With this work, the author concluded that minor linguistic modifications greatly affect the ability of students to solve a math problem, he states that not only the linguistic formulation of the problem is important, but that it is also necessary to understand the situation described in the text of the problem. He mentioned an arithmetic problem with two formulations: "(1) There are five birds and three worms, how many more birds are there than the number of worms?" and "(2) There are five birds and three worms, how many birds will not get a worm?" Problem 1 was solved correctly by 39% of the students, while problem 2 by 79%. In problem 2, the linguistic expression helped students to form a definitive situational model (birds eating worms) that provided them the correct arithmetic structure to solve the problem. In problem 1, however, the relational abstract term "more than" did not provide the same help.

In view of the above, the purpose of this work is to analyze how certain modifications in the base text influence the construction of the situational model of a verbal math problem at the basic level. Our research question is: How does modifying the base text influence the construction of the situational model and the problem solving outcome?

Method

To achieve the established objective two problems with modifications in their linguistic and mathematical structure were applied. We then compared the situational models represented in the drawings that were requested to students immediately after reading the problem. In this work the students' mental constructs were analyzed through the drawings. The analysis is qualitative. The two problems mentioned by Walter Kintsch (1986) were applied to 117 students grades 7, 8 and 9, and 87 students from the first three grades of elementary school. The study was conducted in the city of Puebla, Mexico.

Analysis and Conclusions

The answers obtained from students in grades 7 to 9 did not match Kintsch's results since most students solved both problems correctly; this was possibly due to the fact that his study was at the elementary school level, not middle school. However, we obtained similar results to the author's in the study with elementary school students. Our conclusions are the same as Kintsch's, namely that the complexity of the model of the problem required for the solution of problem 1 is confusing for the students.

Keywords: Gender, Equity and Diversity, Affect, Emotion, Beliefs, and Attitudes, Post-Secondary Education

Student persistence in the STEM disciplines continues to be a national problem, especially for women and underrepresented minorities. Female and male high school students are equally prepared in their mathematics coursework, yet only half as many incoming college female students plan to major in a STEM field (NSF, 2010). One key factor is that women typically do not encounter enough female peer role models in their mathematics classes for them to feel they belong (Lockwood, 2006). For underrepresented students, belonging is crucial for participation and performance (Walton & Cohen, 2007). We present results of an ongoing study involving the use of peer role models to increase women's, (esp. Latina), persistence in the calculus sequence. Marx and Roman (2002) define peer role models as inspiring in-group members who defy negative stereotypes associated with their group (e.g., mathematically-capable females).

In a large, ethnically diverse university, half of the Calc I break-out sections were visited twice by female peer role models (treatment condition) whereas the other half were not (control). At the end of the semester, we administered a Likert survey on feelings of belongingness, personal mathematical ability, attitude toward mathematics, as well as, indicating their intention to continue in the calculus sequence. The results were statistically analyzed as a function of section type (peer role model vs. control) and student gender (male/female). As a measure of persistence, we also looked at looked at how many students enrolled in Calc II/repeated Calc I.

In the control condition, female students' beliefs about their math ability were significantly lower than male students ($p < 0.051$). In the treatment condition, female students' beliefs about their math ability were just as high as that of male students. Regardless of student gender, students who saw a role model were more likely to be enrolled in Calc I/Calc II than those not exposed to a role model. This finding shows promising evidence that exposure to a female peer role model may improve women's mathematics experiences.

EXPLORING STUDENT VOICE IN A HIGH SCHOOL MATHEMATICS CLASSROOM – EMPOWERING STRATEGIES FOR MARGINALIZED STUDENTS

Rachel M. Restani
University of California, Davis
rmrestani@ucdavis.edu

Keywords: Classroom Discourse, Equity and Diversity, High School Education

In traditional math classes, people of color, people from low socioeconomic communities, women, English language learners, students with resource needs, first generation graduates, and other marginalized groups of people are negatively impacted by the lack of opportunities to exchange ideas and engage in rich discussions (Gutierrez, 2002). Social inequalities that are perpetuated by public school systems need to be disrupted by providing access to higher-level mathematics education to all learners (Apple, 1995). For the purpose of teaching and empowering traditionally marginalized students, I explored the following research question: *how do students react to a teacher's attempts to implement discussion-based mathematical practices?* This poster addresses preliminary findings through the example of one classroom observation of several students publically grappling with the context of a math problem. Assuming the role as researcher-teacher, I used sociocultural classroom practices such as individual journal writing, partner talk, small group collaboration, and whole class discussions. As the teacher on record, I used daily field notes, daily audio-recordings, monthly student-journal entries, tri-annual survey questions, and daily lesson plans to provide evidence of how students responded to discussion-based lessons. These artifacts will be systematically coded to determine patterns of student voice in our math class. Similar to others who have researched their own teaching practice (e.g., Lampert, 1985), excerpts from field notes are used to portray specific examples of how students engaged in a whole class discussion.

My findings highlight the extent to which marginalized students engage in mathematical discussions and relate it to their previous experiences. Some students engaged in the practice of arguing, critiquing, and making sense of each other's ideas. Although the participants focused more on the context of the problem than on the mathematical concepts, they were publically sharing their ideas and practicing sociomathematical norms. Additionally, students used the classroom environment to collaboratively discuss mathematical situations while incorporating a variety of different races, socioeconomic backgrounds, genders, and skill levels. The classroom norms created a space for students to simultaneously perform social skills alongside engaging in the CCSS math practices. As the teacher, I was able to use this discussion as a formative assessment of my students' previous interpretations of using graphs to solve problems. The successes and challenges of creating a discussion-based classroom environment can be further analyzed to help math educators determine how to effectively break down traditional math classroom norms.

REPRESENTACIÓN DEL ASPECTO AFECTIVO EN PROFESORES UNIVERSITARIOS DE MATEMÁTICAS DEL ÁREA TÉCNICA

REPRESENTATION OF THE AFFECTIVE ASPECT IN COLLEGE MATH TEACHERS IN THE TECHNICAL AREA

Javier Lezama
CICATA-IPN
jlezamaipn@gmail.com

Virginia Rivera
Universidad Veracruzana
jevisa64@yahoo.com

Palabras clave: Afecto, Emoción, Creencias, y Actitudes

Por lo general, en la enseñanza matemática se deja de lado el considerar los aspectos afectivos de manera explícita, ignorando las repercusiones que esto acarrea en el aprendizaje matemático. Este trabajo parte de este supuesto, analizándose esta situación en el área técnica del nivel universitario (Rivera, 2014; Rivera & Lezama, 2014a). Se parte también del hecho de que el ser humano actúa ante la realidad, no conforme a lo que ésta es en verdad, sino conforme a la representación que de ella se forma en su mente (Moscovici, 1979). Esto se traslada al quehacer docente en matemáticas, resaltándose entonces la importancia de determinar qué representación tienen ellos respecto a esto. Para corroborar la hipótesis propuesta, se plantean dos preguntas de investigación: ¿Qué es lo afectivo en el aprendizaje de las matemáticas en el área técnica? y ¿qué representación sobre el aspecto afectivo tienen los docentes de matemáticas del área técnica?

Con este fin, se aplican entrevistas en profundidad en forma de grupos focales, a cinco colectivos de profesores de matemáticas de diversas carreras del área técnica de una universidad estatal. Ubicada ésta al lado este de México, en el estado de Veracruz. Se emplea la Teoría de Representación Social (Moscovici, 1979), como soporte teórico en la parte experimental; así como la metodología de grupos de discusión con entrevistas en profundidad y la Teoría Fundamentada (Strauss & Corbin, 2012), para las etapas de captura, codificación y análisis de datos respectivamente. Los hallazgos permiten construir una representación de lo que es lo afectivo para el colectivo de profesores en cuestión. Igualmente, pueden determinarse aspectos dejados de lado o minusvalorados por ellos, que afectan el aprendizaje matemático, como mostró ser el caso específico de la categoría de Emociones; misma que mostró –en este caso-, ser parte protagónica también presente en el núcleo central de la representación construida.

Keywords: Affect, Emotion, Beliefs, and Attitudes

Generally, in the teaching of mathematics, considering affective issues in an explicit form is left aside; it is common to ignore the repercussions this has on the mathematical learning. This work assumes this postulation, it analyses this situation in the technical area of college level (Rivera, 2014; Rivera & Lezama, 2014a). It is also accepted as true, that human beings act in the face of reality, not according to what this really is, but according to "its representation" –the they have in their minds-, (Moscovici, 1979). This transfers to the work of teaching mathematics, highlighting the importance of determining what representations teachers have about it. To test the proposed hypothesis, there are two research questions: What is affective in math learning in technical area? and, What is the representation of the affective aspect that teachers in technical area have?

For this purpose, in-depth interviews are applied in focal groups. There were five groups of teachers of mathematics from different careers of technical area participating in this study. They all were from a state university in Eastern Mexico, in the State of Veracruz. Social Representation Theory is used (Moscovici, 1979) as theoretical framework for the experimental section. We used

focus groups with in-depth interviews to collect data, and Grounded Theory (Strauss & Corbin, 2012) for coding and data analysis. Findings allow to build a representation of the affective aspect for the group of instructors involved, and to determine issues left aside or undervalued that affect the mathematical learning. An example is the category of "Emotions", which also turned out to play a main role in the core of the built representation.

CULTURE IN BETWEEN: MUSLIM AMERICAN STUDENTS' CULTURE AND IDENTITIES IN MATHEMATICS CLASSROOMS

Wesam M. Salem
The University of Memphis
wsalem1@memphis.edu

Keywords: Equity and Diversity, Teacher Beliefs, Classroom Discourse

In the wake of domestic terror events and the prevalent anti-Muslim rhetoric, Muslim American students have found themselves living in cultures that are in conflict (Sirin & Fine, 2007) where their cultural and mathematics identities are being positioned in the dominant regimes of representation and constructed as different and as 'others' (Hall, 1990). Informed by the postulations of culturally relevant pedagogy CRP (Ladson-Billing, 1995), I argue that anti-Muslim rhetoric and Islamophobia, if not countered, problematize equity, obstruct the development of students' mathematical identity, and hinder engagement in mathematics classrooms for Muslim students living in the *borderlands* (Cobb & Hodge, 2010).

Theory and Methods

This narrative inquiry study (Clandinin & Rosiek, 2007) uses semi-structured interviews with ten Muslim high school students to explore how they position their mathematics identity when navigating multiple cultural contexts particularly when school system precludes Islamic culture and/or when curricula do not counter Islamophobia. Using narrative inquiry analytic lenses (Chase, 2005), interviews are coded and deconstructed into themes and sub-themes.

Preliminary Results

Preliminary analysis shows that students perceive their interactions in schools as racialized and marginalized as Muslim students. They perceive mathematics as decontextualized space in which enculturation is absent. Narratives of fear, distrust, and the "need to do better to prove self" dominated the conversations as well as references of "them/they" versus "us/we".

Implications

These experiences hold implications for school curricula and instructional practices to reconceptualize educational equity and social justice in mathematics classrooms for Muslim students. Fostering a feel of belonging and inclusion through teaching mathematics with *cultural eyes* is crucial for the development of students' mathematics identity and their success in school.

AGENGY AND PERSISTENCE OF FRESHMAN AND SOPHOMORE UNDERGRADUATE STUDENTS

Angela Stoltz
University of Maryland
astoltz@umd.edu

Diana Bowen
University of Maryland
dbowen85@umd.edu

The purpose of this research was to examine freshman and sophomore undergraduate mathematics socialization and identities and how these related to agency and persistence in undergraduate mathematics. A cross-case, qualitative analysis was conducted using classroom observations, interviews, and survey data, to answer the research question: What social forces impact the mathematics identities, agency and persistence of undergraduate freshman and sophomores? One case study was of an African-American female (Joy) who entered the university through a Student Support Services (SSS) program and was enrolled in a required College Algebra corequisite course. The second case study was of an Asian male and first generation immigrant (Sam) who was enrolled in Calculus III, a non-required advanced mathematics course.

The research was guided by Danny Martin's (2000) Multilevel Framework for Analyzing Mathematics Socialization and Identity Among African-Americans. This framework was developed to examine socio-historical, community, school and intrapersonal forces that contribute to mathematics socialization and identities, agency and persistence (Martin, 2000). Survey and interview questions explored students' mathematics socializations and their beliefs about social forces that impacted their mathematics identities, agency and persistence. Personal identities and goals, personal motivations, and beliefs about mathematics; beliefs about school and classroom forces pertaining to mathematics learning such as classroom experiences, available school supports, and relationships with professors and peers; and the influence of family members, mentors and peers were all examined.

Fitting with Martin's findings (2000), both participants exhibited positive agency in the face of negative social forces. Joy did not have a positive mathematics identity which she attributed to negative school forces in secondary mathematics, but she did have a strong academic identity which she attributed to positive intrapersonal and community forces. She actively sought family and SSS support when faced with negative forces in her undergraduate mathematics class and credited her persistence and success in mathematics to them. Sam had a strong, positive mathematics identity which he attributed to positive school forces in secondary mathematics. When faced with negative forces in his undergraduate mathematics class, Sam persisted independently and credited his success to intrapersonal forces. While Sam's mathematics and academic identities were closely connected, Joy's were not. This finding seems contrary to Martin's and points to the need for further research on successful mathematics students who have weak or negative mathematics identities, as well as the resources students with differing mathematics identities draw on in order to persist and succeed.

MATHEMATICAL PROBLEM-SOLVING IN UNIVERSITY-EDUCATED ADULTS ON THE AUTISM SPECTRUM

Jeffrey Truman
Simon Fraser University
jtruman@sfu.ca

Prior research on mathematics and autism has primarily focused on young children or professors of mathematics. In my reading of the literature, I have found little focused on college students or graduates on the autism spectrum. Exploring this subject and finding particular characteristics or traits of mathematical thinking among such adults is the goal of my present research.

Research Setting

After an initial period of background information and anything else in particular my interviewees wished to share about their perspectives on mathematics, I gave various mathematical tasks to elicit more specific responses. Some of these were used from prior research on a general student population, such as the Magic Carpet Ride sequence used by Wawro et al. (2012) and paradox tasks used by Mamolo and Zazkis (2008).

There were several reported characteristics of people on the autism spectrum which I thought could be promising for mathematics education research. Use of special interests and geometric approaches were drivers of initial questions, but more factors appeared during interviews, particularly with paradox-related tasks. I will give examples of these with a comparison to the particular findings relevant to them in the cases of Joshua and Cyrus.

Method and Results

Particularly due to the work of Temple Grandin, one of the most famous people on the autism spectrum, there is often considered to be an association between the spectrum and visualization or spatial reasoning (Grandin, Peterson, and Shaw, 1998). I found a strong preference for visual, spatial, or geometric reasoning in the interviews I conducted with Joshua, but found the opposite pattern with Cyrus. My suspicion is currently that there may be stronger variance or preference in types of reasoning, but that it is not all necessarily toward the geometric type.

I have also presented several paradox tasks during my interviews; one reason for this was the interplay between visual and algebraic explanations seen in some student responses to these paradoxes. Like many of the students in previous studies (of a general student population without consideration of autism), the people I interviewed found these to be strange and paradoxical. However, the response was notably more positive than those from most students. I also found it notable that I did not see any tendency toward rejecting the mathematical facts after they had been presented from Joshua or Cyrus, unlike in many of the students in the prior studies.

EXPANDING THE BOUNDARIES TO COMMUNITY COLLEGE MATH EDUCATION THROUGH A SITUATED PRACTICE APPROACH

Ruth Urbina-Lilback
University of Connecticut
ruth.urbina-lilback@uconn.edu

Keywords: Equity and Diversity, Post-Secondary Education, Affect, Emotion, Beliefs, and Attitudes

Community Colleges represent an unchartered territory with multiple possibilities for the field of math education research. They are a popular choice in higher education institution. Approximately 34% of the post-secondary enrollment in the 2013 fall semester was attributed to 2-year institutions (National Center for Education Statistics, 2013). Mesa, Wladis and Watkins (2014) noted that math education research in community colleges has been limited, disorganized and in lack of attention to questions of teaching and learning. Based on their thorough analysis of the extant work at these institutions, Mesa et al. (2014) described community colleges as a "new research frontier" (p. 180) and proposed an agenda that would include more practitioner-led research.

This study responds to the observed need for more research on teaching and learning at community colleges, particularly in the area of equity in math education. Community Colleges' classrooms are rich in diversity. Their first-year college students are more likely to correspond to a typically underserved subpopulation (e.g. non-white, low income, no exposure to higher level high school math courses) than their counterparts in four year universities (Mesa et al., 2014). Moreover, the majority of college remediation is done at community colleges, where students not only have to relearn math, but they also have to unlearn misconceptions about what it means to learn math (Mesa et al., 2014). Research from practice in these classrooms offers great insights on equitable math teaching practices with direct implications on college completion and increased educational access for students from underserved populations.

The work presented here is considered to be on-going because data continue to be collected directly out of real-teaching experiences for the past four years at a community college in an urban setting. Though the researcher's practice spans sixteen years at both the high school and the community college level, the research work was formally conducted through journaling, memos and triangulation (Merriam, 2009) to students' feedback. Results confirm the need to create lessons that are flexible and open to re-construction based on students' individualities and their experiences inside and outside the classroom. They also confirm that mathematical misconceptions can be capitalized on to build a stronger more integrative mathematical foundation. The proposed poster would showcase classroom experiences that evidence successful practices. These practices are relevant to equitable teaching at any classroom level (Urbina-Lilback, in press).

BREAKING LANGUAGE BORDERS IN AN ONLINE PRE-CALCULUS COURSE

Julian Viera, MS   Olga Kosheleva, PhD
University of Texas at El Paso   University of Texas at El Paso
jviea1@utep.edu   olgak@utep.edu

Keywords: Equity and Diversity, Post-Secondary Education, Technology, Affect, Emotion, Beliefs, and Attitudes

Language Use in Mathematics Courses

Technology is commonly used in the educational system (Griffiths et al., 1994; New London Group, 1996). Griffiths et al. (1994) found that the impact in 1994 of information technology on the oppressed cultures was debilitating. These researchers found these preliminary results to show that learning mathematics can be positively impacted by technology when converted to a student's native language (Casas et al., 2011).

Participants in this study enrolled in a fully online pre-calculus course offered during the 2014 fall semester. Participants were asked if they changed the software to Spanish. Participants translated the software mostly to understand the instructions or to understand the meaning of mathematical vocabulary. For the most part, they were adamant about keeping the software in English.

Learning Mathematical Topics in English

Participants felt that if they changed a particular problem to Spanish to understand the concept then they would not be able to connect this concept to future topics. They also believed that if they learned a pre-calculus topic in Spanish they might not be able to connect that topic to future math classes. "Because learning in English will avoid math language problems in future classes" stated one participant. Pre-calculus is a gateway course to STEM degrees and careers. The students were aware of this and understood that at a university in the United States, these courses will be taught in English. "It is important to work in English because, after all, we are receiving a professional education in English; we need to understand terms in the proper language."

Discussion

The skills these students learned in Spanish were continually brought to the forefront when confronted with these computations at the college level. The level of proficiency in one language does not appear to be the catalyst for success in an online math course. Participant's use of both languages is independent of the level of proficiency. What is important is how participants use the internet to make meaning of instruction and math vocabulary to comprehend math topics. The "implication therefore is that if bilinguals are strategic language users, they may also be strategic problem solvers, especially if learning to problem solve is viewed as a communication-based experience" (Dominquez, 2011, p. 309).

LINGUISTIC CHALLENGES IN THE KENYA CERTIFICATE OF SECONDARY EDUCATION (KCSE) MATHEMATICS WORD PROBLEMS

Victoria Wambua
Syracuse University
vmwambua@syr.edu

Joanna O. Masingila
Syracuse University
jomasing@syr.edu

Keywords: Assessment and Evaluation, High School Education, Equity and Diversity, Problem Solving

The language of mathematics is a multisemiotic system that draws on not only linguistic, but also symbolic and visual resources (O'Halloran, 2005). Successful readers of mathematical text, therefore, do recognize these resources in a text and understand how they interact to generate certain meanings. The first stage in problem solving is understanding the problem (Polya, 1957), meaning that successful problem solving demands a proper understanding of the problem at hand. Word problems are useful tools for investigating linguistic challenges students may have while trying to understand mathematics texts (Newman, 1977). Fang (2012) noted four hindrances to students' mathematical text comprehension, namely technical vocabulary, nominalization, long noun phrases, and symbolism and visual displays.

The Kenya Certificate of Secondary Education examinations are high-stakes exams done by all Kenyan students completing high school (ages 17 or 18). Considering all of the subjects on the exams, students have performed the worst in mathematics for the last several decades. Although numerous research studies have attributed the poor performance to a number of factors, research investigating the role of language factor in Kenyan high-stakes examination is notably missing. Yet these examinations are written in English, which is a second or perhaps the third language for most students. In doing problems prepared in a language other than their first, students face an additional challenge to comprehend the "third language of mathematics" in a second language (Kenney & de Oliveira, in press). Research has also shown that unnecessary linguistic complexity in mathematics word problems is a major cause of poor performance among English language learners (ELLs) (Barbu & Beal, 2010).

In this study, we used task-based interviews to investigate linguistic challenges faced by Kenyan students solving KCSE word problems in an attempt to empirically test Fang's (2012) framework. We engaged eight KCSE candidates – four males and four females – in solving three KCSE word problems that were deemed linguistically challenging, while responding to prompts that would elicit their understanding. Data collected included students' written work and interviews, which were transcribed. The proposed poster presents the main findings of this investigation and discusses the implications of this research.

mbwood@email.arizona.edu

Keywords: Post-Secondary Education, Problem Solving, Learning Theory, Classroom Discourse

Collaborative learning has seen a recent increase in popularity as an instructional approach in college mathematics courses (e.g., Duncan & Dick, 2000). Collaborative learning in mathematics gives students opportunities to practice the kinds of discourse that lead to effective disciplinary thinking and to ask questions, propose and test ideas, and critique the reasoning of others (Bruffee, 1984; Davidson, 1990). Students benefit from opportunities to listen to explanations from peers and subsequently engage in *constructive activity* such as solving problems and explaining solutions (Webb et al., 1995; Slavin, 1992). What is not well understood are the mechanisms by which collaboration leads to greater mathematical understanding.

We draw from theories about mathematics as narrative (e.g., Solomon & O'Neill, 1998) and about co-construction of narratives (Ochs & Capps, 2001) to conceptualize the collaborative problem-solving process as the co-construction of a "narrative." As students build the "story," they add narrative elements based on their understanding of the mathematical objects in the story, and take detours as necessary when a "subconflict" arises or when they do not have the means to resolve the primary conflict.

In this study, we examine the collaboration among three students in a problem-solving workshop for vector calculus students. In some cases, students borrow narrative elements from one another in order to add to a shared narrative. In others, a student may borrow elements to aid in the construction of a separate narrative that is not shared by the entire group. One student's difficulty in incorporating his own narrative into the group's co-construction may be explained by a difference in "genre," in that the student's narrative follows a different epistemology and style of storytelling than the group narrative.

Awareness of differences among students' narratives, and in the "genres" of these narratives, may help mathematics teachers mediate disagreements among group members so that the members themselves take the lead in comparing different stories, finding points of agreement, and resolving conflicts.

Palabras clave: Educación Secundaria

En este trabajo se presentan los resultados de una investigación cuyo propósito fue determinar qué imagen de los matemáticos y de la matemática tenían estudiantes de nivel medio superior del Instituto Politécnico Nacional. En este estudio una imagen es una representación que un grupo de personas tiene de algo y cuya construcción está basada en elementos sociales y culturales y que son transmitidos a través de interacciones personales y con el medio, dentro y fuera de la escuela. Consistente con esta posición, Rensaa (2006) reconoce que la influencia que forma las imágenes de los matemáticos y la matemática vienen de la escuela, de los pares, parientes o medios masivos. Ella agrupa y representa cada una de estas influencias en dos grupos: sociedad pública y sociedad escolar. En este estudio se identificaron elementos de esas sociedades que formaron las imágenes de algunos estudiantes del Instituto Politécnico Nacional sobre personas cuya profesión es la matemática. El total de estudiantes que participaron en el estudio fue de 170, de ellos hubo 36 mujeres y 134 hombres. El método utilizado en esta investigación fue una variación del DAST (Draw-A-Scientist-Test) propuesto por Chambers (1983), el cual fue retomado y modificado por Aguilar, Rosas, Molina y Romo-Vazquez (2016). El interés de indagar en las creencias de estos estudiantes sobre los matemáticos y la matemática y aportar conocimiento de ello para el caso de estudiantes mexicanos. Además interesó averiguar si existen conexiones entre la imagen que estos alumnos tienen de lo que es un matemático y la posible elección de una carrera profesional como matemáticos u otra carrera afín a esta. El test se divide en dos partes, en la primera se les solicita a los estudiantes que hagan un dibujo de un matemático, en la segunda parte se les hace una serie de preguntas, algunas relacionadas con su dibujo y otras relacionadas con lo que piensan acerca de los matemáticos, como la personalidad de estos y su actividad laboral; también se les pregunta por lo que ellos consideran que es la matemática y su gusto o desagrado hacia ella. Los resultados encontrados muestran que la gran mayoría de los estudiantes tienen dos imagines que coexisten, un imagen positiva de lo que consideran un matemático (que es la que se impone y surge naturalmente) y una negativa que proviene de los medios masivos. En los 170 estudiantes la imagen representativa y positiva de un matemático fue: un hombre de aspecto joven y alegre, el cual no usa barba, bigote ni lentes, viste casual y utiliza un corte de cabello formal. En cuanto a la imagen negativa de los matemáticos que promueven medios masivos, algunos adjetivos que los alumnos mencionan son que el matemático es sarcástico, extraño, loco, sin muchos amigos. En cuanto a sus ideas sobre la matemática predominó una idea positiva sobre ella, les resultan interesantes, divertidas, fáciles y la mayoría declara que son la base de todo.

Keywords: Middle School Education

In this paper we present the outcomes of a research, whose purpose was to know what images middle school students from the National Polytechnic Institute have about mathematicians and mathematics. In our study we adopt the concept of image as: an image is a representation that a group of people has of something, and whose construction is based on social and cultural elements that are

transmitted through personal interactions and interactions with the environment, within and outside the school. Consistent with this position, Rensaa (2006) proposes that the influences that shape students' images of mathematics and mathematicians come from the school, parents, relatives, or mass media. Rensaa groups and represents each of these into two groups: public society and school societies. In this study we identified elements from these societies that shaped the images that a group of IPN students held about people whose profession is mathematics. The students number who participated in the research was 170: 36 women and 134 men. The method used was a variation of Draw-A-Scientist-Test (DAST) suggested by Chambers (1983), this method was modified and adapted by Aguilar, Rosas, Molina, and Romo-Vazquez (2016). The interest of exploring the beliefs of these students about mathematicians and mathematics is to contribute to the knowledge in the Mexican students' case. In addition, we wanted to know if there are links between the image that these students have and the university program they would choose, like mathematics or similar career path. The DAST is divided into two parts. In the first part students are asked to draw a mathematician. In the second part, some questions are asked, some about their drawing and others related to what they think about mathematicians, such as what they think about their personalities and work. Students are also asked what they think about mathematics and whether they like it or not. Our findings show that a majority of the students have two coexisting images: A positive image of what they think a mathematician is (the most common and which appears naturally) and a negative one that comes from the mass media. Among the 170 students, the most representative image from a mathematician was positive: a young looking and happy man, without a beard, mustache or eyeglasses; he wears casual clothing and sporting a formal hair style. In relation to the negative image promoted by the mass media, some adjectives that students mentioned are mathematicians are sarcastic, weird, crazy, without many friends. Regarding their ideas about mathematics, it prevailed a positive idea about this subject; students find mathematics interesting, fun, easy, and most of students express that the mathematics are the basis of everything.

This study examined discussions centered on precise mathematical language use in two fifth grade classrooms. Drawing on episodes from lessons in which teachers focused on encouraging mathematics reasoning, our analysis examines the relationship between precise language use and mathematical justifying. We present three classroom episodes that illustrate facets of the relationship between precise language use and mathematical argument, and explore how blurring the borders of two types of pedagogical tools (attention to precise mathematical language and engagement of students in justifying) promotes enculturation of students into mathematics.

Keywords: Classroom Discourse, Instructional Activities and Practices, Reasoning and Proof, Elementary School Education

Using mathematical language precisely and with understanding is a complex endeavor and one with which many students struggle. In order for students to use language precisely, they must have a clear understanding of the underlying mathematical meanings and relationships associated with particular terms, as well as how terms may be used differently in common language.

Theoretical Framework

Learning Mathematics Language

Learning mathematical language is complicated by many factors. Mathematical terms are frequently used for specific and narrow ideas, whereas common language often uses terms broadly. Such terms may be confusing because the mathematical meaning may differ from the non-mathematical meaning, because multiple terms may be used to describe the same mathematical concept, or because two words sound the same (Kenney, Hancewicz, Heuer, Metsisto, & Tuttle, 2005). Thus, it is possible that a common meaning of a term may be more familiar to students than the mathematical meaning.

Furthermore, using mathematical language precisely can be a challenge for students because meanings of terms may have been obscured in prior lessons and discussions. Language used in mathematics classes has often focused more on the appearance of notation than on the mathematical ideas and relationships represented. These challenges may also lead teachers themselves to struggle with consistently using terms precisely and correctly.

Word knowledge is incremental, multi-dimensional, and interrelated, and words have multiple meanings. Students need multiple encounters with words in a variety of contexts and opportunities to build background knowledge that relates to the words in use (Spencer & Guillaume, 2006). However, vocabulary is not often taught in this manner. Common instructional practices provide students with definitions or ask students to look up definitions. As many definitions are written using words that are not meaningful to students, such approaches rarely lead students to the desired understandings. For terms associated with complex or abstract concepts, which include many mathematical terms,

simply asking students to passively learn definitions has not been shown effective for robust vocabulary development.

One strategy for developing meaning for mathematical terms is to engage students in discussion of their understanding of particular concepts and of the precise meanings of various mathematical terms. In developing understanding of terms, Bransford, Brown, and Corking (1999) highlight the importance of involving learners actively in the generation of word meanings. It is important that learners connect words with concepts and with their prior knowledge. Integrating vocabulary development with other aspects of instruction, so that terms are encountered in context, and discussing connections students are making between terms and concepts are effective ways to support students in making needed connections. Through classroom mathematical discourse, students can develop understanding of mathematics terms and of the underlying mathematics relationships. Such discussions can be effectively embedded in other learning activities such as problem solving or mathematical investigations. "The richer and more varied students' experiences related to particular concepts, the more finely detailed and nuanced their understanding of related terms can be expected to be" (Spencer & Guillaume, 2006, p. 208). Barnett-Clark and Ramirez (2004) remind us,

> As teachers, we must learn to carefully choose the language pathways that support mathematical understanding, and simultaneously, we must be alert for language pitfalls that contribute to misunderstandings of mathematical ideas. More specifically, we must learn how to invite, support, and model thoughtful explanation, evaluation, and revision of mathematical ideas using correct mathematical terms and symbols. (p. 56)

Once mathematical terms are understood, their succinct meanings need to be reinforced throughout students' experiences. For many teachers, engaging students in the *Common Core State Standards for Mathematics* (CCSSM) (National Governors Association Center for Best Practices, Council of Chief State School Officers [NGA & CCSSO], 2010) eight standards for mathematical practice represents a departure from their established teaching practices. CCSSM Practice 6, *Attend to precision*, involves students in attending to precision in a variety of ways, including precise use of mathematical language. "Mathematically proficient students try to communicate precisely to others. They try to use clear definitions in discussion with others and in their own reasoning…. In the elementary grades, students give carefully formulated explanations to each other" (NGA & CCSSO, 2010, p. 8).

Teachers can use development of precise language as a way to engage students in mathematical practices. While attending to precision and engaging students in mathematical practices such as justifying are both considered desirable teaching pedagogies (NGA & CCSSO, 2010; NCTM, 2014), they need not be considered as separate, unrelated pedagogies. The borders of each can be dissolved as the two pedagogies are used in connection with one another. One aspect of this connection is the use of precise mathematical language to act as a catalyst for engaging students in mathematical justifying.

Mathematical Justification

The practice of teaching and learning via mathematical argument/justification affords a practical context with ongoing opportunities for students to deepen their understanding of mathematics and use mathematical language precisely. In mathematical argumentation, the arguer must support or refute a claim with an argument that links the claim to the underlying mathematical principles and relationships. These ideas must be specified precisely and clearly in order for the argument to be understood and accepted by teacher and peers. The goal of peer acceptance of one's argument presents a powerful motivator for students to learn precise meanings of mathematical terms and to use them appropriately.

Mathematical argumentation is itself an important practice for learning and doing mathematics. It

is a key practice of professional mathematicians and is captured in CCSSM Mathematics Practice 3, *Construct viable arguments and critique the reasoning of others*. When engaged in this practice, students

> make conjectures and build a logical progression of statements to explore the truth of their conjectures….They justify their conclusions, communicate them to others, and respond to the arguments of others…. Students at all grades can listen or read the arguments of others, decide whether they make sense, and ask useful questions to clarify or improve the arguments. (NGA & CCSSO, 2010, p. 7)

We view a viable argument as one with a clearly stated claim which is supported by reasoning showing how the claim follows logically from mathematical definitions and ideas that are known and accepted (Adams, Ely, & Yopp, in press). Yopp and Ely (2016) remind us that the argument's viability can only be ascertained when the definitions of the operations and objects in the claim are clear and agreed-upon.

Engaging students in mathematical argumentation benefits their learning in multiple ways. Yopp (2011) suggested that proving, one form of mathematical argument, can be used to understand a mathematical definition. Researchers have found that in mathematics classrooms where students are encouraged to explain and justify their thinking, learners demonstrated both greater achievement and more complex thinking (Boaler & Staples, 2008; Kazemi & Stipek, 2001). Sharing arguments promotes the mathematical understanding of the arguer and of the listening peers. Middle school teachers observed that when making an argument, students must interact with mathematical ideas, determine why a mathematical process works, connect ideas in new ways, refine their own thinking, and develop their mathematical communication skills (Staples, Bartlo, & Thanheiser, 2012). Additionally, student justification allows teachers to discern student thinking (Knuth, 2002) and provides information they can use in making instructional decisions. The teachers in Staples et al.'s (2012) study noticed that students who engaged in justification also developed general learning skills such as perseverance, independence, critical thinking, communication, and the expectation that ideas be supported.

Research Question

Through work with teachers to support students in mathematical reasoning, we have observed many instances of teachers engaging students in discussions of the precise meanings of mathematical terms. In this study we focus on mathematical discourse that centers on the precise meaning of mathematical terms or phrases. We examine the relationship between precise use of mathematical language and student justification. Specifically, we asked, what is the role of discussion of precise mathematical language in supporting student engagement in justification?

Methodology

The findings presented in this proposal are from an NSF-funded research and professional development project that focused on engaging students in mathematical generalization and justification. As part of the larger qualitative study, we examined two fifth grade mathematics lessons that contained class discussions of mathematical language. Both lessons were videotaped and occurred during the first month of the school year in rural school districts in the northwestern United States. While both teachers had an inclination towards focusing on precise mathematical language and justification, one teacher, Ms. K, had gone through two years of professional development as a result of the NSF-funded project. The other teacher, Ms. L, had been involved in a number of unrelated professional development experiences, but had not started work with the NSF-funded project. We selected three episodes from the two lessons in which discussion of mathematical language arose in conjunction with whole-class mathematical justifying. Each episode was analyzed

to determine if and how the discussion of precise language was related to the mathematical justification. The three primary authors discussed the findings regarding the relationship between precise mathematical language and justifying until a consensus was reached.

Findings

We present here three episodes of classroom discussion that illustrate how conversations about precise mathematical language can be used to further student mathematical understandings and lead to student justification. All of the episodes depict a teacher asking students to clarify the mathematical meaning behind terms being used in class and all result in some type of mathematical justifying. The first two episodes are from Ms. K's lesson, and the third is from Ms. L's lesson. Episode one depicts a 15-minute discussion that capitalizes on students' lack of clarity to engage students in justifying why specific fractions are equivalent. Episode two depicts a 15-minute discussion that arose from a student's imprecise use of mathematical language, resulting in a justification of a commonly used generalization (attaching a zero to the end of a whole number when multiplying by 10). Episode three depicts an hour-long discussion that arose from multiple students' use of imprecise mathematical language, resulting in a justification of place value relationships. All names are pseudonyms.

Episode One: Equivalent fractions

In this episode from Ms. K's class, students were presented with a visual pie divided into 8 pieces, 4 of which were shaded, and asked, "What fraction of the pie is shaded?" Multiple students presented answers of 4/8, 2/4, and 1/2. In providing these multiple answers, students implicitly claimed that the three fractions represented the same quantity. Ms. K explicated this claim, writing on the board, "4/8 = 2/4 = 1/2". She then created disequilibrium by stating that the 3 fractions were all different. In making this challenge, Ms. K appealed to the appearance of the fractions as they were written, saying, "4/8 is not the same as 2/4. It's not the same as 1/2. What do I mean by *same*? What does he [student] mean by *same*? Four is not the same as two. … So how is this the same?" Through this challenge, Ms. K prompted students for a justification of why two fractions are equivalent. The opportunity for this justification arose from use of the imprecise and ambiguous term, *same*. While students did not actually use this term, Ms. K introduced it when explicating the students' implicit claim of fraction equivalence. It is apparent that Ms. K's intention during this episode was to highlight the distinction between the appearance of a fraction and the quantity it represents.

At the start of the justifying episode, a student used the phrase *equivalent fractions* as a justification of why the three fractions could be considered the same. While *equivalent* is a more precise term than *same* because it clarifies how exactly the fractions are the same (i.e. in the quantity that they represent, rather than appearance), Ms. K continued to encourage students to unpack the meaning of the word: "So *equivalent* has the root meaning "equal", right? But I've already said to you that 8 is not the same as 4." She continued to press for a more detailed justification by asking how the fractions could be the same. One student offered the explanation that one could divide 4/8 by 2/2 to get 2/4. Another said that all three fractions show the same ratio, saying, "The numerator is half of the denominator." Each additional student justification provided a more complete description of equivalent fractions for the class. Ms. K. continued the lesson as she elaborated on the difference between the appearance of a fraction and the value that it represents: "Four is just a digit. It's a digit. We don't know what its *value* is. … Is four always worth the same amount?" She emphasized her point that digits can represent different quantities depending on their place value by writing 40 and 400 on the board. At the end of the episode, Ms. K connected the mathematical ideas of place value and fractions by highlighting that each fraction could be considered as a division problem, which each yielded the same result.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Episode Two: Add a Zero for Multiples of Ten

In this episode Ms. K serendipitously capitalized on a student's imprecise use of language to launch a discussion of what it means to "add a zero." She also used the discussion as an opportunity to teach conventions for precise use of mathematical language. In the process of unpacking the meaning of "adding a zero," a mathematical claim about relationships involved in finding the product of 6 and 20 was stated and evidence that could be used to justify the claim was documented. The result was a clear statement that they were not adding a zero; they were multiplying by ten. This discussion also helped students to understand that when discussing mathematics, they were expected to explicitly describe mathematical relationships and meanings of operations.

The episode began when Carl described a method for finding the product of 6 and 20: "I multiplied 6 times 2, which is 12, and then I added zero." Ms. K took the mathematical meaning of his words literally, while ignoring the implied meaning regarding how to write the answer. She wrote $6 \times 2 = 12 + 0 = 12$ and then said, "He is saying the answer to 6×20 is 12. Do you agree? Why not?" Amber said, "Because you don't add a zero. You put a zero behind the 12." Ms. K interpreted this statement broadly, writing 12   0, and said, "That's a zero behind it." She then asked, "Why is Ms. K being so silly here?" Kylee responded that sometimes students put things in the wrong places. The teacher agreed and said, "I don't like it when people say: 6×2 and add a zero. You are not adding a zero. What are you actually adding?"

The students clearly had a habit of describing changes in the way the number visually appears when written rather than the mathematical meaning or relationships involved, and therefore did not understand that Ms. K's intention was to show that they were multiplying by ten, and not adding a zero. Another student said, very precisely, "You are adding a zero to the one's place." Ms. K again took the words literally and wrote: $12 + 0$. She said, "I'm adding a zero to the one's place," and then prompted, "You know what you are doing. I want you to be explicit in your thinking" and asked them to talk with a partner.

Ms. K acknowledged the strategy of first multiplying by two as "brilliant" because "it uses multiplication facts we already know." She asked, "What are we really doing here? What's the difference between 120 and 12?" Anna replied, "Zero." Ms. K asked, "What is the value of that zero?" Zoe explained, "Zeros, when added onto a number, it kind of transforms the number. If you add on two zeros – in the tens and hundreds place, it transforms it to one hundred. Zeros are pretty much kind of magic. Cause without zeros, we would be stuck with pure numbers." This response gave Ms. K the opportunity to make explicit a mathematical convention for her class: that there are reasons for the way things happen, and it is important to uncover and talk about those reasons, and to explain why. She said, "Magic makes it seem like there is some trick to it, and not maybe a reason, and that's not true at all. … I always want you to know why you are using a trick. … So I wanted you to understand that when you say *add a zero* what you are really saying is what?" Liam responded, "I noticed something. It takes ten 12's to make 120." This idea is what Ms. K had been waiting for. She emphasized its importance by writing ten 12's in a column, counting them as she wrote. She also wrote 12×10, and repeated, "We are not adding a zero. Chloe said, "We are multiplying by ten," which ended this episode.

Episode Three: Add a Zero for Place Value

This episode began when multiple groups of Ms. L's students worked on a task and then described a pattern they noticed among a list of numbers (specifically, 3, 30, 300, 3000, 30,000, 300,000). During the class discussion, Bob said, "I was just thinking that there was ones with added zeros." Ms. L repeated his phrase "ones with added zeros," which was used by multiple students prior to the class discussion, and then asked, "Do you think that's really true though? Ones with *added* zeros? Are we adding zeros?" Bob responded, "No, you put zeros on them." Ms. L again repeated Bob's wording and implicitly asked students to explain the meaning behind the words. "You

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

put zeros at the end. Okay, but I wonder what that means that we put zeros at the end." She stated, "If we start with three, and we put a zero at the end, we aren't really adding zero, are we?" and then asked the class "What are we doing if we start with three, and we write 30?" As students did not quickly answer, Ms. L encouraged them to describe the meaning of three, to which a few students responded "three ones." She followed by asking what does thirty mean, to which Alex answered "three tens." Ms. L continued the pattern and asked, what does three hundreds mean, and Frank answered "three hundred."

Continuing the justifying activity, Ms. L asked students to discuss how to "get from 3 to 30," clarifying her desire for them to use "multiplication thinking, not addition thinking." Ms. L summarized multiple student responses as she said multiply 3 by 10. Continuing the justification, Ms. L asked how students could get from 30 to 300. Following group discussions, Beth said her group multiplied 30 by 10 to get 300. Ms. L pointed to a previously recorded pattern on the board, and explained that because they said 300 is 3 times 100, they could move the parentheses and say that 300 is 3 times 10 times 10. This move is from (3 x 10) x 10 to 3 x (10 x 10), although Ms. L points rather than saying this explicitly.

As an attempt to encourage understanding of her explanation, Ms. L asked Ted about the solution to 10 times 10, and he answered "100." Another student in Fred's group added that they multiplied 3 by 10 to get 30, and 30 by 10 to get 300, and that one could keep going with that pattern. Ms. L stated that if they multiplied by another 10, it would be 3 times 10 times 10 times 10, and asked students "what is 10 times 10 times 10? " Multiple students responded, "1000," and Ms. L summarized their argument: "Here's our first 10, right? 3 times 10 is 30. And 300, you guys said just add a zero and I said I don't think we can add a zero. So then you said we're multiplying by 10. So we have 300 equals … 3 times 10 times 10. And so you guys are saying each time we multiply it by 10, we have to put in another times 10 each time, don't we?"

Ms. L rephrased her summary: "3 equals 3 times 1. 30 equals 3 times 10. And you guys told me that to get from 3 to 30, I would have to multiply 3 by 10. Then 300, you guys said add a zero, but no, we can't add a zero, so we multiplied 30 by 10 and got 300. And so we said that we could say that that's 3 times 10 times 10. So it's either 30 times 10 or 3 by 100, either way. 3000 is 3 times 10 times 10 times 10. We see a pattern developing. We have one 10 here, two 10's here. And we're not adding tens, we're doing what with our tens?" Students said "Multiplying," and Ms. L responded, "We're multiplying each time by 10. Then, you just said that 30, 000 is 3 times 100 times 100 (a student previously and silently had recorded this on the board). Can he do that? Because 3 times 10 times 10 times 10 times 10 is that the same as saying 3 times 100 times 100? Just for the sake of time, I'm gunna say it is. We will have to talk about that in a couple of days. And then another student said 300,000 is 3 times 10 times 10 times 10 times 10 times 10." A student noted, "Five times." And Ms. L capitalized on the observation: "Five times. Here we had it 4 times; here we had it 3 times; here we had it 2 times; here we had it 1 time."

As time for the class period is running out, Ms. L connected their findings to a place value chart, showing students that each time "you move to the left" you are multiplying by ten, and asked students to think about what happens if you "move to the right." Most of the students responded with "divide" and "by 10" in unison as the lesson ended.

Discussion

Eliminating the borders between the two pedagogical practices of attending to precise language and constructing viable arguments can help improve student engagement in both types of mathematical activity. For instance, the Fraction Episode illustrates how a better understanding of the mathematical meaning behind fraction notation enables students to justify why specific fractions are equivalent. The use of precise language allows for the creation of a viable argument, which subsequently allows students to better understand the appropriate use and importance of precise

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

mathematical language. As these episodes illustrate, teachers can capitalize on the imprecise language often used by students as a way to engage them in unpacking mathematical meanings and justifying mathematical properties or algorithms that are often taken for granted, such as the algorithm of appending a zero to the end of number when multiplying by ten. By increasing their own awareness of students' use of imprecise language, teachers can identify opportunities to engage students more frequently in creating viable arguments or justifications. Additionally, attending to the use of precise language develops an understanding of the culture and nature of mathematical language. While many students may be able to use mathematical terms, they need the additional understandings of *how* and *when* to use mathematical terms. For instance, it is important for students to understand the distinctions between the terms *fraction* and *ratio*, and recognize appropriate circumstances for using each.

Beyond simply knowing the correct term, another insight these three episodes provide is that common language can conflict with mathematical language, and that the pedagogical tool of attention to precision allows teachers to distinguish between the two types of language. For instance, when a person in an everyday context says, "add a zero on the end of that number," it is typically understood as the action of appending a zero. However, mathematical accuracy would require one to say "multiply the number by ten." When common language contradicts mathematical language, it creates a conflict within the class and often promotes misunderstandings about the mathematics. Focusing on the correct use of mathematically precise language helps to engage students in mathematical justifying, and the resulting focus on precision will advance students' skill with future justifications. In other words, use of precise language is a requisite skill in order to develop mathematically valid justifications. Therefore, if we want students to be able to justify, we also need them to develop the ability to use precise language when they are in a mathematical context. When mathematical language conflicts with common language, teachers need to explicitly clarify the mathematical language and consistently use it in classes. This will develop students' abilities to think mathematically and use such thinking to outline mathematical arguments at the proper times. Gaining skill in using mathematically precise language will allow students to create arguments and justifications and do so using mathematical language.

The Add a Zero for Place Value episode was an hour-long lesson that developed student understanding of the precise meaning of the use of zero within the place value number system. It is clear that students assumed everyone knows what it means to "add a zero" to the end of a number, but as Ms. L asked them to unpack the meaning behind the common phrase, it became evident that the class lacked the ability to do so. This episode illustrates the difficulty of developing a mathematically accurate interpretation of common language that is used regularly and taken as understood. As conversations about mathematical meanings and the use of precise mathematical language increase in mathematics lessons, the opportunity for students to develop a deeper understanding of mathematical language and relationships increases as well.

All three episodes point to instances where students seemed to know the correct mathematical language because they used commonly understood terms at the correct time; however, when each teacher attended to the precision of the mathematical language, there was clearly more understanding to be developed. In these episodes, this was accomplished through an unpacking of the mathematical language used within the lesson. We recommend that teachers use the pedagogical tools of attention to precision and encouragement of viable arguments and justifications in conjunction with one another to help students develop deeper mathematical understandings as well as to enculturate students into the mathematical community.

LANGUAGE REPERTOIRES FOR MATHEMATICAL AND OTHER DISCOURSES

Annica Andersson   David Wagner
Malmö University   University of New Brunswick
annica.andersson@mah.se   dwagner@unb.ca

We start with the stance that it is important for educators to understand students' language repertoires in relation to characteristically mathematical conceptualizations and processes. The data in our study of grade 3 to 11 students' language repertoires for conjecture led our attention to competing discourses in the classroom and the consideration that the mathematical language repertoires are also repertoires for friendship, competition, etc. In this paper we use a framework for identifying authority structures in mathematics classrooms to focus on formative communication acts, and then we consider how each act might serve a purpose for positioning the students involved in terms of each discourse that we identify as in play.

Keywords: Classroom Discourse, Equity and Diversity, Problem Solving, Instructional Activities and Practices

Introduction

Because mathematics is mediated through and by language, it is important for educators to understand students' language repertoires for mathematical conceptualizations and processes. As part of a large-scale research project focused on identifying specificities of students' language repertoires, especially in contexts of mathematical investigation, we sought to identify connections between their ways of talking about conjecture and what they think their expressions mean.

In this paper, we use one episode from our data to problematize our fundamental research question. Positioning theory helps us understand the way students' communication acts connect to a variety of discourses, including mathematics. There are many discourses enacted in any classroom context. In addition to mathematics, we found mischief, romance, play, hunger, and more at work. In short, we cannot understand students' communication about mathematical processes without understanding that these acts are also part of their repertoires for the other discourses in play. We argue that the connections among the discourses indexed by students' communications may give us insight into what mathematics is for these students.

Positioning and Discourses

Position metaphors are often used to illustrate the way people relate to each other. Van Langenhove and Harré (1999) have described positioning as the ways in which people use action and speech to arrange social structures. According to this theorization, in any interaction, the participants envision known storylines to help them interpret what is happening. These storylines may be conscious or not. They are contested explicitly or implicitly. A powerful aspect of this theory is its radical focus on the immanent, its rejection of the transcendent. In other words, it considers real only that which is present in the interaction and rejects the power of exterior forces.

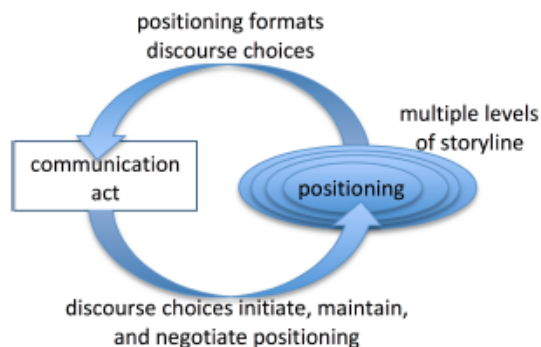
In an analysis of the way this theory was taken up in mathematics education research, Wagner & Herbel-Eisenmann (2009) noted that exterior forces, such as the discipline of mathematics, may be myths, but they can be taken as real in classroom or other interactions because teachers and others may be viewed as representatives of these exterior forces. The classical triad developed by the progenitors of the theory (e.g., van Langenhove & Harré, 1999, p. 18), which connected a speech act to a storyline and a positioning, was reconfigured by Herbel-Eisenmann, Wagner, Johnson, Suh, & Figueras (2015, p. 194), as shown in Figure 1.


Figure 1. Illustrating positioning. (Herbel-Eisenmann et al., 2015, p. 194).

They layered storylines to emphasize positioning theory's claim that multiple storylines may co-exist in an interaction. And they used arrows to highlight the dynamic interaction between a communication act and the exterior storyline—a communication act initiates, maintains, and negotiates positioning within a storyline, and this positioning formats communication acts. For us, this recursive relationship is reminiscent of Foucault's (1982) description of discourses—"practices that systematically form the objects of which they speak" (p. 52). Thus we will use the term *discourse* instead of *storyline.*

For our analysis in this paper we elaborate the diagram into three dimensions (Figure 2).

Figure 2. Extending the positioning model into three dimensions.

We are motivated by our data to avoid foregrounding any one discourse. Thus we position a range of discourses in relation to a communication act. Each discourse may be seen as a slice of the torus though the lines of demarcation between discourses would not be so clear as they are in the diagram; the various discourses are interconnected. A communication act appears as a cylinder passing through the torus. The cross section cut of this 3D figure would appear about the same as Figure 1. The communication act (a slice of the cylinder, which would appear as a rectangle in cross-section) interacts with a discourse (a slice of the torus, which would appear as an ellipse). The arrows show how the communication act constructs the discourse while the discourse constructs the communication act.

Connecting communication acts to discourses

Because positioning theory focuses on people's rights and obligations in interactions, we choose a conceptual frame developed in mathematics education that makes distinctions among such structures. Working from a large-scale quantitative analysis of the communication in mathematics classrooms, Wagner & Herbel-Eisenmann (2014) distinguished among four authority relationships. To identify personal authority, one looks for "evidence that someone is following the wishes of another for no explicitly given reason" (p. 875). Linguistic clues include the presence of *I* and *you* in

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

the same sentence, exclusive imperatives, closed questions, and choral response. To identify discourse as authority, one looks for "evidence that certain actions must be done where no person/people are identified as demanding this" (p. 875). The strongest linguistic clue is the presence of modal verbs that suggest necessity—e.g., *have to, need to, must*. To identify discursive inevitability, one looks for "evidence that people speak as though they know what will happen without giving reasons why they know" (p. 875). The modal verb *going to* is a strong indicator of this structure. Finally, to identify personal latitude, one looks for "evidence that people are aware they or others are making choices" (p. 875). Linguistic indicators include open questions, inclusive imperatives, and indicators of someone changing their mind—for example, *I was going to, could have*.

We emphasize that we identify these authority relationships on the basis of particular communication acts, and try to avoid reading intention. For example, a student may say or do something because s/he thinks that is what the teacher wants, but we look for communication acts that explicitly indicate this authority structure. The intention may be significant, but our attention to language repertoires compels us to look for the communication acts that underlie or motivate this intention. We take the stance that the sense that a student is doing what a teacher wants comes from one or a series of communication acts that set up this discourse.

In this paper we work through a transcript identifying authority relationships. We focus on instances where these relationships appear to change and on aspects that are resilient to change. At the same time we identify exterior discourses that are referenced (We acknowledge that there are further discourses at play that are never explicitly addressed in the transcript, or that are addressed in a way that we do not recognize). In addition to the mathematics, we identified the following discourses in this particular group's work: school work, hobby/game playing, our research agenda, competitiveness, romance, affect in identity, clothing, friendship, body image, and physical/material resources. We considered referring to these other discourses as "distractions" but realized that this word is subjective; yes, romance may distract from mathematics, but mathematics may also distract from romance. Thus we think of the whole set of discourses, including mathematics, as competing and intertwined discourses. In our analysis, for each significant communication act, we ask how the specificities of that act might serve the person's interests within the various discourses. How is mathematics positioned? How does this act position the friendships? How does it project body images? etc.

We chose this particular group of three grade 10 students (approximately 15-years-old) because they made progress mathematically though their teacher did not have high hopes for them working well together. They were given a page with the following task and some images of cubes and cut up cubes (e.g., Figure 3): "A cube was painted red, and then cut into smaller cubes, 3 x 3 x 3. How many of the small cubes have no red faces? How many have 1 red face? 2 red faces? 3 red faces? 4 red faces? 5? 6? How about a cube cut into 4 x 4 x 4? Or 5 x 5 x 5? Or 10 x 10 x 10? Or n x n x n?" They were also given a set of twenty-seven solid white cubes snapped together in a 3 x 3 x 3 configuration. It was possible for students to pull the set apart and reorganize the cubes but they still had to visualize what sides would be painted and what would not.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figure 3. Cube task images.

Applying the Framework

The task involved working in a group and working mathematically with an object that could only be visualized. This kind of investigation work invites (perhaps 'requires') students to decide how they will organize their investigation and themselves while doing the investigation. Steven set the tone:

> 3 *Steven*: All right boys, well, let's get to work. "A cube was painted red and cut into smaller cubes, 3 by 3 by 3…"
> 4 *Peter*: I don't have one.
> 5 *Steven*: You don't have a sheet? [turning to a researcher…] Um, excuse me? He don't have a sheet. [turning back to the group] Okay.

This exchange establishes the positioning in the group. Steven's "let's get to work" (turn 3) suggests personal authority, similar to the way a teacher might demand work from students; he told the others what to do and did not tell them why it would be a good idea or why he had the authority to do so. First we consider how this positions mathematics. It appears that mathematics comprises performance at the behest of someone in authority, performance of certain kinds of procedures or processes (involving shape and number in this case, and probably more generally). This authority structure does not align with conventional views of mathematics being a bastion of reason. Steven also indexes the friendship discourse with "All right boys" (turn 3), and positions himself as a leader in this group of friends (however, we were told by the teacher that these boys were not friends). Connecting these discourses, mathematics is positioned as something one can use to establish authority in friendship, and vice-versa—friendship can be used to establish authority in mathematics. The other discourses we identified in this episode were not yet explicit. We pick up the interaction when the group begins to engage with the task:

> 12 *Steven*: twenty-seven have no red on them. Oh wait, no, that's wrong. [*he holds the large cube and points at small cubes when counting*] 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, … oh, fuck.
> 13 *Doug*: No look…
> 14 *Steven*: It's like, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, …
> 15 *Doug*: All this would, here, here, and here [*pointing*].
> 16 *Steven*: Just the outer layer. Just the outsides.
> 17 *Doug*: Yeah all the other.

Steven was in control of the cubes while Doug and Peter watched him. Though it could appear that they were not paying attention, we know they were paying attention because of what they said later. In turns 12 to 17, there are no expressions suggesting personal authority, discourse as authority, or personal latitude. By deduction, the dialogue might suggest discursive inevitability, but we ask whether it fits the description of this category. There are no instances of *going to*, which is the marker identified by Wagner & Herbel-Eisenmann (2014). However, the students are working as though there is a correct answer that they will identify once they have worked enough at the task (which aligns with the description of this category). Linguistically, this is achieved in a number of ways. Steven counts outside of sentence structure (turns 12 and 14). This suggests that there is only one way to count the objects; no one would count them differently. If they had thought there are different ways of counting, they would qualify their counting with, for example, "if we count [this way] we would get […]." Furthermore, Doug's expression, "this would" (turn 15) suggests that he knows what will happen.

We now ask how these communication acts position the students with the discourses we have identified in the entire session. First, because of the orientation we bring to the research (as

mathematics educators) we are attentive to the expression "this would" (turn 15) because it is a way of indicating a generalization. The expression will appear multiple times later in the transcript as part of a clearer generalization. In the case above, the sentence is incomplete so it is difficult to see Doug's generalization. Second, we found no linguistic references to other discourses. There were markers of some of them throughout the interaction, however; Doug's shirt indexed his hobby, the clothing of all three of them suggested that they identify as male, their proximity and body language could relate to friendship discourses, their physical context connected them to school discourses, our presence in the room and the recording devices potentially reminded them of the research discourse, etc. Nevertheless, the grammar of their interaction, specifically the ways their language suggested inevitability within mathematics, eclipsed the other discourses that potentially could draw their intention. Indeed, their attention was drawn to the recording devices, a girl in another group, and other "distractions" at times in this interaction. This idea of inevitability suggests that there is one way of counting, for example, but it also draws attention away from other discourses—it seemed to be inevitable that they would count those blocks in the way presented in the task. As the conversation continued, there is a change away from discursive inevitability:

18 *Steven*: I wonder if you take it apart? Like this? [*As he takes the cubes apart they do not separate as he intended.*] Fuck. All these, the outer, if you look on the inside… these two sides don't, these two sides don't, take that apart, these two don't…

19 *Doug*: Yeah, but also…

20 *Peter*: Hey Steven, can I see the cube for a sec?

21 *Steven*: One sec.

22 *Peter*: Okay.

23 *Doug*: Once you take it apart you're saying all these would have red, but what he's asking is that if you take an individual cube, so this was right here right, and like

24 *Steven*: Oh.

25 *Doug*: This part would have red, this part would have red, this part would have red on it, so those three sides… er… yeah, three sides would have red.

26 *Steven*: So how many of them wouldn't?

27 *Doug*: Only three cubes… one cube

28 *Steven*: If this whole thing was painted red, how many of these would have no—that's what he's asking, how many of these? Okay, so it would go like this, one, two, oh yeah, so it would be these sides right? It would be this side, this side, this side, this side, and this side. So yeah, it would be like, how many of them? It would be this… no, this side wouldn't have…

29 *Doug*: No, that side wouldn't

30 *Steven*: All right, this side wouldn't and this side wouldn't.

