables 1 and 2 present the analytical frameworks utilized in the study. Peng and Luo (2009) developed a framework to analyze teachers' knowledge of students' mathematical errors (see Table 1). They identified four analytical categories for the dimension of phrases of error analysis, namely, identify, interpret, evaluate, and remediate. The levels within each dimension of teacher knowledge of students' mathematical errors are sequential and hierarchical, with progress from one level to the next, and the different levels of analysis support and complement one another by giving a holistic and structured picture of teacher knowledge of students' mathematical errors.

Table 1: Framework for Phrases of Error Analysis (Peng &Luo, 2009)

Dimension	Analytical categorization	Description
Phrases of error analysis	Identify	Knowing the existence of mathematical error
	Interpret	Interpreting the underlying rationality of mathematical error
	Evaluate	Evaluating students' levels of performance according to mathematical error
	Remediate	Presenting teaching strategy to eliminate mathematical error

Referring to the description, the phrase of remediate actually is responding to students' errors. Analyzing preservice teachers' responses to students' errors of proportional reasoning in similar rectangles, Son (2013) developed a framework to analyze teachers' responses to students' mistakes (See Table 2). According to Son (2013), conceptual knowledge is defined as the explicit or implicit understanding of the principles that govern a domain and the interrelations between pieces of knowledge in a domain. Procedural knowledge is defined as the action sequences for solving problems. Form of address signifies whether teachers deliver verbal or non-verbal information for students to hear and see (this kind of responses usually uses the very words "show" or "tell") or for students to do something and to answer questions (this kind of responses usually uses the very words "give" and "ask"). Act of communication barrier refers to the difficulties students and teachers have

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

in communicating about students' errors. In the over-generalization category, teachers tend to provide too general an intervention that doesn't directly address students' misunderstandings. By using a Plato-and-the-slave-boy approach, teachers assume that students actually know how to solve the problem correctly but simply have forgotten. Therefore, teachers plan to ask students questions in order to help them to recall the math facts and procedures to solve problems. Returning to the basics means simply leading students to return to underlying principle. This method is regarded as either introducing more problems for students or making students forget the original problem.

Table 2: Analytical Framework for PST's Responses to Students' Mistakes (Son, 2013)

Aspect	Categories
1 Mathematical/ instructional focus	Conceptual vs. procedural
2 Form of address	Show-tell vs. give-ask
3 Pedagogical action(s)	Re-explains, suggests cognitive conflict, probes student thinking, etc.
4 Degree of student error use	Active, intermediate, or rare
5 Act of communication barrier	Over-generalization, a Plato-and-the-slave-boy approach, or a return to the basics

Methods

Twenty Chinese teachers and twenty U.S. teachers who have taught Algebra I before or are currently teaching Algebra I participated in this study. While most of the U.S. teachers hold master degrees most of the Chinese teachers have bachelor degrees. The U.S. teachers took more college level math courses than the Chinese teachers did. The group of Chinese teachers are more experienced than the group of U.S. teachers. In terms of the time that students spent on learning Algebra, it seems that Chinese students do not take as many classes as U.S. students do, but Chinese students spend more than twice of the time that U.S. students spend in doing homework. All the participants are currently teaching at high schools that have characteristics typical of each nation's public schools with respect to the students' ethnic, economic, and cultural diversity.

Figure 1 shows the main task used for this study. This problem was developed by Ellerton and Clements (2011) to test teachers' knowledge of quadratic equations. The participants were asked to analyze and respond to Amy's errors. Their written responses were coded in terms of the analytical frameworks shown in Tables 1 and 2. While analyzing the responses, we expected new categories to come out, which would optimize the existing frameworks. We first coded the participants' evaluations of the student's performance on the math topic, then examined whether the participants discovered all the student's mistakes presented in the question scenario, and finally checked whether the participants identified any underlying mathematical concepts and principles that Amy lacked of.

The participants' responses in helping Amy to correct her errors were analyzed in terms of the five aspects as elaborated in Table 2. The conceptual versus procedural distinction was utilized first, followed by the identification of pedagogical actions. After addressing these global oriented characteristics of the teachers' responses, more detailed analysis was conducted with respect to teaching approaches: form of address, degree of student error use and communication barriers. Each participant's response might be assigned more than one code within each category since more than one teaching strategy might be applied.

Students were asked to solve $(x + 2)(2x + 5) = 0$, then to check their answer. One student,

Amy, wrote the following (line numbers have been added):

$(x + 2)(2x + 5) = 0$	Line 1
$\therefore 2x^2 + 5x + 4x + 10 = 0$	Line2
$\therefore 2x^2 + 9x + 10 = 0$	Line3
$\therefore (2x + 5)(x + 2) = 0$	Line 4
$\therefore (2x + 5) = 0 \text{ and } (x + 2) = 0$	Line 5
$\therefore 2x = -5 \text{ and } x = -2$	Line 6
$\therefore x = -\dfrac{5}{2} \text{ and } x = -2$	Line 7

Check: Put $x = -5/2$ in $(2x + 5)$, and put $x = -2$ in $(x + 2)$.

Thus, when $x = -5/2$ and $x = -2$, $(2x + 5)(x + 2)$ is equal to 0×0 which is equal to

0. Since 0 is on the right-hand side of the original equation, it follows that $x = -5/2$ and $x =$

-2 are the correct solutions.

Figure 1. Main task for the study.

Amy in Figure 1 did not have a clear understanding of the following four pieces of mathematical concepts and principles: (1) Rationale of the method of factorization; (2) Zero product property; (3) Difference between "and" and "or"; and (4) Meaning of solutions for quadratic equations. There were three mistakes from Amy's response.

- Mistake 1: Lines 2, 3, and 4 were unnecessary, since the left-side is already factored in Line 1.
- Mistake 2: In Lines 5 through 7, the word "or", and not "and", should have been used.
- Mistake 3: As for the checking process, each solution should have been substituted into both parentheses in the initial equation.

Results

Identify Students' Errors

Most of the Chinese and the U.S. teachers identified that Amy did some unproductive work. Around half of the Chinese and the U.S. teachers noticed that Amy mistakenly checked the solutions. While 80% of the Chinese teachers recognized Amy used "and" to combine the two solutions only 40% of the U.S. teachers identified it. So, the number of the Chinese teachers who found the second mistake was twice as many as that of the U.S. teachers. In addition, the Chinese teachers identified more of Amy's errors in solving the quadratic equation than the U.S. teachers did. Table 3 presents the distribution of US and Chinese teachers in identifying Amy's mistake.

Table 3: Identifications of Amy's Mistakes on Solving the Quadratic Equation

Categories	Chinese (n=20)	U.S. (n=20)
Mistake 1	14(70%)	14(70%)
Mistake 2	17(85%)	8(40%)
Mistake 3	12(60%)	11(55%)
No mistake	1(5%)	2(10%)
One mistake	3(15%)	6(30%)
Two mistakes	8(40%)	9(45%)
Three mistakes	8(40%)	3(15%)

Interpret Students' Errors

As it is shown in table 4, most of the Chinese and the U.S. teachers did not try to identify which mathematical knowledge that Amy lacked of. Among those teachers who interpreted the mathematical knowledge that Amy needed, the Chinese teachers emphasized the difference between "and" and "or" while the U.S. teachers focused on zero-product property.

Table 4: Interpretations of the Mathematical Knowledge that Amy Needed

Category	Chinese (n=20)	U.S. (n=20)
Rationale of the factoring method	2(10%)	1(5%)
Zero-product property	2(10%)	7(35%)
Differences between "and" and "or"	8(40%)	0(0%)
Meaning of solutions of quadratic equations	0(0%)	3(15%)
No interpretation	10(50%)	12(60%)
One interpretation	9(45%)	5(25%)
Two interpretations	0(0%)	3(15%)
Three interpretations	1(5%)	0(0%)

Evaluate Students' Performance

Evaluating Amy's performance, 90% of the Chinese teachers condemned Amy's performance while 10% gave a half and half comment that suggested Amy did something correct but also made mistakes. No Chinese teacher provided positive evaluations. Different from the Chinese teachers, 30% of the U.S. teachers did not evaluate Amy's overall performance. Almost half of the U.S. teachers gave half and half evaluations, whereas 15% of the teachers were positive about Amy's performance. None of the U.S. teacher gave negative evaluations. Thus, the U.S. teachers seem to be more tolerant than the Chinese teachers in front of students' errors.

Respond to Students' Errors

Around 50% of the Chinese teachers did not specifically address any mistake. 20% of the Chinese teachers demonstrated the first and the third mistakes respectively while 45% of them addressed the second mistake, that is, Amy used "and" to connect the two solutions. About one fourth of the U.S. teachers did not respond to Amy's mistakes (see Table 5). While more than fifty percent of the U.S. teachers addressed the third mistake, around 40% of them addressed the first mistake, the second mistake was neglected by most of them.

We found that the U.S. teachers differed from the Chinese teachers in terms of the number of teachers who addressed Amy's mistakes. The same number of Chinese teachers and U.S. teachers responded to two or three mistakes. In terms of Amy's three mistakes, the Chinese teachers highlighted using "or" but not "and" to connect the two solutions while the U.S. teachers emphasized how to check the solutions. Furthermore, it was found that Chinese teachers tended to address Amy's errors conceptually while the U.S. teachers favored conceptual and procedural explanations equally.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 5: Mistakes Addressed by the Teachers

Category	Chinese (n=20)	U.S. (n=19)	Total (n=39)
Mistake 1	5(25%)	7(36.8%)	12(30.8%)
Mistake 2	9(45%)	3(15.8%)	12(30.8%)
Mistake 3	4(20%)	11(57.9%)	15(38.5%)
No mistake	11(55%)	5(26.3%)	16(41.0%)
One mistake	4(20%)	9(47.4%)	13(33.3%)
Two mistakes	1(5%)	3(15.8%)	4(10.3%)
Three mistakes	4(20%)	2(10.5%)	6(15.4%)

Table 6: Mathematical Knowledge Addressed by the Teachers

Category	Chinese(n=17)	U.S. (n=10)	Total(n=27)
Rationale of the factoring method	1(5.9%)	1(10%)	2(7.4%)
Zero-product property	13(76.5%)	10(100%)	23(85.2%)
Difference between "and" and "or"	7(41.2%)	1(10%)	8(29.6%)
Meaning of solutions of quadratic functions	9(53.0%)	1(10%)	10(37.0%)
One piece of knowledge	6(35.3%)	7(70%)	13(48.2%)
Two pieces of knowledge	9(52.9%)	3(30%)	12(44.4%)
Three pieces of knowledge	2(11.8%)	0(0%)	2(7.4%)

Since some teachers addressed more than one piece of conceptual knowledge, the percentage for each knowledge category in Table 6 was calculated out of 100%. As for the four pieces of mathematical knowledge which have been identified as the reasons for Amy's mistakes, most of the Chinese teachers addressed the zero-product property and around half of the Chinese teachers explained the difference between "and" and "or" and the meaning of solutions of quadratic functions. Only one Chinese teacher explained that the rationale of the factoring method was the zero-product property. Also, one U.S. teacher addressed this rationale. While all the U.S. teachers elaborated the zero-product property, the other three pieces of knowledge were overlooked by them. To conclude, the Chinese teachers outperformed the U.S. teachers in both the variety and the quantity of the addressed conceptual knowledge.

Table 7 summarizes local characteristics of the teachers' responses to Amy's errors. The Chinese teachers all applied "show and tell" strategy while some of them simultaneously asked Amy questions to likely include her in the teaching process. Almost half of the Chinese teachers did not employ Amy's mistakes in their responses while the number of the Chinese teachers who actively addressed Amy's errors and intermediately used Amy's errors are equally distributed. Additionally, the Chinese teachers tended to go back to basic knowledge.

Similar to the Chinese teachers, the U.S. teachers also emphasized "show and tell" approach. In terms of "use of student error," most of the U.S. teachers employed Amy's errors when responding to her. Moreover, they tended to hold the thought that Amy just temporarily forgot the knowledge required to solve the equation and she would perform well if they can ask questions to help her refresh the knowledge and procedures.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 7: Local Characteristics of the Teachers' Responses to Amy's Errors

Aspect	Categories	Chinese(n=20)	U.S.(n=19)
Form of address	1. Show and tell	20(100%)	15(78.9%)
	2. Give and ask	7(35%)	6(31.6%)
Use of student error	1. Active use	4(20%)	7(36.8%)
	2. Intermediate use	5(25%)	4(21.1%)
	3. Rare use	11(55%)	8(42.1%)
With/Without communicative barrier	1. Over-generalization	7(35%)	5(26.3%)
	2. Plato-and-the-slave-boy	1(5%)	4(21.1%)
	3. Return to the basics	8(40%)	5(26.3%)
	4. Specific to student error	7(35%)	6(31.6%)

Discussion and Conclusions

We found that the Chinese teachers identified more of the student's mistakes than the U.S. teachers did and they are less tolerant to the student's mistakes than the U.S. teachers. Most of the teachers identified more than one of Amy's errors but they did not address all the identified errors when responding to Amy. Most of the teachers did not interpret the mathematical knowledge that Amy needed while they identifying her errors but they explained the knowledge that they believe Amy needed when responding to her. The Chinese teachers explained the mathematical knowledge conceptually and most of them demonstrated more than one piece of knowledge. In sum, the Chinese teachers outperformed the U.S. teachers in both the variety and the quantity of the addressed conceptual knowledge.

Interestingly, both the Chinese and the U.S. teachers intended to use teacher-centered pedagogical actions that highlighted "show and tell." More U.S. teachers than Chinese teachers seemed to believe that Amy simply needed help to recall all the needed mathematical knowledge so they actively used Amy's mistakes to deduce her lapses in knowledge about solving quadratic equations. The Chinese tended to go back to basic knowledge, maybe this practice is time-consuming but it is helpful for students to solve related problems correctly in the future. This study has implications to teacher educators and professional developers in both US and China.

First, both the Chinese teachers and the U.S. teachers showed the gap between the errors they identified and the errors they addressed. Since it is the errors that teachers addressed help students learn from their mistakes, teacher educators need to consider instructional interventions to help teachers develop strategies and knowledge to identify and address students' errors consistently. Second, both the Chinese teachers and the U.S. teachers applied "show and tell" approach. Teacher-centered instruction helps students to recall what they learned and provides students opportunities to learn what they missed. However, using teacher-centered instructions in front of students' errors can not probe why and how students made the errors. To learn from errors, students should know why and how they made such errors. Therefore, teacher educators need to train teachers to use multiple ways, including both teacher-centered approaches and student-centered approaches, to respond to students' errors. Third, given that the Chinese teachers outperformed the U.S. teachers in both the variety and the quantity of the addressed conceptual knowledge, professional developers may consider sessions to help in-service teachers in U.S. to construct deep conceptual understandings of certain mathematics topics that students usually are challenged by. Of relevance, teacher educators may also consider to adopt professional development sessions to help preservice teachers become sufficient in dealing with students' errors and in supporting students become mathematically competent. Last but not least, since Chinese teachers are more likely to give negative comments and less likely to employ students' errors when responding to students' errors, professional developments that help Chinese teachers build reasonable attitudes towards students' mistakes and develop flexible strategies to deal with students' errors should be considered.

In this exploratory study, we documented teachers' knowledge of children's mathematical thinking as they engaged in the task of anticipating children's strategies for an equal sharing fraction problem. To elicit an array of knowledge, 18 teachers were deliberately selected with a variety of numbers of years participating in professional development focused on children's mathematical thinking. We characterized the flexibility of teachers' knowledge by the number of valid and distinct strategies teachers anticipated and the degree to which these strategies reflected strategies research has shown children typically use. We argue that this flexibility is necessary for teachers to engage in instructional practices that are responsive to children's mathematical thinking.

Introduction

In this study we explored the knowledge that 18 upper elementary teachers displayed as they engaged in the task of anticipating children's strategies for the following equal sharing fraction problem: *A teacher has 4 pancakes to share equally among 6 children. How much pancake does each child get?* To elicit an array of knowledge, we selected for our analysis teachers with a range of numbers of years of participation in professional development focused on children's mathematical thinking. Our goal was to characterize teachers' knowledge of children's mathematical thinking in terms of its flexibility.

We view *knowledge of children's mathematical thinking* as a distinctive type of knowledge that is essential for teaching in ways that are responsive to children's mathematical thinking (Jacobs & Empson, 2016). We take the perspective that teachers' knowledge is situated (Putnam & Borko, 2000) and thus are interested in the knowledge teachers use as they engage in instructional practices that are part of responsive teaching. We focused specifically on the instructional practice of anticipating strategies, adopting what Stein, Engle, Smith, and Hughes (2008) defined as teachers' consideration of the array of strategies students would be likely to use for a given problem and the potential mathematics that could be learned with those strategies. In this study, we focus on teachers' anticipation of the array of strategies students would be likely to use.

Our analysis of teachers' knowledge was informed by the idea of flexibility. We considered the flexibility of teachers' knowledge in two ways. First, we used Whitacre's (2015) focus on the number of distinct and valid strategies that a teacher anticipated. Second, we considered to what degree did the teacher's anticipated strategies provide evidence of knowledge that was organized primarily around children's ways of making sense of the mathematics or around the teacher's own ways? In other words, to what extent was a teacher able to shift perspective and "think like a child"?

This study represents an exploratory effort to document teachers' knowledge of children's mathematical thinking in the domain of fractions as it was used to anticipate children's strategies for an equal sharing fraction problem. Teaching is inherently knowledge intensive. Documenting the

knowledge teachers use in instructional practices such as anticipating strategies is an essential step in promoting the development of expertise in teaching responsively on the basis of children's mathematical thinking.

Conceptual Framework

Teachers' knowledge of students and content has been conceptualized as a type of pedagogical content knowledge involving knowledge of how students learn a specific topic (Hill, Ball, & Schilling, 2008). It includes knowledge of students' strategies, common misconceptions, and typical developmental paths. Although its importance is widely acknowledged, teachers' knowledge of students and content has been the explicit focus of only a handful of studies (e.g., Bell, Wilson, Higgins, and McCoach, 2010).

In the current study, we focused on teachers' knowledge of students' strategies. We asked teachers to anticipate the range of strategies children might use to solve a story problem involving fractions and then to identify which strategies showed the most basic and advanced understanding. We then analyzed these strategies to explore the flexibility of teachers' knowledge. We were interested in two types of flexibility. The first type of flexibility involved the number of valid and distinct strategies anticipated by a teacher (Whitacre, 2015). We defined strategies as *valid* if a teacher's written response provided evidence about a process a child could use to solve the problem and reach a correct answer. Evidence of a process (vs. only an answer) was important because we wanted to elicit teachers' knowledge of children's thinking and not simply whether or not a teacher was able to solve the problem; if a teacher provided only an answer (e.g., "4/6 = 2/3"), the response was not counted as a valid strategy because we could not tell what reasoning the teacher thought the child might use to arrive at that answer. Strategies were further defined as *distinct* if they involved a qualitative difference in the process a child might use (e.g., partition pancakes into sixths vs. partition pancakes into thirds). Strategies were not considered distinct if they differed only in terms of a superficial feature that did not reflect a different process (e.g., partition into sixths and distribute pieces by numbering the pieces vs. partition into sixths and distribute pieces by drawing lines to connect to sharers).

The second type of flexibility involved the extent to which a teacher's anticipated strategies were organized around categories of strategies that children typically use, as documented in past research (Empson & Levi, 2011). The more flexible a teacher's knowledge is in this sense, the more the teacher is able to "think like a child." The less flexible in this sense, the less a teacher is able to see the problem the way a child might. Instead, teachers with less of this second type of flexibility may tend to anticipate strategies that are organized around instructed procedures and conventions—generalized, all-purpose methods that are introduced in school mathematics. Although the use of instructed procedures and conventions is a valuable goal of school mathematics it does not necessarily signify understanding on the part of the child or link to the child's informal strategies. In particular, when procedures and conventions are explicitly taught before children have had a chance to advance their understanding of fractional quantities, children's use of instructed strategies tends to be error-prone and procedurally-driven. Teachers who anticipate strategies mainly in terms of instructed procedures and conventions may be unaware of the role of children's informal strategies in the advancement of children's understanding of fractions.

These two types of flexibility provide a basis for describing the knowledge that enables teachers to be responsive to children's mathematical thinking: the greater the flexibility of teachers' knowledge, the greater their ability to make sense of and respond to children's ever evolving thinking. We therefore identified in teachers' anticipated strategies the degree to which there was a focus on children's typical strategies and noted how instructed procedures and conventions were used.

Focus on children's typical strategies. Children's strategies for equal sharing have been well documented (Empson & Levi, 2011). When invited to solve problems on the basis of what makes sense to them, children use a variety of informal strategies that are driven by their understanding of partitioning and equal distribution to create fractional quantities. There are three main categories of strategies typically used by children to share 4 pancakes among 6 children, distinguished by the progressive abstraction of fractional quantities, which reflect advances in understanding. In the most basic category, children draw models of some sort – often circles or rectangles – and partition them using familiar or easy-to-make partitions such as halves and fourths without consideration for the number of sharers. Pieces are distributed one by one to sharers. This category is called *non-anticipatory direct modeling*. As children's understanding of fractions develops, they continue to draw models and distribute pieces one-by-one, but they partition the models in a manner linked to the number of sharers. If there are six sharers, a child might begin by partitioning one pancake into sixths or two pancakes each into thirds. In both cases, six pieces are created, one for each sharer. This category is called *emergent anticipatory direct modeling*. In the most advanced category of strategies, children operate on mental models rather than drawn models; in particular they understand and are able to use the relationship that one pancake divided among six children is equivalent to one-sixth pancake per child in a variety of ways to figure how much pancake each child gets. They may use notation to support their thinking and express the strategy as $1/6 + 1/6 + 1/6 + 1/6 = 4/6$, $4 \times 1/6 = 4/6$, or $4 \div 6 = 4/6$. This category is referred to as *anticipatory*. Children may also use various combinations and transitional versions of these three main categories as their understanding develops.

Focus on instructed procedures and conventions. Children may also use instructed procedures and conventions while solving an equal sharing fraction problem. For example, they may "invert and multiply" ($4 \div 6 = 4/1 \times 1/6 = 4/6$), simplify fractions to lowest terms ($4/6 = 2/3$), or use long division. Children may use such procedures and conventions because their understanding of fractions has reached a level of fluency in which operations are routine and do not need to be directly modeled or decomposed into simpler computations, as in the informal strategies above. However, children also use such procedures and conventions because they think it is expected rather than because they understand fraction operations well. A procedure such as long division with a repeating decimal answer, for example, is an inefficient choice of strategy for this problem because of the number of steps involved and the difficulty of relating the answer to a fractional size of cake.

Methods

Data and Participants

The data analyzed for this study were taken from a sample of 71 teacher written responses collected to pilot an assessment of elementary teachers' knowledge of children's mathematical thinking about fractions. The teachers were all teaching grade 3, 4, or 5 at the time and reported a number of years of participation in professional development focused on children's mathematical thinking ranging from no participation to three or more years. In selecting our sample our goal was to maximize to the extent possible the variation in teachers' responses with respect to knowledge of children's mathematical thinking. We selected all teachers who reported 3 or more years of professional development focused on children's mathematical thinking and all teachers who reported no years of such PD. This selection resulted in a sample of 18 teachers (9 from each end of the range).

Task

> *A teacher gave this problem to the class:* A teacher has 4 pancakes to share equally among 6 children. How much pancake does each child get?
> a. *Provide 5 different valid strategies that represent the range of strategies that elementary students might use to solve this problem. Write out or draw each strategy the way a student might.*
> b. *Mark the strategy that indicates the strongest understanding of fractions.*
> c. *Mark the strategy that indicates the most basic understanding of fractions.*

Figure 1. The task posed to teachers in the study.

Teachers were given the task in Figure 1 to elicit their ability to anticipate a range of strategies and differentiate the understandings reflected in those strategies. We recognize that the written nature of the data limited the extent to which we could explore teachers' knowledge of children's mathematical thinking captured by this task. In particular, because we could not ask follow-up questions, we did not have in-depth information about the reasoning behind their choices.

Analysis

We began by coding each teacher's set of anticipated strategies for our two types of flexibility: (a) counting the number of distinct and valid strategies and (b) determining the degree to which the teacher's focus was on children's typical strategies. We also identified the specific strategies anticipated by each teacher to get a sense of his or her range focused on children's typical strategies and examined the details of these strategies for consistency with children's reasoning. We also coded each teacher's ability to differentiate the most and least understanding in the strategies. Finally, we synthesized all of this information to develop profiles that reflected teachers' knowledge and its flexibility. Three of the authors double-coded the data, with discussion and resolution of discrepancies.

Findings and Discussion

Teachers' knowledge of children's mathematical thinking as reflected in their anticipated strategies for equal sharing fell into three groups. We discovered that the number of distinct and valid strategies did not differentiate meaningfully between groups of teachers, and so in our profiles we focused on the degree to which teachers' anticipated strategies were consistent with children's typical strategies, both in terms of which strategies were used and the details within those strategies.

Profile 1: Robust evidence of knowledge of children's mathematical thinking

Each teacher in this group anticipated a set of three or more strategies in which the strategies and the details of the strategies were consistent with children's typical strategies. Teachers were also consistent in their assignment of least and most advanced understanding. Overall, these responses reflected teachers' ability to "think like a child." Figure 2 shows a set of these strategies from one teacher in which all of the strategies are consistent with the kinds of strategies children might use, as documented in research. The first strategy, non-anticipatory direct modeling, involved the use of repeated halving and did not exhaust the pancakes. The next strategy, emergent anticipatory direct modeling, involved the use of drawn models to partition the pancakes and then distribute the pieces one by one (by numbering them). The pancakes were partitioned into sixths — a common partition that children use for six sharers — and the final answer in the strategy was expressed in a manner generally consistent with how children might express it. The third strategy, another example of emergent anticipatory direct modeling, involved partitioning all four drawn pancakes into thirds, also a common partition that children use. The fourth, more advanced transitional anticipatory strategy

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

used a drawn model to partition two pancakes each into thirds, then continued with an equation of the form $1/3 \times 2 = 2/3$, showing how a child could use an equation to represent an abstraction of their direct modeling solution.

The flexibility of teachers' knowledge was reflected primarily in this profile by the range of strategies anticipated within the strategy category of emergent anticipatory direct modeling. The majority of teachers' strategies in this group included two if not three different ways to partition and distribute pancakes using drawn models (into sixths, into thirds, and into halves and sixths). Interestingly, each teacher anticipated at most one anticipatory strategy and these tended to be transitional and contain elements of direct modeling strategies, such as the fourth strategy in Figure 2.

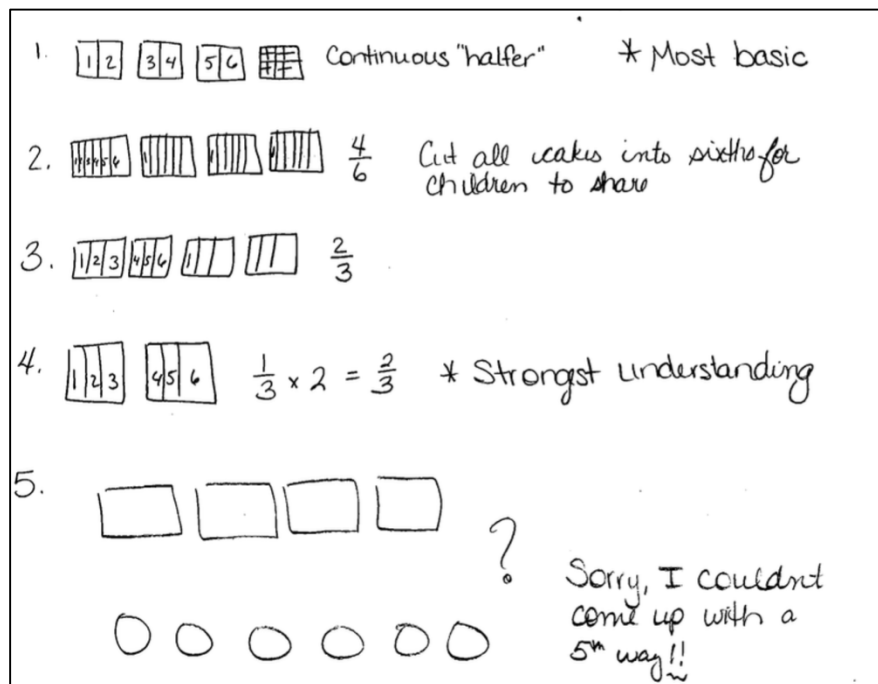

Figure 2. A response with strategies all consistent with children's mathematical thinking.

Profile 2: Limited evidence of knowledge of children's mathematical thinking

Teachers in this group anticipated a smaller number of children's typical strategies – one or two – and the majority of these strategies included details that were inconsistent with the way children might reason in the strategy. For example, virtually all of the direct modeling strategies in this group indicated that children would also simplify fractions to lowest terms or combine fractions with unlike denominators—actions that children who direct model are not likely to perform. The strategy on the left in Figure 3 provides an example that is consistent with what a child might do with a drawn model— the pancakes were cut into sixths and distributed one at a time—yet the simplification of the final answer of 4/6 to 2/3 is inconsistent with what a child using this strategy would likely understand about fractions. Similarly, another teacher anticipated that a child would draw a partition of the first three pancakes into fourths and distribute them, then draw the partition of the last pancake into sixths and distribute, and then combine the final amount, $1/4 + 1/4 + 1/6$, numerically by finding a least common denominator of 12. A child who needed to draw the fractional quantities to make sense of the problem, as in these strategies, would likely not reason mentally to express fractions in lowest terms or combine using least common denominators.

The strategies anticipated by teachers in this group that were in line with children's typical strategies encompassed a smaller range than those anticipated in the first group. For example,

teachers tended to anticipate only partitioning pancakes into sixths in their direct modeling strategies, and the rest of their valid anticipated strategies consisted of instructed procedures and conventions, such as long division or "invert and multiply" for fraction division (e.g., the set of strategies on the right in Figure 3). This combination suggests only a moderate amount of flexibility with respect to thinking like a child. Strategies in this profile were also not accurately assigned to least and most understanding. For example, one teacher indicated that an emergent anticipatory direct modeling strategy (involving sixths) represented the most understanding, whereas an anticipatory strategy that involved adding 1/6 four times represented the least understanding (when children's understanding of fractions actually develops in the opposite direction).

Figure 3. Responses with a mix of children's typical strategies and instructed procedures and conventions.

Profile 3: Lack of evidence of knowledge of children's mathematical thinking

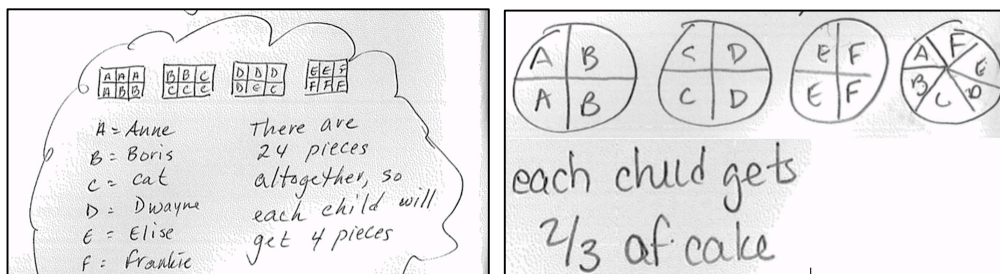
The strategies anticipated by teachers in this group did not include any strategies that fully represented the reasoning children typically use in their strategies. Although each teacher thought that children would use drawn models to solve the problem, the details of how children would use these representations were inconsistent with how children would reason. For example, the strategy in Figure 4 on the left shows the pancakes partitioned into sixths, with the sixths distributed four at a time, an atypical process for a child relying on drawn models to solve this problem. Similarly, the strategy on the right shows the partitions distributed two at a time, also an atypical process for a child relaying on this drawn model. This distribution may suggests that the teacher solved the problem first and then used the answer as the basis for completing the drawn model, in contrast to distributing the pieces one by one, as a child who took the trouble to draw each pancake and partition it into sixths would likely do while solving the problem. Although these teachers had the intuition that children would use drawn models to solve this problem, there was a lack of evidence of knowledge of the typical informal strategies that children would use.


Figure 4. Strategies with details that are inconsistent with children's reasoning.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Similarly to teachers in the second group, teachers in this group did not accurately assign strategies to least and most understanding. They also included some instructed procedures and conventions, though not as consistently as teachers in the middle group. Thus, teachers in this group appeared to have the least flexible knowledge with respect to "thinking like a child."

Conclusions

Imagining how a child would solve an equal sharing fraction problem such as the one in this study requires a teacher to see the problem through a child's eyes. It can be difficult to suspend one's own knowledge of mathematics to engage in thinking the way a child might. Yet teachers must do this to teach in ways that are responsive to children's thinking – they need *knowledge of children's mathematical thinking* to anticipate the strategies children might use, notice children's mathematical thinking, and respond appropriately with supporting and extending moves (Jacobs & Empson, 2016).

The majority of teachers in this exploratory study anticipated at least one strategy that was consistent with children's typical strategies as documented in past research. Among these anticipated strategies, direct modeling strategies were the most common. A handful of teachers anticipated nothing but direct modeling strategies or strategies using drawn models; and among those teachers who anticipated a small range of strategies consistent with children's typical strategies, a direct modeling strategy was always included. The pervasiveness of direct modeling in teachers' anticipated strategies suggests the accessibility of direct modeling as a way for teachers to make sense of children's mathematical thinking and to imagine how a child would solve equal sharing fraction problems.

Teachers' anticipation of direct modeling and other strategies allowed us to identify three knowledge profiles which varied along a continuum and were distinguished primarily by their flexibility in terms of thinking like a child. Flexibility with respect to the number of distinct and valid strategies provided a less useful measure by which to distinguish groups, although we conjecture that as a teacher's knowledge of children's mathematical thinking advances, there would be a corresponding increase in the number of valid and distinct strategies consistent with children's typical reasoning. We also conjecture that this number would include instructed procedures and conventions, although not at the expense of the variety of informal strategies children are known to use to make sense of an equal sharing fraction problem.

In summary we found the idea of flexibility as the extent to which teachers seemed to be able to think like a child not only useful for characterizing teachers' knowledge, but also an important extension to Whitacre's (2015) characterization of flexibility in terms of the number of distinct and valid strategies. The greater this flexibility, we conjecture, the greater teachers' ability to respond to children's ever evolving mathematical thinking during instruction. This exploratory study can be extended in two ways: investigate the knowledge of children's mathematical thinking in a larger sample of teachers systematically selected on the basis of their documented participation in professional development focused on children's mathematical thinking and use methods such as clinical interviewing that elicit teachers' reasoning for the strategies that they anticipate.