Starting in turn 18, Steven's "I wonder" demonstrated an awareness that he can think about the cube structure in different ways. This suggests personal latitude because he expressed awareness of his choice about ways of seeing. This change in authority structure seems to be contagious. Doug's response "Yeah, but also" (turn 19) references personal latitude too. He agreed with Steven and identified that something could be added. And Peter then asked for the cube (line 20), indicating awareness that there is choice about who holds the cube. Steven's response in line 21 then indicates awareness that he can choose whether to honour Peter's request, and then Peter complied, likewise acknowledging that he can agree or disagree with Steven's request for a little more time. This led to the beginning of a conjecture (though not clearly worded) from Steven: "If you take…" (turn 23). Turns 24 to 30 are replete with the word *would*, which we indicated earlier as a marker of discursive inevitability. However, in this case the word has different meaning, specifically a mathematical justification, because it is paired with the subordinate conjunction *if*.

This flurry of personal latitude may be an example of interlocutors picking up discourse patterns from each other. Applied linguistics literature has identified this phenomenon in terms of people picking up each other's words, which is a little different than picking up an authority structure. Positioning theory discusses the possibility of picking up structure from others, as the theory describes (using the language of first-order, second-order, and third-order positioning) how people follow or resist positioning established by others. Nevertheless, as we ask what happened to switch the dialogue from a stream of discursive inevitability to this flurry of personal latitude, we note the possibility that the authority structure was part of the students' repertoires the whole time just waiting to be triggered. It appeared to be triggered by Steven's insight, but one could say this too was triggered by the task inviting a certain kind of thinking. It could also have been triggered by certain classroom norms that honour this kind of interaction. There are lots of possibilities.

Steven's "If you take" (turn 23) is the beginning of a generalization in which he imagined stripping the cube of the outside layer of small cubes, which would leave one bare cube in the middle. The conjunction *if* is strongly associated with conjectures and generalizations throughout the interaction of this group especially in its pairing with *would*: "If …, then … would…" though the word *then* tended to be omitted. This and the other ways of expressing the students' choices to see the cube in different ways supports the development of their mathematical insights, and thus constructs mathematics as a discipline in which people develop insight by making choices about how to see things. These communication acts that index personal latitude can make similar impacts on the other discourses though it is not straightforward to map them because this part of the interaction was focused on mathematics. Nevertheless, the former hierarchy within the friendship discourse, in which Steven had the role of telling his "boys" what to do, was opened up to allow for the others to exercise agency. The finite physical resources were a factor in this negotiation of the object of attention though it is clear from their dialogue to come that both Doug and Peter were manipulating the cube in their imagination as they watched Steven manipulate the physical cube.

Discussion

Our research interest was initially on student language repertoires for mathematics. Our data has led us to connect this to some of our previous work that recognized and identified a range of discourses at work in mathematics classroom contexts (c.f. Andersson, 2011). In reflection we return to the repertoires. We remember that whatever repertoires people have for mathematical thinking and action, these repertoires serve purposes in other discourses as well. In fact, participation in other discourses that share linguistic resources with mathematics informs one's mathematical thinking. And vice-versa; participation in mathematics informs one's thinking and action in other discourses that share linguistic resources.

Thus we argue that mathematics teachers (with the support of mathematics education researchers) would be well-served to develop further understanding of how the characteristically mathematical expressions appear in students' discourses outside the classroom. Such insight would inform the ideas about mathematics the students would have when hearing and using the expressions in mathematics. For instance, two of the students in the focus interaction in this paper were "gamers." We are not very familiar with gamer culture, but we know that participants are in constant interaction with each other, and they are confronted with a continuous and fast-paced stream of choices that impact their progress in the game. Thus the students in our focus interaction would be using the "If … then …would …" construction in their gaming just as they used it in their mathematics. And we wonder how these two environments connect to each other for these students.

PROFILES OF RESPONSIVENESS IN MIDDLE GRADES MATHEMATICS CLASSROOMS

Jessica Pierson Bishop	Hamilton Hardison	Julia Przybyla-Kuchek
University of Georgia	University of Georgia	University of Georgia
jpbishop@uga.edu	ham42@uga.edu	jep94142@uga.edu

In this paper we consider how mathematics instruction that values, attends to, and builds on students' mathematical ideas is realized through discourse. We describe interactions that build on students' thinking and in which students help to determine the direction of mathematics lessons as responsive. Using a framework we developed to characterize the responsiveness of mathematics interactions, we report the variation in responsiveness across seven middle grades classrooms by describing (a) students' mathematical contributions, (b) the moves teachers enact in response to these contributions, and (c) how these two components interact. We found that there are multiple ways to be responsive to student thinking.

Keywords: Classroom Discourse, Instructional Activities and Practices

In this paper we consider how mathematics instruction that values, attends to and builds on students' mathematical ideas is realized through discourse. Discourse by its nature is responsive and relational (Bahktin, 1986; Halliday, 1978). Our goal is to consider a particular feature of discourse rooted in Bakhtin's notion of dialogism and Halliday's interpersonal metafunction—what we have termed responsiveness. We describe classroom interactions that build on students' thinking and in which students help to determine the direction of mathematics lessons as responsive. *Responsiveness* to students' mathematical thinking is a characteristic of interactions wherein students' mathematical ideas are present, valued, attended to, and taken up as the basis for instruction. Interactions can be more and less responsive, and in this proposal we document multiple profiles of responsiveness across middle grades mathematics classrooms. Our proposal addresses the conference theme of *Questioning Borders* by addressing issues of access and participation. In particular, the ways in which conversants are responsive to each other allows them to participate in certain ways, to take on different roles and identities, and ultimately affects how classroom participants engage with the mathematics at hand.

Theoretical Framework & Literature Review

To understand another is a responsive act. One must engage with another's idea and respond to it in order to understand it—though the manner and quality of engagement can vary widely. Bakhtin (1986) explains it as follows: "The fact is that when the listener perceives and understands the meaning (the language meaning) of speech, he simultaneously takes an active, responsive attitude toward it. He either agrees or disagrees with it (completely or partially), augments it, applies it, prepares it for execution, and so on" (p. 68). If understanding is responsive, then so too is speaking (and other forms of communication). In his discussion of speech genres Bakhtin says, "Utterances are not indifferent to one another, and are not self-sufficient … Every utterance must be regarded primarily as a *response* to preceding utterances" (p. 91). We focus on responsiveness because participating in mathematical discourse is inherently a responsive act, for both listeners and speakers. Specifically, we are interested in the degree of responsiveness to students' *mathematical ideas* within classroom settings and the extent to which utterances mutually acknowledge, take up, and reflect an awareness of student thinking. Below we share a brief overview of research related to responsiveness—primarily studies that focus on student thinking—and synthesize findings in order to situate our study.

Broadly speaking, research related to responsiveness can be categorized into two main types of

studies: (a) descriptive studies of classrooms in which students' mathematical thinking is either already prevalent or is developed within a classroom over time, and (b) studies identifying features of instruction that are positively related to mathematical proficiency. The first group of studies takes as a given the desirability and effectiveness of instruction that incorporates student thinking and considers what this type of instruction looks like. Some studies look at specific teacher moves such as a probing sequence of questions (Franke et al., 2009) or a reflective toss (vanZee & Minstrell, 1997). Other studies develop broader frameworks to describe the classroom contexts and features of instruction that influence or constrain whether, how, and in what ways teachers explore student ideas in their teaching. For example, Leatham, Peterson, Stockero, and Van Zoest (2015) developed a framework to identify instances when it might be productive to pursue students' mathematical ideas in-the-moment. Their focus is how to identify a particular type of student contribution—a *M*athematically Significant Pedagogical *O*pportunity to build on *S*tudent *T*hinking or *MOST*. Additionally, research on the construct of teacher noticing has explored requisite knowledge and skills teachers need to be responsive to student thinking. In particular, Jacobs, Lamb, and Philipp (2010) developed a framework for teacher noticing comprised of three interrelated components that has students' mathematical thinking as its foundation. Before a teacher can incorporate student thinking into instruction, she must first *attend* to student ideas and *interpret* their significance before *deciding how to respond*.

The second group of studies identifies features of instruction related to responsiveness that are positively related to improved mathematical proficiency. Many of these studies use quantitative tools to provide evidence that the presence of student thinking is an effective feature of instruction based on a positive relationship between student thinking and outcome measures such as achievement scores, problem solving, and improved dispositions toward mathematics (Carpenter et al., 1989; Ing, et al., 2015; Nystrand et al., 1997). For example, in their work investigating what practices 'press' students for conceptual mathematical thinking, Kazemi and Stipek (2001) found that press for conceptual understanding was positively correlated with students' understanding of fractions. They identified features of discourse that were present in high press classrooms including engaging students in explaining, justifying, verifying, and arguing about their own and their peers' thinking.

Across this literature we see a vision of mathematics instruction that values students' mathematical ideas and seeks to incorporate those ideas into instruction in productive and meaningful ways. Some of the research focuses on discursive moves that can be enacted in-the-moment. Other research considers either how to develop classrooms that value students' thinking or the skills needed to respond to students' thinking. Moreover, researchers have indicated that this type of instruction is not commonplace and is challenging to enact (Pimm, 1987). Our goal in this proposal is to develop a framework to characterize responsiveness in mathematics classrooms and use it to describe the variation in responsiveness across classrooms. The research question guiding our study is, In what ways are middle grades mathematics classrooms responsive to students' mathematical ideas during whole-class discussions?

Methods

Participants and Data Collection

The data in this report are part of a larger study investigating characteristics of productive mathematics discourse in grades 5–7. Participants include teachers and students in seven classrooms across three U.S. states. Participating teachers were recommended by district personnel, faculty researchers, and professional development providers based on the teacher's reputation for using problem solving and discussion regularly during instruction. Our participants were five fifth-grade teachers, one sixth-grade teacher, and one seventh-grade teacher. All were certified in either elementary or middles grades education with 7 to 30 years of teaching experience. For each teacher,

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

we videorecorded and transcribed an introductory lesson on fractions. We chose fractions because it is an important topic and spans the middle grades required content. Lessons were filmed at various points throughout the school year based on when fractions were introduced and ranged in length from 40 to 95 minutes. In our analysis, we used both the video recordings and transcripts, which allowed us access to gestures, student written work, and other non-verbal communication in the classroom.

The Development of a Coding Framework for Responsiveness

We developed a coding framework for responsiveness in whole-class mathematics discussions (Przybyla-Kuchek, Hardison, Bishop, 2015) using the constant-comparative method. The unit of analysis is a segment, which we define as a series of turns of talk with a common focus (e.g., activity or strategy). Our framework comprises two components: (1) students' mathematical contributions and (2) the moves teachers enact in response to these contributions (Figure 1). In this section, we describe the ordered levels for each component of our framework.

		Teacher Moves		
		Low	Medium	High
Student Contributions	None — Minimal			
	Considerable			
	Substantive			

Figure 1. Whole-class responsiveness framework.

Student contributions. Our framework includes four levels of students' mathematical contributions: none, minimal, considerable, and substantive. We define a segment as *None* if it contains no mathematical student contributions (e.g., teacher monologue). *Minimal* segments are dominated by students performing routine calculations, recalling facts, and providing short responses to known-information questions. *Considerable* segments are those in which students share their strategies or other mathematical ideas without justification. Unlike minimal segments, considerable segments contain evidence that students have opportunities to make sense of mathematical content and to share their ideas. *Substantive* segments, like considerable segments, are characterized by students discussing their mathematical ideas; however, in substantive segments, student contributions also include providing justifications, making generalizations, or participating in mathematical argumentation. When considering these elements of students' contributions, we focus on the structure of these contributions rather than on correctness (from our own perspectives). A segment may be characterized by substantive student contributions even if it contains individual turns of talk that might be described as minimal or considerable.

Teacher moves. Our framework includes three levels of teacher moves that reflect the extent to which students' mathematical contributions are made public, taken up, and serve as the basis for instruction: low, medium, and high. In *Low* segments, teachers do not use students' mathematical contributions as the foundation for instruction; low teacher moves include, brushing-off, evaluating, and not reacting to students' contributions. In *Medium* segments, teachers focus on (a) understanding and highlighting individual students' thinking by revoicing student ideas or asking probing questions, or (b) asking classmates to engage momentarily with particular student ideas by asking other students to correct, evaluate, or indicate whether their thinking aligns with another student (e.g., "Who used the same strategy?"). However, teachers do not focus simultaneously on both (a) and (b). In *High* segments, teachers simultaneously focus on student thinking and explicitly direct students to engage significantly with the mathematical ideas of others. High moves include requesting comparisons across student contributions, taking up a student-posed problem as a whole-class activity, asking

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

students to restate or apply another's strategy, and inviting students to ask questions of their peers. As with student contributions, teacher moves are coded holistically at the segment level.

Analysis

Prior to coding each introductory fraction lesson, a member of the research group watched the videorecording and partitioned the lesson transcript into segments. We did not code segments consisting of entirely nonmathematical content (e.g., discussions of norms, transitional time). At least two members of the research group coded each lesson independently using the videorecording and segmented transcript. Each segment was first assigned a student contribution code. Segments without mathematical student contributions (i.e., those coded as none) were not assigned a teacher moves code as there were no student ideas to which teachers could respond. Segments containing mathematical student contributions (i.e., those coded as minimal, considerable, or substantive) were also assigned one of the three teacher moves codes. Sets of independent codes were compared for each lesson, and coding discrepancies were discussed until the coders achieved consensus on a final set of codes for each lesson. In summary, each segment was characterized by a combination of codes corresponding to exactly one of the ten empty cells depicted in Figure 1; we refer to these ten coding combinations as compound codes.

Because lessons varied in terms of minutes of whole-class instruction and segments were defined by shifts in common focus, there was variation in both the number of segments per lesson and number of seconds per segment. Thus, to investigate trends and variation in responsiveness across lessons and classrooms, we weighted each segment's student contribution, teacher move, and corresponding compound code (e.g., considerable–low) according to the instructional time in seconds corresponding to each segment. We then calculated the percentage of whole-class mathematical discussion time accounted for by the respective code.

Illustrating the Framework with Excerpts

In this section we discuss three excerpts from the lessons we analyzed to illustrate different levels of student contributions and teacher moves described in the framework above (See Figure 2). In Excerpt 1, Teacher MA's 6th graders are exploring fractions using a number line on the whiteboard. After a student subdivides the interval from zero to one into 24 parts, Teacher MA asks her students about the representation. The student contributions provide little evidence of students sharing their ideas and consist entirely of short responses to known-information questions wherein the students are attempting to match particular responses predetermined by the teacher. Thus, this segment is characterized by minimal student contributions. For teacher moves, Teacher MA implicitly evaluates students by echoing students' responses and recording them on the whiteboard. When Tucker's response, "three," breaks from the format of the other student responses, Teacher MA corrects his response by providing additional information, "three twenty fourths." Thus, Excerpt 1 illustrates a segment characterized by low teacher moves. Excerpt 2 occurs in Teacher EC's 5th grade classroom, where Leena presents her strategy for determining how much candy each child would receive if five children shared eight candy bars. The student contributions provide evidence of students sharing their mathematical ideas and making sense of mathematical content. While Leena's description contains a hint of justification (e.g., "…*since* there are five students, I split it into five…"), the collective student contributions are best characterized as strategy sharing. By requesting that another student restate Leena's strategy, Teacher EC simultaneously focuses on Leena's thinking and asks other students to engage with her thinking in a nontrivial manner. Throughout the interaction with Jordan, Teacher EC asks additional questions that engage Jordan with Leena's strategy. Excerpt 2 illustrates a segment characterized by high teacher moves.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Excerpt 1: Minimal-Low	Excerpt 2: Considerable-High	Excerpt 3: Substantive-Medium
Tchr MA: So, Mitchell, what's this first line represent?	*Leena:* I drew eight candy bars and since there are five students, I split it into five, so there's fifths. And then I colored in each color equals one person. So there's one fifth from every candy bar and all together that equals eight fifths and turned into a mixed number that's one and three fifths.	*Tchr LE:* Mia said she's adding an eighth here and an eighth here and she got two sixteenths. Right Mia?
Mitchell: One twenty fourth. [As students respond, Teacher MA writes labels on the number line.]		[Mia nods]
		Tchr LE: Okay. Um, Jack.
Tchr MA: One twenty fourth. Victoria, the second line.		*Jack:* I always, uh, thought that you couldn't add up the denominators.
		S48: Yeah
Victoria: Two twenty fourths.		*S49:* Yeah
Tchr MA: Um, Tucker, what's the next line? [overtalk]	*Tchr EC:* Very nice, very nice. So you broke each, oh, can someone explain what she just said? What did she just tell us? Anyone can put it in their own words. What did Leena just tell us? Can someone put it in their own words? Jordan? Want to give it a shot?	*Tchr LE:* Why not?
		Jack: Uh, because it's
Tucker: Oh yes. [overtalk] Uh, three?		*Jonathan:* The number would. The number would get lower.
Tchr MA: Three twenty fourths. Manny?		*Jack:* Oh yeah. The – it would get smaller. Because
Manny: Four twenty fourths.		*S50:* The fraction
Tchr MA: Ida, the next line.	*Jordan:* Um	*Tchr LE:* What it? What is it?
Ida: Five twenty fourths.	*Tchr EC:* I'll help you if you get stuck. Go ahead. What was the first thing that Leena did?	*Jack:* The denominator. Like the whole number.
Tchr MA: Five twenty fourths. Uh, Nancy the next line.		*Fiona:* Fraction (inaudible) smaller.
	Jordan: She drawed the eight candy bars.	*Tchr LE:* But how does that relate to my picture? Well two sixteenths is the same as one eighth. Does – does my fraction get smaller?
Nancy: Six twenty fourths.		
Tchr MA: Cam.	*Tchr EC:* She drew eight candy bars right. Okay, continue.	*Class:* No.
Cam: Seven twenty fourths.	*Jordan:* And then she	*Joseph:* When you add eighths, it wouldn't go up. It would – you would go to a whole number so you wouldn't add – you would just like add, um, the – the top. You wouldn't add the bottom cause then you would never get a whole number.
Tchr MA: Judy.	*Tchr EC:* So she drew the four, eight candy bars and then what'd she do?	
Judy: Eight twenty fourths.		
Tchr MA: Ron.	*Jordan:* And she took, and then she got, then she like all	
Ron: Nine twenty four.	*Jordan:* She divided them into five groups.	
Tchr MA: Gloria.		
Gloria: Ten twenty fourths.	*Tchr EC:* She divided them into five, groups or five pieces, yeah.	*Tchr LE:* What do you mean I'd never get the whole number?
Tchr MA: Claire.		*Joseph:* Cause it would just keep adding on.
Claire: Eleven twenty fourths.	*Jordan:* And then she gave each kid equal amounts but, um,	*S51:* Yeah the denominator would [overtalking]
Tchr MA: Lily.		
Lily: Twelve twenty fourths.	*Tchr EC:* How much did she give each kid?	*Jonathan:* Yeah it would just keep getting lower and lower and lower. [overtalking]
Tchr MA: Luke.	*Jordan:* An equal amount.	
Luke: Thirteen twenty fourths.	*Teacher EC:* An equal amount, okay. And what was the equal amount that she gave to each person?	*Joseph:* The denominator would keep getting. [ovetalking]
Tchr MA: Uh, Jay.		*Gracie:* number but actually it would be getting smaller [overtalking]
Jay: Uh, fourteen twenty fourths.		*Tchr LE:* Oh. If you kept adding the denominators then it would just – you'd never reach a whole.
Alex: Fifteen twenty fourths	*Jordan:* Eight fifths.	

Figure 2. Three excerpts illustrating the responsiveness framework.

In Excerpt 3, Teacher LE asks 5th graders to write equations related to their solutions for an equal sharing problem. When Teacher LE asks students to share their equations, Mia asserts that one-eighth plus one-eighth is two-sixteenths. The students in this excerpt participate in mathematical argumentation as they try to determine the validity of Mia's assertion. Jack generalizes the situation

to adding any denominators rather than considering only the particular equality in question. Throughout the segment, students collectively develop a fairly sophisticated informal proof by contradiction. Consequently, excerpt 3 is characterized by substantial student contributions. Teacher LE initially revoices Mia's claim. Her subsequent moves are predominantly probing questions rooted in understanding particular students' contributions (e.g., "What do you mean I'd never get the whole number?"). Although students engage with others' ideas throughout the excerpt, Teacher LE's moves do not direct students to engage with the ideas of others. As such, Excerpt 3 illustrates a segment characterized by medium teacher moves.

Findings and Implications

We now describe the findings from our analysis of the responsiveness of mathematics classroom discourse. We consider general trends across classrooms, variability in responsiveness both across and within classrooms, and the ways in which student contributions and teacher moves interacted in our data set. In some of the participating classrooms, the majority of the lesson was spent engaging in whole-class mathematics discussions, whereas in other classrooms students spent significant amounts of time in small groups or doing individual work. Across our classrooms, the percent of time spent in whole-class mathematics discussions ranged from 23 to 74% (mean of 49%). The analyses that follow are *only* for time spent in whole-class discussion. Figure 3 displays the distribution of the student contributions and teacher moves as a percentage of time spent during whole-class mathematics discussions in the different categories of our framework.

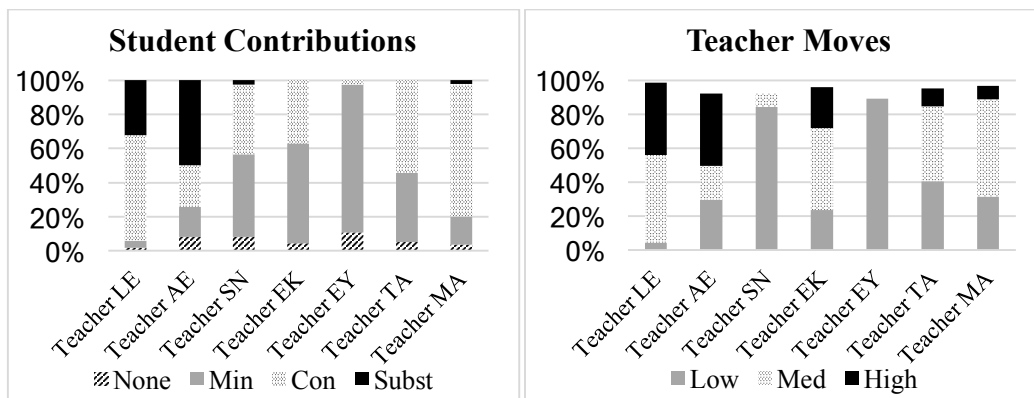

Figure 3. Percentage of time spent across the responsiveness framework categories.

We found that whole-class discussions were not dominated by teacher monologues, but that over 90% of the time students made mathematical contributions during whole-class discussions. In all but one of the classrooms, more than one-third of the time students made substantive or considerable contributions; and in four classrooms, over half the time students made substantive or considerable contributions. In most classrooms, students had opportunities to solve problems and explain, justify, or generalize their thinking during whole-class discussions. Moreover, in five of the classrooms, more than half of the teacher moves were medium or high level. These teachers not only created opportunities for students to engage with mathematics, but in many of the whole-class discussions they focused on and took up students' mathematical contributions. In addition to analyzing the student contributions and teacher moves independently, we also considered how our two framework components worked together during whole class discussions. Teacher AE's responsiveness profile is seen in Table 1.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Responsiveness Profile for Teacher AE based on percent of time during whole-class discussions

			Teacher Moves			
			Low	Medium	High	*Sums*
Student Contributions	None	Minimal	17.8%	0%	0%	*17.8%*
	8.1%	Considerable	0%	2.5%	21.7%	*24.2%*
		Substantive	7.5%	17.4%	20.8%	*45.8%*
		Sums	*25.3%*	*20%*	*42.5%*	

Note that the most common compound code in Teacher AE's classroom was a considerable student contribution paired with high-level teacher moves, occurring just over one-fifth of the time during whole-class discussions. The second most common combination was substantive student contributions paired with high-level teacher moves, also occurring about one-fifth of the time. Thus, in roughly 40% of the time spent in whole-class discussion, Teacher AE supported students' engagement with their classmates' mathematical ideas in order to make sense of, explain, justify, critique, exemplify, or generalize. However, we also see a large percent of minimal-low interactions and segments of no student contributions (i.e., None) in this classroom.

After creating a similar table for each teacher, we found that for four of the classrooms, over 50% of the time spent in whole-class discussions involved considerable or substantive student contributions and medium or high teacher moves (see the shaded cells in Table 1). Each of these four combinations requires students to engage in important mathematical activities and uses the resultant student ideas as the basis for instruction. We noticed that in *all* classrooms, time was spent during whole-class conversation in minimal–low interactions (ranging from 4.4% to 87% of the time). This suggests to us that interactions at the lower levels of our framework are not necessarily negative, but that they play a role in whole-class discussion. However, we believe it is problematic if the majority of time spent in whole-class discussions falls into this category.

We also found that the responsiveness of classroom interactions varied. For example, in Figure 3 we see that the proportion of time teachers responded with high-level moves ranged from 0 to 46.5%, and the proportion of time teachers responded with low-level moves ranged from 0 to 89%. There was also large variability in student contributions with ranges from 3 to 78% and 0 to 46%, respectively, for considerable and substantive student contributions. Moreover, five teachers enacted teacher moves at all levels of the framework and four classrooms had student contributions at all levels suggesting that not only is variation in responsiveness present across classrooms but also within classrooms.

In summary, our data indicate that the kinds of instruction advocated for in existing literature is possible (e.g., Franke et al., 2009; Kazemi & Stipek, 2001; NCTM, 2014). In the interactions we analyzed we found that, for large portions of whole-class discussions, student ideas can be used to drive instruction and that there are multiple ways to be responsive to student thinking. We also found that mathematical interactions were not always in the highest categories for teacher moves and student contributions. Thus, at times, it seems appropriate and necessary to have teacher moves and student contributions at the lower levels of the framework. Additionally, our coding framework was able to adequately capture variation in responsiveness in middle grades mathematics classrooms. Given the variation present in our data, we encourage a variety of student contributions and teacher moves during whole-class discussions wherein a significant proportion of whole-class discussions are characterized by considerable or substantive student contributions and medium or high teacher moves.

In this paper we considered one aspect of mathematics classroom discourse, responsiveness to students' mathematical ideas, but acknowledge that this focus provides a narrow view of mathematics classroom discourse. We believe that there are other important discursive features that can and should be analyzed, and which would showcase our participating teachers differently. In the future we hope to apply our framework to additional lessons in our data and incorporate analyses of other aspects of classroom discourse.

QUESTIONS OF TRUTH: ETHICAL AND MORAL WANDERINGS IN MIDDLE GRADES MATHEMATICS CLASSROOMS AND RESEARCH

Susan Cannon	Stephanie Behm Cross
Georgia State University	Georgia State University
scannon5@student.gsu.edu	scross@gsu.edu

This paper describes two researchers engagement with two teachers as they taught a middle grades mathematics course, Current Events Math, in a large urban school district. The researchers share bits of data and their ethical entanglements as they entered into the site to find the truth about what works in middle grades mathematics classrooms only to realize that truth cannot be found through research. They then grappled with the question of the purpose of research and their roles as researchers in the school and the academy.

Keywords: Research Methods, Middle School Education, Equity and Diversity, Curriculum

Entanglements (Context/Site)

Suppose you were prompted to answer this question in the midst of the 2014 Ebola epidemic: What was the worst Ebola outbreak in history? How might you answer the question? What might you ask yourself? What tools might you use to determine the truth about the question? Middle school students in a charter school in a large urban school district grappled with this question and asked things like *What is worst? How do we measure worst? From whose perspective?* We too—researchers and teachers—found ourselves grappling with these and other questions: What is the interplay between the ethics and the mathematics? How do we raise and attempt to answer ethical questions in the current educational and political environment? What is the relationship between mathematics, truth, and ethics?

This study explores two middle grades mathematics teachers' concepts of ethics and truth as they engaged in a 12-week course. The course, *Current Events Math,* positioned students as researchers who studied current events and used mathematics to consider those events. Observations and interviews were conducted during the 2015-2016 school year and focused on the teachers' experiences teaching the course during 2014-2015 and 2015-2016. In this paper we consider multiple and overlapping layers of ethics: ethics of the researcher in the field, ethics of the teacher towards her students, ethics of the citizen in a community, and ethics of representation in the media.

Theoretical Perspectives/Ways of Seeing/Knowing

This study was composed through interactions between a mathematics educator, a doctoral student and former mathematics teacher, and two practicing mathematics teachers. The format and content of this study are informed by poststructural and post-qualitative perspectives. Though traditional empirical studies have their place in mathematics education, and there have been significant strides in the scope of qualitative research, some of "these versions of knowing express the sense that our inherited ideas have tended to underplay multiplicity, complexity and cultural specificities, none fully captures the postmodern analytical edge that invites a less certain space for research, pedagogy and practice" (Walshaw, 2004, p. 4).

We believe that there are multiple perspectives and versions of truth and that our ethical charge is not to attempt to boil down our impressions and data into one ultimate understanding or truth. Instead, we agree with Neyland that, "the primary ethical domain is not monotonous, regular or predictable; it is shot through with uncertainty and contradiction and cannot avoid ambiguity" (2004, p. 61). Mathematics is often given privilege as both true and unbiased, so it is particularly important to us that ambiguity is recognized within the field of mathematics education. Neyland (2004) refers to mathematics education as "paradigm case subject" (p. 62) in the postmodern ethical agenda

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

because "it is the curriculum subject that can be used to make the strongest case against the project of modernity in education more generally" (p.62). Neyland further asserts that "mathematics educators have the urgent task of undertaking a postmodern re-enchantment of mathematics and a postmodern restoration of the primacy of the direct relationship of responsibility between teachers and students" (p.63). The course, *Current Events Math,* is built upon the foundation of responsibility between teachers and students, which for these particular teachers also includes an outlook towards equity in the world. In considering equity, the students and teachers had to look closely at the numbers that are used to describe and represent events that intersect the lives of students and teachers.

Although numbers are largely seen for their face value by academics and society at large and mathematics is assumed to be objective and unbiased, numbers are often complex representations that are constructed and composed. Because of the complexity of their construction and their sometimes misaligned or ineffective representation, numbers can function to distance decision makers from moral and ethical decisions. In the mathematics course, the teachers and students questioned the truth(s) that different numbers told. In our research, we do not rely on numbers as evidence of a valid and reliable study. Instead, this study brings together data pieces that begin to deconstruct the neutrality of mathematics and numbers.

Entanglements with "data" (methods)

The present study includes "data" from teacher interviews, classroom observations/field notes, photo elicitation, researcher journals, and student and teacher created documents. In considering these documents, the authors viewed them as co-constructed by the authors, participants, school, and students. These documents, from transcribed interviews to student journal entries, do not have single authors or sites of production. The following quotes speak to our views on data and representation: "a fieldnote fragment or video image – starts to glimmer, gathering our attention" (MacLure, 2010, p. 282), "always a body of statements to consider in which the individual words and sentences merely slumber" (Prior, 2003, p. 113), and

> The aim is to 'make materially visible the structure of representation as a trace of temporality and exchange, the fragments as mementos, as ''presents'' re-presented in the ongoing process of assemblage, of stitching in and tearing out (Mitchell, 1994, p. 419 as quoted in Radley, Hodgetts, & Cullen, 2005, p. 278).

The researchers used writing as inquiry following Richardson and St. Pierre (2005), "but they were always already in my mind and body, and they cropped up unexpectedly and fittingly in my writing— figurative, fleeting data, that were excessive and out-of-category. My point here is that these data might have escaped entirely if I had not written; they were collected only in the writing" (p. 970). Through writing as inquiry, the researchers troubled their identities as researchers, former teachers and mathematics educators while acknowledging the complexity of their identities as women, mothers, and friends. Through these intersecting viewpoints, "data is fluid, a chameleon, able to take different "shades" of meaning based on the perspective of the researcher" (Koro-Ljungberg, 2015, p. 47).

As they navigated this research site with colleagues and friends, "ethics explodes anew in every circumstance, demands a specific reinscription, and hounds praxis unmercifully" (St. Pierre, 1997, p. 176). One researcher wrote in her journal, "So, I am here with so much uncertainty and also some confidence in that uncertainty is productive. I am asking myself, "How do I do representation knowing that I can never quite get it right?" (Pillow, 2003, p. 176).

From interview probes, to classroom interactions and hallway encounters, the researchers questioned the ethics of their choices. In reflecting on a transcription, Susan wrote in her journal,

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

> I wonder if I should have probed when she said, "If they just knew me." I paused. I thought about it. I think my reasons for moving on were two fold. One I was hesitant to get too personal on the first meeting and two I was worried about staying on topic and getting through the interview. I think that the first reason might be legitimate; the second in retrospect seems counterproductive. This adherence to the interview guide, is it productive for me? I do not think it is. Here the participant was offering me something emotional and I turned back to content, to math. I shut down this person who is saying she feels unseen. I didn't see her or wasn't comfortable seeing her. Ethically, I signaled that her story wasn't important in the research. How do I come back around to this? I cannot right the wrong, but can I move forward in a way that is productive.

Throughout the research, the researchers began to "see" what they hadn't been seeing. The classroom observations and interviews left the researchers entangled with the concepts and questions of truth and representation and feeling the persistent tug of positivism at their sleeve. Aren't numbers, data, facts materialized manipulations of the cognitive processes involved in measurement? Numbers are "arrested 'moments' of measurement captured through technical decisions" (adapted from Knowles, 2006, p. 512). The research questions became questions about the research. How do we use mathematics/research to produce truths? How do we deconstruct "truths" created through mathematics/research that are dangerous or destructive?

Assemblage(s) (Results/Findings)

During 2014-2015, the students researched Ebola, Michael Brown, gender imbalance and violence towards women in the gaming industry, and gay marriage. In the 2015-2016 school year, topics included Rand Paul, air pollution in China, New Horizons, the European refugee crisis, head injuries in the NFL, and the use of sugar in food. Following is an assemblage of data pieces stitched together by the researchers, some conversations and observations related to these topics and some conversations that got at the larger goals and questions around this course. As mentioned above, one interesting thread that wove through the data was the idea of truth.

Truth from Experience

The students engaged in a study of concussions in professional football. In this unit the students collected and analyzed data and statistics about the likelihood of concussion for particular positions. The working groups in the classrooms were intentionally constructed with one football player in each group. As the students did their analysis there was tension between the *truth* presented by the numbers and the *truth(s)* brought by the group members founded in their experiences on the football field. Is truth running full speed ahead, hearing your breath in your own ears and feeling its moisture on your face, and then a bone crunching hit from the side and the sudden scent of grass and mud? Or is this truth: cornerbacks suffered 10% of the total concussions reported by the NFL in 2013 (Breslow, 2014)? Which is more valid, reliable, and believable? Which one *counts*? How might these truths influence the students' belief in a number?

Truth, Bias, and Prejudice

Truth(s) arose out of biases and numbers and new truths were created through numbers to undo prejudice. As the class researched the shooting of Michael Brown in Ferguson and the subsequent protests, mathematics helped them to understand the injustices that had been occurring there. Elisabeth stated in her first interview,

> Looking at the race issue in Ferguson became a question of math actually. So why do some people feel like it's not fair or not equal? What we could do with Ferguson was to look at the population numbers and the arrest records. We could look at records of police stopping individuals and keep track of those statistics by race over time. As we looked at these numbers

and converted them into a percent, because that was the math we were looking at. When we equalize numbers we're not just looking at the number of people, but we are looking at a number that is kind of stabilized by percent by having the same denominator. The kids were able to say, "oh that's not, that doesn't seem fair." If 70% of the people you know, if they only represent 30% of the community but 70% are stopped, they begin to see that there is inequality there. So then you can go back to the original question of why are there riots, and kids can say "oh because it really doesn't feel fair because out of ten people, 7 of your friends have been stopped by the police, but if you're white only 3 of your friends have been stropped by the police. As a black person, you're like, "hey everybody gets stopped by the police", and as a white person, you're like, "really do we get stopped by the police?" So that piece, that particular instance was getting at the core of why is there rioting aside from the emotional piece there was math behind it. There was math that could help kids understand how somebody who wasn't like them might feel.

When we spoke to Ayesha, who self identifies as Pakistani-American, about what she hoped students would take away from the course, she also spoke about truth from bias, but from a different perspective:

Susan: What are you hoping that students will take away from the course?
Ayesha: A sense of responsibility.
Susan: To whom or to what?
Ayesha: To those around them
Susan: What would that look like?
Ayesha: People who are conscious of what is happening around them and are willing to speak up, are willing to try to get more and willing to change if, not changing the world, changing their environment. Or if you are at the airport and you have someone who is very different that comes and sits next to you being comfortable in that situation.
Susan: Um huh
Ayesha: You know I hope that that is what they get out of it. Looking at me as their teacher is learning that it is ok and if they hear something in the media then they will be like there must be a different side of the story as well or what are the numbers to help you be more conscious.

As we worked together on this research project, we began to recognize that numbers and mathematics help people to see injustices and to recognize prejudices, but that they also have effects that increase bias and prejudice. Then how do we know which number to trust?

Multiple or Conflicting Truths

As mentioned at the start of this paper, the students and teachers studied the Ebola outbreak in the spring of 2014. The class researched the outbreak and asked, what was the worst outbreak in history? To answer this question, they had to wrestle with questions like, *What is worst? And worst to whom or for whom? Does worst mean the highest total number of deaths, or the highest percentages of deaths per infection, or the percentage of the total population that was infected and died during the outbreak?* Elisabeth talked about these multiple or conflicting truths—the idea that "truth" can be used by anyone to pursue any agenda:

I worry sometimes that the idea of social conscious or justice can be used by all people to pursue any agenda. I can say there's uncertainty, and I can say everyone can find their own truth, but the bottom line is the math can help us differentiate between exaggeration and what's really there, so we talk again about the rounding situation looking at politicians and what they say. If we look at the real, the numbers we can actually know, and then the media or politics can change them or

turn them and look at them from another direction, and say no they mean this, but we just looked at them do we think that and why?

Elisabeth talks later in the same interview about interpretation in mathematics:

[Understanding] how to read a graph how to interpret numbers that people use really helps you understand data presented as fact or truth in the media, and so I think you could, I mean statistics are used to support arguments. Numbers are used all the time to validate people's positions on things because somehow that quantitative data feels nonnegotiable. You know a number is a number is a number, and you can't, you know… So understanding what those numbers mean allows you to take a more critical look at whether it's true. You know how you interpret those numbers whether you believe them or not. It's really easy. I think a lot of people come out of school feeling like-- math is hard, math is not something that I understand entirely. So they are willing to take numbers at their face value and what I know to be true is that we interpret numbers in the media and in statistics numbers are interpreted.

Ayesha spoke about her recognition that there are multiple ways to present a topic to students:

When I read something before I show it to my students, I am reading it with a very keen eye. Like what do I want the students, like so there's bias there. So, yeah, it's there. I do want them to have all of the perspectives, so sometimes I will choose something that I don't agree with, like I want them to know the truth, and so I will throw that out. But yeah, I think it does impact because even though I am being fair and providing all the things I'm sure that there are people out there that don't do that because they want that one point of view….

So, if we know there are multiple truths, then there will be conflicting truths. How might middle school students handle this? Ayesha describes a conversation she had with three students about evolution. One student said, "You can't believe in science and god, you can only do one." Ayesha replied, "I believe in science and god. I believe in evolution and god." Another student remarked, "You can't do that if you go in a church, and you tell them you want to be a scientist; they are going to say get out." Ayesha went on to wonder, "they are already starting to have these thoughts so I am wondering when they started and how they have come to this age at 11 or12 years old *knowing* these things…" As a team of women, a team of teachers, researchers, teacher researchers, etc., we found ourselves grappling with what it means to know something in mathematics and in the research we are doing around the teaching of mathematics. What happens when you have multiple and conflicting truths in mathematics and in your research "spaces"?

Students Becoming Capable and Critical Mathematicians

Susan: How do you view the students as they come to you and what's your goal for them as they…?

Ayesha: So, I actually, having taught some of the students before, I do have preconceived notions of some when they come, and I have concerns or expectations based on those preconceived notions. Some of them hold true and some of them don't, but my goal for each of them is that they find some joy. I guess in doing math that was a little bit challenging, so that they could know something, so that they could learn something bigger than math out of it.

Susan: What's bigger than math?

Ayesha: That they could know something that was real or true about the world because of math. And I, or that they could just know that they could know. Like, "I can figure this out. I've got this skill that allows me to know this thing or to think more deeply about this thing." I think that's the piece that feels… I want the kids to feel empowered to be able to ask questions when they see numbers anywhere and to know like, "oh, they got those numbers from

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

somewhere. I could get those numbers and check. I could know that. I could do that thing that they did. Maybe I can't do it right now, but someday I could do it." Anyone of them I would want them to think like, "I could be a NASA scientist. Really, there's so much more to it than just this rate business. But I see now that it's not as scary as it seems to take 5.88 billion and divide by 460,000 to find out the km per minute. I could do that." So, I want them to feel like-- one, I can do that, and --two, I want to do that. I would love for them to think to be thinking I want to do this.

As Elisabeth talked about the course and her hopes for the students, truth came up as well.

Reflection leads us to know things about ourselves that we maybe didn't know before and I think of that in terms of truth, I believe something about this situation and looking at the numbers about it. It may have changed and that for me is now the true thing about this story. And math informed that or helped inform that true thing about the story. That idea of value in math, there are some numbers that are just the numbers and you don't, there's not much you can do but the truth of it I guess, the truth of those numbers is for kids is I can know this I can figure out how to do this. I can know this and that knowing feels like the truth in some ways like it's not a mystery anymore even if it is a mystery, there is a door open to the mystery so I can go through it and figure it out.

What does it mean to prepare students as mathematicians? As critical citizens? As truth seekers? Is questioning all numbers productive or is it crippling? When is questioning too much? When does it just hurt?

Discomfort in Ethical and Moral Work

As they planned the final unit of their course, Susan sat in on the planning session. The teachers began by saying that they did not want to take on a topic that was too depressing. They had just finished 10 weeks of difficult discussions during which students and the teachers were asked to bring more of themselves into the work of school than is typical. Halloween was just around the corner, so the teachers decided to begin a unit on candy. As they got further into this unit, they found that looking critically at this issue was also quite troubling. They watched videos about the use of sugar to hook consumers on particular products, and the damaging effects of sugar on our bodies. How is it that they always ended up in the place where they were discussing things that were troubling? Are we finding disturbing *truth(s)* because we are looking for them? Or are they there whether we look or not, and it is our ethical duty to deconstruct them? What are the ethical and moral repercussions of bringing students and other teachers into the work of looking beyond the singular truth represented? Looking beyond the number and beyond the norm?

Denying Access to Truth

Susan witnessed a conversation between the two teachers where one teacher was relaying to the other that she would not be able to teach enrichment math, *Current Events Math,* in the next term; she would be teaching a remediation math course instead. She was disappointed to have this switch and that there would be no enrichment math classes in the next term. She also expressed understanding that there were 7th graders that really needed support in their math and therefore it was okay to teach the remediation course. Susan asked the question, why is it that we think that we have to teach a remediation mathematics course in a different way than an enrichment mathematics course? Weren't the skills taught in the *Current Events Math* course important for those students in the remediation course as well? How would teaching basic or foundational skills out of a workbook to the 7th grade students function? Would they see themselves as distant from the mathematics, consumers of it, rather than as in relation with it? Don't we want all students to be critical readers of mathematical truth(s)?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Wonderings (Implications?)

Though we resist the term findings, there are important questions that this study brings to light that could be asked in other places and spaces. The multiple and overlapping layers of ethics: ethics of the researcher in the field, ethics of the teacher towards her students, ethics of the citizen in a community, ethics of representation in the media, are ever present, and even as we make moves, the context changes and we wonder how to move responsibly. In Todd's thinking about responsibility, ethics and relationships, she stated,

> what counts as ethical in Levinas's thought is not encapsulated within rule-governed behaviours, ethical codes, or moral precepts that can be secured through stable significations. Rather, the ethical lies within the very ambiguity of communication, within that which slips our cognitive grasp and possession…. For Levinas, communication is inherently ambiguous because it gestures beyond any stable meaning toward the very otherness of the other that marks her as radically distinct from myself. And it is this relation to the other as one of unknowability where the ethical promise – and risk –of ambiguity lies. (2003, p. 33)

If we think back to the football players, we wonder about the truth of experience understood through relationship with others. Should the other students have believed a person they had a relationship with who had experience with the topic or the number derived from many instances and published by scientists?

Is the responsible, ethical thing to do to continually create new interpretations and representations based on the particular context? We are still stumbling and stammering in the moment knowing there is no "right" to get to, no certainty that can calm us. Is the calm then in the acceptance of the ambiguity as promise and the willingness to continue to question, and to ask, and to wonder, and to disrupt?

Rather than concluding we resist conclusion following Koro-Ljungberg (2010). "Instead, unpredictable attentiveness and unexpected relationship with the Other could activate researchers' responsibility and thus enable open and humble data interpretations, as well as study conclusions that avoid definite closure" (p. 608). We question and question and question. In what ways do experience and "truth" interact as we take up teaching—and researching the teaching of—mathematics? How does our distance from a particular construction of a number influence how we read that number and its truth? How does bias impact what we doubt and what we believe? In what ways does the mathematics we "know" interact with these biases? What happens when faced with a problem with multiple or conflicting truths? Do ethics drive the solution? Or mathematics? What, or who, wins? By asking these and similar questions and remaining ambiguous in our understanding of how they might be answered, perhaps we can begin to answer Neyland's (2004) call to "re-enchant" mathematics and mathematics education.

"COMPLICANDO ALGO TAN SENCILLO": BRIDGING MATHEMATICAL UNDERSTANDING OF LATINO IMMIGRANT PARENTS

Kiyomi Sánchez-Suzuki Colegrove
Texas State University
kiyomi@txstate.edu

Gladys Krause
The University of Texas at Austin
gladyshrueda@utexas.edu

The purpose of this paper is to demonstrate the mathematical understanding of Latino immigrant parents in curricular and pedagogical practices in elementary school. The paper seeks to counter widely spread deficit discourses about the parental involvement of Latinos in education. Using data from the Agency and Young Children project, a video-cued ethnographic study (Tobin, Wu, & Davidson, 1989; Tobin, Hsueh, Karasawa, 2009; Tobin, Arzubiaga, & Adair, 2013), we highlight aspects from home that schools can use as resources to build a bridge that supports children's mathematical understanding.

Keywords: Curriculum, Elementary School Education, Equity and Diversity, Mathematical Knowledge for Teaching

Introduction

According to Suárez-Orozco (2001), immigrant children lie "in the margins of two cultures" (p.92). As the children, so too their parents find themselves in this borderline situation. This paper presents data collected from 14 focus groups in two different states. We showed parents a video of a typical day in a first grade classroom to stimulate conversation about their thoughts, ideas, and recollections from their own and their children's academic experiences in schools in the United States and in their country of origin. Although they share a variety of topics and experiences, we focus our analysis for this paper on their experiences related to mathematics instruction.

In this paper we argue that there is a real need of bridging communication between school and parents, particularly in mathematics instruction. We share the view that "parents are underused resources as partners in mathematics learning" (Aguirre, Mayfield-Ingram, & Martin, 2013, p.87). More common, unfortunately, is the deficit view that characterizes parents as lacking interest and involvement in their children's academic experience. Therefore, there is a need to strengthen the relationship between parents and schools to counter these debilitating characterizations. Adding to these already worrisome views, a common misconception arises regarding mathematics instruction: that mathematics is a universal language because it is a language of symbols, therefore culture-independent, and hence the ideal subject for ELL students because matters of language should not substantially affect understanding of the content conveyed (Moschkovich, 2007).

This work presents data that challenges deficit views regarding parent interest and involvement in their children's academic preparation. Latino immigrant parents interviewed for this project are attentive to and aware of their children's academic experiences during mathematics instruction. Parents are willing to support their children's mathematical learning at home, and they understand that teachers and schools do not always recognize their efforts. Parents are conscious of the dissonance between the two cultures and how it interferes in the ways in which they can support their children's learning at home. According to parents in this study, mathematics was the subject area in which parents can see the most concrete differences in methodology and symbology between the country of origin and new country.

The data presented will show not only the cultural differences in the mathematics classroom, but also the importance of communication between teacher and parents in order to improve the academic achievement of students. On this basis, we can start to build a bridge that facilitates the exchange of ideas, concerns, and support between the school and home. We propose that the construction of this

bridge start at the school with teachers prepared to recognize and incorporate the cultural variety present in their classrooms.

Our present work answers the following research questions: How could teachers better support and communicate with Latino immigrant parents when teaching mathematics to their children? How can teachers' understanding of immigrant families' mathematical knowledge potentially improve their practice? How can teachers bridge mathematical understanding and academic support at home?

Literature Review and Theoretical Framework

There is an extensive body of research that examines what a teacher needs to know for teaching mathematics in the elementary school. Many of these studies illustrate how mathematical knowledge does not necessarily translate into mathematical instruction designed for students to develop a deep conceptual understanding of mathematics as envisioned in current reform documents by the National Council of Teachers of Mathematics (2000). NCTM (2000) emphasizes contexts for engaging students in learning mathematics, such as problem solving, reasoning and proof, representations, communication, and connections. The underlying idea is that by engaging students in the practice of mathematics, they should develop conceptual understanding and the ability to reason.

Two research-based theories, Constructivism and Sociocultural Theory, illustrate how students learn. The constructivist approach asserts that students come to the classroom with previous knowledge. Students acquire this knowledge outside the classroom based on experiences with the surrounding world. Students "construct" their own learning. The sociocultural approach suggests that the student can also "construct" knowledge, but typically with the assistance of others who are more "knowledgeable" (Vygotsky, 1978, 1986). Still, both approaches see the student as an active agent in the learning process.

These theories hold important implications for immigrant students' opportunities to use in the classroom environment their previous knowledge from outside the classroom, and for what types of support they receive from more knowledgeable peers. Zevenbergen (2000) has documented how the preferences, behaviors, and attitudes of dominant groups rarely fit with those of the marginalized groups. Her work illustrates a disconnection between theory and practice particularly in the contexts of classrooms where different cultures mix. According to Zevenbergen (2000), cultural and social differences strongly influence how individual students construct their identities when learning mathematics. Civil (2005) explains that some difficulties in learning mathematics may derive from a student's particular social or cultural group and how others perceive their mathematical practices, or from the relationships marginalized groups have to dominant groups.

Extending the constructivist and sociocultural approaches for teaching mathematics, our work stresses the need to provide immigrant students with opportunities to bring their culture into the mathematics classroom. Along with Civil (2005) we highlight the importance of immigrant parents as intellectual resources in their children's education. Moreover, we reject the deficit model that frequently points to the home as the root of academic failure (Civil, 2005). In particular: *"In our view, meaningful inclusion and interaction with students necessitate knowledge of their personal, family, and community backgrounds as well as their social realities"* (Aguirre, et al., 2013, p. 9). But given that teachers and parents are aware of these differences, the task remains of creating a productive mode of communication between school and home.

In the context of the United States, immigrant parents are often stereotyped as uncaring and unengaged in their children's education when they do not participate in the traditional activities that traditionally defined appropriate parental involvement, such as volunteering for school, chaperoning for field trips, and PTA membership (Chavkin, 1993; Riojas-Cortez & Flores, 2009). Latino immigrant parents particularly face individual and institutional barriers when trying to participate in their children's educational experiences: for example, individual characteristics such as socioeconomic status, limited English proficiency, and lack of understanding of cultural norms

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

(Arias & Morillo-Campbell, 2008; Lareau, 1987; Nieto, 1985; Rueda, Monzó, & Arzubiaga, 2003). Also parents face institutional barriers that include schools' deficit views of immigrant parents, the under-preparation of teachers to serve culturally and linguistically diverse families, and the different expectations that minority parents and schools hold for children (Arzubiaga, Noguerón & Sullivan, 2009; Graue, 2005; Graue & Brown, 2003; Riojas-Cortez & Flores, 2009; Baum & Swick, 2008; Whitehouse & Colvin, 2001). Individual and institutional challenges interfere in how parents communicate and participate in their children's schooling. Often deficit discourses in school describe immigrant parents not only as unengaged in their involvement at school, but also as incompetent in helping their children with schoolwork at home. However, there is empirical work that highlights the great value Latino immigrant parents place in their children's education (Valdes, 1996; Epstein, 1995). Lopez (2001) suggest the need for schools to broaden their idea of parental involvement and recognize Latino immigrant parents' culture as important resources at school.

The general need to broaden the borders of involvement for Latino immigrant parents in schools naturally includes specific application in mathematics instruction. It is commonplace to hear non-immigrant parents complaining about the "new" ways for teaching mathematics that widely differ from the "old" ways (the way they learned). One can imagine how such dissonance might be magnified for those parents who grew up in different countries and try to make sense of their children's mathematics homework in the effort to help them. Researchers such as Perkins & Flores (2002) and Moschkovich (2007) have documented the differences in symbols, algorithms and methodologies across different countries. In addition to these differences, there is also a cultural difference. As Civil (2005) documented in her study, immigrant parents traditionally have a great sense of respect for the teacher and tend not to "interfere" in what the teacher has established.

In this paper, we use a Funds of Knowledge (Gonzalez, Moll, & Amanti, 2005) framework. Latino immigrant families bring with them knowledge and experiences, or funds of knowledge, that are not always appreciated and therefore not always conducive to helping them understand the U.S. schooling system. However, the work of Gonzalez and colleagues (2005) views the linguistic and cultural practices of minority communities as capital, particularly when teachers recognize those "funds" and are able to bring them into the classroom. In this study, parents are recognized as knowledgeable of their children's education and their funds of knowledge valued as they share their opinions about, expertise in, and concerns regarding the education their children receive in the U.S.

Methodology

Participants

Participants selected were Latino immigrant parents with children enrolled in U.S. schools from Pre-K through 3rd grade. For the study, fourteen focus groups were conducted in Texas and California with 55 Latino immigrant parents from Mexico, Peru, Guatemala, Chile, Venezuela and Honduras. The sites in Texas included 10 focus groups in two urban and one rural area and 4 focus groups in two urban areas in California. We interviewed 50 mothers and 5 fathers, with levels of formal education that ranged from 5th grade to a Master's degree.

Data Collection

The focus groups were conducted in rural and urban cities for purposes of comparison. Focus groups in Texas were conducted on school grounds during and after school hours in central and southern cities and border towns. The California focus groups were conducted in the Bay and East Bay areas in the homes of participants who agreed to host a focus group with friends and acquaintances who met the above criteria.

Focus groups began with a short explanation of the project and a film. The film represents a typical day in a first grade ESL classroom with a large number of Latino immigrant children. The 20-

minute film captures a variety of scenes throughout a school day, with math, reading, writing, small and large group work, centers and recess, to provide parents with a glimpse of what a school day looks like in a first grade public school classroom in Central Texas. Each focus group watched the same film. Focus groups were audio and video recorded for transcription and translation purposes. Parents viewed the film and discussed what they saw. A member of the research team facilitated each conversation guided by a series of pre-established questions. These questions were used with all focus groups and included aspects of pedagogy, curriculum and parental involvement.

Method

The research team transcribed all focus group interactions. We then coded the transcriptions and used content analysis to identify patterns in the codes. We used debriefing (Merriam, 1998) to think deeply about our initial codes and how to categorize them into more defined themes. Throughout this entire qualitative process, we continually reflected on the data collection and analysis (Creswell, 2003; Merriam, 1998; Stake, 1995; Yin, 2003).

Findings

The data we present in this section focus on two major categories that highlight parents' concerns and ideas about mathematics instruction and curriculum, and the support they provide for their children. These findings are further explored below.

Latino Immigrant Parents' Support

During the focus group interviews, we asked the parents about the school and home responsibilities when it comes to learning. Parents expressed as part of their responsibility the need to help and support their teachers' work at home. In the Bay Area, Perla shared how important it is for her that school and home work as a team.

> *Perla:* [Communication is important] at all times, either because of behavior or academics, and to work as a team, that way we can learn about what they do in the classroom and how we can help at home. And to always keep that communication open. [About] things that are important at home and especially during the summer, because it is mostly when... like that commercial, that makes me laugh, where the kid kind of shakes his head and the letters come out of his ear. It seems terrible to me, but at the same time it is so graphic, it is so… very, very well depicted if I can say that. It is all about keeping a routine as much as we can. I mean, you are not going to be sitting with a notebook doing math every day, but we can play with numbers and find games and make them practice some things, and keep reading. To me that is crucial.

It is important to note in this mother's response that she places high value on open communication and teamwork between the school and home. For her it is also important to know not only about her children's behavior but also about their academic progress and needs. The parent also stresses finding out how she can help at home providing learning opportunities that reinforce what her children are learning at school, especially during the summer months.

In El Naranjo Elementary School in a rural border town in Texas, the focus group discussed ways parents support their children's schoolwork at home. Parents frequently mentioned helping their children with homework. In the following transcript they shared some of the strategies they used while helping their children with math work.

> *Kiyomi*: I have a question, because one of the things that teachers generally ask parents is, "How do you help your child at home with the homework assignments?" Have they asked you this question: "How do you help your child?" I don't know, so I'll ask, how you help your child at home with the homework. Do you help with the homework?
>
> *Marcela*: I help him with the homework.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Kiyomi: With the homework too.

Jazmin: I explain to them, like when doing mathematics and let's assume they are adding, maybe adding 9 plus 3, I tell them make little dots, 9, and then make 3 and then count them all together. That way he is learning, or I show him how to use his fingers... I teach them too.

Marcela: That's how I teach them, with the fingers.

Kiyomi: We all teach that way.

Marcela: But it's that it is different because my mathematics is really different from hers. I actually taught her mathematics, in fact. When she started 2nd grade, I taught her how to divide, because... it is not that I want to brag, but she turned out to be very intelligent. I taught her to divide; then she learned how to multiply. Now, at the Valparaíso High School, forget it ma' [referring to her daughter], I have no idea, that didn't come up in my time.

This transcript shows how parents use a variety of pedagogical methods to teach their children mathematics. Jazmin uses drawings and her fingers as tools to support her children's understanding of addition and subtraction. Marcela shares her story about how her child first learned how to divide and then how to multiply. Traditionally in schools, students first learn how to multiply before they are exposed to division problems. However, research on children's mathematical thinking (Empson & Levi, 2011) has shown that children in grades as early as Kindergarten can solve division problems without having any formal instruction in multiplication facts.

Mathematics, Instruction and Curriculum

During the focus group interviews we asked parents if they noticed any aspects of teaching that were different when compared to their own learning at school. In Las Rosas Elementary School while referring to the video, parents shared some aspects of teaching mathematics that were very different compared to their own learning. In the film first graders were asked to pair and represent the number 10 in different ways by combining number cards and then write the number combinations on a piece of paper.

Ricardo: The way they teach mathematics, I mean, it seems… it seems they are making complicated something so simple.

Liliana: Yes.

Olivia: Yes, I was going to say the same thing (laughs).

Kiyomi: Let me understand, explain it to me: what? how? Give me an example.

Ricardo: That for example, for what they were doing in the video, to add 10, how many options do we have?

Parents at Las Rosas have strong ideas about how mathematics should be taught at school. In this particular case parents disagree with what the teacher is asking children to do. This is a good example of how communication between school and home is important so parents can understand how children are learning and the rationale for the learning experiences at school. The idea behind the task is to develop the student understanding of base-10 concepts. Once students see the different ways in which they can construct the number 10 they can extend this idea to other numbers and develop an understanding of arithmetic operations. In mathematics instruction children are encouraged to explore with numbers. Decomposing numbers in such a way is a fundamental activity for their own mathematical understanding (Carpenter, Fenemma, Franke, Levi, & Empson, 2015).

In Las Rosas, parents continued to discuss mathematical instruction and the following transcript shows the difference in mathematical procedures between Olivia and her first grader Javier while helping him to complete his mathematics assignment.

Olivia: You haven't seen the ones with 6 and 7 that Javier gives me, a bunch of numbers. And I'll tell him, "Kiddo, it was only a division problem," because I know, I help him... nothing but a

division problem: 72 fits in there and that's it, these… . "No, kiddo, it looks like I have to do everything. Enough! Do it yourself!"… because really, when it's like that, I don't know how to do it that way.

Kiyomi: Then, the way they are taught mathematics is different.

Olivia: It turns out more complicated, when really it should be much easier.

In this transcript Javier is completing his homework and his mother is helping him. However Olivia expressed frustration as Javier is expected to solve the problem while documenting the process. She does not understand why he needs to add that step, as it complicates the assignment but does not change the outcome. Parents are willing and able to help their children with schoolwork, but have trouble when their own academic experiences do not match school expectations. It would be helpful if they had a better understanding of the rationale for the assignments their children are required to complete.

Discussion and Conclusions

Mathematics is widely thought of as a universal language. Data from the focus group interviews reveal that, while mathematics is the same across contexts of instruction in various countries, the pedagogical methods can differ in important ways. Parents expressed the willingness and desire to help their children with schoolwork and to provide support whenever possible, but they also expressed a lack of understanding of, and frustration with, the rationale behind the schoolwork. Parents' own school experiences do not necessarily match their children's, causing them to feel helpless in supporting their children academically. This counters deficit discourses that usually portray Latino immigrant parents as uncaring and unengaged. Both teachers and school need to improve support of and communication with families by explaining the curriculum or how to access related information. We argue that this communication needs to be open, such that teachers reach out to families to share and explain the pedagogical practices and methods they implement. Teachers must understand that there are cultural and methodological differences whose acknowledgement and inclusion can potentially enrich their teaching of mathematics. These can broaden the cultural understanding of the teacher and the class. Parents, if invited to the schools, can provide that knowledge, so that teachers can learn and better understand the cultural richness and mathematical thinking that parents and their children bring with them.

PARENT WORKSHOPS FOCUSED ON MATHEMATICS KNOWLEDGE FOR PARENTING (MKP): SHIFTING BELIEFS ABOUT LEARNING MATHEMATICS

Heidi Eisenreich
Georgia Southern University
heisenreich@georgiasouthern.edu

Janet Andreasen
University of Central Florida
Janet.Andreasen@ucf.edu

The purpose of this study was to investigate the extent to which parents of first, second, and third grade students who attended a two-day workshop on mathematics strategies shifted beliefs about learning mathematics as compared to parents who did not attend the workshops. Parents impact their children's mathematics learning when the students are at home working on homework. This can be an important barrier to overcome. The results suggested parents could benefit from workshops focused on solving mathematics problems in multiple ways, similar to ways their children are learning mathematics.

Keywords: Affect, Emotions, Beliefs, and Attitudes, Classroom Discourse, Elementary School Education, Number Concepts and Operations

Introduction

Social media outlets indicate parents are frustrated with the way their children are learning mathematics, such as using multiple solution strategies to solve problems that seem to include unnecessary steps (Garland, 2014; Richards, 2014). This is important because when the children are at home, their parents often take on the role of teacher. Parents want to help their children with homework, but their own personal experiences with learning mathematics were likely procedural (Garland, 2014; Richards, 2014). The purpose of this study was to determine if completing a two-session workshop on mathematics pedagogy and content related to whole number concepts and operations shifted parents' beliefs about learning mathematics. Beliefs were measured by the abbreviated Mathematics Beliefs Scales (aMBS), created by Fennema, Carpenter, and Loef (1990) and later adapted by Capraro (2005). More specifically, the goal was to answer the following question: *To what extent do parents who attend a mathematics workshop on whole number concepts and operations differ, on average and over time, in their beliefs about learning mathematics as compared to parents who do not attend?*

Background

When an elementary-aged child asks his or her parent for help on homework, the parent thinks they should be able to help their child, but then they realize mathematics is being taught differently today than when they were in school (Richards, 2014). Some parents do not understand the justification behind why these new strategies are being used, and think they are a waste of time. Teachers have opportunities to gain a deeper understanding of the mathematics they are to teach through education classes or professional development, but parents may not have the same opportunities. By creating workshops that allow parents to work through the strategies their children use, this study investigated how those workshops influenced parents' beliefs about how students should learn mathematics. After all, parents are their children's teacher when the children are at home. Previous research findings from qualitative studies suggest that parents who participated in parent workshops felt like they (a) increased their content knowledge and improved their attitude towards mathematics (Knapp, Jefferson, & Landers, 2013), and (b) improved relationships between parents and their child (Kreinberg, 1989; Mistretta, 2013) and between parents and the school (Kreinberg, 1989). Although parents may not be confident when helping their child with mathematics homework before participating in the workshops, after participating in workshops parents were more

confident with their mathematics ability when helping their child (Cotton, 2014; Kreinberg, 1989; Marshall & Swan, 2010).

The researcher proposes a connection between parents and preservice teachers (PSTs) due to the lack of quantitative research regarding shifts in beliefs and learning about mathematics by parents. The way PSTs think in terms of solving mathematics problems could be tangentially related to the way parents think about solving mathematics problems before participating in workshops. PSTs come to their education courses with experiences in learning mathematics procedurally, similar to parents. Having a productive disposition in mathematics includes being able to see mathematics as useful and worthwhile. Opportunities to help learners make sense of mathematics may influence their beliefs, especially when the beliefs are called into question. This shift is important because "changes in beliefs are assumed to reflect development" (Oliveria & Hannula, 2008, p. 14). Teachers can do this by solving problems in ways that call existing beliefs into question or by making mathematical discoveries on their own (Liljedahl, Rolka, & Rosken, 2007). Changing teachers' beliefs about mathematics can be difficult, however, because many preservice teachers think mathematics is about memorizing formulas and procedures (Szydlik, Szydlik, & Benson, 2003).

A person's beliefs evolve over time, and are influenced by his or her experiences (Op't Eynde, DeCorte, & Verschaffel, 2002). Richardson (2003) implied there were three different experiences that influenced beliefs: personal experiences, experiences in an instructional situation, and experiences with specific content knowledge. These beliefs shape how a person views different situations, one being the way children learn about mathematics (Richardson, 2003). Most parents of elementary grade students were taught mathematics in more teacher-centered classrooms, where the teacher was the one who determined whether or not the student had the correct answer (Garland, 2014; Richards, 2014). When most of these parents were elementary students they were not encouraged to work with their peers to find more than one solution strategy, but according to "best practice," classrooms today are more student-centered, where the teacher acts as a facilitator and the focus of instruction is on making sense of problems and solutions with lesser emphasis on judging correct answers (Ertmer & Newby, 2013).

Research Design

The current study used a quantitative, quasi-experimental, non-equivalent control group design. The research design was chosen because participants self-selected either the control or intervention groups. The control group included participants who were unable to attend the workshop, but still participated in testing. For both the control and intervention groups, all interactions were conducted face-to-face at the same school site. The school site allowed the researcher to set up a table during school hours to meet with participants in the control group. The control group attended two face-to-face meetings during a time convenient for them. During the first meeting participants completed pretests, and during the second meeting they completed posttests. The majority of control group participants completed pretests and posttests within a two-week period, similar to the time between pretest and posttest for the treatment group.

Parents or guardians of 1st, 2nd, and 3rd grade students at multiple neighboring public elementary schools in Central Florida were invited to participate. For the purpose of this research, "parents" will include any person who takes on that role. First, second, and third grades were chosen because this is when mathematics homework first represents strategies that are likely different from instruction most parents received when they were in elementary school (Garland, 2014; Richards, 2014). The sample was one of convenience, given the location of the participating schools was near the researcher's residence, and parents volunteered to participate.

The abbreviated Mathematics Beliefs Scales (aMBS) (Capraro, 2005), was used to measure parents' beliefs about learning mathematics. The aMBS, originally created by Fennema, Carpenter, and Loef (1990), was developed to measure the mathematical beliefs of teachers. Responses to

questions were measured using a five point Likert scale, ranging from strongly agree to strongly disagree. The original aMBS had 48 items, and because researchers commented that participants complained about the length and repetitiveness of the instrument, an exploratory factor analysis was run on all 48 items (Capraro, 2001). The 18 questions that were chosen because of the analysis explained 46% of the variance and could be split into three factors with six items in each. The three factors were student learning, stages of learning, and teacher practices. One sample question in the student learning subscale is, "Children will not understand an operation (addition, subtraction, multiplication, or division) until they have mastered some of the relevant number facts" (Capraro, 2005, p. 86). One sample question in the stages of learning subscale is, "Children should understand computational procedures before they master them" (Capraro, 2005, p. 86). One sample question in the teacher practices subscale is, "Teachers should allow children to figure out their own ways to solve simple word problems" (Capraro, 2005, p. 87).

The treatment group participated in two workshop sessions created to help parents engage in learning mathematics in ways similar to their children, according to "best practice" such as encouraging students to come up with multiple strategies that would allow them to think flexibly about mathematics. The workshop was repeated a total of three times to allow for flexibility to allow more parents to participate. Each workshop was held for two hours, including the time spent on pretests and posttests, so participants in the treatment group were engaged in learning mathematics content for approximately 2.5 hours, as the other 1.5 hours were used for administrating tests. Pretest for the treatment group was administered at the beginning of the first day of the session, and posttests were administered at the end of the second day.

Following the pretest, participants were asked to solve the following problem, "*Andrea has 14 cookies. Jamie gave her some more. Now Andrea has 32 cookies. How many cookies did Jamie give Andrea?"* Participants were encouraged to use two different methods to solve this problem. Solving the problem using a second strategy was a difficult task initially. All participants solved by subtracting 14 from 32 using the standard algorithm and did not know how to solve using a second strategy. Through questioning techniques participants engaged in using drawings, concrete tools, and other computational strategies to solve problems. Participants made sense of base ten blocks, ten frames, the hundred chart, and an open number line. Then, participants were given another problem. After participants tried to solve a problem on their own using at least two different strategies, they shared their strategies with a partner, and tried to made sense of the different strategies. Participants used the tool that made the most sense to them, and, after sharing with a partner, they had a better understanding of other strategies. The researcher chose the order in which participants shared their strategies from more concrete to more abstract, to help them make connections between the different strategies. Then, possible student errors were discussed, first with a partner then with the whole group. The first error, which involved regrouping, was difficult for participants to communicate where the student made their mistake. They knew the answer was incorrect, but were unable to explain why. Through questioning techniques, participants were able to make sense of why the answer was incorrect. The goal was to encourage participants to "think outside the box" when supporting their children at home.

During the second workshop session, participants were given multiplication and division problems and asked to solve them in two different ways. For example, participants solved the multiplication problem "*Amy has 4 boxes. Each box has 7 bags of chips. How many bags of chips does Amy have?"* First, a participant shared a strategy that involved using repeated addition. The participant drew four boxes and put the number 7 in each one. Then the participant wrote $7 + 7 = 14$, $14 + 7 = 21$, and then $21 + 7 = 28$. Another participant wrote 7, 14, 21, 28 and we had a discussion on the similarities and differences between the two strategies. Later strategies included finding doubles. For example, one participant wrote $7 + 7 = 14$, $14 + 14 = 28$. Participants made a connection between this strategy and the first two strategies, repeated addition and skip counting. Because participants

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

had worked through several solution strategies in the previous workshop, they were able to construct new strategies much easier than when they began the first session. Participants were comfortable sharing with their partner, and then sharing with the group when asked by the researcher. If a tool was not brought up, the researcher would ask a question like, "how could we use ten frames to help us solve the problem?" Through discussion, participants made sense of using an open number line, ten frames, an array, and an area model, in addition to other number strategies. The researcher helped participants to make connections between multiplication and division problems through questioning techniques. In addition, participants made connections between division and addition as well as division and subtraction. By allowing participants to share strategies and make sense of other strategies, they were engaged in the discussion. Finally, participants were given example solutions to determine student errors while using the standard algorithm for multiplication and long division. After the group discussion, participants were given the posttest.

Findings

Participants in this study had students who attended one of four neighboring public elementary schools, all with similar school demographics. The majority of participants had children who attended the school site where the workshops were held, with the second largest population of from the school approximately one mile away from the school site. The breakdown of the number of participants in each of the three treatment groups and the control group is listed in Table 1.

Table 1: Participant Information (Frequencies and Percentages)

		Total
Workshop (42%)	Series 1	6 (21%)
	Series 2	4 (14%)
	Series 3	2 (7%)
Non-Workshop (58%)		17 (58%)

Demographic information was obtained from the 29 parent participants, and the researcher discovered the majority of participants: identified as being "white ($n=22$), were in the 36-45 age range ($n=22$), were either married or in a domestic partnership ($n=24$), earned at least a bachelor's degree ($n=24$), were working full time ($n=21$), and never had a teaching related position ($n=27$). All participants said their child brought home mathematics homework, and some said they helped their child everyday ($n=10$), while others said they never helped their child ($n=5$). The rest of the participants were split on all other options ranging from one to four times per week.

The purpose of this study was to determine the extent to which parents or guardians who attended a workshop on mathematics strategies differed on average and over time with parents who did not attend the workshop regarding beliefs. When statistical significance was found on the aMBS, additional analyses were run on the three different factors to determine which factors had a statistically significant difference.

A two-factor split-plot (one within-subjects factor and one between subjects factor) ANOVA was conducted. The within-subjects factor was time (pretest or posttest) and the between-subjects factor was group (treatment or control). Assumptions of baseline equivalency, homogeneity of variance, independence, normality, and sphericity were tested, and were met for everything except normality and sphericity. The violation of the assumption of normality suggested the increased likelihood of a Type II error, however the ANOVA is a robust test. The assumption of sphericity was violated for each separate test so statistics from the Greenhouse-Geisser conservative F test were reported when analyzing statistical results. Additionally, effect sizes according to Cohen's values (1988), for small (.01), moderate (.06), and large (.14) effect sizes will be reported.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

There was a large effect size (.201) and sufficient power (.708) for the interaction for the between-within factor for the entire aMBS. Additionally, there was a statistically significant within-between subjects interaction effect between group and time ($F = 6.771$, $df = 1, 27$, $p = .015$). ($M_{pre\,x\,control} = 54.41$, $SD = 10.186$; $M_{pre\,x\,treatment} = 50.33$, $SD = 6.401$; $M_{post\,x\,control} = 53.41$, $SD = 10.278$; $M_{post\,x\,treatment} = 56$, $SD = 7.604$). This statistically significant result suggested that there were differences, on average, between treatment and control group over time regarding beliefs reported from the entire aMBS.

Then the aMBS was split into the three factors identified by Capraro (2001), student learning (factor 1), stages of learning (factor 2), and teacher practices (factor 3). While there was a non-statistically significant result for factors 1 and 2, there was a statistically significant within-between subject interaction between group and time ($F = 7.48$, $df = 1, 27$, $p = .011$). ($M_{pre\,x\,control} = 21.71$, $SD = 4.18$; $M_{pre\,x\,treatment} = 20.50$, $SD = 3.12$; $M_{post\,x\,control} = 20.47$, $SD = 4.24$; $M_{post\,x\,treatment} = 23.25$, $SD = 3.33$) for factor 3. Additionally, there was a large effect size (.217) and sufficient power (.751) for the interaction for the between-within factor for aMBS-factor 3. This statistically significant result suggested that there were mean differences, on average between groups over time regarding beliefs about teacher practices. Results are displayed in Table 2 and Table 3.

Table 2: Greenhouse-Geisser Results for Statistically Significant Beliefs

Variable	Source	df_1	df_2	F	p	Partial η^2	Power
aMBS	Time * Group	1	27	6.771	.015	.201	.708
aMBS –F3	Time * Group	1	27	7.48	.011	.217	.751

Table 3: Mean and Standard Deviations for Pretest vs. Posttest Split by Group

	Pre			Post		
	Total	Treatment	Control	Total	Treatment	Control

Conclusions

Results were statistically significant between groups and over time with a large effect size. The treatment group changed their beliefs to ones that were more focused on students constructing their own knowledge. Additionally, there was no statistically significant difference between groups over time for factor 1 (student learning) and factor 2 (stages of learning), but there was a statistically significant change between groups over time for factor 3 (teacher practices) with a large effect size. Parents in the treatment group had beliefs that leaned more towards students learning about mathematics in a learner-centered environment after completing the workshops. Parents in the control group did not shift their beliefs from the pretest to the posttest. This indicates that the workshops may have shifted parents' beliefs about student learning to beliefs that students should learn in a learner-centered environment.

These statistically significant results indicate that parents may have shifted beliefs about student learning through participation in workshops. This supports previous findings related to preservice and inservice teachers (ISTs) that suggest belief change could occur through participation in an instructional situation (Liljedahl, Rolka, & Rosken, 2007; Richardson, 2003). This significance could be explained because parents were participating as learners in a student-centered environment, which was different from the direct instruction they may have experienced as young learners (Garland, 2014; Richards, 2014). Through participation in the workshops, which were learner focused, parents may have understood the importance of allowing *their* child to learn mathematics in a student-

centered environment instead of one focused on the parent guiding their child to the answer. Previous research indicates beliefs are influenced by a person's experiences (Op't Eynde, DeCorte, & Verschaffel, 2002).

One limitation of this research was that participants completed a belief instrument where their beliefs were self-reported. Researchers have found that teachers need to be observed multiple times to determine their underlying beliefs, which can be different from their self-reported beliefs (Cross & Hong, 2012; Leatham, 2006). Due to the similarities of teachers and parents regarding helping a student with a mathematical task, this may be true for parents as well. Because the parents were asked to complete the instrument, their underlying beliefs may not have been apparent. Additionally, instrumentation validity may be a threat because while there was some evidence supporting the reliability and validity of the aMBS (Capraro, 2005), this instrument was not tested on parents and the small sample size in the current study did not support testing statistical validity and reliability evidence for the scores from the instrument. The parents in the study did not represent a random sample because they were selected based on convenience and self-selection, which may have introduced self-selection bias. The lack of random selection from the population limits the generalizability of the study findings. Additional workshops will need to be conducted and data will need to be collected and analyzed in different parts of the country to be able to generalize these findings.

Future research could be conducted in undergraduate and graduate programs. If PSTs and ISTs are involved in this type of research, they might have a better understanding of why it is important to get parents involved in this manner. This could, in turn, help PSTs and ISTs determine common errors students might bring to whole class discussions, and why those errors arise by allowing parents to share solution strategies. Parents may be the biggest supporter for a teacher when working with their child on homework, but parents need the tools that will be most helpful.

Although the duration of the workshops was short, parents who participated in the workshops indicated a shift in their beliefs about learning mathematics to a more learner-centered environment. These statistically significant findings indicated that workshops for parents were beneficial. By giving parents the opportunity to engage in mathematics in ways similar to the way their children learn in the classroom, beliefs about mathematics were challenged. Prior to the workshops, and according to the belief instrument that parents completed, parents' beliefs leaned more towards working *with* their child on homework instead of allowing their child to come up with their own strategies. The findings in this research study suggest more research on parent workshops is crucial.

THE SECOND DERIVATIVE TEST: A CASE STUDY OF INSTRUCTOR GESTURE USE

Nicole Engelke Infante
West Virginia University
nminfante@mail.wvu.edu

We present a case study of how five instructors used gesture when introducing the second derivative test in a first semester calculus class. The second derivative test and optimization naturally evoke hand motions while teaching, making this a fertile ground for studying gesture use in the classroom. Each of the five instructors used a classic optimization problem as a primary example of how one would use the second derivative test to verify that a found value would be a maximum or minimum. We observed the instructors making connections between the algebraic, numerical, and graphical representations of this concept through gesture. The quantity and types of gesture varied greatly by instructor, but there were two key links that every instructor made.

Keywords: Instructional Activities and Practices, Classroom Discourse, Post-Secondary Education

Introduction

There is a large body of work in cognitive science focused on embodied cognition; our knowledge is shaped by our experiences and interactions with the world around us (Lakoff & Nunez, 2000; Nemirovsky & Ferrara, 2009; Nemirovsky, Tierney, & Wright, 1998). Through bodily experiences, such as gesture, our understanding of complex concepts is shaped. As calculus can be considered the study of motion, it is a natural place to examine gesture. There are several problems that require students to visualize/imagine situations involving rate(s) of change – related rates and optimization are two examples. Diagrams and graphs are means of visualization that may facilitate the understanding of many concepts and problems in calculus. While a student may read an example in the textbook and model a solution based on this text, an example presented in class provides the learner an additional modality for learning: the instructor's gestures. An instructor's gestures can give life to a static diagram or a point on a graph. There is a growing body of research that suggests that an instructor's use of gesture can have a positive impact on student learning (Alibali & Nathan, 2007; Hostetter & Alibali, 2010).

Gesture use has recently become the focus of many educational studies. While the literature related to gestures made in undergraduate mathematics classroom is limited (Marrongelle, 2007; Rasmussen, Stephan, & Allen, 2004; Wittmann, Flood, & Black, 2013; Yoon, Thomas, & Dreyfus, 2011), there is a plethora of studies examining gesture in K-12 classrooms (Alibali & Kita, 2010; Arzarello, Paoloa, Robutti, & Sabena, 2009; Cook, Duffy, & Fenn, 2013; Cook, Mitchell, & Goldin-Meadow, 2008; Edwards, 2009; Goldin-Meadow, Kim, & Singer, 1999; Maschietto & Bussi, 2009; Nemirovsky et al., 1998; Roth & Thom, 2009). Goldin-Meadow (2000) stated, "[a] task for the future is to determine how gesture can best be harnessed to improve communication in classrooms" (p. 235) and Roth and Lawless (2002) noted, "little is known about the role of gesture in learning and instruction" (p. 285).

Gesture use in the calculus classroom has not been extensively studied. We seek to address this gap in the literature by examining how instructors use gesture in natural teaching environments. In this paper, we address the questions: What examples does an instructor use to communicate mathematical ideas and concepts? While working through the chosen examples, what key ideas are linked? What gestures does the instructor make while making links for students? This study examines the answers to these questions at one point in time – when the instructor introduces the second derivative test.

Theoretical Perspective

Mathematics instructors often make connections between ideas and concepts. In this research, we focus on what Alibali et al. (2014) defined as a linking episode: segments of discourse in which teachers connect ideas. Note that a linking episode may contain several distinct links. For example, we observed instructors making two distinct links in a single linking episode. We examined the linking episodes that occurred naturally during calculus instruction and the extent to which instructors used varying modalities, particularly gesture, to express links between ideas.

Gestures are a natural part of communication and may convey additional information to the listener to foster comprehension. Yoon et al. (2011, pp. 891-892) indicate "gestures are a useful, generative, but potentially undertapped resource for leveraging new insights in advanced levels of mathematics" (p. 891-892). They further advise that instructors should model gestures for students in lecture. Hence, we want to observe how instructors use gesture to highlight the ideas that they are connecting during a linking episode.

Methods

A qualitative case study methodology (Cohen, Manion, & Morrison, 2011) was used to examine how five instructors used gesture during natural classroom activities that involved the second derivative test. Each lesson in which the second derivative test was introduced was transcribed and broken down into linking episodes as described by Alibali et al. (2014). These linking episodes were then analyzed to determine how many and what types of gesture were used in conjunction with the links being made. Links were coded as multi-modal if they were made using some combination of speech, writing, and gesture, and were coded as uni-modal if they were made in speech alone. In the transcription, speech made in conjunction with gesture are in bracketed pairs: [speech uttered][gesture description].

For this study, gestures were coded according to the static and dynamic categorizations defined by Garcia and Engelke Infante (2012, 2013) and the pointing and writing gestures defined by Alibali et al (2014). Engelke Infante and Garcia examined how students use gesture when solving related rates and optimization problems in first semester calculus and identified two broad categories of gesture use: dynamic and static (Garcia & Engelke Infante, 2012, 2013). Dynamic gestures consist of moving the hands to describe action that occurs in the problem or movements made to represent mathematical concepts. Within dynamic gestures two subcategories were identified: dynamic gestures related to the problem (DRP) and gestures that are not related to the problem (DNRP). We added a third subcategory to dynamic gestures, Dynamic Algebraic. Dynamic Algebraic (DA) gestures are made to indicate how we manipulate quantities in an equation. For example, we often speak of "moving x to the other side" and make an under/over swooping motion with a hand.

Static gestures are made to illustrate a fixed value (length, radius, volume, etc.) or to illustrate properties of a geometric object. Note that while the term static is used, that does not necessarily mean that there is no motion involved. Again, the category of static gestures was further sub-categorized into static gestures related to a fixed value (SFV) and gestures related to the shape of a graph (SSG). SFV and SSG are both primarily types of iconic gestures but may also be metaphoric. Garcia and Engelke Infante (2012, 2013) observed static gestures primarily being used to facilitate diagram construction.

As defined by Alibali et al. (2014), pointing gestures are those used to index objects, locations, and inscriptions in the physical world. Writing gestures are those in which writing or drawing is integrated with speech in a way in which a writing instrument is used to indicate content of the accompanying speech (such as drawing a circle around a term in an equation while stating 'this term'). We further categorized points as either static points (SP-pointing to one static object on the board, such as a point on a graph), tracing points (TP-using a finger, hand or other body part to trace the shape of an object on the board, such as a finger tracing along a tangent line), or generic points

(GP-points directing attention to something that was done before, but not a 'look at this particular thing' type of point).

Results

Here we examine how the five instructors introduced the second derivative test. In each case, the second derivative test was introduced in conjunction with the solution to an optimization problem. All of the instructors used a similar example problem to illustrate the second derivative test – construct a fence that maximizes area for a given perimeter (Instructors A, B, and C) or construct a fence of minimum perimeter for a fixed area (Instructors D and E). Instructors A, B and C introduced the second derivative test on the first day of instruction on optimization while the other two instructors introduced the second derivative test on the second day of instruction on optimization.

We observed that there were two key links made by every instructor. First, every instructor made explicit the link between the sign of the second derivative and the concavity. Second, every instructor made a link between the concavity (shape of the graph) and the optimizing function having a maximum or minimum value. Often, these two links occurred in succession as a single linking episode (see rows two and three of the table). Table 1 summarizes how these key links were made by each instructor and indicates whether the link was accompanied by gesture. Observe that Instructors A, B, and C made all of their links multi-modally while Instructors D and E made about half of their links multi-modally.

Table 1: Links made by calculus instructors while explaining the second derivative test

Linking Episode	Representations Linked*	A	B	C	D	E
f'' – concavity	A-G	1+ (SP - SSG)				
f'' negative – CCD – max	A-G-N	2+ (SSG-SP)	2+ (SSG-WG-SFV)	2+ (SFV-WG-RP)	1+ (GP)	
f'' positive – CCU – min	A-G-N	1+ (SSG-SP)			1+ (SP)	1+ (SP)
CCD – max	G-N	1+ (TP-SP)	1+ (SFV-TP)			
CCU – min	G-N	1+ (TP-SP)		1+ (SSG-SFV)		1
$f' = 0, f'' > 0$ – min	G-N				1	
$f' = 0, f'' < 0$ – max	G-N				1	

*A = algebraic, G = graphical, N = numerical, + = (gestures used); SP=static point, SSG=static shape of graph, SFV=static fixed value, TP = tracing point, WG = writing

In the interest of space, we will examine the differences in how Instructors A, B and C used gesture to highlight key information in their linking episodes. Instructor A presented the second derivative test before starting her example (about 3 minutes), and then reiterated it during her example problem (about 2 minutes). Instructors B and C both explained the second derivative test completely within the context of the example and used 2-3 minutes of class time.

Instructor A

During Instructor A's brief overview of the second derivative test, she drew a generic graph with a maximum and minimum value. As she pointed to the maximum value on her graph, she stated "we know we have [a maximum] [SP]," and then she pointed to the minimum on her graph [on the far right in Figure 1] and stated "we know we have [a minimum] [SP], but we don't know this starting

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

out." She reviewed what a critical value was and asked the students "what does the second derivative tell us?" The students responded, "concavity." She proceeded to make a static point to the maximum on the graph and asked "[what's the concavity right here?] [SFV-graph on far right of Figure 1]" while making a circular motion with her hand around the maximum on the graph. This led to the conclusion that a concave down graph would have a maximum which was pointed to again. Similarly, the class arrived at the idea that a concave up graph would have a minimum. It was then indicated that they would dig into this idea in the next example. Here, we observe Instructor A making explicit the second key link between the concavity of the graph and the existence of a maximum (or minimum) and that she highlights these features on the graph with static gestures.
Figure 1. Instructor A's overview of the second derivative test.

The first example of an optimization problem presented to the class immediately following the discussion of the second derivative test was a problem involving a farmer who wishes to maximize a rectangular area along a river with a given amount of fence. Upon getting to the point in the problem where the maximum needs to be verified, the instructor discussed what the domain of the problem was and in doing so, made several tracing point gestures in reference to her diagram. She then stated, "We could use either the first or second derivative test, but since we haven't seen the second derivative test in action, let's do that." She continued, "So, second derivative, I'm going to look [at] [SP -to the first derivative function] the first derivative, right? So, the derivative of fifteen hundred is nothing and that's negative 4 (writes equation for second derivative on the board)." Her next statement included the first hand gestures relating the shape of the graph and the second derivative test. She stated:

A: So, I have either [a peak][SSG-made a small, cupped hand gesture mimicking the shape of a concave down graph] or [a valley][SSG-made a small, upward swooping hand gesture mimicking the shape of a concave up graph] because the derivative is zero. What does the [second derivative negative mean?][SP-to second derivative function] Concave up or concave down? [Down,] [WG-draws downward parabola shape] so it looks like that. Does that give you a max or min?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Here, we observe Instructor A making explicit both key links with gesture (primarily pointing gestures) in a single linking episode.

Instructor C

The first example of how to solve an optimization problem presented by Instructor C involved finding the dimensions of the largest possible rectangular shaped vegetable garden with a fixed perimeter. As he neared the end of the problem, he introduced the second derivative test. He verbally explained that they computed the value for the second derivative and found it to be negative. At this point, he exclaims, "The second derivative is [ne-ga-tive] [SRF-arms up and out and pointing down with fingers] What does that mean the function is doing? Second derivative. Concave? [Down!] [SRF-points arm and finger down]." Hence, he has made explicit the first key link between the sign of the second derivative and the shape of the graph (concave down).

Next, Instructor C indicated, "When x is 40, the graph is concave down. If you draw just anything that's [concave down] [WG-draws concave down graph on board and makes point at local max] is the point a [maximum point?] [SP-points at the point made on graph]." Here, he made explicit the second key link between the concave down shape of the graph and the function having a maximum value.
Figure 2. Instructor C's gestures to illustrate the second derivative test.

Instructor C then moved to the center of the classroom and exclaimed, "Watch! Watch! Watch!" and made sure that all eyes were on him before he proceeded to summarize the second derivative test with a sequence of large gestures (Figure 2). He demonstrated that a concave down graph would have a maximum value (blue arching motion above the red line) while a concave up graph (blue arching motion below the red line) must have a minimum value. He related each of these ideas back to the idea of a horizontal tangent line (which he indicated with the horizontal red line motion). This was the only instance we observed where the gestures were made as a deliberate part of the lesson.

Instructor B

Here we focus on the distinctly different way in which Instructor B makes the second key link between the concavity and the optimizing function having a maximum. She began by drawing a concave down graph on the board and making a small, one-handed concave down motion like Instructor C, asking whether there would be a maximum or minimum. She then proceeded to point to the maximum on the graph while stating that it was the maximum of the graph (Figure 3a). She took one step to the side of the graph and reiterated that a concave down graph could have a maximum while making the small, one-handed gesture again. Next, she took another step to the side and made a very large two-handed gesture while stating that since it was concave down everywhere, the value would have to be an absolute maximum (Figure 3b) followed by stepping back to her graph on the board and pointing to the maximum again.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 3a. Pointing to the maximum on a concave down graph.
Figure 3b. Large, two-handed gesture for a concave down graph.

While making the second key link, Instructor B was very animated in her use of gesture to make sure students made the connection between the graph being concave down and the function having a maximum value. In fact, during this one linking episode she made the link three times, each of which was multi-modal. Instructor B used a combination of points at the board with large gestures in the space in front her.

Similar to the linking episodes observed by Alibali and colleagues in middle school teachers (Alibali et al., 2014), these instructors were linking several mathematical ideas for their students. Each instructor linked ideas about the second derivative function, the concavity/shapes of graphs, and maximum/minimum values during their lessons. Hence, we conclude that any linking episode about the second derivative test should include the link between the sign of the second derivative and the concavity and the link between the concavity (shape of the graph) and the optimizing function having a maximum or minimum value. However, from Table 1, we know that the manner in which these links are made can vary greatly. Indeed, Instructor D, summarized these key links uni-modally (in speech alone) by saying: "The first derivative test tells us that if f prime is equal to zero and f double prime is positive, we have to have a local min. If f double prime, if f prime is zero, f double prime is negative, we have to have a local max. If they're both equal to zero, we don't know." Note that these verbal statements fail to capture the link between concavity (shape of the graph) and the existence of a max/min.

Conclusion

While each of the instructors used a similar example problem to introduce the second derivative test, there was significant variation in the linking episodes used to convey the key ideas of the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

concept. As other studies have indicated, we observed that instructors frequently used gesture when referring to a graph or diagram to illuminate key features of the object. These findings support theories about connections between diagrams and gesture presented by de Freitas and Sinclair (2011).

As observed by (Alibali et al., 2014), instructors were often making links between the various representations of the concept. Four of the five instructors used a gesture that was depictive of a concave down (up) graph while emphasizing with words that a concave down graph would have a maximum (minimum) value. Some instructors went beyond this, as Instructor B did, and pointed at least once to the maximum on the graph that she had drawn.

Not all instructors used the same quantity or distribution of gestures. However, quantity is not the only measure of gestures usefulness. An appropriately timed gesture of a particular type may be equally important. For example, Instructor C made certain that his students would be paying attention to at least one sequence of gestures he made. Future research will employ a design experiment in which we will examine the impact of particular gestures used during instruction on student learning. We will assess students' learning based on whether they learned from an instructor who deliberately incorporated particular gestures or an instructor who did not purposefully incorporate gesture into the lesson. In time, we expect to create an online catalogue of lessons to showcase how the deliberate incorporation of gestures can enable instructors to foster greater understanding of calculus concepts in their students.

TEACHERS' INSTRUCTIONAL PRACTICES WITHIN A CONNECTED CLASSROOM TECHNOLOGY ENVIRONMENT TO SUPPORT REPRESENTATIONAL FLUENCY

Yasemin Gunpinar
St. Catherine University
ygunpinar@stkate.edu

Stephen J. Pape
Johns Hopkins University
stephen.pape@jhu.edu

The purpose of this study was to examine the ways that teachers use Connected Classroom Technology (CCT) to potentially support achievement on translation problems that require moving between algebraic representations. Four mathematics classrooms were chosen based on their gain scores on pre- and post-test Algebraic translation problems. Two classrooms with the highest and the lowest gain scores were chosen among the classrooms with pre-test scores that were below 50%. This study used video-recorded observational data and found that teachers in effective classrooms created environments wherein students used multiple representations simultaneously and translated between representations through discussion. In contrast, teachers in less effective classrooms fostered environments wherein students used representations independently and missed opportunities to translate representations through discussion.

Keywords: Instructional Activities and Practices, Technology

Representational fluency is a cognitive competence that includes being able to interpret and construct representations as well as translate flexibly between them (Sandoval, Bell, Coleman, Enyedy, & Suthers, 2000). It is considered both a mechanism for supporting the development of deep conceptual understanding (Duncan, 2010; Pape & Tchoshanov, 2001) and a means of assessing conceptual understanding (Suh, Johnston, Jamieson, & Mills, 2008).

Representational fluency not only supports conceptual understanding but is also an essential component for problem solving (Nistal, Van Dooren, Clarebout, Elen, & Verschaffel, 2009). Students are more successful when they possess the ability to translate between representations as well as use multiple and non-symbolic representations (Brenner et al., 1997; Nathan & Kim, 2007). The education community continues to emphasize the importance and need for developing representational fluency (National Governors Association Center for Best Practices, Council of Chief State School Officers [CCSSO], 2010). However, students leave school without attaining representational fluency (Ainsworth, Bibby, & Wood, 2002; Herman, 2007; Knuth, 2000).

There are at least two factors that potentially support the development of representational fluency: communication and technology. Through communication, representational fluency may be supported by active engagement in discussions about interpretation, construction, evaluation, comparison, and generalization of representations (Warner, Schorr, & Davis, 2009). The development of representational fluency may be supported by allowing for quick access to multiple representations (e.g., symbolic, tabular, and graphical) through technology (Bieda & Nathan, 2009). Because evidence suggests that communication and technology may separately support students' developing representational fluency, the present study investigated instruction that is characterized by the use of Connected Classroom Technology (CCT) with the aim of examining the relationship between these instructional strategies and increasing such fluency.

Connected Classroom Technology

CCT are wireless communication systems that connect the teacher's computer and students' handheld technology (Pape et al., 2013, p. 169). These systems are designed to provide greater opportunities to discuss connections among multiple representations. Recent studies emphasize a sociocultural perspective that focuses on the relationship between learning opportunities and students' abilities to take advantage of these opportunities during learning (Gee, 2008). CCT

provides at least two learning opportunities that support the development of students' representational fluency. These opportunities include "the mobility of multiple representations of mathematical objects" and "the ability to flexibly collect, manipulate and display to the whole classroom representationally-rich student constructions, and to broadcast mathematical objects to the class" (Hegedus & Moreno-Armella, 2009, p. 403). Jim Kaput once postulated, "wireless connectivity 'inside' the classroom would change the communicative heart of the mathematics classroom" (Hegedus & Penuel, 2008, p. 171). CCT's progression has potential to enact this transformation.

The Texas Instruments (TI) Navigator system includes two components to support representational fluency: Screen Capture and Activity Center. With Screen Capture, teachers can project a "snapshot" of students' calculators. This feature allows both teachers and students to compare the representations through productive discussion. With Activity Center, the teacher can project a coordinate plane on which students submit points, equations, and graphs. Another affordance is that it promotes examination and analysis of patterns as well as justification of mathematical generalizations (Hegedus & Moreno-Armella, 2009).

These components provide a context for effective classroom discourse because they are designed to publicly display multiple linked representations. The public display of students' mathematical constructions in conjunction with the communication of ideas and strategies fosters representational expressivity (Hegedus & Moreno-Armella, 2009). Also, the activities in the activity center with multiple representations may support translation between representations (Bostic & Pape, 2010), which are distinguishing characteristics of mathematical proficiency (CCSSO, 2010; Kilpatrick, Swafford, & Findell, 2001). Although teachers have found CCT to be an efficient means of instruction, there is little evidence that demonstrates or evaluates its effectiveness in relation to supporting representational fluency (Vahey, Tatar, & Roschelle, 2007).

Method

Teachers who participated in classroom observations during the third year of a four-year project were chosen for the present study. Forty of the 41 teachers' classroom observations served as the initial pool of observations with one being eliminated due to poor audio quality. Data sources consisted of classroom videos (typically two class periods), their verbatim transcripts, and algebra pre- and post-test. The length of each observation was between 48 and 97 minutes. To measure representational fluency, translation problems were extracted from the pre- and post-tests. Translation problems are those in which the initial representation (i.e., input) and the answer's representation (i.e., output) are different (Nathan, Stephens, Masarik, Alibali, & Koedinger, 2002).

There were two criteria for participant selection. First, classroom observations that focused on quadratic equations were considered. Second, classrooms with initial mean pre-test scores below 50% were considered. Among the classroom observations, the two teacher's classrooms with the highest gain (i.e., Ms. BW and Ms. MB) and the two teachers' classrooms with the lowest gain scores (i.e., Ms. MA and Ms. JR) were selected. Gain scores were calculated as the percentage of the maximum possible change (i.e., (Post – Pre)/ (Maximum Score (100) – Pre)). The cases were viewed without knowledge of effectiveness. Selected teachers' demographic information is listed in Table 1.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Teacher Participants Demographic Data

Classroom	Teachers	Year of CCT use	Undergraduate Major	Graduate Major	Years Teaching Experience
Effective	Ms. BW	2	Pre-Vet Med	Ph.D., Animal Feeding/Animal	13
	Ms. MB	3	Communication	MA, Journalism	3
Less Effective	Ms. MA	2	Mathematics	MA, Educational Computing	21
	Ms. JR	2	Mathematics	Curriculum and Instruction	20

This research employed a qualitative study design and analysis (Hatch, 2002) with the intent of providing contrasting or illustrative instances in instructional use of representations. To increase the credibility and validity of the conclusions, *usefulness, the chain of evidence, truthfulness,* and *reporting style* strategies were applied (Gall, Gall, & Borg, 2007).

Results

The teachers' practices in terms of how they supported students to engage with representations were explored in this study. Following the initial coding, the classes' effectiveness status was identified, and cross-case analysis of the two categories of cases were compared. Two major themes that potentially support representational fluency were identified. In each subsection, a theme and how it was practiced in both effective and less effective classrooms is described.

Using Different Translations

Unidirectional and bidirectional translations were observed during these classroom observations. Unidirectional refers to translating between different representations within the same activity (e.g., Symbolic1 → Graphical → Symbolic2) and bidirectional refers to translating between the same representations within the same activity (e.g., Symbolic1 → Graphical → Symbolic1). The students in all four classrooms frequently used different unidirectional translations. In effective classrooms, however, unidirectional translation was observed only once in Ms. MB's classrooms. All unidirectional translation sequences and the longest sequence of translations were observed in Ms. BW's classroom, an effective classroom. Many unidirectional translations were observed in Ms. MA's classroom video recordings, a less effective classroom. Although Ms. JR did not include translations in her first class period, the longest unidirectional translation among less effective classrooms was observed in her classroom. Although many unidirectional translations were observed in less effective classrooms, the students did not generally translate between representations; instead they observed their teacher's translations. Translations used in the unidirectional category are summarized in the Table 2.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 2: Unidirectional Translations

Classroom	# of Translations	Translation Sequence	Teacher Practiced
Effective	One	Graphical → Symbolic	Ms. MB
	Two	Symbolic1 → Graphical → Symbolic2	Ms. BW
		Tabular → Symbolic → Graphical	Ms. BW
	Three	Symbolic1 → Graphical → Symbolic2 → Verbal	Ms. BW
	Four	Symbolic1 → Graphical → Tabular → Symbolic2 → Graphical	Ms. BW
Less Effective	Two	Symbolic1 → Graphical → Symbolic2	Ms. MA
		Symbolic → Tabular → Graphical	Ms. MA
		Pictorial → Tabular → Graphical	Ms. MA
		Tabular → Symbolic → Graphical	Ms. MA
	Three	Symbolic1 → Graphical → Symbolic2 → Graphical	Ms. MA
	Four	Symbolic1 → Graphical → Tabular → Symbolic2 → Graphical	Ms. JR

In addition to unidirectional translations, one of the main features that differentiated the effective and less effective classrooms was the presence of bidirectional translations, which were observed only in the effective classrooms. Using four translations including bidirectional translation in Ms. BW's class might have improved her students' translation abilities because it includes many representations and translations (Figure 1).

(a)   (b)   (c)

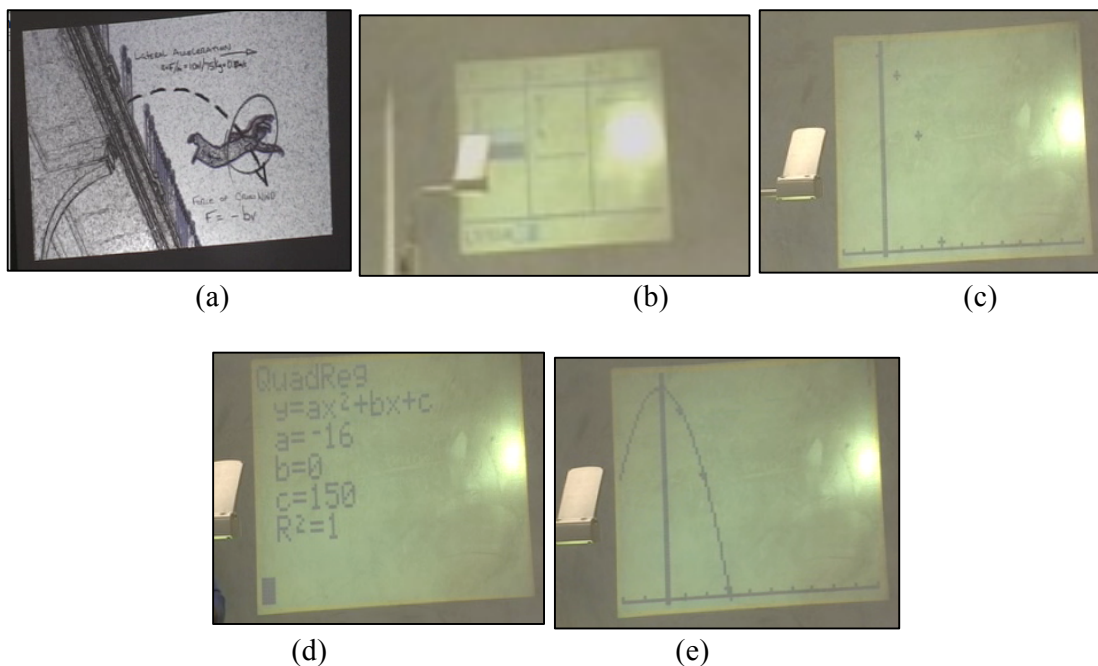
(d)   (e)


Figure 1. Screenshots from the students' work on the detective problem. This figure illustrates the use of (a) pictorial, (b) tabular, (c) graphical, (d) symbolic, (e) graphical representations, respectively.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 3 displays the sequences of translations in each of the effective classrooms. Although, there was only one bidirectional translation in each of the effective classes, the activities in which these translations were observed occupied a substantial amount of class time.

Table 3: Bidirectional Translations

Classroom	# of Translations	Translation Sequence	Teacher Practiced
Effective	Two	Symbolic1 → Graphical → Symbolic1	Ms. MB
	Four	Pictorial → Tabular → Graphical1 → Symbolic → Graphical1	Ms. BW
Less Effective	None		

In this study cycling translations were observed where students iteratively translated between representations bidirectionally until they reached the correct solution. Both teachers in the effective classrooms provided tasks that allowed their students to view multiple representations simultaneously (Figure 2).
Figure 2. Using dynamic representations simultaneously. This figure demonstrates the cycling translation between graphical and symbolic representations.

These students saw that each modification they made to the coefficients simultaneously changed their graph. They could see the coordinates of a point on the parabola while changing the point's location. Finally, cycling translations were observed twice in effective classrooms: (a) two translations with one cycling, and (b) three translations with one cycling. On the other hand, in the less effective classrooms, a cycling translation (i.e., Symbolic → Graphical ↔ Symbolic) was observed only once in one of Ms. JR's class (Table 4).

Table 4: Cycling Translations

Classroom	# of Translations	Translation Sequence	Teacher Practiced
Effective	At least two	Symbolic → Graphical ↔ Symbolic	Ms. BW
	At least three	Pictorial → Symbolic → Graphical ↔ Symbolic	Ms. MB and Ms. BW
Less Effective	At least two	Symbolic → Graphical ↔ Symbolic	Ms. JR

These translations were not, however, used within a real-world context, and the students did not interpret the representations. Ms. JR also gave many hints during the cycling process, which potentially limited the students' independent thinking. An additional difference was the fact that representations were not generally dynamically linked within the less effective classrooms. The students in these classrooms typically explored representations independent of one another.

Students perform better when they use more and multiple representations (Bostic & Pape, 2010; Herman, 2007; Nathan & Kim, 2007), when they have the ability to translate between representations (Brenner et al., 1997), and when they use non-symbolic representations (Suh & Moyer, 2007). Although students in both the less effective and effective classrooms used multiple representations, only the students in the effective classrooms generally used bidirectional and cycling translations. Since the new version of handheld calculators enables bidirectional translations (Özgün-Koca & Edwards, 2009) and repairing representations is a practice that supports learning (Warner et al., 2009), teachers can create environments where students have the opportunity to modify their representations until they arrive at the most accurate representation of their thinking. The students might be more successful if they can use bi-directional and cycling translations in conjunction with multiple unidirectional translations.

Scaffolding Translation through Teachers' Questioning

The teachers in the effective classrooms, Ms. MB and Ms. BW, asked questions to promote students' translation between representations. Ms. BW usually asked questions requiring short answers. When Ms. MB realized that her students seemed lost or confused or if she needed a student to clarify an answer, she would ask follow-up, open-ended, or hypothetical questions. Ms. MB invited all students to participate. She also encouraged them to share their solutions and opinions while solving the problems.

The teachers in the less effective classrooms, Ms. MA and Ms. JR, missed many opportunities to create discussion-rich environments. Also, by providing hints or asking questions that led to obvious generalizations, both teachers did not adequately challenge their students during problem-solving activities. Thus, the questioning techniques they used did not require the in-depth thinking that would encourage students to make translations between representations. In addition, Ms. MA and Ms. JR did not sufficiently interact with their students when they made mistakes. Instead, they quickly provided explanations. When discussing alternative ways of solving a problem, Ms. MA often started using her method without allowing her students adequate time to think for themselves.

Significance of the Study

This study provides a description of four teachers' practices and provides models for how teachers might construct their classroom to better promote their students' representational fluency abilities. They may offer examples to mathematics teacher educators when they prepare pre-service teachers or provide professional development for in-service teachers.

Teachers should be aware of their students' representational knowledge and seek technological or cognitive tools to visualize their students' thinking. Through the use of CCT such as the TI-Navigator, instructors can monitor and assess their students formatively to adapt their instruction based on their students' needs and misconceptions. Ultimately, teachers should create environments for students to interpret representations by linking them to real-world scenarios. Students should not only be able to see multiple representations on one screen but should also see the changes to a representation as its related representation (i.e., algebraic) is modified. Moreover, students should be provided more opportunities to make judgments about the accuracy of their representations and to change them as appropriate during problem-solving activities, which can be accomplished by including activities that require bi-directional and cycling translations. In addition, teachers should frame questions that facilitate students' developing understanding of representations and translations over time. One way to promote such sustained thinking is to foster discussion-rich environments.

NOT ALL QUESTIONS ARE ALIKE: CREATING A CATEGORIZATION FOR STUDENT QUESTIONS IN MATHEMATICS LESSONS

Melissa Kemmerle
University of Michigan
mkemm@umich.edu

Students ask a variety of questions during mathematics lessons. Some questions focus on procedures or formal notation, while others focus on ideas, connections, or representations. Student questions are important as they provide vastly different learning opportunities for students. In order to support teachers as they help students learn to ask productive questions in mathematics lessons, we need to first understand the types of questions students ask. This paper describes the process of creating a categorization for student questions in middle and high school mathematics classrooms.

Keywords: Classroom Discourse, Middle School Education, High School Education

Question asking is an important part of the learning process. The National Council of Teachers of Mathematics (NCTM) *Principles and Standards for School Mathematics* (2000) states that "students gain insight into their thinking when they formulate a question about something that is puzzling to them." Question asking affords students opportunities to extend their own understanding of lessons as well as to raise personal concerns about topics discussed in class (Daly, Kreier, & Roghaar, 1994). Posing questions not only shapes students' thinking, but also exposes it, which provides opportunities for teachers to learn more about their students' understanding (Marbach-Ad and Sokolove, 2000). Students who ask questions retain material better than those who do not (Marbach-Ad & Sokolove, 2000), and asking questions in mathematics lessons is linked with motivation (Stipek, Salmon, Givven, Kazemi, Saxe, & MacGyvers, 1998).

While it is clearly a useful activity for students to ask questions in classrooms, students often refrain from asking questions because they fear a negative reaction from their teacher (Pearson & West, 1991). Students also avoid asking questions because they "don't want to look stupid" in front of their peers (Kemmerle, 2013). Unfortunately, students who most need the benefits of question asking are often the ones who are afraid to ask questions, and over time, lower-achieving students ask fewer and fewer questions (Good, Slavings, & Mason, 1988). The converse is true as well— confident students who feel empowered in their learning ask more and more questions over time and reap the benefits (Kemmerle, 2013). Pearson & West (1991) found that higher achieving students ask more substantive questions, and lower-achieving students ask more procedural questions.

Research has focused on student question asking in science education (see Marbach-Ad & Sokolove, 2000; Kelling, Polacek, & Ingram, 2009; Rop, 2002 for examples) and in English Language Arts instruction (see Rosenshine, Meister, & Chapman, 1996 for a review), and studies have looked at *teacher* questioning patterns in mathematics classrooms (see Boaler & Brodie, 2004; Boaler & Humphreys, 2005) but there are very few studies that specifically address *student* question asking in *mathematics* classrooms. The importance of the issue as well as the gap in the literature prompts my desire to contribute to this area. In order to better understand the dynamics around student question asking in mathematics lessons, it is helpful to develop understanding of the different kinds of questions students ask while they are learning mathematics. This paper presents analysis and a categorization of such questions. In order to do this, I observed six middle school and high school mathematics classrooms and collected all student questions that arose during my observations. This produced 1,737 student questions which were grouped into 15 distinct categories. Initial inter-rater reliability came in at 74% which caused a further refinement of the codes until full agreement was reached. Details of the categorization follow.

Methods

Data Collection and Analysis

The study focused upon six classrooms chosen to offer a variety of instructional styles. The choice of substantially different learning environments enabled me to compare, contrast, and synthesize student questions across the cases (Miles and Huberman, 1994). See Table 1 for a summary of the six participants.

Table 1: The Six Teachers in this Study

Teacher	Grade	School and Classroom Information
Mr. Cordoba	8th	Small charter school in an urban district; 100% of students eligible for free/reduced lunch; mostly Latino/Hispanic student body; teacher focus on social justice and an "open" approach to mathematics (Boaler, 1998); approximately 50% of class time spent in small groups
Ms. Lyndon	7th	STEM middle school in an urban district with an emphasis on design thinking methodologies; 60% of students eligible for free/reduced lunch; student population is mostly Latino/Hispanic, Asian, and White; approximately 75% of class time spent in small groups
Mr. Ezzo	6th	Affluent suburban middle school where only 4% of students qualify for free/reduced lunch and student population is mostly white; teacher espouses a fairly "traditional" approach to instruction; teacher encourages his students daily to ask many questions.
Ms. Gibson	10th/12th	Medium sized high school in a mostly white but economically diverse school district; teacher uses a non-traditional curriculum designed to blend algebra, geometry, trigonometry, statistics in a four-year mathematics sequence
Ms. Kapoor	9th	Nationally-ranked, large high school in an extremely affluent suburban area; mostly white and Asian student population; classroom instruction consists mostly of lecture and note-taking; school culture is extremely competitive
Ms. Chang	10th	Independent day and boarding school for students who will be the first in their families to go to college; located in a historically underserved neighborhood; teacher blends traditional with innovative methods of instruction and values self-efficacy and sense-making

Data for this study consisted of approximately 45 hours of transcribed videotape, extensive field notes, semi-structured interviews with classroom teachers, and student surveys. I went through several iterations of transcription of the videotapes—during the first pass through the videos, I highlighted all student questions in the dialogue and took notes about each student question, thinking carefully about the function of each student question (Saxe, 1991). After I had worked through all the transcripts once, I went back and open-coded them again, using what I had learned the first time through the transcripts. I started to see patterns and similarities in the student questions and further refined my codes as I worked through more and more transcripts (Glaser and Strauss, 1967). I collaborated with my research group (Engle, Conant, & Greeno, 2007) about possible functions or purposes of student questions. We considered specific student questions that might epitomize a certain kind of question, in other words, a "case" of a kind of question (Shulman, 1992). I used the transcripts from my interviews with each teacher to gain more insight into their thoughts and feelings about how student questions affect mathematics instruction and student learning and to understand

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

more about why different types of student questions appear in different classrooms. Lastly, I used short-answer responses from student surveys to hear directly from students about their experiences asking questions in their mathematics lessons and to triangulate my findings.

Results

What types of questions did students ask?

I begin by describing each of the classroom contexts and illustrating the types of questions that were asked in each of these classrooms. Mr. Cordoba believes students should be "active participants in mathematical activity through generating and discussing mathematical ideas in class." He presents his students with tasks that require high cognitive demand (Smith & Stein, 1998), and asks them to collaborate (more than half of class time is spent in small group work). See Table 2 for a small sample of questions Mr. Cordoba's students asked during my observation along with my initial codes for each question. The curiosity in Mr. Cordoba's students' questions and the desire to extend mathematical ideas to slightly different situations is notable. Mr. Cordoba's students also asked questions with the goal of helping each other learn.

Table 2: Questions from Mr. Cordoba's classroom

Student Question	My initial code
Can I rephrase his question?	Helpful to classmate/community building
Can k be an odd number, like 27, and could you still have x and y the same number?	Mathematical curiosity question; also seeking specific information
If k were to be bigger and the k was a negative, where would it be?	True extension question--student is changing a few components of the problem and thinking about what that would mean
What is your equation to figure out y?	Seeking procedural/algorithm information
How did you get k is zero?	Seeking conceptual information
How does it show it in the trend line? Would it ever cross the x line?	Mathematically curious question/Representation question; seeking conceptual information
Does your y have to be negative?	Seeking conceptual information, explanation, meaning
Can your x be bigger, like if your number is 24 or lower, can the number you're multiplying be bigger and multiply by a decimal?	Another true extension question. Also shows mathematical curiosity

Ms. Lyndon's approach to teaching mathematics is to emphasize sense-making, intellectual risk taking, and mathematical communication in her classroom. Ms. Lyndon's students spend the majority of class time collaborating on group-worthy tasks (Cohen & Lotan, 2014). Ms. Lyndon intentionally and consistently teaches her students how to ask each other questions and how to work together to solve problems. See Table 3 for a sample of student questions from Ms. Lyndon's classroom and note that her students ask questions that think critically about various approaches to problems. They seek to make connections from one idea to the next and they want to find the best or most efficient approach to a problem.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 3: Questions from Ms. Lyndon's classroom

Student Question	My initial code
How does this relate to Alyson's method?	A question that connects a new mathematical idea to something already known/ A different approach question
In the corners, should we write $n-1$?	Student is wanting to know what teacher expects for the presentation of the work
So how did you get your picture?	Student wants to understand a visual representation of the mathematics
What's useful about this?	Mathematically curious question; also seeking connection to other mathematics, other subjects, or the real world
How did you get 34?	This could be a question that only seeks for procedural information, but looking closely at the context reveals that the student is trying to understand conceptually
Wait, why did you minus it?	Student trying to understand the mathematical procedure
I'm confused about x. What does x mean?	Asking for clarification
What's good about this method?	Procedure/algorithm question, but it's more than just asking how to do something; it's thinking critically about the merits of the method itself

Mr. Ezzo's approach is what some might call traditional: every day class begins with a scoring of the previous night's homework, followed by a lecture on new material. Mr. Ezzo espouses a "closed" (Boaler, 1998) approach to mathematics in that each student is expected to solve mostly context-free problems each day in the precise way they are taught by their teacher. See Table 4 for a sample of student questions from Mr. Ezzo's classroom and note that in Mr. Ezzo's class, many students are focused on getting the right answer, pleasing the teacher, and making sure they score well on homework and exams.

Table 4: Questions from Mr. Ezzo's classroom

Student Question	My initial code
I did 2 and 75 hundredths, does it count?	Meeting teacher's expectations (about presentation of answer)
What was the answer to 23 again?	Seeking information about a correct answer
Wait, how is it 3 out of 5?	Seeking meaning/conceptual information
Should we copy that down?	Classroom routine/meeting teacher's expectations about note-taking
Could we also just do 4 over 10?	Clarification question—this feels conceptual, knowing that 4/10 is equivalent to 2/5; this question is also focused on form of the answer
Once you find the first one, don't you just have to keep adding it on to find the next one?	Question about a procedural/method
Do you think we'll be able to do some homework in class?	Classroom routine question
Is it okay if I do it the way you just showed us?	Seeking go-ahead for a particular method
Can we do any of these ways on the test?	Assessment question

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Ms. Gibson considers herself a math reformer and uses a non-traditional curriculum that "requires a great deal of collaboration, investigation, experimentation, and question asking." Ms. Gibson expects her students to present their mathematical thinking at the board each day and she emphasizes sense-making and a safe learning environment. See Table 5 for a sample of student questions from her classroom. These questions suggest that Ms. Gibson's students want to understand the mathematics conceptually and also to know how the mathematics is useful.

Table 5: Questions from Ms. Gibson's classroom

Student Question	My Initial Code
Why are you finding the inverse?	Seeking conceptual information
Are all the lines called curves on a graph?	Question about terminology
I don't understand that last part. Why do we need the 225?	Seeking conceptual information, seeking to understand
Don't we need two measures to find the minor arc and don't we only have one?	Clarification, trying to better understand the procedure
Would you put this kind on the test?	Assessment
Do you want me to try to explain?	Community building
I have a question about when I would use a t-table, like at a job.	Application to real world

Ms. Kapoor's classroom follows a traditional format of homework review, new lecture, and new homework. For the most part, Ms. Kapoor students sit quietly and take notes throughout instruction. Ms. Kapoor states that she wants her students to be ready for college and "expects a lot" from her students. Ms. Kapoor's tests are known to be extremely difficult. Table 6 offers a sample of student questions from Ms. Kapoor's classroom. These questions suggest that Ms. Kapoor's students are anxious to please her and to score well on assignments and exams.