In this study we explored to what extent middle school teachers were able to appropriately identify proportional situations when presented with various mathematical structures and if there were relationships between attributes of the teachers and their ability to identify proportional situations. Interestingly, there were no strong relationships aside from teachers' perception of their knowledge of mathematics and their ability to identify proportional situations. Teachers were also found to correctly identify proportional situations significantly more often than non-proportional situations. Nearly one third of the teachers misidentified non-proportional linear situations as proportional. Thirteen participants' responses to such a situation were analyzed qualitatively resulting in some common knowledge resources that they appeared to use when attempting to identify whether a situation was proportional or not.

Keywords: Teacher Knowledge, Rational Numbers, Mathematical Knowledge for Teaching

Purpose and Background

Proportional reasoning is an important content area that has gained prominence in middle school mathematics. One indication of this is that the Common Core State Standards for Mathematics (National Governors Association & Council of Chief State School Officers, 2010) have made "ratios and proportional reasoning" its own content domain for grades 6 and 7. Despite this recognition, there has been little focus on proportional reasoning in research in relation to its importance (Lamon, 2007), including research on teachers' knowledge of the domain. The research that is available on teacher knowledge of proportions indicates that, like students, teachers struggle with proportions (e.g., Akar, 2010; Harel & Behr, 1995; Orrill, Izsák, Cohen, Templin & Lobato 2010; Post, Harel, Behr, & Lesh, 1988; Riley, 2010).

One fundamental way of demonstrating proportional understanding is in the ability to identify when a situation warrants the use of proportional reasoning, which pertains to the mathematical structure of the problem rather than other identifiable aspects. Orrill et al. (2010) observed that middle school teachers had trouble identifying situations as appropriate or inappropriate for using proportional reasoning. For example, often when teachers were given a problem with three values and asked to find a missing fourth value, teachers tended to treat it as directly proportional even if the actual relationship was inversely proportional. Teachers also struggled to reason about proportions in a qualitative task that asked them to compare one pile of blocks to another pile similar to those tasks used by Harel, Behr, Post, and Lesh (1992).

These findings suggest that when teachers do not rely on a strong mathematical understanding of proportions to evaluate a situation, they draw on understandings that may be based on something other than mathematical structure when deciding whether a situation is proportional. In this paper, we explored the extent to which middle school teachers were able to identify proportional situations and whether there was a relationship between the teachers' backgrounds and their ability to identify proportional situations? To further explore this, we investigated whether there was a relationship between the underlying mathematical structure of the situation presented and the teachers' ability to

identify proportional situations. We followed this with an analysis of the knowledge resources our participants invoked when identifying a non-proportional, linear situation. We see this work as border crossing because we are looking at the between proportions and other relationships. Specifically, we are investigating middle school teachers' abilities to recognize the border between situations that are and are not proportional. We conjecture that without such recognition teachers will struggle to use appropriate reasoning to make sense of a given situation.

Theoretical Framework

We work from the knowledge in pieces perspective (diSessa 1988, 2006), which asserts that individuals hold understandings of various grain sizes that are used as knowledge resources in a given situation. These resources are connected, over time, through learning opportunities that lead to the refinement of the resources and the development of rich connections. Having a series of robust connections allows a knowledge resource to be available in more situations. This is parallel to the research on expertise that has shown that experts have both more knowledge and a different organization of knowledge than novices in their domain (Bédard & Chi, 1992). It is also aligned with Ma's (1999) interpretation of teachers' need for profound understandings of fundamental mathematics. By having a robust set of knowledge resources that are coherently connected, we posit that teachers will be more able to access their myriad understandings to apply them to a wider range of mathematics and teaching situations than others whose knowledge resources are less coherently connected. We refer to this richly connected collection of knowledge resources as being *coherent* and assert that more coherent teachers will be better able to support student learning (e.g., Thompson, Carlson, & Silverman, 2007). This approach differs from much research on teacher knowledge in that we are not trying to identify deficiencies in teachers' understanding of mathematics, rather, we are trying to understand how teachers understand the mathematics they teach and how different knowledge resources are drawn upon for solving problems and teaching.

Methods

This study is part of a larger project investigating teachers' knowledge of proportional reasoning for teaching. In this section we will describe the participants of the study as well as our data collection and analysis procedures and tools.

The participants included a convenience sample of 32 in-service, grade 5-8 mathematics teachers, whose teaching experiences ranged from 1 to 26 years. The participants were from four states. They taught at a variety of schools (public, private, and charter). Twenty-four of the teachers identified as female and eight identified as male. Six of the teachers identified as a race other than white.

The data analyzed for this study were collected through a multiple-choice assessment and clinical task-based interview. We selected those items designed to assess teachers' ability to differentiate between situations that are or are not proportional. The items (n=20) were drawn from three existing assessments designed to measure teachers' proportional reasoning abilities. We also collected data on attributes of teachers' backgrounds including: the number of years teaching, number of mathematics and methods courses taken, and teacher's self-efficacy. To do this, we relied on seven, five-point Likert scale items taken from the Learning Mathematics for Teaching assessments (Learning Mathematics for Teaching, 2007).
Figure 1. Screenshot of Thermometers task.

We carried out an exploratory data analysis of the proportional reasoning items, followed by a correlational analysis and a non-parametric comparison of group centers to investigate the first three research questions. The results of the analysis led us to analyze the Thermometers task from the clinical interview. Thermometers, a dynamic sketch, presented the participants with two thermometers, one red and one blue, whose lengths could be varied by dragging a point on a number line (as shown in Figure 1). Two scenarios were shown to participants (one at a time) and with each scenario participants were asked: (a) whether there was a relationship between the thermometers; (b) whether the relationship was proportional; (c) whether they could provide a rule and a story problem or real-world situation for that relationship; and (d) whether they see a scale factor involved in the situation. For this study we analyzed the participant's responses to the first scenario where the thermometers were designed to maintain a constant difference of two units in length of the lines as the point on the slider is dragged from left to right, shown in Figure 1. This situation represents a non-proportional linear relationship between the two thermometers.

Table 1: Codes of Knowledge Resources Used in Thermometers Task

Code	Description
Comparison of Quantities	States that ratio as a comparison of two quantities.
Covariance	Recognizes that as one quantity varies in rational number the other quantity must covary to maintain a constant relationship.
Unit Rate	Uses the relationship between the two quantities to develop sharing-like relationships such as amount-per-one or amount-per-x.
Equivalence	Describes proportion as a relationship of equality between ratios or fractions.
Between Measure Space	Asserts that the ratio between the quantities in a proportion stays constant.
Scaling Up/Down	Uses multiplication to scale both quantities to get from one ratio in an equivalence class to another.
Horizon knowledge	Demonstrates knowledge that extends into mathematics beyond proportions
Relative Thinking	Demonstrates multiplicative reasoning about the change in a quantity relative to itself or another quantity. This includes re-norming.
Proportional Situation	Recognizes that a situation involves proportional reasoning.
Rule	Shares a verbal or written rule (e.g., Red = Blue - 2) stated in a way that conveys a generalizable relationship.
One Unit at Time	Describes the relationship between the two quantities as increasing by one unit at a time

The qualitative analysis of the participant's responses was carried out by coding the participants' utterances using a coding scheme (Table 1). The scheme was developed using open coding (Corbin & Strauss, 2007) and refined across several interviews. It was specifically designed to consider knowledge resources related to proportional reasoning. We note that this specific task was non-proportional, so there were other resources that the participants drew on to engage with the thermometer scenario. Our coding relied on a binary approach in which each utterance was coded as a 1 or a 0 based on whether a particular knowledge resource was observed. Every interview was

coded by at least two researchers and 100% agreement was reached on all coding.

Results

Question 1: Extent of Correct Identification of Proportional Situations

The 32 teachers in this sample were largely able to correctly identify proportional situations. For the 20 situations analyzed, the mean number correct was 15.22 (SD=2.97). The range of correct answers was 7-19.

Table 2: Kendall's tau b Correlation Coefficients

	# Items Correct		Min	Max	Mean	SD
	Kendall's tau b	Sig. (2-tailed)				
Years Teaching Math	.144	.272	0	26	9.20	7.202
Math Courses	.135	.352	1	4	3.13	.92
Methods Courses	-.012	.932	1	4	2.59	1.01
I enjoy teaching mathematics	.000	1.000	3	5	4.72	.581
Mathematics isn't my strongest subject to teach	-.271	.065	1	5	1.69	1.120
I consider myself a "master" mathematics teacher	.255	.070	1	5	3.03	1.177
Overall, I know the mathematics needed to teach this subject	.278	.063	3	5	4.34	.653
I have strong knowledge of ratio, proportional reasoning, and rate	.483[**]	.001	2	5	3.81	.738
I have strong knowledge of all areas of mathematics	.281[*]	.050	1	5	3.09	.963
My knowledge of ratio, proportional reasoning and rate is adequate to the task of teaching these subjects	.343[*]	.017	1	5	3.94	1.105

Note. Math and Methods courses measured on a scale of 1 to 4 with 1 corresponding to no classes, 2 to one or two classes, 3 to three to five classes, and 4 to six or more classes. *$p \le .05$, **$p < .01$*

Question 2: Relationship between Attributes of Teacher's Background and Ability to Identify Proportional Situations

In response to the second research question a correlational analysis was done using Kendall's tau B (shown in Table 2), which is a non-parametric measure of correlation appropriate for small samples (Field, 2013). Interestingly there was no significant correlation between the number of items the teachers answered correctly and the number of college mathematics or methods courses. There was also no significant correlation between the numbers of years teaching and the number of correct responses. However, there was a significant correlation between the number of items answered correctly and the teachers self-rating of their knowledge of mathematics; of ratio, proportional reasoning, and rate; and of perceived ability to teach these subjects. Further investigation in this area is needed as these results are not generalizable given the sample size.

Question 3: Relationship between Mathematical Structure and Appropriateness

In response to the third research question we looked to see if there was a relationship between the underlying mathematical structure of the situation and teachers' abilities to determine whether it was proportional. Using the non-parametric Mann-Whitney U-test we found that the median number of teachers who correctly identified the proportional situations was 31 for each of the seven items that was proportional. The median number of teachers who correctly identified the non-proportional situations was 23 for each of the 13 non-proportional items. Using the Mann-Whitney U-test, we

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

found that this was a significant difference (U=3.00, z=3.34 p=.0002, r=.75). This means that the teachers were better at appropriately identifying proportional situations than they were at identifying non-proportional situations. Further analysis revealed a clear pattern in the relationship between the mathematical structure of the item and the number of teachers able to correctly identify it as proportional or not (Figure 2). There is a clear stratification of the number of appropriateness items that teachers responded to correctly based on the underlying mathematical structure of the situation presented. There is also a statistically significant correlation (Kendall's tau-b -.889, p<.0001) between the mathematical structure and the correctness of teachers' responses.

Figure 2. Structure of appropriateness items with number of correct responses.

Interestingly, nearly one-third of the teachers misidentified non-proportional linear situations as proportional. Linear functions are a significant and heavily emphasized topic in school mathematics and therefore are important for teachers to be able to differentiate from the more specific case of proportional situations. This finding led us to further investigate the knowledge resources these teachers used when evaluating the appropriateness of proportional reasoning in a linear situation, specifically the Thermometers task.

Question 4: Resources Used in Determining Whether a Situation Involved Proportion

Preliminary results from analysis of reasoning by thirteen of the participants on the non-proportional Thermometers task are shared here. Eight participants (Group 1 - Heather, Eileen, Ella, Matt, Alan, Magen, Larissa, and Tonya) correctly identified the situation as non-proportional. Three participants (Group 2 - Tori, Kathleen, and Allison), first identified the situation as proportional but changed their mind during the interview to identify the situation as non-proportional. In fact, Tori changed her mind twice and ended by identifying the situation as proportional. Two participants (Group 3 - David and Bridgett) identified the situation as proportional. All names are pseudonyms.

Proportional Knowledge Resources. Many participants in Groups 1 and 2 used rules, scaling up and/or down, and equivalence to appropriately identify this Thermometers task as non-proportional. All the participants in Group 1 were able to provide a clear *rule* that stated the generalizable relationship between the two thermometers. For instance, Ella claimed that "the blue equals the red plus two". On the other hand, the participants from Group 2 and Bridgett (Group 3) did not provide a rule even when they were asked explicitly to do so. David (Group 3) was able to provide a rule, however he incorrectly identified the relationship as a proportional one. Creating a generalizable rule was a knowledge resource that participants in Group 1 used when they correctly identified the situation as non-proportional from the beginning.

Three participants from Group 1 (Tonya, Larissa and Meagan) used the idea of *scaling up/down* to explain why the relationship between the two thermometers was not proportional. For example, Larissa stated, "if the red was at one and blue was at two and it was a times two and then two and then four, then yes, it would be proportional. But not in this case." Allison (Group 2) also used this knowledge resource to resolve the issue she had with the difference between the thermometers being "always just two". At first she claimed, "it's proportionally it's going up the same when you drag it". However, as she continued to move the thermometers, she said, "If they were similar it wouldn't always be two because if something's four and two, if I double it to eight, that would be four if they were proportionally the same. And that's not happening here." She used multiplication to determine the equivalent ratios that would be found in a proportional relationship (*Scaling Up/Down*), and then determined that the relationship was non-proportional.

Two participants from Group 2 (Tonya and Larissa) explained the situation as non-proportional by using the idea of *equivalence* "because it's add two, there's no equivalent; the fractions created wouldn't be equivalent" (Larissa). Surprisingly, David (Group 3), who incorrectly identified the relationship as proportional, shared an accurate definition of proportions but said he was "having a hard time putting that onto this [the thermometers situation]".

Additive Knowledge Resources. Consistent with previous research on the use of language that suggests additive reasoning (e.g., Lamon, 2007; Nagar, Weiland, Orrill, & Burke, 2015), nine out of thirteen participants (at least one from each group) drew on the idea of *One Unit at a Time*. These participants claimed that the thermometers move "up one unit at a time" (Heather, Group 1). The participants used this resource to determine whether the situation was proportional and/or to explain why the situation is not proportional. For instance, Eileen (Group 1) said, "both of the bars…are moving by one unit amount…which means they are not moving in proportion to each other." Tori (Group 2) at first determined that the situation is proportional, but then she explained that when she thinks "of that [the relation between the bars] as a fraction, three fifths" and then dragged "it to where the blue is at eight, the red is at six. That's not proportional". Interestingly, she continued to explore the relationship and found that there is a constant relationship where "for every increment for red, there's an increase of one for the blue" and determined it to be a proportion. Both Bridgett and David (Group 3) also used this knowledge resource. Like Tori, David found the idea of *One Unit at a Time* as related to proportion when he claimed that "talking about the slope, the rate, it is proportional, they're going up one unit". Bridgett did not mention this resource in the context of proportion.

Conclusions

Determining whether a given situation was proportional or not was most challenging for our participants when the situation was non-proportional. Interestingly no attributes of the teachers' background seemed to relate to their ability to identify a proportional situation. Participants were able to successfully use *Rule*, *Scaling*, and *Equivalence* to identify non-proportional situations. The use of additive reasoning was common across participants (nine out of thirteen) regardless of their ability to correctly identify the situation as proportion or not. Since proportional reasoning is multiplicative

this could suggest that teachers have the same tendency to rely on build-up strategies as their students (Lamon, 2007).

Surprisingly, we also did not observe participants relying on comparisons of quantities to determine whether the relationship was proportional. We find this interesting because the basic definition of a ratio is a multiplicative comparison of two quantities, something the participants did not draw upon in their reasoning. Instead, most of the participants referred to ratios but used additive language as they described their thinking. This suggests that teachers may not draw upon their understanding of ratio as comparison when they identify proportional situations. We noted that they did not seem to clarify whether the comparison was additive or multiplicative nor did they appear to rely on the definition of ratio which would have suggested comparing quantities rather than build-up strategies (Lobato, Ellis, Charles & Zbiek, 2010).

Our research suggests two main findings. First, teachers seem to understand their own mathematical abilities. This is important because it contradicts the widespread warnings about the suspect nature of self-reported data. At a large grainsize, these teachers had a relatively accurate assessment of their understandings. Second, there may be knowledge resources that are more useful for determining whether a situation is proportional. The teachers in this study had greater success with *Rule*, *Scaling*, and *Equivalence* than with other resources that were tried. These findings suggest that professional developers could rely more on teachers to provide insights into their own needs in content knowledge development. It also suggests that teacher development should potentially include explicit discussion of the use of different approaches to reason about the proportionality of a situation. Future research should also explore if these participants use of knowledge resources is representative of middle grades teachers.

El estudio de objetos tridimensionales en el currículo mexicano se aborda en toda la educación básica. Sin embargo, hay pocos estudios sobre el conocimiento matemático para la enseñanza de los profesores al respecto. Este reporte da cuenta de un acercamiento a dicho conocimiento, a partir de la observación de las clases, que tres profesoras de sexto grado ponen en juego cuando enseñan a sus estudiantes a calcular el volumen de prismas en dos escuelas de la ciudad de México. Los resultados muestran evidencias respecto a ciertos subdominios del conocimiento matemático para la enseñanza. Si bien hay fortalezas en dicho conocimiento, también algunas carencias, lo que muestra la necesidad de construir espacios formativos (inicial y continua) donde el análisis y discusiones favorezcan el aprendizaje de conocimientos tanto geométricos como didácticos que requieren para su práctica docente.

Palabras clave: Geometría y Pensamiento Geométrico y Espacial, Conocimiento Matemático para la Enseñanza, Educación Primaria

Introducción

La geometría posibilita en los estudiantes el estudio de las figuras del espacio y sus relaciones. El espacio geométrico es construido a partir de la exploración empírica que parte de un espacio real y llevado hacia una abstracción geométrica. Su enseñanza en México, y en particular el estudio de la geometría tridimensional, permea el currículo de toda la educación básica (SEP, 2011). Los aspectos a trabajar son "la exploración de las características y propiedades de […] cuerpos." Y "el conocimiento de los principios básicos de la ubicación espacial y el cálculo geométrico." (p. 73), donde la mediación del profesor y por tanto, sus conocimientos matemáticos y didácticos, son esenciales.

El aprendizaje del volumen de cuerpos geométricos, en particular, presenta dificultades. El conocimiento del profesor respecto de este contenido tiene mayor relevancia, si cabe, que respecto de la enseñanza de otros contenidos de menor dificultad para el alumno. Parte de estas dificultades se relacionan con su estrecha relación con la capacidad (Freudenthal, 1993; Saiz, 2002; Zevenbergen, 2005), la distinción entre los conceptos matemático y físico de volumen (Saiz, 2002) y la importancia de la visualización en su comprensión (Gutiérrez, 1998).

El conocimiento que tienen los profesores de educación primaria sobre la geometría tridimensional es una problemática que ha sido poco estudiada (Aslan-Tutak & Adams, 2015; Tekin & Isiksa, 2013). Los estudios reportados en relación con dicho conocimiento del profesor en formación y/o en servicio ponen de relieve dificultades en aspectos conceptuales y de habilidades espaciales. Así, Zevenbergen (2005) señala que profesores en formación tienen obstáculos similares a los alumnos en primaria vinculados con el desarrollo de su sentido numérico, de medición y espacial. Carencias que limitan su competencia para identificar en sus alumnos errores asociados, por

ejemplo, con resolución de problemas de cálculo de volúmenes. Profesores para primaria en formación señalan que en sus cursos de matemáticas y su didáctica, no logran desarrollar una comprensión profunda sobre contenidos de geometría elemental. También reconocen la importancia de las representaciones y habilidades visuales en este tópico de las matemáticas (Aslan-Tutak y Adams, 2015). En cuanto a la comprensión de cuerpos geométricos, Dorantes (2008) mostró carencias respecto a los conocimientos de un grupo de profesores relacionadas con la identificación de características de poliedros en términos de sus aristas, vértices y caras; la exploración de éstos mediante la observación en diferentes perspectivas y el cálculo de su volumen. Estos resultados coinciden con los de otros estudios (Saiz, 2002; Bozkurt & Koç, 2012). En particular, Çakmak *et al* (2015) encontraron que las definiciones dadas por estudiantes y los ejemplos y maneras de resolver problemas, son análogos a los usados por sus maestros en las clases y en muchos casos presenta limitaciones.

El objetivo de la investigación en la que se enmarca este reporte fue identificar y describir el *conocimiento matemático para la enseñanza* evidenciado en profesores de sexto de primaria en la enseñanza del volumen de prismas (Moctezuma, 2015).

Visualización geométrica, representaciones y volumen de objetos tridimensionales

La percepción visual apoya a la geometría tridimensional puesto que las representaciones visuales constituyen un medio esencial de anticipación. Los alumnos tienden a depender de la información visual, según los resultados de investigaciones como la de Gal & Linchevski (2010). La atención inicial en geometría se centra más en los objetos que en los procesos debido a que el interés se enfoca en las propiedades figurales percibidas por medio de los sentidos e interpretadas por la reflexión mental mediada por una representación espacial. Sin embargo, toda representación particular a la vez que proporciona cierta información, oculta otra y puede ser difícil recuperarla para quien la está interpretando. Para Del Olmo *et al* (1993) las dificultades de los niños al medir el volumen se pueden originar por la falta de manipulación previa; no dominan la visualización espacial, al carecer de la habilidad de manipular mentalmente figuras rígidas.

Existen diferentes formas de representar los cuerpos geométricos para fines didácticos: en perspectiva, paralela, isométrica, por niveles, ortogonal y mediante desarrollos planos. Cada uno de ellos requiere el aprendizaje de convenciones para interpretarlas y el desarrollo de habilidades para reproducirlas (Gutiérrez, 1998). Los tipos de representaciones utilizadas en los libros de texto de quinto y sexto grado de primaria (SEP, 2012)[i] para proyectar cubos, prismas y pirámides son las representaciones paralelas, isométricas y mediante desarrollos planos. Sin embargo, como se mostrará más adelante, hay desconocimiento de los profesores sobre dicha diversidad que tienen impacto en el uso que se les dan a las mismas en clase.

Conocimiento matemático para la enseñanza de los prismas y su volumen en primaria

El conocimiento para la enseñanza toma su caracterización desde los conocimientos planteados por Shulman (1986) y detallados, para el caso de las matemáticas, en los subdominios del *Mathematical Knowledge for Teaching* (MKT) de Ball, Thames & Phelps (2008). Estos autores diferencian dos grandes dominios: Conocimiento del Contenido y Conocimiento Didáctico del contenido. El primero recoge el contenido que el profesor está enseñando y su fundamentación. El *conocimiento del contenido* se subdivide en Conocimiento Común del Contenido (conocimiento de una persona instruida en ese contenido) (CCK[ii]), Conocimiento Especializado del Contenido (conocimiento del contenido que distingue al profesor) (SKC) y Conocimiento del Horizonte matemático (HCK). El *Conocimiento didáctico del contenido* incluye los conocimientos que posee el profesor con respecto a la enseñanza del contenido, su aprendizaje, y el currículo escolar. El *Conocimiento del contenido y los Estudiantes* (KCS) es la unión de la comprensión del contenido y saber lo que los estudiantes pueden pensar o hacer en matemáticas. Involucra la identificación de los

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

conceptos previos y anticipar probables dificultades de aprendizaje y concepciones erróneas respecto al contenido matemático a enseñar. El *Conocimiento del Contenido y la Enseñanza* (KCT) conjuga la comprensión del contenido y su familiaridad con los principios pedagógicos para enseñarlo. Finalmente, el *Conocimiento del Currículum* (KCC) incluye el conocimiento del profesor delas matemáticas como asignatura: su estructura, y los aprendizajes que se espera lograr con los alumnos al culminar su Educación Primaria.

En este reporte se dará cuenta sobre ¿Qué conocimiento matemático para la enseñanza, pone en acción un profesor al impartir una lección sobre el volumen de prismas en sexto de primaria?

Metodología

La investigación realizada tiene un enfoque cualitativo con un alcance descriptivo. Los datos principales provienen de lo que tres profesoras (que participaron de manera voluntaria) hacen en sus clases de matemáticas cuando enseñan el contenido de volumen de prismas.

La investigación se realizó entre 2014 y 2015 en dos escuelas primarias públicas de la ciudad de México, ubicadas en la periferia. Las profesoras impartían sexto grado y todas las asignaturas, entre las que se incluye Matemáticas. Las tres tienen más de 25 años de experiencia docente y son de formación normalista. Consuelo (C) es experta en quinto y sexto grado de primaria, mientras que Laura (L) y Rocío (R) han transitado de primero a sexto grado[iii] (nombres ficticios). Las tres, han impartido los temas de sexto grado durante dos años previamente a esta investigación. Este grupo de estudio fue tomado de manera intencionada, y se hizo un seguimiento a sus prácticas durante varias sesiones de clase, donde se abordaron temas vinculados con geometría tridimensional (en este reporte nos centraremos sólo en una lección referida al volumen de prismas).

El trabajo de campo se desarrolló durante trece meses en distintas fechas del año escolar. Las clases fueron videograbadas y transcritas. Para extraer información sobre los conocimientos movilizados por las profesoras se utilizaron tres instrumentos: observación no participante en clases, diario de campo y entrevista semiestructurada (esta última con el objetivo de completar la información obtenida de la observación).

Para el análisis de las clases observadas se utilizaron categorías prefijadas por el observador. Se partió de la descripción de los subdominios del MKT y de su concreción en los indicadores diseñados por Sosa (2011), adecuándose al nivel y contenido específico a analizar. Éstos se fueron refinando durante el proceso de investigación hasta obtener los indicadores definitivos.

En el libro de texto, la lección "¿Cuántos cubos hay en el prisma?" consta de cuatro actividades (SEP, 2012, pp. 162-163). Nos centraremos en las dos primeras, en las que los alumnos deben calcular el volumen de cuatro prismas rectangulares a partir de la cantidad de unidades cúbicas en las aristas (Figura 1.a). En A y B se identifican las tres dimensiones (largo, ancho y altura) y se muestran unidades cúbicas, mientras que en el prisma C se muestran marcas que permiten deducir la medida de longitud de únicamente dos aristas del prisma (Figura 1.b).

Un análisis a priori de esta lección permitió identificar una transición de un tratamiento unidimensional del volumen (usándose como unidad de medida un cubo) a uno tridimensional (calculándose a partir de las longitudes ancho, largo y alto), si bien el título de la lección destaca el primero. Además, en la actividad 3 se relacionan las nociones volumen y capacidad.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figura 1. Actividades propuestas para el trabajo con volumen de prismas (SEP, 2012, pp. 162-163).

Conocimientos puestos en acción. Descripción de resultados y discusión

En el análisis de las tres sesiones observadas surgen dos elementos de interés sobre el conocimiento de las profesoras: el tratamiento uni/tridimensional del volumen y cómo calcular la medida no dada de una arista en el caso C de la actividad 2.

Una de las profesoras, Rocío, trata el volumen en todas las actividades desde una perspectiva tridimensional. De este modo, pierde sentido la pregunta final que plantea la actividad 2 ("¿Cuál será la forma más rápida de calcular el volumen de un prisma?"). Desde un inicio, Rocío ubica el largo, el ancho y la altura de cada prisma como paso necesario para el cálculo de su volumen:

> Rocío (R): Recuerden tomar en cuenta las tres dimensiones que habíamos hablado, saquen el volumen […] la cantidad de prismas que tienen esas figuras, la cantidad de unidades […]
> R: […] ¿Cuántas unidades son? Aquí [figura 1.b, apartado A] de base, de ancho 6, de largo 6 y de altura 6. Entonces multiplicamos 6 por 6 por 6 y nos da 216 […] En la figura B ¿Cuál es la base, el largo, el ancho? […] ¿Cuáles son las medidas? […] ¿Cuál es el largo?
> E8: 6 por 9
> R: […] Multiplicamos 9 por 6, […] 54… 54 por 6 […] 324. [La profesora escribe en el pizarrón 324 cm^3].

> (Fragmento 1 de la sesión de Rocío)

Rocío no hace una distinción explícita entre el tratamiento unidimensional y el tridimensional para el cálculo de volumen de prismas. Parece que no establece diferencias entre ambos tratamientos del volumen y ni percibe la necesidad de trabajar primero desde una perspectiva unidimensional para justificar la tridimensional por sus ventajas prácticas, ni la incidencia de dicha secuencia en la comprensión de la magnitud volumen.

Sin embargo, Laura, plantea la posibilidad de que los alumnos calculen el volumen de los prismas dados en la actividad 2 por el procedimiento que ellos consideren adecuado, surgiendo de este modo procedimientos usando una unidad de volumen y otros, haciendo uso de la longitud y tridimensionalidad del prisma.

> Laura (L): [Lee] completa el prisma, ¿Necesitamos completarlo? […]
> E5: Sí.
> L: ¿Llenarlos de cubitos?
> E5: No.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

L: ¿Tú qué opinas, E7, […]. A ver, ¿necesitamos completar los prismas?
E7: También podemos multiplicar.
L: Multiplicar, ¿tú qué estabas haciendo?
E7: Estaba multiplicando base por altura y después por ancho.
L: […] Y tú ¿qué estabas haciendo? [dirigiéndose a E8]
E8: Contándolos.
L: Contando los cubitos, […] Completen, cada quien tiene su método de sacar el volumen.

(Fragmento 1 de la sesión de Laura)

Los estudiantes refieren tanto el tratamiento unidimensional como el tridimensional para calcular el volumen; la profesora por su parte da libertad a los estudiantes para aplicar el método que prefieran. Parece que Laura distingue implícitamente entre el procedimiento unidimensional y el tridimensional para calcular el volumen de prismas (SCK) aunque no se observa que precise el tratamiento unidimensional de manera insistente como lo hace con el tridimensional.

Por otro lado, uno de los aspectos que resultan más problemáticos de la lección está vinculado con la actividad 2 (Figura 1.b) puesto que la representación del prisma C no permite inferir visualmente la longitud de una de sus aristas. La discusión que surge en la clase se relaciona con la unidad de medida. En las tres sesiones se observan formas diferentes de orientar esta situación, lo que pone de manifiesto distinto conocimiento matemático para la enseñanza de las profesoras. Este conocimiento se relaciona con el papel de la unidad en el proceso de medida, y su conceptualización (SCK); el conocimiento de la posibilidad de usar unidades de medida no convencionales (KCC); la diferencia entre medida, unidad, instrumento y procedimiento de medida (SCK) y las confusiones habituales de los alumnos al respecto (KCS); la dificultad de los alumnos para reconocer y usar unidades e instrumentos no convencionales (KCS); y el carácter aproximado de la medida (SCK).

Rocío no parece ser suficientemente consciente del papel de la unidad en el proceso de medida y del papel que juega conceptualmente en el concepto de medición (SCK), así como de las dificultades que esto origina en los estudiantes (KCS). Así, para solventar el problema que se plantea a la hora de calcular el volumen del prisma C (actividad 2), decide medir con una regla:

R: [Dirigiéndose a un estudiante] Préstame tu regla. [La usa para medir en su libro]
E7: 1 centímetro es de dos cubos.
E5: Son 5 centímetros.
E8: Son 6.
R: Si está de medio centímetro, entonces cada uno de los lados son medio centímetro. Entonces si yo mido…¿Quién decía que 11? Son 11 […]
R: ¿11 por ocho? [la maestra sigue midiendo] De altura son 10, fíjate bien: son 5 centímetros, cada una de las unidades está representando medio centímetro; son 10 unidades. Midan con su regla. Cada una de las unidades que nos está representando el libro mide medio centímetro, son cubos que miden medio centímetro.
[…]
R: Recuerden que en este cubo que está, en este prisma que está representado ahí, está el largo, el ancho y la altura. El largo es 11.
E8: Son 11 por 10 por 8, entonces… [La profesora mueve la cabeza en señal de aprobación]

(Fragmento 2 de la sesión de Rocío)

Rocío desecha las medidas de longitud que ya están dadas en el prisma (según la unidad que se indica) y mide con la regla cada una de las dimensiones (largo, ancho y alto). Usa el centímetro como unidad de medida de longitud, estableciendo la equivalencia entre el centímetro y la unidad de longitud dada en la actividad (medio centímetro).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

La representación dada en la actividad muestra que el prisma mide 5 unidades de ancho y 6 de altura; el largo no se sabe. El resultado de la medición de la maestra es 4cm para el ancho, 5.5 cm para el largo y 5cm para la altura. Ella lo traduce como 8 para el ancho, 11 para el largo y 10 para la altura.

Decide tomar una unidad de medida de longitud diferente a la que muestra el libro de texto y no precisa dejar claro a los estudiantes que ha cambiado la unidad de longitud para las tres dimensiones del prisma al calcular el volumen. Además, la elección de la unidad y el instrumento de medida de longitud que toma puede suponer no tomar en consideración la concepción errónea de los alumnos de que para medir (una cantidad de longitud) es necesario usar unidades del sistema métrico decimal (en este caso cm) e instrumentos convencionales (KCS).

En la sesión de Consuelo, también se recurre a una regla convencional (graduada en cm) para resolver la situación:

Consuelo (C): […] ¿Qué hicieron para tomar las medidas del prisma que está en la letra C?
Estudiante 9 (E9): Medí con una regla.
C: […] ¿Quién hizo algo diferente? [Señala a un estudiante y le pregunta] ¿Tú también mediste con una regla?
E5: Sí, pero medí lo de abajo para ver si […] tenía lo mismo de ancho.
C: Si tenía lo mismo de ancho… ¿Tú mediste el ancho, E7?
E7: Yo medí cuánto medía una rayita, pero se complicaba con la regla en los palitos y yo medí los seis cubitos con la regla y luego ver cuántos cabían en el ancho y en el largo.
C: Me puedes decir ¿qué mediste?¿Cuántos cubos están de largo en esa figura?
E7: De largo eran 7, de ancho eran 4 y de altura eran 6.
E5: De ancho son 5.
E3: Son 6.
C: 4, 5, 6… ¿Cómo vamos a saber?
[…]
C: Bueno, recuerden cuando lo hicieron por unanimidad, muchas veces nuestras reglas no son exactas […] [y se obtienen] diferentes medidas.
E7: A mí me dio 8 milímetros […]
E8: Midió un centímetro casi.
C: Un centímetro casi pero no exacto. […] Entonces vamos a tomarlas todas como de un centímetro; si es de un centímetro, E8 dime de cuánto va a quedar la medida a lo largo de ese prisma.