Table 6: Questions from Ms. Kapoor's students

Student Questions	My initial Code
When do we get the test back?	Seeking information about assessment, indicates concern for his/her grade
Is this right?	Seeking confirmation of a correct answer or method
Is there a calculus [state] test? What's the last year we have to take it?	Seeking information about an assessment
How many pages are on the test?	Question about assessment
Where do you want us to turn this in?	Classroom routine, meeting teacher expectations
Do you want us to draw it or label all the points?	Note-taking question, shows desire to please teacher
Wouldn't you have to do the angle bisector, inscribe the circle, and then do some nightmarish math?	Seeking confirmation of a method/procedure/approach
"What's the center of the triangle, would that be the orthotriangle? Circumcenter?"	Terminology question
"This just occurred to me, when it says counterclockwise 90 degrees, does that mean around the origin?"	Seeking information about meaning, conceptual information
"So what do I do here?"	Seeking information about procedure

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Finally, Ms. Chang, the youngest of all six teachers, recently earned her teaching credential at a teacher education program that focuses on teaching for understanding. She states that she wants all her students to "understand the math on a deep level." The mathematics department at her school developed the curriculum she uses, and Ms. Chang expects all her students to participate actively each day by taking notes, asking questions, and presenting problems at the board. Table 7 shows student questions from Ms. Chang's classroom. These questions suggest that Ms. Chang's are interested in getting the right answer and understanding and exploring the mathematics.

Table 7: Questions from Ms. Chang's classroom

Student Questions	My Initial Code
"Did I do it right?"	The student seeks confirmation from the teacher that she is correct.
"Is it okay to graph the original one first, and then shift it?"	Seeking information/approval about a method or approach
"Why is the period still 2π?"	Seeking conceptual information
"If the 2 was a ½, would it be a stretch?"	The student is exploring and speculating mathematically. Mathematically curious question; extension question
"Can I explain?"	Community building
"Do you put that in increments of π if you were to label it?"	Representation/notation question
"So, what is a phase shift?"	Terminology question
"How many points are on the quiz?"	Assessment question

As I observed and analyzed the student questions in Ms. Kapoor's and Ms. Chang's classrooms, I realized that no unusual or unexpected student questions emerged, thus indicating that I had reached data saturation (Marshall, 1996; Guest, Bunce, & Johnson, 2006). I thus stopped data collection and focused my efforts on refining, naming, and describing my categories. When determining the boundaries of each student question category, I thought carefully about the specific functions different questions served for the students asking them (Saxe, 1991). After many iterations of sorting and thinking about names for the categories, I produced 15 categories (See Table 8).

Table 8: Not All Questions are Alike—Student Question Categorization

Question Category	Examples from Transcripts
Form of Answer	-Do I have to show it as a repeating decimal, or can I round up?
Correct Answer	-But what is the answer? -I got 3 and 7 tenths, does it count?
Assessment/Grading	-Could I get extra credit for this? -How many points are on the quiz?
Meeting Teacher's Expectations	-Wait, do we copy down the percents bar model too? -Did I do it right?
Seeking Procedural[1] Information	-How did you get 16? -What is your shortcut for filling in your t-table?
Seeking Conceptual[1] Information	-Why did you have to cross out the 40 and the 10? -Why is the period still 2π? -Why are you finding the inverse?
Visual Representation --Conceptual --Informational	-If your x were to get bigger and then the trend line, would your points, can it ever cross the x line? -Where would it be on the graph? -Do you put that in increments of π if you were to label it?
Community Building	-Can I rephrase his question? -Do you want me to explain?
Making Connections	-How does this connect with what Alyson did? -Did you all use the same method to find all of your k's?
Mathematical Curiosity/ Extension	-Can k be an odd number, like 27, and could you still have x and y be the same number? -If k were to be bigger and the k was negative, where would it be? - If the 2 was a ½, would it be a stretch?
Terminology	-So what is a phase shift? -What's the center of the triangle, would that be the orthotriangle? Circumcenter? -Are all the lines called curves on a graph?
Application to Real-World	-I have a question about when I would use a t-table, like at a job. -What's useful about this?
Clarification/Confirmation	-Do you mean like that there is only some in the positive side and none in the negative side?
Notation	-Should I write f(x) or y?
Classroom Routine	-Can we go over 9? -Will there be time at the end to work on homework?

Conclusion

In this paper, I present a categorization schema for student questions within mathematics lessons. Such a categorization helps define and articulate differences between the various types of questions students ask in mathematics lessons. This tool can help researchers, educators, and teachers think more carefully and analytically about the student questions within mathematics lessons. This type of analysis will potentially lead to deeper, more conceptual, more curious mathematical questions from students.

Endnotes

[1]The difference between Seeking Procedural Information and Seeking Conceptual information is difficult without the context. While it is usually possible to identify the other categories with just the question alone, these two categories are often hard to differentiate without the before and after dialogue.

UNPACKING TEACHERS' PERSPECTIVES ON THE PURPOSE OF ASSESSMENT: BEYOND SUMMATIVE AND FORMATIVE

Rachael Kenney	Lane Bloome	Yukiko Maeda
Purdue University	Purdue University	Purdue University
rhkenney@purdue.edu	lbloome@purdue.edu	ymaeda@purdue.edu

The current age of standardization and accountability in education presents a need for educators to be proficient consumers and producers of data. To understand what mathematics teachers see as the purpose of data and assessment, as well as their perceived needs in these areas, we administered a survey to all mathematics teachers in two school districts in the Midwest. We analyzed perceptions of the purpose of assessment using a framework that breaks from the common formative/summative divide and considers the purpose(s) for assessment as being nuanced and potentially multi-faceted. The responding teachers demonstrated a robust working knowledge of assessment focusing on purposes that serve students, teachers, schools, and states. Responses also indicated that there are gaps in connecting the purposes of assessment and their knowledge on how to implement assessments in ways that meet these purposes.

Keywords: Assessment and Evaluation, High School Education, Teacher Knowledge

In the current climate of accountability, school administrators and teachers face unprecedented demands to be assessment-literate and use a wide range of data to inform educational decisions that document and promote student achievement. Accordingly, *data-driven decision-making* (DDDM) has become a central focus for educational policy and practice at all levels as an innovative strategy for school system and instructional reform (Gill, Borden, & Hallgren, 2014; Luo, 2008; Mandinach, 2012). DDDM is broadly defined as "the use of data analysis to inform choices involving policies and procedures" (Gill et al., 2014, p. 338). It is a complex undertaking, even for experienced educators and administrators equipped with quantitative skills (Mandinach, 2012). Developing the data literacy required for effective implementation of DDDM involves systematic experience with a variety of data (Mandinach & Gummer, 2013), including demographic, behavioral, achievement/ performance, attendance, financial, policy, programmatic, and compliance data. The data most under teacher and school control, however, are gained from classroom or school-level assessment. With this study we address a critical need to understand teachers' current assessment practices and current understanding of how to connect instruction, assessment, and related data in a way that can inform teaching practice (Datnow & Hubbard, 2015).

It is estimated that teachers spend up to one half of their classroom instruction time on some form of assessment (Stiggins, 1999). What then, do teachers see as the purpose(s) for devoting teaching time to this activity? In this paper, we share one piece of a larger study of DDDM by focusing on the critical component of assessment. We address the research questions: (a) *What do mathematics teachers see as the main purposes of assessment, and* (b) *what challenges impede teachers' use and understanding of assessment data?*

Background & Framework

Effective DDDM requires adequate *data literacy*, which can be broadly defined as the ability to understand and use data effectively to inform decisions (Mandinach & Gummer, 2013). Data-literate educators are a driving force of student learning, and ensure the continued success and funding of their schools in the era of accountability where data-based evidence plays a prominent role in both instructional and evaluative decision making (Orland, 2015). *Assessment literacy* is a critical component of data literacy, often defined broadly as being able to recognize sound assessment, evaluation, and communication practices to benefit student learning and achievement (Stiggins,

1999). As part of data literacy, educators integrate assessment results with other data reflecting content, context, perception, motivation, process, and behavior (Mandinach & Gummer, 2013).

Assessment, including both high-stakes and classroom assessments, can be one of the most influential activities in education. Research, however, suggests that teachers enter the profession with insufficient practice and knowledge for developing assessments for learning, evaluating student progress, and interpreting data (Bocala & Boudett, 2015; Popham, 2009; Volante & Fazio, 2007). When courses are offered in teacher education, topics tend to focus on the use of assessment for evaluating student outcomes rather than on the use of assessment as part of student learning (DeLuca & Klinger, 2010). Moreover, programs do not prepare preservice teachers to develop assessment skills that are adaptable to diverse student populations (DeLuca & Lam, 2014).

There is a large body of research on assessment, with significant attention given to clarifying the role of school assessment. For example, Griffin (2008) suggests that the most fundamental role of assessment is to help interpret observable behaviors in order to infer learning; "the more skills are observed, the more accurately generalized learning can be inferred" (p. 195). Assessment can be used to provide information to make decisions about student achievement (i.e., assessment *of* learning) and to support ongoing student learning (i.e., assessment *for* learning) (Stiggins, 2005). The distinction between summative and formative assessment, which are often distinguished by purpose, timing, or level of generalization (Black & Wiliam, 1998; 2003; Harlen, 2005; Sadler, 1989), is a prominent feature of the majority of this literature base. The fact that the purpose of assessment can be interpreted in a number of different ways is, according to Newton (2007) one of the most basic points for an educator to appreciate. Newton cautions, however, against reducing the purpose of assessment to two or three categories:

> We give the wrong message when we try to simplify assessment purposes by allocating them to a small number of categories (such as formative, summative and evaluative): we imply that the sub-purposes within those categories are importantly alike. This risks the impression that results which are fit for one sub-purpose within a category will be fit for the other sub-purposes as well…this is contrary to the impression that ought to be given to policy-makers, to ensure that wise decisions are made. (p. 161).

Newton suggests that the dichotomy between summative and formative assessment has been ineffective in understanding the nuanced nature of assessment and may hinder advancements in assessment theory. Bennett (2011) concurs that the use of assessments in support of learning is not limited to a certain kind of assessment such as formative or summative, because more than one type of assessment can contribute to judgments about students' achievement. Making distinctions of some sort, however, is useful because it helps us consider what assessment practices teachers are using and for what purposes.

In our work, we take the perspective of Newton (2007) who claims that, "to avoid getting ourselves confused, and to avoid confusing others, we need to use the language of assessment with greater precision" (p. 157). To this end, we choose to focus on the language that practicing mathematics teachers use to describe their understandings of the main purposes of assessment in their schools with the hopes of breaking the common borders between summative and formative distinctions. Newton shares at least three levels at which the purpose of assessment can be distinguished, including: (a) the *judgment* level—which concerns the technical aim of an assessment event (e.g., the purpose is to derive a standards-referenced judgment, expressed as a grade); (b) the *impact* level—which concerns the intended impacts of running an assessment system (e.g., the purposes are to ensure that students remain motivated, and that all students learn a common core); and (c) the *decision* level—which concerns the use of an assessment judgment, the decision, action or process which it enables. Newton further illustrates a range of purposes that may occupy discourse at

this last level. We use these (shown in Table 1 along with judgment and impact levels) as an initial framework for unpacking secondary mathematics teachers' descriptions of assessment purposes.

Table 1: Purposes of Assessment, Initial List (Newton, 2007; 2010)

Level	Categories	Description
Decision	Social Evaluation	Judge the social or personal value of students' achievements
	Formative	Identify proximal learning needs, guiding subsequent teaching
	Student monitoring	Decide whether students are making sufficient progress in attainment in relation to expectations or targets
	Transfer	Identify educational needs of students who transfer to new schools
	Guidance	Identify the most suitable courses, or vocations for students to pursue, given their aptitudes
	Institution monitoring	Decide whether institutional performance – relating to individual teachers, classes or schools – is rising or falling in relation to expectations or targets
	Resource allocation	Identify institutional needs and allocate resources
	Program Evaluation	Evaluate the success of educational programs or initiatives, nationally or locally
	Placement	Locate students with respect to their position in a learning sequence
Judgment		Derive a standards-referenced judgment, expressed as a grade
Impact		Ensure that students remain motivated, and that all students learn a common core

Methods

We addressed the research questions for this study by conducting a survey with teachers across two school districts in the Midwest.

Participants

School District A is a small district with 2,200 students. It is located in a rural area and it has implemented evidence-based decision making since the 1990s. There is one middle and one high school in District A. The district has a history of high academic performance, maintaining a higher passing rate of state mandated test than the state average for the last eight years. School District B is also rural with 6,700 students. It has two middle schools and one high school. District academic performance has declined somewhat over the last eight years. District B has not yet formulated a strong culture of DDDM. A total of 99 mathematics, science, and language arts teachers at the middle and high schools and 16 administrators participated in the online survey. Of these, 29 mathematics teacher survey results were analyzed for the current investigation.

Data collection and Analysis

The survey was designed by the research team by drawing on current research and assessment/data related reports from the U.S. Department of Education. The survey contained both open-ended and multiple-choice items and was designed to allow us to identify respondents'

perceptions of the purpose(s) of assessment and DDDM. The survey was distributed through Qualtrics®, an online survey tool. We focused our analysis on three survey questions:

1. What do you feel are the three main purposes of assessment in your school? (open-ended)
2. What do you see as your biggest areas of need?
3. What do you see as the biggest challenges related to using data from student assessment?

Survey responses were summarized descriptively for this paper to understand teacher and administrators' understandings of the purpose of assessment, challenges in meeting assessment goals, and teachers' current assessment practices. We used Newton's (2007, 2010) list of purposes (Table 1) to guide the axial coding analysis of open-ended items.

Findings

Purpose of assessments

Coding teachers' responses to the question, "What do you feel are the three main purposes of assessment in your school?" allowed us to expand our framework and further understand the variety of ways in which teachers view assessment use. From the 29 responding teachers, we received 75 distinct responses to this item. Some responses could be broken up into separate statements that fit different codes, resulting in a total of 87 total coded statements in our data. Table 2 provides the summary of the axial coding analysis these 87 statements from the mathematics teachers' responses. After initially coding responses to fit under the decision, impact, or judgment levels described above (Newton, 2007), we identified who seemed to the target of assessment decisions, impacts, or judgments – students, teachers, schools, or the state. We analyzed these codes further to identify where they fit in our framework and created additional codes that we posit to be beneficial in capturing the nuances of teachers' perceptions.

Table 2: Teacher Identified Major Purposes of Assessment

Levels	Focus	Codes	N
Decision Level	Students	Formative - Pre-assessment	2
		Formative - Instruction	9
		Formative - Student mastery	13
		Student monitoring (long term)	13
		Resource allocation - remediation	3
		Placement	2

	School	Institution monitoring - School accountability	9
Impact Level	Students	Encouragement	5
		State Exam Practice	4
Judgment Level	Students	Grading	5
	School	Collect data	6
	State	Meet a requirement	4

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Focus on students. The majority of responses focused on the assessment purposes that targeted students (57 out of 87). These were found at all three levels. Coded responses at the decision level were broken down into three separate categories of what Newton (2010) referred to as formative (where the purpose of assessment is to "identify students' proximal learning needs, guiding subsequent teaching" (p. 392)): (a) to preassess students' prior knowledge, (b) to make decisions during class about whether students had mastered a concept, and (c) to make decisions about how to move forward with instruction. Some examples of responses coded into these categories include:

- "Determine if a student has mastered a concept." (*mastery*)
- "In my classroom I use them to find out students ability to recall and apply concepts." (*mastery*)
- Student scores are then used as a tool to adjust my lessons." (*instruction*)
- "To determine where students currently are with a certain standard before it is taught." (*pre-assessment*)

Student mastery formed the largest group under the formative code (*n*=13). Student monitoring was also coded for 13 responses, and was distinguished from the formative categories if the response implied that assessment served a purpose of determining student learning or growth over time (instead of within a lesson). Some examples include:

- "To measure growth of knowledge."
- "To make sure students are learning the state standards."
- "To see what students learn and retain throughout the year."
- "To determine how much students know after teaching standards."

At the impact level, which concerns the intended impacts of assessment, teachers reported assessment purposes that target students. This student-mindedness was evidenced by identifying assessment as a tool for keeping students motivated and allowing students to practice for high-stake state exams. For example:

- "Assessment gives students clearer goals to help put more emphasis and importance on learning the content; it works well for students as an incentive to grow." (*encouragement*)
- "Prepare students to succeed when taking state standardized tests." (*practice*)

One teacher added that assessments were "almost like a reward in the sense that students are given problems they've been training themselves for and are given a number or letter grade showing how much they know."

Only five teachers made mention of giving grades as a purpose of assessment. These responses were coded at the judgment level, as they described a technical aim of assessment.

Focus on Teacher/School/State. The survey results revealed that teacher, school, or state accountability is a common purpose that teachers see for assessment. At the decision level, these foci appeared as responses indicating that assessments are used to "compare teachers," "Determine if a teacher is an effective teacher", and "to make sure everyone is teaching the same content."   These and similar responses were coded under institutional monitoring, but focused on teacher accountability. Additional responses claimed that assessments were to "compare to other schools," "calculate school performance," and "let the public how the school is doing."   These were coded as institutional monitoring with a focus on school accountability. Additional comments coded as focusing on assessment purposes for the whole school included six responses that explained the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

purpose of assessment in basic terms, "to get data," which is a technical aim of assessment (and thus coded at the judgment level) in their school.

Some negative connotations of assessment were also found at the judgment level, with four teachers indicating that assessment served the purpose of "making the state happy" or meeting state requirements. One teacher added that they served the state by "reporting numbers that don't tell the whole story", indicating frustration with the roles that s/he sees assessment playing at the school or state level.

Areas of Need and Challenges

Table 3 summarizes the areas of needs relative to assessment and data practices that teachers identified in their responses. As shown above, a large number of teachers identified long-term student monitoring as a significant purpose of assessment. However a majority also identified collecting useful growth data as a major area in which they need additional guidance or support. Similarly, teachers identified examining student data to identify which instructional practices work best for which students and analyzing with an equity lens as problematic areas. However, a majority also indicated little to no need with help on adapting instructional activities to meet students' individual needs in this same question. It is possible that teachers see this activity as disconnected from the use of data or assessment. It is also interesting to note that none of the teachers made mention of differentiation of any kind in their descriptions of the purposes of assessment above. It will be important to follow up on this issue in interviews with the teachers. A majority of the mathematics teachers did feel that they were well practiced with designing assessments aligned to state standards, which is not surprising given the current influence of state exams on teaching practices.

Table 3: Teacher Identified Area of Need

Need	Some to Great Need	No to Little Need
Collecting useful growth data.	18	7
Examining student data to identify which instructional practices work best for which students	18	7
Analyzing data through an equity lens.	16	9
Collaborating and sharing ideas with colleagues regarding data inquiry and analysis issues	16	9
Structuring the district organization and practices to support data-driven decision-making.	14	11
Communicating with families about student progress.	12	13
Developing curriculum-embedded formative assessments.	12	13
Interpreting assessment data to identify gaps in student achievement	12	13
Adapting instructional activities to meet students' individual needs	10	15
Designing assessments aligned to standards.	8	17

Additional challenges in using assessment data for instruction were identified in teachers' survey responses, including resource limitations, significantly, time. Teachers also perceive some major challenges in being able to access multiple sources of student data in useful ways to guide decision-

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

making, and many suggested that they were not prepared or did not have adequate guidance for making instructional decisions from assessment data.

Conclusions

The teachers who responded to our survey have a working knowledge of multiple purposes for assessment. This runs contrary to the sentiment in current literature that teachers enter the profession with deficient assessment literacy and that this skill deficit remains throughout their professional careers (Bocala & Boudett, 2015; Popham, 2009; Volante & Fazio, 2007). In discussions about what teacher education can do to provide assessment-related professional development, the focus is often on the presumption that teachers do not have a strong knowledge base for assessment literacy. The data presented here does not really support this. Through their professional experiences or training, teachers have well-developed ideas about the varied purpose of assessment and what they want to be able use them for. What there does seem to be is a gap in their ability or understanding of how to enact assessment and data use in a way that serves the purposes they know they can serve.

Our results suggest that the key to developing teachers' assessment literacy is not to inundate pre-service and in-service teachers with information about the technical uses of assessment. Instead, it would be beneficial to use teachers' existing assessment knowledge base to craft professional development opportunities targeted at developing their skills at linking this knowledge base to actionable instructional strategies. To this end, it seems critical to find ways to provide time and incentives for teachers to collaborate with their colleagues in sharing assessment data and share best practices for linking assessment data to instructional adjustments. The more advanced perceptions on the purpose of assessment came from statements that focused on the students as the benefactors of assessment (rather than on teacher or school accountability). Thus is also seems important to help teachers direct their discourse away from a primary focus on state exams as "the" assessment and reflect more directly on daily teaching practices that involve assessment, prompting teachers to continually reflect on the goodness of fit between their assessments and their purpose(s). These strategies are critical components to include when focusing on the development of a school and district-wide culture of DDDM and data sharing.

The teachers' descriptions of purposes of assessment support the need to broaden the distinctions that we make as a field beyond summative and formative. These words did not appear in teachers' descriptions and to not adequately capture the wide variety of roles they see assessment playing in their classrooms and schools. Our use of Newton's work (2007) as an initial framework proved useful in unpacking the teachers' perceptions in a meaningful way. We feel this is a positive step in helping teachers and teacher educators develop more productive discourse around the use of assessment for guiding instruction in classrooms.

There is a paramount need for teachers to be assessment-literate in this age of standardization and accountability. Our survey suggests that teachers have the skills and knowledge to answer this call. However, teachers report that they need support and guidance transforming their working knowledge of assessment into habits of using this data to inform dynamic instruction. As mathematics educators, we have the resources to provide this guidance, creating an opportunity for us to work together with teachers to ensure that their students are given every opportunity to receive quality experiences in the mathematics classroom.

We theorize about ambiguity in mathematical communication and define a certain subset of ambiguous language usage as imprecise. For us, imprecision in classroom mathematics discourse hinders in-the-moment communication because the instance of imprecision is likely to create inconsistent interpretations of the same statement among individuals. We argue for the importance of attending to such imprecision as a critical aspect of attending to precision. We illustrate various types of imprecision that occur in mathematics classrooms and the ramifications of not addressing this imprecision. Based on our conceptualization of these types and ramifications, we discuss implications for research on classroom mathematics discourse.

Keywords: Classroom Discourse, Instructional Activities and Practices, Standards

The border between effective and ineffective communication of a mathematical idea can be crossed based on the use or misuse of a single word. Communication is necessarily problematic, requiring constant negotiation of meaning (Sfard & Kieran, 2001; Voigt, 1994). We never know exactly what someone else means by what they say; we infer those meanings. Communication in general, and classroom communication in particular, works because of our overall assumptions of shared meaning (Cobb, Yackel, & Wood, 1992)— for most of the words we use we assume that the individuals around us have constructed meanings that are fairly comparable with our own meanings. Though unwarranted inferences cause miscommunication, classroom discourse would come to a standstill if teachers followed every student statement with, "Please explain what you mean." Whether consciously or not, we are constantly judging whether the words others use can stand on their own or seem to require clarification.

Those who look closely at the complexities of communicating in mathematics classrooms see one particular aspect of communication—sometimes referred to as ambiguity (e.g., Barnett-Clarke & Ramirez, 2004; Barwell, 2003)—as both inherent (and thus unavoidable) and as providing opportunities for learning. As Barwell (2003) stated, "It is the potential for ambiguity inherent in all language that allows students to investigate what it is possible to do with mathematical language, and so to explore mathematics itself" (p. 5). There is a subset of ambiguous situations, however, that we see as a barrier to mathematical communication, as hindering the negotiation of mathematical meaning in the moment. We have come to refer to such situations as imprecise. We see attention to imprecision as a critical, but possibly overlooked, aspect of the mathematical practice of attending to precision (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). The practice of attending to precision often focuses on mathematical precision, like when a student uses equal in place of congruent, or when a student incorrectly strings together expressions using equal signs. Although these situations call for improved mathematical precision, we can typically infer what the student means—there is not a need to improve mathematical precision for communication to continue. We, instead, focus on language precision in the context of mathematics—when clarifying what has been said will increase the likelihood that all members of the classroom community can successfully and reliably make sense of the mathematics at hand. In this paper we define this *imprecision*, then describe and provide examples of different types of

imprecision. We conclude by theorizing about issues related to not addressing imprecision and ways to productively address it. We see this work as critical to our ongoing research to understand the teaching practice of productive use of student mathematical thinking.

Defining Imprecision

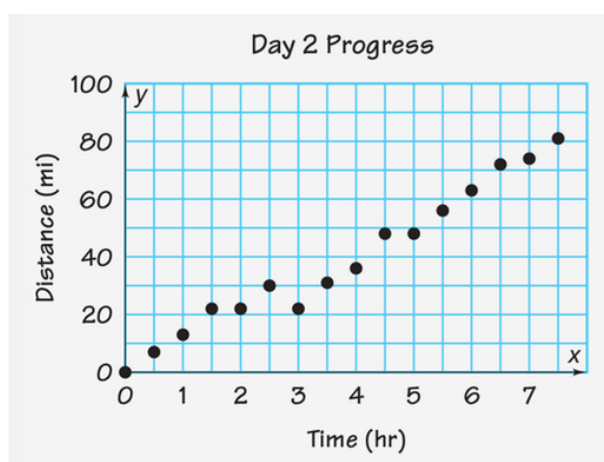
We now discuss an example derived from an excerpt of classroom mathematics discourse in order to motivate our definition of imprecision. In a class where students have been studying data about a group of bikers on a multi-day trip, they are examining a graph where distance is measured by the distance from a given city (see Figure 1). In a discussion about Figure 1, the class has interpreted the plotted points at times 1.5 and 2 as an indication that the bikers are stopped on the interval between 1.5 and 2 hours. A student then volunteers, "And then they went up." The teacher asks, "What do you mean, 'They went up?'" to which a number of students respond by making hand gestures, raising their hands up as they move from left to right.


Figure 1. Bikers' progress (from Lappan, Fey, Fitzgerald, Friel, & Phillips, 2006, p. 12).

We see the student statement, "And then they went up," as imprecise because it is unclear to what the student is referring by *they*. In this context *they* could easily refer to either the bikers on the road or the dots on the graph, and these two interpretations mean very different things in this context. The teacher seems to recognize a communication problem and pushes for clarification. Notice, however, that the students' responding gestures seem to indicate their understanding of the word *up,* but the ambiguity remains. What might be missing from the teacher's effort to clarify? We believe the ambiguity persists because the students do not know which part of the phrase *they went up* the teacher is referring to—*they* or *up*. This excerpt illustrates how imprecise language can hinder mathematical communication, creating a situation where individuals are talking past each other because of how they have interpreted the word *they*. We believe the teacher's response could have been more productive had the request for clarification zeroed in on the specific part of the student sentence that was unclear. Had the teacher responded to the student statement with a more-specific question such as, "When you say, 'they went up,' what do you mean by *they*?" students would have been better positioned to clarify their meaning and the discussion could have proceeded accordingly.

Ambiguity as illustrated here creates a moment when clarification is needed in order to continue the sense-making activity, and when lack of clarification will likely cause a breakdown in the negotiation of meaning. We have come to view this type of ambiguity in the following way: If a part of speech is used such that it can be interpreted in multiple viable ways, and the existence of those interpretations causes the overall meaning of the statement in which it occurs to be unclear, then we refer to both the part of speech and the statement in which it occurs as *imprecise*. We use viable

interpretations to mean interpretations some students in the class might reasonably infer given the context in which the part of speech is used. We do not consider viable extreme or outlying interpretations that are unlikely to exist in the given classroom context. Thus, for us, imprecision in classroom mathematics discourse hinders in-the-moment communication because the instance of imprecision is likely to create inconsistent interpretations of the same statement among individuals.

Types of Imprecision

In this paper, we present a theory that both researchers and practitioners can use to analyze mathematics classroom discourse. Although this is a theoretical paper, it was both prompted and informed by empirical work conducted as part of the National Science Foundation (NSF)-funded *Leveraging MOSTs* project. A central component of that project was the conceptualization of instances of student thinking teachers should take advantage of in the moment they occur during classroom discourse, what we called MOSTs—Mathematically significant pedagogical Opportunities to build on Student Thinking (Leatham, Peterson, Stockero, & Van Zoest, 2015). The associated MOST Analytic Framework provides characteristics and criteria for identifying MOSTs and for articulating why some instances fall short of being prime in-the-moment opportunities to build on student mathematical thinking. The foundational characteristic of a MOST is student mathematical thinking, and the first criterion of this characteristic is that *student mathematics* must be inferable. Thus, as we analyze student contributions to classroom mathematics discourse, we first attempt to articulate the *student mathematics* of each student's turn, or in other words, restate their comment in complete sentences or thoughts and replace pronouns and gestures with their referents when possible. In applying this framework, we often found ourselves in situations where we could not infer the student mathematics of an instance. Although at times this inability to infer the student mathematics stemmed from incomplete or inaudible statements, there were many times when student statements could be heard and seemed to be complete, but wherein we still could not make an inference. It was in this context that we came to realize that our inability to infer the student mathematics was due to language ambiguity—there were multiple viable interpretations of what the student had said. We began to wonder about these ambiguities and their effects on classroom discourse. This paper is a result of the theoretical work that followed. The examples in this paper are based on examples of imprecision we observed in middle school mathematics lessons that were analyzed for the *Leveraging MOSTs* project.

Because of the centrality of "parts of speech" to our definition, we categorize types of imprecision according to these parts of speech. The four basic parts of speech that occurred most frequently in our instances of imprecision are subject, object, adjective, and verb, and are thus our four main types of imprecision. That "parts of speech" ended up having the explanatory power that it did as we theorized about classroom imprecision was a surprisingly straightforward way of capturing what was a complex problem for us, one with which we grappled for a long time. The related grammatical phenomenon of unclear referents is a typical topic in textbooks on grammar, but not so common in research related to oral communication and learning to write and speak in general. When research does attend explicitly to unclear referents it tends to be research on those who are acquiring a second language (Block, 1992) or who have learning challenges such as delayed development (e.g., Eigsti, de Marchena, Schuh, & Kelley, 2011) or dementia (e.g., Almor, Kempler, MacDonald, Andersen, & Tyler, 1999). The theory presented in this paper contributes to the literature by extending a focus on language imprecision to typical classroom mathematics discourse and the complexity of orchestrating that discourse.

Subject

The subject of a sentence is the person, place, or thing that is doing or being something. Subjects are either nouns or pronouns and can be imprecise if it is not clear which person, place, or thing is

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

being referenced. We first share an example of how the use of a pronoun as the subject of a sentence can be imprecise in a mathematics classroom and then an example of an imprecise demonstrative pronoun.

Pronoun. In the previous example – "And then they went up." – the subject of the sentence is they and they is imprecise because of the ambiguity of its referent. As mentioned before, in this context, they could be referring to the dots on the graph or to the bikers on the road. These alternate possibilities for the subject of the sentence result in very different mathematical interpretation for the overall meaning of the sentence. But, if we know whether they is referring to bikers or dots, it is easier to infer the meaning of went up and thus the meaning of the entire sentence.

Demonstrative pronoun. Demonstrative pronouns are pronouns such as *this, that, these,* and *those* that point to specific things. In a class discussion about slopes of linear equations, a student says, "That has a positive slope." The precision of this statement depends on the context in which it occurs. If there is a single linear equation on the board or being talked about, then it is likely clear what subject is being referenced and there is no imprecision. If, however, there are multiple linear equations on the board and only one of them has a positive slope, then the student statement is imprecise because the demonstrative pronoun *that* could be referring to either of those equations and thus there are multiple viable interpretations of the statement—the meaning behind the student statement is very different depending on which equation they are referencing. Were the teacher to seek clarification here, awareness that the imprecision lies with the demonstrative pronoun that is the subject of the sentence might lead to a question such as, "What has a positive slope?"

Object

Similar to the subject of a sentence, objects are either nouns or pronouns and are imprecise when it is not clear which person, place or thing is being referenced. If the object is a pronoun or demonstrative pronoun, the imprecision can occur in the same way it occurs in the subject of the sentence, and clarification is best if it hones in on the imprecise object itself. In the case of an object, however, another type of imprecision can occur, one that generally does not occur with subjects (in the English language): the object of a sentence can be implied. Such imprecision can occur with objects of a verb and with objects of an adjective.

Implied object of verb. Consider the teacher-student interchange when a teacher says, "What about unit rate? Could we use unit rate to solve this proportion [6/4=f/10]?" and a student responds, "Yes, by dividing." From the context we can infer that the student is saying, "We can use unit rate to solve the proportion 6/4=f/10 by dividing." The latter part of the sentence, however, is incomplete; the verb *divide* has an implied object and therefore there is no indication of which numbers are to be divided. There are several legitimate possibilities for these numbers, not to mention several others that might reveal misconceptions about the "unit rate" strategy or about proportions in general. We thus see the statement *by dividing* as an example of imprecision because of an unclear implied object of a verb. A teacher could zero in on the part of speech that created the imprecision by asking, "Which numbers would you divide?" thus acknowledging the unclear part of the statement and pushing for an articulation of the object.

Implied object of adjective. In an 8th grade algebra class, students were learning about the composition of functions and were given two equations: $P=2.50V - 500$ and $V=600 - 500R$, where profit (P) is related to the number of visitors (V) to an amusement park, and the number of visitors (V) is related to the probability of rain (R). Students were first asked to determine the profit when the probability of rain is 25% and then to find the probability of rain when the expected profit is $625 (from Lappan et al. 2006b, p. 25). After students had worked on these problems, the teacher said, "So, when they tell you a value of a variable, you substituted that variable with the value they told you. So, you guys were okay with that part. Why do you think the second part was kind of hard?" A student responded, "Because you had to do the opposite." In this statement the word *opposite* is an

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

adjective and we know what it means. What we do not know is what object this adjective is describing—the opposite operation, the opposite order or the opposite process. Any of these objects are viable interpretations of what the student has said. Thus the statement is imprecise because the implied object of the adjective *opposite* is imprecise.

Adjective

Adjectives, words that describe nouns, are sometimes the culprit of the imprecision. For example, a teacher might ask, "Could we still use *that* strategy?" in a context where multiple strategies have been discussed. For students to answer this question they need to know which strategy is under consideration—the demonstrative adjective *that* is imprecise. Or suppose a class is discussing a graph displaying a dozen points and a student says, "Find the distance between those points." In order to pursue this line of reasoning, and for the class to follow along, the class needs to know which of *those* points the student is considering.

The adjectives in these examples are demonstrative adjectives—in essence they are pronouns being used as adjectives. Note how slight variations on these examples change the part of speech that is imprecise. Compare "could we still use *that*" with "could we still use *that* strategy". In the first case the pronoun *that* is the object of the sentence. In the second case *that* is a demonstrative adjective. The second sentence is "less imprecise" in that we at least know that the object of the sentence is a strategy, we just do not know which strategy. This distinction matters because, whereas in the first sentence one would seek broader clarification of the object of the sentence with a question such as, "Could still use what?", in the second sentence the clarification question could be much more precise—"Could still use *which* strategy?". The more one can hone in on the part of speech that is imprecise the more precise one can be in seeking clarification.

Verb

To understand a sentence, one must understand the subject's action, or the *verb*. This understanding is particularly important in mathematics because of the many carefully defined mathematical verbs like *add*, *divide*, *solve*, *invert*, and *integrate* that are used to communicate specific actions. A common type of imprecise verb use is the use of generic, colloquial action verbs such as *work*, *do*, and *make*, which do not have precise meanings in a mathematical context and thus can often be interpreted in more than one way. In a sense, these generic action verbs are used like pronouns to replace more precise mathematical verbs.

The following example illustrates how use of generic action verbs can create imprecision. It comes from the same 8th grade algebra class mentioned previously where students were using the equations $P=2.50V - 500$ and $V=600 - 500R$. Students were able to solve for P given R relatively easily, but many struggled when asked to solve for R given P. During a conversation about that struggle, a student said, "[In the first case you] just do the equation instead of doing multiple step equations." Here the student used the verb *do* in a general, colloquial way; it is not clear what she meant by "do the equation" or "doing multiple step equations," and whether each use of *do* is the same. She may have meant solve the equation(s), evaluate the equation(s), substitute something within the equation(s), or manipulate the equation(s). Because there are multiple viable options for what was meant by *do*, the student statement was imprecise. This student seemed to have something valuable to contribute to the mathematical conversation about students' struggles with this task, but the imprecision hindered her communication. To clarify this imprecision, the teacher could ask the student to clarify what she means by *do* when she says, *"do the equation."* This teacher response would hone in on the verb imprecision while simultaneously legitimizing the student statement as an important contribution to the mathematical conversation.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Commonality Across the Types

Across these various types of imprecision, one particular commonality stands out. Multiple viable interpretations occur when generic or implied words are used in place of more specific words. Pronouns are a wonderful tool for streamlining communication, but when their referents are unclear from context, imprecision occurs. Further complicating matters, the English language allows for specific subjects and objects to be completely absent, creating an even deeper layer of inference and associated possibilities for imprecision. Our examples of imprecise verbs also fit this pattern, as noted earlier, as these verbs are used in a generic way, almost like a pronoun.

Ramifications of Not Addressing Imprecision

Imprecision could cause a student to think they do not understand something when, in reality, there is just a breakdown in the negotiation of meaning because of an imprecise statement. When an imprecise statement is not explicitly addressed, students are likely left unaware that what has been said is imprecise. If the teacher implicitly infers the meaning of an imprecise statement, students are likely not aware of the sense making that the teacher has engaged in, so have no idea that their interpretation of the statement is different from the teacher or other students in the class. In addition, there seems to be a norm in classrooms that a teacher moving on implies that what was said was clear or true. If a student cannot make sense of an imprecise statement, they may not know whether they lack understanding or there was a problem with what was said. In other words, they may think their own understanding is flawed because it does not reconcile with the imprecise statement when, in fact, the imprecise statement is where the flaw lies.

Furthermore, a number of instances of imprecision we have observed have led to the creation of simultaneous, yet parallel inconsistent conversations, wherein various participants proceeded with differing interpretations of an imprecise statement, in essence talking past each other. Because imprecision occurs when a word, statement or action has more than one viable interpretation, communication is hampered when part of the class adopts one of those interpretations and another part of the class adopts a different interpretation.

These two main ramifications of imprecision—student confusion and parallel conversations—have serious implications regarding the teacher's and students' experience in the classroom. First, students might disengage from the class discourse because of their inability to make sense of an imprecise statement. When imprecision occurs and students are confused or when their understanding does not align with the teacher's, some proactive students might push on the issue until the imprecision is cleared up and the confusion is resolved. Unfortunately, this is likely the exception as many students are unwilling to challenge a teacher or stall progressing discourse. These students are likely to remain confused, ultimately causing them to disengage from the discourse because of their inability to make sense of the ensuing conversation, all caused by unaddressed imprecision. Second, these ramifications may cause the teacher to miss opportunities to better understand a student's thinking, and thus miss opportunities to further that student's and the class's understanding of the mathematics at hand. Since we began to think about imprecision as we observed it during the MOST project, we particularly emphasize this implication. When a student's utterance is imprecise and when the teacher does not address that imprecision, the teacher is not able to articulate the *student mathematics* of that student's statement with confidence. Without that understanding, they are not able to effectively further that student's thinking about the mathematics at hand, nor are they able to use that student's comment to further the rest of the class's understanding. Third, there could be repercussions for students' mathematical understanding. For instance, in the "they went up" example, failure to explicitly address the imprecision could cause or reinforce the misconception that a graph is a picture of the physical situation.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Explicitly Addressing Imprecision

Student mathematical thinking should be at the heart of classroom mathematics discourse (e.g., National Council of Teachers of Mathematics, 2014). In order for students and teachers alike to fully benefit from students making their thinking public, teachers need to recognize and then attend to roadblocks that hinder the effective communication of the intended ideas. To do this effectively, a teacher needs to attempt to internally make sense of student comments in order to recognize instances of imprecision; then it is critical to push for clarification when imprecision occurs to allow others in the classroom to also make sense of what is being said. Although it is unwise to ask for clarification about every student statement, it is equally unwise to never seek such clarification. Some teachers, particularly novice teachers, may be reluctant to push for clarification from their students because they feel such requests may come across as a lack of mathematical understanding on their part. Members of a classroom community should recognize that a push for clarification is not an indication of weak mathematical understanding, but rather an acknowledgement of the importance of clear communication and evidence of the centrality of students sharing their thinking to mathematics teaching and learning.

As we saw in the example of "they went up," even when teachers seem to recognize that something is amiss, their requests for clarification may miss the mark and thus not solve the problem. If teachers can learn to attend to precision by attuning themselves to the specific cause of imprecision (i.e., the particular part of speech that is imprecise), they can ask for clarification that hones in on just what it is the student needs to clarify. Such clarification specificity has at least three advantages. First, this specificity helps the student to know what aspect of their communication was problematic, providing guidance for them as they seek to clarify their ideas. Second, this specificity scaffolds the entire class as they try to negotiate the meaning of what has been said. Third, and perhaps most important, it sends the message that most of what a student has said has been taken as understood—as understandable and meaningful. Such messages play an important role in helping students to gain confidence in their abilities to contribute legitimate, useful mathematical thinking. By explicitly addressing an instance of imprecision, teachers legitimize all students' efforts to make sense of others' ideas; they also model the importance of attending to precision.

In conclusion, we see attending to imprecision as a critical and possibly overlooked aspect of the study of the productive use of student mathematical thinking in classroom discourse. Future research could use this conceptualization of imprecision as a tool that could help us better understand the barriers to effective classroom discourse. We believe that this tool is also readily accessible to teachers in their in-the-moment analysis of classroom discourse, thus blurring the border between research and practice.

TEACHER ATTRIBUTES AND SCHOOL CONTEXT: WHAT ARE THE BARRIERS TO DISCOURSE IN ELEMENTARY MATHEMATICS?

Carrie W. Lee
East Carolina University
cwlee5@ncsu.edu

Temple A. Walkowiak
North Carolina University
tawalkow@ncsu.edu

This study utilized a multilevel model to examine the relationship between teacher attributes, school context, and the characteristics of the discourse within novice elementary mathematics lessons. MKT and teacher beliefs were significant predictors of the level of student explanation within teachers' lessons while school SES and perceived levels of support accounted for variance in the overall mathematics discourse community.

Keywords: Classroom Discourse, Elementary School Education, Mathematical Knowledge for Teaching, Teacher Beliefs

Introduction

Research has shown that elementary teachers are often anxious about teaching mathematics due to their prior experiences (Stevenson & Stigler, 1994), hence the work of teacher preparation programs to reverse this trend among their preservice teachers (PTs). Preparation programs strive to build PTs' confidence in teaching mathematics by improving their specialized content and pedagogical knowledge. One element of mathematics teaching and learning on which teacher preparation programs typically focus is the use of mathematical discourse to support students' justification and explanation of ideas. The importance of mathematical discourse has been supported by research (e.g., Michaels & O'Connor, 2015), emphasized in standards (National Governors Association Center for Best Practices, Council of Chief State Officers [NGA & CCSSO], 2010; National Council of Teachers of Mathematics [NCTM], 2000), and echoed in the recently published *Principles to Actions* (NCTM, 2014).

Despite the emphasis on the importance of discourse, research has shown that high-quality mathematical discourse is not the norm in U.S. classrooms (Michaels & O'Connor, 2015); therefore, more research is needed to understand the borders that promote and hinder its actualization in elementary classrooms, particularly for novice teachers who recently graduated from programs advocating its use. This study aims to fill that void by examining the relationships among teacher attributes, school contextual factors, and mathematical discourse. By studying novice teachers, we attempt to investigate the bridge between teacher preparation and induction into the profession and the borders that are productive or problematic for the implementation of high-quality discourse.

Theoretical Perspective

To study the co-construction of discourse within the mathematics classroom, this study employs a situative approach to learning (Lave & Wenger, 1991; Cobb & Yackel, 1996). A situated perspective allows one to conceptualize the teacher as an influential "old timer" in the classroom community of practice where students learn the expected norms through their interactions with the teacher and fellow classmates (Lave & Wenger, 1991, p. 29). Further, broader school contextual factors are often considered when attempting to fully situate learning.

This study attempts to gain insight into the mathematical communities established in novice teachers' classrooms by examining the classroom using various units of analysis. We first focus on the novice teacher's "distinct way of being" (Skott, 2009, p. 31) by attending to attributes measured at the individual level. Next, we explore the school context in terms of teachers' perception of support and school demographics, which shed light on the sociocultural influences. Lastly, using a participatory lens, we explore the nature of the classroom community of practice through an

examination of the type of discourse that occurs within mathematics lessons. As a result of various units of analysis within the community of practice, we are able to explore associations between teacher attributes, context, and mathematical discourse.

Related Research

Discourse

From a situative perspective, communication is essential to the development of mathematical concepts and therefore is a necessary component of quality mathematics instruction (Cobb & Bowers, 1999). If students are to engage in authentic practices of mathematicians, then they need opportunities to discuss mathematical ideas and justify their reasoning (Lave & Wenger, 1991).

When communicating ideas, students challenge and reinforce the learning within the classroom (Sfard, 2006). In order for this co-construction of knowledge to be possible, students must feel comfortable and supported in their efforts to dialogue with one another and the teacher. The sociomathematical norms are developed through interactions between the teacher and the students (Cobb & Yackel, 1996). The types of questions posed, opportunities for student-to-student discourse, and solicitation of students' ideas are ways that the teacher explicitly and implicitly sets the norms and builds the discourse community.

In addition to the overall participation of students in the community discourse, the level to which students explain and justify their reasoning depends upon the teacher's actions. As teachers press for further explanation, they can simultaneously model the "sophistication" expected within mathematical responses (Cobb & Yackel, 1996). Michaels, O'Connor, and Resnick (2008) state that teachers support "accountable talk" by holding students accountable to their reasoning and knowledge.

Teacher Attributes

The teacher is influential in the classroom community of practice (Lave & Wenger, 1991) by drawing upon his/her knowledge and beliefs when making instructional decisions, and in turn cultivating the community norms. First, teachers need specialized content and pedagogical knowledge, often referred to as mathematical knowledge for teaching (MKT), to effectively facilitate mathematics learning (Ball & Bass, 2003). Research has shown that teachers' MKT influences the use of standards-based instructional practices (Hill et al., 2008) and student achievement (Hill, Rowan, & Ball, 2005). This study takes a closer look at the discourse within the community of practice to better understand the relationship to teachers' MKT.

In addition to knowledge, research has indicated that teachers' instructional practices are related to their beliefs about mathematics (Stipek, Givvin, Salmon, & MacGyvers, 2001), beliefs about teaching and learning (Walshaw & Anthony, 2008), and beliefs about their own ability to teach (Beard, Hoy, &Woolfolk Hoy, 2010). The mathematics education field continues to sort out definitions within the beliefs literature (Philipp, 2002), but this study addresses teachers' epistemological beliefs (beliefs about the nature of mathematics and learning) and personal mathematics teaching efficacy (PMTE; Enoch, Smith & Huinker, 2000).

School Context

The school culture in which a classroom community of practice is situated has impacts on actualization of the teachers' goals for his/her classroom (Skott, 2009). Teachers specifically cite administrative and team-level support as influential in their instructional choices (Cobb, McClain, de Silva Lamberg, & Dean, 2003). This study accounts for teachers' feelings of support, specifically in regards to mathematics instruction.

Well documented within research is the relationship between socioeconomic status (SES) and students' mathematics achievement (e.g., Ma & Klinger, 2000). However, studies analyzing the associations between mathematics instruction and SES are often using broad categories such as procedural or conceptual instruction; there has been little attention to the interactions within the classroom. This study examines the discourse community and level of explanation and justification and their relationships to the overall SES of students.

Methodology

Participants

Participants in this study were 118 novice elementary teachers in their second year of teaching. Participants, with an average age of 23, taught in various elementary schools across one southeastern state and also completed their undergraduate teacher preparation program at public universities within the state. Propensity score matching (Fan & Nowell, 2011) was used to create a comparable sample based on college entrance characteristics including SAT/ACT and high school grade point averages. From this sampling technique, teachers were identified and recruited to participate. Overall, the sample was 98% Female and 85% Caucasian which is representative of alumni of the preparation programs. Descriptive analysis of school level information showed that 70% of teachers in the sample taught at schools that were classified as Title 1 schools and had over 50% of student receiving free and reduced price lunch.

The participants attended a one-day summer session before their second year of teaching. The session included: training on how to use an instructional log (not a focus of this study); training on how to effectively video record instruction; and data collection on a variety of surveys and assessments. The surveys and assessments utilized in this study will be described in the measures section. The training on video recording prepared the participants for recording three mathematics lessons (a focus of the current study) across their second year of teaching.

Nine teachers submitted 1 video, 18 teachers submitted two lessons, and 89 teachers submitted three or more lessons. Teachers with less than three lessons were retained in the analysis because past research using the same observational measure found that less than one percent of the variance in scores on the M-Scan measure (described below) was attributable to the number of observations (Walkowiak, Berry, Meyer, Rimm-Kaufman, & McCracken, 2014).

Measures

The level of Mathematics Discourse Community (MDC) and level of Explanation/Justification (EJ) are the two outcome variables. Dependent variables include teacher-level attributes related to knowledge and beliefs: MKT, PMTE, and EB. Also, school contextual variables are dependent variables and include school SES (percent free and reduced price lunch; FRPL), grade level, and perceptions of the school support.

Mathematics Scan (M-Scan) Observational Measure. The M-Scan is an observational protocol that measures the presence and extent of standards-based mathematics teaching practices (Berry et al., 2010). Of the measure's ten dimensions, this study specifically examines two: Mathematics Discourse Community (MDC) and Explanation and Justification (EJ). The indicators for MDC are *teacher's role in discourse, sense of mathematics community through student talk, and questions*. The indicators for EJ include *presence of explanation/justification* and *depth* of *explanation/ justification*. A trained observer rates a mathematics lessons on these dimensions using a 7-point scale that is divided into three levels: low (1-2); medium (3-5); and high (6-7). There are specific descriptions for each level that are thoroughly defined in the coding protocol. The M-Scan development team gathered sources of evidence of validity and score reliability (Walkowiak et al., 2014).

Mathematical Knowledge for Teaching (MKT) Measure in Number and Operation (N&O). The MKT-N&O measure consists of 26 items designed to measure teachers' mathematical knowledge for teaching number and operations (Hill, Schilling, & Ball, 2004). This particular form of the MKT was selected because a majority of K-5 content is focused on number and operations. Item response theory models (IRT) were used with the data and the IRT reliabilities for the different domains of the MKT-N&O were good to excellent, ranging from .71 to .84. Participants completed the MKT-N&O via an online interface; they were allowed to use paper and pencil. Scores were recorded in a master database as an IRT score relative to the national sample.

Mathematics Teaching Efficacy Beliefs Instrument (MTEBI). The PMTE subscale of the MTEBI measure (Enochs, Smith, & Huinker, 2000) is comprised of 13 items and uses a 5- point Likert scale (strongly disagree, disagree, uncertain, agree, and strongly agree) with "strongly agree" denoted by a 5. The PMTE subscale measures a teacher's belief in his or her own ability to effectively teach mathematics. In the developers' work, reliability analysis produced an alpha coefficient of 0.88 (N = 324) (Enochs, Smith, & Huinker, 2000).

Mathematics Experiences and Conceptions Surveys (MECS). The MECS (Jong, Hodges, Royal, & Welder, 2015) was designed to measure pre-service and novice teachers' attitudes, beliefs, and dispositions toward mathematics teaching and learning. This study utilizes the beliefs subscale from the MECS-Y1 version, which is designed for teachers in their first three years of teaching. Validation work (Jong et al., 2015) reported relatively high reliability of this subscale (α= .78). To provide a more precise categorization of epistemological beliefs (EB), an exploratory factor analysis was conducted and revealed three factors within the beliefs domain, which are classified as epistemological beliefs about the nature of mathematics (Nature, α= .60), epistemological beliefs about the use of calculations (Calculations, α= .70), and epistemic value of mathematics (Value, α= .81). These three subgroups are used in the analysis.

Teachers' perceptions of school level support for mathematics instruction (TPSS). Participants also responded to 6 items that gauged their perceptions of barriers within their school to quality mathematics using the *scale significant problem*, *somewhat of a problem*, or *not a significant problem*. An index of TPSS (possible range 6-18) was created from these items to provide a measure of the level of support the teacher felt in regards to mathematics instruction.

School contextual variables. A measure of the school's SES was created using the percentage of students receiving free or reduced price lunch (FRPL). The grade level for each teacher was recoded to create a grade band variable. Kindergarten, first, and second grades were considered primary grades, while third, fourth, and fifth grades were considered intermediate grades.

Analysis

The first step in the quantitative analyses was to measure the discourse present in each lesson using the M-Scan observational measure. A team of five coders was trained on the M- Scan observational protocol during a 12-hour training facilitated by a co-developer of the measure. Each coder established 80% within-one in comparison to the master coder on each of the 10 dimensions. The team met every other week for drift check meetings.

Next, to allow for more meaningful interpretation of results, z-scores were calculated for participants' MKT scores. Other dependent variables including PMTE, EB subscales, FRPL, and TPSS were grand-mean centered to provide a meaningful zero. That is, zero for each variable is interpreted as the sample mean and allows results to be interpreted in reference to this sample.

Central to the study, a series of multilevel means-as-outcomes analyses were performed using SAS software to examine the proportion of variance in the classroom discourse dimensions, MDC and EJ, that is explained by teacher attributes and school context. By examining the variability in MDC and EJ across multiple lessons, multilevel modeling (MLM) is a powerful and flexible approach compared to techniques, such as multiple regression, because estimates of both between-

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

person and within-person variability are possible (Lee & Bryk, 1989). Additionally, multilevel modeling uses all available data from each participant and can effectively manage unequal data (Raudenbush & Bryk, 2002).

MDC and EJ were entered into the model as Level-1 variables. Each teacher's PMTE score, EB subscales, and MKT score were entered as Level-2 variables because they describe attributes of the teacher. School contextual variables, FRPL, TPSS, and grade level, were entered as Level-2 variables due to the fact that TPSS represents teachers' perceptions of their school support, grade-level is viewed a classroom characteristic, and school level variables are associated with teacher due to the fact that teachers are not at the same school.

A fully unconditional model/null model (Raudenbush & Bryk, 2002) was conducted to determine the variability within teachers (Level 1) and the variability between teachers (Level 2) on the variables of MDC and EJ. The null model for each dependent variable, MDC and EJ, would serve as the reference to explain variation within the sample. This model was conducted to ensure that there was sufficient variability at Level 2 to warrant continuation with analyses.

Next, a sequential Means-as-outcomes Regression was conducted to test the main effect of predictors at Level 2 (i.e., MKT, PMTE, EB subscales, and TPSS) on teachers' MDC and EJ, separately. First MKT was entered into the model, followed by teacher attributes (PMTE, EB subscales), and lastly school contextual factors (FRPL, TPSS, grade level). For each model, significant main effects, significant interactions, and percentage of variance explained between teachers were examined.

Results

Results from the full unconditional or null model indicated that 37% of the variability in the level of MDC was between teacher (τ_{00}= .51, z=4.57, p<.001) and 63% was within lessons for an individual teacher (σ^2=.88, z=10.50, p<.001). The fully unconditional model for EJ indicated that 33% of the variability in the level of EJ was between teacher (τ_{00}= .75, z=4.25, p<.001) and 67% was within lessons for an individual teacher (σ^2=1.51, z=10.46, p<.001). These results indicated sufficient variability for further analyses.

Mathematical Discourse Community (MDC)

Table 1 displays the results of the multilevel analyses for MDC. When MKT was entered into the model by itself (Model 2), it was marginally significant (p=.06). However, when controlling for efficacy and the EB subscales, MKT was not a significant predictor of the level of MDC (Model 3). The Nature subscale was a significant predictor of the level of MDC (p<.05). That is, teachers with more sophisticated/standards-based beliefs about the nature of mathematics also tended to have higher levels of MDC within their lessons on average, when controlling for levels of MKT and PMTE. For each scale point increase in the *Nature* score, the MDC score on average would increase .08 points. In comparison to the null model, Model 3 accounted for 24% of 37% variance between teachers.

In the next step (Model 4), school context variables were added. When controlling for all other variables, *Nature* (p<.05), FRPL (p<.05), and TPSS (p<.05) accounted for a significant amount of the variance between teachers in their scores on MDC. For each unit increase in the *Nature* score, one would expect the average MDC score to be .13 units higher while for each unit increase in the FRPL percentage, one would expect an average decrease of .80 units on MDC. Finally, for each unit increase in TPSS, the expectation is a .06 unit increase in MDC. Overall, Model 4 accounts for 24% of 37% variance between teachers on their MDC scores.

Table 1: Estimated Effects of Teacher Attributes and School Context on the Level of Mathematical Discourse Community

Fixed Effects, MDC, β_0		Model 1 DF=118	Model 2 DF=115	Model 3 DF=109	Model 4 DF=100
		(SE)	(SE)	(SE)	(SE)
Intercept, γ_{00}		3.78**(.08)	3.79** (.08)	3.79** (.08)	3.79**(.11)
Teacher Attributes

$**p < .001, *p < .05$

Explanation & Justification (EJ)

Subsequently, models were fit to examine the relationships between all dependent variables and EJ (see Table 2). MKT was entered into the model alone (Model 2), and it was a significant predictor of EJ ($p<.05$). In the next step, controlling for PMTE and the EB subscales, MKT remained a significant predictor of the level of EJ ($p<.05$), and the *Nature* subscale was significant as well ($p<.05$). That is, for each unit increase in MKT score, EJ was expected to increase .22 units. Also, teachers with more sophisticated/standards-based beliefs about the nature of mathematics tended to have higher levels of EJ within their lessons, and for each scale point increase in the Nature score, the EJ score on average would increase .13 points. In comparison to the null model, this model accounted for 14% of 33% variance between teachers on their EJ scores.

In the final step, school context variables were added. When controlling for all other variables, MKT ($p<.05$), and *Nature* ($p<.05$) remained significant predictors of EJ, while no school contextual variables were significantly related to the level of EJ. When controlling for the other variables, for each unit increase in a teacher's MKT score, one would expect the average EJ score to be .24 units higher. For each unit increase in the *Nature* score, an increase of .17 on EJ is expected. This model accounted for 23% of the variance between teachers on EJ scores.

Discussion

The purpose of this study was to examine teacher attributes and school context in regard to their relationship to the overall mathematical discourse community and the level of student explanation and justification in novice teachers' mathematics lessons. MKT had a significant positive relationship with the level of EJ in a teacher's lesson, but did not impact the MDC. That is, a teacher's level of MKT does not seem to influence their likelihood to solicit student ideas or allow opportunities for student-to-student talk, but it does impact the level of questioning posed to promote students' explanation of ideas. This aligns with previous studies that have shown that teachers with higher MKT are more likely to respond to students' thinking and provide rich opportunities with the mathematics (Hill et al., 2008). This finding supports programmatic efforts within teacher preparation programs that strive to increase PTs' MKT.

$**p < .001, *p < .05$

The field continues to diverge in their conceptions of epistemological beliefs. This study teases apart distinct elements of epistemological beliefs and found that teachers' beliefs related to the nature of mathematics were predictive of the MDC and the level of EJ within their classrooms. It seems plausible that a teacher must believe that mathematics is an interactive discipline before employing discourse-based teaching strategies. This finding confirms the importance of attending to and explicitly addressing PTs' beliefs because beliefs may be a border preventing some teachers from constructing opportunities for classroom discourse.

School contextual variables, FRPL and TPSS, also accounted for differences between teachers' MDC. Teachers within schools with higher FRPL had lower levels of MDC, meaning that on average students of low SES had less opportunity for sharing their ideas with their teacher and fellow classmates. This finding supports previous research that students of SES receive more procedural instruction (Desimone & Long, 2010) in that procedural instruction is less likely to include discussions of ideas. Also, teachers reporting higher levels of school support in regards to mathematics instruction were also more likely to solicit student ideas and allow time for students to discuss mathematical ideas with one another. This positive relationship between the school culture and classroom practice has implications for administrators and instructional support personnel (e.g., coaches) as they work to promote quality instruction. Messages need to align between the mathematics education field and the school culture to advance discourse-rich classrooms. School context is influential; next steps for this work will include a more in-depth examination of the discussions in classrooms of a variety of SES. SES should not be a border that keeps some students out of mathematical conversations because it is those conversations that provide access to the mathematics.

Here, we report on the development of a theoretical framework for mathematics teaching that looks aside from common traditional / reform dichotomies. Attention is focused on managing the amount of new information students must attend to, while structuring that information in a manner that allows discernment of key features and continuous extension of meaning. Drawing on and combining ideas based on mastery learning and on the variation theory of learning, we propose an alternative where fluency and emergent knowing are inseparable and mutually reinforcing, and motivation is based on success and the challenge of pressing the boundaries of knowing. Gains in student achievement associated with this framework have been significantly faster than national norms.