(Fragmento 1 de la sesión de Consuelo)

Como se ilustra en el diálogo, Consuelo considera la posibilidad de que el volumen que se está calculando no sea exacto sino aproximado y como unidad de medida, considera inicialmente el centímetro cúbico, aunque no lo explicita en sus acciones. La profesora conduce a los estudiantes hacia el uso de la regla para que por medio de un consenso, se defina la unidad de medida de longitud de la dimensión que está faltando, a partir de las longitudes conocidas y así poder calcular el volumen del prisma C.

Finalmente, Laura, hace un tratamiento diferente de la situación. Propone el uso de la unidad de medida que viene dada en la actividad y de un instrumento de medida usando dicha unidad.

L: […] ¿Cuántas medidas tiene […] la figura C?
E10: Una.
L: Nada más una ¿Qué podemos hacer para obtener la otra?
E2: ¿Multiplicando?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

L: ¿Multiplicando? Pero si no tenemos medida, ¿por qué lo vamos a multiplicar? [La profesora toma una hoja de cartulina, recorta una tira, la gradúa con la longitud de segmentos de una arista, la llama reglita y regresa con E10]. Vamos a medir la única medida que tenemos, la voy a marcar en esta reglita, esta va a ser mi reglita para medir las otras aristas. ¿Cuántas medidas tengo ahora?

E5: 3.

L: ¿Cuántas necesito para sacar el volumen? Pues nada más esas, entonces, ¿estaba muy difícil? Y ¿qué hicimos? Con nuestra reglita vimos cuántas veces cabe en cada una, ahora saquen el volumen. […] [E7 la coloca en su libro para medir una arista del prisma B, pero no sabe cómo utilizarla. La profesora muestra cómo hacerlo sobre una arista del prisma C diciendo:] Esta medida corresponde a lo que ya tienen ustedes, ¿Creen que les puede servir?

E7: No o ¿sí?

L: Ah, no sé, pues ve. […]

E7: 1, 2, 3, 4, 5, 6.

L: Ponle número para que no te equivoques. Ahora…¿Cuántas medidas te faltan? […]

E7: 1, 2, 3, 4, 5, 6, 7… ¿7?

L: 7 anótale ahí. Tienes tres medidas ¿Puedes sacar ya el volumen? […]

L: Si midió con regla, no se dio cuenta que esto no equivale a un centímetro, es menos de un centímetro, son como 8 milímetros [La profesora nuevamente saca su tira graduada] Por eso medí la misma que está marcada en el libro y la ocupé aquí y la ocupé acá. […]

<div align="right">(Fragmento 2 de la sesión de Laura)</div>

En contraste con Rocío, Laura usa otras estrategias para resolver el problema del cálculo de volumen del prisma C, construyendo un instrumento para hacer una medida directa de longitudes. Esto evidencia el uso adecuado de unidades de medida no convencionales (KCC).

Reflexiones finales

Al resolver problemas que involucran volumen emergen diferentes estrategias como uso de estimación, de dibujos, de representaciones con material concreto, uso de algoritmos, conteos, etc. Esta pluralidad de estrategias y su uso adecuado en la clase de matemáticas involucra conocimientos del profesor, tanto del propio contenido, y su relación con otros conceptos, como de su didáctica. Sin embargo, el trabajo realizado por Rocío y Consuelo evidencia un apresuramiento por una aproximación tridimensional del volumen, por el uso de la fórmula y de la unidad cm^3 (SCK y KCS), y evidencian dificultades para trabajar con unidades de medida no convencionales (KCC). Zevenbergen (2005) señala que este enfoque domina la mayor parte de las prácticas matemáticas escolares y en los programas de formación del profesorado, pues parece que "los adoctrinan en esta forma de trabajar" (p. 16). Además, como se mostró en los fragmentos de las tres profesoras, si no se tiene confianza en el conocimiento que se posee y cuando hay respuestas incorrectas, principalmente buscan resolverlas en un contexto aritmético y no geométrico. En este reporte se da cuenta de cómo analizar conocimientos matemáticos (o carencias) propios de su profesión como profesoras de matemáticas. Sin embargo, se requieren más investigaciones que fortalezcan la aproximación teórica para acceder a estos conocimientos.

A partir del análisis de las prácticas de las tres maestras, consideramos al igual que Zevenbergen (2005) y Aslan-Tutak & Adams (2015), que en los programas de formación inicial y continua así como de desarrollo profesional, se requiere de involucrar a los docentes en prácticas transformadoras donde la exploración y la compresión de los procesos sea el centro y no el obtener una respuesta correcta; donde el análisis de las actividades realizadas por los estudiantes sean analizadas a fin de reflexionar sobre sus aprendizajes; y tengan oportunidades para establecer conexiones entre distintos

conceptos geométricos (Bozkurt & Koç, 2012). Además de que desarrollen actividades en las que profundicen sus propios conocimientos geométricos.

The study of three-dimensional objects is undertaken in the Mexican curriculum throughout all levels of basic education. However, few studies relate to the mathematics knowledge needed to teach those ideas. This report represents an approach to the study of such knowledge. The approach is based on an account, developed from class observations, of three six grade teachers and their use of mathematics knowledge in teaching their students to calculate the volume of prisms, in two schools in Mexico City. The results provide evidence related to some sub-domains of mathematics knowledge for teaching. While there are some strengths related to this knowledge, teachers also showed that there is room for improvement. This speaks to the need to develop training spaces (both for pre-service and in-service teachers) where the analysis and discussions stimulate learning of both the geometric and pedagogical knowledge needed for teaching practice.

Keywords: Geometry and Geometrical and Spatial Thinking, Mathematical Knowledge for Teaching, Elementary School Education

Introduction

Geometry enables students to study figures within space and their relationships. Geometric space is built on the basis of empirical exploration of a real space that is taken to a geometric abstraction. In Mexico, teaching these ideas and, in particular, the study of three-dimensional geometry pervades the entire basic education curriculum (SEP, 2011). Aspects to be worked on include: "exploration of the characteristics and properties of [...] three dimensional shapes" and "knowledge of the basic principles of spatial location and geometric calculation" (p. 73). In these topics teacher mediation is key, thus the mathematics and pedagogical knowledge of teachers is essential as well.

Learning the volume of three-dimensional shapes is particularly difficult for students. Consequently, the relevance of teacher knowledge regarding this content is even greater, if possible, than that for teaching other content that is less difficult for students. Some of these difficulties are related to the close relationship between the notions of volume and capacity (Freudenthal, 1993; Saiz, 2002; Zevenbergen, 2005), the distinction between the mathematics and the physical concepts of volume (Saiz, 2002) and the importance of being able to visualize the concept in order to understand it (Gutiérrez, 1998).

Few studies have looked at elementary school teachers' knowledge of three-dimensional geometry (Aslan-Tutak & Adams, 2015; Tekin & Isiksa, 2013). Said studies underscore pre-service and/or in-service teacher difficulties related to conceptual and spatial skills. Thus Zevenbergen

(2005) states that pre-service teachers face similar obstacles as elementary school students, obstacles that are linked to the development of number sense, measurement and space. These are shortcomings that hamper their ability to identify errors among their students, associated for example with solving volume calculation problems. Teachers in training for elementary school state that, in their mathematics and teaching courses, they fail to develop a profound understanding of elementary geometry contents, while they recognize the importance of representations and visual skills in this area of mathematics (Aslan-Tutak & Adams, 2015). As for understanding 3D shapes, Dorantes (2008) points out the shortcomings in the knowledge of a group of teachers related to identifying characteristics of polyhedra, in terms of their edges, vertices and faces, exploring them through observation from different perspectives and calculating their volume. Such results coincide with those of other studies (Bozkurt & Koç, 2012; Saiz, 2002). In particular, Çakmak, Baş, Işık, Bekdemir, and Özturan (2015) finds that student definitions, examples and ways of solving problems are analogous to those used by their teachers in classrooms, and in many cases these methods are limited.

This report is part of a broader research project that seeks to identify and describe the *mathematics knowledge for teaching* evidenced by sixth grade teachers in teaching the volume of prisms (Moctezuma, 2015).

Geometric visualization, representations and volume of three-dimensional objects

Visual perception supports the learning of spatial geometry, because visual representations are an essential means of anticipation. According to research, such as Gal & Linchevski (2010), students tend to rely on visual information. The initial focus in geometry teaching relies more on the objects than on the processes, since the primary interest is on the figural properties as perceived by the senses and interpreted by mental reflection mediated by way of spatial representation. However, while any representation of a 3D shape highlights some features of the information, it hides others that may be difficult to retrieve for the person interpreting the representation. Del Olmo et al. (1993) explain that children's difficulties when measuring volume may originate from an absence of prior manipulation. They do not master spatial visualization given that they lack the ability to mentally manipulate rigid figures.

There are different ways of representing geometric objects for teaching purposes: in perspective, parallel, isometric, layered, orthogonal and nets of three-dimensional figures. Each of them requires learning conventions to interpret them, and developing skills to reproduce them (Gutiérrez, 1998). The types of representations used in the fifth and sixth grade textbooks (SEP, 2012)[i] for projecting cubes, prisms and pyramids are parallel and isometric projections, as well as nets. However, as will be shown below, teachers are unaware of such diversity between the different representations, which impacts their use in the classroom.

Mathematics knowledge for teaching prisms and volume in elementary school

Characterization of knowledge for teaching is based on the ideas of "Pedagogical content knowledge" (PCK) as presented by Shulman (1986) and later specified in greater detail in the case of mathematics, in the sub-domains of Mathematics Knowledge for Teaching (MKT) by Ball, Thames, and Phelps (2008). The latter authors differentiate between two domains: *subject matter knowledge* and *pedagogical content knowledge.* The former domain includes content that the teacher is teaching, as well as its foundations. It is subdivided into *Common Content Knowledge* (knowledge of a person instructed in that content) (CCK[ii]), *Specialized Content Knowledge* (content knowledge that distinguishes teachers) (SCK) and *Horizon Content Knowledge* (an awareness of how mathematics topics are related across the span of mathematics in the curriculum) (HCK). *Pedagogical content knowledge* includes knowledge possessed by the teacher with respect to teaching the content, learning and school curriculum. *Knowledge of Content and Students* (KCS) is the combination of

content comprehension together with knowing what students can think or do in mathematics. It involves identifying previous concepts and anticipating likely learning difficulties that students may face, as well as misconceptions regarding mathematics content. *Knowledge of Content and Teaching* (KCT) combines content comprehension and familiarity with pedagogical principles so as to teach that content. Finally, *Knowledge of Content and Curriculum* (KCC) include teacher knowledge of mathematics as a subject, which includes its structure, and the learning that students are expected to achieve upon completion of their elementary education.

The question addressed in this report is: What mathematics knowledge for teaching is put into practice by teachers as they give a lesson on the volume of prisms in sixth grade?

Methodology

This research follows a qualitative approach with a descriptive scope. The main data are derived from the classroom practice of three teachers (who participated voluntarily), as they teach mathematics content related to the volume of prisms.

The research was conducted between 2014 and 2015 in two public elementary schools located in the outlying areas of Mexico City. The teachers taught all sixth grade subjects, including mathematics. All three teachers had more than 25 years of teaching experience and were graduates of a teacher-training college. Consuelo (C) is an expert in fifth and sixth grade, while Laura (L) and Rocío (R) have taught first through sixth grades[iii] (all names are pseudonyms). The three teachers had taught the sixth grade subjects for two years prior to this research. The study group was chosen intentionally, and the subjects' practice was followed over the course of several class sessions, during which the topics addressed in class related to three-dimensional geometry (this report focuses solely on a lesson related to the volume of prisms).

Fieldwork took place at different times of the school year over a period of thirteen months. The lessons were videotaped and transcribed. Three instruments were used in order to collect as much information on teacher knowledge as possible: non-participatory observations of different lessons, a field diary and a semi-structured interview (the latter for the purpose of supplementing the information obtained during the observations).

The observer used preset categories for analysis of the lessons observed. The categories are based on the description of the subdomains of MKT and their solidification into indicators as designed by Sosa (2011). The categories were adapted to the elementary level and specific content to be analyzed. The researchers refined the categories during the research process until the final indicators were obtained.

In the textbook, the lesson entitled "How many cubes are in the prism?" consists of four activities (SEP, 2012, pp. 162-163). Here we will focus on the first two, in which the students have to calculate the volume of four rectangular prisms from the amount of cubic units on the edges (Figure 1.a). In prisms A and B, the three dimensions (length, width and height) are identified and cubic units are shown; while in prism C some ticks are shown that allow the students to infer the measurement of the length of just two of the prism edges (Figure 1b).

In an a priori analysis of the lesson, the researchers identified a transition from a one-dimensional treatment of volume (using a cube as the unit of measurement) to a three-dimensional treatment (calculated using length, width and height), even if the title of the lesson highlights the former. Moreover, in the third activity the notions of volume and capacity are addressed.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figure 1. Activities proposed for working with volume of prisms (SEP, 2012, pp. 162-163)

Knowledge put into action. Description of findings and discussion

Two aspects of interest arose concerning teacher knowledge during our analysis of the three sessions observed, namely: a) the one/tridimensional treatment of volume, and b) how to calculate the unknown length of one of the edges in case C of activity 2.

One of the teachers, Rocío, treats volume in all the activities from a tridimensional perspective. As such, the last question raised in activity 2 becomes useless ("What is the fastest way to calculate the volume of a prism?"). From the very beginning, Rocío locates the length, width and height of each prism as a necessary step to calculate prism volume, as follows:

Rocío (R): Remember to take into account the three dimensions that we talked about, calculate the volume […] the number of prisms that those figures have, the number of units […]

R: […] How many units are there? Here [figure 1.b, section A] at the base. The width is 6, the length is 6 and the height is 6. So we multiply 6 times 6 times 6 and we get 216 […] In figure B, what are the base [sic], length, and width? […] What are the measurements? […] What is the length?

E8: 6 times 9.

R: […] We multiply 9 times 6, […] 54… 54 times 6 […] 324. [The teacher writes 324 cm^3 on the board].

(Fragment 1 from Rocío's session)

Rocío does not explicitly distinguish between the one-dimensional and the three-dimensional treatments for calculating prism volume. It would seem that she does not mark the differences between both treatments of volume, nor does she perceive the need for working with the one-dimensional perspective first so as to justify the tridimensional perspective, given its practical advantages; nor does she perceive the incidence of that sequence on comprehension of the volume magnitude.

However, Laura makes it possible for her students to calculate the volume of the prisms in activity 2, using the procedure the students deem appropriate. Hence, two different procedures arise. The first uses a unit of volume, while the second uses the length of the edge and the three-dimensionality of the prism.

Laura (L): [Reads] Complete the prism, do we need to complete it? [...]

E5: Yes.
L: Fill them with cubes?
E5: No.
L: What do you think, E7, [...] Let's see, do we need to complete the prisms?
E7: We can also multiply.
L: Multiply, what were you doing?
E7: I was multiplying the length of the base times height, and then times width.
L: [...] And what were you doing? [Addressing E8]
E8: Counting them.
L: Counting the cubes [...] Complete. Everyone has his or her own method of obtaining the volume.

(Fragment 1 from Laura's session)

The students refer to both the one-dimensional and the three-dimensional treatments for obtaining the volume, while the teacher gives them the freedom to apply the method they prefer. It seems that Laura implicitly distinguishes between the one-dimensional and the three-dimensional procedures for calculating prism volume (SCK), although she does not appear to specify the one-dimensional treatment with as much insistence as she does with the three-dimensional treatment.

One of the most difficult aspects of the lesson relates to activity 2 (Figure 1b). Representation of prism C does not enable a visual inference of the length of one of its edges. The discussion that arises in class relates to the unit of measure. In the three sessions, different ways of guiding this situation are observed, and this can be taken as different manifestations of MKT of these teachers. The knowledge relates to the role of the unit in the process of measuring and its conceptualization (SCK); knowledge of the possibility of using unconventional measurement units (KCC); the difference between measurement, unit, instrument and measurement procedure (SCK) and typical student misconceptions on the subject (KCS); student difficulty in recognizing and using unconventional units and instruments (KCS); and the approximate nature of the measurement (SCK).

Rocío does not seem to be sufficiently aware of the role of the unit in the measurement process and its conceptual role in the notion of measurement (SCK), as well as of the difficulties triggered amongst the students (KCS). Thus, to solve the problem that arises when calculating the volume of prism C (activity 2), she decides to measure using a ruler:

R: [Addressing a student] Lend me your ruler. [She uses it to measure in her book]
E7: 1 centimeter is two cubes.
E5: There are 5 centimeters.
E8: There are 6.
R: Yes, it is half a centimeter. So each of the sides is half a centimeter. So, if I measure… Who said that 11? It's 11 [...]
R: 11 times 8? [The teacher continues to measure] Height is 10, pay attention: it is 5 centimeters, each of the units represents half a centimeter; it is 10 units. Measure it with your ruler. Each unit represented in the textbook measures half a centimeter. The cubes measure half a centimeter.
 [...]
R: Remember that in this cube that is, that in this prism represented here, we have the length, width and height. The length is 11.
E8: It is 11 times 10 times 8, then… [The teacher nods to show approval]

(Fragment 2 Rocío's session)

Rocío discards the length measurements already given in the prism (according to the unit given) and measures each of the dimensions (length, width, and height) with a ruler. She uses the centimeter as a

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

unit for measuring length, establishing equivalence between the centimeter and the unit of length given in the activity (half a centimeter). The representation given in the activity shows that the prism is 5 units wide and 6 units high; the length is unknown. The teacher's measurement results are 4 centimeters wide, 5.5 centimeters long and 5 centimeters for the height. She translates this into 8 for the width, 11 for the length and 10 for the height. She decides to take a different unit of length measurement than what is provided in the textbook and does not make it clear to the students that she has changed the length unit for the three dimensions of the prism in order to calculate the volume. Moreover, the choice of the unit and the length measuring instrument used may lead us to assume that she is not taking into consideration a possible student misconception, in which the student assumes that in order to measure (a length) it is necessary to use the metric system (in this case cm) and conventional instruments (KCS).

Consuelo also resorts to use of a conventional ruler (graduated in cm) to resolve the situation:

Consuelo (C): […] What did you do to take the measurements of the prism in C?
Student 9 (E9): I measured with a ruler.
C: […] Who did something else? [She points to a student and asks the student] Did you also measure with a ruler?
E5: Yes, but I measured the bottom part to see if […] it had the same width.
C: If it had the same width… Did you measure the width, E7?
E7: I measured the length of one little line, but it was complicated with the ruler on the lines, and I measured the six little cubes with the ruler and then saw how many of them fit into the width and the length.
C: Can you tell me what you measured? How many cubes are there lengthwise in that figure?
E7: Lengthwise, there are 7, 4 on the width and 6 on the height.
E5: The width is 5.
E3: There are 6.
C: 4, 5, 6… How are we to know?
[…]
C: Well, remember when you did it unanimously, often our rulers are not precise […] [and] different measurements [are obtained].
E7: I got 8 millimeters […]
E8: It measured almost a centimeter.
C: Almost a centimeter, but not exactly. […] So, let's take them all as [if they were] one centimeter; if it is one centimeter, E8, tell me how much it will be lengthwise for the prism.

(Fragment 1 Consuelo's session)

As illustrated in the dialogue, Consuelo considers the possibility that the volume being calculated may not be precise, but rather approximate; and initially, she considers the cubic centimeter as a unit of measure, although she does not make this explicit though her actions. The teacher encourages her students to use the ruler so that, by consensus, they define the unit of measure for the unknown length, based on the known measurements so as to calculate the volume of prism C.

Finally, Laura treats the situation differently. She proposes to use the measurement unit given in the activity and use of a measurement instrument that uses that same unit.

L: […] How many units does […] figure C have?
E10: One.
L: Just one. What can we do to get the other one?
E2: Multiplying?

L: Multiplying? But, if we do not have the measurement, what are we going to multiply it by? [The teacher takes a piece of cardboard, cuts a strip, graduates it with segments equal to the ones that are marked on one of the edges, and calls it "the little ruler". Then, she turns back to E10]. We will measure the only measurement that we have and I'll mark it on this "little ruler". It will be my little ruler to measure the other edges. How many measurements do I have now?

E5: 3.

L: How many do I need to calculate the volume? Just those ones; so, was it very difficult?

And what did we do? With our little ruler we saw how many times it fits into each one, now calculate the volume. […] [E7 puts it on her textbook to measure an edge of prism B, but does not know how to use it. The teacher shows the student how to do it on an edge of prism C, and says:] This measurement corresponds to what you already have; do you think this can be useful to you?

E7: No or yes?

L: Oh, I don't know, you have to check […]

E7: 1, 2, 3, 4, 5, 6.

L: Put numbers in so that you don't make a mistake. Now… how many units are you missing? […]

E7: 1, 2, 3, 4, 5, 6, 7… 7?

L: 7, write it down there. You have three measurements. Can you obtain the volume now? […]

L: If you measured with a ruler, you did not realize that this is not equivalent to one centimeter. It is less than a centimeter. It is about 8 millimeters. [The teacher again pulls out her graduated strip.] That is why I measured the one marked on the textbook and used it here and used it there […]

<div align="right">(Fragment 2 Laura's session)</div>

As opposed to Rocío, Laura uses other strategies to solve the problem of calculating the volume of prism C, by building an instrument to make direct length measurements. This demonstrates the proper use of unconventional units of measure (KCC).

Final Thoughts

When solving problems that involve the notion of volume, different strategies emerge, such as estimating, use of drawings, representations using concrete material, algorithms, counting, etc. This plurality of strategies and their appropriate use in mathematics class involve teacher knowledge, both of the content itself and its relationship with other concepts, as well as its didactics. However, the work done by Rocío and Consuelo shows a hastening to use a three-dimensional approximation of the volume, use of the formula and of cm^3 as the unit (SCK and KCS). Moreover, working with unconventional units of measure (KCC) proves difficult for them.

Zevenbergen (2005) points out that this approach permeates most school mathematics practices and teacher preparation programs, because it seems that they "indoctrinate them in this way of working" (p. 16). In addition, as shown in the three teacher fragments, if the teacher is not confident of the knowledge she possesses, then when wrong answers come up the teacher primarily seeks to solve the problems within an arithmetic rather than a geometric context. In this report, the authors illustrate how to analyze mathematics knowledge (or a lack thereof) *per se* that pertains to their profession as mathematics teachers. However, more research is needed to strengthen the theoretical approach to access that knowledge.

From the analysis of these three teachers' practices, we agree with Zevenbergen (2005) and Aslan-Tutak and Adams (2015) in that initial and lifelong teacher preparation programs and in professional development, teachers need to be involved in transformational practices where exploration and

understanding of the processes are the core, rather than finding the right answer; where student activities are analyzed in order to reflect upon their learning; and where they have opportunities to make connections between different geometric concepts (Bozkurt & Koç, 2012); in addition to their being able to carry out activities that deepen their own knowledge of geometry.

Endnotes

[i] In Mexico, primary education is free and compulsory. To this end, the Ministry of Public Education (SEP) generates materials such as free textbooks for the students and teacher guides, which are mandatory for all primary schools.

[ii] We will use the acronyms in English: SCK (Specialized content knowledge), KCS (Knowledge of Content & Students), KCT (Knowledge of Content & Teaching), KCC (Knowledge of Content & Curriculum).

[iii] The teachers' ages are: Rocío is 53, Laura is 55 and Consuelo is 59 years old.

EXTENDING HORIZON: A STORY OF A TEACHER EDUCATOR

Rina Zazkis   Ami Mamolo
Simon Fraser University   University of Ontario Institute of Technology
zazkis@sfu.ca   ami.mamolo@uoit.ca

We present a story of a teacher educator's response to a 'disturbance' and describe how her experience enhanced her personal mathematical knowledge and influenced her teaching. In our analysis we attend to different levels of awareness that support a teacher educator's work and illuminate the qualities of a teacher educator's knowledge, in particular, knowledge at the mathematical horizon.

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge, Advanced Mathematical Thinking

Numerous studies on mathematics teacher development have demonstrated that mathematics teachers learn through their teaching experiences (e.g., Leikin and Zazkis, 2010). This learning is multi-faceted and includes personal pedagogical growth, gaining further insights into students' thinking, learning about the feasibility of various instructional approaches, learning about implementing new curricula or technological tools, as well as enhancing personal mathematics. We extend this research on teachers' "learning through teaching" by focusing on a teacher educator, a teacher of teachers.

FOCUS ON TEACHER EDUCATORS

Research on the work of teachers of mathematics has devoted significant attention to teachers' knowledge and its various facets. Consequently, research on the work teacher educators follows suit (e.g., Jaworski, & Wood, 2008). This is evident, for example, in the working session at the International Group for the Psychology of Mathematics Education Conference on "Mathematics teacher educators' knowledge" (Beswick, Goos & Chapman, 2014.) Within multifaceted discussions on educators' knowledge, our focus is on personal mathematical knowledge in the work of teaching (Watson & Chick, 2013). In addition to knowledge of a teacher, personal mathematical knowledge of a teacher educator includes the ability to mobilize his/her knowledge in supporting teacher development. In particular, this support includes task design aimed at enhancing teachers' mathematical and pedagogical knowledge (Liljedahl, Chernoff & Zazkis, 2007). Particular qualities of teacher educators' knowledge that enable task design in support of teacher development, and how this knowledge develops and manifests, continue to be open areas for investigation.

THEORETICAL CONSTRUCTS

To gain insight into a teacher educator's personal mathematics knowledge, how this can develop through the act of teaching and the subsequent implications for teaching, we rely on an integration of two theoretical perspectives: Mason's *levels of awareness* (1998), and an extension of the notion of *knowledge at the mathematical horizon* (Zazkis & Mamolo, 2011).

Levels of Awareness

According to Mason (1998), awareness in and for teaching has 3 three different forms:

- *Awareness-in-action*: the ability to act in the moment. This level of awareness in teaching is recognized when a teacher poses a certain question, corrects a mistake, suggests an answer or selects a task, but is unable to justify or explain his/her choice.

- *Awareness-in-discipline*: awareness of awareness-in-action. This awareness is essential in order to articulate awareness-in-action for others. According to Mason, the one important distinction between the two kinds of awareness involves the ability "to do" in contrast with the ability to instruct others. Teachers who possess awareness-in-discipline are able to articulate the choices they make in instructional situations.
- *Awareness-in-counsel*: awareness of awareness-in-discipline. This awareness is essential in order to articulate awareness-in-discipline for others. It describes one's sensitivity to what others require for building or enhancing their awareness.

Each form of awareness may refer to being explicitly or potentially aware, where the former emerges from the latter by noticing change (shifts of attention). Thus, if we wish (and we do) that mathematics teachers are able to articulate the choices they make for pupils in instructional situations (awareness-in-discipline), then a teacher educator must develop sensitivity to what may foster awareness-in-discipline for her students (and so possess awareness-in-counsel).

Knowledge at the Mathematical Horizon (KMH)

As an extension of Ball and Bass' (2009) notion of horizon content knowledge, KMH is identified by Zazkis and Mamolo (2011) as a teacher's use of mathematical subject matter knowledge "beyond" the requirements of school curricula in a secondary or elementary school teaching situation. Ball, Thames, and Phelps (2008) describe horizon knowledge as "an awareness of how mathematical topics are related over the span of mathematics included in the curriculum" (p. 403). This notion was developed by Ball and Bass who focused on teachers' knowledge of "students' mathematical horizons."

Zazkis and Mamolo (2013) extended the notion to teachers' horizons by making a connection to Husserl's philosophical description horizon, which relates to an individual's focus of attention. In particular, when an individual attends to an object (be it conceptual or physical), the focus of attention centers on the object and (some of) its properties, while the 'rest of the world' fades to the periphery and thus exists in the object's horizon (Follesdal, 2003). A teacher's horizon knowledge can therefore be interpreted as an awareness of a mathematical object's periphery, and can be characterized by a flexibility in focus of attention such that relevant properties, generalities, or connections, which embed the object within a greater mathematical structure, are accessed in teaching situations. A teacher's KMH is influenced by her propensity for exploring and studying new (for her) mathematics; teachers of different (school) levels may have vastly different objects of focus, different senses of the mathematical 'landscape', and thus different breadths to their horizons.

We draw a link between a teacher's KMH and Mason's notion of awareness-in-discipline, as knowledge of how mathematical topics are related as per their specific properties or underlying general structure provides a basis for understanding and articulating mathematical choices made in teaching. When considering a teacher educator's KMH, we note that both the objects of focus and the breadth of horizon extend beyond the awarenesses of the mathematics teacher. In what follows, we seek to refine the notion of KMH to suit studying the work of mathematics teacher educators.

Research question: How can the work of a teacher educator be explained in terms of levels of awareness and knowledge at the mathematical horizon?

THE STORY IN TWO ACCOUNTS

In presenting our story of Naomi – an experienced teacher educator, who has taught both content and methods courses in mathematics education – we follow Mason (2002) in distinguishing between *account-of* and *accounting-for*. The term *account-of* refers to a brief but vivid description of the key elements of the story, suspending as much as possible emotion, evaluation, judgment or explanations. This serves as data for *accounting-for*, which provides explanation, interpretation, value judgement

or theory-based analysis. Naomi, the main character of our story, is an amalgamation of the authors' experience. This is consistent with the narrative inquiry methodology, where "narrative inquiry is aimed at understanding and making meaning of experience" (Clandinin & Connely, 2000, p. 80).

Account of

Naomi's class of prospective elementary school teachers, working on conversion of square units, considered the following "area problem":

> *An architect is building a model of a park, in which every 10 meters are represented by 3 centimeters. There is a lake in a park. The area of the lake is 7200 square meters. What is the area of the lake in the model?*

The problem and its solution scheme paralleled a task that was previously discussed and resolved in class. The approach in class had been to build a proportion to solve the problem, and Naomi expected students to do the same in this case. The solution scheme for the task suggested:

> *Since 10 m are represented by 3 cm, then 100 m^2 are represented by 9 cm^2.*
> *Possible proportions useful for solving the problem include:* $\frac{7200}{x} = \frac{100}{9}$ *or* $\frac{7200}{100} = \frac{x}{9}$,
> *which yield as a final answer:* $x = 648$ *cm^2.*

While Naomi expected students to note the relationship that 100 square meters are represented by 9 square centimeters and use this for resolving the problem, not all students took that approach. Mikey, for instance, composed a different solution:

> *7200 = 80 × 90*
> *if 10 meters = 3 cm, then*
> *80 meters = 24 cm*
> *90 meters = 27 cm*
> *Then, 24 × 27 = 648, so the area of the lake on the model is 648 cm2.*

Naomi recalled the following conversation with Mikey:

Naomi: Mikey, please explain how you got your answer.
Mikey: If the lake had length of 90 meters and width of 80…
Naomi: Did you know the shape of the lake?
Mikey: So if it were a rectangle…
Naomi: Have you ever seen a rectangular lake?
Mikey: I pretended it was, and I got the correct answer.
Naomi: And what if it were a different rectangle, would you get the same answer?
Mikey: I have not checked, but this one worked.

Upon additional prompting, Mikey could not explain why his approach was appropriate; "it worked" seemed to be a sufficient reason to accept its correctness. Naomi, unsure at that moment how to explain the situation, diverted the issue, pointing out that Mikey's representations were inappropriate and that the equality sign in the presented solution was repeatedly misused (such as in claiming "*10 meters = 3 cm")*.

Upon reflection, Naomi realized why assigning random measures results in a correct answer. One can think of the shape in the model as an image of the shape of the lake under the transformation of dilation/scaling. This transformation preserves area-relations in a way that equal area shapes are always transformed to equal area shapes. This invariance under transformation is why the student's solution resulted in a correct answer: It calculated the area of a particular scaled shape, and this area is invariant across all the shapes that are images under dilation of the shapes with the same area. While this understanding of mathematical structures was accessible to Naomi, it was not immediate

and it did not seem evident in her teacher candidates, and as such she saw the 'incident' as an opportunity to develop related knowledge among her prospective secondary mathematics teachers.

Naomi developed a task in which she presented a problem and a solution, similar to that of Mikey's, and asked her students to imagine how a conversation between a teacher and student addressing the problem could continue, and to present it in a form of a scripted dialogue. Furthermore, Naomi invited her students to include commentary on how they personally understand the situation and to explain it to a "mathematically mature" colleague. These invitations were aimed at directing possible shifts of attention amongst teacher candidates' that could foster awareness-in-discipline as they attempted to articulate why specific instructional moves were made.

The scripts produced by prospective teachers served as a springboard to class discussion. This included consideration of a variety of pedagogical approaches, but focused on why the student's solution resulted in a correct answer. (A precise mathematical reason was absent in the scripts). Naomi introduced the concept of transformations of dilation/scaling using the dynamic geometry software Geometer's Sketchpad. (The software was familiar to the students, but the particular transformation was not). Her students used the software to explore the features of this transformation, including its invariants.

Accounting for (or Analysis)

Naomi's encounter with Mikey elicited for her a moment of disturbance – it was an unexpected solution and one for which she could not come up with an immediate and satisfactory, at least for herself, rebuttal. In response Naomi revisited the mathematics herself and in doing so, her awareness was broadened on two counts – first with respect to the aforementioned mathematical connection, then with respect to the pedagogical value of addressing such an interpretation as Mikey's.

As a teacher of mathematics, has Naomi learned mathematics as a result of her encounter with the unexpected student solution? After all, she was sufficiently familiar with the transformation of dilation in order to explain the phenomenon mathematically. The situation is similar to that described by Leikin and Zazkis (2010) in which teachers are hesitant to admit learning mathematics through teaching. Often their inability to use relevant mathematics in an instructional situation was explained as "I knew this, but have never thought about it". We agree with Leikin and Zazkis in their claim: "we consider anew "thinking about it" – when an instructional situation presents such an opportunity – as an indication of learning. In this case LTT [learning through teaching] can be thought of as transferring existing knowledge from teachers' passive repertoire to their active one" (p.19).

In Naomi's case she drew a connection between modeling tasks and particular geometric transformations, notions that were not explicitly linked for her before the experience of disturbance. This new connection highlights a change in Naomi's KMH: it broadens the periphery of the modeling task to include connections to the (initially) seemingly disparate topic of invariance under dilation. Knowledge of such connections corresponds to knowledge of major disciplinary ideas and structures and as such instantiates one of the elements of Ball and Bass's (2009) conception of horizon knowledge. Further, it embeds the particular mathematics originally at Naomi's focus of attention (conversion of square units) within a broader mathematical world. It was her awareness of the 'broader world' which allowed her to articulate for herself and her students why the particular features of the geometric transformation of dilation allow the random assignment of convenient measures to lead to a correct result.

This situation illustrates how knowledge beyond the specific curricular requirements is pertinent to mathematics teaching. A teacher's personal mathematical knowledge provided a deeper appreciation of the mathematics at hand, as well as a broader view of the salient features of the content. The technique of applying a transformation or mapping that preserves certain properties allows an individual to shift from working in a potentially unfamiliar space to one in which known properties aide in resolving the problematic situation. Such values and sensibilities, typically

acquired in advanced mathematics courses at the undergraduate and graduate levels, embed particular topics or concepts within a broader, more general, mathematical world, and as such are included within a mathematical object's outer horizon. These sensibilities correspond to the habits of thoughts and methods of resolutions that Mason attributed to *awareness-in-discipline.* They provide insight into why certain relationships are true and aide in the articulation of said truth.

The goals of the "area problems" were focused on appropriate conversion of square units, building proportions and developing proportional reasoning and computational relationships. The moment of disturbance provoked a shift in attention, redirecting Naomi's line of vision towards alternative mathematical ways of reasoning with the task. This shift enabled a formal resolution and it illustrated not only the facts and techniques of the discipline of mathematics, but also the "habits of thought, forms of fruitful questions, and methods of resolution of those questions" (Mason, 1998, p. 259) characteristic of awareness-in-discipline. However, in developing awareness-in-counsel, as a teacher educator, Naomi's aim is to share this interesting link with prospective teachers and in turn support their own development of awareness-in-discipline.

As a teacher educator, Naomi developed a task for prospective teachers, which has both mathematical and pedagogical value. We suggest that it was Naomi's awareness-in-counsel that invited her to reflect on the contingency of the situation as one which would be of benefit in preparing teacher candidates and in turn she developed an activity that could help broaden her students' perspectives. As Mason put it, awareness of awareness-in-discipline "is what supports effective teaching of that discipline" and allows "for structuring tasks and encounters from which [students] can learn" (1998, p. 260). In what follows, we offer an account-for that attends to Naomi's awarenesses of the discipline of mathematics-teaching.

In particular, clearly, the immediate goal for prospective teachers was to imagine an interaction with a student and present it in the form of a dialogue. In doing this, the prospective teachers considered their pedagogical response to a mathematical dilemma presented by the student's solution. However, Naomi's goal extended beyond involving teachers in playwriting. She considers the task as a vehicle for (1) extending personal mathematical experiences of teachers beyond the prescribed curriculum by drawing stronger connections between various topics in mathematics (e.g., units conversion and transformations); and (2) anticipating possible solutions and evaluating potential reactions to those. Both of these goals connect to fostering teachers' KMH – broadening the peripheral vision of teachers as they focus on particular mathematical objects by connecting the objects both to other mathematical topics, as well as to how students could interpret and reason with those objects based on their prior learning experiences.

The scripting task builds on growing research which attends to various pedagogical motivations for involving students in playwriting (e.g., Zazkis, Sinclair, & Liljedahl, 2013; Zazkis & D. Zazkis, 2014). The benefits of this approach were summarized for prospective teachers, for researchers and for teacher educators (ibid.). Focusing on the latter, the scripts or plays written by prospective teachers can be used as a tool for teacher development. In particular, the scripts can be used to discuss and highlight appropriate pedagogical approaches, to direct further attention to learners and their thinking, and to shift prospective teachers' thinking about preparation to instruction, beyond the traditional "lesson plan". These activities nurture shifts in attention that may raise teachers' awareness of the contingent nature of teaching while providing them with experiences from which they may later draw when responding to unanticipated scenarios.

In an attempt to foster awareness-in-discipline (of mathematics) for her students, Naomi set a task that could provoke a similar disturbance in others and thus trigger a shift in their awareness. Such tasks are intended to "provoke students into rehearsing or exercising skills, but which at the same time attract their attention away from the skill to be automated" (Mason, 1998, p. 259). The skill of responding to student interactions (with appropriate pedagogical sensitivities and strategies)

was to be rehearsed through the particular task developed by Naomi, but attention was meant to be attracted by the unexpected mathematics.

Naomi's use of scripting tasks exemplifies her awareness-in-counsel of the benefits for preparing teachers in this way – the essential awareness for enhancing the awarenesses of others manifested in the design and development of the task, as well as in the follow up task and discussion. In addition, this particular task developed by Naomi not only invites teachers to examine their approaches to a student solution, but also invites them to revisit their personal mathematics and think mathematically in an unfamiliar situation.

The scripting approach allows the discussion to revolve around the particular approaches presented by the group of prospective teachers. Without singling out a particular student, Naomi initiates a discussion by presenting several different approaches from the scripts and inviting a reaction. The 'scripting-first' tactic provides all students with an opportunity to think and rethink their reaction. This usually does not happen in a whole-class discussion, where the first speakers may influence the ways others consider the task. Further, this opportunity to think and rethink the reaction does not have time constrains. The students may consult any resource or each other, should they choose to do this. This an important difference between script-writing and role play, where the player has to "think on her feet", rather than provide a thoughtful and possibly adjusted response. The time to provide a thoughtful response to a moment of contingency, as a structural aspect of the scripting task, creates space for deeper mathematical engagement – and thus enhancement of teachers' KMH – than is afforded by role play activities. The opportunity to imagine and re-imagine a teaching scenario is geared towards enhancing teachers' noticing, both by completing the task as assigned as well as considering the approaches of classmates in the subsequent classroom discussion. Structuring a task such that students are provided with such an opportunity again shows Naomi's awareness of what are important encounters from which to develop knowledge at the mathematical horizon.

Thus, Naomi's response to a disturbance, coupled with her choice to draw to the attention of her prospective teachers the contingent nature of teaching, illustrates the awareness-in-counsel of a teacher educator.

AWARENESS OF HORIZON OF TEACHER EDUCATORS

When Mason (1998) identified different levels of awareness, the intended discipline in his descriptions was the discipline of mathematics. In our analysis of the work of a mathematics teacher educator we point to yet another discipline – that of mathematics-teaching. With this view, a teacher educator's awareness-in-counsel, which is the awareness that is employed to develop mathematics teachers' awareness-in-discipline (of mathematics), can also be described as the teacher educator's awareness-in-discipline of mathematics-teaching. This awareness results in the development of mathematically salient scenarios that could provoke a moment of disturbance for prospective teachers. We turn our attention now towards the mathematical knowledge required to notice and appreciate such saliency.

We suggest that it is the knowledge at the mathematical horizon of teacher educators (KMHTE) that includes knowledge of what mathematics will catch the attention of prospective or practicing teachers and provoke a disturbance that enables the shifts of attention required to develop their own horizon knowledge (KMH). The disturbance which shifts attention must also provide an invitation to extend the mathematical awareness of teachers in connection to what is applicable for students. It must provide opportunities for teachers to respond without readily available routines and thus incite a shift from awareness-in-action to awareness-in-discipline. At the focus of attention for Naomi is both the specific mathematics content, as well as its contextualization in student/teacher thinking. At the periphery of Naomi's attention is the horizon, accessible via her awareness-in-counsel.

Analogously to a teacher's KMH, we suggest that a teacher educator's KMHTE may be described as having both an inner horizon and an outer horizon. As before, we conceptualize horizon

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

as the connections, features, and generalizable properties related to an object of thought and which embed that object within a greater structure. At the inner horizon are features of that object, which are specific to it, yet not at the focus of attention. At the outer horizon are the major disciplinary ideas, practices, and underlying structural components which situate the particular within the general. With respect to KMH, the object of focus is mathematics and as such the features, ideas, practices, and structures of the horizon are also mathematical.

For KMHTE, the object of focus is student/teacher thinking about mathematics, and as such, the features, ideas, practices, and structures of the horizon include a breadth and complexity not already encompassed by KMH. Awareness-in-counsel broadens a teacher educator's ability to direct (and retain) teachers' attention toward mathematical connections and structures, such that they enhance both their mathematical understanding, as well as their abilities to convey relevant aspects of this understanding to (and for) their future students.

CONCLUDING REMARKS

A mathematics teacher educator's disciplinary knowledge is multi-faceted and complex. It combines awareness of pedagogical practice, of mathematical content and processes, of the cognitive, social, affective, and environmental factors associated with thinking and learning. Indeed, an exhaustive list of the "required" knowledge for mathematics teacher education would be near impossible. We focused our attention on the personal mathematical knowledge of an experienced mathematics teacher educator and described how this knowledge was triggered and further developed. Inasmuch as mathematics may not be separated from mathematics pedagogical knowledge, mathematics may not be separated from mathematics education pedagogical knowledge – it is an essential component of the knowledge required to foster the professional growth of the individuals tasked with the responsibility of supporting students in their learning of mathematics.

Various researchers have suggested that teachers' personal mathematical knowledge makes a difference in their ability to plan for instruction (e.g., Watson & Barton, 2011) as well as respond to teaching situations in general, and situations of contingency in particular (e.g., Chick & Stacey, 2013; Rowland, Huckstep, & Thwaites, 2005; Watson & Chick, 2013). We extrapolate that this suggestion is also applicable for teacher educators. The main difference, however, is that the 'students' of a teacher educator are (in our case prospective) teachers, and therefore the teaching situations adhere to the learning of teachers. With this in mind, we illuminated some of the qualities of a teacher educator's mathematical knowledge for teaching – specifically, knowledge at the mathematical horizon – and her extended awarenesses.

REHEARSALS OF TEACHING: ATTENDING TO MATHEMATICAL KNOWLEDGE FOR TEACHING

Hala Ghousseini
University of Wisconsin-Madison
ghousseini@wisc.edu

Sarah Lord
University of Wisconsin-Madison
salord@wisc.edu

We investigate how pedagogies of enactment that simulate the work of teaching, like rehearsals, afford practice-based work on mathematical knowledge for teaching (MKT). The analysis of 30 rehearsals from elementary methods courses shows that the teacher educator supported teachers' learning of MKT inside problem spaces emerging in the process of eliciting and representing student ideas, and through four types of interventions that helped novices consider aspects of their performance in relation to the mathematics and student learning.

Keywords: Mathematical Knowledge for Teaching, Teacher Education-Preservice

Research in mathematics education has established that high quality instruction requires mathematical knowledge for teaching (MKT). Ball, Thames, and Phelps (2008) describe MKT as the mathematical reasoning, skills, and understanding that are involved in various tasks of teaching. They identified a number of distinct domains of MKT, including: (a) common content knowledge (CCK), (b) specialized content knowledge (SCK), (c) knowledge of content and students (KCS), and (d) knowledge of content and teaching (KCT). CCK includes, for example, fluency with standard computational techniques. SCK is mathematical knowledge that is particular to teaching, such as choosing and using mathematical representations. KCS combines knowing about students with particular understandings about mathematics. KCT combines knowing about pedagogical issues that affect learning and specific mathematical understanding. In mathematics teacher education there has been increased awareness of the importance of MKT for novice teachers. Scholars have argued that to be effective, teachers not only need to *have* MKT but also learn it *for use* in the dynamic interplay of content with pedagogy in teachers' real-time problem solving (Ball & Bass, 2000). However, teaching MKT remains a challenge for teacher educators precisely because the nature of this knowledge is intertwined with practice, and requires supporting teachers in being able to use it adaptively in various situations.

In supporting novice teachers (NTs) to learn the complex work of teaching, some current approaches to teacher education employ pedagogies of enactment (Grossman & McDonald, 2008) that focus teacher learning on a set of principled instructional practices derived from research on student learning and professional standards. However, given that research on the nature of these pedagogies is in its early stages, it is still unclear how these practice-focused approaches to teacher learning can attend to the development of MKT. This study investigates this problem in the context of *rehearsals*—a teacher education pedagogy that approximates the actual work of teaching (Grossman et al., 2009) by engaging NTs in the deliberate practice (Ericsson, Krampe, & Tesch-Römer, 1993) of well-specified instructional activities with targeted coaching by the teacher educator (Lampert et al., 2013). We focus on how the teacher educator infuses considerations for MKT in the continuous back and forth that takes place in rehearsal.

Theoretical Framework: Problem Spaces and Guided Participation

Rehearsal as a teacher education pedagogy simulates the work of teaching where an NT leads an instructional activity while other NTs participate as students. Rehearsals are not scripted; they allow for improvised performance in response to student thinking and problems of practice (Lampert et al., 2013). Rehearsals open up *problem spaces* in which teacher educators (TEs) and NTs work together to develop new understandings. For Lampert (2010), problem spaces involve the relationships that

teachers manage as they support students' learning of content. They consist of various kinds of problems of practice that "arise in establishing and maintaining relationships with students and subject matter, and [where] the work that must be done to solve them is socially and intellectually complex." (p. 22). Lampert explains that problems of practice arise inside these relationships because of the constraints and possibilities that participants generate through their actions during instruction. In the context of teacher education, these problem spaces can provide TEs with opportunities to guide NTs participation (Rogoff, 1995), engaging them in a form of inquiry during which they actively seek to attend to these constraints and possibilities using available physical, social, and intellectual resources (Cook & Brown, 1999).

Study Context and Methods

The context of the study is mathematics "methods" courses for elementary NTs at three public universities in the US. The courses are part of a collaborative effort to design a model that enables NTs not only to develop knowledge about teaching and mathematics but also the ability to use the knowledge in actual interactions with children. Central to the model are instructional activities (IAs), designed as containers for the instructional practices, principles, and mathematical knowledge that NTs need to learn and be able to use in interaction with students (Lampert, Beasley, Ghousseini, Kazemi, & Franke, 2010). NTs rehearse the IAs publicly in front of their peers and the TE. Guiding participation in this setting, the TE acts as both coach and simulated student, enabling both the rehearsing NT and others in the group to study the range of actions a teacher might take in response to student mathematical thinking.

The data consist of 30 video-recorded rehearsals. The video-analysis software Studiocode© was used to create instances of video that were of two kinds: (a) instances where an NT was leading an IA as a teacher with other NTs and the TE participating as students (*NT Rehearsing*), and (b) instances where there were pauses in the simulation for exchanges between the TE and NTs (*TE/NT Exchange*). In order to understand how the TE supported opportunities for NTs' learning of MKT, we coded the above instances for the work that was being done in relation to the domains of MKT: common content knowledge (CCK), specialized content knowledge (SCK), knowledge of content and teaching (KCT), and knowledge of content and students (KCS). Concurrently, we analyzed for the way the teacher educator supported such participation by thematically coding the different interventions that she made during rehearsals.

Results

We start with a summary of the work that occurred during rehearsals in relation to MKT, and then provide a short vignette from one rehearsal to illustrate our findings. Our analysis revealed that novice teachers participated in two main ways in relation to MKT: (a) unpacking the mathematics as learners of the subject matter, and (b) enacting two types tasks of teaching that required mathematical insights and considerations: posing questions and using representations. These tasks were central aspects of the instructional activities that the novices rehearsed. Some key themes that emerged under these two tasks during either NT Rehearsing instances or TE/NT Exchanges included choosing representations, introducing a new representation, attending to the precision of representations, connecting representations, using representations to attend to mathematics, using questions to elicit answers or explanations, using questions to check on students' understanding, and using questions to emphasize a mathematical point. The analysis of the TE/NT Exchanges showed that the teacher educator supported opportunities to work on MKT by (a) providing insight into student thinking or the mathematics, (b) facilitating novices' unpacking of the mathematics, (c) noting affordances and constraints of instructional moves in relation to MKT, and (d) suggesting instructional moves based on MKT. The teacher educator provided this support inside problem spaces emerging in the context of enacting the tasks of teaching listed above. The teacher educator's interventions reflected

considerations for the development of novice teachers' MKT, and occurred in a continuous back and forth between novice teachers enacting particular practices and the teacher educator helping them consider aspects of their performance and their consequences in relation to student learning of the mathematics. The following excerpt of a rehearsal illustrates the kind of interactions that occurred between the TE and novice teachers, and depicts the way the teacher educator infused considerations for KCS and KCT in the work of eliciting and representing student thinking.

Vignette: Launching a Subtraction Problem and Attending to a Student Strategy.

Molly (All names are pseudonyms), the NT in the role of the teacher, starts launching a strategy sharing activity where students were to contribute in different ways to the solution of a problem. She states, "We are going to work on a problem today: 76 – 27." She then writes the problem on the board vertically, placing 27 under 76. As she prepares to continue with her instructions, the teacher educator intervenes: "Okay, actually, one thing I want you to do differently is, don't write the problem vertically like that. Write [the numbers] horizontally." The TE explains that stacking the numbers vertically encourages students to "imagine the standard algorithm for subtraction in their head," rather than producing a range of informal strategies, which is the goal of the instructional activity. Molly follows the TE's feedback and rewrites the problem horizontally.

Molly gives the students a little time to solve the problem and then asks them for their responses. She solicits three different answers: 49, 43, and 51. We focus on what happened when she elicited Nora's strategy for arriving at 49.

> *Molly*: How did you get 49 here? [Writes 49 at the end of the number sentence]
> *Nora*: I broke 27 up into 20 and a 7, and then I thought that 76 - 20 is 56. Then 56 – 7 is 49.
> *Molly*: [Looking skeptical] You just knew [that 56 – 7 is 49]? Like, how did you count it?
> *Nora*: I knew that, if I took a 10 from the 5, and I had a 4, I'd have a 16 minus 7 is 9, and then I
>   brought down my 4.

Molly represents Nora's strategy on the board. She decomposes 56 into 40 and 16, and then writes 16 – 7 = 9. Her action prompts another NT in the audience to exclaim, "That is a complicated way to do it!" In response, the TE intervenes, suggesting that 56 – 7 is, in and of itself, a good problem to give to students, because it taps into their invented strategies for subtracting across a decade, "You just go back 6 and then you go back 1 more." She also explains that most adults tend to use the traditional algorithm for such a problem, while kids often find more efficient ways to solve it. "Kids would count backwards, 55, 54, 53, …"

Guiding NTs' participation with considerations for MKT. Two problems of practice emerge in this vignette, opening opportunities for the TE to intervene and infuse the problem space with considerations for MKT. First, in her intervention following Molly's representation of the math task on the board, the TE signaled a problem of practice that could result from writing the subtraction problem vertically. Given the importance of allowing students to contribute in different ways to the solution of the problem, this vertical representation could limit the variety of solutions that students would present. The TE drew the NTs' attention to this problem by providing insight into how students might respond to such a representation (KCS), highlighting a general tendency in students to rely on the traditional algorithm when the numbers are stacked in this manner. Later when Nora said that she "just knew" that 56 – 7 is 49, Molly pressed her to explain her reasoning, and with her body language exhibited her perception of some constraint in relation to Nora's answer, suggesting that the leap from 56 to 49 is not trivial. The TE used this problem space to note how mathematical tasks that require students to subtract across a multiple of 10 on the number line could help support students' number sense (KCT). She also provided insight into how students may approach such a task: (a) counting back and (b) bridging across a multiple of 10 to subtract. Both of the TE's interventions supported the NTs in attending to both knowledge of content and students (KCS) and knowledge of

content and teaching (KCT) *in* practice—in the moment to moment problem solving that teachers face in their work.

Discussion

Our findings suggest that pedagogies of enactment like rehearsals afford work on MKT. In the rehearsal of instructional activities, novice teachers have opportunities to consider and unpack mathematical ideas in the context of carrying out particular tasks of teaching like posing questions to launch a problem and using representations to attend to student thinking. The analysis of the vignette illustrates the way these opportunities play out with guidance from the teacher educator who uses her interventions during feedback exchanges to weave considerations for mathematics and pedagogy. When NTs participate in rehearsal, they have opportunities to unpack the mathematics from the perspective of both teachers and students. The TE strategically guides their participation toward multiple domains of MKT often simultaneously.

We end by highlighting two main contributions of this study. First, with content knowledge needs for pre-service teachers—especially at the elementary level—being so high, this study illustrates how MKT can be worked on in "methods" courses in ways that integrate the study of content with pedagogy. Second, this study illuminates how practice-based approaches to teaching MKT situate novices' learning about content in the face-to-face aspects of the work of teaching and in problem spaces where they actively engage this knowledge by attending to affordances and constraints that arise as a result of their experimentation with practice.

This exploratory qualitative study describes how teachers in a yearlong professional development project conceptualized and used formative assessment within their instruction. The study focuses on how teachers interpreted formatives and the instructional decisions that teachers made. This paper documents the shifts in the lenses teachers adopted when interpreting student work and the instructional decisions that are possible based on the information teachers gain from looking at student work.

Keywords: Assessment and Evaluation, Instructional Activities and Practices, Learning Trajectories, Teacher Education-Inservice/Professional Development

Introduction

For decades, the research community has called for a shift in assessment practices towards assessment to inform instruction as opposed to evaluating learning (Black & Wiliam, 2009). Bridging formative assessment theory into practice is not a simple, straightforward endeavor (Allen & Penuel, 2015). Research has found that teachers' use of formative assessment practices remains limited (Otero, 2006). Dixon & Haigh (2009) point out that teachers experience difficulty translating what they know about assessment into practice. Therefore, it is important to understand how to support teachers to increase their effective use of this tool. This paper responds to the gap noted in the research (Dixon & Haigh, 2009) regarding the steps teachers take when interpreting formative assessments. It addresses the questions: (a) What qualities do teachers look for when analyzing assessments or observing students? and (b) How are teachers incorporating formative assessment information to make instructional decisions?

Theoretical Framework

For this paper, we use the definition of formative assessment provided by Black and Wiliam (2009), practice is formative when evidence is collected, interpreted, and *used* to enhance instruction with the purpose of improving instruction. The student information is the *feedback* that is used to tweak the instruction cycle to better adapt to the needs of the student. Teachers correlate two sets of information: the learning target (Where are they going?) and the student's current understanding (Where are they now?) to form an educated guess to plan the next best steps to support students achieving the latter.

Formative assessment is often described as a collection of practices and instructional techniques (Konrad, 2014). Underneath the instructional practices lies the three components of formative assessment: (a) collection of information, (b) analysis of student data, and (c) inclusion of analysis with instructional decisions.

Methods

Participants and Setting

This study was conducted in a western state. The thirty-nine teacher-participants constituted teachers from various elementary and middle schools across the district. During the summer session, teachers developed content knowledge (CK) and pedagogical content knowledge (PCK) through

active engagement with the Mathematical Practices. Follow-up sessions focused on supporting teachers' use of formative assessment.

Data Sources

This study drew on multiple data sources. Data was collected from teacher survey, field notes from each PD session, and focused reflections. *Survey.* Responses were marked on a five-point Likert-type scale. Teachers self-assessed the degree to which they were implementing the Whole Class Discussion Framework (*Whole Class Mathematical Discussions,* Lamberg, 2013). This framework was used to identify to what extent teachers report that they were implementing researched based practices in their classrooms. *Focused reflections.* Focused reflections provided researchers with direct input from the teachers. *PD field notes.* Field notes were typed for each PD session. This was ideal to develop an understanding of how teachers were tackling tasks that required use of formative assessment knowledge.

Data Analysis

Quantitative analysis of the Whole Class Discussion Framework pre- and post- questionnaire recorded changes in the group means. Qualitative analysis of reflections and field notes utilized the grounded theory approach (Strauss & Corbin, 1990). Using the grounded theory approach (Strauss & Corbin, 1990), transcripts from the focused reflections and PD field notes looked for patterns of responses. These were coded and grouped into concepts to understand and describe first, how teachers made sense of information gained from formative assessment and second, what instructional decisions arose from teachers' analysis of the data.

Results

Initial knowledge of formative assessment

All teachers indicated they engaged in formative assessment practices in their classrooms. Teachers employed thirty different types of assessment. The majority (not all) of the participants indicated a focus on right or wrong answers. Time was one challenge teachers felt affected their integration of formative assessment. Others revealed difficulty knowing what instructional steps to take based on analysis of data, stating that they can see the misconception but didn't know what to do with it. Overall, the group is representative of the research literature (Sondergeld, Bell & Leusner, 2010) in their commitment to using formative assessment and the challenges they express with implementing this instructional tool.

Several themes emerged surrounding shifts in how teachers thought about and used formative assessment.

Interpretive Lens: Determining What to Value. Prior to PD, the main purpose of analyzing student work was determining correct or incorrect answers. Post PD, teachers looked for the strategies and underlying thinking behind student answers as indicators of student understanding. This is evidenced in statements such as "you [the teacher] can't tell if a student understands just from the score."

Instruction Adjustments: Pacing to Planning. Pre PD, teachers mainly used the information to *pace* their lessons. The group transitioned from pacing lessons to building lessons that incorporated student understandings "to get them to the next level." This is evidenced by one teacher's statement that her goal is to "look at problems in the whole unit and try to sequence for student success based on what they bring with them or initial understandings."

Authority Change: Curriculum to Student. In the beginning, teachers "moved on" to the next lesson according to district or curriculum pacing guides or when a sufficient percentage of students

had "gotten it." The group began placing student mathematical development first, incorporating the students' current understandings to dictate next instructional moves.

Discussion and Conclusions

Overall, we found that teachers believed in the formative assessment process. Our findings of the teacher formative behaviors before they participated in the PD also support Riggan and Oláh, (2011) that intentions alone did not lead to effective use of formative assessment.

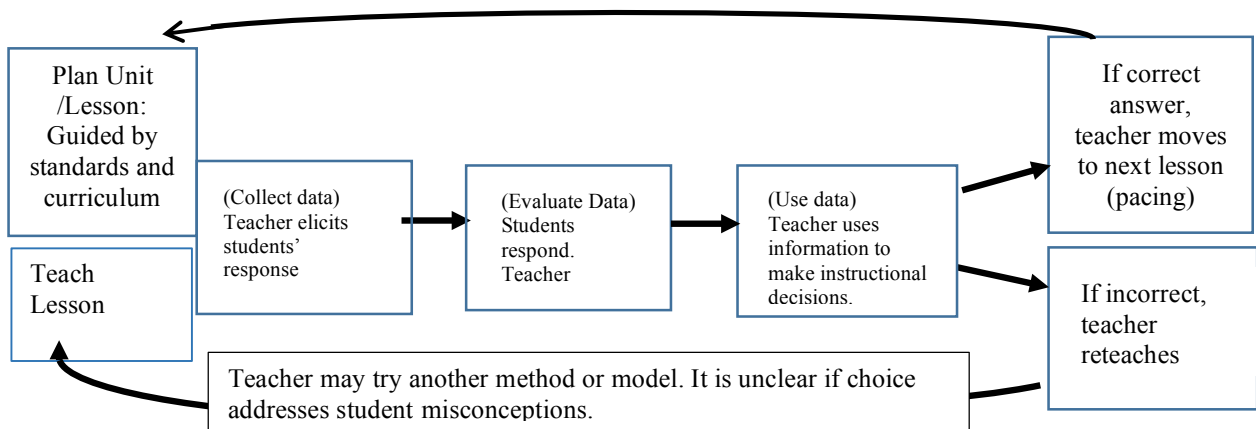
Comparative analysis of how teachers interpreted and used data before and after PD led to the construction of two parallel but different models that capture the relationship between the beliefs of teachers, what they prioritized as important, and the formative cycle outcomes that are associated with each (models adapted from Buck & Trauth-Nare, 2009). We employ the definitions of Wiliam (2010) to describe the two different paths, *monitoring* and *diagnostic*. These definitions include both the evaluative lens and possible instructional decisions.


Figure 1: Monitoring Decision Cycle.

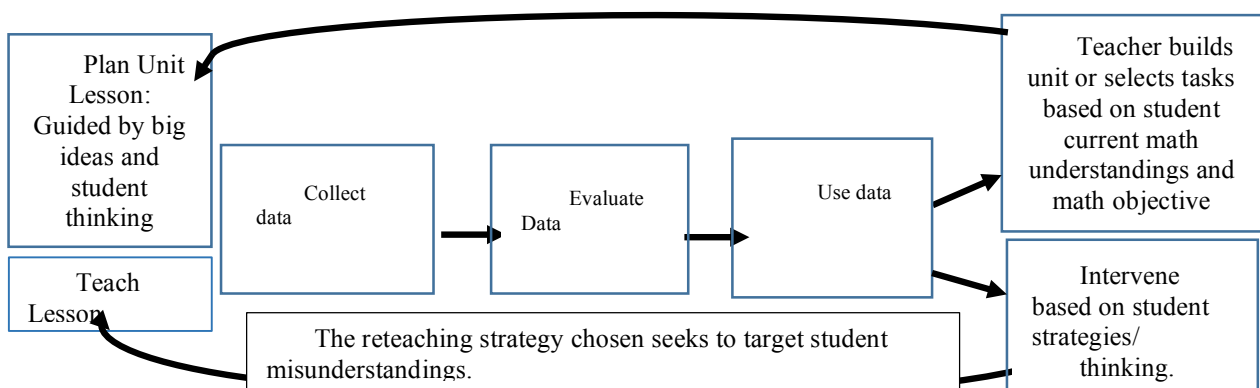
When teachers operated in a *monitoring decisions cycle* their evaluative stance was dialed in on whether answers were correct or the steps in an algorithm. The adoption of this lens limited their ability to professionally notice students' developing mathematical concepts. The information gained from adopting this lens also limited teachers' instructional choices. The information limited instructional decisions to the pacing of lessons.


Figure 3: Diagnostic Decision Cycle.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Teachers in the *diagnostic decision cycle* sought to pinpoint student thinking when evaluating data. Instructional decisions made from this evaluative stance mentioned students in relation to instructional next steps taken as opposed to curriculum pacing.

On the whole, the teachers required support at various stages within the process, building content knowledge, development of different lenses to interpret student work, and how to intertwine the two knowledge areas (mathematics and students) within lesson design. This reflects findings in the literature that teachers do not automatically connect assessment and instruction (Yeh & Santagata, 2015; Otero, 2006). The teachers did not shift their practices until provided facilitation and opportunity to connect and reflect. However, it is important to be mindful that professional development within these areas is not the only factor affecting teaching practices. Participants voiced frustration within their school context. Therefore, it is important to note that applying PD requires negotiation across contexts (Cobb, McClain, Lamberg, & Dean, 2003). Teachers also expressed gratitude for being provided the *time* during PD to engage and collaborate with colleagues, "we so rarely have time to do that!" This implies that teachers perceive their school context is not providing the *time* to interact with the formative assessment process, a factor expressed by teachers in the study by Allen and Penuel (2014) as well.

In this paper we describe bonusing as a strategy to continuously extend students' mathematical understanding from tasks initially offered in the classroom. While this strategy resembles enrichment activities often described in approaches based on Mastery Learning, there are fundamental differences in our use of assessment and the nature of the tasks we propose. After two years of implementing this strategy as part of the Math Minds initiative, we have found that teachers perceived bonusing as relevant and engaging for students. However, they experienced difficulties in the implementation of this strategy. In this paper, we draw from interviews with 14 elementary teachers to identify difficulties they perceive while attempting to implement bonusing. We propose the use of Variation Theory of Learning to inform the creation of bonus material and discuss connections to knowledge for teaching.

Keywords: Elementary School Education, Mathematical Knowledge for Teaching, Instructional Activities and Practices

Introduction

At the Math Minds initiative, a partnership that aims to improve mathematics instruction at the elementary level (Metz, Sabbaghan, Preciado Babb, & Davis, 2015), we have come to perceive bonusing as a strategy that fosters both a positive attitude towards mathematics and a deep mathematical understanding. However, teachers in this initiative have consistently indicated that creating and posing bonuses is challenging (Preciado Babb, Metz, Sabbaghan, & Davis, 2015). In this paper we extend our findings on these challenges and propose that Marton's (2015) Variation Theory of Learning could inform the creation of bonus material. We also discuss implications for the development of educative curricular material (Davis & Krajcik, 2005) that supports the learning of both students and teachers.

Similar to the enrichment activities in Mastery Learning (Guskey, 2007), the teachers' guides used in this initiative advise teachers to "be ready to write bonus questions on the board from time to time during the lesson for students who finish their quizzes or tasks earlier" (Mighton, Sabourin, & Klebanov, 2010, p. A-8). Suggested strategies include: changing to larger numbers or introducing new terms or elements; asking students to correct mistakes or complete missing terms in a sequence; varying the task or the problem slightly; looking for applications of the concept; and looking for patterns and asking students to describe them. In this paper we use the broader term bonus 'tasks'—instead of 'questions'—to include activities that are not necessarily questions. We concur with Bloom (1968) that these extension activities, or bonus tasks, should not just be a way to keep students busy while supporting other students. We believe that bonusing has a positive effect on students' attitudes and dispositions towards mathematics. Teachers are encouraged to pose bonus questions for all students, including those who perform lower in class, as suggested by Mighton (2007), the developer of the resources used in the Math Minds initiative.

We contend that the Variation Theory of Learning (Marton, 2015) has the potential to inform the selection or the creation of bonus tasks. Example spaces, as defined by Watson and Mason (2005), with sufficient variation can prompt learners to distinguish critical features of mathematical entities. For Marton "the secret of learning is to be found in the pattern of variance and invariance experienced by learners" (p. xi). Such patterns allow the learner to discern critical features required to learn a particular concept or skill.

Methods and Data Sources

Our data for this report were drawn from interviews conducted in 2015 with 14 teachers, as well as data from documented weekly classroom observations at two urban elementary research schools. The interview transcripts were analyzed with a focus on teachers' difficulties implementing bonusing—motivated by early research results showing that teachers found bonusing to be quite challenging (Preciado Babb et al., 2015). The research team, comprising two graduate students and four researchers, met every week to discuss and analyze data.

Findings

By comparing teachers' perceived difficulties from the interviews with our classroom observations, the following four categories of difficulty were identified.

Lack of experience and knowledge

Many teachers agreed that once they became more familiar with the resource, bonusing would become a less challenging task. The following excerpt is similar to many other teachers' comments:

> And just with working with you on bonusing and I think that the practice that I've had will definitely help me next year. I don't think next year will be as much of a struggle for me.

We documented many instances where students were asked to create their own bonuses. The interviews revealed that, in some cases, students created questions were difficult for the teacher to answer, as evidenced in the following comment:

> Usually if it's bonusing and students create their own bonusing or suggest something that is beyond the curriculum there have been times where I'm like, "I don't know the answer to that," and I don't know…how should I answer that question? Do I set them up to answer it on their own, or do I show them so that they don't get confused? That's when I hesitate. Usually with the JUMP questions I should know how to answer it because the teacher's book leads you.

The challenge of not being able to answer a student's proposed bonus could be due to the teacher's lack of mathematical knowledge or to a disposition that makes him or her reluctant to engage in unfamiliar situations. The last sentence of the excerpt suggests that the teacher relied on the "teacher's book" to deal with questions from the resource, reinforcing the idea that the difficulty was due mainly to a lack of mathematical knowledge.