Introduction and Purpose

Recent calls to find a balance between allegedly opposite instructional approaches—commonly dichotomized as "traditional" and "reform" approaches—have at times posited these extreme approaches as complementary, suggesting that the two may productively interact. For instance, Ansari (2015) claimed that "[I]t is time to heed the empirical evidence coming from multiple scientific disciplines that clearly shows that math instruction is effective when different approaches are combined in developmentally appropriate ways" (para. 14). In this paper, we argue that such seemingly contradictory approaches are in fact very similar in significant ways and propose a 'third way' that addresses important features not stressed by either approach.

The work reported here developed from our work with the Math Minds initiative, which is a five-year partnership between a large school district, a mathematical charity, a children's support group, a university education faculty, and a funder. It is aimed at improving mathematics teaching and learning at the elementary level. More specifically, it aims to deepen understanding of relationships between teachers' knowledge, curricular resources, professional development, and students' performance, a combination not commonly addressed in the literature. In particular, we are working to identify features of resources that can support the development of teachers' mathematical knowledge for teaching. Here, we outline key principles that we have identified as significant for teaching mathematics and then contrast these principles with other approaches. While our primary aim here is theoretical, we also provide a brief statement regarding impact on student achievement.

Theoretical Perspectives

While there are widely varying approaches to teaching mathematics, most approaches may be placed somewhere along a continuum with respect to the degree of emphasis they place on (A) mastery of fixed algorithms as a means of achieving procedural fluency and (B) conceptual understanding and mathematical process (*cf*. Star, 2005). They may similarly be placed along a second continuum according to the degree of (A) teacher guidance or (B) student responsibility for developing their own strategies and procedures (*cf*. Chazan & Ball, 1999). While both A's are often

associated with traditional approaches to teaching mathematics and both B's are often associated with reform approaches (*cf.* National Council of Teachers of Mathematics [NCTM], 1989), even attempts to balance (A) and (B) must by definition buy into one or both dichotomies (*cf.* Ansari, 2015; NCTM, 2006; Common Core State Standards Initiative [CCSSI], 2015). What we propose is not a compromise, but something that shifts attention to features seldom addressed by either: In this light, A's and B's emphases turn out to have some surprising similarities. Perhaps most notably, both A and B (and points between) typically require students to attend simultaneously to multiple pieces of new information.

Although the notion of cognitive load has been primarily used to critique Type (B) (*cf.* Kirschner, Sweller, & Clark, 2007), it can also lead to difficulty in Type (A) approaches that present complex procedures that require simultaneous attention to multiple pieces of new information. Here, Marton's (2015) Variation Theory of Learning provides a helpful framework for analysis. Marton argued that "we can only find a new meaning through the difference between meanings" and that "the secret of learning is to be found in the pattern of variance and invariance experienced by learners" (p. xi). More specifically, these patterns of variation are divided into three main categories: contrast, generalization (or induction), and fusion. Contrast allows separation or discernment of a critical feature by varying only the thing one wants to draw attention to; generalization separates the ways a previously discerned feature or object can vary, and fusion recombines features that have been separated. When variation is not carefully structured, learners may overlook significant discernments critical to the intended object of learning. In addition, individual items may be perceived as either unique and difficult or as boring and repetitive, with no further meaning to be potentially gleaned from the juxtaposition of different items or from their combination in increasingly complex arrangements.

Type (B) approaches typically aim to engage students in mathematical contexts that help them make sense of mathematical relationships through processes such as problem solving, reasoning, proof, communication, representation, and making connections (*cf.* CCSSI, 2015; Kilpatrick, Swafford, & Findell, 2001; NCTM, 2000; Western and Northern Canadian Protocol, 2006). While it is possible to attend to these features in conjunction with mastery and careful variation, the importance of doing so is typically not made explicit. For example, in our own work outside of this project, we have noted that with an emphasis on multiple strategies, students have often remained unaware of the connections between them. Problems too complex for students to unpack on their own have prompted teachers to do so *for* them. Further, some students have engaged in ways that allowed them to bypass key learning objectives.

In documenting the difficulties teachers sometimes face when transitioning away from transmission-based models of math instruction (Type A), Swan, Peadman, Doorman, and Mooldjik (2013) noted that teachers may "at first withdraw support from students and then recognise the need to redefine their own role in the classroom" (p. 951). In our work, we have not asked teachers to begin with complex problems nor to withdraw key supports but have instead focused directly on what *different* supports might look like, and how these might contribute to both sense-making and continuous extension of mathematical knowing.

A key motivating principle of this study is the conviction that virtually all students are capable of learning challenging material (in our case, mathematics) if given appropriate supports (Bruner, 1960). From the outset, we discussed with teachers the importance of nurturing a growth mindset (Blackwell, Trzesniewski, & Dweck, 2007), which includes the belief that mathematical ability is learnable rather than innate. We explicitly advocated a mastery approach to learning (Guskey, 2010), with an emphasis on parsing material into manageable pieces, assessing continuously (also see Wiliam, 2011), moving forward as students demonstrate independent mastery, and extending as needed to ensure challenge for all. We further distinguish our approach through use of what we call *micro*-variation, in which we treat variations that might otherwise be seen as trivial as legitimate

obstacles (Metz et al., 2015). By structuring variation in a responsive manner, we have worked to nurture classroom environments where all can succeed and be challenged. Motivation is thus based on success and continuous growth (Malone & Lepper, 1987; Pink, 2007).

Building on the Marton's Variation Theory of Learning (*cf.* Gu, Huang, & Marton, 2004; Kullberg, Runesson, & Mårtensson, 2014; Marton, 2015; Park, 2006; Runesson, 2005; 2006; Watson & Mason, 2005; 2006), we have worked to avoid the fragmentation that can happen when curricula are parsed into tiny pieces. By using systematic variation (Park, 2006) to draw attention to key ideas that are often overlooked and by considering how these may change within and eventually between topics, we have aimed to support the development of rich webs of interconnected understanding (for both teachers and students). These webs then allow the continued emergence of new understanding (Davis & Renert, 2014).

Mode of Inquiry

We began the study with the intent of exploring the impact of a mastery approach to learning with an explicit focus on structured variation. The study draws on multiple sources of data (classroom observation, video-taped classes, teacher and student interviews, informal conversations with teachers, and standardized tests) to inform next steps. The principles that currently guide our work have been both informed by and used to inform a supporting resource and an associated professional development program for participant teachers. The primary study site is a small K-6 elementary school with a history of low achievement. Our work is consistent with Cobb, Confrey, diSessa, Lehrer, and Schauble's (2003) description of design-based research in that it involves "both 'engineering' particular forms of learning and systematically studying those forms of learning within the context defined by the means of supporting them" (p. 9). Also consistent with a design focus, our work has been subject to ongoing test and revision, continuously informed by classroom observations and interactions with teachers and students. It has also developed in response to insights gained through regular meetings among members of the research team and meetings involving the research team, school leaders, and a representative from the teaching resource used to support the initiative. Relationships among initiative partners are deeply reciprocal: School leaders contribute their expertise and inform the other partners of school-based needs as well as learn from the expertise of the others; the person who represents the resource offers support to both teachers and to the research team in accessing key features of the resource and maximizing their potential, while also gathering feedback that will be used to improve the resource. The research team relies on the insights and expertise of the school-based leaders and the resource representative, while offering feedback based on research observations.

As part of the initiative, teachers were provided with guides, resource materials, and student materials that support our emphases on growth mindset, mastery learning, continuous assessment, and careful attention to variation. With these in place, ongoing professional development has emphasized the importance of appropriate parsing and pacing of instruction, continuous assessment and feedback, and strategies for extending work beyond that provided in the resources. In working with teachers as they attempt to use these ideas and materials, we have found it useful to clarify distinctions between this approach and the more familiar (A) and (B) approaches described earlier as dichotomies; while perhaps overgeneralized if taken all together and taken in their extreme forms, these have provided useful points of contrast for what we here describe as approach (C).

Distinguishing a Third Way

We now offer a summary of our current thinking on these matters. Here, we refer to (A) and (B) to elaborate the dichotomies we presented earlier, while (C) represents our own current thinking. Importantly, we see (C) not as a balance but as something significantly different from either (A) or (B). Perhaps most notably, (C) *asks students to attend to one new idea at a time, where both (A) and*

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

(B) tend to require simultaneous attention to multiple topics, whether those be (A) elements of complex procedures or (B) multiple topics / strategies. By systematically varying one thing at a time, (C) invites continuous extension and elaboration of meaning rather than the articulation of meaning found in given applications (as is common in A) or broad contexts (as in B). Therefore, in (C), fluency and understanding are mutually supporting rather than competing. Considerations of the role of practice follow closely from these views, with (A) using repetitive practice to build fluency, (B) using embedded practice presumably made meaningful through context, and (C) offering practice through continuous extension. Positions (A) and (B) tend to result in a wide range of achievement: In (A), some students successfully master content, while others do not, where (B) intentionally allows multiple entry points and open-ended paths. Position (C) supports the mastery of a common base of understanding that may be personalized through extension.

In working with teachers, we have found it important to draw attention to the manner in which selected resources offer variation, both so that teachers can draw student attention to such variation and so that they can adapt given examples in ways that support struggling learners and those who require extension. In Tables 2 and 3, we offer examples to clarify the distinctions we are attempting to make; here, Task Sets A, B, and C correspond to the same distinctions we have described in terms of a traditional (A) / reform (B) dichotomy and a proposed alternative (C).

In Table 1, Task Set A offers focused practice with grouping coins to make particular values, but both the values and the numbers of coins vary from item to item. As a result, there is limited value in looking for connections between individual items: The sequence does little to scaffold such relational thinking. For instance, a student fluent in calculating differences might note that moving from $0.30 to $0.45 with two additional coins would require an additional dime and nickel. However, a similar transition makes less sense in moving from $0.45 to $0.55 with three additional coins. In addition to regrouping coins, working effectively with Set B requires a systematic approach to finding *all* combinations. If both re-grouping money values and exploring combinations are new to students, this question likely varies too much at once; importantly, only students who work systematically are exposed to meaningful variation among items, while others may choose a more random approach to finding possible coin values. In Set C, only the number of coins varies, and students are not (*yet*) responsible for *creating* the variation that prompts attention to relationships between subsequent items (as in Set B).

Table 1: Three ways to vary coin-grouping tasks

A	B	C
Using quarters, dimes, and / or nickels: Make $0.30 with 3 coins. Make $0.45 with 5 coins. Make $0.55 with 8 coins. Make $0.60 with 6 coins.	Find all the ways to make $0.45 with quarters, nickels, and dimes.	Using quarters, dimes, and nickels: Make $0.45 with 3 coins. Can you do it with 4 coins? Can you do it with 5 coins? Can you do it with 7 coins?

In Table 2, the distinctions between the sets are perhaps even more pronounced. In Set A, the numbers were chosen to allow variation in the size of number and number of factors (though of course bigger numbers do not always have more factors); while this may offer practice with creating factor trees, it does little to direct attention to ways that prime factors can make particular number structures visible, as too many features change from item to item. To successfully complete Set B, students must discern many relationships between prime factors and factors, not the least of which is that a particular pattern of unique and non-unique prime factors will always yield the same number of factors (e.g. 2 x 2 x 3 has the same number of factors as 3 x 3 x 5, as both follow an a x a x b pattern); here, the onus is on students to organize their work in a manner that allows exploration of

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

particular patterns of variation. If they fail to do so, the variation they experience will be largely random. By carefully controlling how much is changing, Set C1 can be used to draw attention to the fact that regardless of how a number is factored, the prime factors are always the same (which is not obvious to many students). Similarly, C2 draws attention to patterns in the structure of numbers; teachers and students alike are sometimes surprised to discover that doubling a number does not double the number of prime factors.

Table 2: Three ways to explore prime factors

A	B	C1	C2
Make factor trees for each of the following: 15 18 40 60	What is the smallest number with 14 divisors? Use patterns in prime factors to help you explore this problem.	Make a factor tree for 36. Can you do it another way? Another? Another? What is the same/different about your solutions?	Make a factor tree for each of the following. In each set, what changes from one to the next? 8, 16, 32, 64 5, 25, 125, 625 10, 100 1000, 10,000 25, 50, 75, 100

In sessions for professional development, we have observed that teachers who worked through these examples noted that the tasks in the (C) sets made it easier for them to recognize important ideas as well as to create their own extensions (something that most have struggled with): They, too, were prompted to think differently by this arrangement of content. In other words, when a resource offers clearly structured variation, both teachers and students engage differently with the content. This is not to say that the tasks in A and B have *no* place if properly contextualized within an appropriate sequence; rather, our key point is that *C serves a critical purpose that is often overlooked.*

While our aim here is primarily theoretical, we note that evidence based on weekly classroom observations shows students who previously struggled have become more willing to take part, and many students have become excited to keep pushing their understanding to new levels. We have also noticed a consistent improvement in mathematics basic skills. The school's total math scores on the Canadian Test of Basic Skills (Nelson, 2014) improved over a two-year period at a rate that was significantly faster than the national normed population gains [$F(2,70)=6.977$, $p=.002$]. Overall, the model indicates that the mean total math score increased from an estimated average score of 43.5 (national average=50) to that of 47.0 [$t(60.42)=3.732$, $p<.001$], with roughly equal gains over the national normed population in each year (year one = +1.7%, year 2 = +1.8%).

Conclusions & Significance

The approach briefly described in this paper resembles current research emerging in the UK that has emphasized combining mastery learning with structured variation (*cf.* National Centre for Excellence in Teaching Mathematics, 2014; Schripp, 2015). Two features that set our work apart from these efforts are (a) the emphasis on what we have been referring to as *micro-variation* and (b) attention to intrinsic motivation by using micro-variation to continuously elaborate understanding

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

and increase levels of challenge in ways that are accessible to all. We argue that it is not enough to combine instructional approaches; rather, it is necessary to transcend the borders of restrictive dichotomies. As we suggested in the beginning, we see (C) as an alternative to approaches that, when considered in terms of how content is structured, turn out to be more similar than typical traditional vs. reform dichotomies suggest. Based on results from the first three years of the program, we propose that combining mastery learning and structured variation in a context that attends closely to continuous assessment, intrinsic motivation, and emergent knowing holds great promise for improving student achievement in mathematics and for supporting teachers in achieving these goals.

Considering this third way opens up new avenues for research. It will be important to investigate strategies to support teachers who are using this approach. We are interested in the interaction between educational curricular material and teachers' knowledge.

EQUITABLE PARTICIPATION IN A MATHEMATICS CLASSROOM FROM A QUANTITATIVE PERSPECTIVE

Inequity is a pressing concern in the mathematics education community. Recent research shows how inequity in everyday classroom interaction can shape student participation in subtle ways. This paper focuses on a tool, EQUIP, which uses a quantitative approach to illuminate aspects of such inequities. EQUIP cross-tabulates relatively low-inference indicators of classroom interaction with demographics (e.g., gender, race), in order to highlight inequities in participation across different groups of students in a given classroom. We present analyses of whole-class discussions in an elementary mathematics classroom taught by an experienced teacher with strong commitments to equity. Findings show that even though in most ways participation was distributed equally by gender and race, an intersectional analysis revealed statistically significant inequities for Latin@ male student participation.

Keywords: Equity and Diversity, Classroom Discourse, Gender, Research Methods

Equity is a theme that cuts across seminal policy documents in mathematics education (National Council of Teachers of Mathematics, 1989, 2014; National Research Council, 1989). The fundamental idea is that mathematics should be accessible to all students, rather than to only the privileged few (Ernest, 1991; Gutiérrez, 2002). And yet, while there has been some progress on this front, research shows that mathematics remains relatively inaccessible for children of color, young women, and students living in economically marginalized communities (Oakes, 2015).

In researching equity at the classroom level, prior research has conceptualized equity in terms of students' access to opportunities to participate in mathematical discourse and classroom activities (Esmonde, 2009; Herbel-Eisenmann, Choppin, Wagner, & Pimm, 2011; Langer-Osuna, 2011). Grounded in sociocultural perspectives that view participation and learning as fundamentally linked (Lave & Wenger, 1991; Nasir, 2002), much of this work has utilized qualitative methodologies. Indeed, our own work to date on equity in mathematics classrooms has been qualitative in nature (see Shah, 2009, 2013). However, the resource-intensive nature of high quality, in-depth qualitative analysis can make it difficult to conduct such research on a large scale. In this paper, we ask: what are the potential affordances (and limitations) of a quantitative approach to analyzing equity in classroom interaction, and how might quantitative approaches complement extant qualitative methodologies?

This paper introduces a classroom observation tool for analyzing equity-related patterns in classrooms called EQUIP (**E**quity **QU**antified **I**n **P**articipation). EQUIP offers a way of gathering and analyzing quantitative data on relatively low-inference dimensions of classroom participation. To illustrate our approach, we present an analysis of participation patterns in an elementary mathematics classroom taught by a highly experienced teacher with strong commitments to equity. Findings show that while in most ways participation was distributed equally by gender and race, an intersectional analysis (i.e., cross-referencing gender and race) revealed significantly lower levels of participation for the Latin@ males in the class. We argue that a quantitative methodological approach made it

possible to identifying this inequity for Latin@ males, which otherwise may have been too subtle for even an equity-minded teacher to notice. We conclude by reflecting on how quantitative and qualitative methodologies for studying equity in mathematics classrooms might complement each other.

Conceptualizing Equity in Terms of Participation

Equity and equality are distinct concepts and should not be conflated. Whereas equality means that all students are treated in an identical manner, equity means that students should be treated in a fair manner (Gutiérrez, 2002; Secada, 1989). Achieving equity might involve one group of students being treated differently than another group of students. However, in certain situations, equality can be thought of as a baseline, or minimum requirement, for equity.

From a theoretical standpoint, we follow other researchers in conceptualizing equity in terms of student participation in classroom practices (see Boaler, 2008; Esmonde, 2009; Langer-Osuna, 2011). All students should have opportunities to participate in the disciplinary practices constitutive of the learning process, such as sharing ideas, asking questions, and justifying one's reasoning (Bransford, Brown, & Cocking, 2000). In order to provide students such opportunities, teachers should allot students ample time to engage in classroom discourse (Ball, 1993; Cazden, 1988;).

Equitable participation is about both *who* participates and *how* students get to participate (Wager, 2014). On a basic level, an equitable classroom can operationally be defined as one in which the amount of participation proportionally aligns with the demographics of the class. For example, if Black students make up 21% of the students in the class, then approximately 21% of class participation should be by Black students. However, beyond the issue of *who* participates, opportunities to participate should also be of a cognitively demanding nature (cf. Stein, Grover, & Henningsen, 1996). A classroom where all students participate—but only in low-level, Initiate-Response-Evaluate sequences—would be considered less equitable because students are not afforded opportunities to act as sense-makers.

Intersectionality

Building upon decades of work by activists, Kimberlé Crenshaw coined the term *intersectionality* to highlight complexities in the lived experiences of women of color that cannot be captured by examining race or gender alone (Crenshaw, 1991). Taking up intersectionality in Black feminist studies, Patricia Hill Collins defines intersectionality as "particular forms of intersecting oppressions," noting that "intersectional paradigms remind us that oppression cannot be reduced to one fundamental type, and that oppressions work together in producing injustice (Collins, 1999, p. 18). Mathematics education researchers have also leveraged intersectional perspectives to address issues of equity that affect traditionally and historically marginalized students in schools (e.g., Esmonde & Langer-Osuna, 2013; Gutiérrez, 2013). As we will show, our work is informed by the concept of intersectionality.

Methods

Video data were collected during a two-week, university-based elementary mathematics summer program. The program consisted of 30 hours of instructional time (3 hours per day, for 10 days), which focused on fraction representations and how to participate in mathematical discourse. A typical class session involved small-group work, individual work, and whole-class discussions (WCDs). The course instructor had over 30 years teaching experience and a strong disposition towards equity. During the program, the instructor collaborated with various colleagues in the mathematics education community to discuss pedagogical issues, such as how to manage equitable student participation.

The program consisted of 30 rising 5th grade students, who had been identified as struggling at

their home schools by coordinators of the summer program. Racial demographics were as follows: 21 (70%) Black Students, 5 (17%) Latin@ students, and 4 (13%) White students. Gender demographics were evenly distributed between male and female students within each racial category. The forthcoming analysis focuses on classroom interactions in WCDs, which are a centerpiece of mathematics classrooms at all grade levels, and thus represent an important context for study.

Analytical Approach

The field has produced observation tools for analyzing mathematics classroom activity, several of which account for issues of equity (e.g., Schoenfeld, 2014; University of Michigan, 2006). However, a limitation of these tools—perhaps because equity was not their primary conceptual focus—is that they do not illuminate how opportunities to learn can become inequitably distributed across markers of difference (e.g., gender, race, language proficiency). The EQUIP analytical approach is predicated on three basic equity-related questions: 1) who gets to participate; 2) what is the nature of that participation; and 3) how are different forms of participation distributed across the students in the class? That is, do all students participate in cognitively rich ways, or are those opportunities only made available, for example, to the White and Asian students, or male students, or English dominant students in the class?

EQUIP uses "participation sequences" as a fundamental unit of analysis. A participation sequence is a consecutive sequence of verbal turns between a single student and a teacher. When another student speaks, a new participation sequence begins. Each participation sequence is coded using the following relatively low-inference dimensions of participation: *WCD type, solicitation method, student wait time, talk length, type of student talk, teacher solicitation, and explicit evaluation*. These dimensions concern: whether or not the discussion was mathematical (*WCD type*); whether and how the teacher solicited the student's participation (*solicitation method*); the level of mathematical explanation requested of the student (*teacher solicitation*); the time allotted by the teacher prior to the first verbal turn in the participation sequence (*wait time*); the level of mathematical explanation provided by the student (*type of student talk*); the most number of words uttered by a student in a single uninterrupted talking turn (*talk length*); and whether or not the teacher verbally assessed a student's response (*explicit evaluation*).

Findings

Overall, the data show considerable evidence of equitable classroom activity. The interactive style of WCDs in this particular classroom provided students opportunities to participate in rich mathematical discussions. This is evidenced by: the length of student talk, long wait time, and minimal explicit evaluation by the instructor. With respect to the length of student talk, students contributed on average 31 words per participation sequence, which indicates participation that goes beyond abbreviated or simple contributions. Further, wait time exceeded three seconds in 71% of participation sequences, which indicates that students were given time to think before responding to teacher solicitations. Finally, the teacher did not explicitly evaluate student responses in 80% of participation sequences.

In the next sections, we complexify these initial findings by disaggregating the data by gender and race, as well as by conducting an intersectional analysis by gender and race simultaneously.

Disaggregation by Gender

There were generally equal levels of participation for male and female students. We used a chi-squared test to determine whether there were any statistically significant differences in the quantity and quality of participation. Table 1 focuses on three dimensions measured by EQUIP that provide information about student participation: participation sequences, WCD type, and the type of student talk. For participation sequences, there was no significant difference by gender. For WCD Type, a

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

chi-squared analysis also showed no difference by gender in student participation across mathematical and non-mathematical WCDs, $X^2 = 0.2193$, $p > 0.05$. For type of student talk, a chi-squared analysis also showed no difference by gender across four different types of student talk, $X^2 = 4.1227$, $p > 0.05$. While three dimensions related to teacher moves did show significant differences by gender, the effect sizes (Cramer's V) were "small" or "very small."

Table 1: Participation Sequences for WCD Type and Student Talk by Gender

	Participation Sequence ($n = 1343$)	WCD: Math ($n = 1067$)	WCD: Non-math ($n = 276$)	St. Talk: What ($n = 393$)	St. Talk: How ($n = 40$)	St. Talk: Why ($n = 321$)	St. Talk: Other ($n = 586$)
Female	647 (48%)	518 (80%)	129 (20%)	205 (32%)	21 (3%)	147 (23%)	273 (42%)
Male	696 (52%)	549 (79%)	147 (21%)	188 (27%)	19 (3%)	174 (25%)	313 (45%)

Disaggregation by Race

Compared with gender, analysis showed greater disparities in student participation by race. There were significant differences in student participation by race in nearly all of the dimensions. For the sake of continuity, this section focuses on the same three dimensions as in the previous section: participation sequences, WCD type, and the type of student talk (see Table 2).

For participation sequences, a chi-squared test indicated a significant difference by race, $X^2 = 18.581$, $p < 0.05$. The effect size (Cramer's V = 0.083) was small. As shown in Table 2, Black students were more likely to participate, while Latin@ students were less likely to participate. For WCD type, a chi-squared test indicated no significant difference by race, $X^2 = 0.1038$, $p > 0.05$. For type of student talk, a chi-squared test showed a significant difference by race, $X^2 = 11.1139$, $p < 0.05$. The effect size was very small (Cramer's V = 0.0644).

Table 2: Participation Sequences for WCD Type and Student Talk by Race

	Participation Sequence ($n = 1340$)	WCD: Math ($n = 1067$)	WCD: Non-math ($n = 276$)	St. Talk: What ($n = 393$)	St. Talk: How ($n = 40$)	St. Talk: Why ($n = 321$)	St. Talk: Other ($n = 586$)
Black	1018 (76%)	810 (80%)	212 (21%)	301 (30%)	32 (3%)	230 (23%)	458 (45%)
Latin@	150 (11%)	119 (79%)	30 (20%)	50 (33%)	5 (3%)	35 (23%)	57 (38%)
White	172 (13%)	138 (80%)	34 (20%)	42 (24%)	3 (2%)	56 (33%)	71 (41%)

Intersectional Analysis by Gender and Race

When considered independently, analyses indicated that, in general, participation by gender was more equally distributed, but that participation by race was somewhat inequitable. An intersectional analysis of gender and race revealed additional nuances in the equity dynamics of this classroom (see

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 3). For WCD type, a chi-squared test indicated a significant relationship, $X^2 = 30.2288$, $p < 10^{-7}$. Using a Fisher's exact test, we found that the effect size was small for mathematical WCDs (Cramer's V = 0.168) and medium for non-mathematical WCDs (Cramer's V = 0.292).

In addition to inequities in *who* participated in WCDs, we found inequities in the quality of student participation. A chi-squared test examining the relationship between the types of student talk and the intersection of race and gender showed that the relationship between the variables was significant for Why-level student talk, $X^2 = 15.5739$, $p < 0.001$. The effect size was small to medium (Cramer's V = 0.220).

A key finding here was that Latin@ male students in the class were much less likely to participate in Why-level Student Talk than any other group of students. From the previous discussion about racial patterns (Table 2), the data show that Latin@ students overall were less likely to participate in Why-level talk compared with Black and White students. However, the intersectional analysis reveals a gender disparity between Latin@ male and female students. In fact, in terms of the overall participation, the number of female Latin@ students' participation sequences was 2.75 times the number of male Latin@ students' participation sequences. This is striking in relation to the more modest differences between genders among both Black and White students.

Table 3: Participation Sequences for WCD Type and Student Talk by Race and Gender

	Participation Sequence (n = 1340)	WCD: Math (n = 1067)	WCD: Non-math (n = 276)	St. Talk: What (n = 393)	St. Talk: How (n = 40)	St. Talk: Why (n = 321)	St. Talk: Other (n = 586)
Black Female	447 (33%)	362 (81%)	85 (19%)	139 (31%)	16 (4%)	97 (22%)	194 (43%)
Black Male	575 (43%)	448 (78%)	127 (22%)	162 (28%)	16 (3%)	133 (23%)	264 (46%)
Latin@ Female	111 (8%)	85 (77%)	26 (23%)	38 (34%)	3 (3%)	27 (24%)	43 (39%)
Latin@ Male	38 (3%)	34 (89%)	4 (11%)	12 (32%)	2 (5%)	8 (21%)	14 (37%)
White Female	89 (7%)	71 (80%)	18 (20%)	28 (31%)	2 (2%)	23 (26%)	36 (40%)
White Male	83 (6%)	67 (81%)	16 (19%)	14 (17%)	1 (1%)	33 (40%)	35 (42%)

Discussion

A key takeaway from this study is that even in the classroom of an experienced, equity-minded teacher, inequities can emerge. In a sense, this is an important but unsurprising finding. Classrooms are complex spaces, and noticing subtle inequities can be difficult for even the most highly trained, well-intentioned teachers. Still, tools like EQUIP can support both researchers and practitioners in identifying inequities in classrooms. In our view, the methodological approach described here represents a step in that direction.

Overall, the data suggest that this was a classroom characterized by rich opportunities for students to participate in whole-class discussions. When disaggregated by gender and race, the data show minimal differences in participation. This is remarkable considering that there were over 1,000 participation sequences in the data set. However, an intersectional analysis revealed inequity in Latin@ male participation. Disaggregated analyses of this kind at increasing levels of granularity that account for intersectional subjectivities can provide important nuance to discussions of equity. This quantitative approach emphasizing relatively low-inference (but high leverage) dimensions of

classroom activity has the potential to facilitate research on equity at scale.

To be clear, in highlighting the affordances of this approach, we do not mean to suggest that equity can be reduced to a mere "technical" concern (Secada, 1989). Equity—as distinct from equality—revolves around deep philosophical questions of fairness and justice that cannot be fully quantified. Students' subjective experiences around issues of equity are also critically important (Martin, 2006). That is, independent of the numbers, students must also *perceive* classrooms to be equitable spaces. Thus, in the spirit of looking across methodological borders, our goal is to consider how quantitative and qualitative methodologies might complement each other in mixed methods approaches to researching issues of equity in classrooms.

FROM SPEAKING TO WRITING: THE ROLE OF THE REVERSAL POETIC STRUCTURE IN PROBLEM-SOLVING

Susan Staats
University of Minnesota
staats@umn.edu

Speakers in conversation typically repeat and modify earlier comments. In mathematics conversations, these repetitions, or poetic structures, can facilitate the collaborative discovery of mathematical relationships. A close analysis of 90 turns of an algebraic problem-solving conversation reveals eight types of poetic structures. This report summarizes the general results of the analysis and highlights the role of a particular type of poetic structure, the reversal. In a reversal poetic structure, two elements switch places syntactically, for example, subject and predicate or adjective and noun switch roles. Students working with no teacher intervention used the reversal poetic structure as they rearranged variables and coefficients in their verbal method, and as they transitioned from a spoken method to written mathematical notation. This analysis highlights the ways in which speaking supports mathematical thinking.

Keywords: Classroom Discourse, Problem Solving, Algebra and Algebraic Thinking

Introduction

Speakers of all languages repeat each other. Because repetition is pervasive in daily speech (Du Bois, 2014), it can contribute to mathematical problem-solving conversations. This paper highlights ways in which particular types of repetition—poetic structures—facilitate students' mathematical learning. Poetic structures occur when speakers repeat the grammatical structures of phrases spoken before, perhaps changing words or small aspects of grammar. This paper reports on the role of a particular poetic structure, the reversal, in an algebraic problem-solving session. In this mathematical conversation, the reversal poetic structure was associated closely with the transition from verbal problem-solving to written mathematical notation.

This study contributes to research on language as a resource for mathematical learning, which developed from studies of multilingual classrooms (e.g. Barwell, 2015; Planas & Setati-Phakeng, 2014). Language-as-resource research is concerned with issues such as code-switching, the influences of educational policy on classroom communicative practice, and language as a resource in formal vs. informal mathematics discourse. Collaborative learning pedagogies rely fundamentally on students' linguistic interaction. It seems intuitively correct that small changes to previous statements can account for collective mathematical constructions. Poetic structure analysis grounds this intuition in observable conversational actions. Because repetition is so commonplace, its analysis can deepen our understanding of the ways in which language facilitates learning in multilingual classrooms, or in monolingual classrooms in any language.

Theoretical Foundation

Dialogic syntax, an emerging research focus in linguistics, forms the theoretical foundation for this analysis (Du Bois, 2014; Sakita, 2006). Dialogic syntax recognizes that as speakers repeat prior statements—their own or those of others—they reproduce syntactic arrangements that create meaningful relationships across sentences and across speakers. Hearers decode and respond to the meanings that are created at these structural levels beyond the sentence. For example, in the hexagon task described in this paper, Sheila's *minus 2…times 2* is recast in Joseph's clarifying question:

78 *S:* So number of hexagons would be 4 times 6 minus n minus 2. So 4 times 6 would be 24. Number of hexagons would be 1, 2, 3, 4. 4, uh, times 2.

79 *J:* Times 2 or minus 2?

The verbs *minus* and *times* shift within Sheila's and Joseph's comments separately, and are repeated across their comments, while retaining focus on the direct object of *2*. This example highlights the ways in which speakers use repetition to negotiate mathematical conjectures. Dialogic syntax proposes this coordination as a "new, higher order linguistic structure…the coupled components recontextualize each other, generating new affordances for meaning" (Du Bois, 2014, p. 360). The field of dialogic syntax holds this exchange as a new type of grammar, in which linguistic structure is no longer confined to the sentence or to a single speaker.

Du Bois (2014) provides a useful review of the theoretical antecedents of dialogic syntax, which draw from a wide range of fields, including linguistics, anthropology, literary theory, and cognitive science. He identifies four foundational themes, some of which resonate with prior research in mathematics education. The first theme, parallelism, refers to the concrete repetitions within nearby utterances. In the example above, Joseph's *minus 2* is parallel to his *times 2*, and both are repetitions of the endings of Sheila's sentences. Staats (2008) highlights ways in which these parallel, poetic structures can express both inductive and deductive mathematical reasoning. Oslund (2012) uses poetic structures in teachers' narratives to trace their shifts across fraction metaphors that were familiar or unfamiliar to their students.

Underlying grammatical parallelism is the principal of indexicality, or the capacity of language to refer to or point to other words and to elements of the situational context. Indexical words like *this*, *that*, and variable names like *n* have been associated with mathematical activities such as generalization and collaborative learning (Barwell, 2015; Radford, 2003). Parallelism occurs when units larger than a word—*times 2*—"point to" corresponding units like *minus 2*, creating bundles of indexicality.

Du Bois' second theme, analogy, refers to the meanings created through manipulation of similar units. For example, *times* and *minus* are alternatives within the frame of mathematical operations. The third theme, priming, is the experimentally-measured tendency to repeat lexical or syntactic units (see Staats & Branigan, 2014 for a discussion of applications and limitations within mathematics education research).

The fourth theme, dialogicality, has received slightly more attention in mathematics education research. Barwell (2015) following Bakhtin (1981), discusses three orientations of dialogicality: multivoicedness, multidiscursivity, and linguistic diversity. The first of these, multivoicedness, recognizes that all speech has a history. Speakers recast words and meanings from their past interactions each time they talk. This paper provides an analysis of multivoicedness in a mathematical problem-solving session. Overall, then, dialogic syntax is a new framework for mathematical education research, but through its interdisciplinary character, it shares theoretical antecedents with research on language as a resource for mathematical learning.

Participants and Task

Sheila and Joseph are undergraduate students who participated in a paid problem-solving session outside of class that was audio- and video-recorded. They had recently completed a university class in precalculus. Their task was to find an equation for the perimeter of a string of *n* adjacent hexagons, arranged so that pairs of interior sides are removed from the perimeter. They worked for about 40 minutes without any teacher intervention; about nine minutes of the conversation are analysed here. The task includes diagrams for hexagon strings for n = 1 to n = 4 hexagons, shown in Figure 1. The task also includes a table of values for n = 1 to n = 5 hexagons and the corresponding perimeter. A correct answer is *p = 4n + 2*. The task was based very closely on a proposed measure of readiness for undergraduate study (Wilmot, Schoenfeld, Wilson, Champney, & Zahner, 2011, p. 287).

Figure 1. Task diagrams for *n* = 1 to *n* = 4 hexagons.

Methods for Identifying Poetic Structures

The first 90 turns of the conversation were coded using a spreadsheet to note the ways in which a phrase formed a poetic structure with a previously spoken phrase. It was necessary to develop a coding protocol because a phrase can repeat elements of several previous phrases. The coding approach relied on a combination of close attention to the syntax of poetic structures and grounded theory coding to iteratively improve the choices about what phrases counted as repetitions of prior statements (Charmaz, 2006). The resulting system was comparatively conservative. In Gries (2005), for example, any repetition of syntax counts as repetition, even if all the words change. The phrase *3 times 2* would be considered a repetition of the phrase *4 minus 1*, because both involve a subject-verb-object construction. However, mathematics education audiences are concerned with language that facilitates mathematical learning. To better focus on continuity of mathematical topic, then, two phrases had to share syntax and at least one word in order to be considered a repetition. When multiple previous utterances could have been the foundation of a repetition, I chose the most recent one. Overall, then, this method undercounts poetic structures in comparison with related linguistics research, because it prioritizes continuity of mathematical topic.

Each repetition was classified as either *Internal* or *Across*. An internal repetition refers to repetitions within a single turn at talk by a single speaker. An across repetition refers to repetition involving two distinct turns at talk. An across comment could refer to a comment that the same speaker said in one of her previous turns at talk, or to a comment from the other speaker. I recorded the most recent turn in which the phrase occurred, even if this was within the same speaker's conversational turn; what the earlier phrase was; whether there was a change in speaker; and whether the phrase was a nearly-perfect duplicate of the previous line or a transformation of it.

I separated the conversation into four episodes, each representing a mathematical insight that the students achieved together. In episode 1, turns 1- 28, Sheila and Joseph filled a table of values on the task sheet for n = 1 to 5 hexagons and the corresponding perimeter. In episode 2, turns 29-58, they determined that they should calculate perimeter rather than area. In episode 3, turns 59-71, they initiated the idea that the shared interior sides of the hexagon strings required them to subtract two, but they did not resolve how many times to subtract two. In episode 4, turns 72-90, they expressed a

correct verbal method, and wrote a formula in which both H and N stand for the number of hexagons, #H(6) – 2(N – 1) = .

Results: Types of Poetic Speech

A close analysis of 90 turns at talk shows that poetic structures occurred very frequently. Coding produced just over 50 across repetitions and just over 55 internal repetitions. Out of 90 turns at talk, about 30 were very short comments, such as *Okay*, *Yup* or *Oh, okay, there we go*, which were too short or non-mathematical to produce poetic structures under the coding protocol. On average, then, there were about 1.75 poetic structures per substantial conversational turn.

The analysis revealed eight types of repetitions that contributed to the discovery of mathematical relationships. There were in addition poetic structures of that didn't fall into a clear type. The types were: List, Echo, Comparison, Contrast, Interposed List, Consolidation, Expansion and Reversal. Elsewhere, I describe the ways in which these eight poetic structures allowed Sheila and Joseph to gradually construct a method for solving the hexagon problem through repetitions, with small changes, of recent statements (Staats, 2016). Here, I briefly describe each type of poetic structure and I discuss in more detail the role of the reversal poetic structure.

In Episode 1, echoes and lists predominated. Sheila and Joseph began their exploration by counting the sides of the n = 1 to n = 4 hexagon diagrams. As Sheila counted the perimeter of the n =1 diagram with: *1, 2, 3, 4, 5, 6. 6,* she used a list—from 1 to 6—and an echo in the form of the second "6." At turn 15, Joseph also used echoes and lists: *So, this would be 1, 2, 3, 4, 5, 6, 7, 8, 9, 10. 10.* The students began to fill the table for number of hexagons and the perimeter. An *Interposed List* at line 24, allowed Sheila to coordinate the independent and dependent variables: *so we're just putting in the 1 to 6, 2 to 10, 3 to 14.* At line 27, Joseph used a *Comparison* poetic structure, *22 for 5*, to extend the interposed list and to help complete the table of values.

In episode 2, Joseph suggested drawing additional interior line segments so that they could use the geometry of triangles and the formula P = 2L + 2W. Sheila suggested focusing on the exterior perimeter instead, and comments in line 52:

> 52 *S:* Complete the table showing the number of hexagons in 1 chain along with the perimeter. So then we're counting all the sides, so it'd be 6L. For 2 it'd be 1, 2, 3, 4, 5, 6, 7, 8, 9, 10. 10L.

This is a *Consolidation* poetic structure, because a list from a previous turn, *1, 2, 3, 4, 5, 6, 7, 8, 9, 10*, has been fit inside a previous comment from turn 24: *2 to 10*. Consolidation is similar to another poetic structure in this conversation, *Expansion*, which first occurs are line 62:

> 62 *S:* Uh, so this would be 6L. 6. And then this would be 10L minus 2. Minus 2. This would be 2, 4 minus 4. This would be 6. 18L. So the total number of sides minus 2 on this side. So it'd be, uh, 6. 6, and then this would be, uh, 12 minus 2. So.

Here, there is a poetic structure repetition of the form /*this would be 6L*/t*his would be 10L…*/*This would be 2, 4 minus 4*/ *This would be 6. 18*/. Here, the short list *2, 4* and a moment later, *6*, were the first attempts to count the interior sides. This is an expansion of the comment /*this would be 6L*/t*his would be 10L…*/ with a new list. Expansion differs from consolidation because expansion introduces a new element that had not been spoken before.

At turn 79, the *Contrast* poetic structure occurred, which we saw above, when Joseph clarified, *Times 2 or minus 2?*, The final type of poetic structure for this conversation, the reversal, is discussed more thoroughly below.

It is important to note that each of the eight poetic structure types is a discursive move that could easily occur in a non-mathematical conversation. Contrast could occur, for example, as *steamed rice or fried rice?* A comment *Mark has some advice for you* could prompt the reversal: *Well, I have*

some advice for Mark! Because these poetic structures are all general discursive options, when they occur in mathematics conversation, they help us identify moments when language is a resource for mathematical learning.

Discussion: The Role of the Reversal Poetic Structure

Different types of poetic structures emerged and were prominent in different episodes of the hexagon conversation. In Episode 1, for example, many of the poetic structures were simple ones— echoes or lists. The reversal poetic structure emerged in Episodes 3 and 4. In a reversal poetic structure, two elements switch places syntactically. For example, subject and predicate or adjective and noun switch roles, as in *10 minus 12* versus *12 minus 10* or *negative two* versus *two negatives*. Reversal occurred in six turns, 62, 75, 76, 78, 81, and 90. Sheila and Joseph tended to use the reversal poetic structure as they arranged variables and coefficients in their verbal method, and as they transitioned from a spoken method to written mathematical notation.

Reversal first occurred as Sheila's internal repetition in turn 62, when she began to count the interior sides of the hexagon diagrams. This was the first time either student mentioned "minus" or subtraction.

62 *S:* Uh, so this would be 6L. 6. And then this would be 10L minus 2. Minus 2. This would be 2, 4 minus 4. This would be 6. 18L. So the total number of sides minus 2 on this side. So it'd be, uh, 6. 6, and then this would be, uh, 12 minus 2. So.

Sheila mentioned the perimeter first for the n = 1 and 2 diagrams: *6L*, and then *10L minus 2.* Then she mentioned the interior sides for the n = 3 diagram: *This would be 2, 4 minus 4.* The reversal occurred next, at the n = 4 diagram, when she switched the order of the interior sides and the perimeter: *This would be 6. 18L.* This reversal of the previous comment seems to represent Sheila's shift from a quantity that she understands well—perimeter—towards the quantity that she needs to understand better. The reversal seems to facilitate her focused attention on a new pattern in the diagram.

In turn 75, there is an across reversal from turn 72. In turn 72, Sheila commented on *total number of hexagons times six.* In turn 75, Joseph switched the order to place the 6 first: *So it'd be like 6 times x per se number of hexagons.* The phrase *number of hexagons* had been spoken before, but only while reading from the task page. Sheila's *total number of hexagons* at 72 was the first time that the *number of hexagons* was used as an independent phrase for conjecturing. Joseph's reversal at turn 75 was notable because he proposed shifting to a more standard way of speaking and writing, in which coefficients precede variables. As he said this, he wrote on the same paper as Sheila was working on: 6(x) —.

At turn 76, Sheila does not take up Joseph's suggestion immediately, but she does use reversals in turns 76 and 78 as she grapples with the n = 4 hexagon case.

76 *S:* Uh, divided, um, um, 4. 4 minus, minus n 2. Uh, like n would be the total number. 1, 2, 3, 4, number of cases. So, like in statistics the number of cases would be n and that would be your number minus 2. So 4 h, 4 h would be your number of hexagons. [At turn 77, Joseph responds: Yup.]
78 *S:* So number of hexagons would be 4 times 6 minus n minus 2. [Here, she wrote: 4(6) – N – 2]. So 4 times 6 would be 24. Number of hexagons would be 1, 2, 3, 4. 4, uh, times 2.

Sheila uses an internal reversal at 76 by switching the variable *n* with its description, number of cases: *n…would be the total number…number of cases would be n.* Her final comment in turn 76: *4 h, 4 h would be your number of hexagons* was reversed at 78 so that it began with hexagons: *So number of hexagons would be 4.* A moment later, but still at 78, Sheila incorporated Joseph's *6 times* from line 75, which is an across repetition: *So number of hexagons would be 4 times 6…*and she

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

began to build the subtraction of the interior sides, though inaccurately at this point: *So number of hexagons would be 4 times 6 minus n minus 2.*

In turns 75 to 78, there are reversals across the word *times*, and there are reversals of the variable *n* and the description of the variable. A possible interpretation of these reversals is that they represent some tension between topic of focus of each speaker. Joseph's reversal helped him propose the beginning of a formula that was written in a standard format, but that leaves the variable, *number of hexagons* in the terminal position. In contrast, Sheila is working on how to start with the number of hexagons—at this moment, the n = 4 case—and perform calculations on n = 4 in order to verify the perimeter of 18. As a verbal representation, saying *number of hexagons* first stabilizes the quantity for further conjecturing and calculation. Sheila used a couple of reversals to get the 4 into a convenient position to calculate with it. Brian was moving towards a standard form of writing mathematics, but Sheila was still focused on working out the algebraic relationships regarding the interior sides.

In this passage, then, we can hear the transition from reading the task (the phrase *number of hexagons),* to proposing a written form; (*6 times x per se number of hexagons*); to writing it as 6(x) —; to recasting it in an easier verbal form for conjecturing (*So number of hexagons would be 4 times 6 minus n minus 2*). Analysis of poetic structures, and especially the reversal poetic structures, helps to highlight these transitions across several ways of experiencing and representing mathematics.

The reversal poetic structure was also associated with writing in turn 81. Sheila and Joseph were still working on the n = 4 hexagon case. They knew that six times four yields 24, that they must subtract pairs of interior sides, and they must get 18, but they didn't know how many twos to subtract. Here, Sheila subtracted 8 instead of 6 to account for the interior sides.

80 *S:* Negative 2 would be negative 8. So 24 minus 8 is how much?
81 *J:* Wouldn't it be 24 plus 8 because there's these two negatives? I'm sorry. There's these two negatives.

The reversal in line 81 is that Joseph's *two negatives* reverses Sheila's *Negative 2* in turn 80. In this phase of the conversations, the students were working on the written statement, where both H and N stand for the number of hexagons: 4H — N — 2.   There is some ambiguity because there were several erasures and the angle of the video recorder did not capture each moment well. However, it is clear that Joseph used a reversal to focus Sheila's attention on a problem with the written notation.

The final reversal occurred in line 90. In line 90, Sheila first articulates a correct method for the task. By the end of line 90, Sheila had written: 24 — 2(4 — 1) = 18.

90 *J:* So this would be 2, 4, 6. So that would be 1, 2, 3, 4, 6. So let's see, 1, 2, 3. So number of insides, 4, so 4 minus 1 times, uh, 4 minus 1, so this would be 2 into 4 minus 1 equals, right? So that would be 3. 3 times 2 would be 6. 6 from 24 is 18, right?

As Sheila said the phrase *2 into 4 minus 1 equals*, she wrote 24 — 2(4 — 1), so it seems reasonable to consider that for Sheila, the word *into* meant *times.* The reversal poetic structure occurred when Sheila's phrase *so 4 minus 1 times* was reversed so that *4 minus 1* took the second position after the operation *times* or *into*: as *2 into 4 minus 1*. The *4 minus 1* reversed position from beginning to end of its phrase. This reversal poetic structure co-occurs with Sheila's decision to write the two before the parentheses of (4 — 1), and so this is a third case in which reversal facilitated the transition of a verbal method into a standard written format.

Conclusion

Each time we speak, we cross a border. We acknowledge the common ground of previous statements and offer, through shifts in our sentences, a pathway forward. Applying this perspective to

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

mathematical conversation can highlight the small collaborations—equally linguistic and mathematical— that must take place as mathematical insight develops. In this conversation, poetic structure reversals helped students shift from verbal and computational methods into standard ways of writing mathematics. The reversal poetic structure may prove to be concerned with positioning important mathematical entities, and therefore, it may facilitate movement between different mathematical representations, ones that are read, spoken and written. The theoretical framework for this analysis, dialogic syntax, is an interdisciplinary, border-crossing perspective that provides several rich directions for future research in mathematical discourse. Dialogic syntax draws attention to the subtle precision of informal language in supporting mathematical discovery.

CROSSING "THE PROBLEM OF THE COLOR LINE": WHITE MATHEMATICS TEACHERS AND BLACK STUDENTS

Carla R. Bidwell   David W. Stinson
Metropolitan Regional Educational Service Agency   Georgia State University
carla.bidwell@mresa.org   dstinson@gsu.edu

In this paper, the authors explore—within an eclectic theoretical framework of critical theory, critical race theory, and Whiteness studies—the life experiences of four White high school mathematics teachers who were "successful" with Black students. The data were collected through three, semi-structured interviews, conducted over a 5-month time period. Through a cross-case analysis of the data, three commonalities among the teachers were identified as being significant contributors to their success in teaching Black students. Two commonalities the participants themselves felt strongly about, and a third became apparent during the cross-case analysis: (a) forming meaningful relationships with students, (b) engaging students in racial conversations, and (c) reflecting both individually and collectively with colleagues on issues of race and racism. Implications for classroom practice and teacher education are discussed.

Keywords: Equity and Diversity, High School Education, Teacher Beliefs

Prologue

One of the most often cited passages from W. E. B. Du Bois's classic text *The Souls of Black Folk* (1903/1989) is the statement regarding the capital "T" problem of the twentieth century: "The problem of the twentieth century is the problem of the color-line,—the relations of the darker to the lighter races of men in Asia and Africa, in America and the islands of the sea" (p. 10). World and U.S. history make available numerous incidents that have transpired that validate this prophetic statement and illustrate how the color line was problematic for the twentieth century, and has continued to be problematic for the twenty-first century (Stinson, 2013). How might mathematics educators become knowledgeable of the ways in which they are implicated (or not) in (re)producing and regulating the problem of the color line? How might mathematics educators learn to reduce (if not eliminate) the problem of the color line, at least in mathematics classrooms (Stinson, 2013)?

Introduction

Jacqueline Jordan Irvine's 1990 book *Black Students and School Failure: Policies, Practices, and Prescriptions* has become somewhat of a classic for those who research issues of Black children and schooling. In many ways, Irvine's book can be thought of as a modern-day version of Carter G. Woodson's 1933 classic *The Mis-Education of the Negro*. What Irvine provided in her book is one of the initial counter-analyses—or counter-narratives, if you will—to the emergence and proliferation of the Black–White "achievement gap" analyses found in both the scholarly and the popular presses of the 1970s and 1980s (see, e.g., Bradley & Bradley, 1977; Maeroff, 1985).

One component of Irvine's (1990) analysis is the importance of "cultural synchronization" between Black children and teachers (and administrators) to Black students' school success. The concept of cultural synchronization, for Irvine, is based on anthropological and historical research that suggest "black Americans have a distinct culture founded on identifiable norms, language, behaviors, and attitudes from Africa" (p. 23; see also Hilliard, 1992). Irvine also provided an analysis of how a lack of cultural synchronization between Black children and teachers can contribute to Black students' school failure. Hilliard (1992) argued that cultural misunderstandings—or a lack of cultural synchronization, if you will—between Black children and (White) teachers

has been shown to lead to errors in the estimation of a student's or cultural group's: (1) intellectual potential (the consequences of which—mislabeling, misplacement, and mistreatment of children—are enormous); (2) learned abilities or achievement in academic subjects such as reading; and (3) language abilities. (p. 372)

In many ways, the enormous errors (and oftentimes harm) brought about by a lack of cultural synchronization begs the question: Do Black children need separate schools (i.e., schools with Black teachers, teaching Black children)? Du Bois (1935), more than 80 years ago, asked this very question. He concluded: With all things being equal, "the mixed school is the broader, more natural basis for education for all youth" (p. 335). But given that things are seldom (if ever) equal, the "Sympathy, Knowledge, and the Truth [about Black children's lives and academic abilities found in the segregated school] outweigh all that the mixed school can offer" (p. 335).

Within the context of mathematics education, Martin (2007) asked a similar question: Who should teach mathematics to Black children? Through a cautioning of missionaries and cannibals, Martin argued for an "experience lens" when thinking about who should teach mathematics to Black children. His experience lens argument—"that achievement outcomes among [Black] students are indictors of the way that they experience mathematics learning and participation as [Black students]" (p. 15)—is similar to Irvine's (1990) cultural synchronization. In that, the experience lens necessitates, among other things, that effective teachers of Black children possess (or have the desire to develop) in-depth knowledge of Black children's socio-cultural and -political life experiences and take seriously their role in positively shaping Black children's racial, academic, and mathematical identities. What might be learned from successful Black mathematics teachers, teaching Black children was the focus of Chazan, Brantlinger, Clark, and Edwards's (2013) extensive research project. Specifically, they challenged the taken-for-granted notions of the knowledge base and resources needed to be an effective mathematics teacher of Black children (p. 2). Similar to Martin, Chazan and colleagues (see also Johnson, Nyamekye, Chazan, & Rosenthal, 2013; Birky, Chazan, & Farlow Morris, 2013; Clarke, Badertscher, & Napp, 2013) suggested that it might be the in-depth knowledge of Black culture and the unwavering belief of the brilliance of Black children (see Leonard & Martin, 2012) that determine who is (or is not) an effective teacher of Black children.

Problem Statement and Research Questions

Altogether, what Du Bois, Woodson, Irvine, Hilliard, Martin, and Chazan and colleagues have argued is the importance of having Black teachers, teach Black children. Or, more generally, they argued for teachers who are synced or responsive (see Gay, 2010) to Black children's culture and life experiences. They did not, however, argue that only Black teachers are effective with Black children. In fact, Irvine (1990) explicitly noted that the justifying of cultural synchronization does not "ignore the fact that some white teachers are excellent teachers of black children or that some black teachers are ineffective with black children, treating them with disdain and hostility" (p. 61). But these "some white teachers" who are "excellent teachers of black children," who are they? What makes them excellent? How are they different from other White teachers? Similar to Chazan and colleagues (2013), the purpose of this study was to determine what might be learned from well-respected mathematics teachers of Black children. But here, unlike Chazan and colleagues, our focus was on well-respected or "successful" White teachers. Three questions guided the study:

1. How do the life histories of successful White mathematics teachers of Black children influence their decision to teach Black children?
2. How do these life histories influence their pedagogical practices as successful White teachers of Black children?
3. How do successful White mathematics teachers of Black children view the role of their Whiteness in their teaching?

Theoretical Framework

This project was framed within an eclectic theoretical framework (Stinson, 2009). Critical theory (e.g., Bronner, 2011) served as the overarching framework, while critical race theory (CRT; e.g., Tate, 1997) and Whiteness studies (e.g., Leonardo, 2002) brought the complexities of race and racism to the forefront (see Figure 1). In effect, we borrowed theoretical concepts and methodological procedures from different theoretical paradigms, which we used side by side throughout the research project. Similarly to Koro-Ljungberg (2004), we do not view qualitative research projects that contain elements from more than one theoretical paradigm as an ontological and epistemological failure, but rather as representing "a planned mixture of theoretical and philosophical assumptions, fluxing commonalties, and complicating rhizomatic (see Deleuze & Guattari, 1987) intersections of theoretical understandings" (p. 618).

Critical theory kept us focused on what it might mean to conduct "'good' education research" (Hostetler, 2005) in the public interest (Ladson-Billings & Tate, 2006); it made us think not about "how things [are] but how they might be and should be" (Bronner, 2011, p. 2). CRT and Whiteness studies allowed the participating teachers (and us) to challenge racial hierarchies; to reflect on and discuss the roles of race, racism, and White supremacy in schools and in society at large; to examine the racial dynamics between student and teacher; and to begin to understand how the teachers' racial experiences may have influenced their classroom practices. No study on race, particularly one focusing on the dynamic relationships formed between White teachers and Black students, should be absent of these theories. Given that we believe that racism and White supremacy are two sides of the same coin, an analysis of race and racism without a critical examination of the hegemony of White supremacy would be dangerously incomplete (see Hilliard, 2001).

Figure 1. Three theories intertwined.

Methods

Four teachers—Caroline, Carrie, Oliver, and Patt (pseudonyms)—were the participants of the study. Each teacher self-identified as White, taught high school mathematics (ranging from a low of 4 years to a high of 23 years), and each had experienced success in teaching Black children. (For complete details of participant selection and methods, see Bidwell, 2010). The data were collected through three, semi-structured interviews conducted and transcribed by the first author, over a 5-month time period. The first interview allowed participants the opportunity to (re)tell their stories, beginning with childhood and continuing on to the present as mathematics teachers of Black students. The conversations documented during the second round of interviews centered on Gary Howard's (2006) book *We Can't Teach What We Don't Know: White Teachers, Multiracial Schools*, which the participants were asked to read and reflect on prior to the second interview. (Engaging

participants in literature prior to interviews has been proven beneficial in other studies; see Jett, 2009; Shildneck, 2009; Stinson, 2008.)

Reading Howard's (2006) book acted as a catalyst for engaging in complex discussions on race, White hegemony, color blindness, and the development of an anti-racist White identity. Howard's prose became somewhat of an invisible but participating third person during the interview. This invisible person, so to speak, assisted in making the often-difficult task of discussing race approachable, and gave both the participants and the interviewer a language to engage in "race talk" that permitted richer and more descriptive conversations. The third and final interview was followed by an opportunity for participants to critically read and provide feedback on the transcripts of their previous two interviews; it also served as a follow up to those conversations, a method of "member checking," so to speak. (This method of member checking has been effectively used in other studies with practicing mathematics teachers; see Wilson, Cooney, & Stinson, 2005.)

Findings

As the four participants shared their life stories, they often included intimate and uncomfortable details of their lives. They, however, led the discussions. They chose which stories to share and which would remain unspoken. Although most of these teachers had limited exposure to or knowledge about the theories that framed the study and guided data analysis, in their storytelling they all demonstrated tenets of critical pedagogy (see, e.g., Freire, 1970/2000, 1998). They were willing to be disruptive and were extremely reflective about every topic discussed. Not one of these teachers particpated in "dysconscious racism" (King, 1991); that is, they did not accept poor performance from their students as "just the way it is." They were so comfortable in their teaching, that they were willing to change a lesson while it was being taught for the benefit of their students. They questioned their own teaching as it happened just as they questioned the ideas discussed during the interviews. And as was somewhat hypothesized at the onset of the study, all four teachers employed, to some degree, culturally responsive (Gay, 2010) or relevant (Ladson-Billings, 1994) pedagogy in their classrooms. Similar to Ms. Rossi, the sixth-grade mathematics teacher in Ladson-Billings's (1994, 1995) study, these teachers (a) believed that all their students could succeed, (b) saw themselves as part of the community, (c) built strong relationships with students that often extended beyond the classroom, (d) encouraged students to work together collaboratively, and (e) were passionate about mathematics and were willing to scaffold content for students when gaps in their knowledge became apparent.

Through a cross-case analysis of the data, three commonalities among the teachers were identified as being significant contributors to their success in teaching Black children. Two commonalities the participants themselves felt strongly about, and a third became apparent during the cross-case analysis: (a) forming meaningful relationships with students, (b) engaging students in racial conversations, and (c) reflecting both individually and collectively with colleagues on issues of race and racism. Given the limitation of space, each commonality is discussed only briefly here.

Forming meaningful relationships with students. Caroline, Carrie, Oliver, and Patt all developed strong relationships with their students and viewed those teacher–student relationships as an essential part of their jobs. These relationships, however, were not superficial. Rather, they were genuine relationships developed out of these teachers' capacity to empathize with their students. All four teachers in this study subscribed to Ladson-Billings's (1997) belief that "we must come to develop caring and compassionate relationships with students—relationships born of informed empathy, not sympathy" (p. 706).

All four participants spoke extensively about their personal experiences in relationship building and reasons why they believed these relationships to be necessary. Carrie asserted that forming relationships (or not) with students could "make or break the deal" (Interview 1) in being able to connect with students. She emphasized the importance, for her, of extending those relationships

beyond the classroom by attending extra-curricular events in which her students participate. Oliver desired to strengthen his relationships with students by living in the community with them rather than residing in a distant suburb. Caroline recognized the potential for her (especially as a White woman) to be a roadblock to her students' learning if she failed to connect with each of them individually. She acknowledged that her students already have many socio-cultural and -political barriers that can keep them from being successful but, as she stated, "If a student has an issue with the teacher, then nothing's going to be learned" (Interview 1). And Patt, who was known in her community for "taking in" troubled students in times of crisis, claimed, "I think addressing a child's affective domain is the most important thing to be able to teach them" (Interview 2). Unfortunately, as both Patt and Martin (2007) pointed out, there is widespread failure to recognize that there are different skills needed to be effective with non-White children and that one of those important skills is for a teacher to be able to connect with her (or his) individual students.