Difficult to bonus without going beyond the concept to be learned

Some teachers found it difficult to bonus without moving away from the goal of the lesson or the concept to be learned. In the next excerpt, a teacher commented on the students who usually finish early and/or who understand the content of the lesson faster than others:

> They know they're doing well and they know what's coming next; they can anticipate that. And so, it's tricky for me to bonus them without moving away from the goal of the lesson. So, to give them bonuses that challenge them and that they find exciting without changing the curriculum for them.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

When teachers were asked to provide suggestions to the research team for improving the initiative, several teachers insisted that they needed more pre-made bonus tasks that they could implement in their classrooms:

> Anything that you can sort of give us that's like ready-made or ready to go on. … And bonusing is a tricky thing that you have to, I guess, get your head around.

This particular difficulty based on the goal of the lesson relates to the range of students' ability in the classroom, as explained in the next paragraph.

Difficult to be responsive and improvise in bonusing

Most of the teachers asked for "ready at hand" bonuses because they didn't know how to integrate flexible bonusing in their plans. They claimed that this was due in part to the wide range of ability between students. Teachers found it very difficult to create bonuses in the class or to modify planned bonuses in response to classroom situations. This is evident in the following:

> Just 'cause of the variety of students. And I'm not as confident in making those bonusing 'cause … when I think I'm bonusing with a small step, I find that I'm bonusing with a big step, and the kids look at me with blank faces and I'm like, "Okay, what did I do wrong there?" I think it puts the teacher in a tough position 'cause you have to bonus for each individual student and it's almost like you need to do it right there on the spot because if you plan it you have no idea.

In the previous excerpt, the teacher acknowledged that some bonus tasks turned out to be very difficult for the class, even though the teacher was "bonusing with a small step." Similar to the requests for 'ready-made' bonus questions, some teachers complained about the lack of bonus questions in the teachers' guides for bonusing at a level appropriate for the students.

Limited time to create and implement bonusing

Sometimes teachers indicated time constraints that made it difficult to create and implement bonusing. For example:

> When it [the teacher's guide] says, 'Advanced' or 'Bonusing' in the extra questions: They're nice for bonusing those students that need that type of bonus. For the class that I'm teaching right now, I find that I'm not using that as much. It's something that we don't get to just in terms of pacing but it is nice to have there just in case.

In this excerpt, the teacher acknowledged that students were not challenged with bonuses. This claim contrasts with the explicit directive of the resource to create bonuses, as well as with the shared perceptions from other teachers that bonusing is an important part of the program.

Time to prepare bonus material was a concern for some teachers. We observed that some of them made efforts to create bonus questions attractive to students:

> I find that just due to level of needs in my class sometimes I don't—I find myself struggling with the time to get around to them. And there's such a range of students that I find that being able to prepare ahead of time's not always a reality if you're planning five other subjects for the day.

It is not clear whether this teacher was creating the bonuses or just planning to use bonus tasks from the resources. In either case, planning for bonusing was perceived as time consuming.

Discussion

In the difficulties described above we perceived a need for particular knowledge required to create bonus material. Teachers consistently requested more ready-to-use bonus questions and even teachers with two years or more in the initiative indicated a need to improve the way they create bonus tasks.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

The difficulty in creating bonus tasks in response to students' range of ability also supports the idea that there is a particular knowledge teachers require for bonusing. We believe that a collection of ready-to-use bonus material, either from the resource or from the research team, is neither practical nor sufficient. In order to be responsive to students' needs in the classroom, teachers should be able to create bonus tasks on the spot with ease. Being able to improvise according to how the class unfolds would also reduce the time constraints for preparation.

Our analysis also revealed a particular perception of bonusing as something that has to be done at the end of the class, and only if time allows it. This perception of bonusing is restricting and might entail additional time for preparation.

We propose that Marton's (2015) Variation Theory of Learning holds great promise for supporting teachers in the creation of bonus tasks. Bonus tasks may be created by varying the original task in ways that allow new explorations and discoveries within the same concept or topic in a lesson, or in a way that represents an opportunity to apply (generalize) the same principle to different cases. Therefore, a future venue of research is how an understanding of this theory might inform teachers' implementation of bonusing in their classrooms.

We conclude with a potential implication for the development of and research on curricular material. Just as *educative curriculum materials* (Davis & Krajcik, 2005) can support teachers' learning, we believe that resources that teachers use in their classroom can facilitate the creation of bonus tasks and thereby further impact their knowledge for teaching mathematics. For instance, we have found that many tasks in the resources used in this initiative are presented in sequences of items with a clear pattern of variation, and very often with explicit suggestions for bonuses. Teachers can learn from the resource by paying attention to the patterns of variation related to key mathematical concepts and ideas in the examples and tasks presented to students. However, we need to better understand what teachers need to know to take advantage of the educative materials and what features the educative materials need to embody to draw teachers' attention to key mathematical ideas.

THE IMPORTANCE OF QUANTITATIVE REASONING IN MIDDLE SCHOOL MATHEMATICS TEACHERS' PROPORTIONAL REASONING

Matthew B. Weber	Amie Pierone	April Strom
Arizona State University	Scottsdale Community College	Scottsdale Community College
matthew.b.weber@asu.edu	amie.pierone@gmail.com	april.strom@scottsdalecc.edu

In this paper we describe a study involving middle school mathematics teachers who are participating in a large-scale professional development program designed to improve their conceptual understanding of mathematics. The design and implementation of this study were guided by the research question: In what ways do teachers reason through tasks designed to elicit proportional reasoning? Our analysis of the data was conducted through the lens of quantitative reasoning as described by Thompson. We highlight the issues that arose when some teachers performed numerical operations on values that they did not clearly connect to quantities.

Keywords: Number Concepts and Operations, Mathematical Knowledge for Teaching, Teacher Education – Inservice/Professional Development, Teacher Knowledge

Discussion of the Literature

Research in mathematics education over the last several decades has emphasized the importance of building rich conceptions of proportionality, specifically in the early grades (Kaput & West, 1994; Thompson, 1994). More recently, efforts have been made to institute a greater focus in the middle grades on proportional reasoning from a quantitative perspective through the adoption of the Common Core State Standards for Mathematics and the Standards for Mathematical Practice (National Governors Association, 2010), which calls for students to *reason abstractly and quantitatively*.

Thompson (1994) defines a *quantity* to be a measureable attribute of an object. Quantities are not objects themselves; they exist in the mind of the person who is imagining them. The *value* of a quantity is the numerical result of a measurement, and a measurement is a multiplicative comparison of the magnitude of the quantity to the magnitude of some unit-of-measure. Thompson (2011) describes a *quantitative operation* as the act of either combining two quantities (additively or multiplicatively) or comparing two quantities (additively or multiplicatively). A quantitative operation should not be confused with a numerical operation, which is the act of combining or comparing two numerals.

Reasoning with quantities is foundational to robust proportional reasoning. According to Lesh et al. (1988), proportional reasoning is the capstone of elementary school mathematics and the cornerstone of high school mathematics. Cramer et al. (1993) outlined several components involved in proportional reasoning, including understanding the multiplicative relationships that exist within proportional situations and being unaffected by the situational context or the types of numbers in the task. Kaput and West (1994) found that the context of the problem, the language of the task, the kinds of quantities involved, and the numerical values of the quantities all impact student thinking. This paper adds to these findings by discussing the impact on proportional reasoning when people disassociate measurements from the quantities they measure.

Methodology

This study focused on nine middle school mathematics teachers who were participating in a two-year professional development program led by mathematics educators and researchers at a community college in the southwest. Leveraging Goldin's (2000) principles, researchers used semi-structured, task-based interviews for investigating teachers' thinking while working through tasks involving proportional relationships. Each teacher participated in five one-hour videotaped

interviews during their participation in the program. The research team analyzed all interview sessions with the goal of characterizing teachers' thinking and reasoning as they grappled with the mathematical tasks. The design of this investigation and subsequent data analysis were guided by the following research question: In what ways do teachers reason through tasks designed to elicit proportional reasoning? In this paper we present data from one of the tasks used in this study: The Juice Task.

Suppose 3/5 of a cup of juice gives you 4/3 of your daily serving of vitamin C.

What amount of your daily serving of vitamin C is in 1 cup of juice?

What amount of juice is needed for a full daily serving of vitamin C?

Discussion of the Data

In this section we discuss data from two teachers, referenced as Adam and Kim. While working on the Juice Task, Adam produced the expected answer in part *a*, but not in part *b*. His written work is displayed in Figure 1.
Figure 1. Adam's written work on part *a* and part *b* of the Juice Task.

The video data revealed that Adam used the operations of division and multiplication in part *a*, but resorted to the operation of subtraction in part *b*. For part *a*, Adam pointed to the 3/5 and 4/3 and stated "these are kind of a proportion or ratio where if I do something to [3/5] to get [1/5], then I do the same here (points to 4/3) to here (points to blank box), then it keeps the same ratio." Adam then divided 3/5 and 4/3 both by 3 to get 1/5 and 4/9. He then multiplied each of these results by 5 to get 5/5 and 20/9. He concluded that 20/9 of a daily serving of vitamin C is in one cup of juice. In part b, Adam did not use multiplication or division. Instead, he stated "I need to get [4/3] down to…um well, maybe I don't do the per unit…what I really need to do is get it down to 3/3 because that would equal one daily serving. So, I have subtracted 1/3." Adam then subtracted 1/3 from both 4/3 and 3/5, and concluded that 4/15 of a cup of juice would provide a full serving of vitamin C.

Adam may have used subtraction in part *b* because he was focused on *reducing* 4/3 of a serving down to one full serving. His objective in each part was to obtain the number 1 (either for cups in part *a* or for servings in part *b*) and he did not restrict which operations he could use. His guiding principle was to do to one value the same thing he did to the other value. This suggests that Adam was not mindful of the quantitative operations underlying his numerical operations. Removing 1/3 from 4/3 through the numerical operation of subtraction is sensible if these numerals are values of measurements in compatible units, i.e. if 1/3 and 4/3 are both measurements of servings of vitamin C. If Adam had been attentive to the unit of 1/3 perhaps he would have realized that removing 1/3 *of a serving* from 3/5 *of a cup* is not reasonably accomplished by the numerical operation he used (i.e., 3/5 – 1/3). Perhaps Adam was thinking that he was removing 1/3 *of a cup* from 3/5 of a cup, as well as removing 1/3 of a serving from 4/3 of a serving. In this case, because he was trying to do the same thing to both values, he would have had to reason that removing 1/3 of a serving is equivalent to removing 1/3 of a cup, which contradicts the premise of the task.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

We now consider Kim's thinking. While working on the Juice Task, Kim produced the expected answer in part *b,* but not in part *a*. Her written work is displayed in Figure 2.

Figure 2. Kim's written work on part a and part b of the Juice Task, in the order that she progressed through the task.

Although Kim produced the correct answer for part *b*, the video data provided limited evidence that she was sensibly reasoning about the quantities. When questioned about her choice to divide 3/5 by 4/3 she stated, "To figure out, uh, just how many groups of 4/3 fits into 3/5 and take it from there… And it was either multiply or divide and division made more sense." Note that her language, "how many groups of 4/3 fits into 3/5," is indicative of the quotitive division model (Simon, 1993). We now explore some possible ways that Kim was thinking using the quotitive division model. It is not clear to us from the data whether Kim was mindful of the quantities. Suppose she was. Since the amount of vitamin C and the amount of juice are directly proportional, one could effectively convert 4/3 servings to cups of juice and then wonder how many 4/3 servings (measured in cups) fit into 3/5 of a cup. This quantitative operation should lead Kim to conclude that *one* copy of 4/3 servings fits into 3/5 of a cup, because 4/3 servings corresponds to 3/5 of a cup. As another possibility, the quantitative operation associated with wondering "how many groups of 4/3 *servings* fit into 3/5 *of a cup*" would yield the numerical operation that Kim used (3/5÷4/3) only if *servings* and *cups* were interchangeable units (i.e. 4/3 servings corresponds to 4/3 cups); this contradicts the premise of the task. We conclude that despite her utterance, Kim could not have been thinking about the quantities as well as the quotitive division model. It is possible that despite her language, Kim was thinking using the partitive division model (Simon, 1993). If 3/5 of a cup were fit into 4/3 servings, partitive division would yield the numerical operation 3/5÷4/3, which would reveal the amount of juice per whole serving. However, the data do not indicate that Kim used the partitive division model. This analysis of the data suggests to us that when Kim said that division "made more sense," she was referring to the *result* of the division rather than the operation itself.

Kim's first attempt at part *a* also suggests that she was focused on evaluating the reasonability of results of numerical operations rather than attending to quantitative operations. After dividing and multiplying 3/5 and 4/3 she stated, "I'm trying to look at the numbers to see if they make any sense." In her second attempt, however, she sought to (1) determine the "value of each group," i.e. the amount of vitamin C in each 1/5 cup of juice; (2) subsequently determine the amount of servings in 2/5 cups of juice; and (3) combine this amount with the given amount of vitamin C in 3/5 cups of juice. She incorrectly determined that 4/15 servings were in 1/5 cups of juice by "dividing 4/3 of the daily serving into five equal groups because my denominator here (points to 3/5) is five." Using this information, she proceeded to add 8/15 [servings in 2/5 cups of juice] to 3/5 [original amount of juice]. She concluded there were 17/15 servings in one cup of juice. Had Kim been mindful of the referents associated with 8/15 and 3/5, she may have avoided the error of inappropriately using numerical addition to combine the two quantities.

Conclusion

This research adds to the body of work on factors that influence proportional reasoning by investigating the ways in which teachers reason through tasks designed to highlight proportional relationships. The initial data reveals that teachers in this study struggle to attend to quantities and quantitative operations in proportional situations. The data suggests that teachers disassociate measurements from the quantities they measure and simply operate on the numerals. We have found this issue to be a source of complexity as teachers grapple with tasks involving proportional quantities.

ADVANCED MATHEMATICAL KNOWLEDGE FOR TEACHING: A CASE OF PROFESSIONAL TEACHING KNOWLEDGE INFLUENCING INSTRUCTION

Chantel C. Blackburn
Pacific Union College
cblackburn@puc.edu

Teachers require some level of *advanced mathematical knowledge* (AMK) so that they can situate their mathematical work appropriately within a disciplinary context. There is little agreement, however, regarding how AMK can be acquired by and developed in teachers (e.g. Ball & Bass, 2009; Clay, Silverman, & Fischer, 2010; Davis, 2011). Further, the potential AMK that is useful for teaching may involve a great deal of tacit knowledge (Clay et al., 2010; Davis, 2011; Silverman & Thompson, 2008), making it difficult to detect through observations alone (Polanyi, 2009). Consequently, little is known about teachers' AMK used in practice.

This study was designed to illuminate the role of AMK in the practice of elementary mathematics teaching through observations of the mathematics teaching of a fourth grade teacher (Tasha) and, through conducting semi-structured, in-depth interviews, identifying the nature of the AMK she employed. In one particular episode, Tasha was teaching a lesson during which she made the decision that initiated a shift in the mathematical focus of the lesson from calculus concepts (e.g. discriminating between features of the graph that represent speed and changes of speed) to parametric relationships (i.e. representing the relationship between speed and distance as functions of time) due to a mismatch between the contextual information in curriculum materials and the goals of the lesson.

This case demonstrates that teachers may benefit from preparatory or professional development experiences that expose them to calculus ideas and support their interpretation of related curriculum tasks. More research would be required to identify if introducing calculus concepts to all elementary teachers would prove helpful on the wide scale. Alternatively, I propose that perhaps the construction of curriculum materials should account for the kinds of structural knowledge teachers may lack. In particular, it may be helpful to identify those mathematical structures with which teachers may have limited experience and incorporate teacher support into their curriculum materials where deviations are likely to occur.

CALCULUS STUDENTS' IDEAS ABOUT FUNCTIONS: IDENTIFYING OPPORTUNITIES TO SUPPORT TEACHER LEARNING

Laurie Overman Cavey
Boise State University
lauriecavey@boisestate.edu

Patrick R. Lowenthal
Boise State University
patricklowenthal@boisestate.edu

Keywords: Mathematical Knowledge for Teaching, Algebra and Algebraic Thinking

We describe the first phase of a study aimed at developing video-based instructional modules for secondary mathematics teachers. We began by consulting the literature on figural pattern tasks (c.f. Rivera, 2010) and teachers' ability to interpret student work (c.f. El Mouhayar & Jurdak, 2012). Interpreting student work on figural pattern tasks requires awareness of different problem solving strategies, such as recursive and constructive, and how students might use them with tasks that require different levels of generalization (El Mouhayar & Jurdak, 2012).

We conducted one-on-one interviews with 17 high school calculus students to capture authentic student work and reasoning on a figural pattern task. As students worked through each task, we asked students to document their work on paper and to explain their thinking aloud. Two video cameras were set up to capture the written work and discussion. Student interview data were initially coded according to strategy type: constructive, deconstructive, or recursive. Additional coding resulted in four categories for teacher learning (CTL): 1) Deciphering students' cryptic notations; 2) Recognizing what is correct in a slightly flawed strategy, 3) Recognizing a strategy that is "close" to a more advanced strategy, and 4) Making connections between different strategies.

The CTLs are a first step in designing video-based modules grounded in authentic student work with explicit learning goals for developing teachers' capacity to work with student's ideas. For example, Student A's response presents an opportunity for teachers to attend to a correct constructive strategy that breaks down in the final calculations (CTL2), while Student B's response presents an opportunity for teachers to attend to a transitional phase in writing explicit functions based on recursively defined patterns (CTL3). Both responses involve interpreting somewhat cryptic notations (CTL1), and together, they afford opportunities to make connections between ideas such as where the recursive addition of 8 can be observed in a constructive approach (CTL4).

Figure 1. Work samples from Student A and Student B. Together they illustrate all four CTLs.

Keywords: Mathematical Knowledge for Teaching, Teacher Education-Preservice

One of the overarching aims of a teacher education program is to support "doers/students" of mathematics in becoming "teachers" of mathematics. This transition requires candidates to reorient from thinking about how they do mathematics to engaging with students and their work, understanding student representations, and planning instruction accordingly. To scaffold this transition, we developed a five-step Mathematics as Teacher Heuristic (MATH). This heuristic was designed based on Mathematical Knowledge for Teaching (MKT) (Silverman & Thompson, 2008) and the Noticing Framework (Jacobs, Lamb & Philipp, 2010). Our research question is "How do teacher candidates develop knowledge of teaching mathematics for conceptual understanding?"

Twenty-two teacher candidates completed the following five-step process using student work samples collected from authentic classroom settings: 1) solve a rich task as a "doer;" 2) assess/analyze authentic student work samples associated with the same task; 3) consider good questions to ask struggling students; 4) develop scaffolded instructional materials addressing student challenges, difficulties, and misconceptions; and 5) reflect on the process.

Through the analysis of the data, two major themes in the process of transforming were revealed: (a) teacher candidates building on what they noticed in the student work in the remaining parts of the MATH consistently; and (b) teacher candidates not building on or having gaps in what they noticed that then impacted on their work in the rest of the MATH. Teacher candidates with weak Key Developmental Understanding (KDU) (Silverman & Thompson, 2008) and/or unsuccessful noticing tend to be unsuccessful in decentering their own ideas. Consequently, they addressed what was lacking in the student solutions and posed more leading than scaffolding or imposed their own way of solving mathematics problems rather than empowering students.

We conclude that teachers need to be engaged in activities not only emphasizing the importance of separating teachers' understanding from the hypothetical understanding of the learner, but also recognizing the importance of self-reflection in the development and evolution of teacher knowledge, beliefs, and attitudes. The MATH model in this study includes reflection on the overall process of the activity including reflecting on preservice teachers' reflection on key developmental understandings of own and students and their plan of practice. For practicing teachers, reflection should be expanded to reflecting on students' learning and practice in the context of instruction.

EXPLORING CONNECTIONS BETWEEN TEACHERS' MATHEMATICAL CONTENT KNOWLEDGE AND ITS RELEVANCE TO TEACHING K-12 MATHEMATICS

Zareen Gul Rahman	Debasmita Basu	Karmen Yu
Montclair State University	Montclair State University	Montclair State University
rahmanz1@montclair.edu	basud2@montclair.edu	Yuk4@montclair.edu

Students learn the concept of linearity early in their school careers and frequent reinforcement makes them prone to apply it without discretion (De Bock, 2002). Consequently, they struggle to develop higher-level conceptual understanding of mathematical topics like differential equations because of their assumptions of linearity (Brabham, 2014). It is important therefore to introduce rate of change as it relates to both linear and non-linear models. We created an instructional unit with the goal to make connections between secondary and advanced mathematical topics. Specifically, our research question is: How does the knowledge of chain rule impact secondary school teachers' understanding and teaching of the rate of change?

Our project is informed by the idea of Mathematical knowledge for teaching (MKT), specifically, "horizon knowledge" which gives teachers a mathematical "peripheral vision" (Ball, Thames, & Phelps, 2008). It provides a larger view of mathematics that gives the teachers a sense of where to place the content that they are teaching and how it is connected to higher level mathematics (Ball & Bass, 2009).

Our unit was designed to engage the teachers in discourse by posing a series of thought provoking questions. This led the participants, experienced secondary school teachers, to examine the relationship between the instantaneous rates of change, the constant rate of change, and the chain rule. At the end of the lesson, the participants shared their reflection on the topic, both verbally and in writing. The class was audio taped and observation notes of the lesson were taken. Data was analyzed to find recommendations for content and pedagogy. We also recorded any connections between secondary and tertiary mathematics and student misconceptions on this topic. In the future, we plan to revise our unit and conduct this study with pre-service mathematics teachers.

THE RELATIONSHIP BETWEEN TEACHERS' MATHEMATICS CONTENT KNOWLEDGE AND OBLIGATION TO THE DISCIPLINE

Mollee Shultz   Patricio Herbst
University of Michigan   University of Michigan
mollee@umich.edu   pgherbst@umich.edu

Keywords: Mathematical Knowledge for Teaching, Instructional Activities and Practices

This poster focuses on mathematics teachers' *obligation to the discipline* (Herbst & Chazan 2012), which refers to the expectation that teachers will represent the discipline of mathematics appropriately. The study uses scenario-based assessments (Weekly & Polyhardt, 2006) to examine the extent to which teachers are disposed to alter "question the borders" of customary practice on account of this obligation and the mediating role of subject matter knowledge for teaching (SMK; Ball, Thames, and Phelps, 2008). We hypothesized that SMK would significantly predict the obligation to the discipline, because teachers with more SMK would be more willing to breach customary practice to represent their knowledge.

Methods

We collected responses from high school in-service mathematics teachers to three instruments. The study included participants from all states and distributed proportionally over five regions. The Justification of Actions instrument had 16 items that ask participants their agreement on a 6-point Likert scale with a teacher's decision to depart from an instructional norm and instead attend to their obligation to the discipline. The Decision instrument contained sixteen items, each of which required the participant to choose between four different decisions that differed in the extent to which they altered customary practice. The MKT-G instrument had 8 common content knowledge (CCK) questions and 20 specialized content knowledge (SCK) questions which we used to score SMK.

Two multiple regression analyses were conducted. The first used the average Justification of Actions rating as the outcome variable, SMK as the predictor variable, and controlled for number of college math courses. The second used the average Decision rating as the outcome variable, an average Justification of Actions rating as the predictor, and controlled for SMK. Because missing data was dropped and not all participants completed every instrument, the samples were slightly different for the two models.

Results

In the first regression (R^2=0.059, F(3, 318)=6.66, p<0.001), we found that CCK score significantly predicted the amount of obligation to the discipline, (B=-0.085, t(322)=-3.49, p=0.001). In the second regression, (R^2=0.208, F(3, 333)=29.20, p<0.001), we found that a higher level of disciplinary obligation predicted a higher tendency to decide to breach normative behavior (B=-0.261, t(337)=-8.17, p<0.001).

PROSPECTIVE TEACHERS' ATTENTION TO REALISM AND CONSISTENCY IN A CHILD'S TEMPERATURE STORY

Nicole M. Wessman-Enzinger	Dana Olanoff	Jennifer M. Tobias
George Fox University	Widener University	Illinois State University
nicole.enzinger@georgefox.edu	dolanoff@widener.edu	jtobias@ilstu.edu

Research tells us that prospective teachers (PTs) struggle to think conceptually about integer addition and subtraction, often focusing on procedures (Bofferding & Richardson, 2013). When PTs are asked to reason conceptually and apply contexts to integer addition and subtraction number sentences, they often do not utilize temperature contexts (Wessman-Enzinger & Tobias, 2015). When PTs do utilize temperature as a context, they often struggle to pose stories. Yet, in their work as teachers, PTs will need this skill, as well as the ability to move beyond posing stories. PTs will need to make sense of stories that children pose, judging the realism of the story and the use of mathematical operations supported by the story.

Seventy-seven elementary and middle school PTs participated in a study where they explored integer addition and subtraction tasks. This poster reports on The Sabrina Task, which engaged the PTs in sense making around a child's temperature story posed for the integer addition number sentence $-9 + -6 = \square$. The child's story: *It is -6 degrees 2 days ago. It was -9 yesterday. Now it is -15 degrees,* both did not contextually make sense (realism) and did not support the operation of addition (consistency). PTs' were asked whether the story made sense with the given number sentence and to justify their answers. Seventy-four PTs' written justifications were analyzed in relation to whether or not they believed that the story matched the number sentence, and what their justifications were. While 63 of the 77 (81.8%) PTs confirmed that the story did not match the number sentence, less than half of the PTs included realism in their justification, and only half of the PTs included consistency.

The results of this study imply that PTs need further experiences both in looking at integer operations in specific contexts, like temperature, and in making sense of integer stories, such as those posed by children. Despite instructional experiences including tasks such as these and the fact that task containing The Sabrina Problem appeared at the end of those instructional experiences, the PTs' justifications showed gaps in both their attention to realism and to consistency. These results indicate that we need to engage prospective teachers in these types of tasks more often. Specifically, PTs need more opportunities to reflect on realism and consistency in temperature problems, as well as problems in other contexts. Additionally, research is needed into how PTs' responses about realism and consistency are related, within temperature contexts and otherwise.

EFFECTS OF A HISTORY OF MATHEMATICS PROFESSIONAL DEVELOPMENT COURSE ON TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING

Diana White
University of Colorado Denver
diana.white@ucdenver.edu

A consensus has emerged recognizing that mathematics teachers need mathematical knowledge that are specific to the work of teaching mathematics, yet much work remains on how to facilitate the development of this knowledge in teachers. Professional development is crucial, but the interplay between content courses and mathematical knowledge for teaching remains only loosely understood. While significant research has been done on professional development specifically designed to align with the development of certain types of mathematical knowledge for teaching, little work appears to have been done on how mathematical knowledge for teaching can develop indirectly. In this study, we examined the impact of participation in a four credit hour history of mathematics course on mathematical knowledge for teaching, as measured by the Learning Mathematics for Teaching (LMT) instrument (Hill, Schilling & Ball, 2004). Previous studies have reported that higher teacher performance on the LMT is correlated with the presentation of richer mathematics in the classroom (Hill, et.al., 2012) and with higher student achievement (Hill, Ball & Rowan, 2005).

Two subscales of the LMT were administered to 50 teachers over three course offerings across two years. The repeated measure ANOVA revealed a significant main effect of Test Form, $F(1, 63) = 108.31$, $p < .001$. Overall, Geometry scores were significantly higher than the Patterns Function and Algebra scores (M(SD) = .62(.75) and -0.07(.86), respectively), and this pattern was consistent across all three sites. The interaction of Test Form x Workshop Site was not significant, $F(2, 63) = .52$, $p = .60$.

There was also a significant main effect of Time Administered, $F(1, 63) = 15.17$, $p = <.001$. Posttest scores were higher on average than pretest scores (M(SD) = .39(.85) and .16(.85), respectfully). The interaction of Time Administered x Test Form was not significant with, $F(1,63)=.19$, p-.29. Further more, the interaction of Time Administered x Workshop Site was also not significant, $F(2,63) = 1.13$, $p = .29$, indicating that all three sites shared a pattern of differences between pre- and post-test administration and supporting the combination of data across sites for the planned comparisons tests. Overall, there was a larger difference in means for the pre- and post-test scores for Patterns Function and Algebra than for Geometry (M(SD) = .29(.59) and .18(.58), respectively).

HOW EXPOSURE TO ADVANCED MATHEMATICS MAY IMPACT TEACHER'S UNDERSTANDING AND TEACHING OF SECONDARY MATHEMATICS

Keywords: Algebra and Algebraic Thinking, Teacher Knowledge, Advanced Mathematical Thinking

It has long-been accepted that effective teaching practice stems not only from well-developed pedagogical practice, but also from advanced subject matter knowledge (Cochran, King, & DeRuiter, 1991). Despite evidence that stronger teacher knowledge of mathematical subject matter might have a positive impact on classroom instruction and student achievement, our understanding of how teachers' knowledge of advanced mathematical content impacts instruction and student achievement is still lacking. This study examines (1) how does secondary mathematics teachers' exposure to advanced mathematics impacts their understanding of secondary algebra? (2) How does exposure to abstract algebra impact secondary teachers' understanding of inverses? This study employs Mathematical Knowledge for Teaching (MKT)(Ball, Thames, & Phelps, 2008) as a means of improving teaching practice and student outcomes, according to which the connection between secondary and tertiary mathematics utilizes both mathematical content knowledge as wells as pedagogical content knowledge. The aspect of MKT on which we primarily focus is 'Horizon Content Knowledge', which helps develop an inclusive vision regarding how advanced tertiary mathematical content knowledge can be linked back to secondary mathematics (Ball et al., 2008). In this study, we investigate teachers' current understanding of operations used in solving equations and how attention to advanced algebraic structures and their properties may impact conceptual understanding and future instructional practices.

Participants were 14 in-service and pre-service teachers in a master's level mathematics education course. The researchers first provided participants with a mathematical content knowledge questionnaire to gain insight into the participants' conceptual understanding of algebraic operations and inverses. Then, the researchers taught a short abstract algebra lesson with a focus on group structures and modular arithmetic. During the lesson, participants were engaged in small and large group discussions, which were videotaped and all written artifacts were collected for future analysis. After initial analysis and coding of data, changes in participant's understanding of inverse were observed. Participant's original understanding was that inverses were operations that "undo" each other. Exposure to group structures as a component of the abstract algebra lesson prompted participants to consider identities with respect to a binary operation and consider the operation-element duality of inverses.

STAGES IDENTIFIED IN UNIVERSITY STUDENTS' BEHAVIOR USING MATHEMATICAL DEFINITIONS

Valeria Aguirre Holguín
Universidad Autónoma de Ciudad Juárez
valeria.aguirre@uacj.mx

This paper reports and describes some of the observations and conclusions drawn from a study developed to find information on undergraduate students' spontaneous actions and reactions to mathematical definitions that are new to them. There were 23 participants from a transition-to-proof course. They were interviewed individually on a particular mathematical definition. The analysis of the interviews was iterative and consisted mainly of three phases. During the first two phases students' behaviors were observed and identified in order to categorize commonalities of their responses and actions. In the third phase, a search-back through the data was done for additional supporting evidence of the commonalities previously observed. This third phase allowed making a more general classification of the various behaviors observed. Participants were classified into five different stages in using mathematical definitions according to their behaviors when working with a particular definition.

Keywords: Reasoning and Proof, Advanced Mathematical Thinking, Mathematical Knowledge for Teaching

Introduction and Research Questions

The role of definitions in mathematics is fundamental. Professors apparently expect students to be able to grasp definitions and then proceed to do something with them (Alcock, 2010). Nevertheless, "Many students do not categorize mathematical definitions the way mathematicians do; many students do not use definitions the way mathematicians do, even when the students can correctly state and explain the definitions; many students do not use definitions the way mathematicians do, even in the apparent absence of any other course of action." (Edwards & Ward, 2004). This study aims to shed light on how undergraduate students proceed when they are presented with new (to them) mathematical definitions by addressing the following questions: How do students make use of mathematical definitions new to them? What are their spontaneous reactions? What contributes to their difficulties with "unpacking" and using abstract mathematical definitions? How do they use a definition in three different settings: examples, proofs, and true/false questions? This research falls within the scope of a framework developed by Selden and Selden (1995, 2008). I particularly focus on the part of the framework referring to operable interpretations of statements and formal and informal forms of a mathematical statement.

Literature Review

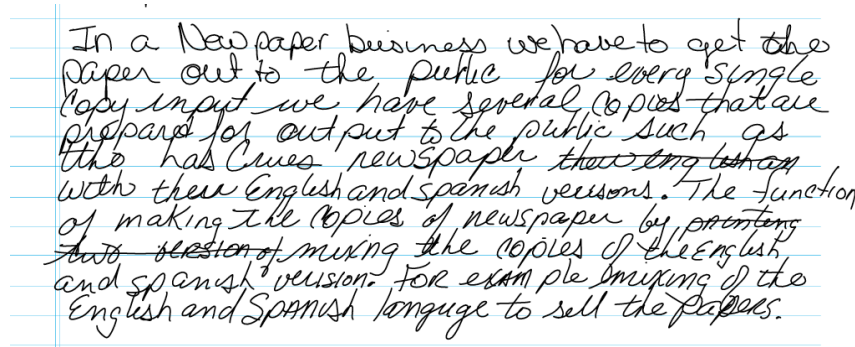
Research has revealed that students have a variety of difficulties understanding and using definitions, many of which could be attributed to the "structure of mathematics as conceived by mathematicians and the cognitive processes involved in concept acquisition" (Vinner, 1991). According to Tall (1980), "concept image is regarded as the cognitive structure consisting of the mental picture and the properties and processes associated with the concept…Quite distinct from the complex structure of the concept image is the concept definition which is the form of words used to describe the concept." A mismatch between the concept image developed by an individual and the actual implications of the concept definition often leads to obstacles in learning. The work of several researchers has confirmed this. Parameswaran (2010) has addressed how mathematicians approach new definitions; her research shows that examples and non-examples play a very important role in the process of learning a new definition. However, students are not frequently asked to generate

examples, most of the time they are provided with a worked-out example or an illustration (Watson & Mason, 2002). Although there are some studies addressing students' and mathematicians' use of definitions in the construction of proofs, there seems to be a lot more investigate in respect to students' perceptions of mathematical definitions.

Methodology

I conducted a series of semi-structured task-based interviews with voluntary participants taking a transition-to-proof course. There were five definitions: function, continuity, semigroup ideal, isomorphism, and group, spanning most of the course. I interviewed 23 volunteer students individually. For each definition, 4-5 students were interviewed approximately two weeks before that particular definition came up in the course, to assure they had not seen it before (in class). The interviews were audio-recorded, and the students used LiveScribe pen in order that their real-time responses could be analyzed. I wanted the interviews to address the following four main points. First, I wanted the students to be presented with a definition for the first time, that is, they were interviewed about a definition that they had not yet seen in class. Second, I also wanted to test their ability to interpret the definition, so I asked the participants if they were able to come up with some examples that could illustrate the definition. Third, I looked for information on their ability to make use of the definition in the construction of a proof that required no more than the definition itself. And fourth, I was interested in the way they could reason about true/false statements involving the definition. These four points were addressed by the design of five handouts, presented one after the other to each student individually in a 60 to 90 minute interview. This design was partly inspired by the work of Dahlberg and Housman (1997) and the work of Housman and Porter (2003). The first phase of the analysis was done considering each of the five definitions separately. I concentrated on only one definition at a time, analyzing all the data on the five handouts for the four to five respective students considering that definition. The second analysis was done by handout. I looked at the general performance across all handouts, considering one handout at time, across all participants.

Results

From a detailed observation and analysis of students' actions working with definitions newly introduced to them, a general perspective on students' behaviors has been developed. There seem to be various stages that the participants were in during their attempts to use mathematical definitions in the three different settings of this study; evaluating examples, constructing proofs, and answering true/false statements presented in five handouts. Students were initially provided with a handout containing only a definition, and then other four handouts with the different tasks were given. As a result of the analysis five stages (0-4), listed and described in detail in the following sections, were identified. These stages are not intended to be a definitive set of steps through which a student must pass in order to use definitions appropriately, but they describe and categorize the different behaviors observed amongst the 23 participants of this study. Each one of the participants worked on only one of the five definitions (function, continuity, group, ideal, and isomorphism) and was classified in one of the five stages according to their performance during the 60-90 minutes of the semi-structured interview. Further explanation and details about the design of the whole study (such as the mathematical definitions and the handouts) can be found in Holguin (2015). This paper exhibits only one of the main results.


Description and evidences of each of the stages

Stage 0: Unawareness. Students at Stage 0 see and treat mathematical definitions as everyday words. A student is in Stage 0 if he/she does not see mathematical definitions as having meanings separate from the everyday linguistic meaning of the words used in them. Such students relate the words in a mathematical definition to words used in everyday language or to everyday situations.

They make connections to their previous knowledge, but those connections are not necessarily mathematical. Mathematical symbols are often hard to interpret perhaps because in the everyday linguistic context definitions rarely have symbols involved as mathematical definitions often do. This behavior was observed in two of the 23 students, Fay and Gaby. Fay was working with the definition of function. She wants to become a secondary mathematics teacher. When she was asked to explain the definition in her own words she said:

Fay: …a function is like a machine; you put something in to get something out. Like a machine that makes copies of a newspaper in English and Spanish…

Then the interviewer asked her if she could write down her thoughts. Figure 1 shows what Fay wrote.

Figure 1. Fay's thoughts about function.

Fay was classified in Stage 0 because the example she came up with exhibits a lack of awareness of the distinction between mathematical and everyday definitions. At best, she understood function as a process (machine) that gives a final product when some inputs are provided. But she gave an example of a newspaper copy machine that produces both English and Spanish versions. One can interpret this as indicating that she might be trying to express the mathematical property of a function of having one and only one output for every input, but has expressed it the wrong way around. She was assigning several copies to a single input, which violates the second condition of the given definition of function. In addition, she was blending her somewhat fuzzy mathematical ideas with an inappropriate real life situation.

Gaby was an engineering major; she was also asked to explain her understanding of the given definition. She read the definition of a group and she replied the following.

Gaby: A group is not a group if there is not different components or… you know, several elements. So if it were only one element you wouldn't call it a group. I think that's why [it] is telling you that if there is a g element of G and then there is a g' which is an element also of G, and those things comb... you know, make a group. To be a group I think you need to have more than one element."

One can see that Gaby is using the everyday meaning of the word "group". Later in the interview Gaby was asked to provide an example:

Interviewer: Can you think of a particular example? Can you tell me the properties that an object would need to have in order to be a group?

Gaby: OK, so you have to have an element, or actually each… you have to have a semigroup, each element has to have a subset... for example, I don't know, this is what I can picture, like the school. The school is a [with emphasis] school, as a whole, but it has different colleges, the university has colleges, there is colleges that belong to the university and each college has

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

departments, like for example like a g', so departments, colleges, you know, are composed for and there... you know, the university, which equal university. That's the way I see it.

Gaby's example, as Fay's, is a blending of a real life situation with pieces of mathematical knowledge (some ideas from set theory). In Gaby's case, I find it harder to speculate which mathematical properties might be involved in her explanation. The only thing I see is that she might be thinking that the prefix "semi" before the word "group" implies that a semigroup is something smaller than the group but contained in it. While explaining the definition in her own words, she also drew the diagram in Figure 2.
Figure 2. Gaby's diagram about group.

From this diagram and the conversation we had about it, I see that she might have been thinking of *g* (by itself) as a subset of *G* instead of as an element. And perhaps she was trying to illustrate the property of having an identity element, that is to say, the part of the definition of group stating that for each *g* in *G* there is a *g'* in *G* such that *gg'=g'g*=1. For the aforementioned reasons, Fay and Gaby were classified in Stage 0.

Stage 1: Awareness. Some students seemed able to recognize the differences between mathematical definitions and everyday definitions. They seemed to be aware of the importance of mathematical definitions, but they seemed to find them too complicated to make use of them or to think of examples of them. They seemed to make strong connections to definitions previously seen in other mathematics classes or to any mathematical concepts that seemed familiar to them, or that they thought were related to the particular presented definition. Students in Stage 1 did not demonstrate a recognition of how, why, what, or when to use mathematical definitions; there five out of the 23. The following excerpts illustrate these students' behaviors.

Carlos was majoring in engineering technology and was interviewed on continuity. He was told at the beginning of the interview, as every participant had been, that he was being given a definition. He read it and immediately afterwards he started talking. The following is a piece of what he said.

Carlos: This is like a weird... a weird problem
Interviewer: Have you seen this definition before?
Carlos: I have seen some of the symbols... in this class... in Algebra, Precalculus, Technical Calculus. I haven't seen absolute value symbols in this class yet, or continuous.
Interviewer: How about other classes?
Carlos: Continuous? Oh yeah! yeah! in calculus! Like natural log e be continuous… or they already gave a problem like saying here is a chemical that grows continuously at so and so, yeah that's the kind of problems I had.
Interviewer: And what was the meaning of continuity in those cases?
Carlos: The symbol e, then is e like decaying continuously or growing continuously, so yeah that's where. But for this problem, I don't know, is kind of like... I never... I don't how to approach it.
Interviewer: Well I am not giving a problem; it is just a definition, all I am asking is to read it and I'm just trying to see what you can see in it. So do you get some meaning from it? Do you get what it is telling you?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Carlos: Yeah, just slightly... well you are telling there is a function from R to R, so something from R has to be in R. And the a is an element of R which is in f function continuous and... I don't really know about continuous 'cause we never did continuous so... or either greater than... I'm like what is that? Even delta... I know what is going from here, [pointing to the function] but I get knocked out here...[pointing to the inequalities] I'm like what is going on? I don't even know.

Interviewer: Well, but you said you have seen or heard the word "continuous" before, can you come up with some examples of something that has to do with continuous functions?

Carlos: Yeah, OK. I can just make it up, right?

Interviewer: Yes, yes, definitely.

Carlos: Mmmm... should I use like a chemical? or just say a dead body decays...

[Carlos continues to write what is shown in Figure 3]

Figure 3. Carlos' continuous function example.

It seems interesting that Carlos' first reaction was to think there was a problem to solve. His first words after reading the definition were "this is like a weird problem", when there was no problem at all. Every participant of the present study was provided with the same explanation and instructions about the procedure of the interview. It is not clear to me why Carlos thought of the definition as a problem. It might be due to the fact that, as stated by him, he did not understand much about what was being stated.

Another behavior worth noticing is the connection with previous knowledge from other mathematics classes about a function that grows or decays continuously. This once more demonstrates that students use their concept images whether or not they match the concept definition. These behaviors identify Carlos in Stage 1; he used mathematical terms to communicate his thoughts but he didn't get much from the information in the definition, he basically ignored it.

Stage 2: Contextualization. By contextualize, I mean being able to identify when and where to use a certain mathematical definition. Some students seemed to understand that a given definition makes sense within a particular situation of a particular area of mathematics, and that it is in such context that the definition should be used in the way it is stated. They were aware of their previous mathematical knowledge, but they seemed to understand that their previous knowledge might not always be helpful. There were 3 participants presenting this behavior.

Fred was majoring in mathematics. He worked with the definition of function.

Fred: I have never seen this definition before ... I have heard the word function from previous math classes, Calc I, II, III, trig and Precalc… It helps with graphing, but we are not going into graphing here.

One could see that, from looking and reading the definition, Fred had noticed a difference. He said that he hadn't seen this definition before, but he had definitely heard the word "function" before. He distinguished, without being told to, that this was a different context compared to others where he had used the definition previously.

Frank was an engineering major. He considered the definition of function. The following excerpt shows what he said after reading it.

Frank: So… what do I do?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

> *Interviewer*: Well… there is nothing to do now…It is only a definition, for now it's just reading it… Have you seen this definition before?
>
> *Frank*: It does sound like a derivative, because of the prime. [Clarification provided.]
>
> *Interviewer*: Now, have you heard the word "function" before?
>
> *Frank*: Yes, in Calculus, 191, 192, Differential Equations, I don't think I heard of function when I did Statistics, but yeah, in almost every math class … A function is like machine. And so a function is basically like a, this is the way some people do it, like here is a machine [drawing] and then so you have *x*, which is the independent variable and it goes through this machine.

Frank was classified in Stage 2 because although he was not strictly following the given definition, he seemed to know that some mathematical concepts are common to different mathematics courses. He was also using his knowledge from previous mathematics classes.

Stage 3: Implementation attempts. In Stage 3, a student is able to recall, look for, and attempt to use/follow mathematical definitions, not necessarily with success. Some participants appeared to understand the context in which the given definition was relevant; they tried to stick to it as much as possible. This does not necessarily imply that the student had acquired/developed the ability to use the definition correctly, but at least he/she appeared able to understand the importance of considering the explicit and/or implicit details of the definition. Students in this stage seemed to know there is something embedded in each part of the definition that needs to be unpacked. But still they didn't fully unpack the definition and use it on the tasks included in the handouts. There were 9 students identified in this stage.

Candy worked with the definition of continuity at a point. She was a graduate student in the Department of Curriculum and Instruction. This excerpt from the interview shows her explanation of how she was trying to prove a statement that required only the use of the definition, namely, that f:R→R defined by $f(x)=2x+3$ is continuous.

> *Interviewer*: So what is your approach? What are to trying to prove?
>
> *Candy*: OK, so I'm trying to prove this function is continuous. So you just let out your specifications, let *R* be the real numbers, let it be a function defined by the *2x+3*...and so... there is going to be... I want to use this definition... the definition for continuous and just sort of work that, so I didn't know if I should... suppose... that there is... but...[whispers reading the definition] I don't know if I need to prove that there is an 'a' also in the reals or... or not, or should that... yeah, I guess I'm not really quite sure... we have the reals over here and they are following this function 2*x*+3, and there is an element in here [R] that is mapping to this element in here [R] and... so that... I want to see...oh! I guess that would be, I guess I should use this... OK... so to me, maybe I wanna assume that there is an "*a*" in *R* such that this and that is true but... yeah... I... I'm not quite sure… I don't know I'm going around in circles…

Above we can notice that Candy was trying to follow the definition, she even stated that. Candy was the participant that best represented Stage 3. In her interview she seemed to be trying very hard to use and understand what the definition stated.

Stage 4: Accomplishment. This last stage can be described as the stage of successful manipulation of the definition. Students at this stage were able to use the definition appropriately and according to the particular mathematical setting. These students had passed, perhaps implicitly, through all previous stages and they were, somehow, able to determine whether or not a mathematical object satisfied the given definition. Please notice that I am not claiming that students at this stage had achieved conceptual understanding of the definition, however they demonstrated the ability to stick to the definition and used it appropriately during the interview. Conceptual understanding might have occurred but I'm not accounting for it in this study. The following excerpts

show some of the students' work that I considered a successful usage of the given mathematical definition. There were 4 students in this stage.

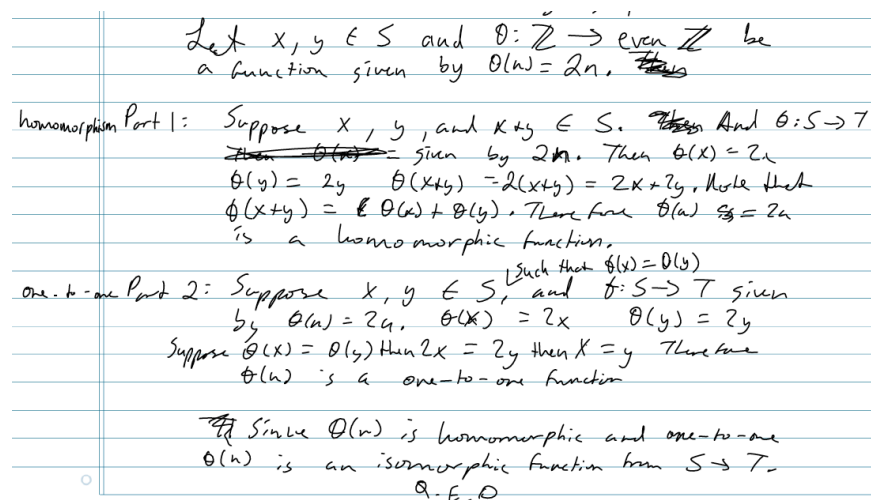
Scott worked with the definition of isomorphism. Scott was a mathematics major. In the following portion of his work (see Figure 4) one can see that he was able to unpack and use the definition appropriately, in particular, in attempting a proof.


Figure 4. Scott's proof attempt.

Scott was using the proof framework suggested in class. This proof could have been written better, but Scott's attempt let me see that he was able to use and unpack a definition that had been newly introduced. For this reason, he was classified in Stage 4.

Summary and Conclusions

After identifying each participant as in one of the five stages, I noticed that these stages appear to be nested. Thus it is a conjecture that the process of getting to use a mathematical definition appropriately is teachable. One can attempt to learn how to be competent at it. Many opportunities for student success might be hidden behind the quality of communication between the teacher and the learner. However, to test this conjecture further research would be needed. The present study provides evidence that using mathematical definitions can be a difficult task for students, often expected to do it straightforwardly. I find it important to remark that conceptual understanding of the mathematical definition is not necessarily involved in these stages. These stages describe solely students' behavior reading and using mathematical definitions. Although to account for conceptual understanding was not the aim of this study, it is plausible that knowing in which of these stages a student is situated could be a fundamental early step towards the development of conceptual understanding. Being aware of the stage in which a student is, can make us more sensitive to their behaviors and the obstacles they face in attempting to consolidate their formal mathematical skills.

THE ROLE OF DIAGRAMMATIC REASONING IN THE PROVING PROCESS

Adalira Sáenz-Ludlow   Anna Athanasopoulou
Univ. of North Carolina at Charlotte   Univ. of North Carolina at Charlotte
sae@uncc.edu   aathanas@uncc.edu

The paper focuses on student-teachers' geometric diagrams to mediate the emergence of different proofs for a geometric proposition. For Peirce, a diagram is an icon that explicitly and implicitly represents the deep structural relations among the parts of the object that it stands for. Geometric diagrams can be seen as epistemological tools to understand explicit and hidden geometric relations. The systematic observation of and experimentation with geometric diagrams triggers abductive, inductive, and deductive reasoning which allows for the understanding of the conditions given for a geometric construction and its necessary logical consequences. We adopt Stjernfelt's model of diagrammatic reasoning to analyze two proofs for a geometric task posed to student-teachers who participated in a four-month classroom teaching experiment.

Introduction

Peirce conceptualizes *sign* as a holistic triadic entity (*object*, *sign-vehicle*, *interpretant*). The word *sign* is sometimes used to refer to the *object* itself and, other times, to the mode of representation of that o*bject*. Peirce (1906) makes reference, through the paper, to the sigh being a general as to its object and as to its matter. The reader, then, is left with the task of interpreting either meaning from the context in which the word *sign* is used. His addition of the *interpretant*, as the third component of the sign, is one of his many significant contributions to semiotics. This component takes into account the effect of the sign-vehicle in the mind of the Person who interprets, uses, or produces it.

Peirce also classifies sign-vehicles as icons, indexes, and symbols according to their relation with the *object* they stand for. Fisch (1986) argues that this triad is not an autonomous species of sign-vehicles as if it were dogs, cats, and mice. Rather, it is a nested triad in which more complex sign-vehicles contain and involve specimens of simpler ones. Symbols typically involve indices which, in turn, involve icons. In other words, icons are incomplete indices which are, in turn, incomplete symbols.

The icon is a sign-vehicle that bears some sort of resemblance or similarity to its *object*. Peirce subdivides the icons into three types: images, diagrams, and metaphors. He argues, icon-diagrams have structural similarities with the structure of their *Objects*. This enables the observation, experimentation, and the emergence of inferential reasoning. He calls this amalgamated thinking *diagrammatic reasoning*. The index, instead, has a cause-effect connection to its *object*, and it directs the attention to its *object* by blind compulsion that hinges on association by contiguity (CP 1.558, 1867). The symbol, instead, hinges on intellectual operations, cultural conventions, or habit (CP 3.419, 1892).

> By diagrammatic reasoning, I mean reasoning which constructs a diagram according to a precept expressed in general terms, performs experiments upon this diagram, notes their results, assures itself that similar experiments performed upon any diagram constructed according to the same precept would have the same results, and expresses it in general form. (CP 2.96, 1902)

Diagrams as Tools for Inferential Thinking

Peirce defines icons far beyond their merely perceptual aspects: "A great distinguishing property of the icon is that by the direct *observation* of it other properties concerning its *object* can be

discovered than those which suffice to determine its construction" (Peirce 1895, Quoted in Stjernfelt, 2007, italics added). He clearly establishes diagrams as icons and as the only sign-vehicles from which more can be learned about the *object* beyond the grammar and syntax of their construction. While physical diagrams remain in the field of perception, new relations among their parts can possibly emerge by means of thought-experimentation and imagination. A diagram, then, can be characterized in one's mind in a variety of ways, "…as a token, as a general sign, as a definite form of relation, as a sign of an order in plurality, i.e., of an ordered plurality or multitude" (Robin 1967, Catalogue number 293, p. 31). The diagram, being an icon, has some kind of similarity with its *Object* in the sense that it displays the interrelations between the parts of the *object* in a skeleton-like sketch (Stjernfelt, 2007).

Peirce also argues that "the iconic diagram and its Initial Symbolic Interpretant constitute what… Kant calls *schema*, which is on one side an object capable of being observed while on the other side is a General" (NEM, p. 316) and that more can be learned about its *object* by contemplation of the explicit and implicit relations hidden in the diagram. In fact, he considers that diagrams are *epistemological tools* for inferential thinking. According to him "all necessary reasoning is diagrammatic" (Robin 1967, Catalogue number 293, p. 31).

Being a student of Kant's, Peirce adopts and adapts Kant's concept of geometric construction: "such a construction is formed according to a precept furnished by the hypotheses; being formed, the construction is submitted to the scrutiny of *observation*, and new relations are discovered among its parts, not stated in the precept by which it was formed, and are found, by a little *experimentation*, to be such that they will always be present in such a construction" (CP 3.560, italics added). This operational definition entails that once an empirical diagram is constructed what follows is some kind of mental experimentation and inferential experimentation.

A classic example of inferential manipulation and experimentation is Euclidean geometry. "Euclid first announces, in general terms, the proposition he intends to prove, and then proceeds to draw a diagram, usually a figure, to exhibit the antecedent condition thereof" (NEM, p. 317). Nowadays, given the dragging mode of dynamic geometry environments, the manipulation of geometric figures is expedited and, with it, the possibility of intentional experimentation. The observation of variant and invariant relations among the elements of the figure facilitates the conjecturing of its properties as well as the process of proving or disproving them. Stjernfelt, a semiotician, who has dedicated articles and books to the analysis of Peirce's diagrammatology, extensively argues that his definition of icon is non-trivial. This definition, he argues, avoids the weakness of most definitions of similarity because of its connection to the notion of observation and inferential experimentation to discover additional pieces of information about the *object* it stands for.

> …all deductive reasoning, even simple syllogism, involves an element of *observation*; namely, deduction consists in constructing an icon or diagram the relations of whose parts shall present a *complete analogy* with those of the parts of the object of reasoning, of experimenting upon this image in the imagination, and of observing the result so as to discover unnoticed and hidden relations among the parts (CP 3.363, italics added).

Diagrammatic Reasoning Process

Stjernfelt captures the essence of the process of diagrammatic reasoning in Figure 1. This is to say, a process which is rooted in perceptual and mental activity to produce chains of inferences. This figure is especially useful for thinking about proving and problem-solving processes. This skeleton-like figure, which is an icon-diagram itself, synthesizes a manifold of relationships that amalgamate the construction of a diagram, the observation of structural relations among its parts, and the physical and mental manipulation to produce a chain of deductions so as to attain a conclusion.
Figure 1. Diagrammatic reasoning process (Stjernfelt model, 2007).

In addition, Stjernfelt also describes this process in terms of the emergence of evolving interpretants generated during the transformation of diagrams. In this transformation, the implicit aspects of the *object* of the diagram are unveiled by means of the analogy between the relations among the characteristic properties of the object and the structural relations among the parts of the diagram. That is, the interpreting Person transforms icon-diagrams into sign-vehicles that have more and more symbolic aspects that hinge on mental operations and inferential reasoning. It is in this sense that "symbols grow," as Peirce says, because the meanings of their *objects* grow deeper and more general in the mind of the interpreting Person. A sequence of interpretants generated in this process is described by Stjernfelt (2007, p. 104) as follows:

a. Symbol (1)
b. Immediate iconic interpretant: Initial pre-diagrammatic icon-token that is rule-bound
c. Initial interpretant: (a+c) constituting the <u>initial transformand diagram</u>, the 'Schema' diagram-icon
d. Middle interpretant: the symbol-governed diagram equipped with possibilities of transformation (with two sources, **a** as well as **c)**
e. Eventual, rational interpretant: Transformate diagram
f. Symbol (2): Conclusion
g. A post-diagrammatical interpretant (different from **b**): This interpretant is an interpretant of **a**, but now, the diagrammatic reasoning is enriched by the <u>total interpretant of the concept **a**</u> [represented by Symbol (1)].

It is important to note that transformate diagrams are substantially contained in the transformand diagram with all its significant features. That is, diagrammatic reasoning is the process by which the interpreting Person intentionally endeavors both in the observation and manipulation of initial diagram-tokens (transformand diagrams) to mentally enrich and transform them (transformate diagrams) so that hidden relations among the parts of the *object* can be unveiled. These transformations facilitate the inference of the hidden structure of the *object*.

Methodology

A constructivist four-month classroom teaching-experiment on the teaching-learning of geometry was conducted with nine pre-service and in-service mathematics student-teachers who were taking a geometry methods course using the Geometer's Sketchpad (GSP). The main goal of this experiment was to improve student-teachers' ability to conjecture and to prove geometric propositions in plane Euclidean geometry using the GSP. An inquiry approach was used in which tasks were posed, drawings were constructed and manipulated by the students, conjectures were made, and proofs were generated. Student-teachers proved geometric statements in class and in homework assignments using this inquiry approach. They completed weekly homework assignments of at most seven tasks using the GSP. At the beginning of the semester, student-teachers were given a pre-test with twelve

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

tasks to be solved using pencil and paper. At the end of the semester, they were given a post-test with thirteen tasks to be solved using the GSP. The purpose of these tests was to observe the influence, in the student-teachers' proving process, of the dynamic diagrams constructed, observed, and manipulated in the GSP environment.

Here we analyze, from the diagrammatic reasoning point of view, two proofs that pre-service student-teachers produced for task#1 in homework #9. This task could be proved in different ways: without using auxiliary lines and using auxiliary lines. The core of the geometric argument for each of the proofs was the conceptualization of congruent triangles embedded, implicitly or explicitly, in the diagram.

Data Analysis

In homework #9 student-teachers were given seven tasks. Task#1 was the following (see Figure 2):

> **Construct an isosceles triangle △ABC (AB ≅ AC). Extend the congruent sides BA and CA from the common vertex A and take AD = AE respectively. Let point M the midpoint of the base BC.**
> **Prove that the triangle △MDE is an isosceles triangle.**

Figure 2. Task#1 given to student-teachers.

There are many different ways to prove this task but only one without the use of auxiliary lines. Only one student-teacher completed the proof this way. Four student-teachers constructed auxiliary lines EB and DC and completed the proof. Two student-teachers used the property that the median from the vertex-angle in an isosceles triangle is also perpendicular bisector. The other two student-teachers were unable to complete the proof because they constructed an incorrect drawing by extending the sides AB and AC from vertices B and C. The teacher wrote her proof and then presented it to the class.

First Proof

When the student explained her proof to the class, she showed on the computer screen the sequence of diagrams (Figures 3a, 3b, & 3c). This sequence conceals a sequence of interpretants, in the mind of the student-teacher (the interpreting Person), that allowed her a mental transformation of the same physical diagram (transformand diagram, i.e., Figure 3a) into transformate diagrams (Figures 3b & 3c) to conceptualize geometric relations. Finally, she presented the written proof of the given statement.

She constructed a robust isosceles △ABC using two radii of a circle centered on the vertex-angle A. In the extensions of sides AB and AC, from vertex-angle, she constructed congruent line segments AD and AE respectively. She continued with the construction of the midpoint M on base BC and of the △EMD (see Figure 3a). Then the student-teacher wrote down the given information $\overline{AB} \cong \overline{AC}$ and $\overline{AD} \cong \overline{AE}$ (see Figure 3b) as well as the proof that △BDM is congruent to △CEM by SAS. For the congruence of the triangles she explained that $\overline{MB} \cong \overline{MC}$ because point M is midpoint of base BC; $\overline{DB} \cong \overline{EC}$ because $\overline{DA} + \overline{AB} \cong \overline{EA} + \overline{AC}$; and $\angle ABC \cong \angle ACB$ as base-angles of isosceles triangle △ABC. The congruence of triangles △BDM and △CEM implies $\overline{DM} \cong \overline{EM}$ proving that triangle △DME is isosceles (see Figure 3c).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 3. (a) Initial construction; (b) Focus on isosceles triangles ΔABC and ΔADE; (c) Comparison of triangles ΔDMB and ΔEMC.

Following is also the description of the sequence of interpretants generated:

- *Inmmediate iconic interpretant:* Visual perception of two isosceles triangles ΔABC and ΔADE and the triangle ΔEMD (Figure 3a, i.e., transformand diagram).
- *Initial Interpretant*: A realization that adding congruent line segments ($\overline{AB} \cong \overline{AC}$ and $\overline{AD} \cong \overline{AE}$), by parts, would generate new congruent line segments ($\overline{DA} + \overline{AB} \cong \overline{EA} + \overline{AC}$ then $\overline{DB} \cong \overline{EC}$) (Figure 3b, i.e., transformate diagram).
- *Middle Interpretant*: ΔDMB and ΔEMC have two congruent sides ($\overline{DB} \cong \overline{EC}$ and $\overline{MB} \cong \overline{MC}$) and the respective angles between them are also congruent ($\angle ABC \cong \angle ACB$) being the base angles of isosceles ΔABC (Figure 3b, i.e., transformate diagram).
- *Rational interpretant*: Given that ΔABC is isosceles with $\overline{AB} \cong \overline{AC}$, the congruence of the base angles is implied ($\angle ABC \cong \angle ACB$). From the fact that point M is the midpoint of side BC, the congruence of BM and MC is also implied ($\overline{BM} \cong \overline{MC}$). Also using the congruence $\overline{DB} \cong \overline{EC}$ triangles ΔDMB and ΔEMC are congruent by SAS. (Figure 3b, i.e., transformate diagram).
- *Eventual rational interpretant*: Line segments $\overline{DM}$ and $\overline{EM}$ are the third sides of congruent triangles ΔDMB and ΔEMC; thus these line segments have to be congruent (Figure 3c).
- *Post-diagrammatical interpretant*: Consider triangles ΔEMC and ΔDMB. How are they related?
- $\overline{BM} \cong \overline{MC}$ (point M is the midpoint of $\overline{BC}$)

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

- ∠ABC ≅ ∠ACB (base-angles in the isosceles triangle ΔABC)
- $\overline{EC} \cong \overline{DB}$ ($\overline{EA} + \overline{AC} \cong \overline{DA} + \overline{AB}$ because $\overline{EA} \cong \overline{DA}$ and $\overline{AC} \cong \overline{AB}$ adding by parts)
- Therefore, ΔEMC ≅ ΔDMB by SAS and the corresponding sides $\overline{EM}$ and $\overline{DM}$ are congruent making triangle ΔEMD an isosceles triangle (Figure 3c, i.e., transformate diagram).

Her written proof certainly corresponds to the inferred intepretants from her diagrams (see Figure 4):

> **Given M is the midpoint of BC, ∴ CM = BM**
> **Given isosceles △ABC, ∴ AC = AB and ∠C = ∠B**
> **Given AE = AD, then AE + AC = AD + AB, ∴ EC = BD**
> **Therefore, triangles △EMC and △DMB are congruent by SAS.**
> **This implies that ME = MD making triangle △MED isosceles triangle.**

Figure 4. First proof of Task#1 without auxiliary lines.

In the above proof, the student-teacher used direct relations between congruent corresponding sides and angles of isosceles triangles in the diagram to prove the congruence of triangles ΔEMC and ΔDMB. Then she implied the congruence of line segments $\overline{EM}$ and $\overline{DM}$. Thus, she proved that ΔEMD is isosceles.

Second Proof

The four student-teachers who used the auxiliary line segments $\overline{EB}$ and $\overline{DC}$ gave essentially the same proof (see Figure 5).
Figure 5. Drawings using the auxiliary line segments EB and DC.

Figure 5 presents the diagrams that four student-teachers gave using auxiliary lines EB and DC (or DB and EC). Below is the proof written by one of the four students, which corresponds to the first diagram on the left in Figure 5. The other student-teachers wrote similar proofs presenting the same argument (see Figure 6).

> AB ≅ AC, AD ≅ AE, and BM ≅ CM through the construction. Also, ∠CAD ≅ ∠BAE (Task 1). Thus, by the Side-Angle-Side Theorem △ABE ≅ △ACD. Since △ABE ≅ △ACD and BE corresponds to CD, BE ≅ CD and ∠ABE ≅ ∠ACD = a. By Homework 8 ∠ABC ≅ ∠ACB = y. Thus ∠EBM = x+y = ∠DCM. Thus by the Side-Angle-Side Theorem, △EBM ≅ △DCM. Since △EBM ≅ △DCM, ME ≅ MD. Therefore △MDE is an isosceles triangle since two of its sides are congruent.

Figure 6. Second proof of Task#1 using auxiliary lines.

This student-teacher started with the relations $\overline{AB} \cong \overline{AC}$ and $\overline{AD} \cong \overline{AE}$ according to the construction of the isosceles triangles in Figure 5 and he also used the congruent vertical angles ∠CAD and

$\angle BAE$. He proved that triangles ΔABE and ΔACD are congruent by SAS. From this he implied that corresponding sides and angles are congruent ($\overline{BE} \cong \overline{CD}$ and $\angle ABE \cong \angle ACD$). Using the congruence of the base angles $\angle ABC \cong \angle ACB$ in the isosceles triangle ΔABC and the congruence $\angle ABE \cong \angle ACD$, he proved that $\angle EBM \cong \angle DCM$ as sums of congruent angles. Combining the relations $\overline{BM} \cong \overline{MC}$, $\overline{BE} \cong \overline{CD}$, and $\angle EBM \cong \angle DCM$, he proved the congruence of triangles ΔEBM and ΔDCM by SAS. An implication of the congruence of triangles ΔEBM and ΔDCM is that $\overline{EM} \cong \overline{DM}$. Thus, he concluded that ΔEMD is isosceles.

The above description can be unfolded into a sequence of diagrams that conceals a sequence of interpretants in the mind of the student-teacher (the interpreting Person). These interpretants allow for mental transformations of the same physical diagram (transformand diagram, i.e., Figure 7a) into transformate diagrams (Figures 7b, 7c, & 7d) to conceptualize other geometric relations and, finally, the proof of the given statement.

(a)   (b)

(c)   (d)
Figure 7. (a) Initial construction; (b) Comparison of triangles ΔABE and ΔACD created by auxiliary lines EB and DC; (c) Comparison of triangles ΔEBM and ΔDMC; (d) Conclusion triangle ΔEMD is isosceles.

- *Immediate iconic interpretant:* Visual perception of triangles (transformand diagram) constituted by two isosceles triangles (ΔABC and ΔADE) and also ΔEMD (Figure 7a, i.e., transformand diagram).
- *Initial Interpretant* A realization that drawing line segments $\overline{EB}$ and $\overline{DC}$ would generate two new sets of triangles: ΔEAB and ΔDAC & ΔEBM and ΔDCM (Figure 7b, i.e., transformate diagram).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

- *Middle Interpretant*: The segments $\overline{EM}$ and $\overline{DM}$ which are sides of ΔEBM and ΔDCM are also sides of ΔEMD. (Figure 7c, i.e., transformate diagram)
- *Rational interpretant*: A realization that $\overline{AB} \cong \overline{AC}$ are congruent sides of the given isosceles ΔABC. $\overline{AD} \cong \overline{AE}$ is a structural relation of the task. $\angle EAB \cong \angle DAC$ are vertical angles. Thus, ΔEAB and ΔDAC are congruent by SAS. Then both, the congruence of line segments $\overline{EB}$ and $\overline{DC}$ and the congruence of angles $\angle EBA$ and $\angle DCA$ are implied. (Figure 7b, i.e., transformate diagram)
- *Eventual rational interpretant*:
- How the line segments $\overline{EM}$ and $\overline{DM}$ could be compared? To which other triangles do they also belong? Triangles ΔEBM and ΔDCM are the triangles with the line segments $\overline{EM}$ and $\overline{DM}$ as sides (Figure 7c, i.e., transforme diagram).
- *Post-diagrammatical interpretant*:
- Compare triangles ΔEBM and ΔDCM
- $\overline{BM} \cong \overline{MC}$ (point M is the midpoint of $\overline{BC}$)
- $\overline{EB} \cong \overline{DC}$ (implication from the congruence of triangles ΔEAB and ΔDAC)
- $\angle EBM \cong \angle DCM$ (adding by parts congruent angles $\angle EBA \cong \angle DCA$ and $\angle ABM \cong \angle ACM$)
- Therefore, $\Delta EBM \cong \Delta DCM$ by SAS and the corresponding sides $\overline{EM}$ and $\overline{DM}$ are congruent making triangle ΔEMD an isosceles triangle (Figure 7d, i.e., transformate diagram).