Engaging in racial conversations

Caroline, Patt, and Oliver strongly believed that their willingness and ability to engage in racial conversations with students allowed them to seem more "real" to their students and played a vital role in their overall success in teaching Black children. In fact, for these three teachers, avoiding race talk was simply not an option:

> If you like [your students], you'll find that it is your place to bring [race] up. I mean, if you're a White teacher, and especially in my situation where most of the kids live very insular lives and they don't deal with a lot of White people—it's their chance to know you. (Patt, Interview 2)

It is important to note, however, that in these teachers' classrooms, race was not discussed merely as a means of building relationships. They believed racial differences between teacher and student, as well as differences among students themselves, should not be ignored and that discussions about race, in general, were healthy discussions in which to engage. As Irvine (1990) claimed, "lack of synchronization *increases*, not decreases, when teachers and administrators pretend that they don't notice students' racial membership" (p. 26, emphasis added). Although race talk often naturally ensued from conversations among students, these teachers themselves, at times, initiated discussions about race and incorporated them into their mathematics lessons. These racial discussions provided not only an opportunity for students to grow and learn about racial differences but also allowed the teachers to grow as they moved forward (and sometimes backward) on a continuum of racial understandings (see G. Howard, 2006).

Reflecting both individually and collectively with colleagues on issues of race and racism

Through the course of the three interviews with each of the participants, Caroline, Carrie, Oliver, and Patt were all extremely reflective. Caroline, who was working in a racially and ethnically diverse urban school, shared that the faculty openly talked about race and discussed ways to facilitate these conversations with students. Carrie, on the other hand, taught in a similar school where race was never discussed among faculty; yet, she still reflected a great deal about the interactions among students and those between students and faculty of different races. All four teachers seemed to naturally take on the role of reflective practitioner (see Schön, 1983) and were willing to be disruptive with any issue that concerned the welfare of their students (see Freire, 1998).

The participants became particularly reflective during the conversations about G. Howard's (2006) book. On the topic of White dominance, Carrie reflected, "How do you ever break it and how does society ever break it when some people won't even admit that it exists or matters" (Interview 2)? And Caroline, reflecting on her own childhood where she was taught not to "see" color, admitted that she subscribed to a colorblind ideology when she began teaching. But during Interview 2, she shared, "I think it's just important not to think about them [students] as all being the same and also

not to classify them in a certain way, but just to try to appreciate their cultures which I think is something that I'm still working on as a teacher." Three of the participants identified as being situated in the immersion/emersion stage of racial identity development (G. Howard, 2006), one stage prior to the autonomy stage, which G. Howard describes as a time when "we are engaged in activities to resist the many manifestations of oppression" (p.97). Caroline, Carrie, and Oliver all shared that they each do not do enough on a daily basis to fight racism. As Oliver stated, "It's not enough to just teach in this school, but I've got to be active or I'm not going to disrupt anything" (Interview 2).

Discussion and Closing Thoughts

In the study described here, the lived experiences of four successful White mathematics teachers were examined within an eclectic theoretical framework—one that allowed these teachers to think critically about their own life histories, their pedagogical practices, and the role their own Whiteness plays in their teaching. The three commonalities that were identified during data collection and analysis assisted in painting a picture of what might be envisioned as a successful White mathematics teacher of Black children; one who crosses the problem of the color line so that she (or he) might be more culturally synced with her students. But where does this lead us, as educators, going forward? The answer lies in the practices of teacher educators charged with the initial preparation and the ongoing professional development of mathematics teachers, and in the many district and state leaders who support teachers' professional growth throughout their careers.

The traditional method of teaching pre- and in-service teachers about non-White cultures—too often a mere one semester "required" multicultural course—must be extinguished. Teacher educators must go beyond surface exposure of "other people's" (Delpit, 2006) cultures, what Ladson-Billings called a "foods-and-festivals" approach to culture (1994). They must delve deep beneath the surface to explore the complexities of both their own and their students' cultures through (continuous) multicultural, anti-racist education (Gay & T. Howard, 2000; G. Howard, 2006; Ladson-Billings, 1994; McIntyre, 1997). Pre- and in-service teachers, especially those who are White (i.e., White folks too often avoid race talk), need safe spaces in which to discuss race, challenge White hegemony, and confront assumptions about their own and other's cultures. As G. Howard (2006) explained, "We cannot help our students overcome the negative repercussions of past and present racial dominance if we have not unraveled the remnants of dominance that still lingers in our minds, hearts, and habits" (p. 6). In these safe spaces, pre- and in-service teachers need to learn and engage in dialogue about social injustices while being provided "opportunities to critique the system in ways that will help them choose a role as either agent of change or defender of the status quo" (Ladson-Billings, 1994, p. 133). And lastly, pre- and in-service mathematics teachers need to learn to "care with awareness" (Bartell, 2011) as they learn about and engage with culturally relevant mathematics pedagogy (e.g., Gutstein, Lipman, Hernandez, & de los Reyes, 1997; Waddell, 2014; Tate, 1995).

Many of the experiences and conversations that should take place in teacher preparation programs should also continue throughout a teacher's career. In multi-ethnic, -racial, and -cultural school settings, ongoing professional development needs to be provided to: (a) support teachers in understanding the importance of strong teacher–student relationships and teach strategies to help build those relationships; (b) assist teachers in making connections to the surrounding communities; (c) engage teachers in multicultural, anti-racist education; and (d) develop teachers as reflective practitioners. G. Howard (2006) asserted: "An unexamined life on the part of a White teacher is a danger to every student" (p. 127). But teachers cannot be expected to examine their own lives without some direction; they need safe spaces in which to dialogue with fellow teachers about race and White hegemony. It is the responsibility of building-level administrators to create these spaces and devote time for teachers to engage in racial dialogue. And in the end, it is the responsibility of *all* who support teachers to be committed to improving education for Black children by providing

meaningful experiences that allow us *all* to examine ourselves, our children, and the racialized society in which we teach and learn.

An important aspect of effective teaching is taking advantage of in-the-moment expressions of student thinking that, by becoming the object of class discussion, can help students better understand important mathematical ideas. We call these high-potential instances of student thinking MOSTs and the productive use of them building. The purpose of this paper is to conceptualize the teaching practice of building on MOSTs as a first step toward developing a common language for and an understanding of productive use of high-potential instances of student thinking. We situate this work in the existing literature, introduce core principles that underlie our conception of building, and present a prototype of the teaching practice of building on MOSTs that includes four sub-practices. We conclude by discussing the need for future research and our research agenda for studying the building prototype.

Keywords: Classroom Discourse, Teacher Education-Inservice/Professional Development, Teacher Education-Preservice

Mathematics education researchers recognize the important role student mathematical thinking plays in crafting and carrying out quality mathematics instruction (e.g., Fennema et al., 1996; Stein & Lane, 1996). The field has begun to understand how to effectively use written records of student work to support mathematics learning (e.g., Smith & Stein, 2011), but much less is known about how to effectively use in-the-moment student thinking that emerges during whole-class discourse, often fertile ground for valuable student mathematical thinking (Van Zoest et al., 2015a, 2015b). In fact, research has documented that many teachers fail to notice or act on opportunities to capitalize on such thinking to further students' mathematical understanding (Peterson & Leatham, 2009; Stockero, Van Zoest, & Taylor, 2010).

Although research in mathematics teacher education suggests the benefits of instruction that uses student thinking (e.g., Franke & Kazemi, 2001), what it means to "use student thinking" is not well defined. For example, our interviews with secondary school mathematics teachers about productive use of student thinking revealed a range of perceptions. Some teachers viewed validation of student participation as productive use, others felt a discussion of student errors was not productive because it would confuse students, and still others saw productive use occurring when student thinking (correct or incorrect) was made the object of consideration for other students in the class (Leatham, Van Zoest, Stockero, & Peterson, 2014). These results highlight a need to develop a common understanding of and vocabulary for talking about productive use of student thinking in order for the field to better communicate about this important aspect of effective teaching. These interviews also revealed that some teachers felt differently about productive use of student thinking depending on the grade and ability level of their students; these teachers felt that it was possible to make student thinking the object of consideration for their advanced classes, but not for their beginning or remedial classes. Given what we know about the benefits of engaging students with each other's thinking, this perspective creates an inappropriate restriction on students' opportunities to engage in considering

each other's thinking. A challenge to the field is to prompt teachers to question such artificial borders and to provide them with tools that support them to productively use the thinking of all their students.

Not all student thinking warrants the same consideration by the class, however, since it is not all about mathematical ideas, nor does it always provide leverage for accomplishing mathematical goals. Leatham, Peterson, Stockero, and Van Zoest (2015) described a framework to identify those instances of student thinking—MOSTs—that provide such leverage. To move work related to the teaching practice of using student thinking forward, it is critical that teachers and teacher educators develop an understanding of productive use of high-leverage instances of student mathematical thinking—what Leatham et al. (2015) called *building* on MOSTs. As a first step toward developing this understanding and providing a common language for the field, the purpose of this paper is to conceptualize *the teaching practice of building* on MOSTs.

Theoretical Framework

Our theorizing about the teaching practice of *building* on student thinking takes as its foundation the framework for identifying student thinking worth building on developed by the MOST research group (Leatham et al., 2015; Stockero, Peterson, Leatham, & Van Zoest, 2014; Van Zoest, Leatham, Peterson, & Stockero, 2013). We defined MOSTs—**M**athematically Significant Pedagogical **O**pportunities to Build on **S**tudent **T**hinking—as occurring in the intersection of three critical characteristics of classroom instances: student mathematical thinking, significant mathematics, and pedagogical opportunities. For each characteristic, two criteria were provided to determine whether an instance of student thinking embodies that characteristic. For student mathematical thinking the criteria are: "(a) one can observe student action that provides sufficient evidence to make reasonable inferences about *student mathematics* and (b) one can articulate a mathematical idea that is closely related to the student mathematics of the instance—what we call a *mathematical point*" (p. 92). The criteria for significant mathematics are: "(a) the mathematical point is *appropriate* for the mathematical development level of the students and (b) the mathematical point is *central* to mathematical goals for their learning" (p. 96). Finally, "an instance embodies a pedagogical opportunity when it meets two key criteria: (a) the student thinking of the instance creates an *opening* to build on that thinking toward the mathematical point of the instance and (b) the *timing* is right to take advantage of the opening at the moment the thinking surfaces during the lesson" (p. 99). When an instance satisfies all six criteria, it embodies the three requisite characteristics and is a MOST.

MOSTs are instances of student thinking worth *building* on—that is, "student thinking worth making the object of consideration by the class in order to engage the class in making sense of that thinking to better understand an important mathematical idea" (Van Zoest et al., 2015b, p. 4). Such use encapsulates the core ideas of current thinking about effective teaching and learning of mathematics. Thus, building on MOSTs is a particularly productive way for teachers to engage students in meaningful mathematical learning. After discussing related literature, we share our current conceptualization of the teaching practice of building on MOSTs.

Related Literature

We see our work as connecting and contributing to research both on professional noticing—attending to, interpreting, and deciding how to respond to student mathematical thinking (Jacobs, Lamb, & Philipp, 2010)—and on teaching practices that enact and coordinate these decisions. This section elaborates on these two areas of contribution.

We see studies of professional noticing as generally falling into two categories: (a) noticing *within* an instance of student thinking, and (b) noticing *among* instances (Stockero, Leatham, Van Zoest, & Peterson, in press). Noticing *within* studies include interventions in which teachers (or prospective teachers) are given a specific instance of student thinking that they are asked to analyze, using media such as one-on-one student interviews (e.g., Schack et al., 2013) or student written work

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

(e.g., Fernández, Llinares, & Valls, 2013). In such studies, the task of the teacher is not to identify which instances to analyze, but instead, to notice what is happening *within* the instance of student thinking they are provided. Noticing *among* studies typically use classroom video (e.g., Sherin & van Es, 2009; van Es, 2011) as a medium for teachers to select the instances they deem important, and to write about or explain why those particular instances were important or interesting. Most of these studies, however, do not assign value to any particular instances, beyond the broad category of student thinking. We contend that, in order to productively use student mathematical thinking, teachers need to learn how to coordinate the skills of noticing *within* and noticing *among* instances of student mathematical thinking. The MOST Analytic Framework (Leatham et al., 2015) provides a tool for attuning teachers and researchers to this coordination and our current conceptualization of productive use of student thinking provides a theoretical characterization of what this coordination might look like in practice.

The theorizing we are doing about the teaching practice of building on MOSTs has the potential to contribute in substantial ways to understanding the third component of noticing, *deciding how to respond* (Jacobs et al., 2010). Most studies of noticing, particularly those in the noticing *within* category, ask teachers to propose a "next move." There is not yet a common understanding in the field, however, of what makes those next moves more or less productive, particularly during a whole-class discussion. In the case of one-on-one student interviews, asking a question or proposing a follow-up task to the student that is based on evidence of the student's understanding would generally be considered a productive move (see, e.g., Jacobs et al., 2010). In a whole-class setting, however, where the teacher needs to work toward engaging many students in making sense of the mathematics on the table, what makes a next move productive is more complicated. In fact, our work suggests that this practice requires a series of teacher moves. Unpacking and clearly articulating this collection of moves, of which our theorizing is a first step, is requisite for helping teachers to improve their use of student thinking in the classroom.

Prior work related to teacher responses to student mathematical thinking has also influenced our efforts to theorize the teaching practice of building on MOSTs. Research has identified a number of patterns in mathematics teachers' responses to student thinking. Mehan (1979) coined *IRE*—Initiation, Response, Evaluation—to describe a common pattern of classroom interaction where the teacher's main response to elicited student thinking is to evaluate it. An IRE interaction is an example of what Wood (1998) referred to as *funneling,* where the teacher's response is intended to corral students' thinking within predetermined and often narrowly-defined parameters. By contrast, Wood characterized certain other teacher responses as *focusing*, in which, for example, a teacher might ask "clarifying questions to keep attention focused on the discriminating aspects of the solution" (p. 175). Clarifying questions are just one example of the many types of productive questions teachers might ask in response to student mathematical thinking. Unfortunately, Boaler and Brodie (2004) found that questions geared toward "gathering information, leading students through a method" (p. 777)—funneling questions—characterized the vast majority of questions in US classrooms using a traditional mathematics curriculum. Although 60-75% of the questions asked by teachers using an NSF-funded reform curriculum were also of this type, the remaining 25-40% covered a broader range of more productive questions. Boaler and Brodie's (2004) findings highlight the additional learning opportunities afforded students who are exposed to a broader range of questions. These findings also point toward the value in teaching practices that engage with and capitalize on student mathematical thinking.

As we have argued elsewhere (Leatham et al., 2015), work on the cognitive demand of tasks (e.g., Stein, Smith, Henningsen, & Silver, 2009) and on orchestrating classroom discussions around rich mathematical tasks (e.g., Smith & Stein, 2011) has also been influential in conceptualizing the productive use of student mathematical thinking in classrooms. The MOST framework and our theorizing about the teaching practice of building on MOSTs is related to Smith and Stein's (2011)

practices of monitoring, selecting and planning how to sequence student thinking that is observed as they work on a task, but extends Stein and Smith's work by focusing on *recognizing* and *responding* to potentially productive student thinking in the moment that it occurs. There are two particularly important differences between the MOST work and that of Stein, Smith, and colleagues. First, the MOST work focuses a broader range of contexts in which student thinking can emerge, including student questions that arise during a lecture or student comments that emerge during a discussion of homework. Although high cognitive demand tasks certainly create opportunities for student thinking to occur, we have also found high-potential instances of student mathematical thinking in classrooms that lack rich tasks. The MOST framework applies to the broad range of instructional situations in which student thinking might emerge in mathematics classrooms. Second, our work on building focuses on responding to student thinking *at the moment in which it occurs* during a lesson, rather than on monitoring and selecting student work and then purposefully sequencing the presentation of that work later in the lesson (see Smith & Stein, 2011). Although student thinking can be valuable to use at a later point in a lesson, our work has convinced us that there are certain instances of student thinking that lose their instructional value if they are not acted on immediately and in particular ways. The purpose of this paper is to conceptualize a productive response to MOSTs—the teaching practice of building.

Our Current Conceptualization of The Teaching Practice of Building

We base our conception of *building* on core principles of quality mathematics instruction that we distilled from current research and calls for reform. The NCTM, for example, in their *Principles to Actions* document (2014), states that students "construct knowledge socially, through discourse, activity, and interaction related to meaningful problems" (p. 9), and that "effective teaching of mathematics facilitates discourse among students to build shared understanding of mathematical ideas by analyzing and comparing student approaches and arguments" (p. 10). We see embedded in these statements four core principles of quality mathematics instruction: mathematics is at the forefront, students are positioned as legitimate mathematical thinkers, students are engaged in sense-making, and students work collaboratively. We have applied these principles to the productive use of MOSTs in Figure 1. An important aspect of this application is that in the first principle, the mathematics that is at the forefront is the mathematics of the MOST—mathematics closely connected to the student thinking under consideration. We use these core principles to determine whether a given use of a MOST is productive.

Principles Underlying our Conception of Productive Use of MOSTs
1. The mathematics of the MOST is at the forefront.
2. Students are positioned as legitimate mathematical thinkers.
3. Students are engaged in sense making.
4. Students are working collaboratively.

Figure 1. Principles underlying our conception of productive use of MOSTs**.**

In our initial work identifying productive use of MOSTs, we focused on the productivity of a single teacher move that followed a MOST, but we quickly realized that this approach was insufficient. Because teaching is a complex system (Stiger & Hiebert, 1999), one needs to look beyond single actions, such as inviting students to share solutions at the board, to characterize effective teaching. Similarly, trying to ascertain productive use of MOSTs by only focusing on discrete teacher moves misses the real purpose of those moves. To evaluate productive use, one needs to consider the combining and coordinating of teacher moves. We thus conceptualize the teaching practice of *building* as several teacher moves woven together to engage students in the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

intellectual work of making connections between ideas and abstracting mathematical concepts from consideration of their peers' mathematical thinking.

To highlight the distinction between the teaching practice of building and the moves that may or may not be part of the practice, consider a teacher who invites two students to share their different, but both correct, solution strategies for a problem. The initial move of inviting the students to share their thinking could be the start of building because the teacher is inviting the whole class to consider the two students' mathematical thinking. Consider two different moves the teacher could make once the strategies have been shared: (a) the teacher says to the class, "See, there are many correct ways to solve problems like this and you can use whichever method makes the most sense to you," and moves on to the next problem; and (b) the teacher asks the class, "What similarities and differences do you notice in these two strategies?" and engages the students in a discussion about those noticings. Although the initial setup move was the same (making the two student solutions public), we see here that the follow-up moves vary significantly in their potential to accomplish the building goal of students coming to understand important mathematical ideas. Specifically, variations in follow-up moves might cause the resulting practice to deviate from any of the four principles underlying our conception of productive use of MOSTs listed in Figure 1: (1) the mathematics of the instance could be abandoned, (2) the teacher could trivialize students' contributions, (3) the overall practice (regardless of the actor) could focus on recall of facts or on procedural steps rather than on making sense of the underlying structure of the mathematics, or (4) the teacher could limit or eliminate engagement with the idea beyond the individual who contributed the instance. Thus, although a move that makes student thinking public *may* be part of a broader building practice, such a move does not imply engagement in the practice—building is more than a single move.

As we have begun to think about what collection of teacher actions meet the requirements of building, we have theorized that there are four sequential sub-practices of building, each consisting of a move or collection of moves, as well as some prerequisites. Before teachers can build, they must have completed two prerequisite actions: (1) invited or allowed students to share their mathematical thinking; that is, elicited student mathematical thinking, and (2) recognized that an instance of student thinking is a MOST—a high-potential instance of student thinking. In addition, the success of a teacher's enactment of the building practice is influenced by the norms present in the classroom. One such prerequisite norm is that students listen to and make sense of each other's thinking. The absence of that norm would greatly inhibit successful building.

Once these prerequisites are satisfied, we hypothesize that there are four sub-practices of the teaching practice of building; our current building prototype is outlined in Figure 2. The first sub-practice of building is to ensure that the student mathematics of the MOST—the object of consideration—is clear. We say the teacher should *make precise* what it is that students are meant to consider. Sometimes a MOST has been communicated in such a way that both the object and the need to engage with it are obvious and no further action is needed, but often the teacher must focus the class on what student thinking is to become the object of consideration. The second sub-practice turns the object of consideration—the student mathematical thinking—over to the students. We use the term *grapple toss* because it captures two key aspects of this sub-practice—the teacher must "toss" the student thinking of the MOST over to the students to be considered, and they must do so in such a way that the students are positioned to "grapple" with the object of consideration in order to make sense of it. The third sub-practice involves orchestrating the students' process of making sense of the MOST. We use *orchestrate* to mean, "arrange or direct the elements of (a situation) to produce a desired effect, especially surreptitiously" ("Orchestrate," n.d.). Although this orchestration could require only a few teacher moves, this sub-practice could easily consist of a large and complex collection of moves. The fourth sub-practice is to facilitate the extraction and articulation of the important mathematical idea from the discussion; that is, to *make explicit* that idea.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

> **Sequence of Sub-Practices of the Teaching Practice of Building on MOSTs**
> 1. Make the object of consideration clear (make precise)
> 2. Turn the object of consideration over to the students with parameters that put them in a sense-making situation (grapple toss)
> 3. Orchestrate a whole-class discussion in which students collaboratively make sense of the object of consideration (orchestrate)
> 4. Facilitate the extraction and articulation of the mathematical point of the object of consideration (make explicit)

Figure 2. Building prototype: Our current conception of the teaching practice of building**.**

Given that our understanding of this practice is primarily theoretical at this point, further research is needed to study the building prototype. Our plans for future research include studying the prototype by (1) analyzing current teacher responses to MOSTs to see the extent to which those responses coordinate our core principles; and (2) generating instantiations of the building prototype and engaging in a similar analysis of these responses. Specifically, this direction for future research will allow us to refine our building prototype by addressing three primary research questions: (1) What teaching practice(s) coordinate the core principles underlying productive use of MOSTs? (2) How do teachers' responses to MOSTs align with the core principles underlying productive use of MOSTs? and (3) In what ways, if any, do teachers' responses to MOSTs empower or disenfranchise students (particularly those from traditionally underrepresented populations) with respect to mathematics? Once the teaching practice of building on MOSTs is better understood, it will be possible to design professional development to support teachers in improving their abilities to build on MOSTs.

Conclusion

Conceptualizing the teaching practice of building is a first step towards achieving the goal of productively using students' mathematical thinking during instruction—a central tenet of effective teaching (e.g., NCTM, 2014). There is little research about the complex but essential practice of responding to student thinking *in the moment*, yet this is something that teachers face every day. Our conceptualization of building contributes to a common understanding of and vocabulary for talking about productive use of student thinking that will support the field in communicating about this important aspect of effective teaching. Better understanding the in-the-moment practice of building on MOSTs—particularly opportune instances of student thinking—has the potential to significantly impact mathematics instruction for all students. Focusing attention on student thinking and how it can be built on supports teachers in looking for the mathematics present in instances of student thinking, and thus helps to avoid deficit thinking (e.g., Frade, Acioly-Régnier, & Jun, 2013) and making judgments based on student characteristics rather than the content of their thinking. Having a systematic way to interpret student mathematical thinking (i.e., the MOST Analytic Framework, Leatham et al., 2015) and a mechanism for responding to MOSTs (the teaching practice of building) positions teachers to question artificial borders that prevent them from engaging all their students—no matter what their ability or experience level—in these important learning opportunities.

SOCIOMATHEMATICAL NORMS AND INCLUSION IN MIDDLE SCHOOL

Amanda C. Allan
York University
amanda_allan@edu.yorku.ca

This paper presents initial findings from a project investigating sociomathematical norms in two grade five classes. Here I focus on the different sociomathematical norms perceived by students in the two classrooms and how these norms contributed to students' sense of inclusion.

Keywords: Instructional Activities and Practices, Equity and Diversity, Middle School Education

Introduction

Why should we be concerned about sociomathematical norms in middle school in particular? A compelling argument rests in Sullivan, Tobias, & McDonough (2006, p. 81), who assert that "the very students who have most to gain from active participation in schooling are those who are most difficult to engage" and note that students' sense of exclusion from school mathematics frequently begins in the upper primary years (grades 5-7). Much has been written on students' feelings of exclusion from school mathematics (e.g. Nardi & Steward, 2003), often focusing on either the circumstances of individual students, or on broader systemic problems or societal constructs that are beyond the influence of the classroom teacher. Here I argue that teachers – especially middle school teachers – may wish to attend to sociomathematical norms, as these norms are one of the few elements largely within the control of the teacher that can contribute to students' sense of inclusion. This work contributes to the conference's stated theme of questioning borders within mathematics education, as students' sense of inclusion is a key factor in the literature on social justice and equity in mathematics education (e.g. Skovsmose, 2007).

Theoretical Framework: Sociomathematical Norms

Yackel & Cobb's work in sociomathematical norms "aims to account for how students develop specific mathematical beliefs and values" (1996, p. 459). They differentiate between social and sociomathematical norms; for example, taking class time to discus multiple, different solutions would be a social norm, while sociomathematical norms convey what is valued mathematically, e.g. what counts as a mathematically "different" solution. Fukawa-Connelly (2012) reviews the literature on sociomathematical norms and confirms that "norms and beliefs influence each other and as one changes, so does the other" (p. 403), making norms an appropriate lens through which to view students' beliefs about math and whether these beliefs lead them to feel included or excluded from school mathematics.

Students play a significant role in creating and maintaining sociomathematical norms, but the process is guided by the teacher, who represents the discipline of mathematics in the classroom, (Bowers, Cobb, & McClain, 1999). In addition to explicit statements teachers make about their mathematical expectations, there are many implicit ways teachers endorse sociomathematical norms. For example, teachers' reactions to students' questions and solutions demonstrate what mathematics is valued, as "the teacher acts as a participant who can legitimize certain aspects of the children's mathematical activity and implicitly sanction others" (Yackel & Cobb, p. 466).

Levenson, Tirosh & Tsamir (2009) note that most studies regarding sociomathematical norms focus either on the teacher's perspective or on observable actions in the classroom, but typically do not address "what students view as being normative in their classrooms" (p. 171). They identify "three aspects of sociomathematical norms: teachers' endorsed norms, teachers' and students' enacted norms, and students' perceived norms" (p. 173). This paper focuses on students' perceived

norms, exploring these perceptions primarily through students' responses to interview questions regarding mathematics, including "What does it mean to be good at math?"

Research Questions & Methodology

The study was situated in two grade five classes at the same private school. Each class had a single teacher who taught mathematics as well as other core subjects. The two teachers, Wendy and Frank, were both experienced teachers, but fairly new to teaching grade five. (It was Wendy's first year and Frank's third.) The classes were similar in makeup (by gender, race, and ability levels). Both classes were small, with 12 and 13 students.

This paper explores the question: *What is the relationship between students' perceived sociomathematical norms and their sense of inclusion in school mathematics?* This question is addressed mainly through interviews with the students, and is infused by classroom data collected during the researcher's visits to the two classrooms. The researcher spent three weeks in each class, documenting the environment through video recordings and field notes in order to develop a rich understanding of students' experiences of the mathematics learning environment. In subsequent interviews, students discussed their perceptions of their math classes and the topic of mathematics in general. Student answers to interview questions were coded according to themes that emerged; for example, for the question "What does it mean to be good at math?" the categories that emerged were speed, understanding, job/success, and teaching/sharing.

Results/Discussion

Wendy's math classes generally followed the same format each day, with students gathering for a Smart Board lesson from the prepared materials provided by the school's math program. After the lesson, students returned to their desks to complete the work pages associated with the lesson. Certain students were allowed to do "bypass", completing only the first two and last two questions, after which they could work on an extension task or help their classmates.

Frank's math classes rarely followed such a pattern. Frank held many mini math classes as questions came up in other subject areas that could be linked to mathematics, and the time slot ascribed to math class was often used for work that tied in another subject as well. Frank held an explicitly stated teaching philosophy, shared with his students, that "Everything is connected to everything" and felt that the division between mathematics and other subject areas was artificial.

What mathematical thinking is valued?

Key in the creation of sociomathematical norms is the teacher's ability to legitimize or sanction certain lines of mathematical thinking (Yackel & Cobb, p. 446). In Wendy's class, while discussing what types of things can be divided into halves, Oliver has an idea. Oliver's ideas are often unconventional. As he approaches the board, chalk in hand, Wendy pauses.

Wendy: Is this nonsense, or is this worthwhile math?
Oliver: If you have twelve people… I mean, if you have eleven people…
Wendy: I'm going to ask you again. Is this nonsense, or is this mathematically worthwhile?
Oliver: Well… it's mathematical.
Wendy: But is it worthwhile?

Oliver accepts Wendy's words as gentle teasing, not as criticism; Wendy met students' less conventional ideas with amusement, but it was clear that a diversion would not be made to accommodate them. Her description of questions that veered off the lesson plan as "nonsense" or not "worthwhile" contributed to the perceived sociomathematical norms of Wendy's classroom.

In Frank's class, lesson plans were more fluid. When the class began a unit on ancient civilizations, students spent one class visiting stations that included artifacts from various cultures

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

(pictures of pyramids, a Mayan calendar wheel, etc.). Students then met in a circle to discuss what mathematics they saw in the various artifacts, and their conversation spanned angles, ratios, perimeters, circles, pi, and more. During the research period, Frank would often modify his teaching based on student questions, and an interesting question could lead to a lengthy class discussion. At one point, Paul, a high-achieving student, took over the class, reorganizing the furniture and arranging his classmates in order to illustrate his thinking.

The researcher speculated that this contrast in how the teachers dealt with questions that fell outside their lesson plan could shape students' perceptions of the sociomathematical norms in the classes, and this was borne out by the interview data.

Interviews

Since student comfort was paramount, selection processes for student interviews were modelled on the work of Nardi & Steward (2003) on "quiet disaffection" in mathematics, with students choosing whether to be interviewed individually or in small groups. Most students in Wendy's class preferred to be interviewed individually, while nearly all students in Frank's class chose groups. This could suggest that the norms (endorsed or perceived) in Wendy's class led students to see mathematics as an individual activity, whereas the norms in Frank's class placed more emphasis on the collective. Other patterns were apparent, particularly in which students felt excluded from the class discourse. The higher-achieving students in Wendy's class expressed frustration at having to sit through Smart Board lessons and not being allowed to move ahead or go at their own pace. Still, when asked to recall classroom interactions where they asked questions that were labeled "nonsense" or "a technicality", these students tended to agree with Wendy's implication that their questions were essentially a distraction. This speaks to the role of students in establishing sociomathematical norms, suggesting that these students endorsed the sociomathematical norms they perceived in Wendy's class, even while pushing against them.

In Frank's class, a different group of students felt excluded from the conversation. Here, Charlotte, Ben, and Abbie admit to feeling left out when the class gathers in a circle, and explain why the part of math class they like best is "math blast", where students complete work sheets:

Ben: It's easy. Easier than listening...
Allan: It's easier to do the questions on your own than to sit in a group and talk about them?
Ben: Yes, because it sometimes gets confusing in your head when you're in a group and you can't write it down. You've got to think it all in your head when he asks a question.
Abbie: When other people are talking about different answers, and then I'm thinking of something else, then it kind of mixes me up.
Charlotte: Sometimes if it's hard, it's hard to think it out in your head, you need paper.
Ben: Then if there's only one answer and someone says it... [*shrugs*]

Later, Liam recalls the time when Paul took over the class, enlisting his classmates in moving tables to help him illustrate an idea. Liam sees Paul as shaping the discourse of Frank's class in a way that Liam can't, endorsed by the sociomathematical norms of their shared classroom.

In addition to students' explicit descriptions of their mathematics classes, their perceptions of sociomathematical norms can be inferred from their responses to some interview questions, including "What does it mean to be good at math?" In their responses, Wendy's students stressed speed and accuracy, while Frank's students focused on connection and understanding.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Student responses to "What does it mean to be good at math?"

Class	Sample responses	Frequency
Wendy	It means to be quick, to know the answer quickly It means that you can figure out problems really quickly It means that you can do it frequently and with minimal mistakes If someone asks you a question, you'll get it in a couple of seconds.	speed: 4 understanding: 1 job/success: 3 teaching/sharing: 0
Frank	You probably understand it pretty well You notice math all the time, when you're everywhere else You understand…and want to go beyond the expectations [It] means to be able to share it with other people, to teach	speed: 0 understanding: 5 job/success: 1 teaching/sharing: 2

Conclusion

My focus here is on students' perceived norms, which is why I look to student interviews. Among the sociomathematical norms perceived by Wendy's students were the great value placed on speed, organization, and accuracy. These norms were enacted explicitly through Wendy telling her students their workbooks would be graded on "organization and correctness of answers" and implicitly through the obvious status assigned to students who were allowed to do "bypass", as well as the dismissal of questions that fell outside the planned outcomes of the lesson. Among the sociomathematical norms perceived by Frank's students were the value placed on originality, finding connections, and asking questions that pushed the boundaries of the mathematics being studied. There were also relevant social norms that were unique to Frank's class, including what he described as the "culture of risk taking" that he tried to foster.

Each class included a range of abilities, but there were patterns in which students felt included or excluded by the sociomathematical norms they perceived. In Wendy's class, higher-achieving students struggled with the constraints of Smart Board lessons and the valuing of speed and accuracy over creativity; meanwhile, in Frank's class, some lower-achieving students perceived that a few of their classmates shaped the classroom discourse in ways they were unable to, and felt excluded by the value placed on originality, connection, and risk taking.

Students' sense of exclusion can often be attributed to factors outside the classroom, leaving teachers unsure how they can intercede. Though no single classroom could fit every student, I suggest here that teachers may wish to attend to sociomathematical norms, as these norms are one of the elements largely within the control of the teacher that can contribute to students' feelings of inclusion in middle school mathematics.

WRITING MATHEMATICAL EXPLANATIONS IN LINGUISTICALLY DIVERSE ELEMENTARY CLASSROOMS

Leslie Banes
University of California, Davis
lcbanes@ucdavis.edu

New standards and assessments place increasing pressure on teachers to help students write mathematically, a task few are prepared for. How teachers interpret the push for "explanations" will impact all students, especially those learning math in their second language. This study engaged two 5th grade teachers in professional development over one year exploring features of mathematical explanation and designing lessons that highlight rhetorical moves of this new genre. Quantitative and qualitative data expose the most valued features of written explanations, the importance of attention to audience, a possible trajectory of students' writing development, and ways to move language learners beyond set phrases. This work sheds light on how teachers and students learn what it means to write an explanation, with implications for professional development and assessment practices.

Keywords: Elementary School Education, Design Experiments, Classroom Discourse

Purposes

This study highlights findings from a year-long professional development program with two 5th grade teachers and their 58 linguistically diverse learners (LDLs) as they implement classroom practices designed to support students in writing mathematical explanations. New assessments require that students "write to explain" on a variety math tasks, with little clarification of what constitutes a "good" versus "poor" explanation. Math educators define "explanation" in varied and competing ways (e.g. Bicknell, 1999; Kazemi & Stipek, 2001), and although several studies document classroom practices that promote development of *oral* explanations, few studies emphasize *written* explanations. Moreover, recent surveys indicate writing instruction is strikingly rare in elementary math lessons (Banilower et al., 2013).

Rather than expecting students to develop desired forms of communication in mathematics through exposure alone, it may be necessary to explicitly teach them, drawing students attention to ways language is used to communicate particular types of meaning (e.g. Schleppegrell, 2007). However, there may be danger in emphasizing correct language forms to the detriment of deep mathematical thinking (Moschkovich, 2012), requiring teachers to carefully consider the tension between scaffolding too much or too little, and between narrowing or broadening what will be accepted as valid explanations in their classrooms. This study aims to increase our understanding of (a.) what counts as a "good" explanation, and (b.) how students' writing develops over the course of a year in project classrooms.

Data Sources

As part of a larger program of research, this study features data from two second-year teachers who both recently received their master's degrees and demonstrated special interest in LDLs and mathematical communication. These teachers volunteered to take part in professional development, meeting with the researcher and two other teachers at least once a month for 3-hour workshops over one year, from June 2015 to June 2016. The first four workshops consisted of discussion prompted by readings, teachers writing their own "ideal" explanations, listing and ranking features in order of importance. Then, a rubric including the features deemed most important to project teachers was co-designed, piloted, and refined. Subsequent workshops focused on analyzing students' written work and creating lessons to support students in developing written explanations.

Data sources at the time of analysis include transcriptions and artefacts from 7 monthly teacher workshops and the following data collected from each class: video-taped interviews with five focal students (10 total), three informal observations (6 total), three video recorded project-developed lessons (6 total), and 7 explanation writing prompts (406 total). After substantial side by side scoring practice, students' written explanations were scored by their teachers using the project-developed rubric. Twenty percent, selected randomly from each class, were double by the researcher and a 90% inter-rater agreement was obtained, with agreement defined as within 1 point of overall score (out of 16). A coding system was developed for qualitative analysis of students' written explanations and teachers' reflections and discussion during workshops. The coding process included repeated readings and open coding with iterative refinement.

Ms. Velasquez's 5th Grade Class

Ms. Velasquez is a bilingual teacher in a two-way immersion program. She teaches in a small school with 75% of students economically disadvantaged. She alternates between languages, teaching one math unit in English and the next in Spanish. Half of her 27 students are Latina/o, ten white, and 3 African American. Fourteen students are native Spanish speakers; seven are currently identified as ELs. Additionally, 13 students are native English speakers learning Spanish, i.e. Spanish learners (SLs). Ms. Velasquez describes her class as "high in mathematics" and ready for the challenge of learning how to share their mathematical thinking via writing. Data for this class include students' writing, lessons, and interviews in both Spanish and English.

Ms. Holt's 5th Grade Class

Ms. Holt teaches in a high-poverty urban elementary school with 98% of students economically disadvantaged. Seventy percent of students are Latina/o, 11% Asian, 8% African American, and 4% white. Twenty-one of Ms. Holt's 31 students have a native language other than English, with 15 currently classified as ELs. She describes her class as "low mathematically" and although many students still struggle with basic math facts, she emphasizes "learning how to show evidence of *why* an answer is correct is really important." However, Ms. Holt also expressed concern that many of her students have better developed speaking skills than writing skills, and thus their content knowledge may not be apparent on assessment tasks that require writing.

Results

What Counts as a "Good" Explanation?

Both teachers agreed from the beginning that the most important features of an explanation are that it *shows reasoning* and *provides convincing evidence,* reflecting the belief that "full explanations" include more than procedural narration of the steps taken. In discussion during the first workshop, Ms. Holt reflected, "There's procedural recounting where they say the steps how they did the math, but the *explanation* is explaining why, the reasoning, the justification."

Teachers differed in their values of several features of written explanations. While Ms. Velasquez placed high value on the feature *direct answer to question*, Ms. Holt ranked this as one of the least important features, reasoning that she could usually infer her students' final answers from the work they show. Additionally, Ms. Velasquez ranked the feature *appropriate mathematics vocabulary* as one of the least important features, explaining that students can communicate their mathematical ideas in many ways even when they don't know the proper terminology. In contrast, Ms. Holt consistently ranked it in the middle, noting that developing students' academic vocabulary was heavily emphasized by administration.

Teachers' ranking of features of written explanations in July, October, and January, show some shifts in their notions of an ideal explanation. Both teachers' comments in workshop discussions

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

demonstrate a shift toward placing higher value on *use of drawings and diagrams*, and on *multiple solution strategies*. Both of these features were found to support students in communicating their reasoning and providing evidence that their ideas make sense mathematically. During the January meeting, teachers were asked to look through their class's writing samples and choose the "best" explanations. All five explanations selected included a clear written description of both what steps the student took to solve and why they took those steps. Further, four of the explanations were written with the structure "I [multiplied] because [reason]," and three included more than one way to solve.

Audience and Purpose Matter

Students were given two different explanation prompts with very similar mathematical tasks involving place value. One was a short prompt, asking students to replace a digit in a number and explain how the value of the number changes, similar to items on many standardized tests. The other was written as a letter from a character we named Puzzled Peter. It explains a situation in which he is buying cupcakes for the whole school and misread one of the digits in the number of students. He thinks he only needs 5 more cupcakes, but his friend Sara thinks he needs 500 more cupcakes. The letter concludes asking students to help him figure out who is correct and to use convincing evidence so he knows he won't waste his money. Though both tasks contained the same mathematical concept and both asked for an explanation, Ms. Holt's students wrote an average of 6 more words on the letter prompt than the short prompt, and Ms. Velasquez's students wrote an average of 4 more words. Several students wrote more than 20 additional words when the prompt was written as a letter with a clear audience and a purpose for producing an explanation. In addition to simply writing more, students produced higher quality explanations on the letter prompt, with rubric scores averaging 1.6 and 2.5 points higher (out of 16) than on the short prompt.

Developmental Trajectories: Building on Procedural Narratives

The first explanations students wrote were primarily procedural narrations. In our January workshop Ms. Holt reflects on her students' beginning-of-the-year writing, "At first my students started sequentially, 'first I did this, then I did this, finally I got my answer.'" She describes how engaging students in lessons that build their understanding of what it means to write a rich mathematical explanation has increased her faith in students' capacity to write mathematically: "When we worked on the shared writing activity, they had great ideas to put on the poster to make it convincing." She elaborates, "Now that I have seen what my students have come up with, I know that they can provide those components of an explanation."

After a lesson in which students practiced scoring sample explanations with a simplified rubric and self-assessed their own writing, we asked them to reflect on ways they could improve their explanations. Approximately 25% said they would tell *why* they decided to solve the way they did (e.g. "to make my score bigger I had to say why I did 10x1.5"). Other common responses include adding visuals, writing more, and solving more than one way. Moreover, Ms. Velasquez noted a key shift in her students' writing after their self-assessment with the rubric: "I saw that students began to understand the difference between an answer and an explanation." Students began, not only to write more but to include many features of a rich explanation that go far beyond procedural narration, including presenting solid supporting evidence and explaining visuals in writing so they may be interpreted by a distant audience.

Language Learners: Moving Beyond Set Phrases

At the beginning of the school year, several language learners used fixed lexical phrases that were the same across several of their explanations, despite changes in the mathematical task. Moreover, these phrases often did not match the way the students actually solved the problem. For

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

example, one EL used the phrase, "I use my drawing and the model," when it was clear from her work shown that she did not use a drawing or a model to solve the problem. This phrase showed up in four of her written explanations between August and November, and only once does it appear she may have actually used a drawing to solve. Similarly, several Spanish learners in Ms. Velasquez's class used set phrases when writing in Spanish, but not when writing in English, their dominant language. For example, "Pienso que la respesta es ____ por que hice las matematicas" (I think the answer is ___ because I did the math). Because these "chunks" of language can be retrieved whole from memory, they contribute to students' fluency, accuracy, and cohesion (Lewis, 1997). Importantly, use of set phrases may allow students to produce language associated with many different functions while they are acquiring the language of instruction. However, after the third project-developed lesson in which students analyzed mentor texts by highlighting phrases used to introduce, sequence, and reason, students' explanations included a wider variety of phrases and syntactic structures. Thus, as students engaged in meaningful experiences reading and writing mathematical explanations, their linguistic repertoires may have begun to expand.

Discussion and Significance

This study helps shed light on the features of written mathematical explanations valued by project teachers. Showing reasoning and providing convincing evidence were valued most highly, with visuals playing an important role in communicating students' reasoning. However, these features present a very different picture of "mathematical explanations" than those emphasized on current national assessments. The text box format of standardized assessments may severely limit the resources LDL students can draw upon to communicate their understanding and call into question what we want students to learn about what counts as mathematical communication. Developing writing tasks that more closely mirror the ways mathematical writing is used outside the classroom has the potential to broaden the resources and repertoires LDL students may draw upon to communicate mathematically. Being explicit about our expectations, the features of explanation we value, and the language used to achieve them, is like "letting them in on the secret" (Brisk & Zisselsberger, 2010).

pault@oregonstate.edu

Few studies of post-secondary mathematics instruction have investigated the mathematics that is offered by instructors in College Algebra courses, which historically have had high failure rates. Using Speer and colleagues' framework for analyzing post-secondary mathematics teaching practice, the study described here aimed to understand the differences in the mathematics provided by instructors for the concept of solving rational equations. Four instructors' lessons were video recorded and analyzed using this framework. Findings include that the mathematics varied widely and was often problematic. Recommendations for further analysis and professional development for mathematics instructors are provided.

Keywords: Post-Secondary Education, Instructional Activities and Practices

Few studies have investigated mathematics instruction in post-secondary contexts, and, as a result, post-secondary mathematics instruction is not well understood (Speer, Smith, & Horvath, 2010). Most explorations of post-secondary mathematics instruction have focused on upper-division courses such as Real Analysis or Abstract Algebra. The small number of investigations of mathematics instruction in lower-division courses have focused mostly on pedagogical techniques (e.g., Mesa, Celis, & Lande, 2013). In order to gain an understanding of the *mathematics* that is taught to students in lower-division courses, the study described here provides insight into the mathematical content that is presented by instructors in College Algebra courses. Such a study is important in understanding undergraduates' progress in mathematics, given that approximately half of the 700,000 students taking College Algebra in the U.S each year fail to complete the course (Haver et al., 2007).

Background and Theoretical Framework

Although students have multiple resources such as lectures, textbooks, tutors, peers, and video tutorials to rely on for their learning of mathematics, the mathematical content offered by instructors during class time remains a significant component of what students learn; as stated by Porter (2002), "students are more likely to learn the content that they are taught" (p. 3), and Weinberg, Wiesner, and Fukawa-Connelly (2014) agree that "what students take away from lecture is closely linked to what they learn" (p. 168). Thus, investigating the mathematics that is offered to students by their instructors is important to understanding what they learn in a course. Moreover, Porter (2002) acknowledged that content is often taken for granted in investigations of mathematics instruction. Knowing that content, an influential component of student learning, is often overlooked, it becomes crucial to investigate the quality and presence of mathematical content provided by instructors during class time. The selection of mathematical concepts taught and the methods used to present them can have detrimental effects on student learning. For example, students will not write down mathematical ideas provided during lecture if they cannot see how they are connected (Weinberg et al., 2014), implying that students are potentially missing important mathematical notions. Nardi, Jaworski, and Hegedus (2005) provide another example of how the quality of mathematics offered by instructors has a negative impact on students' understanding, noting that "compartmentalization" of mathematics can have a damaging effect on students' ability to "transfer tools across topics" (p. 297). Further, Bergqvist and Lithner (2012) found that students whose instructors provided algorithms without meaning or motivation came away with different understandings of mathematics than the

instructor intended. Therefore, providing motivation for topics and making connections between concepts is essential for promoting effective student learning in mathematics.

Observations of mathematics instruction have been fairly common in K-12 settings for several years, but corresponding techniques in post-secondary contexts are fairly new. In both settings, with a few exceptions, lesson content has been largely ignored for an observational focus on pedagogical moves (Porter, 2002). However, Mesa, Celis, and Lande (2013) state that "when attending to what teachers say and do in the classroom, the quality of the mathematics becomes crucial" (p. 121). Recently, Speer et al. (2010) offered a preliminary framework for analyzing post-secondary mathematics teaching practice. This framework describes seven elements of teaching practice including time allocation, sequencing of content, posing questions and using wait time, preparing and evaluating, representations and relationships, and motivating content. This preliminary framework provides a foundation for content-focused observations in undergraduate mathematics classrooms.

Methodology

Due to historically high failure rates nationally and locally, the lecture-based College Algebra course at a large, public university was redesigned in order to increase student engagement in mathematics during class time. Class sizes were reduced from 180 to 60 students, and class time was reorganized into four one-hour sessions per week, with the second and fourth sessions designated as time for students to work on small-group activities. A community of instructors worked together to choose content and develop the course schedule, activities, and exams that would be used across all sections of the course. The instructors, chosen for their backgrounds in mathematics and prior experience teaching the course multiple times in its traditional form, each provided significant input in the development of the redesigned course. Moreover, to cultivate a community of practice (Wenger, 1999) that would support the modification of their instructional methods from lecturing to assisting of groups of students in their learning, the instructors were offered two days of pre-term professional development. In addition, the instructors continued to meet weekly throughout the year (Edwards, Haven, & Small, 2011) that the redesigned College Algebra course was offered.

At different points during the year of implementation, four instructors' classrooms were video recorded; this data was initially collected with the goal of determining whether the instructors were enacting practices that would support the student engagement model. However, based on observing the wide variation in the mathematics presented to students, it became clear that a more immediate focus should be about how instructors presented mathematical topics and whether those presentations would provide guidance for students' work during group activities. Thus, the recordings were analyzed using two aspects of Speer et al.'s (2010) framework for analyzing teaching practice: how the instructor motivates specific content and how the instructor represents mathematical concepts and relationships (p. 107). In particular, video clips featuring each instructor teaching one mathematical concept, namely solving rational equations, were identified and analyzed through the lens of this framework.

For each video clip, questions chosen to correspond to the two components of the framework were answered: How is the concept introduced? What does the concept mean, and how does the instructor explain this meaning? Do instructors relate the concept to any other mathematical ideas that the students have already seen? If so, what is this connection like? The following questions were also considered to provide additional information about the mathematics present in each the clip: How is the process explained? Is it procedural, conceptual, or both? Is the mathematics provided rigorous and correct? The answers to these questions allow for direct comparison of the instruction provided in each video clip. Furthermore, the video clips were viewed independently by three researchers who met to discuss their findings and revisit the videos to confirm their observations and conclusions.

Findings

Given their similar backgrounds in mathematics and the close work of the instructors, it was assumed that the mathematics offered to students would be similar, if not identical. However, significant differences were found not in the pedagogical practices but instead in the mathematics that was offered to students. Below we present one particular case that illustrates these differences -- the case of rational equations. We chose to focus on the instructors teaching this topic because of its importance in future courses such as Differential Calculus.

The Case of Rational Equations

After learning about rational functions and their properties in College Algebra, students are introduced to rational equations; both of these topics are important to subsequent mathematics courses. Rational equation problems often involve an arithmetic combination of rational expressions and require the student to find one or more solutions to the equation. One way to solve rational equations consists of determining a common denominator which is then applied to the equation to simplify it. However, this application varied between instructors without mention of the other possible solution methods, as described below.

We observed variation in how the concept of solving rational equations was motivated by the instructors as well as in the procedure for solving rational equations. For example, two of the instructors motivated the process of solving rational equations by first providing examples of adding rational numbers with unlike denominators by obtaining common denominators. These two instructors then related this process to an example of a rational equation, with correspondences between the two examples (rational numbers and rational equations) made explicit. However, these two instructors diverged in how they solved the equations, with one instructor rewriting all rational expressions in an equation so that they had a common denominator, combining the rational expressions, and then solving by ignoring the denominator. The other instructor solved the rational equations by multiplying each rational expression by the common denominator in order to eliminate it from the denominators from the equation.

In contrast, one instructor motivated the concept of solving rational equations solely by discussing a fractional equation $?/7 = 0$. In this case, the instructor focused on what the numerator must be in order to make the equation true and then related this thought process to a rational equation example. This method of motivating the process for solving rational expressions represents a significant departure from not only the other instructors but also the textbook and assignments that were presented. However, like the other instructors, this instructor also used the idea of rewriting all expressions with a common denominator. All of the instructors discussed the need to determine whether the solutions satisfied the original rational equation. In one case, an instructor related this notion to one similar in the context of solving radical equations. Another instructor addressed the problem of a solution causing division by zero. One of the instructors explained the need to identify valid solutions, but did not offer motivation or connections to other mathematical ideas. Finally, in watching the video clips, we observed only one instructor providing both a symbolic representation and a pictorial representation of rational expressions. In particular, this instructor first represented rational numbers by drawing bars and circles divided into equal parts, and shading of those parts. The instructor used the equal sizes of shaded shapes as a way to motivate the necessity of a common denominator. This representation and idea was then connected to the need for a common denominator for rational expressions.

Discussion

Holding these findings up against the research literature on what students learn and take away from mathematics classes, we observed that the instruction on solving rational equations was often compartmentalized and did not make connections to other mathematical concepts or ideas.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Algorithms for solving the equations were often provided without meaning. In teaching mathematics in these ways, the students in these instructors' courses might come away with incomplete ideas about mathematics and without the ability to "transfer across topics" (Nardi et al., 2005, p. 297). Porter (2002) noted that "the content of instruction is an essential variable in research on factors affecting student achievement" (p. 3). In a course with such large failure rates, continued investigation of the content presented by instructors in this course will help to uncover these factors. Speer and colleagues' framework (2010) allowed us to focus on particular aspects of mathematics instruction and provided a valuable tool for investigating how mathematical topics were motivated and represented. However, the framework did not help to capture other mathematical features of instruction. As one example, the instructors also used varied mathematical language and some language was imprecise (e.g., expression versus equation) and incorrect (e.g., use of word undefined rather than indeterminate; which is an important distinction for students who continue on to calculus courses). Thus, future analysis of the mathematics instruction these video clips will aim to develop a more fine-grained and mathematics-focused lens. Finally, reflecting on the professional development that was offered to these instructors, it seems that little time was spent addressing the *mathematics*. Based on our observations in this study, we recommend that professional developers who offer training for changing instructional practice should also allow a significant amount of time to address what mathematics is offered, which problem-solving methods are emphasized, and what and how instructors will teach mathematics.

CHALLENGING A SOCIAL NORM TO ESTABLISH EFFECTIVE SOCIOMATHEMATICAL NORMS IN AN ELEMENTARY CLASSROOM

Lisa A. Brooks
University of Central Florida
lisa.brooks@ucf.edu

This qualitative study documents the establishment of new social norms in a second grade classroom in which the teacher allowed students to speak directly to one another without having to raise their hands during whole group mathematics instruction. The students initially viewed mathematics as a set of rules to follow and exhibited the role of passive recipients of information. This changed as students were provided opportunities to participate in discussions in a different way.

Keywords: Classroom Discourse, Elementary Education, Instructional Activities and Practices

Introduction

Research has provided ways in which teachers can engage their students in mathematical discourse, but has not addressed the issue of how established social norms impact student discourse. Numerous studies have established the merit of focusing on students constructing their own knowledge during mathematics instruction (Brownell, 1945; Carpenter, Fennema, & Franke, 1996, Cobb, Hodge, & Gresalfi, 2011). These researchers have provided a wealth of data to support the need for teachers to allow and highlight student discourse during instruction.

Framework/Literature

The intersection of social constructivism and sociolinguistics provides a framework for this study. The work of Vygotsky and Luria (1930) created a foundation of theory that establishes the necessity of engaging students in discourse. After conducting a series of experiments with young children, they determined that children use speech as they make sense of tasks in which they are involved. They found that as tasks became increasingly more challenging, the speech of the children also increased.

Mathematics reform efforts stress the importance of dialogue in the classroom. Students are expected to participate in a dynamic classroom in which they explain, justify, and question solutions (Cobb, Yackel, & Wood, 1992). When students participate in this type of environment, they build on their understanding as they engage with their peers. Recent efforts have proven successful for changing the expectations for student discourse during mathematics instruction (Chapin, Anderson, & O'Connor, 2003; Kazemi & Hintz, 2014).

Methods

To develop a better understanding of the negotiation of social norms, an ethnographic study was conducted with a second grade teacher, "Mr. Sharp" and his students. The goal was to describe the development of new social norms when students were no longer required to raise their hands to speak. Within this context, it was possible to learn more about how mathematical discourse patterns develop.

During the study, pre and post interviews were video recorded with the teacher and students. Video and audio recordings were also used to capture mathematics lessons. These were later analyzed with field notes taken during mathematics instruction. The teacher provided "member checks" of the information compiled during five weeks of mathematics instruction.

Analysis

Social and sociomathematical norms exist in all classrooms. Understanding these norms may provide an understanding of changes that have the potential to enhance students' experiences with mathematics. This section will describe qualities of social and sociomathematical norms in existence prior to the study and at the conclusion of the study. Social norms can be viewed as established expectations for behavior in a group setting. They can be explicitly stated or implicitly understood. Sociomathematical norms are "Normative aspects of mathematical discussions that are specific to students' mathematical activity" (Yackel & Cobb, 1996, p. 458). Effective sociomathematical norms support a negotiation of meaning. This entails establishing what constitutes an acceptable mathematical explanation and a legitimate challenge. There is also a focus on solution methods being 1) different from others and 2) sophisticated (Cobb, Hodge, & Gresalfi, 2011).

Typical Instruction

At the beginning of the study "Mr. Sharp" shared that he valued student talk and felt that he could learn about his students' mathematical conceptions and misconceptions by listening to them. However, there was a mismatch between what he valued and what he enacted during his typical mathematics lessons. While he stated the importance of having students explain their reasoning, there was no evidence of him actually doing so during instruction. His practices were not aligned to the tenets of what he espoused.

Polly and Hannafin (2011) suggest that teachers have faulty assumptions related to their enactment of student-focused instruction. Mr. Sharp's initial patterns were consistent with this research. The pre-existing sociomathematical norms were focused on procedural rather than conceptual understanding. The initial social norms, including the norm of raising hands to speak, contributed to the development of traditional sociomathematical norms that focus primarily on the actions and verbalizations of the teacher.

Student Interviews

Interviews with the students provided insight into their thinking in regard to the pre-existing social and sociomathematical norms in their classroom. When the students were asked about talking during mathematics, their responses conveyed the value of silence during math lessons. The questions were as follows: Do you talk a lot during math class? Why/Why not? Tell me about the kind of talking you do during math. The student responses are listed in Table 1.

Table 1: Sample of Beginning and Ending Interview Responses About Talking

Student	Beginning Interview Response	Ending Interview Response
Sam	No, unless it's to answer a question because most the times I know the answer. Most of the times when I raise my hand, I really don't get picked sometimes. Basically, I think in my head. Sometimes I think about the questions.	Sometimes. When we talk about shapes and how much sides and vertices they have I might talk to tell how much sides and vertices and how they make the shapes.
Charlese	Not really because I'm kind of shy. Sometimes I might get the wrong answer and I feel shy. I tell the teacher the answers like when he asks me, what is something like fifty times two, it's one hundred.	Sometimes. I'm shy. Well, I talk about what we're focused on like being an active listener and trying to do that.
Emma	No, we don't talk a lot in math because we are learning. We usually talk to the person next to us about what could the answer to the question be.	Yes, because we have to discuss the answer. Like we disagree or agree and we repeat what they said and we tell our answer. We talk about what the answer might be.
Bay	Maybe a little. Maybe talking to my friends about I got my tooth pulled this weekend…	No, because you can only talk to your friends about math.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

At the beginning of the study, the sociomathematical norms perpetuated an expectation that students were recipients of information during mathematical discussions. Student talk was limited to answering the questions provided by the teacher. It was interesting that the students equated listening with learning. Student responses indicated a focus on talking about answers to questions. Notably absent were descriptions of engaging in mathematical discussions related to the process of the mathematical tasks.

Marcus made an interesting comment about talking a lot in reading. It was his understanding that math class had a different set of expectations for talking. His impression was that talking occurred during reading class but not in math class.

Bay, on the other hand, equated the talking that she did during math class with getting in trouble. When asked if she talked a lot during math class, she assumed that meant the kind of talking that got her in trouble with the teacher.

As indicated by the interview responses at the end of the study, the students in the class developed a different mindset towards discussions during mathematics lessons. They no longer viewed their role as silent recipients of information. It was evident through the interviews with the students that new sociomathematical norms were established. Students, through their direct discussions, sought mathematical agreement and accuracy. Mathematical misunderstandings were viewed as opportunities for conversation and growth. When students shared their mistakes, it helped others in the class determine the source of the mistake and in turn provided further opportunities for understanding.

Modified Instruction

The qualities of discussions that occurred when students could speak without raising their hands were markedly different than the discussions that occurred at the beginning of the study. Rather than answering questions, the new expectation for students was that they would explain their reasoning and bring clarity to their justifications. Another quality was that of making sense of the thinking of others.

Sociomathematical norms were established concurrently with the new social norms. As students were given the opportunity to speak openly and join the conversation, their comments were geared toward bringing accuracy and meaning to the discussion.

Discussion

Figure 1 summarizes which of Mr. Sharp's actions and verbalizations supported or undermined the establishment of more effective sociomathematical norms during his mathematics lessons.