In the above proof the student-teacher used auxiliary lines EB and DC. Then he used direct relations between congruent sides and angles to prove, first, the congruence of ΔEAB and ΔDAC and, then, the congruence of ΔEBM and ΔDCM. From the last congruence of triangles he implied the congruence of line segments $\overline{EM}$ and $\overline{DM}$. This proves that ΔEMD is an isosceles triangle.

Conclusion

The significance of *diagrammatic reasoning* in the teaching-learning of geometry during the proving process is analyzed in this paper. The Stjernfelt's model of *diagrammatic reasoning*, based on Peirce's own definition, was adopted. Essentially, diagrammatic reasoning consists of the systematic observation of a geometric diagram, the experimentation with the geometric diagram, and the inferential reasoning emerging from the observation of unveiled relations among the elements of the geometric diagram. Observation allows the visual perception of the explicit relations between the elements of the diagram. Experimentation with the diagram verifies these relations and facilitates the investigation of further relations. Finally, inferential reasoning emerges mediated by prior geometric knowledge and it makes possible the completion of the proving process.

Given the spatial and visual nature of Euclidean geometry, thinking and proving without diagrams seems to be an impossible task. Thus gaining awareness of diagrammatic reasoning as an epistemological tool appears to be useful for teachers to direct not only their own thinking but also the thinking of their students.

THE EFFECT OF WORKED EXAMPLES ON STUDENT LEARNING AND ERROR ANTICIPATION IN ALGEBRA

The present study examines the effectiveness of incorporating worked examples with prompts for self-explanation into a middle school math textbook. Algebra 1 students (N=75) completed an equation-solving unit with reform textbooks either containing the original practice problems or in which a portion of those problems were converted into correct, incorrect, or incomplete examples. Students completed pre- and posttest measures of conceptual understanding, procedural problem-solving skill, and error anticipation. Results indicate the example-based textbook assignments increased students' procedural knowledge and their ability to anticipate errors one might make when solving problems. Differences in students' anticipation of various types of errors are also examined.

Keywords: Algebra and Algebraic Thinking, Cognition, Middle School Education

Introduction

Over the past few decades, a significant body of work in cognitive science has provided evidence for the Worked Example principle, which argues for having learners spend some of their practice time studying worked out examples of problem solutions rather than solving all of the problems themselves (e.g., Sweller & Cooper, 1985; Sweller, 2006). Several studies have confirmed the effectiveness of studying worked examples in computer-based classrooms (Booth, Lange, Koedinger, & Newton, 2013; Kim, Weitz, Heffernan, & Krach, 2009; Paas, 1992) and in traditional mathematics classrooms (Booth, Cooper, Donovan, Huyghe, Koedinger & Pare-Blagoev, 2015; Booth, Oyer, Pare-Blagoev, Elliot, Barbieri, & Koedinger, 2015), though none to date have examined its effect in reform classrooms. Further, studies have also expanded on the worked example principle to suggest that having students self-explain the examples (Renkl, Stark, Gruber, & Mandl, 1998), gradually fading the support provided in correct examples (Atkinson, Renkl, & Merrill, 2003), and having students also consider incorrect examples (Siegler, 2002) can have enhanced learning benefits for conceptual and procedural knowledge, both of which are critical in mathematics (NMAP, 2008).

Despite this solid body of support, these practices are not typically undertaken in real world classrooms; the incorporation of incorrect examples is looked upon as a particularly foreign practice. In the United States, teachers tend to shy away from talking about errors (Lannin, Townsend, & Barker, 2006) at least in part due to the fear that their students will adopt the errors in their own problem solving (Santagata, 2004). However, students can learn a great deal from considering errors. Two established theories provide explanations for how studying errors can be useful for learning. Ohlsson's (1996) theory suggests that explaining why an error is wrong can help learners identify the particular features of the problem that make the solution incorrect; this can lead to refinement of problem solving skills and remediation of misconceptions. In addition, Siegler's (1996) overlapping waves theory maintains that individuals know and use a variety of (correct and incorrect) strategies for solving problems, and those strategies compete for use each time a problem is encountered. Studying errors is thought to be an effective way of helping learners accept that those particular strategies are wrong and prompting them to construct and strengthen other, correct strategies (Siegler, 2002).

Consistent with these theories, recent research has found that error reflection is indeed beneficial to learning. For example, having students think about and correct their own errors can lead to greater engagement and improved problem solving skill (Cherepinsky, 2011; Henderson & Harper, 2009);

studying the errors made by others may be even more effective (Yerushalmi & Polingher, 2006), in part because it exposes students to multiple perspectives other than their own (Siegler & Chen, 2008). Incorporating incorrect examples into class assignments and prompting students to explain why they are incorrect has been found to be particularly beneficial for improving conceptual understanding (Booth et al., 2013)

Thus, there is growing consensus that students can learn effectively from explaining errors. However, textbooks don't often include incorrect examples, and creating materials and lessons that include incorrect examples can be very time consuming for teachers. Some curriculum materials have recently been developed and tested and are available for use (e.g., see Booth et al., 2015). However, these efforts are only useful for the content they have explicitly been developed for—the considerable work that goes into such efforts does not translate directly for other content areas. One possible solution would be to ask students to think about the kinds of errors that might be made and explain to themselves why those solutions would be incorrect. But are students able to anticipate the types of errors other students might make? And might explaining worked examples improve students' ability to anticipate errors? These questions are a main focus of the present study.

The Present Study

There were two main purposes in this study. First, it aimed to replicate and extend previous results showing that the use of worked examples with self-explanation prompts is effective for students learning mathematics in real world classrooms. Prior results have found that in traditional mathematics classes, where procedural knowledge is typically emphasized and conceptual knowledge may be lacking, assignments containing correct and incorrect examples to explain along with problems to solve were more effective for improving both conceptual and procedural knowledge than assignments in which students solved all of the problems themselves. In the present study, correct, incorrect, and partially completed examples were incorporated into reform mathematics classrooms, where conceptual knowledge is typically emphasized through rich problem-based activities, but procedural knowledge may suffer (NRC, 2004). We hypothesize that worked examples will still be effective in a reform classroom and investigate differences in effectiveness for conceptual vs. procedural knowledge.

The second purpose of this study was to examine students' ability to anticipate the types of errors other students might make when solving equations, and determine if this ability is improved after experience explaining correct and incorrect examples, which highlight features of problems for which students might have misconceptions and demonstrate incorrect methods for solving the problems. We will examine the types of errors that students anticipate and determine how the anticipated types of errors change after instruction in general and/or the worked examples intervention.

Methods

Participants

Seventy-five 8th grade Algebra I students from an inner-ring suburban middle school in the Midwestern United States participated in the study (55% female; 59% African American, 21% White, 15% American Indian/Alaskan, 4% Asian, and 1% classified as other ethnicities). The study employed a quasi-experimental design where students were assigned to the treatment and control groups according to their rostered section of Algebra I. The four sections of Algebra I were taught by two teachers, with each teacher having one treatment and one control class. In all, 37 students (49%) participated in the experimental group while 38 students (51%) participated in the control group. All of the Algebra I classes utilized the Connected Mathematics Project 2 Curriculum (CMP2; Lappan, Fey, Fitzgerald, Friel, Phillips, 2006) CMP2 includes rich, problem-based investigations

during classroom lessons, and provides a variety of practice problems for students to solve afterward as classwork and/or homework. This study took place during the *Say It With Symbols* unit, which focuses on understanding symbols in algebraic equations.

Measures and Coding

A single, experimenter-designed paper-and-pencil test was utilized for this study and administered as both pretest and posttest. The test included three types of items: conceptual knowledge, procedural knowledge, and error anticipation.

Conceptual knowledge. To examine students' conceptual knowledge about problem features, we used 21 items focused on the meanings of different terms in an equation, identification of equivalent expressions, and categorization of functions as linear, quadratic, or exponential. The percentage of these items answered correctly was computed for each student at pretest and at posttest.

Procedural knowledge. To examine procedural skill, we used 9 items which asked students to solve multi-step equations, simplify expressions using the distributive property, and evaluate formulas at given values. The percentage of these items answered correctly was computed for each student at pretest and at posttest.

Error anticipation. To evaluate ability to identify errors that others might make when solving multi-step equations, we utilized one item which asked students what mistakes they thought a seventh-grader might make in solving the equation $5x - 2 = 8$. In total, they were asked to identify two potential errors. Student responses were coded first in terms of whether or not the provided responses were reasonable, and then by the type of error referenced: mistakes involving variables (e.g., handle the coefficient separately from the variable), like terms (e.g., subtract 2 from 5x), negative signs (e.g., subtract 2 from both sides instead of adding 2), equals sign (e.g., perform an operation to one side and not the other), operations (e.g., adding two numbers instead of multiplying), other reasonable errors, or unreasonable errors. For each type of error, students were scored in terms of whether at least one of their responses fit in that category.

Procedure

Prior to beginning the *Say It With Symbols* unit, all students took the paper-and-pencil pretest. Instruction for the treatment and control classrooms was kept constant within teacher (e.g., Teacher A provided the same lesson to both her treatment class and her control class). The only difference between conditions is that when students were to work on their practice problems, treatment classes were given an adapted version of the *Say It With Symbols* book. In the adapted book, approximately 26% of the practice problems were replaced with a correct, incorrect, or partial example of a solution to that problem. Teachers could assign as many or as few practice problems as they desired as long as the same items were assigned to both their treatment and control groups. When the unit was complete, teachers administered the paper-and-pencil posttest to all students.

Results

To examine the effectiveness of the treatment for improving students' conceptual and procedural knowledge, we conducted a 2 (condition: treatment vs. control) x 2 (time: pretest vs. posttest) x 2 (measure: conceptual vs. procedural) RMANOVA, with repeated measures on time and measure. The analysis yielded a main effect of time ($F(1, 73) = 23.50$, $p < .0.001$, $\eta_p^2 = 0.24$), with students performing better at posttest (M = 52%) than at pretest (M = 41%). The main effect of measure was also significant ($F(1, 73) = 52.97$, $p < .0.001$, $\eta_p^2 = 0.42$), with students performing better on conceptual items (M = 52%) than on procedural items (M = 41%). There was a significant time by measure interaction, $F(1, 73) = 15.43$, $p < .0.001$, $\eta_p^2 = 0.17$), with students improving more from pretest to posttest on procedural items (31% to 48%) than conceptual items (51% to 55%). Finally,

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

there was a significant interaction between time and condition, $F(1, 73) = 4.66$, $p = .0.034$, $\eta_p^2 = 0.04$, revealing that students in the treatment group improved more from pretest to posttest (42% to 57%) than students in the control group (40% to 46%). No other main effects or interactions reached significance.

To examine the types of errors anticipated by students and how this anticipation changes with instruction and worked examples intervention, we conducted a 2 (condition: treatment vs. control) x 2 (time: pretest vs. posttest) x 6 (error type: variable, like terms, negative signs, equals signs, operations, and other reasonable errors) RMANOVA, with repeated measures on time and error type. The analysis yielded a main effect of time, $F(1, 73) = 23.92$, $p < .0.001$, $\eta_p^2 = 0.25$), with a greater likelihood of anticipating reasonable error responses at posttest (23%) than at pretest (14%). There was also a significant interaction between time and condition, $F(1, 73) = 4.77$, $p = .0.032$, $\eta_p^2 = 0.06$), with the likelihood of anticipating reasonable errors increasing more from pretest to posttest for the treatment group (12% to 24%) than for the control group (17% to 22%). The main effect of error type also reached significance, $F(5, 69) = 10.51$, $p < .0.001$, $\eta_p^2 = 0.43$). Post-hoc tests with Bonferroni correction revealed that variable, like terms, and negative sign errors were more likely to be anticipated than equals sign and other reasonable errors; variable errors were also more commonly anticipated than operations errors (see Figure 1). Finally, there was a significant interaction between time and error type $F(5, 69) = 2.47$, $p = .0.041$, $\eta_p^2 = 0.15$). Follow-up paired-sample t-tests revealed that the likelihood of anticipating three types of errors increased from pretest to posttest: Like terms (12% to 39%; $t(74) = 4.37$, $p < .001$), operations (8% to 19%; $t(74) = 2.04$, $p = .045$), and other reasonable errors (4% to 15%; $t(74) = 2.38$, $p = .020$).

Discussion

Results from the present study replicate and extend prior studies on the effectiveness of worked examples in mathematics learning in two important ways. First, they demonstrate that incorporating worked examples into students' practice in reform classrooms is a useful practice. Even though such classrooms are more focused on conceptual understanding than traditional classrooms, studying and explaining worked examples leads to improved learning over problem-solving practice alone. In particular, improvement in procedural knowledge as a result of worked examples may be especially helpful in reform classrooms.

The second type of extension provided by the present study is that practice containing worked examples, many of which prompt students to reflect on incorrect procedures, leads to an increased likelihood that students will be able to anticipate errors that other students might make. If teachers want to make learning from errors a more prominent part of their classrooms but do not have access to—or time to create—relevant error-centered lessons, it may be desirable to have students that can think about potential errors on their own and reflect on why those anticipated errors are problematic. Introducing assignments with incorrect examples earlier in the process may train students to anticipate such errors on their own. However, further research is needed to examine the mechanism underlying this improvement and determine whether and how error anticipation skill transfers from one particular type of content to another. For example, if students' error anticipation skill improves after worked example assignments in a linear equations unit, would they be more likely to anticipate errors for solving quadratic equations? For graphing linear functions? For geometry? The answers to these questions are likely different depending on whether error anticipation improves because students get used to reflecting on errors in general or because they are exposed to examples of errors specific to that content area.

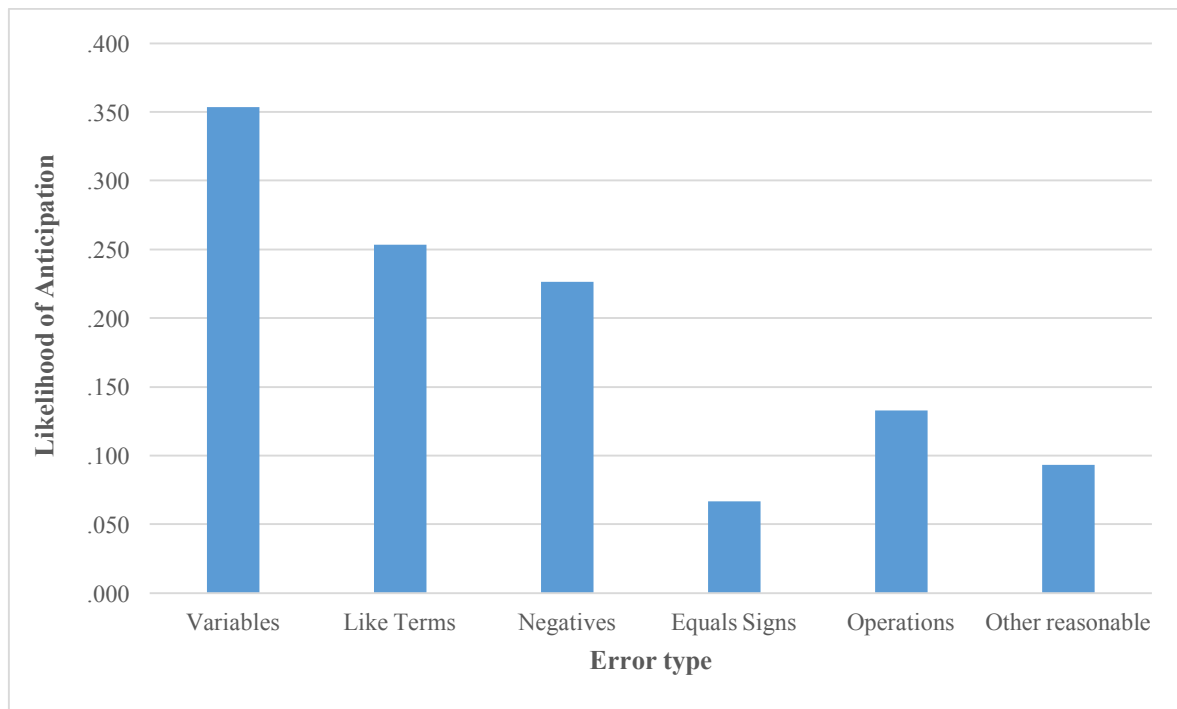

Figure 1: Likelihood of anticipation by error type.

The present study also revealed differences in the types of errors students tend to anticipate. Errors dealing with variables, like terms, and negative signs were the most frequently anticipated across time points, and anticipation of like terms, operations, and other reasonable errors were most likely to increase after students gained more knowledge about the content area. This is interesting for several reasons. For instance, prior research has identified the types of algebraic errors that are the most prevalent for Algebra I students (Booth, Barbieri, Eyer, & Pare-Blagoev, 2014). This work suggests that one of the types of highly-anticipated errors in the present study—those involving negative signs—are highly prevalent in equation-solving activities, but that the other two highly-anticipated error types—variables and terms errors—are not among the most prevalent in that content area. This indicates that students may be likely to anticipate negative sign errors because they see (or make) them frequently. However, it is not clear why students would be likely to anticipate variables or terms errors if they are not frequently made. Further study, perhaps with think aloud data collection, is necessary to determine how students come up with the errors they anticipate. A combination of think aloud and classroom observation data would also enable us to examine differences in these anticipations at pretest vs. posttest and determine why certain types of errors become easier to recognize after instruction on the topic. Knowing what the teachers are highlighting in their lessons may help explain why anticipation of certain error types increases while other types do not. If a teacher aims to get students to anticipate a wider variety of errors, further intervention targeted at helping students notice less anticipated errors may be necessary.

"RELATIONAL" EQUITY: ELEMENTARY STUDENTS CO-CONSTRUCT A SOCIAL-MATHEMATICAL POWER DYNAMIC DURING COLLABORATIVE ENGAGEMENT ON EQUIVALENCE TASKS

We report a qualitative analysis of elementary school students engaged in collaborative problem solving involving mathematical equivalence tasks. We build on previous research showing that students often use strategies based on either operational or relational understandings of the equal sign. We closely analyze three cases and identify nuanced aspects of the social interaction that influence whether and how students develop and use operational or relational strategies toward a final solution. Students' demonstrated understandings of the equal sign during collaboration aligned with those identified in past research. We argue that a social-mathematical power dynamic was co-constructed in each of the dyads, and the ways students navigated that dynamic affected the quality of individual engagement and therefore learning.

Keywords: Cognition, Elementary School Education, Equity and Diversity, Problem Solving

Previous Literature on Mathematical Equivalence and Study Objectives

Understanding that the two sides of an equation must represent the same quantity is crucial for the development of algebraic reasoning. However, many children struggle to understand the equal sign as a *relational* symbol that connotes this equality relationship. Instead, children aged 7-11 often define the equal sign in *operational* terms, describing it as a cue to add all the numbers in the problem (McNeil, 2007; Perry, Church & Goldin-Meadow, 1988). Additionally, when children of this age solve equivalence problems such as $3 + 4 + 5 = 5 + \_\_$, they often add all of the numbers together and mark 17 as the final answer (McNeil, 2007; Perry et al., 1988).

One key to solving mathematical equivalence problems correctly may be noticing the atypical location of the equal sign in these problems. When children aged 7-11 are asked to reproduce equivalence problems from memory, they often place the equal sign at the *end* of the problem rather than in the *middle* (e.g., a child will recall the problem above as $3 + 4 + 5 + 5 = \_\_$; McNeil & Alibali, 2004). This particular pattern of errors may be due to the fact that children in the United States rarely practice arithmetic problems that do not take the typical form $a + b = c$ (McNeil et al., 2006). Extensive practice with this problem format may lead children to expect that the equal sign will always appear at the end of a problem (McNeil & Alibali, 2004). Accurate encoding of the location of the equal sign in mathematical equivalence problems is closely related to using strategies based on a relational understanding of the equal sign to solve these problems correctly (e.g., Crooks & Alibali, 2013; McNeil & Alibali, 2004).

Although the association between accurate encoding of the equal sign and use of correct strategies to solve equivalence problems is well documented, no research to date has investigated how noticing the location of the equal sign leads to the development of improved problem-solving strategies within a naturalistic setting. The current study is a secondary analysis of video data from a larger, ongoing study of children collaborating to solve equivalence problems (Brown & Alibali, 2015). Our goal was to identify nuanced aspects of social interaction that affected whether noticing the location of the equal sign influenced how children solve the problems. We present a qualitative micro-analysis of a series of selected transcript segments.

Methods

The data reported here were drawn from a larger project involving 38 pairs of second and third grade friends. Each pair participated in one 45-minute session in which they completed a pretest, collaboration episode, and posttest. During the pretest, participants worked individually to solve four mathematical equivalence problems and to complete tasks assessing their understanding of the equal sign as a relational symbol. Following this pretest, the pair worked together to solve two additional equivalence problems. The collaboration episode was filmed for later transcription and analysis. The posttest was similar to the pretest and was used to assess whether the children had developed any new strategies during the collaboration episode.

This report focuses on the collaboration episodes of three pairs of children. None of the six children solved any of the pretest problems correctly. Most of the incorrect strategies they used at pretest were consistent with an operational understanding of the equal sign. Our goal is to explore what happens when children notice the location of the equal sign in the problems. We selected one pair in which the children noticed the equal sign and began to generate a relational strategy, but did not use this correct strategy to solve the problems. We also selected two pairs in which the children noticed the equal sign, generated a relational strategy, and used this correct strategy. However, the latter two pairs differ greatly in the quality of their collaboration and in the amount of learning. Comparing these pairs illuminates how social-mathematical asymmetry can influence the outcomes of peer collaboration (Gutiérrez, in press).

Results

In the following sections, we present data from three pairs of children. Each pair was instructed to work together to solve two mathematical equivalence problems, but to write down their final answers and indicate their certainty about those answers by themselves. Children had a large sheet of paper on which they could write during their collaboration, and the problems were presented on smaller sheets. For each case, we first provide a brief overview to highlight certain points of the interaction, anticipating the transcription and line-by-line analysis that follows. (Note: due to space constraints, we provide partial transcriptions for some of the pairs.)

Pair 1: The case of Elsa and Morgan

Problem 1 (8 + 5 + 4 = 4 + ___). In this excerpt, Elsa attempts to influence the pair's work and control the environment from the outset. For example, in transcript Lines 1–4, Morgan moved the problem sheet closer to them but Elsa moved the problem to a different location. Morgan momentarily spoke up (Line 5), suggesting that she wanted to argue about the placement of the problem or about Elsa's edict, but she then acquiesced so they could move on. This tiny slice of interaction mirrors the broader episode, in which Morgan puts forth an idea and temporarily resists Elsa's opposing idea before giving in and adopting Elsa's strategy.

From a mathematical perspective, Elsa's actions strongly suggest that she did not perceive Problem 1 as an arithmetic problem at all. She argued that the problem was actually a numerical "pattern" (i.e., a sequence of numbers governed by an unknown rule that determines each entry), thus she ignored the plus signs and the equal sign as well. Morgan momentarily bought into the idea of a "pattern" (Line 9) but then quickly moved to a strategy based on a different conception of the problem—one that recognizes the plus signs and the equal sign (Lines 11–17).

In our analysis below, we argue that Morgan's strategy contained the seeds of an emerging relational strategy that both children could have profited from exploring further; however, these seeds ultimately went untilled due to Elsa's influence on the collaboration (Lines 18–21). Thus, an asymmetric power dynamic was co-constructed by Morgan and Elsa and an opportunity to enter into dialogue and productively explore a new (relational) strategy was missed.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Morgan: [moves problem closer, orients it so that it's visible to them both]

Elsa: Can—can you not put that [Problem 1] on the paper? [moves Problem 1 to the center of the table]

Morgan: Yeah.

Elsa: Or how about there on the paper? That's good, on the paper.

Morgan: Wait! [glances at Elsa then looks back down at the problem; indicating each number on the left side in the problem with her marker as she speaks] eight plus five plus four equals— and that's the middle [indicates the equal sign], but [indicating the blank space "__"] four plus five plus eight wont FIT.

Elsa: No, what would be after that?

Morgan: A five?

Elsa: [briefly glances in the interviewer's direction, then back to the worksheet] Wai—ooh yeah! Would—it's a pattern!

Morgan: Ay, yeah!

Elsa: And we have to figure it out. It's eight, five, four [writes "8 5 4" on the big sheet]. Ooh three! I think.

Morgan: Wait, no! //Eight [writes "8" on the big sheet]..

Elsa: //I think it's three.//

Morgan: Five [continues writing, "8 5"]..wait!

Elsa: Four.

Morgan: Plus [writes a plus sign in her inscription, "8+5"], //plus four [continues writing, "8+5+4"]..

Elsa: //It's counting down.// [adjusts in her seat, leans in farther] It's counting down!

Morgan: Equals four plus five plus eight. [completes inscribing her equation as she talks, "8+5+4=4+5+8"]

Elsa: No we have to, we have to—the answer to the problem is [writes "3" at end of her string of numbers, as "8 5 4 3"] three.

Morgan: [gazes at Elsa's string of numbers "8 5 4 3"] Oh! [scribbles over and completely blacks out her equation]

Elsa: *Because* it's counting down. [writes "3" on her answer sheet]

Morgan: Oh! Eight, five, four, three. [writes "8 5 4 3" above her scribble, then puts down marker, picks up pencil, writes "3" on her answer sheet]

Morgan begins by reading the problem aloud, and pauses to note that the equal sign is in the middle of the problem, suggesting that the equal sign's location struck her as unexpected (Line 5). In this same turn, she expresses confusion, because she wants to balance the equation by repeating the numbers from the left side on the right, but there was only room for one number in the answer space (Line 5). This reveals her nascent understanding of the equal sign as a relational symbol; this idea could have led them to a correct strategy had they pursued it.

While Morgan is contemplating her emerging strategy, Elsa offers an alternative: that the problem is a "pattern" and they need to find the next item in the sequence (Lines 8, 10). Thus, Elsa does not view the string of characters as an arithmetic problem. At first, Morgan accepts this idea (Line 9), but then temporarily returns to her own strategy (Lines 11–17). Morgan's actions (Lines 15, 17) indicate a strong commitment to her emerging idea and getting it down on paper; she does not acquiesce to Elsa's attempts to get her attention and completes writing her equation as "8+5+4=4+5+8." However, this brief moment of agency is broken by Elsa's statement that the answer is three (Line 18). Morgan quickly agrees to Elsa's suggested answer, using her marker to cross out all the written work she had produced (Lines 19, 21). Morgan appears to be on the cusp of

understanding the equal sign as a relational symbol, but because Elsa guides the interaction through her comments and actions—and because Morgan allowed her to do so—Morgan was persuaded to abandon her emerging understanding in favor of Elsa's pattern strategy which, in this context, was less effective.

Problem 2 (9 + 7 + 5 = ___ + 9). On the second problem, Morgan made statements that assert her status as an equal collaborator (Line 23), yet her contribution still went unrecognized by Elsa. Thus, the emerging social relation that was being co-constructed remained asymmetric. From a mathematical perspective, they proposed a final solution that was based on the same "pattern" game as for Problem 1 and again ignored both the plus signs and the equal sign.

> *Elsa*: Nine... uh. [giggling] I have no idea.. What's nine plus seven plus—
> *Morgan*: Wait! This is question number two. Since the other one was going *down*, this one might be going UP.
> *Elsa*: No, because see [indicating numerals on the problem sheet] nine, seven—oh counting by twos? No counting by *odd* numbers.
> *Morgan*: Yeah!

Interestingly, this time it is Elsa who initially suggests a summation strategy (Line 22), and Morgan reminds her that they are looking for a pattern. Once reminded, Elsa quickly returns to the pattern approach, but also quickly rejects Morgan's suggestion that the pattern "might be going up" (Lines 23 & 24). Both have fully adopted Elsa's idea that the goal is to find a pattern within the sequence of numbers, and neither child references addition or the equal sign. Elsa continues to drive the interaction, suggesting a series of possible patterns, and proposes a solution of "3"—the next odd number, counting down—that Morgan immediately takes up.

After the collaboration episode, when the children solve equivalence problems individually on the posttest, neither child used a correct, relational strategy. Thus, neither seems to have benefited from the collaboration, despite the fact Morgan appeared to have the seeds of a relational strategy. We argue that the nature of their collaborative interaction made it impossible for this nascent correct strategy to fully emerge and be beneficial for either child.

Pair 2: The Case of Dylan and Shawn

Problem 1 (8 + 5 + 4 = 4 + ___). Dylan and Shawn represent another case of an asymmetric power dynamic. Just prior to the excerpt below, both children made statements about potential solutions, however the conversation flowed mostly in one direction. Dylan acknowledged Shawn's propositions but Shawn did not give any indication that he considered Dylan's ideas. Shawn kept his gaze on the problem, whereas Dylan made several attempts to make eye contact, suggesting that he wished to check in with Shawn as they went along, but this never occurred. Shawn and Dylan essentially worked separately (as indicated by overlapping speech and unacknowledged turns of talk), each developing his own understanding of the problem. Shawn eventually articulated a solution based on a relational understanding of the equal sign (Line 26), placing Dylan in a position to "buy in" to Shawn's strategy and abandon his own approach (Line 27). The only time Shawn looked away from the problem was to assert his proposed solutions.

> *Shawn*: [referring to the left side of the equation] So that's 17. [leaves tip of pencil on left "8"; glances in Dylan's direction] Four plus *what* equals 17?
> *Dylan*: Four plus what? Four plus... well// [looks at Shawn] it's four so of course there's ten.
> *Shawn*: //Four.// [quickly glances up in Dylan's direction] Four plus three!
> *Dylan*: Wait! What?! [lifts gaze up, staring out at nothing in particular]

Shawn: [glances up at Dylan] Four plus 13! [reaches for problem, orients it so that he can write "13" on it]

Dylan: Four plus—oh yeah! Yeah! Plus 13.

At the outset of their collaboration, Shawn immediately begins adding the numbers on the left side of the equation, while Dylan's attention is drawn to the middle of the equation, suggesting that the structure of the problem is unfamiliar to him. When Shawn offers a strategy based on a relational understanding of the equal sign (Line 26), Dylan leaves his train of thought and attempts to follow Shawn's (Line 27). Dylan's final utterances (Lines 31) suggest that he agrees with Shawn's relational strategy; however, he may simply be appropriating Shawn's method without the relational understanding of the equal sign that undergirds it (Line 31). As Dylan records his final answer, his facial expressions, posture, and tone suggest that he is still uncertain about their final solution, despite the fact that he acquiesces to Shawn.

Problem 2 (9 + 7 + 5 = ___ + 9). The opening moments of Dylan and Shawn's interaction with Problem 2 showed great promise of authentic and equitable collaboration. They worked in tandem for several turns of talk, and successfully determined that the left side of the equation sum to 21. However, in approaching the right side, this emerging intersubjectivity broke down, and they began to work separately again. Shawn used the relational strategy they had used on Problem 1, whereas Dylan offered a strategy, based on an operational conception, of adding all the numbers: "Oh! That would be.. that would be 21 [referring to the left side] and then plus nine [referring to the right "9"]. So.. hmm." This cognitive–conceptual divergence resulted in a communication break-down that was not successfully repaired. For the remainder of their interaction, Dylan attempted to make sense of what Shawn had proposed, but to no avail. In the end, the pair offered the final answer of "12" that was proposed by Shawn. Despite his agreement, Dylan's speech and nonverbal behavior suggest that he was not convinced; he appeared dejected when he gave in to Shawn. Even as they wrote down "12" on their worksheets, Dylan quietly says that he thinks the answer might be something different.

In both excerpts involving Shawn and Dylan, they both reached correct solutions using a relational strategy. However, the social power dynamic that was simultaneously co-constructed, in and through their discursive productions, was asymmetric and, moreover, was not beneficial for both children. When Dylan and Shawn solved additional problems individually on the posttest, Shawn solved all four problems correctly, while Dylan solved only one correctly. This outcome suggests that, although Shawn gained insight into the underlying structure of the problems and how to approach them effectively, the *quality* of his engagement with a peer left much to be desired from a *relational equity* perspective (Boaler, 2008) (see below).

Pair 3: The Case of Marie and Jenny

Problem 1 (8 + 5 + 4 = 4 + ___). Marie and Jenny both immediately interpreted the first problem as involving arithmetic, and together they added the left side to arrive at 17. Moving beyond this point proved to be challenging; they worked in tandem to add the left side but reached an impasse when they arrived at the equal sign. They could not easily reconcile how the left side, which they both agreed was 17, was equal to "4", and the extra "blank" on the right side was also lost on them. They seemed on the cusp of giving up, but instead reexamined the problem. This process led Marie to see the equation in a new way and she proposed a relational solution strategy. The transcription below begins as Marie launched excitedly into an elaborate explanation in which she used both speech and gesture to communicate her newfound conceptualization to Jenny. Jenny, in turn, attended to Marie's speech and gestures and took up what Marie was attempting to explain (Lines 32–34). Together they arrived at the correct final solution based on a *shared* relational understanding. They worked mostly in tandem, sometimes interrupting one another and in some cases finishing one another's sentences.

Marie: Four. No.. Maybe it's like [leans back], so that's 17 [indicates left "8"; at this point, her speech speeds up and she speaks excitedly] so four [indicates the "4" on the right side] plus [indicates plus sign] what [indicates "blank"] would make it seventeen [both hands open, palms facing up and slightly towards each other, gesturing to left side of gesture space] also [shifts her hands to right side of gesture space], which makes it equal together. [Brings hands together, palms toward her chest, tips of fingers of the two hands touch]

Jenny: I don't get what you're saying.

Marie: So like.. that's 17 together [gesture underlines left side with pencil] so four [points with her whole hand to the RS "4"] plus what [point to the blank] would make that 17 [fingers and thumb bunched together in a "wide pinch" position, gestured at the right side] so that these two [index points to the left "4" then the right "4"] are equal together [hands open, fingers spread, palms toward each other as if holding something]? So since this is 17 together [drags hand across entire left side of equation, her hand in a pinch shape, with her thumb underlining the equation and her other fingers tracing above the equation]..

Jenny: Oh.. [releases tension she was holding in her posture then leans back]

Marie: Four [indicates right "4"] plus what [uses same dragging gesture as before, on right side] makes that equal together? Like, 17 [indicates left side with pencil] plus four [indicates right "4"] makes 17 [indicates blank],// makes it equal [waves hands, both open and facing down, back and forth above the whole equation]?

Jenny: //So should we// write 13? [Poises pencil above the blank, looks at Marie]

When Jenny expresses confusion about Marie's emerging relational strategy (Line 33), Marie offers an in-depth explanation. Jenny understands the strategy after this explanation and even offers the answer before Marie does (Line 37).

Problem 2 (9 + 7 + 5 = ___ + 9). Unlike Shawn and Dylan, the strategy that was articulated by Marie and Jenny during Problem 1 was robust enough that they were able to maintain it as a shared strategy and use it to solve Problem 2. Marie and Jenny were now acting in concert, sharing the discursive space, and this resulted in an efficient, authentic, and equitable interaction centered on a shared task. They approached Problem 2 enthusiastically and expeditiously, both stating at the same time, "Like we did it last time." Marie again used complex gestures and speech to articulate a relational strategy that was now shared with Jenny (Line 38).

Marie: Well, let's count it up. So seven plus five [covers up left "9" with her left thumb, and points to left "7" and left "5" with her right hand], what does that [cup shape under the left "7 + 5," grouping the numbers together], cause the nine is already used [indicates left "9" then the right "9," then she covers both nines, one with each hand]. So [indicates left "7 + 5"] seven plus five equals?

Both Marie and Jenny went on to solve all four individual posttest problems correctly after the collaboration episode.

Summative Comments Across All Three Pairs

All three dyads notice the location of the equal sign in the problems, and one child in each pair shows at least partial knowledge of the equal sign as a relational symbol. Despite these similarities, the three dyads differ greatly. Elsa does not consider Morgan's relational strategy, but rather asserts her own pattern strategy—one that lives outside of the realm of arithmetic and mathematical equivalence. She ultimately persuades Morgan to abandon her line of thinking in favor of the pattern strategy. In contrast, Shawn and Dylan eventually agree to use a relational strategy to solve the problems during the collaboration episode. However, both of these dyads experience a similar type of asymmetry in their interactions. While Elsa persuades Morgan to abandon a correct line of thinking,

Shawn forges ahead with his relational strategy and Dylan eventually accepts Shawn's answer despite not understanding it. Finally, although Marie and Jenny have a brief moment of asymmetry when Marie first offers her relational strategy and Jenny expresses confusion, the way these children navigate the asymmetry leads to both children learning. Marie works to help Jenny join her in her understanding so they can move forward together. This is in contrast to Shawn, who seems to drag Dylan along despite his protests. Marie and Jenny both make an effort to get on—and *stay on*—the same page, something that was missing in the other dyads, in which one of the two children was always leading the way.

Discussion and Implications for "Relational" Equity

In the spirit of the conference theme, "without borders" (sin fronteras), the analysis presented here is a first step toward bridging educational psychology and mathematics education research, with a focus on both the conceptual challenges that elementary students face when dealing with a certain genre of mathematical activity (equivalence problems), and the social aspects of collaboration with a peer. Our main finding, in broad strokes, is that students navigated an emergent power dynamic, and this dynamic in turn affected the quality of engagement and consequently, their learning. From a psychological perspective, this finding bears on classic questions about where new ideas come from and why they are (or are not) taken up. Our findings support the hypothesis that noticing the atypical location of the equal sign in mathematical equivalence problems can lead to the development of relational strategies, but our findings also suggest that the social context in which the act of noticing occurs may partially determine whether students develop and use a relational strategy.

From a mathematics education perspective, this finding bears on issues of equity and inclusion. Equity in mathematics education can be conceptualized in terms of issues related to status hierarchies, participation, and identity. Most relevant to this report is Boaler's (2008) notion of *relational equity* (where "relational" refers to "social relationships" not "relational understandings of the equal sign"—but we appreciate the coincidence in terminology). Boaler defines relational equity as "equitable [social] relations in classrooms; relations that include students treating each other with respect and considering different viewpoints fairly" (pg. 168). Boaler proposes that we focus on the *quality* of students' interactions during collaboration. We find her notion of relational equity useful for articulating the implications of our findings.

Boaler (2008) argues that when students come together to collaborate on mathematical tasks, they are not only learning content and concepts, but they are also learning and reifying values such as respect and responsibility. Specifically, Boaler assumes "that the ways students learn to treat each other and the respect they learn to form for each other will impact on the opportunities they extend to others in their lives in and beyond school" (pg. 168). We agree.

It is important to note that Boaler's notion of relational equity was developed in the context of a diverse, urban high school and refers to the ways in which students interacted with others from different social classes, cultural groups, and ability levels. Our data come from an educational psychology study involving clinical interviews, and our participants were demographically homogeneous. That said, we nevertheless propose a corollary to Boaler's definition: we argue that relational equity is contingent on an emergent social-mathematical power dynamic that is co-constructed, in situ, via students' actions and discourse (Gutiérrez, in press). Boaler, too, sees that (asymmetric) power dynamics play a role in mathematics learning:

> A common problem in the enactment of group work is an uneven distribution of work and responsibility among students, with some students doing more of the work and others choosing to opt out or being forced out of discussions." (Boaler, 2008, pg. 171)

This definition applies to the ways the children in our study responded to one another's mathematical perceptions and actions. Morgan's and Dylan's discursive contributions, for example,

were not taken up and discussed with their partners. In a sense, their personal meanings of the equal sign were "forced out" of the semiotic space. The lack of relational equity in these two cases is striking when compared to the case of Marie and Jenny. In this pair, Marie sensitively responded to fact that Jenny was falling behind. Moreover, when Marie viewed the equal sign as a relational symbol before Jenny, there was a possibility of another social-mathematical hierarchy emerging, yet Marie demonstrated a strong commitment to Jenny's learning, as indicated by her use of an elaborate array of communicative means. This kind of complex communication, commitment, and respect was not found with Dylan and Shawn, nor with Morgan and Elsa, which leaves us with two very different versions of "relational" equity.

WHAT DO STUDENTS ATTEND TO WHEN FIRST GRAPHING PLANES IN R^3?

This paper considers what students attend to as they first encounter R^3 coordinate axes and are asked to graph y = 3. Graphs are critical representations in single and multivariable calculus, yet findings from research indicate that students struggle with graphing functions of more than one variable. We found that some students thought y = 3 in R^3 would be a line, while others thought it would be a plane. In creating their graphs, students attended to equidistance, parallelism, specific points, and the role of x and z. Students' use of these ideas was often generalised from thinking about the graphs of y = b equations in R^2. A key finding is that the students who thought the graph was a plane always attended to the z variable as free.

Introduction

The inclusion of multivariable topics in K-12 mathematics has been proposed as a way to increase mathematical competence for all students (Ganter & Haver, 2011; Shaughnessy, 2011). Because multivariable topics share similarities with their single variable counterparts, many researchers studying student learning of multivariable topics focus on how students generalise across these contexts (e.g., Dorko & Weber, 2013; Jones & Dorko, 2015; Kabael, 2011; Yerushalmy, 1997). Graphs are critical representations in calculus, yet students struggle with creating graphs of multivariable functions (Kabael, 2011; Martinez-Planell & Trigueros, 2012) and finding the intersection of multivariable functions' graphs and fundamental planes (Trigueros & Martinez-Planell, 2010). Additionally, students' correct understandings about graphs in R^2 may interfere with their learning about graphs in R^3. Some students graph $f(x,y) = x^2$ as a parabola rather than as a parabolic surface or may draw $f(x,y) = x^2 + y^2$ as a cylinder or a sphere because they are accustomed to $x^2 + y^2$ representing a circle in R^2. These examples illustrate that as students think about the graphs of multivariable functions, they generalise the ways they think about graphs in R^2. We sought to further explore this, with the hypothesis that learning more about what students attend to when graphing can help instructors emphasize the productive connections students see across situations and address the sorts of overgeneralisations described above. Toward that end, we focus on the following research question: *what do students attend to as they first think about graphing a particular fundamental plane (y = 3) in R^3?*

Background Literature and Theoretical Perspective

Graphing in three dimensions requires students to coordinate three quantities, as well as shift from thinking of *y* as a dependent variable to considering a *z* that is dependent on *x* and *y*. This is a difficult generalisation to make. Students may give an *(x,y,z)* tuple as an element of the domain or range (Kabael, 2011) or may give the range as *y* values (Dorko & Weber, 2013), indicating that they have not reconceptualised *y* as an independent quantity, and do not necessarily think of *f*(x,y) as an output or the height of the graph at a particular *(x,y)*. As another example, Martinez-Planell and Trigueros (2012) described a student who drew $f(x,y) = x^2$ as a parabola on the *xz* plane and insisted that although the point (2,1,4) satisfied the equation, it was not on the graph. Students also have trouble determining the intersection of a surface with fundamental planes (a plane of the form *x = a, y = b, z = c* for a constant *c*). Trigueros and Martinez-Planell (2010) found that students who had taken multivariable calculus knew that these were planes, but weaker students had trouble placing such planes in a set of manipulatives and drawing the planes on a 2D image of a multivariable graph.

Stronger students could place the planes, but had difficulty determining the intersection of such planes with a multivariable surface.

Martinez-Planell and Trigueros' research has been in the context of developing a set of activities to help students learn how to graph multivariable functions. They found that notation may hinder students' multivariable graphing attempts. One of Martinez-Planell and Trigueros' (2012) students drew $f(x,y) = x^2$ as a parabola on the xz plane and was unsure whether or not she was in two or three dimensions. She gave the intersection of $f(x,y) = x^2$ and $y = 1$ as "two points," which the researchers interpreted as thinking of the graph in two dimensions. The same student drew a correct three-dimensional graph for $z = x^2$. Familiar notations, such as $x^2 + y^2$ (a circle in R^2) may result in students thinking that the graph of $f(x,y) = x^2 + y^2$ is a cylinder or a sphere (Martinez-Planell & Trigueros Gaisman, 2013; Trigueros & Martinez-Planell, 2010). The researchers subsequently altered the activity sets to avoid familiar notations, so it is unknown if students are able to use such notations productively. We build on these' authors work by considering how students' conceptions of single-variable functions' graphs interact with their conceptions of graphs of multivariable functions. Findings from other studies indicate that students can often successfully leverage their single-variable knowledge to make sense of multivariable topics (e.g., Dorko & Weber, 2013; Jones & Dorko, 2015; Kabael, 2011; Yerushalmy, 1997), and we wanted to study whether this was also the case when students graph in three dimensions.

Theoretically, we consider that using knowledge from a single-variable context to make sense of a multivariable context is an example of generalisation, or "the influence of a learner's prior activities on his or her activity in novel situations" (Ellis, 2007, p. 225). We think about generalisation from an actor-oriented transfer perspective (Ellis, 2007; Lobato, 2003). This perspective privileges what students see as similar across situations, even if the similarities they perceive are not normatively correct.

Data Collection and Analysis

We interviewed 11 differential calculus students who had not yet received instruction regarding R^3. We felt this would let us observe students' initial sense-making and generalisations in real time. This paper focuses on data from two tasks: students' graphs of $y = 2$ in R^2 and $y = 3$ in R^3. Before giving students the second task, we showed them an image of xyz axes and explained that the xy plane was flat with the z axis perpendicular to it. We used a tabletop (xy plane) and a pen (z axis) to show students what these axes looked like in 3D[1]. We asked follow-up questions such as "why did you draw a [line, plane] here?" We audio and video recorded the interviews and used LiveScribe pens. We transcribed the interviews and used the transcripts in data analysis.

We chose to focus on these problems because of reported difficulty students experience with multivariable functions' graphs, and also because fundamental planes can help students complete graphing and other tasks in calculus (e.g., visualising graphs; the boundaries in multiple integration). Hence it seemed valuable to explore how students might think about equations of the form $y = c$ in R^3 (and we specifically chose $y = 3$).

We used the constant comparative method (Strauss & Corbin, 1998) for data analysis. We first observed that some students had drawn $y = 3$ in R^3 as a line, others had drawn it as a plane, and two drew a line but then thought the graph might be a plane. We hence coded students in two categories: (1) students who drew a plane or said they were unsure whether the graph was a line or plane, and (2) students who drew a line. We then looked at the data a second time, asking how students might have arrived at their answers. Students' reasoning involved words and phrases such as parallel, equidistant, "all x points," "z can be any value," "x can be any value," "I don't think that x and z really have like any effect", "all values of x and z", variables as "not mattering," x and z being "any value," and "no matter what x or z is." We also observed students think about specific points, such as "if you say $x = 2$ and $z = 2$, it's going to be 3." We noticed that these utterances seemed to group

themselves into three broader, non-mutually-exclusive categories: reasoning using equidistance and parallelism, reasoning about *x* and *z*, and considering specific *(x,y)*, *(y,z)*, and *(x,y,z)* tuples.

Finally, we looked for patterns in how students had thought about the graphs, and whether their graphs were planes or lines. That is, we looked specifically to see if there were something common to all of the students who drew the graph as a plane, and all the students who drew the graph as a line. We noticed that the difference between the graphs seemed related to whether or not the students explicitly attended to *z* as a free variable.

Results

In this section, we first focus on the seven students who thought the graph was a plane or might be a plane, and then on the students who drew a line. All of the seven plane students thought about *x* and *z* values in some way. Three began by thinking about all values of *x* and *z*, then thought about specific *(x,y)*, *(y,z)*, and *(x,y,z)* tuples. The other four focused on all values of *x* and *z*, but did not think about specific points. We contrast these students' work with the four students who drew a line. Two of the line students thought about parallelism, one thought that the lack of *x* and *z* in the equation meant the graph would be "flattened down" and hence a line, and one seemed to have difficulty orienting himself to R^3. In this section we contrast data from the plane and line students.

Plane: Thinking about *x*, *z*, and specific points

Three students reasoned that the graph was a plane by first thinking about all *x* and *z* values, and then considering specific *(x,y)*, *(z,y)*, and/or *(x,y,z)* tuples (Table 1). Thinking that these points had to be on the graph of the function seemed to help S3 and S7 figure out that the graph was a plane. In particular, S3 began with two lines that looked like a plus sign, intersecting at (0,3,0). She drew the horizontal line to represent that *y* equaled 3 no matter what *x* was, and the vertical line to represent that *y* equaled 3 no matter what *z* was. Testing points not on those lines such as *(x,y)* = (2,3) and *(z,y)* = (1,3) allowed S3 to conclude, "I guess I drew a plane." Note that while S3 thought about two variables at a time, S7 first thought about two variables at a time when she said "*x* evaluated at any point will be *y* = 3" and then gave the 3-tuple (2,3,2) as a point on the graph. S13, who was unsure whether the graph was a line or a plane also used a 3-tuple, commenting "So I feel like you can be given like *x* = 0, but *y* = 3, and *z* equals something, and I feel like that could correlate." We speculate that in thinking about specific points, the students were focused on something concrete, and this afforded their realisation that the graph was a plane. Notably, none of the students who considered specific points said that the graph was a line. This suggests that having students consider specific *(x,y,z)* tuples may be a powerful tool for helping them create correct graphs.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Considering Specific Points and Drawing a Plane

S3	No matter what x or z is, y is always going to equal 3… I want to draw a line like this [indicates a line following the gridline for $y = 3$ on the xy plane] and a line like that [indicates a gridline parallel to the z axis and going through $(0,3,0)$]. So what it's saying here is if x were 1, y equals 3, or if $x = 2$, $y = 3$. And here too if z were 1, y is always going to equal 3 here... I guess I drew a plane... [a plane makes sense] when it is drawn out like that.
S7	So here's 3, we've got x, or the y, but then it's also going to be for all the z values, since z evaluated at any point will be $y = 3$. So I guess it would come out to be a plane… I kind of just thought since x evaluated at any point on the graph equals 3, since the function is basically saying all, it's saying $y = 3$ at all points on the graph, any point you evaluate, so if you say $z = 2$ and $x = 2$, it's going to be 3.
S13	So it would be, $y = 3$ would go, I want to say it would be like right here. [Draws a line at $y = 3$ that is parallel to the lines on the notebook; Figure 1]. I guess I'm just trying to relate it back to this, these equations [gestures to $y = 2$] and it just goes straight through…Here if it continues, it goes through x [meaning if she extends the line in Fig. 1, it will go through the x axis]. Then you would have an x and y value, which is the only reason why I feel like it's wrong. [using makeshift actual 3D axes]… I think it would go this way [Figure 2]. Just cuz it can't go this way [points to a line that would roughly go through $(0,1,0)$ and $(1,0,0)$] because then it will hit x, this way it doesn't hit any other points because z goes, negative z goes straight down. So I feel like this way it would go, it would hit the 3 …it could be like a line or it could be like a sheet but I feel like a sheet just makes more sense because then you can do, I was just given x and y, but you can be given, I am assuming you can be given like $x\, y\, z$ and plot those points. So I feel like you can be given like $x = 0$, but $y = 3$, and z equals something, and I feel like that could correlate.
Figure 1: S13's first graph of $y = 3$ in $\mathbb{R}^3$.
Figure 2: S13's second graph.

Plane: Thinking about x and z (but not specific points)

Three students determined that the graph was a plane by focusing on x and z as able to take on any value, though they did so in different ways. S8 thought about equidistance and parallelism, while S5 and S12 thought about the graph "stretching out" in the direction of a free variable(s) (Table 2).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 2: Thinking about *x* and *z* and Drawing a Plane

S8	$Y = 3$ would be something like this, where this distance right here between each, between *y* and each of these axes would be 3, I think. I'm thinking that because if you take like this thing, and that would be everything except for *y* [shades *xz* plane]... I'm thinking of this plane in relation to *y* and having *y* be every distance that is 3 away from that plane. Actually, *y* = 3 wouldn't just be this circle, ... it would be an entire plane... it has to be parallel to *x*, and this has to be parallel to *z*, so it would be this plane right here that is 3 away from the plane that *x* and *z* creates... like for the last question when *y* is equal to 2, that is every value that is 2 away from *y* = 0, right? So I'm thinking that like *y* = 0 would be the same as this [*xz* plane]. So it's 3, it's 3 in the positive [*y*] direction it's going to be parallel to *x* in the same way that this line right here [draws $y = 2$ in R^2] is parallel …to the *x* axis.
S5	So if *y* = 3, *z* can be any value so it extends in the *z* direction like that, and *x* can be any value, so it extends in the *x* direction like that, and it forms a plane on the, like that… I just thought about this sort of logic, that if there's a variable that doesn't affect the equation then it just kind of stretches out into that direction.
S12	So maybe, maybe it would be like this [draws and shades plane]. Well this would kind of just be like just a flat sheet of paper on the *y* = 3, because all *x* values are 3, and then I guess you assume that all *z* values, since it's only, the only variable in the equation is *y* = 3, then it would have to be *y* = 3 for all *x* and *z* values. It's kind of just like a, I think it's supposed to be like a flat sheet kind of, like a piece of paper, and it's on *y* = 3, so it's supposed to encompass all the *x* values for negative and positive, and all the *z* values for *z*, positive *z* and negative *z*. They're all on *y* = 3... Well, I just thought like since *y* = 2 it should be like this, so if it's *y* = 3 it's like that, like all *x* values are *y* = 3. And *z* is going this way, so it must be, since there's no *z* in the equation, then it must be covering all this area.
S10	I'm going to extend that like that, so then that's 3. And this is on that like *x* plane, *xy* plane… I mean it looks pretty linear. I mean like it might be a sheet, but… like if it weren't a line, it would definitely be a sheet that extends into the *z* plane... because a line is like infinitely small points, like a line of points, and then if it extended into the next dimension, it would be, it would just be another line going in the other, perpendicular to that line of points.

S8 began by thinking about *y* = 3 as "three away" from the *x* and *z* axes, and drew a circle centred at (0,3,0), parallel to the *xz* plane. Importantly, the act of drawing the circle seemed to make him realise that the *x* and *z* axes lie in the *xz* plane, and hence *y* = 3 would be a plane that is "every distance that is 3 away from that plane." He appeared to confirm this idea by thinking about the plane as "parallel to *x* and… parallel to *z*", and referred back to the *y* = 2 question where the line was "2 away from *y* = 0" and parallel with the *x*-axis.

S5 generalised that the graph would stretch out in the direction of a free variable from having previously graphed $f(x,y) = x^2$ and noticing that because *y* can take on any value, the graph is a parabolic surface[2], which he saw as "stretching out" a parabola into a trough shape. Similarly, S12 realised that *y* would be 3 for all *x* and *z* values, so the graph would need to "cover" all *x* and *z* values. For these students, noticing that *x* and *z* were free allowed them to realise that the graph was a plane. S10, in contrast, did not explicitly say that *z* could take on any value, but her comment that the graph might be a "sheet" seemed to indicate that she knew, like S5 and S12, that *z* was free. Her reasoning that the graph could be a plane, however, seemed to come from finding a 3D analogue of a line. We infer this from her comment "if it extended into the next dimension." Such an extension to

R^3 seemed to come from thinking of $y = 3$ as a line on the xy plane composed of an infinite number of points, and drawing a line through each of those points, perpendicular to the $y = 3$ line. This reasoning is somewhat similar to S3 (above) who drew two perpendicular lines, then tested points to see if the graph were a plane.

In summary, the commonality to students in the *Thinking about x and z (but not specific points)* category is that realising that z could take on any value allowed them to draw a plane. To summarize the plane students more broadly, we speculate that attending to z, whether in the form of z as a free variable taking on any values or by considering specific points, allowed these students to create correct graphs.

Line

Of the four students drew $y = 3$ as a line, two of them did not mention z. Both of these students explicitly referred back to the graph of $y = 2$ in R^2, and generalised that since $y = 2$ is parallel to the x axis, $y = 3$ should also be parallel to the x axis. S6 described this as "following the x axis," which seemed to us to be attending to parallelism (Table 3).

Table 3: Attending to Parallelism to Draw a Line

S6	So $y = 3$. So on an xy graph [draws R^2 axes] at 3, would be going this way. So on the y, following the x. So [switches to R^3 axes] this would be on the y, this is the 3 point on the y, and it's following the x axis.
S9	So if this is, if this is y is equal to 3, then I'm wondering if it will just go parallel with the x axis, but just at, but just at the y is equal to 3 point… just kind of like looking here [goes back to $y = 2$] it's like parallel to the x axis at whatever y point because it's just that straight line, so if this is like y is equal to 3, I'd assume just for all x points that you know y would equal to 3. [I think the graph is a line] just cuz when it's just equal to you know 3, it just means no matter what x value there's like nothing, it's just 3. So it would be a line, there's no, you know, changing or anything because your y is only 3. It's not like interacting with, with anything else.

Unlike S8 (above), these students did not mention the z variable. We believe that S8's attention to z, which came in the form of shading the xz plane, allowed him to see that $y = 3$ would also be parallel to the z axis, which in turn helped him see that $y = 3$ was a plane. If we contrast the three students who used parallelism, two of them drew a line but did not attend to z, and one drew a plane and attended to z. This suggests to us that thinking explicitly about the z variable as free supports students in drawing correct graphs.

The final two students thought about z, but rather than realizing that z is free, these students thought z and x "can't change" or that they "don't have any effect" (Table 4). S11 mentioned that the symbols z and x were absent from the equation, and she then referred back to the $y = 2$ graph and said "it'd still just be like this," though she recognised that she was in 3D. We infer that because the $y = 3$ equation and $y = 2$ equation look the same (both having no x and no z), S11 generalised that $y = 3$ in R^3 would be a line just like it is in R^2.

S1 had trouble orienting himself in R^3, which may have contributed to his drawing a line. That is, he seemed to have so much trouble figuring out the structure of the three axes that he would have been unable to think of specific points, or coordinating parallelism in multiple directions. The student also assumed that, rather than being free, the z and x variables could not change at all. This may have resulted in his drawing a line contained on the xy plane, because such a line never intersects the x or z axis. Thinking about x and z as unable to change directly contrasts thinking of them as able to take on any value, as S3, S5, S7, and S12 (who all drew planes) did. This suggests that part of students' success in graphing $y = 3$ depended upon their ability to think of z as free.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 4: *x* and *z* as Not Changing and/or Having No Effect

S11	It stays on like that like *xy* plane because there's no like *z* and there's no *x*, so it'd still just be like this [points to *y* = 2 in R2], but flattened down…because it's still just like a constant number, so no matter like, no matter like what the other ones are, it's just going to be that one number, which is just like a straight line across the thing... I don't think that *x* and *z* really have like any effect to *y* = 3 because there's no *x* and *z* variable in there, but it just like makes it like 3D... But it's, the function's still just like one line on the *y* axis.
S1	So the *z* direction, the *z* can't change and the *x* can't change, and the *y* would kind of have to be like at a diagonal [*the line y=3, when drawn on standard axes on paper looks to be at a diagonal*], but staying at *y* = 3. I can't really like see how to do it, but you'd find the spot where *y* = 3 for both *x* = 0 and [*the interviewer interrupted to ask the student to draw on the paper*] this might be a struggle, I'm not sure if I know - so this is going up, this is going this way, *x, y, z*…Yeah, *z* is the vertical here. The *x* value, so yeah. I'm not really sure which one I should mark as *y* = 3, though... so this would be *y* = 0, I'll just say this is the positive direction, 1, 2, 3, so *y* = 3 here, and I guess I would just use this line for *y* always equal to 3.

Discussion and Conclusions

We found that when students first try to graph *y* = 3 in R^3, some draw a line and some draw a plane. The students who drew planes seemed attend to *z* in a way that allowed them to realise that *z* is a free variable. Some students did this by thinking that *z* could take on any value, and hence the graph would extend in the *z* direction. Others tested particular points, indicating that they knew they could pick any value for *z*. Realising these points satisfied the *y* = 3 criteria seemed to help these students see the graph as a plane. Finally, students attended to parallelism and equidistance from the *y* = 2 case. Nearly all of the students referred back to the *y* = 2 in R^2 question, and their ways of thinking about the multivariable graph generalised properties from this single-variable case. For instance, some generalised *y* = 2 for all values of *x* in R^2 so *y* would equal 3 for all values of *x* and *z* in R^3, and others generalised that *y* = 2 is parallel to the *x* axis in R^2 so *y* = 3 is parallel to the *xz* plane in R^3.

That some of the students in this study drew *y* = 3 in R^3 as a line, as it would be in R^2, supports Kabael (2011) and Martinez-Planell and Trigueros' (2012) findings that students' knowledge of the shapes of graphs in R^2 may interfere with their learning about graphs in R^3 and Trigueros and Martinez-Planell's (2010) finding that students have difficulty with fundamental planes. However, other students in our study productively leveraged properties of *y* = 2 in R^2 to correctly graph *y* = 3 in R^3. This suggests that instructors can build on students' intuitive notions, perhaps first eliciting what students think a graph might look like and then asking what role *z* plays in such a graph. Finally, because some of our students found thinking about specific points to be helpful, we agree with Martinez-Planell and Trigueros (2012) that instructors can help students think about 3D graphs by asking whether a particular *(x,y,z)*-tuple is on the graph. Further, we agree with Martinez-Planell and Trigueros (2012) that students should have the experience of constructing a 3D graph point-by-point. This affords learning that an *f(x,y)* value is the function height at a point *(x,y)*, and we think it primes students with the strategy of thinking of specific points as being useful for determining the shapes of graphs.

The setup of the *y* = 2 in R^2 and *y* = 3 in R^3 tasks is a possible limitation of this study. One could argue that the order of the questions prompted students to refer back to the *y* = 2 task. While this is true, the fact that many students referenced back to it in productive ways (e.g., equidistance,

parallelism) implies that instructors might consider pairing graphs like $x = a$ and $y = b$ in R^2 with an introduction to fundamental planes.

Endnotes

[1]Such a demonstration does not guarantee that students understood how such a coordinate system works; in fact, researchers have found that students often must develop a schema for R^3 through specific actions like plotting *(x,y,z)*-tuples and working with fundamental planes (Martinez-Planell, & Trigueros, 2012; Trigueros & Martínez-Planell, 2010).

[2]S5 was the only student to have graphed this multivariable function before the $y = 3$ task analysed here.

PLOTTING POINTS: IMPLICATIONS OF "OVER AND UP" ON STUDENTS' COVARIATIONAL REASONING

Kristin M. Frank
Arizona State University
Kristin.Frank@asu.edu

In this study I investigate Saldanha and Thompson's (1998) claim that conceptualizing a coordinate pair in the Cartesian coordinate system as a multiplicative object, a way to unite two quantities' values, supports students in conceptualizing graphs as emergent representations of how two quantities' values change together. I presented three university precalculus students with an animated task showing varying values of two quantities along the axes and asked each student to sketch a graph of how the two quantities changed together. In this paper I document the difficulty students encountered when they did not conceptualize a coordinate pair as a multiplicative object. I address why the convention of "over x and up y" inhibits students from constructing a coordinate pair as a multiplicative object and I provide recommendations for supporting students in constructing coordinate pairs as multiplicative objects.

Keywords: Cognition, Modeling, Instructional Activities and Practices

Researchers continue to provide evidence that students have difficulty interpreting and constructing graphs (e.g., Monk, 1992; Oehrtman, Carlson, & Thompson, 2008). Specifically, researchers suggest that students do not typically think about graphs as representations of how two quantities' values change together (e.g., Dubinsky & Wilson, 2013; Thompson, 1994). Instead, as Moore and Thompson (2015) described, many students conceptualize graphs as shapes and curves and reason based on their perception of the shape of the graph. Moore and Thompson called this *static shape thinking* and explained that a student who engages in static shape thinking might, for example, understand slope as the property of the line that determines whether the line falls or rises as it goes from left to right.

An alternative way of thinking about graphs is what Moore and Thompson (2015) called *emergent shape thinking*. They explained,

> Emergent shape thinking involves understanding a graph *simultaneously* as what is made (a trace) and how it is made (covariation). As opposed to assimilating a graph as a static object, emergent shape thinking entails assimilating a graph as a trace in progress (or envisioning an already produced graph in terms of replaying its emergence), with the trace being a record of the relationship between covarying quantities. (p. 4)

Central to this conception of graphical representations is an understanding that a point in the Cartesian coordinate system represents the projections of two quantities' values whose measures are represented on the axes (Figure 1). This intersection point in the plane is the object the student then imagines tracing while engaging in emergent shape thinking.

In this paper I extend Moore & Thompson's work by examining how a student's conceptualization of points in the Cartesian coordinate system might inhibit or support her in engaging in emergent shape thinking. In particular, I address why the conventional activity of plotting points by going over *x* units and up *y* units does not support students in engaging in emergent shape thinking.
Figure 1. A point as a projection of two quantities' values represented on the axes.

Background

When one engages in emergent shape thinking she is engaging in covariational reasoning; activities involved in reasoning about how two varying quantities change in relation to each. Saldanha and Thompson (1998) provided one conception of covariational reasoning[1]. They explained,

> Our notion of covariation is of someone holding in mind a sustained image of two quantities' values (magnitudes) simultaneously. It entails coupling the two quantities, so that, in one's understanding, a multiplicative object is formed of the two. As a multiplicative object, one tracks either quantity's value with the immediate, explicit, and persistent realization that, at every moment, the other quantity also has a value. (Saldanha & Thompson, 1998, pp. 1-2)

This suggests that for Saldanha and Thompson engaging in covariational reasoning involves three mental actions: (1) conceptualizing quantities, (2) imagining quantities' values varying simultaneously, and (3) coupling two quantities through a multiplicative object.

For Saldanha and Thompson, multiplicative objects do not necessarily involve the numerical operation of multiplication. Instead, Thompson and Saldanha extend the work of Inhelder and Piaget (1964) and conceptualize multiplicative objects as mental constructions an individual makes when uniting two or more attributes simultaneously (Thompson, 2011b). Thompson provided the following examples of multiplicative objects:

1. A student can construct a rectangle's area as a multiplicative object that unites the rectangle's length and width.
2. A student can construct a point in the Cartesian plane as a multiplicative object that unites the distance of the point from the horizontal axis with the distance of the point from the vertical axis. (*ibid*, p. 47)

As Saldanha and Thompson (1998) explained, when a student constructs a multiplicative object he organizes his thoughts about the relationship between two quantities' varying values. As a result, whenever he imagines variation of one quantity he necessarily imagines the other quantity also having a value. For example, suppose a student imagines the values of x and y varying together. If the student constructs the point (x, y) in the Cartesian coordinate system as a multiplicative object then as he imagines the value of x varying he understands that the value of y necessarily has a value as well. With this conception of a point in the plane, the student can conceptualize graphs as emergent representations of how quantities' values change together.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Methods

I conducted one-on-one task-based interviews with three university precalculus students, Sara, Carly, and Vince. All three students were in their first year of university and had declared a major in a STEM field. Thus, these students were taking precalculus to fulfill a pre-requisite for a required calculus course. The interview consisted of two phases. The first phase was a clinical interview (Clement, 2000). I engaged the students in tasks I anticipated would support me in understanding their meanings for tabular and graphical representations. The second phase of the interview was a task-based-teaching interview (Steffe & Thompson, 2000). My primary teaching goal was to support students in conceptualizing a graph as an emergent representation of how two quantities change together.

The main task in the teaching interview was based on an item from a diagnostic instrument (Thompson, 2011a). This animated item was originally designed to support researchers in better understanding in-service secondary mathematics teachers' meanings for covariational reasoning. For the purpose of this interview, I intended for this task to help me understand the nature of the multiplicative object a student constructs when she engages in covariational reasoning.

I showed each student a video that depicted a red bar along the horizontal axis and a blue bar along the vertical axis. As the video played, the lengths of the bars varied simultaneously in such a way that each bar had one end fixed at the origin. (See Figure 2 for selected screenshots from the video). The horizontal (red) bar's unfixed end varied at a steady pace from left to right while the vertical (blue) bar's unfixed end varied unsystematically. I explained to each student that the length of the red bar represented the varying value of Quantity A and the length of the blue bar represented the varying value of Quantity B. I asked each student to sketch a graph that represented how the lengths of the two bars changed together. I anticipated that students would be successful sketching a graph if they could imagine placing a point in the plane as a way to simultaneously represent the values of two quantities. Thus, this task assessed whether students saw the conventions of graphing in the Cartesian coordinate system as a way to simultaneously represent two quantities values.

The video played repeatedly until the student completed the task. The student had the opportunity to pause the video at any point. While students chose to pause videos used in previous tasks of the interview, none of the students chose to pause this video while completing the task. I engaged each student in three versions of this task. From the student's perspective, in each version of this task the length of the red and blue bars varied in different ways with respect to experiential time. From my perspective, this meant that each version of the task represented a different continuous functional relationship between the varying values of two quantities.