Teacher Actions and Verbalizations That Support Effective Norms
• Stating expectations
• Bringing attention to student discourse
• Modeling
• Providing challenge
• Maintaining complexity

Teacher Actions and Verbalizations That Undermine Effective Norms
• Highlighting student-teacher discourse
• Interrupting
• Demanding participation
• Requesting single word or choral responses

Figure 4. Actions and verbalizations that support or undermine effective norms

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Making the change of allowing students to talk directly to each other without raising their hands proved to be a complicated task. It was often a matter of taking two steps forward and one step back. Negotiating social and sociomathematical norms is a lengthy process that is likely to look differently in different classroom settings.

Our society needs a generation of students that have the capability to be independent thinkers. Our teaching strategies in elementary mathematics classrooms have the potential to teach students to persevere and thrive when they encounter academic challenges. Elementary students have something to gain when they learn to take ownership of their ideas and can openly share their ideas during mathematics instruction.

FRONTERAS DE INTERACCIÓN ENTRE LA INVESTIGACIÓN Y LA ENSEÑANZA: PARADIGMAS EN TRANSICIÓN

INTERACTION AND BORDER-CROSSING BETWEEN RESEARCH AND TEACHING: PARADIGM SHIFT

Margarita Itzel Curiel Neri
Cinvestav IPN
micuriel@cinvestav.mx

Claudia Margarita Acuña Soto
Cinvestav IPN
claudiamargarita_as@hotmail.com

En este trabajo hacemos un análisis teórico sobre la forma como los hallazgos de Investigación en Educación Matemática (IEM) se encuentran relacionados con indicadores para la enseñanza a través de ciertos paradigmas de investigación los cuales están presentes en las reformas educativas y estos sufren de un proceso que llamamos de adelgazamiento natural al transformarse en indicadores para los maestros, cruzando así fronteras. Hemos reconocido la existencia de dos tipos de interacciones sustanciales en esta transición de paradigmas: 1. Existen tres actores en el tránsito de los paradigmas: (a) La comunidad de IEM, (b) Los diseñadores educativos y (c) La comunidad de profesores y 2. Algunas reformas dejan huellas profundas, contribuyendo a la formación de una memoria histórica. Constataremos la memoria histórica y personal de los profesores en la etapa empírica.

Palabras clave: Teorías del aprendizaje, Estándares (en sentido amplio), Análisis del currículo.

Introducción y Problemática

En este trabajo nos proponemos entender el proceso que los resultados de investigación sufren desde que son formulados por la IEM hasta llegar al salón de clase, por lo que es de gran importancia enfocar en detalle las diversas perspectivas implicadas en el fenómeno de manera que podamos reconocer las interacciones que le dan cuerpo.

En este reporte hablaremos de dos primeros núcleos de tránsito, ya que consideramos que el proceso completo consta de tres actores principales: (a) La comunidad de IEM, (b) Los diseñadores educativos y (c) La comunidad de profesores.

Hemos llevado a cabo una investigación documental exploratoria y explicativa, con base en una revisión bibliográfica y hemerográfica en el terreno de la investigación educativa en matemáticas.

Consideraciones Desde una Primera Frontera, La Investigación

En esta primera parte mostraremos algunos de los supuestos de importancia que hemos encontrado relativos a la forma como se relacionan los resultados de investigación con los diseños educativos de la comunidad de la educación matemática, desde la perspectiva de los avances teóricos y sus supuestos centrales o paradigmas de investigación.

Los resultados de la IEM, Ciencia de Diseño, su validez y alcances

En primer lugar consideramos que la IEM es una disciplina científica (Godino, 2010), y más específicamente una Ciencia de Diseño (Lesh & Sriraman, 2010) lo que hace de ésta una disciplina muy amplia en lo relativo a sus principales problemáticas y objetos específicos de estudio. Suponemos que existen dos tipos de resultados de acuerdo a los dos campos de desarrollo de la disciplina: (1) Los que aportan al desarrollo teórico de la disciplina (teóricos) y (2) Los que aportan a las aplicaciones para la mejora de la educación matemática (prácticos) (Sierpinska & Kilpatrick, 1998). Aunque los primeros puedan inducir a los segundos.

Además, la validez de los resultados o hallazgos de investigación depende principalmente de la categoría de *pertinencia* en su contexto de uso, y es de gran importancia que los hallazgos de

investigación puedan soportar situaciones de *reproducibilidad* mediante las cuales sea posible controlar tanto las condiciones iniciales como las propiedades emergentes de las interacciones entre los (tres) sistemas complejos implicados, según Lesh & Sriraman (2010) estos son: (a) Sistemas de la vida real, (b) Sistemas complejos que desarrollan los humanos para modelar o comprender los anteriores y (c) Los modelos que desarrollan los investigadores para describir y explicar las habilidades de los primeros modelos –De acuerdo con Lesh & Sriraman (2010), los modelos son diseños que permiten considerar situaciones realistamente complejas y se apoyan típicamente en una variedad de teorías–.

Para los fines de este trabajo, debido a la amplitud del tema en cuestión, consideraremos solamente algunos de los hallazgos que han trascendido notoriamente, tanto dentro de la propia teoría educativa como en el contexto de la aplicación para la enseñanza y aprendizaje de las matemáticas a través de los últimos tiempos.

La Conformación de Paradigmas en la Teoría y las Propuestas Educativas

Desde nuestro punto de vista y de acuerdo con Kuhn (1962), "Los paradigmas son logros científicos universalmente aceptados que durante algún tiempo suministran modelos de problemas y soluciones a una comunidad de profesionales" (p.94) de tal forma que le permiten a la comunidad en cuestión afinar los resultados obtenidos y entonces surgen novedades que pueden incluso provocar cambios sustanciales en las teorías.

Dicho lo anterior, pensamos que los paradigmas de investigación en educación matemática influyen fuertemente en el terreno práctico del quehacer de la misma y son indicadores que en última instancia se consideran para proponer líneas de actuación que se concretan, con base en ciertos intereses, como actividades y expectativas específicas para los profesores.

En un esfuerzo por conjuntar las aportaciones más representativas de la IEM en determinado periodo, Wegerif (2002, p.10) reconoce cuatro orientaciones hacia el aprendizaje: 1.Conductismo, 2.Cognitivismo/Constructivismo, 3.Humanismo y 4.Participacionismo. Este es un ejemplo de la producción de diferentes paradigmas en la IEM, estas orientaciones además se pueden caracterizar de acuerdo con cinco cuestiones fundamentales, tres de índole filosófica: (1) Idea del proceso de aprendizaje, (2) Localización del aprendizaje, (3) Propósito en la educación; y dos más de índole práctico: (4) Vías de transferencia y (5) Rol del educador.

Para este trabajo partimos de que son dos las formulaciones (o paradigmas) básicas ampliamente aceptadas presentes en casi todo marco teórico actual del campo: (a) La corriente constructivista y (b) Las teorías socioculturales, a partir de ellas podemos detectar supuestos generales que sustentan y apoyan a la IEM y estas son consideradas al perfilar las prácticas de Enseñanza y Aprendizaje (EyA), de la siguiente forma:

Tabla 1: Dos paradigmas básicos para la IEM. Fuente Principal: Gutiérrez & Boero (2006)

Paradigma	Propuesta filosófica epistemológica *Perspectiva de EyA* →	Interpretación educativa *Intervención didáctica* →	Elementos de prácticas educativas
Constructivista	La génesis de la cognición se apoya sobre todo en un proceso constructivo	El conocimiento es el resultado de la actividad del que aprende	Uso de manipulables, conflicto cognitivo y resolución de problemas
Socio-Cultural	El desarrollo intelectual es una transición desde la unidad social hacia la identidad individual a través de una compleja acción mediada	La capacidad de aprendizaje depende en gran medida de las oportunidades que ofrece el contexto	Zona óptima de intervención, influencias interpersonales y sistemas semióticos de representación

Para la transición de los paradigmas teóricos a las propuestas educativas, consideramos como determinantes los objetivos de difusión y el contexto educativo, lo que provoca un proceso natural de adelgazamiento de los hallazgos teóricos que en principio aportan las teorías. Sólo de esta manera pueden éstos ser usados por los diseñadores educativos quienes deben establecer los objetos de

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

estudio, los objetivos y la forma cómo estos se presentan en la clase, por ello decimos que los paradigmas teóricos se transforman en este tránsito en *paradigmas de uso o populares* al interior de las distintas comunidades participantes del fenómeno de enseñanza-aprendizaje.

Aportaciones Desde una Segunda Frontera, Los Diseños Educativos

En esta segunda parte del análisis, describiremos los tipos de interacciones entre propuestas de investigación que han provocado los cambios de paradigmas, y las propuestas educativas desarrolladas con base en ellas, de manera que se reconoce un primer nivel de interpretación y uso de resultados de investigación para la práctica educativa.

Para mostrar un escenario de transición entre las propuestas teóricas para la educación y la tarea de los diseñadores para proponer planes y programas de estudio en matemáticas, vamos a abordar a La reforma de la Matemática Moderna (MM) como una reforma global representativa.

Implementación de una Propuesta Educativa, el Caso de la Matemática Moderna

Antes de la reforma de la MM existía un paradigma dominante: el conductismo, y dicha reforma dio paso a un cambio de postura, la que podemos observar a partir de dos propuestas básicas, como se observa en la figura 1.

Observamos que la reforma de la MM implementó novedades para la educación matemática que, aunque finalmente resultó inadecuada de manera global, aportó importantes aspectos que se retomaron en las posteriores transformaciones educativas, específicamente: (a) Buscar la unificación de las prácticas de enseñanza, (b) Modernizar los contenidos incluyendo estructuras simples de la matemática e (c) Integrar prácticas matemáticas como la deducción, la abstracción y la actividad de resolver problemas.

Antes de la reforma:
Actividades educativas apoyadas casi exclusivamente en la memorización. Énfasis fundamental en aspectos pedagógicos (de tipo conductista). Las tareas presentadas a estudiantes son esencialmente teóricas, alejadas de contextos de aplicación. Se presenta discontinuidad entre dos estrategias de enseñanza relevantes: la procedimental y la deductiva.

Después de la reforma:
(Desde Francia, 1970) Se retoma la preocupación por enseñar otros contenidos y estudiar matemáticas funcionales en áreas profesionales, enfocándose en la comprensión de la relación entre las matemáticas y la realidad del mundo. (1980) Se puso el acento en las estrategias de resolución de problemas, elementos de aplicación y una enseñanza que permitiera la experimentación, el razonamiento y la argumentación

Figura 1. Posturas educativas antes y después de la MM. Fuentes: Kline (1976) y Gispert (2014).

Las propuestas de la MM, o las propuestas planteadas a través de grandes reformas, no se abandonan del todo, porque son retomados elementos que integraran posteriores diseños educativos debido a que resultaron de utilidad, lo que apoya la idea de la construcción de una memoria histórica en lo relativo a la trascendencia de los paradigmas de investigación a través de distintas reformas educativas, que si bien está sujeta a cambios también muestra rasgos de permanencia entre las comunidades respectivas.

Observaciones Finales

Reconocer el carácter científico de la IEM nos da oportunidad de: (1) Hablar de tipos de resultados ampliamente reconocidos y (2) Establecer de qué forma pueden éstos ser útiles y válidos para la educación matemática. Además, pensar en esta ciencia como de Diseño permite: (1) Enfatizar

el papel de los intereses iniciales de esta actividad *vs* las necesidades de su uso práctico en la educación, (2) Establecer lo relativo a la validez o *pertinencia* de los hallazgos de investigación e (3) Indicar su necesario carácter consustancial de *reproducibilidad* para su implementación en los modelos educativos.

Los resultados de investigación dentro de la comunidad de IEM toman cuerpo dentro de grandes estructuras teóricas y sus fundamentos se observan a través de lo que hemos llamado *paradigmas de investigación*, éstas sustentan supuestos ontológicos y epistemológicos, y contribuyen con indicadores para el desarrollo de la práctica educativa en matemáticas.

Actualmente, desde nuestro punto de vista, es posible reconocer la existencia de dos paradigmas básicos aceptados ampliamente como válidos para la IEM, los que distinguimos como *El Paradigma Constructivista* y *El Paradigma Socio-Cultural*, que aportan diferentes perspectivas de enseñanza y aprendizaje y herramientas para la intervención didáctica.

Observamos que dichos paradigmas sufren naturalmente un proceso de simplificación o *adelgazamiento* en aras de su divulgación, pero aun siendo esta la base de apoyo, los diseñadores de planes y programas de estudio toman también en consideración otros intereses específicos, lo que posiciona a dicha comunidad, por su tarea de diseño, como un primer nivel de tránsito para la interpretación de los resultados de investigación para propuestas prácticas.

Las comunidades de usuarios de los resultados de investigación necesitan reformular los paradigmas teóricos de manera que se privilegien algunos indicadores para su uso, lo cual provoca que se formen los que estaremos llamando *paradigmas populares*.

Con base en la idea de la formación de una *memoria histórica* en la esfera institucional tenemos el paso por dos fronteras: (1) Los paradigmas de investigación y (2) Los paradigmas de uso o populares, los primeros son producto de la investigación y los segundos de la terea de los diseñadores educativos.

Lo anterior nos permite contar con categorías de análisis para rastrear los resultados de investigación hasta el salón de clase, esto es, a través de una *memoria histórica personal* en el profesor, fundamentada por la eficiencia de sus prácticas docentes y de su experiencia a través de distintas reformas.

In this paper we make a theoretical analysis on how the findings of Research in Mathematics Education (RME) are related to indicators for teaching trough certain research paradigms, which are present in educational reforms and these suffer a process that we call of natural thinning, transforming into indicators for professors, and thus crossing boundaries. We have recognized the existence of two types of substantial interactions in this process of paradigm shift: 1. There are three actors involved in the paradigm shift: (a) The community of RME, (b) Educational designers and (c) The community of professors; and 2. Some educational reforms leave profound marks, contributing to the formation of a historical memory. We will verify the existence of a historical and personal memory in mathematics professors through an empirical study.

Keywords: Learning Theory, Standards (broadly defined), Curriculum Analysis

Introduction and Subject Matter

In this paper we aim to understand the process suffered by research results from their formulation posed by the RME to their reach to the classroom, so it is very important to approach in detail the various perspectives involved in such phenomenon in order to recognize the interactions that shape it.

In this report we discuss two initial transit cores, as we believe that the entire process consists of three main actors: (a) The RME community, (b) Educational designers and (c) The community of professors.

We have carried out an exploratory and explanatory documentary research, based on a selected bibliography review in the field of research in mathematics education.

Considerations from a First Frontier, Research Endeavour

In this first part we show some of the main assumptions we identify about how research results relate to educational designs of mathematics education community, from the perspective of theoretical advances and its core assumptions or research paradigms.

The Results of the RME, a Design Science, Validity and Scope

First of all we consider that RME is a scientific discipline (Godino, 2010), and more specifically a Design Science (Lesh & Sriraman, 2010) which makes this a very broad discipline with regard to their main problems and specific objects of study. We assume that there are two kinds of results according to two general fields of development of the discipline: (1) Those which contribute to the theoretical development of the discipline (the theoretical ones) and (2) Those that contribute on the applications for the improvement of mathematics education (the practical ones) (Sierpinska & Kilpatrick, 1998), while the first may lead to the latter.

In addition, the validity of results or research findings mainly depends on the category of *relevance* in its context of use, and is of great importance that research findings can withstand *reproducibility* situations by which it is possible to control both the initial conditions and emergent properties of interactions between the (three) complex systems involved; according to Lesh & Sriraman (2010) these are: (a) real life systems, (b) complex systems developed by humans to model or understand the first ones, and (c) Models developed by researchers to describe and explain the skills of the previous models –According to Lesh & Sriraman (2010) models are designs that allow consider realistically complex situations and typically rely on a variety of theories–.

For the purposes of this paper, because of the breadth of the subject matter, we consider only some of the findings that have transcended markedly, both within the educational theory itself and in the context of the applications for teaching and learning of mathematics through recent times.

Formation of Paradigms within Educational Theory and Proposals

From our point of view and according to Kuhn (1962), "Paradigms are universally accepted scientific achievements that for some time provide models of problems and solutions to a community of professionals" (p. 94) so as to allow the community concerned refine the results obtained and then novelties emerge that may even lead to substantial changes in theories.

That stated, we think that the research paradigms in mathematics education strongly influence its field of practical endeavor and are indicators that ultimately are considered to propose courses of action which materialize, based on certain interests, as activities and specific expectations for professors' practice.

In an effort to bring together the most representative contributions of the RME over a certain period of time, Wegerif (2002, p. 10) recognizes four orientations towards learning within the discipline: 1. Behaviorist, 2. Cognitivist/Constructivist, 3. Humanist, and 4. Participatory. This is an example of the production of various different paradigms in the RME; these guidelines may be also characterized according to five fundamental issues, three of them are of philosophical nature: (1) View of the learning process, (2) Locus of learning and (3) Purpose in education; and two more of practical nature: (4) Transference pathways and (5) Educator's role.

For this study we draw from the premise that there are two basic formulations (or paradigms) widely accepted present in almost every current theoretical framework of the field: (a) The constructivist school and (b) the socio-cultural theories, departing form them we may detect general assumptions that sustain and support the RME and these two formulations are taken into account when profiling Teaching and Learning (T&L) practices, as follows:

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Two basic paradigms for the RME. Main source: Gutiérrez & Boero (2006)

Paradigm	Philosophical and epistemological proposal	Educational Interpretation	Elements of educational practices
Constructivist	The genesis of cognition is based primarily on a constructive process	Knowledge is the result of the learner's actions	Use of manipulatives, cognitive conflict, and problem solving
Socio-Cultural	Intellectual development is a transition from the social unit to the individual identity through a complex mediated action	Learning capability depends largely on the opportunities offered by the context	Zone of proximal development, interpersonal influences and semiotic systems of representation

(*T&L perspective* → between columns 2 and 3; *Didactical approach* → between columns 3 and 4)

For the theoretical paradigm shift into educational proposals we regard as determining the objectives of dissemination and the educational context, which causes a natural thinning process of theoretical findings in principle provided by theories. Only in this way can they be used by instructional designers who must establish the objects of study, the objectives and the way these are set out in class, thus we say that the theoretical paradigms are transformed over this transit in *paradigms of use or popular paradigms* within different communities participating in the phenomenon of teaching and learning mathematics.

Contributions from a second border, Educational Designs

In this second part of the analysis, we will describe types of interactions between research proposals caused by paradigm shift, and the educational proposals developed based on them, in a way that a first level of interpretation and use of research results for educational practice may be recognized.

In order to show a shift scenario among theoretical proposals for education and designers' role in proposing plans and programs of study in mathematics, we will address the educational reform of Modern Mathematics (MM) as a representative global reform.

Implementation of an Educational Proposal, the Modern Mathematics Case

Before the reform of Modern Mathematics (MM) there was a dominant paradigm: behaviorism and this reform led to a shift of approach, which can be noticed from two basic proposals, as shown in Figure 1.

We notice that the reform of MM implemented innovations for mathematics education which, even though ultimately this reform proved inadequate globally, it contributed important aspects that were taken up in subsequent educational restructurings, specifically: (a) Pursue the unification of teaching practices, (b) Modernize contents including simple mathematical structures and (c) Integrate mathematical practices such as deduction, abstraction, and problem solving activities.

Before the reform:
Educational activities supported almost exclusively on memorization. Fundamental emphasis on pedagogical aspects (behaviorist type). The tasks presented to students are essentially theoretical, away from application contexts. There is discontinuity between two relevant teaching strategies.

After the reform:
(From France, 1970) Concern about teaching other contents and studying functional mathematics in professional areas is resumed, focusing mainly on understanding the relationship between mathematics and the real world. (1980) The emphasis was placed on strategies of problem solving, application elements and an instruction that would allow experimentation, reasoning and argumentation.

Figure 1. Educational approaches before and after MM. Information sources: Kline (1976) & Gispert (2014).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

The MM proposals, or in general the proposals posed through major reforms, are not abandoned altogether since some elements are retaken to integrate into further educational designs because they turned out to be useful, which supports the idea of the building of a *historical memory* with regard to the transcendence of research paradigms through various educational reforms, albeit it is subject to change it also shows traits of continuity between the respective communities.

Concluding Remarks

Recognize the scientific disposition of the RME gives us the opportunity to: (1) Talk about types of widely recognized results and (2) establish how they can be useful and valid for mathematics education. Also, thinking about it as a design science allows us to: (1) Emphasize the role of this activity's initial interests *vs* the needs of practical use in education, (2) Establish aspects related to the validity or *relevance* of research findings, and (3) Indicate the essentially inherent character of *reproducibility* needed to implement the findings into the educational models.

Research results within the RME community take shape within large theoretical structures and its foundations are observed through what we call *research paradigms*, they support ontological and epistemological assumptions, and contribute with indicators for the development of educational practice in mathematics.

Currently, from our point of view, it is possible to recognize the existence of two basic paradigms widely accepted as valid for the RME, which we distinguish as *The Constructivist Paradigm* and *The Socio-Cultural Paradigm*, which provide different perspectives of teaching and learning, and tools for didactic intervention.

We note that these paradigms naturally undergo a process of simplification or *thinning* in the interest of outreach, but even this being the base of support, designers of study programs and curricula also take into account other specific interests, which position the design community, because of its design endeavor, as a first level of transit for interpretation of research results towards practical proposals.

Communities of users of research results need to reformulate the theoretical paradigms in a way that some indicators for their use are privileged, which causes to form what we call *popular paradigms*.

Based on the idea of building a *historical memory* in the institutional sphere we pass through two borders: (1) research paradigms and (2) paradigms of use or popular paradigms; the former are the result of research while the latter result from the educational designers endeavor.

This allows us to have categories of analysis to track the research results to the classroom; that is, through a *personal historical memory* in the professor, based on the efficiency of their teaching practices and their experience through various reforms.

TEACHERS' MOTIVATIONS AND CONCEPTUALIZATIONS OF FLIPPED MATHEMATICS INSTRUCTION

biriscis@missouri.edu

Although an increasing number of teachers report flipping a lesson or their entire class, little is known about what leads teachers to this decision or how they implement flipped instruction. Understanding these factors is important because it can allow teacher educators and researchers to investigate ways to support teachers in enacting practices that can achieve their goals and improve student learning. In this study we examine two teachers' motivations for and conceptualizations of flipped instruction. We discuss the ways in which these motivations aligned, or not, with their enactments and suggest implications for research and practice.

Keywords: Instructional Activities and Practices, High School Education, Technology, Curriculum

Although a majority of teachers report flipping (Smith, 2014), research has not kept pace. Further, studies of flipped instruction tend to treat it as a uniform approach in which teachers assign lecture videos for homework and do problem sets in class (e.g., DeSantis et al., 2015). Our study, however, has revealed great variation among flipped classes in terms of both the homework assigned and the work conducted in class. It is also likely that teachers have different motivations for implementing flipped instruction. We examined two mathematics teachers' motivations for and conceptualizations of flipped instruction in order to better understand varying perspectives of this instructional model.

Background

Teachers have long been central to innovations and reforms in mathematics education and their perceptions of such efforts are important to consider. Smith (1996) revealed that teachers' feelings of self-efficacy shifted with reform efforts because high-quality teaching was no longer equated with giving clear demonstrations. Similarly, the rise of flipped instruction may entail a new set of skills associated with high-quality teaching, such as creating compelling videos for homework or the ability to facilitate discussions in class that build on video homework.

Adopting flipped instruction may also be analogous to adopting new curricular materials. Lloyd (2008) found that such changes take time for teachers as they have to manage both the students' expectations of how to participate and their own comfort with the new curricular vision. Although flipped instruction is not a curriculum, it still requires teachers to grapple with the purposes of homework and in-class activities and to manage students' expectations of their role in their own mathematics learning. Some literature is emerging (e.g., Moore, Gillett, & Steele, 2014; Palmer, 2015) with first-hand accounts of instructors' experiences flipping and we add to this work by answering the following questions: What were the teachers' motivations for flipping their mathematics classes? How did they intend to enact flipped instruction and what did they perceive to be the outcomes of doing so? This work can help inform the development of support for teachers who are flipping their classes and direct future research on flipped learning.

Method

Two teachers participated in this qualitative study. Ms. Schaefer was a mathematics instructor at a community college and taught a flipped college algebra course. Though she had flipped lessons previously, the course we observed was the first she had fully flipped. In contrast, Ms. Temple, an eighth grade teacher, had been flipping her mathematics course for five years.

We conducted three cycles of observation in Ms. Schaefer's class. For each cycle we conducted audio-recorded pre- and post-lesson interviews to allow Mrs. Schaefer to describe the lesson we observed and her instructional decisions related to the flipped format. We also video recorded the three lessons. Additionally, we collected copies of Ms. Schaefer's videos and any tasks she used in class. Ms. Temple's data was collected from a distance and so we conducted a single initial interview with her. We conducted two observations in Ms. Temple's class, complete with video recordings and copies of her instructional materials. We also collected survey data from the teachers, which consisted of 48 item (26 multiple choice, 22 open-ended) in order to identify their implementation and perspective about flipped instruction. For the present study, the primary data sources include the interviews, surveys, and course materials.

With regard to analysis, the research team first identified sections of the interview and survey data in which the teachers discussed flipped instruction. The team then open-coded (Strauss & Corbin, 1990) these excerpts using analytic memos focused on the particular aspects of instruction the teachers discussed. From this initial coding, we met to collapse codes into the following themes: flipped experience, flipped benefits, flipped struggles, flipped in-class work, flipped at-home work, views of students, video use in class, vision of flipped instruction, students' needs, resources for flipped, student experiences, differences between flipped and traditional, and student views of flipped. These themes were used to examine each teachers' perspectives in relation to the research questions.

Findings

In this section we discuss the teachers' motivations for flipping their instruction, then discuss the ways in which the teachers conceptualized their enactments and the perceived outcomes from it.

Motivation for Flipping

Ms. Temple began flipping her class five years ago after learning about other teachers who were flipping. She discussed a specific encounter with a colleague as an impetus for flipping:

> He just said, "Hey, I think you should try this. It's really cool how much time you get with your kids in class. I think you would love it." After he bugged me for a couple months, I said, "Alright, what the heck, I'll try it." So I tried it with my advanced class and I was like "Oh my gosh, this is so cool!" … I can talk to these kids and physically see what they are doing.

Her colleague's encouragement led to Ms. Temple's implementation of several flipped lessons. However, she did not fully flip an entire course until her student teacher worked with her to develop a set of video lessons. Once she had created the videos and implemented the lessons, Ms. Temple said that her students' engagement served as encouragement to continue flipping.

Similar to Ms. Temple, Ms. Schaefer began flipping her class after hearing about the benefits of flipping from other teachers. Ms. Schaefer's motivation centered on her desire to increase interaction with students and she was drawn to the prospect of helping students develop deeper mathematical understandings. "I liked the idea of having time to deepen the understanding of math and make the real world connections that you typically do not get to do."

Enactments of Flipped Instruction

In addition to the similarities driving their initial forays into flipped instruction, both teachers had nearly identical ways of defining flipped instruction. In her survey response, Ms. Schaefer defined flipped instruction by describing the students' experiences, "Students watch prepared videos or reading assignments prior to class. Then we use class time to really dive into the material and get a better understanding of the concepts." Ms. Temple provided a similar definition of flipped instruction in her survey response, "I see flipped instruction as a method to deliver the basic content outside of

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

class and then work together and dig deeper in class together." The teachers viewed the underlying structure of this format as one in which teachers assign instructional videos for homework and practice problems in class. Despite their agreement that flipped instruction provides teachers the opportunity to provide students with a deeper understanding of mathematics, the teachers' visions for the day-to-day implementations differed.

At-home activity. Students in both teachers' classes were assigned instructional videos to watch at home. Rather than select ready-made videos such as those from Kahn Academy, the teachers created their own videos. Ms. Schaefer's videos were created using an iPad application that allowed her to capture her explanations as she wrote on her iPad. Ms. Schaefer expected her students to watch the videos and take notes as though they were attending a typical mathematics lecture. Although Ms. Temple also created lecture videos, her students' homework included those videos in conjunction with mathematics problems aligned with the videos' content. This was possible because Ms. Temple used iBooks to develop her homework. The iBooks format allowed her to include text, video, and interactive questions in a single file.

Although both teachers' homework assignments were meant to instruct students on the mathematical concepts, their instructional videos highlighted differences in their instructional practice. Ms. Schaefer presented information to the students and included a number of examples. She also pointed out a number of common pitfalls students should avoid. In contrast, Ms. Temple's homework included many anticipatory questions or activities followed by examples and explanations of a particular concept. This instruction was then followed by further opportunity for students to complete related problems. More drastic differences were evident in the teachers' conceptualization and enactment of in-class activity, as described below.

In-class activity. Ms. Schaefer and Ms. Temple had different conceptions for how to utilize in their class time with students. When deciding how to utilize her in-class time, Ms. Schaefer developed a routine for her flipped mathematics class. She referred to her format as "30-30-30." This meant that for each 90-minute class, she would spend the first 30 minutes answering students' questions on the homework video, the second 30 minutes on worksheets that she had created to reinforce the ideas from the video, and the final 30 minutes for students to complete practice problems and ask questions. Because the students tended to work at their own pace and there were no planned whole-class discussions during these segments; the students tended to work independently or with partners throughout the entire class. During this time, Ms. Schaefer walked around to provide assistance as needed.

Ms. Temple's in-class implementation differed substantially from Ms. Schaefer's. Ms. Temple did not have a fixed format but she did have several typical routines she followed.

> When they get to class they sit in groups of three or four facing each other. Typically, there is a math starter when they walk in … And then normally they go into their team discussions … then they practice in class. And it's kind of old school math practice. It might be textbook problems. It might be a handout … And then they do a quick check … Then the process starts all over again. And they usually go home with "You're going do these two pages in your notes. Here is the reading part and the video that goes along with it." And then we just repeat the cycle. And not every day is just practice. But that is just kind of more typical.

Ms. Temple's class included more purposeful grouping of students and several points at which she checked in with the whole class. Thus, while students in both classes were given some flexibility in terms of the pace at which they worked, Ms. Temple's students were typically at a similar point at the end of class because of the routine check-ins whereas Ms. Schaefer's students tended to have more variation in how far they progressed by the conclusion of a class meeting.

Perceived Outcomes from Flipped Instruction

Both teachers' discussions of the benefits of flipped instruction centered on students' collaboration in class. Ms. Temple described the defining difference between her flipped and traditional classes as student engagement, saying, "In my traditional class they (observers) wouldn't hear kids talk as much… In my flipped class, kids are talking all the time about math… and helping each other all the time." Ms. Schaefer similarly reported collaboration as the big difference between her traditional and flipped classroom. Thus, both teachers thought that because instruction was delivered via homework, the flipped model freed up class time for students to work together on mathematics.

Although the teachers agreed that the additional class time was beneficial, they reported different impacts of flipped instruction on their relationships with students. Ms. Temple said flipped instruction allowed her to develop deeper relationships with her students. She said, "I think I know my students better than I ever have, both mathematically and not mathematically." Ms. Schaefer did not feel the same way and discussed that she found it harder to build relationships with students because she only interacted with them when they had questions.

Conclusion

Ms. Schaefer and Ms. Temple had similar motivations for flipping their instruction but there was variation in the degree to which the motivations aligned with their enactments. Both teachers desired to enhance opportunities for students to develop conceptual understanding but the teachers differed in the ways in which they structured class time and activity for students to develop these understandings. For both teachers, the vast majority of their preparation time was spent on creating the video homework but they recognized the in-class time was perhaps even more vital with regard to the students' mathematical learning. Future research in this area should attend to both the at-home and the in-class portions of flipped instruction and should consider the potentially new skills and challenges that may arise from enacting flipped instruction.

FEELING THE SQUEEZE: FACTORS CONTRIBUTING TO EXPERIENCING A LACK OF TIME IN COLLEGE CALCULUS

Jessica Ellis	Estrella Johnson	Bailey K. Fosdick
Colorado State University	Virginia Tech University	Colorado State University
ellis@math.colostate.edu	strej@vt.edu	bailey@stat.colostate.edu

Calculus is an important course for STEM-intending students, yet has been shown to dissuade students from pursuing STEM due to poor teaching and being overstuffed with material. This report examines factors related to students' reporting a lack of time spent in class for students to understand difficult ideas. This work is part of a large, national study on college calculus, and provides an ideal landscape to examine these questions on a large scale. We find a number of factors related to experiencing negative opportunities to learn for students, such as student gender, the lack of previous calculus experience, and reports of poor and non student-centered instruction. These results point to a number of ways to support students in class.

Keywords: Curriculum, Instructional Activities and Practices, Post-Secondary Education, Data Analysis and Statistics

Calculus is an important course for students who intend to pursue STEM, and yet has been shown to dissuade students from pursuing STEM due to poor teaching and being overstuffed with material (Ellis, Kelton, & Rasmussen, 2014; Seymour & Hewitt, 1997). Because it serves a variety of STEM-related client disciplines, each with their own applications of calculus concepts, a lot of content is often expected to be covered. This has lead to interesting debates about both the breadth of and depth at which topics should be covered (e.g., Yoshinobu & Jones, 2012; Wu, 1999). How instructors perceive and respond to the high amount of content they are expected to cover is likely to affect students' experiences in Calculus I. In this paper, we explore what factors are related to a student's perception that there is enough time in class to learn difficult ideas. This analysis gives insight into the variability in perceived pacing of the course.

Introduction

Presumably, the more content taught in a course, the more content a student can learn in a course. In this way, the amount of material covered is directly related to the students' *opportunities to learn* (OTL) in a course. However, the sheer number of topics in a course is just one facet of OTL. As summarized by Reeves, Carnoy, and Addy (2013), the OTL construct comprises three components: (a) content coverage (list of topics and subtopics covered), (b) content exposure (amount of time devoted to instruction and time-on-task), and (c) content emphasis (which topics are selected for emphasis). There are many factors that influence content coverage, exposure, and emphasis, including interactions between the instructor and the students, student preparation (and the perception of preparation), and the results of formative and summative assessments.

While instructors ultimately dictate the pacing of the course, they may experience internal or external pressures that influence how they manage their course. For instance, 99% of Calculus I students are not math majors, with 30% pursuing engineering degrees (Bressoud, Carlson, Mesa, & Rasmussen, 2013). As a result, Calculus I is primarily a service course, where the client disciplines (engineering, physics, chemistry, etc.) have a strong influence over what topics are taught. Additionally, because of the large number of sections taught at a university in any given semester, Calculus I courses are very often coordinated (Rasumussen & Ellis, 2015). In this paper, we seek to understand what factors influence the perceived OTL from the student's perspective. Specifically, we seek to investigate characteristics of students who reported a negative OTL experience in Calculus I. Examples of negative OTL experiences include an inability for students to realize a provided OTL

(e.g., content was presented but the student did not have adequate time, preparation, or support to learn the material) and limited OTL (e.g., there was little time-on- task or an insufficient amount of material covered).

Methods

Project Background

Data for this project comes from the Characteristics of Successful Programs in College Calculus (CSPCC) project (NSF DRL # 0910240). CSPCC is a national study designed to investigate Calculus I in the United States, and involved online-surveys sent to a stratified random sample of Calculus I students at the beginning and end of the fall 2010 term. These surveys sought to investigate a number of different questions, and provided a comprehensive understanding about the landscape of Calculus I nationally, as well as providing further insight into student experiences in these courses. We have complete data (related to all questions that we address in these analyses) for 2,562 students.

Data collection and analysis

For this analysis, we use the following question as a proxy for perceived OTL: "My Calculus instructor allowed time for me to understand difficult ideas" with answer options (1) strongly disagree, (2) disagree, (3) slightly disagree, (4) slightly agree, (5) agree, and (6) strongly agree. Answers 1-3 were grouped together to indicate that the students reported that there was not enough time in class for them to understand difficult ideas, and answers 4-6 were grouped together to indicate that the students reported that there was enough time in class for them to understand difficult ideas.

What does it mean to report that you do not have enough time to understand difficult ideas? There are three components embedded within this question: what it means to have enough time, what it means to understand, and what are difficult ideas. In this paper, we are interested in student's ability to realize the OTL present in the class. Therefore, we are most interested in attending to whether or not students thought there was enough time for them to learn what was presented in the course. However, students in the same class may respond differently to this question not only because they perceived the pacing differently, but rather because they have different perspectives on what it means to understand an idea or different perspectives on what ideas are difficult. Thus, reporting that there was not enough time may indicate that the student (a) felt that instructor taught too fast for them to understand difficult ideas, (b) the instructor's teaching style did not help the student to understand difficult ideas, (c) the student was not prepared for class and so, perhaps regardless of instruction, she would not feel that there was enough time to understand difficult ideas, or (d) the student may not believe that she could understand the difficult ideas of calculus.

To begin to disentangle the multitude of factors related to the perceptions on the pace of the classroom, we conduct a regression model to understand what factors predict students' perceptions of the amount of time to understand difficult ideas. We use the binary responses to the "time for difficult ideas" question as the outcome and a number of questions from the beginning- and end-of-term surveys related to the potential explanatory factors.

Table 1 lists the factors that were hypothesized to be related to perceptions on pacing and the survey questions used in the analysis to investigate each factor. One may expect that marginalized or vulnerable populations would have less agency and influence over what happens in class, and so that marginalized or vulnerable populations would report negative OTL experiences. We specifically attend to gender because multiple studies indicate that women are more likely to leave their STEM intentions after their experience in introductory STEM courses such as Calculus I (e.g., Ellis, Fosdick, & Rasmussen, 2015; Hill, Corbett, St. Rose, 2010). We investigate the impact of classroom features as characterized by two aggregate variables of student reports of "Instructor Quality" and

"Student Centered Instruction." One may expect that reports of poor instructor quality and less student centered practices would be related to negative OTL experiences. We include previous calculus experience, standardized math test score, and the level to which the student agreed with the statement "I believe I have the knowledge and ability to succeed in this course." The first two variables characterize actual student preparation, and one may expect that less preparation would be related to negative OTL because if students are not prepared they may be less able to actualize OTLs and thus report negative OTLs. The third variable is related to students' perception of their ability to actualize OTLs rather than their actual ability. The final factor that we investigate is related to what it means to succeed in calculus. Students were asked if student success in calculus is more reliant on students' ability to solve specific kinds of problems or to form logical arguments. These questions target perceptions of what it means to actualize OTLs and provide insight into how students conceptualized "difficult ideas" in Calculus I.

Table 1: Factors and variables used in analysis

Factor	Variables used in analysis
Traditionally marginalized or vulnerable populations	• Gender
Classroom features	• Instructor • Student reports of "Instructor Quality" • Student reports of "Student Centered Instruction"
Student preparation and perception of student preparation	• Previous calculus experience (none, HS, college) • SAT/ACT mathematics score • AbilityToSucceed: "I believe I have the knowledge and ability to succeed in this course" (agree versus disagree)
What it means to "succeed" in calculus	• SuccessPerception: "My success PRIMARILY relies on my ability to": 1,2,3=1 ("solve specific kinds of problems"), 4,5,6=2 ("make connections & form logical arguments")

We fit a logistic mixed-effects regression model containing all variables in Table 1. Instructor was included as a random effect to account for unmeasured characteristics of the instructor that may contribute to pacing perceptions.

Results and Discussion

Two variables are associated with reporting negative OTL: identifying as a women versus identifying as a man, and having no previous calculus experience versus having had taken calculus in high school. This means that students who are women and students who have not taken calculus before are more likely to report negative OTL compared to men and compared to students who took calculus in high school. Three variables are associated with reporting positive OTL: perception of having the ability to succeed, reporting more student-centered practices, and reporting higher instructor quality. Of all associations, the strongest is from instructor quality. This indicates that the biggest factor related to reporting positive OTL is the perception of a "good" instructor – one who listens to your questions, makes time outside of class, encourages students to continue studying mathematics, and is approachable (among other qualities). Finally, three variables were not statistically related to reporting negative OTL: reporting that success is related to making connections and forming logical arguments versus ones ability to solve specific kinds of problems, standardized test percentile, and having had taken calculus in college versus previously taking calculus in high school. This analysis offers some insight into how we might create positive OTL in our own classrooms. This includes preparing students before they enter calculus so they feel confident in their

abilities and engaging in "good teaching" practices in the classroom like listening to students' questions, making time outside of class, and encouraging students to continue studying mathematics. This also calls attention to the disparity between experiences of similar students who differ in gender, with female students equally prepared to male students reporting less time to understand difficult ideas in class. This finding calls in to question how equitably we are providing opportunities in class, not just between men and women but also between students from underrepresented minorities and low socioeconomic status, and encourages more work to be done in this area.

CLASSROOM MATHEMATICS DISCOURSE IN A KINDERGARTEN CLASSROOM

Hala Ghousseini	Sarah Lord	Aimee Cardon

ghousseini@wisc.edu	salord@wisc.edu	cardon@wisc.edu

This study provides an analysis of classroom discourse at the kindergarten level. We illustrate how young learners can participate in mathematics discourse and how the teacher can support their engagement. The teacher in our study played a crucial role in supporting students' talk through practices that promoted collaboration around important mathematical ideas, and the provision of resources that allowed students to communicate about their reasoning with others.

Keywords: Classroom Discourse, Instructional Activities and Practices

Classroom discourse is integral to mathematics instruction at all levels. The expectation that all students will engage in mathematics discourse is central to the Common Core State Standards, which emphasize practices like conjecturing, justifying, and reconciling different ideas to analyze a problem situation (CCSSI, 2012). This work is challenging at all levels, but perhaps especially for very young learners who are still developing their general oral language skills while at the same time beginning to acquire academic language.

In mathematics, in particular, research suggests that children as early as kindergarten can consider alternative strategies and are capable of sophisticated mathematical thinking (Carpenter, Fennema, Franke, Levi, & Empson, 2014). Learning mathematics in the early years, however, is tied to students' development of language and communication skills (Greenes, Ginsburg, & Balfanz, 2004). Classroom mathematics discourse requires not only that students have the language facility to participate in general discussions, but more specifically that they are able to use language to communicate reasoned academic mathematical messages that others can understand and respond to. The teacher has a critical role in supporting student engagement in such practices, and research in mathematics education provides helpful insights into the work that teachers do in such a role. However, there is very little research on how students as young as kindergartners engage in mathematics discourse and how teachers support them in the process given their level of mathematical and linguistic development. Our work in this study aims to address this point. We use the case study of a kindergarten classroom to examine the questions "How can kindergartners participate in mathematics discourse? How can teachers support kindergartners' mathematical discourse?" Our findings highlight the way kindergartners can draw on resources available to them as young learners to engage in making mathematical claims and providing explanations. We highlight two main aspects of the teacher's work in supporting the students' discourse: her use of resources that facilitate mathematical communication, and her promotion of collaboration among the kindergartners around key mathematical ideas.

Theoretical Framework

A socio-constructivist perspective on mathematics teaching and learning frames our views of discourse and its development in the classroom (Cobb, 1994). Students' collaborative engagement in mathematics discourse supports their construction of an understanding of mathematical concepts and fosters their disposition to see mathematics as sensible and worthwhile (Michaels, O'Connor, & Resnick, 2007). Developing this level of intellectual work by young children requires intentional work on the part of the teacher, who among other things needs to "provide a range of experiences, opportunities, resources and contexts that will provoke, stimulate, and support children's innate intellectual dispositions" (Katz, 2015).

Our interest in the central role of the teacher in supporting students' development of discourse is

grounded in three teaching commitments, identified by Ball and Bass (2003) as: the *integrity of the mathematics*, the *collective as an intellectual community*, and *taking individual student's thinking seriously*. Teachers attend to the integrity of mathematics through the promotion of mathematical ways of reasoning when they press students for conceptual thinking that emphasizes not only the sharing of strategies but also explanations and justifications. Attending to the work of the community as a collective rests on the assumption that mathematical knowledge is socially constructed and validated. Helping students to engage in collective mathematical activity requires supporting their abilities to listen to and represent others' ideas, even those with which they disagree. Teachers convey their attention to student thinking in the way they hear or see the mathematical details of students' strategies, and highlight them for other students using various representations.

Methods

The study focuses on Ms. Sanders (pseudonym), a kindergarten teacher who participated in a larger study of K-5 mathematics teachers and their enactment of ambitious teaching practices. About 65% of the students at Ms. Sanders' school are economically disadvantaged, and about 6% of the students are English Language Learners. Ms. Sanders' students are representative of the demographics of her school. The ambitious nature of discourse that was evident in her class motivated us to conduct a more in-depth analysis of her practice.

We created video transcripts of five mathematics lessons from Ms. Sanders' classroom collected over the course of one academic year. Focusing mainly on the whole class discussion part of the lessons, we used grounded theory (Glaser & Strauss, 2009) to thematically code the transcripts, noting patterns in students' mathematical communicative practices and the teacher's work in supporting their discourse. We grouped these patterns into categories that reflected the students' participation structures and Ms. Sanders' instructional approaches in supporting their mathematics discourse in ways that attended to the three commitments in our theoretical framework. We each individually examined the data for themes, and then met as a research group to confirm or disconfirm our findings, and negotiate our disagreements.

Findings

Our analysis revealed that the students in Ms. Sanders' classroom consistently engaged in mathematics discourse during whole-group instruction. The following practices characterized the participation structure: (1) Students consistently explained their thinking using various resources around the classroom; (2) Students followed established classroom norms, which promoted engagement in productive mathematics discourse. These norms included sharing ideas, attending to errors respectfully, and listening and responding to one another's thinking; (3) In response to Ms. Sanders' questions, students shared solutions to a problem, explained the reasoning behind their solutions, and worked collaboratively to increase the clarity and sophistication of their explanations with the help of both the teacher and other students.

Our analysis of the ways Ms. Sanders supported her students' participation in mathematics discourse revealed that she leveraged two main categories of work: (1) using - and orienting students to - resources that facilitate mathematical communication, and (2) promoting collaborative work around the mathematics in a way that is responsive to student thinking. Ms. Sanders' facilitation of whole group discussion also followed a consistent pattern in which she solicited various student solutions to a problem, pressed them for explanations, and oriented them to each other's ideas by asking them to restate someone's idea or explain someone's reasoning. In the process she used verbal and written representations to support students' explanations and reasoning, and infused more precise use of language into the discourse. In the following sections we describe the role of both the teacher and students in the use of resources to communicate ideas and in collaborative work on mathematics.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Using Resources

Ms. Sanders and her students consistently drew on a variety of material and conceptual resources in communicating their thinking. Material resources include displays (e.g., number lines), pictorial representations, and manipulatives. Conceptual resources consist of common language (e.g., math words and symbols) and a taken-as-shared knowledge base built around students' ideas. In our analysis, we noted three specific ways Ms. Sanders supported her students' mathematics discourse with resources: (1) She made resources available around the classroom and physically within the students' reach, (2) She established the norm of moving freely around the room to seek resources to support one's thinking; and (3) She frequently oriented students to resources they could use in supporting their explanations.

In several instances of our data, we noted how students used resources in their explanations both as a direct response to a teacher's suggestion and through their own spontaneous initiative. As an example, in one lesson, the students were sitting in front of a pocket chart where the number of days the class has been in school was represented with bundled sticks (100s, 10s, 1s). They had just counted collectively 9 sticks in the ones' pocket. Ms. Sanders asked them "how many days until we make another group of 10?" A student, Aiden, replied "one." When asked to explain, Aiden stood up and pointed to the 9 on a hundred's chart that was hanging on the side of the board. He stated, " Because this is when we start, [then pointing to the 10 on the hundred's chart] and this is when we put 10." Here Aiden did not use the hundred's chart per the teacher's request, but readily reached for it to support his thinking. Our findings suggest that such behavior was typical of other students' use of resources in this class while explaining their thinking. Ms. Sanders' use of the phrase "group of ten" is an example of the way she oriented students to available conceptual resources. Later in this discussion (as we will illustrate next), Aiden uses this language to more clearly explain his thinking.

Collaboration Around the Mathematics

Ms. Sanders facilitated students' participation in discussions by promoting expectations for sharing one's reasoning. For example, Ms. Sanders would often say to the students, "Be ready to share with us how you knew that your answer was correct." Furthermore, she facilitated discussion among the entire classroom community by consistently orienting students to each other's thinking, asking students to evaluate their classmates' assertions and apply their reasoning to others' ideas. She used discourse structures such as "turn and talk," which gave students an opportunity to practice communicating about an idea with a partner before sharing with the whole group. Furthermore, to support the kindergartners' engagement with each other's ideas, we found that Ms. Sanders revoiced student responses in particular ways: Following a student's explanation, she often *narrated* student thinking to make key aspects of it visible to the class and to model the use of academic language. She also consistently *inserted specific mathematical language* during her narration to teach these young learners how to communicate reasoned mathematical messages.

The following excerpt illustrates Ms. Sanders's use of the practices described above. The excerpt continues from the example provided earlier, where after Aiden explained his reasoning in relation to "how many days till we make a ten?" by pointing to the hundred's chart, the teacher moved the chart to the center of the board and pressed Aiden to clarify his thinking.

> Ms. Sanders: What do you mean this is where we start, Aiden? Why do you start at 9?
> Aiden: [Pointing to the ones' place of the pocket chart with bundled sticks] That's our one.
> Ms. Sanders: So Aiden is looking at the ones' place and he found that we have 9 ones today. And then what did you say next, Aiden?
> Aiden: You take one more hop and you make a group of ten.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Ms. Sanders: So he says, "one more hop, and we make a group of ten." [Looking at the class while pointing to the 10 on the hundred's chart] How does Aiden know that we're making a group of ten? Isabel, what about that number tells us that we are making a group of ten there?

Isabel: Because we are having one more hop.

Ms. Sanders: Ok, can someone add on? She said, "We've got one more hop." How do we know we've got a group of ten here?

The excerpt illustrates the way Ms. Sanders used Aiden's thinking as a resource for helping the class attend to the idea of place value. By pushing the hundred's chart the center of the board, she legitimized his use of such representation to explain his thinking. She also supported Aiden's explanation by revoicing it with more precise language, inserting the notion of "the ones' place" and repeating the key idea of "a group of ten" intentionally during the exchange. Her press to have Aiden clarify his reasoning around these ideas supported him in being able to provide a reasoned mathematical message using more precise language. One can note, for example, how Aiden responded to Ms. Sanders above by saying, "You take one more hop and you make a group of ten." Then, she repositioned Aiden's contribution as the focus of the classroom community, engaging other students in practicing mathematical explanations using precise language that she reinforced in the process. This is evident in Ms. Sanders' response to Isabel, where she inserted the notion of "a group of ten" in inviting others to add to her explanation.

Discussion and Conclusion

The case of Ms. Sanders provides an existence proof that kindergartners are capable of engaging in sophisticated discourse, but to do so, they need specific supports that build on their developing knowledge and communication skills as young learners, and the resources available at their disposal. Ms. Sanders acted intentionally to gently guide discussions toward more precise language and mathematical ideas. Her use of narration and repetition of key mathematical points were aspects of her work that we found to be supportive of kindergartners' participation in mathematics discourse. They helped reposition contributions for the work of the collective.

SMALL GROUP LEARNING ENVIRONMENTS IN MIDDLE GRADES CLASSROOMS

Daniel J. Heck	Jill V. Hamm
Horizon Research, Inc.	University of North Carolina-Chapel Hill
dheck@horizon-reseach.com	jhamm@email.unc.edu

This study of middle grades classrooms addresses small group learning environments through an integration of three frameworks for examining mathematics tasks, peer cultures, and mathematics discourse. Naturalistic observations of classrooms provide illustrative episodes of limited group functioning when aspects of each framework are problematic and of high group functioning when aspects of all three frameworks are of high quality and work in concert.

Keywords: Classroom Discourse, Instructional Activities and Practices, Middle School Education

Small group learning environments promote opportunities for conceptual learning and powerful mathematical work (e.g., Esmonde & Langer-Osuna, 2013). Facilitating students' group work presents challenges for teachers because their influence on what transpires in groups is indirect. Effective group work depends on tasks that are challenging and appropriate for group efforts, peer interactions that support collaboration, and group discourse that promotes engagement and meaning-making (Cohen, 1994). This paper reports on foundational work of a research study of small group learning environments in middle grades mathematics classrooms, addressing the research question: How is the functioning of small group learning environments characterized by aspects of mathematics tasks, peer cultures, and mathematics discourse?

Conceptual Background

The operational definition for our central construct is: High functioning group work occurs when students are individually engaged and collegially communicating, seeking and receiving the help they need from one another, to explain, justify, and make meaning of mathematical ideas. This definition draws on three frameworks that we integrate to analyze mathematics tasks, peer cultures of effort and achievement, and mathematics discourse in small group learning environments. We use these frameworks to describe group functioning, to understand challenges teachers face, and to craft ways to help teachers deliver on the promise of small group work.

Mathematics Tasks

Students' work with mathematics content is operationalized through tasks. The structure and expectations of written tasks denote a set of demands for students, such as providing an answer, showing work, justifying a method, representing, and making meaning. In the context of group work, the Mathematics Task Framework depicts how tasks evolve at three critical transition points. First, when the teacher assigns a task, expectations are communicated by the written task. Second, the teacher sets up and structures the task, providing further expectations or constraints. Third, as students engage with a task, their own expectations and propensities influence the nature and quality of mathematical work they do (Stein, Grover, & Henningsen, 1996).

Peer Cultures of Effort and Achievement

Peer Cultures of Effort and Achievement reflect the activities, routines, and norms that students develop in interaction with one another, which communicate the acceptability, desirability, and value of effort and achievement. Teachers can influence peer cultures by setting expectations for students' social behaviors, providing opportunities for social interaction among students, and scaffolding the kinds of social interactions they would like students to have with classmates (Hamm & Hoffman, 2016).

Mathematics Discourse

Implicit in the assignment of tasks to student groups is the expectation that students will communicate with one another. Tasks demanding conceptual mathematical thinking must be matched by group discourse that supports a focus on reasoning, justification, and connections. Teachers can make expectations for group discourse purposeful and explicit via strategies that engage students in productive discussion (Webb et al., 2014). The Mathematics Discourse Matrix (Malzahn, 2013) specifies four key dimensions: (a) *explaining* ideas, representations, solutions, or justification; (b) *questioning* for an answer, explanation, justification, meaning, or connection; (c) *listening* to another's ideas for understanding, interpreting, evaluating, or comparing; and (d) using formal or informal, verbal or non-verbal *modes of communication*.

Naturalistic Study of Small Groups in Mathematics Classrooms

Initial data collection and analysis for the study of small group learning environments involved observations in classrooms of 11 teachers (in 2 school districts, one municipal, one rural; in 4 middle schools and 1 high school; spanning grades 6-9). Two researchers observed each classroom for two block periods, or three single periods, keeping field notes as data. We also audio-recorded the work of small groups ranging from pairs to groups of four, and five to fourteen student groups per classroom. The observed lessons were conducted just as the teacher planned, with no intervention or expectation other than the inclusion of small group work.

Our analysis in this phase considered the functioning of each small group in light of the three frameworks underlying high functioning group work. Our intent was to qualitatively characterize the work of student groups using the main concepts of the three frameworks. The results presented below illustrate an example of group work that is high functioning when the key aspects of tasks, discourse, and peer culture worked in concert to support students' conceptual engagement with mathematics. We also share examples from our results that illustrate episodes of group work that are lacking on key aspects of each framework. These examples show specific challenges teachers and students encounter when the task, discourse, or peer culture do not support students' engagement with conceptual mathematics. Key evidence is underlined.

Results: Illustrative Episodes of Small Group Functioning

In the episode below, group functioning is limited by the students' actions that reduce the demands of the *mathematics task* of analyzing relationships among lines in graph and equation form. Within this group, the students are actively avoiding challenge and meaning making the teacher seeks. The group is "on task," but it is not the conceptual task that was intended.

T: Tell me something about the lines. I'm talking about the lines.
S2: They're the same lines, just that one is in a different spot, because the y-intercept and …
T: What do you mean by …The same line usually means one on top of the other.
S1: The same line means they have the …
S2: Identical lines. Identical. That doesn't mean on top of each other, it means they're visually the same. There you go.
T: Well, then all lines are the same, they're just rotated and moved. All lines are the same.
S1: <u>Are you nitpicking on purpose?</u>
T: No, I'm just trying to get some …
S2: <u>You're doing it on purpose.</u> *S1:* Yeah.
T: Some other differences or comparisons.
S2: <u>It's entirely on purpose. You're just trying to make us think harder than we have to.</u>

The *peer culture* of the group in the next episode features a devaluing and dismissal of one student's attempted contributions toward a problem of finding surface area, leading to limited group

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

functioning. Although S3 attempts to share ideas relevant to the group's work, the other group members refuse to engage with this student's efforts. In this case, two of the students shut down what otherwise might have been a more inclusive and productive group effort.

> *S4:* What other boxes did you guys want to try? Or do you not trust me on the surface area?
> *S5:* I want to try the stack.
> *S6:* (*to S4*) I don't trust you.
> *S5:* (*to S4*) Well, since you didn't write any of your work down to show us.
> *S4:* Look, I wrote it down.
> *S5:* Ok, that is like in a very small …
> *S4:* (*Points to work to show groupmates*) Is that a 19 or a 190?
> *S6:* (*Flatly*) It's a 19.
> *S4:* (*Frustratedly*) It's not a 190? How is that not a 190?

Although engaged with the task of finding surface area of a cylinder, the group's *mathematics discourse* in the following episode remains superficial. The discussion is confined to the procedures of the task, without addressing justification or meaning for their work. The students may have deeper understandings of the task, or may have conceptual questions about the mathematics content, but the conversation provides little evidence of these understandings or questions, and consequently, minimal opportunity for the group to engage with them.

> *S7:* Did you get 12.6? Not for the answer, for the first [part].
> *S8:* For the first set, yeah.
> *S9:* Wait, I got 1102.14.
> *S8:* That's what …
> *S7:* No, that's what I got [for the final answer]. Mine was for the first step.
> *S8:* High five. You are awful at high fiving. So then, times 2 right?
> *S9:* You don't … no. No, it's done.
> *S7:* You have to find the whole surface area. S9: Nawww.
> *S8:* No, see you have to do this times two, because there's two. Then you have to find the circumference.
> *S7:* You have to find the circumference.
> *S8:* No, then you do the circumference of the whole thing, and then times it by 100.
> *S9:* Wait, are we done?
> *S8:* (*Sarcastically*) Nooooo.
> *S9:* We still have more?

In contrast to the other episodes, the students in the group episode below are grappling with the demands of a task to find the surface area of a tube (a cylinder with a concentric cylinder cut out). They show clear concern for justification and meaning of their work. The peer culture supports an inclusive process in which students are comfortable sharing ideas, and seeking help to understand which student's idea is appropriate for the task. The group's discourse includes evidence of explanations, questions, listening, and use of multiple modes of communication geared toward developing a solution that reflects shared understanding of the mathematics.

> *S10:* But we have to like … don't we have to subtract the bigger circle from the smaller circle? Right? To be able to do … ok.
> *S11:* No, because we count the inside circle and the outside of the circle.
> *S10:* No, but like the outside circle, since there's nothing there, so we don't count that as the surface area. So we have to subtract the …
> *S11:* No, we don't subtract.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

S10: We have to subtract the area from the smaller circle.

S11: We add it.

S10: Why would you add it?

S11: Because, you want to find the whole entire surface area. So that counts the outside and the inside. So this is surface area (*outside face*), and this is surface area (*inside face*).

S10: Yeah, but I'm talking about the empty circle that's there. You don't add that in.

S11: It's surface area; it's not volume.

S10: Oh … no. But like, the empty circle. There's nothing there to like … I mean …

S11: See, this is counted as surface area, and around the shape is counted as surface area.

Conclusion

Small group work integrates a mathematical task, a peer culture, and student discourse. Naturalistic data from middle school mathematics classrooms demonstrates that when these three dimensions are of high quality, small group work can support deep engagement with meaningful mathematics, and peer support for learning. Yet, other episodes reveal that when any single dimension is out of balance or of poor quality, group work suffers. Key next steps involve investigation of elements of lesson design and teaching moves that strengthen quality and support balance across the three dimensions to support higher group functioning.

ENACTING MATHEMATICAL ARGUMENTATION: MARILYN'S STORY

Sharon Heyman
University of Connecticut
Sharon.heyman@uconn.edu

Changing mathematics instruction to meet the expectations of the Common Core State Standards is challenging. This case study examines one teacher, Marilyn, who endeavored to promote mathematical argumentation as described in the CCSS. The results demonstrate that this requires an understanding of what mathematical arguments are as well as using effective pedagogical moves. A teacher may have a strong vision, but developing the kinds of questions and prompts to move to that vision is challenging. We can learn a great deal from understanding Marilyn's successes and challenges as she worked to enhance her practice.

Keywords: Instructional Activities and Practices, Classroom Discourse

Introduction

The Common Core State Standards in Mathematics (CCSSM)(NGA & CCSO, 2010) require significant changes in the way mathematics is taught in the United States. The eight Standards for Mathematical Practice (SMP) delineated in the CCSSM describe the mathematics proficiencies and habits of mind necessary for *all* students to be competitive in post-secondary education and in the 21st-century workplace.

To realize these outcomes, teachers need support in understanding these proficiencies and in implementing new instructional strategies. This case study is the story of one 6th-grade intervention teacher, Marilyn, who enacted learning from a professional development program that targeted the understanding and implementation of SMP #3. Marilyn's goal was to help her students improve their ability to develop mathematical arguments and critique the reasoning of others, both verbally and in writing. Individual stories such as this capture the complexities of implementing change, a slow and – at times – inefficient process. Specifically, the research question asks: *What are some of the successes and challenges teachers encounter when working with students to develop valid arguments and critique the reasoning of others?*

This case study was conducted as part of a larger 15-month professional development project – Bridging Practices Among Connecticut Mathematics Educators (BPCME). Forty teachers in grades 2-11 participated in BPCME, which involved 80 hours of workshops and monthly meetings throughout the school year. An important focus of the PD was developing a deep understanding of argumentation by analyzing student work, viewing classroom videotapes, and participating in a variety of interactive activities to establish a collective understanding of mathematical argument. Based on the Toulmin model (Toulmin, 2003) the Project established that an argument needs a stated claim, mathematical evidence, and a warrant; a good argument logically connects the evidence to the claim in a way that is accessible and understood by the community. The participants collaborated throughout the school year to support enactment.

Prior Literature

This study is grounded in situated learning theory (Lave & Wenger, 1991), focusing on learning as embedded in a sociocultural context. The learner does not gain "a discrete body of abstract knowledge which (s)he will then transport and reapply in later context. Instead, (s)he acquires the skill to perform by actually engaging in the process" (p. 14). In teacher learning, the classroom is viewed as the primary site for instructional development (Cobb & Bowers, 1999).

Marilyn participated in a community of practice with other teachers during a professional development program and worked to improve her own instruction by developing a community of

practice in her classroom. However, expecting elementary school children to support each other's mathematical understanding in a community of practice is problematic. For example, when Nathan and Knuth (2003) studied a 6th-grade teacher as she attempted to enact reform math teaching strategies, they found that during her first year she mostly provided analytic scaffolding of mathematical ideas. This reinforced her role as the "expert" and didn't give students the chance to construct their own learning. To encourage her students take more responsibility, she used more social scaffolding of norms for social behavior and discourse expectations in the second year. However, without the teacher guidance, student-led discussions lacked the mathematical precision and depth previously provided by the teacher. Other researchers (e.g. Cobb, Wood & Yackel, 1993; Forman, Larreamendy-Joerns, Stein, & Brown, 1998) also documented challenges in the enactment of reform mathematics. It is critical to share individual teacher's experiences, since each teacher, classroom, and school is unique. More research is needed concerning the day-to-day reality of enacting new mathematics practices.

Context: The Case Study Teacher

Marilyn was a math interventionist at Belmont School, located in a semi-urban district in the northeast. Of the 406 students enrolled at Belmont, 252 are students of color (62%). Marilyn is an African-American female who taught elementary school for 14 years in the district before coming to Belmont. As an interventionist, she co-taught and provided small group instruction to students identified as needing extra support. She sought to create a supportive environment so that her students felt safe trying different strategies to solve problems. Marilyn had high expectations for her students as evidenced by her expectation that even though they needed extra math support, they were capable of developing mathematical arguments.

As a case study teacher, Marilyn collaborated closely with me during an intervention class of six students that met for 45 minutes weekly for ten weeks. Her goal was to apply her learning from BPCME to improve students' confidence about mathematics, get them to explain their thinking, and eventually develop mathematical arguments both verbally and in writing.

Methodology

During our collaboration, Marilyn was interviewed three times (pre, mid- and post-interviews), lessons were observed and videotaped eight times, and student work was collected. In addition, the data collected from the summer workshops were available: pre- and post- Learning Mathematics for Teaching (LMT) assessments (Hill, Schilling & Ball, 2004), confidence surveys, teacher analyses of student responses to argumentation questions, teacher solutions to math content problems, reflections, and exit slips. Because this paper focuses on Marilyn's challenges and success as she implemented her new learning, the analysis draws heavily on the interviews and classroom observations.

The first step of the data analysis process was coding transcriptions of the interviews and eight lessons to better understand Marilyn's successes and challenges in promoting mathematical argumentation. I developed *initial codes* (Saldana, 2012) to document the strategies she used to support discourse: Positive Reinforcement, Sharing Mathematical Solutions, and Prompts to Explaining Reasoning, Communicate Mathematically, and Explain Others' Solutions. In her own way, Marilyn had *deconstructed* (Grossman & Shahan, 2005) argumentation into smaller components, or sub-practices, that supported discourse, though not specifically argumentation.

The next step was to develop three *second-order codes* that targeted the specific sub-practices of argumentation that were discussed in BPCME. I re-coded the transcripts to identify Marilyn's prompts and questions that (1) pressed for the development of a logical chain of mathematical reasoning; (2) pressed for student explanations of *why* mathematics supported the claim rather than telling the step-by-step procedures; and (3) required students to evaluate other students' arguments.

At the same time, I developed several *time-ordered matrices* (Miles & Huberman, 1994) to track changes in quantity and quality of Marilyn's questions and in student discourse.

Results and Discussion

Marilyn took what she learned in BPCME and developed manageable practices around discourse. However, teaching in ways that resonated with the BPCME vision of mathematics was not easy for her. During the ten-week observation period, she experienced several successes and faced several challenges. In the end, she did not move her students to meet the CCSSM standard of constructing viable arguments and critiquing reasoning of others.

Marilyn's greatest success was that she developed a trusting environment in which her students were comfortable expressing their mathematical thinking. Considering that her students were identified as needing intervention, this is no small accomplishment. Based on the initial codes, over time there were more instances of students volunteering to share without needing prompting and fewer instances of Marilyn providing positive reinforcement. By the end of the ten weeks, all but one (Tina) regularly presented his or her work publicly. Most striking was the change in Corey, who was very quiet in the beginning but became one of the primary presenters.

Through her prompting, Marilyn also made students aware of several mathematical practices: finding more than one method to solve a math problem; communicating clearly so that others understand; and being aware that stating a step-by-step procedures is not an explanation of why. Perhaps, if given more time, some of these practices would have become part of the students' repertoire.

Marilyn also faced several *challenges*. Thinking of the appropriate questions and prompts to get students to develop logical arguments and be astute enough to critique others is challenging. In the second-order coding I looked for class argumentation and commented on what was present and what was missing. I found instances where Marilyn tried, but didn't ask questions that really pressed students deeply. As demonstrated in one observation towards the end (5/18), Marilyn was still unable to get students to critique each other's logical reasoning.

> *Marilyn*: So how many of you solved your problem like Corey?
> *Jonathan*: I did 4 X 4.
> *Marilyn*: Did you do like Gerry did?
> *Jonathan*: I guess it's like Gerry's but without fractions.
> *Marilyn*: Can you show us yours then? (Jonathan shows his work.)
> *Marilyn*: So is there more than one way to solve this problem?
> *Students(chorus)*: Yes.

This is a typical example of Marilyn prompting for logical reasoning, but then being satisfied having students present different solution strategies. Developing questions to prompt for mathematical argumentation is complex. One factor that might have made it particularly difficult for Marilyn is that, as stated in her first interview, she struggled with math as a child. Although her MKT score increased as a result of her participation in BPCME, perhaps she was uncomfortable pressing students since her own depth of understanding was fragile. Another potential factor was that she had previously taught literacy and tended to incorporate literacy strategies into teaching math. For example, the time-ordered matrix demonstrated that throughout the ten-week study, 62% of Marilyn's prompts used social scaffolding (Nathan & Knuth, 2003), which successfully promoted student discourse. However, social scaffolding does not necessarily promote the kind of discourse necessary for justification of mathematical arguments.

Moreover, Marilyn's teaching environment presented logistical challenges. The study was brief—changing teacher practices cannot reasonably be expected to occur in ten weeks. Also, there were multiple conflicting initiatives pressuring teachers at Belmont School, making it difficult to

schedule PLCs. Consequently, Marilyn had little opportunity for collegial sharing with other BPCME teachers that may have provided her with further support.

The combination of the complexity of the kind of change Marilyn was attempting and the outside factors that existed made it difficult for her to fully accomplish her goals. However, during her final interview, she reported that the project was a valid learning experience that she felt made her a better teacher. She understood what a mathematical argument was and knew where she wanted her students to be, even if she couldn't quite get them there yet.

Implications and Conclusions

In most classrooms, students are not challenged to justify their thinking, develop arguments, and critique the reasoning of others. Few teachers are prepared to support their students to develop this practice. More research is needed that describes real classrooms when teachers undertake this daunting task. Understanding argumentation is necessary but not sufficient; teacher educators need to be mindful of questioning skills to press for logical reasoning. The more we know about individual teacher's experiences, the better equipped teacher educators will be to create significant learning experiences that will lead to enactment.

As the population of the United States becomes more diverse, there is a pressing need to build teacher education courses to better prepare elementary teachers to teach students from diverse backgrounds in equitable and culturally responsive ways. In this pilot study, we examine how activities designed for a course within a virtual world environment for elementary education pre-service teachers supports pre-service teachers to uncover their biases, assumptions, and beliefs about students from different social identities. Our findings reveal the pre-service teachers were very receptive to learning in the virtual world about diverse learners, and they openly discussed their biases and assumptions about students.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices, Equity and Diversity

Introduction

As the population of the United States becomes more diverse, there is a pressing need to build teacher education courses to better prepare elementary teachers to teach students from diverse backgrounds in equitable and culturally responsive ways. To address this need, we designed a course for elementary education majors that uses a virtual environment populated by students of diverse social identities to support pre-service teachers' (PSTs) understanding of individual differences and diverse cultures and communities. Although research indicates that teaching can be deeply resistant to change (Kennedy, 1999), recent research suggests that practice-based strategies can support change in teachers' pedagogies (Lampert, Beasley, Ghousseini, Kazemi, & Franke, 2010; Windschitl, Thompson, & Braaten, 2011). According to the InTASC standards, "Teachers must have a deeper understanding of their own frames of reference (e.g., culture, gender, language, abilities, ways of knowing), the potential biases in these frames, and their impact on expectations for and relationships with learners and their families" (p. 3). Therefore, within the course, PSTs are provided opportunities to (1) develop awareness of their hidden biases and stereotypes of who can and cannot do mathematics and science and (2) rehearse alternative responses and practices that serve students of diverse social identities more equitably. Prior to fully implementing the course with our pre-service teachers, we piloted activities we designed to examine how the activities help unmask PSTs' hidden biases. Consequently, the purpose of this study is to examine how the virtual environment can be used to support PSTs to uncover their hidden biases, assumptions and beliefs about diverse students from different social identities.

Theoretical perspective

In the quest to not only integrate equity issues into the course curriculum but frame it as a vital component of teaching mathematics, we drew on Villegas and Lucas' (2002) vision of culturally responsive teachers. They describe culturally responsive teachers as: (a) being socioculturally conscious, (b) having affirming views of students from diverse backgrounds, (c) seeing themselves as responsible for and capable of bringing about change to make schools more equitable, (d)

understanding how learners construct knowledge and are capable of promoting knowledge construction, (e) knowing about the lives of their students, and (f) designing instruction that builds on what their students already know while stretching them beyond the familiar. While the course incorporated each of these components, for the purpose of this study, we focused on how PSTs develop affirming views of students from diverse backgrounds. Teachers who have affirming views of students from diverse backgrounds "acknowledge the existence and validity of a plurality of ways of thinking, talking, behaving and learning" (Villegas & Lucas, 2002, p. 23). Teachers' views of students affect the learning opportunities of students and affirming teachers positively affect student achievement.

Course Context

The researchers developed a course that integrated the virtual world and traditional environment to prepare PSTs to teach mathematics and science in culturally responsive ways. Through combining virtual and traditional environments, the course "authentically" engages PSTs in practice-based rehearsals with diverse learners in ways that are typically not possible in traditional courses. The virtual school environment was constructed using OpenSim, a free, open source multi-platform 3D virtual world. For the course, the researchers developed twenty student avatars (visual representations of a person in a virtual environment) and corresponding background case profiles, which represented a diverse set of students' social identities. The PSTs had the opportunity to assume the "identity" of their assigned student avatar in the course. In addition, the PSTs designed their own "teacher" avatar, which was a virtual version of themselves, which reflected the social identities most salient to them as teachers. Throughout the course, the PSTs (1) unpack their own biases, behaviors, and assumptions related to students' mathematics and science identities; (2) analyze how their instructional decisions support or hinder mathematics and science learning for students of all social identities; (3) establish classroom norms that encourage mathematics and science participation for students of all social identities; (4) incorporate students' everyday understandings and experiences in ways that support their mathematics and science identity construction; and (5) use discursive practices such as eliciting student thinking and drawing on students' funds of knowledge that have been linked with increased learning among students from non-dominant groups. By participating in the course, PSTs will develop a deeper understanding of and be better prepared to meet the needs of all the students in their classrooms.

Methods

This preliminary research took place during the Fall 2015 semester at a university located in the Midwest region of the United States. The researchers recruited three undergraduate students who were majoring in elementary education and seeking either a mathematics or science endorsement. Prior to participating in the study, the undergraduate students completed an elementary mathematics methods course and a course in multicultural education. The three participants were white females who would student teach the following semester. For this study, we piloted activities and assignments that will be used in a course we developed for elementary PSTs.

Data Collection and Analysis

The undergraduate students (henceforth referred to as PSTs) participated in five two-hour video-recorded sessions. During the sessions, the undergraduate students (1) learned to navigate their avatar in the virtual world, (2) designed their teacher avatar in the virtual environment, (3) assumed the "identity" of an assigned student avatar, and (4) participated in a classroom teaching scenario as their student avatar in the virtual world. After each session, we had a debriefing session with the PSTs where they reflected on the activities and shared their thoughts and ideas on the assignments and ways to improve it. Two stationary cameras captured how the PSTs engaged in the activities and

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

their dialogue as they engaged in the activities. In addition, the PSTs wore camera glasses to individually capture their interactions in the virtual world.

The PSTs were assigned a student avatar and were provided a case profile of their avatar. The case profile included the student's (1) name, (2) age, (3) race, (4) ethnicity, (5) sex, (6) socio-economic status, (7) faith/religion, (8) (dis)ability, (9) parental employment, (10) first/home language, (11) family structure, (12) household information, (13) student quotes about schooling/living experiences, (14) family/community cultural practices, (15) family or community history, (16) educational history (IEPs, test scores, experiences with other teachers, etc.), (17) parental involvement, (18) information about previous mathematics and science learning, (19) former teacher gossip, (20) interests and experiences outside of school, and (21) personality. The PSTs read through their case profiles, logged into the virtual world where they saw the representation of their student avatar, and discussed their initial thoughts and perceptions of their new identity. The PSTs used Jing within the virtual world to record a 3 - 5 minute autobiography of themselves as the student avatar. Within their autobiography, the PSTs addressed the following prompts: (1) Who are you?; (2) What three words describe you and why?, (3) What is a typical weekday in your home?; (4) What is a typical weekend?; (5) How do you feel about mathematics and science and why?; (6) What do you find easy about learning mathematics and science, and what do you find challenging about learning mathematics and science?; and (7) What do you want me to know about you?

Two of the researchers individually analyzed the video recorded sessions and recorded autobiographies. We individually wrote analytic memos (Maxwell, 2005) based on the data. We then identified patterns within the data related to the PSTs' biases, assumptions, and beliefs about students with different social identities.

Results

Prior to receiving the case profile on their student avatar, the PSTs had an opportunity to discuss their initial assumptions and beliefs about the student based solely on the student's name and what the student looked like. For example, when the PST saw Alejandro as an avatar, she was initially confused because she did not expect him "to be a white boy with red hair." She assumed Alejandro's name sounded Hispanic, and she had a preconceived image of what Alejandro would look like as a Hispanic boy, which was not representative of the avatar. Moreover, the PST noticed Alejandro was dressed in overalls. She was perplexed that a kid who looked Caucasian with red hair wore overalls. Furthermore, she thought only farmers and African Americans wore overalls. But, she soon refuted the notion that Alejandro was a farmer because he only wore one strap, and "farmers would not necessarily wear one strap on their overalls because they are wearing them for a purpose." In actuality, Alejandro was a biracial (African American and Filipino) nine year-old from a middle class family who lives in an apartment near the elementary school. Both of his parents were college graduates, and his mother was a trained nurse from the Philippines.

After the PST received and read the case profile of Lupe, she researched Lupe's cultural heritage to provide additional information to her autobiography. She knew that Lupe was an eight-year old Hispanic Latina whose primary language was Spanish. Her family was from Mexico, and her father was undocumented. Her family's socio-economic status was in the lower income bracket. She liked mathematics, but she struggled with it; and she was not confident in her problem solving skills. In Lupe's autobiography, the PST explained that it was customary for her and people from her culture to be fashionably late. She commented,

> In my research I focused on her Latina and Mexican culture so the site I found said not being on time was socially acceptable, which I never really thought about it, but I work with someone who is and we do something and she always show up 20 minutes late.

Since the PST experienced this assumption, she generalized it to be true for the entire culture.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

As researchers, we noticed particular items Lupe did not discuss in her autobiography. Similarly, we noticed how the PST who assumed the identity of Melissa did not include specific details in her autobiography, which may factor into the PST's biases and assumptions about Melissa. Melissa was a ten-year old Native American whose ethnicity was Meskwaki. Her family was very close, and her extended family lived on the Meskwaki Settlement. She attended tribal school on the Settlement during kindergarten - second grade. When she transferred to her current school, she was tested and identified for special education services. Her teacher said she was a "good kid, but very quiet and a slow learner." After reflecting on her autobiography, the PST realized Melissa's case profile did not say she "did not like this new school." The PST acknowledged that it was "something I assumed because she has been struggling and she has not made any new friends at the new school." In addition, the PST discussed her (Melissa's) religion of Christianity in great detail, but the case profile also mentioned the Meskwaki religion was extremely important. This was not discussed in the autobiography.

Discussion

Although the PSTs were familiar with playing video games like Sims, they were not accustomed to seeing characters/avatars that were non-white or avatars in wheelchairs or on crutches. One PST stated, "It [avatars of color and avatars in wheelchairs] was something I definitely did not expect to see." Through engaging in the pilot activities the PSTs openly shared their biases, assumptions, and beliefs about students from various social identities. These biases, assumptions, and beliefs influence how teachers and PSTs instruct mathematics to their students, which ultimately impacts students' learning of mathematical content. It is important that we, as mathematics teacher educators, take the time and engage our PSTs in tasks and activities that give them the opportunity to expose their biases and beliefs so it does not negatively affect their teaching practices. Once their biases and assumptions are revealed, and the PSTs acknowledge their biases, the PSTs will then be able to develop an affirming view of students from diverse backgrounds. This in turn, will help PSTs develop deeper understandings of and be better prepared to meet the needs of all students in their mathematics classrooms.

STRUCTURAL CHANGES IN COLLECTIVE ARGUMENTATION IN A COMMUNITY OF MATHEMATICAL INQUIRY

Nadia Stoyanova Kennedy
New York College of Technology, CUNY
nkennedy@citytech.cuny.edu

This report describes an inquiry into the process of argumentation in a community of mathematical inquiry format. The study explores changes in the structure of argumentation with logical-mathematical problems in a dialogical group setting with 21 fifth grade students. It concludes that the process exhibits an alignment of group members' participation in the collective argumentation process, suggesting a process of internalization, which the author illustrates through an analysis of the argumentation macrostructure and its changes over the course of one year.

Keywords: Classroom Discourse, Instructional Activities and Practices, Reasoning and Proof

Background

Argumentation, here denotes a social activity in which subjects engage each other with the goal of coordinating different perspectives through justification of their assertions. An important assumption is that argumentation implies a dialogical dimension, for dialogue is the condition for the emergence of new perspectives within and between the participants (Forman, Larreamendy-Joerns, Stein, & Brown, 1998). From a dialogical point of view, engagement in an argumentation discourse obliges the participants either to justify their positions and to examine their claims in the light of the claims of others, or to balance both justification and negotiation processes in a third way (Leitão, 2000). Both processes prompt awareness of oppositions between the views or beliefs of participants, and reflection on the information they are provided with.

Numerous studies suggest that the experience of being exposed to conflicting views in a context of argumentation leads to significant restructuring of participants' understanding of a topic (Forman et al., 1998; Leitão, 2000; Van Eemeren & Grootendorst, 1994; Krummheuer, 1995; Resnik, Salmon, Zeitz, & Wathen, 1993; Pontecorvo, 1993). Other researchers note that examining opposite sides of an argument does not always lead the participants to a change of views, but rather to further polarization (Stein & Miller, 1993; Perkins, Allen, Hafner, 1983; Kuhn, 1991). Toulmin (1969) offers something of an explanation of this discrepancy by emphasizing the importance of developing rational canons and proper habits of inference, which can serve as stepping-stones for argument-building mechanisms.

Attempts have been made to analyze the different patterns and mechanisms of intellectual exchange that occur during argumentation. Toulmin (1969) has proposed that the "layout" of an argument—data, warrant, backing, conclusion--represents an ideal model of substantive argumentation, and provides a tool for the analysis of argument structures. However, some studies suggest complex relationships between the structure of an argument and the functional aspects of argumentation (Krummheuer, 1995), between argument structure and the nature of the situation in which the collective argumentation happens (Resnick et al., 1993), and between argument structure and the distributed thinking among the participants, who set the shared framework for interpreting an argument (Forman et al., 1998; Inagaki, Hatano, & Morita, 1998). Reflection upon these complex issues poses a methodological question not only as to how to set up a systematic and meaningful unit for the analysis of argumentation itself and changes in its structure.

Most of the research done on students' reasoning and argumentation (e.g. Pontecorvo & Girardet, 1993; Resnick et al., 1993) tends to restrict its sphere of examination to so-called argumentative operations—namely justifications, concessions, oppositions, and counter-oppositions, all based on an

argumentation model offered by Toulmin (1969). This study operates under the assumptions that argumentative operations, although they are the major constructive elements of reasoning, are not the only critical moves involved in the process of argumentation, and that in fact other critical moves contribute to the process on an essential level. The study suggests that in the course of the group inquiry throughout the year, participants begin to align their individual arguments and to use auxiliary operations that help build more complex argument structures.

Research

The research study here described was conducted in a self-contained fifth grade classroom in a suburban public elementary school in northern New Jersey over the course of one year. The 21 students involved in this project were 10 and 11 years old. The study was intended as primarily qualitative and naturalistic in nature. More specifically, I adopted a "grounded theory" approach (Glaser & Strauss, 1967) in order to analyze the structure of argumentation process, and trace how it evolves in and through argumentation.

In keeping with grounded theory, I examined the argumentation process—comprised of a sequence of arguments--and took the argument itself as a unit of analysis in order to explore patterns of change. An argumentation process may consist of one or more single arguments. This complex unity of individual arguments may be thought of as the *macrostructure* of the process. Nor are arguments the only building blocks of the larger structure—they are accompanied by other functional elements such as explanations, clarifications, reformulations, summarizations, questions, etc., that facilitate the formation of the single arguments and their sequences. My research question was concerned with the analysis of and changes in the macrostructure of argumentation in a community of mathematical inquiry. The analysis focuses on the macroscopic argumentation structure, i.e. the pattern of organization and the sequence of the single arguments that comprised the argumentation process.

The exploration of the argumentation macrostructure is based on a comparison of two samples of transcripts. The first four transcripts from the whole series of conversations were selected to comprise the first sample, and the second sample is a collection of the last four transcripts. The categories developed through an open coding of the transcript yielded a picture of the changes in the argumentation structure as progressing from argumentation with a mostly chaotic structure of disconnected arguments towards a structure exhibiting argument alignment schemas, i.e. individual arguments aligned through various links. These argumentation schemas were further "saturated" by searching through the two samples of transcripts—that is, by looking for instances representing the respective schemas.

Analysis

The macrostructure of the first sample displayed a notable tendency toward dissociation in the sequencing of arguments. The argumentation sequence is marked by strings of isolated claims--most of which are enthymemes, which are not connected—i.e. either derived from or referred to—to any of the others. There were no links between them--the macrostructure was characterized by, not a logical sequence, but a chaotic structure of disconnected arguments.

Overall, the profile of the first sample of transcripts displays a macrostructure composed of a series of single arguments, some of which are distinctly dissociated from their ancestors and predecessors. A significant number of consecutive arguments lack any explicit or implicit links between them, which rendered the argumentation sequence chaotic and difficult for the inquirers to follow. It makes the argumentation dependent on the "translation" and "bridging" function of the facilitator (Kennedy, 2009). The chaotic argumentation structure is isomorphic with the chaotic functioning of the group inquiry process, triggering attempts by the facilitator to impose order on the argumentation process.

The macrostructure of the second sample of transcripts exhibits quite a different organization of the argument sequence. Close scrutiny of the latter discloses a new pattern in student responses—that is, aligning their arguments with those preceding them. This new pattern is broadly reminiscent of what Pelerman & Olbrechts-Tyteca's (1969) call "argumentative association," which refers to the identification of an associative relation between two elements that were previously regarded as disconnected. In this case an associative intervention of this type will be identified as an *argument alignment schema*. Two types of argument alignment schemas can be identified in the data. The first type pertains to what will be referred to as *alignment with agreement* with the previously presented argument.

The argument alignment schema can display different structures. First, a process of argument alignment takes place—or a linkage of the argument to be advanced with an already proposed argument. Second, this alignment might be further coupled with a restatement, a clarification (unpacking), or an amplification of the already proposed argument. Below is a brief example of *alignment with clarification* found in Sarah's response (albeit incorrect) in the following excerpt from a discussion about a chiming clock[1].

> *Rashaad*: If you just do 6 times 2 is 12….if you just double….and five times is 10, so…uh, it will be 10 seconds.
> *Sarah*: I agree with Rashaad. Here are 5 fingers and only 4 spaces. [She uses her fingers] How many spaces are there between 6 fingers? [She holds her fingers wide open] That's 5. If you have another 6 [strokes], that will be 5 more spaces, so there will be 10 spaces altogether.

We found that the use of these different schemas contributed to building a serial argument which was in turn composed of several subarguments (or "stages"), in which the conclusion of one served as a premise for the subsequent subargument. It appears then, that the use of the alignment argument schema in its different modalities--the simple, the clarification, and the amplification schema-- may function as a springboard for the argumentation building process.

Another type of alignment argument schema identified in the data will be referred to as *alignment with disagreement*. On such occasions, the student most often signalled her alignment with the phrase "I disagree with." This alignment with disagreement schema differs from alignment with agreement in that it usually bridges two or more often contradictory or divergent arguments--the argument presented by the speaker and the one already presented—and a new conclusion is often juxtaposed with the previous conclusion. The new argument may be presented as counter to the previous argument, but it functions as an intersection that forces the group to make a decision as to which argument is sound. The next example shows an argument with alignment with disagreement that follows soon after Sarah's intervention.

> *Vincent*: I disagree. Some people were saying that it takes 10 sec, but they say 5 sec. here and then another 5 sec. here *separately*, …and don't count the second in between. If you count it … it would be 11 seconds.

Conclusion

In summary, it would appear that the "ideal" structure of both types of alignment argument schemas includes: 1) the signaling of alignment by "agreement" or "disagreement" by a key phrase; 2) a restatement which may include clarification of all or part of the previous argument; 3) the presentation of a new argument consistent with the previous one, which may a) strengthen, amplify, or extend the previously stated conclusion, b) the advancement of a counter argument which leads either to a refutation or a modification of the previous argument, or c) a synthesis of a) and b).

The study's findings suggest the presence of an "invisible," spontaneous at first, and inherently educable collective argumentation structure in group deliberation of this kind, and identifies patterns of change in that structure.

Endnotes

[1]The Chiming Clock problem reads as follows: A clock strikes 6 times in 5 seconds. How long would it take the clock to strike 12 times?

PRESERVICE ELEMENTARY MATHEMATICS TEACHERS' DECISION MAKING: THE QUESTIONS THEY ASK AND THE TASKS THEY SELECT

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Preservice elementary mathematics teachers' choice of questioning sequence in a hypothetical representation of practice was examined in comparison with their choice of follow-up task. Findings indicate that preservice teachers' task choice, and their rationales for task choice, has a statistically significant influence on their choice of questioning sequence.

Keywords: Classroom Discourse, Teacher Education-Preservice

Background and Overview

Teachers' questioning strategies during mathematical discussion strongly influence students' engagement in and understanding of mathematics (e.g., Franke et al., 2009; Hufferd-Ackles et al., 2004). Most recommendations designed for teachers encourage the use of probing questions and sequences that press students to make mathematical meaning. However, Kosko (2014) found that elementary preservice teachers (PSTs) have a stronger preference for prompts that generate discussion (i.e., soliciting statements and descriptions from other students). Although the amount of teaching experience and associated knowledge are potential factors of incluence, recent study of inservice teachers' mathematical questioning suggests a complex interaction between instructional context, pedagogical disposition, and mathematical knowledge for teaching (Kosko, in press). It is probable that a similarly complex interaction occurs for PSTs. The present study seeks to examine a portion of this system by focusing on how variation in mathematical task interacts with the pedagogical decision of question sequence.

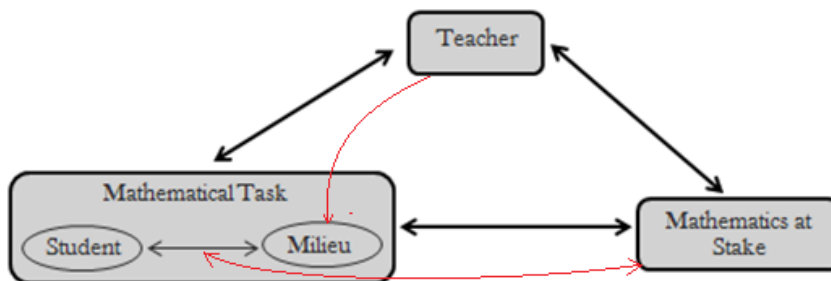
The present study positions itself in Herbst and Chazan's (2012) theory of practical rationality. The theory suggests that teachers can justify their pedagogical decisions by appealing to aspects of their individual disposition (i.e., pedagogical knowledge, content knowledge, beliefs) or to aspects that the teacher is socially nested in (i.e., instructional norms, professional obligations). Specifically, teachers of mathematics use their practical rationality to justify their pedagogical decisions. In the case of facilitating mathematical discussions, an elementary teacher must negotiate a social space that includes multiple students with individual needs, but must also take into account the mathematical knowledge at stake. Herbst and Chazan's (2012) adaptation of the instructional triangle offers a useful visualization of part of this interaction with regards to practical rationality (see Figure 1). Teachers may interact with the posing of the mathematical task, but may also operate more directly by supporting the milieu of the task in which the student interacts: where milieu serves as the environment that students interact with to engage in the task. This latter 'support of the milieu' often serves as scaffolding and includes, among other things, teachers' use of questioning. Thus, Herbst and Chazan's (2012) adaptation of the instructional triangle suggests that a teachers' questioning can directly affect the milieu the student interacts with in working on the mathematical task. Yet, the mathematics at stake influences both how the teacher may consider such questions and how the student may interact with the milieu the teacher is scaffolding.


Figure 1. Herbst and Chazan's (2012) adaptation of Cohen et al.'s (2003) instructional triangle.

The study of mathematics teachers' practical rationality for instruction necessarily requires attending to the instructional context. Herbst et al. (2011) describe the use of comic-based representations of practice as one means of providing a common instructional scenario in which multiple teachers may interact. Describing the use of the LessonSketch platform, Herbst et al. (2011) suggest that "comics with cartoon characters offer a semiotic resource that enables a high degree of control…over the possibility of creating alternatives, highlighting issues of tactical decision-making" (p. 94). In the context of the present study, this affordance allows for the presentation of different potential mathematical questioning sequences a teacher may use for a given instructional scenario, as well as the tasks they may pose throughout a lesson. Specifically, the present study presented PSTs with two completed questioning sequences to select following an initial framing of the instructional scenario. PSTs were then presented with the same two options for the mathematical task to follow the questioning sequence choice. Recalling Herbst and Chazan's (2012) adaptation of the instructional triangle (see Figure 1), this approach allows for the examination of how PSTs consider the mathematics at stake through their choice of questioning and rationale for the task they select. Specifically, a PST's choice of a follow-up task in an instructional scenario should logically follow from the mathematics at stake in the lesson at-large, and also be informed by the interaction between the student and milieu of the prior task. Therefore, the choice of questioning sequence used to scaffold the milieu of the prior task should also align with the mathematics considered at stake by the teacher.

Methods

Data were collected from 63 PSTs enrolled in three sections of an elementary mathematics methods course between January and December 2015. As part of the methods course, participating PSTs completed an online experience via the LessonSketch platform. The experience included three components. In the first part of the experience, PSTs reviewed the stem of an instructional scenario in which the depicted second-grade teacher, Mrs. Cox, asks one of her students, Jasmine, to explain why 8+17=10+15 is true. Jasmine replies that "It's true because it's all 50." Prompted for further explanation, Jasmine states that "8 plus 17 is 25. 25 plus 10 is 35. 35 plus 15 is 50." PSTs are then presented with two multi-slide question sequences, along with student responses, summarized in the purpose statements below. PSTs were asked to select the sequence most appropriate to improve students' mathematics learning:

- "The teacher needs to encourage additional student participation to have other strategies for how the problem was solved and compare those strategies."
- "The teacher needs to press Jasmine to explain her thinking more clearly until Jasmine recognizes something is not working with her explanation."

Each above statement was followed by three slides depicting the teacher's prompts and student responses. Following the choice of questioning sequence, PSTs were then asked to select one of two

tasks (see Figure 2). Finally, PSTs participated in a forum in which they shared their rationales for their choices and discussed the pedagogical "pros and cons" of the different options available.

Task 1:
  "Using Cuisenaire rods along a double-sided number line, have students create a number train to show 8+17 and another train to show 10+15."
Task 2:
  "Using a number balance, have students represent 8+17 on one side of the balance and 10+15 on the other side."

Figure 2. Descriptions of mathematical tasks following decision of questioning sequence.

PSTs' choice of questioning sequence and their choice of manipulative-based task were compared using a Chi-Square analysis. Table 1 presents the resulting contingency table with observed counts in normal text and expected-by-chance counts in italicized text. Results suggest that PSTs' choice of questioning sequence and manipulative-based task was not independent from chance ($\chi^2(df=3)=6.00$, $p = .014$). Examination of Table 1 indicates that PSTs who chose the "press for meaning" sequence were relatively more likely to choose the double-sided number line than expected by chance, and less likely to select the number balance than expected by chance. Likewise, PSTs who chose the "generate discussion" sequence were relatively more likely than expected by chance to choose the number balance, and less likely to choose the double-sided number line.

Table 1: Contingency table for tasks and question sequences

	Number Balance	Double-Sided Number Line with Cuisenaire Rods	Total
Generate Discussion *multiple strategies*	40 *36.5*	6 *9.5*	46
Press for Meaning *single strategy*	10 *13.5*	7 *3.5*	17
Total	50	13	63

A Systemic Functional Linguistics approach (SFL) was used to examine PSTs' rationales for their choices ($n=18$). Following Chieu et al. (2015), PSTs' rationales for decisions were identified following logical indicators for conjugation (because, so, if-then). Rationales for task choice and for questioning sequence were both examined. Regarding rationales for task choice, four themes emerged from analysis across posts: the choice of task aligns with the mathematical meaning for the equals sign ($n=17$); the choice of task accounts for composing/decomposing numbers ($n=4$); the choice of task provides a visual/concrete representation of the mathematics ($n=8$); and the choice of task accounts for numeric value ($n=4$). Next, data were quantified to examine the statistical effect of PSTs' stated rationales on the choice of task. A lambda statistic was calculated for each rationale. Only one lambda statistic was found to be statistically significant. Specifically, the presence of rationales to *account for the composing and decomposing of numbers in the equations* reduces the

error in predicting the choice of selecting a double-sided number line with Cuisenaire rods by 57% (L=.57, p=.023). Thus, PSTs who identified the mathematics involved in recognizing number combinations were more likely to choose the double-sided number line. For example, one PST stated that having students use Cuisenaire rods requires students "to break the numbers further apart (ex: 17= one 10 rod, and one 7 rod) and that would require background knowledge of breaking a whole number apart into smaller sums to make up the number."

Rationales for questioning sequence were examined with two common themes emerging: the choice of question sequence facilitated Jasmine's individual needs, or the choice of question sequence facilitates the social space of the mathematics discourse. Interestingly, these rationales were found to be statistically similar across question choice. Thus, in the examination of PSTs' rationales for their choices, the only rationales with predictive power were those related to the mathematics pedagogical features of the manipulative-based tasks, and the mathematics each afforded. Confirmatory evidence for this finding comes in the form of four PSTs' explicit change of choice in the forum discussions to change from using the number balance to using the Cuisenaire rod activity. Specifically, conversation in the forum suggested that four these PSTS, composing/decomposing number was an important facet for understanding equivalence. By contrast, no PSTs identified a change from using Cuisenaire rod activity to the number balance activity.

Discussion and Conclusion

The findings from the present study suggest that certain mathematics considered by PSTs to be at stake directly affects the tasks posed. Further, the mathematics at stake may indirectly, but significantly, affects the questions posed by PSTs. In the case of the present study, PSTs who considered composing/decomposing of number were proportionally more likely to select a probing sequence instead of a generate discussion sequence. However, findings suggest that other justifications, both of the mathematics and the questioning sequence, were statistically similar across PSTs' decisions. Thus, PSTs' mathematical questions may be predicted, and facilitated, by the mathematics considered at stake in instructional scenarios, but only in regards to certain mathematics concepts at stake.

THE DISCOURSE OF BILINGUAL MATHEMATICS TEACHING AND LEARNING

José Manuel Martínez
Michigan State University
mart1580@msu.edu

Mathematics teachers in bilingual contexts have reported not being prepared to teach both mathematics and language. As a response, research efforts have recommended instructional strategies that, although desirable in any context, are particularly important in bilingual classrooms. In this study I report the initial stage of a larger study involving a second grade classroom in a public Spanish immersion school in the US, and a fourth grade classroom in a private English immersion school in Colombia. I interpret data through the lens of definitions of Discourse and situated perspectives on bilingual mathematics learners. Data suggest that teachers and students create a Discourse particular to bilingual mathematics classrooms. Such conceptualization will support the ongoing exploration of nuanced, contextualized instructional strategies and other ways of being that are unique to bilingual mathematics classrooms.

Keywords: Classroom Discourse, Instructional Activities and Practices, Equity and Diversity

In spite of the increase in the number of bilingual students in American public schools, many teachers report not being prepared to teach mathematics in bilingual contexts (Tan, 2011). This dichotomous view has led to teaching tensions, such as how much attention to give to mathematics teaching and how much attention to give to language teaching. Previous studies have responded by recommending instructional strategies (for an example and list of references see Chval, Pinnow & Thomas, 2015). Among the recommended strategies are scaffolding, using multiple representations, providing several terms to refer to the same concept, suspending language-related feedback to focus on students' mathematical ideas, and attending to gestures as a way of communicating mathematical ideas. Although these strategies seem necessary to teach mathematics any context, the strategies seem to be particularly important in bilingual classrooms.

In this study, I present the overall characterization of a Discourse that is particular to bilingual mathematics classrooms. This characterization is the initial part of a larger ongoing study. I analyze two different bilingual contexts, exploring examples of classroom episodes and teachers' insights. I provide examples of characteristics of a distinct Discourse that both bilingual mathematics contexts seem to share. Finally, I discuss implications for future research, including the author's ongoing research: supporting an exploration of nuanced and contextualized instructional strategies and other ways of being that are unique to bilingual mathematics settings.

Theoretical Framework

Gee's (2011) definition of Discourse, and Moschkovich's (2002) characterization of situated perspectives on bilingual mathematics learners support this study's characterization of a Discourse that is particular to bilingual mathematics teaching and learning contexts.

Big D Discourse

Gee (2011) defined big D Discourse as

Distinctive ways of speaking/listening and often, too, writing/reading coupled with distinctive ways of acting, interacting, valuing, feeling, dressing, thinking, believing, with other people and with various objects, tools, and technologies, so as to enact specific socially recognizable identities. (p. 37).

Based on this definition, Discourses are ways of being based on what and how socially recognizable communities act. For the purpose of this paper, for teachers and students to participate in particular Discourses implies to communicate and interact in particular ways. Students and teachers' participation in a particular Discourse also implies engaging with specific tasks, in distinctive ways, using certain resources. Those ways of being are particular to the identities of being teachers and being students, in a schooling setting. Those ways of being are socially discernible ways of being.

Gee (2011) defines three components of a Discourse. First, **social language** is "a specific variety of language" (p. 39). Social language determines what syntax participants use, and the contextualized meanings of certain words. For the purpose of this study, teachers and students use language in a particular way during the schooling experience. Certain ways to give directions or to address each other using spoken language are particular to teachers and students' interactions during schooling situations. Second, **figured worlds** are what a person considers to be typical or normal in a particular context. A figured world might be taken for granted, subconscious, and unquestioned. A part of teachers and students' figured worlds might be that the teacher is the one who gives directions, and distributes turns during class discussions. Third, **social practices** are observable activities that people in a particular community do together. Discourse participants might be unaware of taken for granted, unquestioned social practices. A social practice in which teachers and students engage might be for students to sit in a circle at a carpet at the front of a classroom, while the teacher stands by the board asking questions.

Situated perspectives on bilingual learners

Moschkovich (2002) extended some of Gee's earlier ideas about Discourse to the context of bilingual mathematics learners. Moschkovich (2002) proposed the notion of learning as participating in mathematics discourse practices. Examples of those mathematics practices are precision, brevity, and generalizing. She also argued that understanding the nuances and intricacies of mathematics learning in bilingual contexts implies attending to meanings of words in particular situations, the resources participants use, and the practices in which students engage.

Based on Gee's (2011) definitions of Discourse introduced above, I extend Moschkovich's (2002) conceptualization of mathematics learning in bilingual contexts as participation. Instead of regarding mathematics teaching and learning in bilingual contexts as participation in a Discourse of mathematics, I use empirical data to characterize mathematics teaching and learning in bilingual context as a distinctive Discourse in and of itself.

Methods

Here I report the initial data that guides subsequent stages of a larger study. The larger study is an ongoing exploration of classroom discourse in two different bilingual mathematics classrooms. Current parts of the study, not reported here, expand data collection to conduct discourse analysis of interactions in both classrooms over a more extended period of time.

Sites and Participants

One site was a second grade classroom in which all 23 students were English native speakers, studying mathematics in a Spanish immersion program. This public school is located in a Midwest state in the US, and all students came from low-income families. The teacher is an American female, English native speaker who had taught for 7 years at the elementary school level. She had taught in bilingual contexts for 5 years. The other site was a fourth grade classroom in which all 24 students were Spanish native speakers, studying mathematics in an English immersion program. This was a middle class, private school located in Colombia, South America. The teacher is a Colombian

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

female, Spanish native speaker who had taught for 10 years. All her teaching experience had been in bilingual settings at the elementary school level.

Data Collection

Data included class video recordings, field notes, and transcripts of interviews with each one of the teachers. During the last week of the 2014-2015 school year, I observed three consecutive days of mathematics classes, video recording during the third day of observation. The video camera focused on the teacher, following interactions between teacher and students. Observational and analytic field notes (Glesne, 2006) complemented video recordings. One of the interviews with the teachers took place prior to the observations. A second interview took place after the observations, observing and discussing the teacher's video.

Data analysis

I followed Powell, Francisco, Maher's (2003) framework for video analysis: (1) repeated attentive viewing; (2) using descriptive annotations referenced to specific time markers; (3) identifying critical events. I considered critical events those that could potentially exemplify these two components of Discourse, as defined by Gee (2011): social practices, and social language. I transcribed critical events, including spoken language and non-verbal communication. I then analyzed the transcripts, coding social practices, and social language. Social practices codes included the resources participants use, cooperation among students, and the use of multiple representations to communicate mathematics ideas. Social language codes include the language used (English, Spanish, or both), intonation, volume, and variation in speed of speech. Subsequently, I shared these examples with each one of the teachers, as teacher and researcher watched the video of their respective class. The teachers and I attempted to unveil teachers' figured world about teaching mathematics in bilingual contexts. To make teachers' figured worlds explicit, I elicit awareness of some of the social practices.

Findings

Data suggests that research sites share social practices, social language, and figured worlds.

Social practices

The teachers identified in their videos example of several social practices. The teachers related some of those social practices to bilingualism, including: teachers and students' use of non-verbal communication to support spoken language; displaying and referencing mathematical ideas on the board and poster; and students' communicating and explaining mathematical ideas. Although not captured in video, both teachers mentioned that they interact with their colleagues to support their language and their mathematics understandings. Both teachers parallel that practice to students' cooperation to support each other's mathematics and language.

Social language

Teacher identified three main characteristics of how teachers and students use language. First, participants use of both languages, Spanish and English, at different moments. Second, teachers noticed frequently modulating the speed of their speech based on students' reactions. Third, both teachers and students intentionally used the language that more clearly expresses any given mathematical concept. For example, in the Spanish immersion school, the class was discussing the clues that would help children discover a mystery number. A student who was mainly using English (his native language) joined the teacher in using the word *impar* (Spanish word for odd to refer to numbers). The Spanish word for even is *par*, and the Spanish word for odd is *impar*. Knowing the root *par*, and that the suffix *im* implied negation, helped the student categorize numbers as even or

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

"not even." The student used of the Spanish word *impar*, emphasizing the syllable *im*, to indicate that the number he was looking for was not even.

Teachers' figured worlds

During a preliminary interview teachers described a variety of instructional strategies of which they were aware, including: scaffolding, focusing on multiple connotations of particular words, and providing sentence stems to support students' production of spoken language. While observing their respective video during the second interview, however, teachers did not refer to their instructional moves as strategies. Instead, they referred to those moves as normal ways to teach their class. When asked about the instructional strategies enacted in the video we were watching, the teacher in the Colombian English immersion school answered "No sabría decirte, porque yo actúo así en clase siempre (risas). No sé." She added, "[in that episode] estaba dando una instrucción. No sabría cómo más [dar la instrucción] ¡Normal!" In several occasions, instead of referring to her instructional moves as strategies, the teacher described the episodes as normal and usual: "No sé... Porque pues, para mí esto es la instrucción de clase normal."

Discussion

The teachers and students in this analysis seem to go beyond participating in the discourse of mathematics with English as social language, and participating in the discourse of mathematics with Spanish as social language. Instead, they seem to establish a Discourse particular to bilingual mathematics teaching and learning. As such, that Discourse involves specific figured worlds–visions of what teachers and students consider normal in their context–, and particular social practices that teachers engage with but of which they are unaware. That Discourse of bilingual mathematics teaching and learning overlaps but differs from a general mathematics discourse, as well as from a mathematics discourse in which English is the mean of communication, or one in which Spanish is the mean of communication. It overlaps but is different from participating in Discourses considered examples of "good math teaching" in general. That particular Discourse provides more affordances to participants than its constituent parts–English math discourse, and Spanish math discourse–. Exploration of bilingual mathematics learning contexts as a distinct Discourse can help understand teaching as a way of being in a particular context. This conceptualization could explain some instructional strategies as situated and responsive, as opposed to discrete, prescriptive, and universal. It also could inform teacher education toward modeling and fostering particular ways of being, as opposed to recommended decontextualized blanket statement strategies. This conceptualization also highlights multiple resources that are unique to bilingual mathematics learning contexts. Thus, it contributes to shift attention from perceived challenges to the powerful affordances of teaching mathematics in bilingual contexts. My purpose is not to generalize or make claims about all bilingual mathematics classrooms. Instead, this initial exploration of particular characteristics of bilingual mathematics classrooms guides the ongoing more detailed analysis of Discourse.

PARENTS' PERCEIVED COMMUNICATION ABOUT MATH CURRICULUM

P. Janelle McFeetors	Lynn M. McGarvey

Parents' growing concerns about the "new math" are drawing public attention. Rather than dismiss such concerns, understanding parent perceptions and garnering their support is essential to ongoing curriculum transformation and children's success. In this paper, we present the preliminary findings of a phenomenographic study examining parent perceptions of children's mathematics learning. We focus specifically on the sources of curriculum related communication identified by parents: (a) homework, learning tasks, and other products the children brought home, (b) direct reports from teachers and schools, (c) the child's problem solving demonstrated outside of school, and (d) public media coverage (e.g., newspaper).

Keywords: Elementary School Education, Curriculum, Policy Matters

Purpose of Study

I don't know what the new math curriculum that my kids are learning is all about. There has been no serious explanation and communication whatsoever why they changed something that had worked perfectly fine into something that vague. I don't know enough about the new math; but I don't feel right to compete with what they are being taught in school. So I try to learn with them but here comes my frustration: the new way doesn't work for me. (Parent)

The comment above describes the tension expressed by many parents regarding the perceived lack of communication about changes to mathematics teaching and learning today. In Canada, the tug-of-war between "new math" and "back to the basics" is being played out with much media attention. Decades of research consistently demonstrate the advantages of conceptually-based approaches to mathematics learning in multiple areas including problem solving, modelling, disposition, inclusivity, and equity (e.g., Baroody, 1999; Boaler, 2002; Henry & Brown, 2008; Russell & Chernoff, 2013; Thompson, et al., 2013). However, communication of reforms and advantages has not reached parents—even those potentially open to change. Unconvinced and frustrated parents have joined coalitions (e.g., WISE Math) and launched petitions (e.g., Tran-Davies, 2013) in an effort to oppose curriculum reforms and return to basic skills, standard algorithms, and mastery through memorization.

Recognizing the challenge to communicate reforms, our research aims to identify fruitful ways to engage in productive conversation about mathematics curriculum reform with parents. In this paper, we present preliminary findings from a study aimed at understanding parents' experiences with and perceptions of mathematics curriculum change. In particular, we focus on the sources of curriculum-related communication described by parents as a way to identify useful avenues to communicate current expectations for mathematics learning.

Perspective

Parental involvement in children's educational experiences has far-reaching benefits such as improving achievement, increasing motivation, and reducing anxiety (Pattall, Cooper & Robinson, 2008). Parents are viewed as an "untapped resource for improving mathematics performance" (Hyde

et al., 2006, p. 136). Yet, parental involvement, particularly in mathematics, is frequently viewed to be ineffective and potentially detrimental to learning (Bartlo & Sitomer, 2008). We seek to avoid a deficit framework of parent involvement by drawing on a common theme in current literature that attempts to describe and shape parent perception and involvement (Lightfoot, 2004; Civil & Bernier, 2006; Marshall & Swan, 2010; Peressini, 1998). Furthermore, meaningful parent involvement includes not only communication about their children's performance, but also accessing explanatory sources of the curriculum rationale and discourse, especially in the context of curriculum reform (Remillard & Jackson, 2005). In this study, we build on our previous work of reframing public opposition into collective concerns (McGarvey & McFeetors, 2015a, 2015b) by gaining in-depth understanding of the existing communication approaches as perceived by parents in order to assist in knowing how to dialogue with and empower parents to fully participate in their children's learning. Phenomenography offers the conceptual framework and methodological approach to achieve our project objective.

Research Methodology

We used phenomenography (Marton, 1986; Marton & Booth, 1997) to inquire into the range of parents' perspectives on mathematics curriculum change and how it has been explained to them. It affords portrayal of a broad range of perspectives. Researchers draw phenomena into participants' awareness to characterize and understand their perspectives. Qualitative data consisting of participants' explanations of their views are collected and then organized into categories using emergent criteria based on similarities and differences (Akerlind, 2012). The categories are substantiated through rich description of data excerpts, emphasizing the meaning of participants' perspectives through the relationships among categories to provide a mapping of the field of inquiry. The variation in participants' perceptions, in turn, aids researchers in interpreting the phenomenon under study.

Data Collection

Forty parents from urban and rural communities in a Western Canadian province participated. They completed a demographic questionnaire and participated in one of ten focus groups taking place in their respective communities. Focus groups, each approximately two hours long, were used as generative sites of data collection with the knowledge that differing parent perspectives required participants to explain their perspective to others, allowing us to notice differences in their concerns for their children's mathematical learning and in their experiences of the mathematics curriculum. We sought to develop a finely nuanced understanding of the dimension of variation within parents' perspectives. Therefore, focus groups were structured to prompt parents to address four key components: 1) parents' observations of their child's learning and the curriculum; 2) parents' recollection of their own mathematics learning; 3) parents' effort and interactions when helping their child with mathematics at home; and, 4) parents' expectations about their child's mathematics learning. Individual follow-up interviews were conducted with fifteen parents to elicit further specific examples for the four key components and to seek clarification in understanding perspectives shared in the focus group.

We used a constant comparative approach in sorting statements made by the parents in the focus groups and individual interviews to identify qualitatively different perceptions expressed. The sorting process was comprised of an initial individual reading and a second group comparison. Generated categories were analyzed for their portrayal of the widest range of perspectives and were further substantiated through rich data excerpt descriptions. In this paper we focus on parent descriptions of the ways in which information about their child's learning and curriculum reforms were communicated to them. In listening to parents' perspectives of hearing about mathematics curriculum

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

reforms, we found that there were existing forms of communication that we might leverage in order to elicit parents' full participation in their children's mathematical learning.

Results

Across the four components guiding data collection, parents articulated some characteristics in their children's mathematics learning that they attributed to current reforms such as knowing multiple strategies for computation, being able to explain their thinking, and using manipulatives and technology. Many parents also expressed a perceived lack of practice needed to develop fluency in computation.

Parents acquired knowledge of their children's progress in math mainly through four venues: **(a) homework, learning tasks, and other products their children bring home to finish:** *"The biggest thing to know how my kids are doing is homework. That's something I can actually do with them, to know exactly what they're working on."*

(b) direct reports from teachers and schools: *"Once in a while my kid comes home with a piece of test paper with some math questions and a mark he gets. He's supposed to get it signed and returned back to the teacher." "I get email from the teacher about my kid's weekly progress. Then I would ask her about it. It gives you a starting point to actually talk about math, less like pulling teeth. This provides me the ability to be more engaged."*

(c) the child's command of math concepts as demonstrated in their problem solving outside of school context: *"I pulled out the multiplication cards and he had them all right and he using his fingers for some of the computation. He's like, 'Okay, that's a 3 and I can double it' and I could hear him working it out loud. I can tell perhaps there was some mathematics teaching occurring as opposed to just sheer memorization."* and

(d) public media coverage, such as television, newspaper, and the Internet: *"I heard the term 'Discovery Math' from the news mentioning a petition against it. That's the only time when I caught onto the fact that 'Hey, the kids are doing something different than what I thought they were doing.'"*

Parents expressed dissatisfaction with the frequency and volume of the products reported back home, which were considered the primary source of communication. The observations in everyday life and media coverage as indirect sources often issued confusing and even conflicting information. Overall, parents indicated limitations in understanding their children's mathematics learning and a lack of communication around the rationale and pedagogy of the mathematics curriculum. In our presentation, we will further illustrate each category with excerpts from the parent-participants' statements.

Discussion

Our study provides a new perspective to address the "math wars" by specifying sources parents acquire information of the children's mathematics learning and curriculum reform. The research results offered insights into parents' interpretations of curriculum as well as sources shaping their interpretations. Inconsistencies were found between parents' direct contact with mathematics teaching and comprehension of the curriculum rationale, which lead parents to generate presumed understandings about mathematics curriculum reform. However, despite various assumptions, parents indicated a strong desire for communication about current approaches to mathematics and curricular expectations and genuine interest in supporting their children. As we question borders erected between parents and their children's mathematics learning in school, we can begin by enhancing the systems already used to communicate mathematics learning with parents. The research findings, therefore, will open up further possibilities of dialogue with public audiences and engender their support for curriculum reforms addressing the diversity of children learning mathematics.

OPPORTUNITIES FOR MATHEMATICAL INTERACTION THROUGH PRESCHOOL ROUTINES

Lynn M. McGarvey
University of Alberta
lynn.mcgarvey@ualberta.ca

Nicole M. Jamison
University of Alberta
nicolec@ualberta.ca

This report presents the findings of the first phase of a professional development project with preschool teachers working alongside mathematics educators. Six preschool teachers were interviewed to identify specific examples of mathematical activity within regular classroom routines such as arrival, snack time, circle time, centres, and clean up. From the interviews the teachers identified a wide range of examples that took place through purposeful planning for circle time and centres. Fewer activities were identified by individual teachers during snack and arrival routines, but collectively they shared several opportunities including sorting, patterning, counting, and measuring. The range of examples demonstrates promise for the collaborative professional development in the next phase of the study.

A preschool classroom is a busy place. Children are often engaged in many different activities simultaneously: filling containers at the sand table, building towers in the blocks area, or arranging furniture in the dollhouse. All of these activities offer rich opportunities for mathematical thinking, but the teacher plays a critical role in making the mathematics explicit through comments, questions, and contributions to activities. The importance of mathematics learning in the preschool years has become prominent in research and policy (English & Mulligan, 2013). Yet, mathematical thinking, beyond counting and shape labelling, has not been part of the educational experiences of many preschool teachers. As a result, opportunities for mathematical interactions may go unnoticed (Ginsburg, Lee, & Boyd, 2008).

In this paper, we report on the preliminary findings of a professional development project with preschool teachers working alongside mathematics education researchers. In the first phase of the study, six preschool teachers were interviewed to establish their current practices with regard to integrating mathematical opportunities into classroom activities. These practices form the baseline for the professional development phase of the study that took place in spring, 2016. The project is based on the following research questions: What do preschool teachers notice as opportunities for teacher-child mathematical interaction in the classroom? And in what ways might collaborative professional development expand our capacity for noticing and articulating opportunities for mathematical interaction in a preschool classroom?

Conceptual Framework

In recent years there have been advances in the field of professional development of preschool teachers (Sheridan, Edwards, Marvin, & Knoche, 2009); however, research that honours the knowledge and expertise of these teachers is needed. Our interest is in contributing to the transformation of pedagogical practice by working alongside preschool teachers to advance the teaching of mathematics in the early years. The study takes into account the goals of professional development articulated by National Council of Teachers of Mathematics (NCTM, 2010) including building teacher mathematical knowledge, making connections to practice, improving dispositions, strengthening ongoing collegial relationships, and fostering "teachers' capacity to notice, analyze and respond to student thinking." With these features in mind, the methodological framework for our study is conceptualized within the professional development literature of "teacher noticing" (Sherin,

Jacobs, & Philipp, 2011). According to Mason (2002), "every act of teaching depends on noticing" (p. 7). Yet, what one notices is a function of a person's experiences, dispositions, educational philosophies, and cultural backgrounds. Becoming sensitized to previously unnoticed opportunities may mean articulating and challenging personal perspectives allowing teachers to move beyond habitual responses in familiar situations.

Methods

The six participants teach children ages 3-5 in three different preschool sites and in four different classrooms. One setting is a stand-alone junior kindergarten while the other two settings are pre-kindergarten programs housed in elementary schools. All participants hold bachelor's degrees—five in education and one in music—and two participants also hold master's degrees. Most of the teachers are relatively new to teaching preschool and range in experience from three to eight years. The five participants who hold bachelor's degrees in education taught in other elementary grades before choosing to teach in preschool.

The data reported in this paper is based on a 30-minute semi-structured interview with each of the six participating teachers. The interviews took place in the participants' school in or near their classroom and consisted of (1) demographic information of their teaching experience; (2) memories of and comfort with mathematics; (3) prompts to recall recent examples of mathematical interactions and activities in classroom routines such as arrival/greeting, circle time, centre time (e.g., house, blocks, sand/water, arts and crafts), snack time, clean up, and others; and (4) challenges or concerns with regard to addressing mathematics beyond what they were currently doing in the classroom.

Findings

Close reading of the interview transcripts revealed that all of the teachers could recall many specific and recent examples of mathematical activities taking place in their classroom. Many of the activities, particularly with regard to centres and circle time, were purposefully planned to include mathematical content such as counting, measuring, sorting, and patterning. Collectively, the teachers could also recall a range of mathematical ideas embedded into some of their other regular routines and they added examples from other routines or components of the program such as music class and lining up activities (see Table 1 next page). The teachers clearly recognized many opportunities for mathematical interaction in their daily activities in the classroom.

When asked what curricula or resources they used to plan for mathematical activity, they all mentioned that they did not have a specified program or curriculum at the preschool level, but four of the six teachers said they referred to the kindergarten curriculum for direction and occasionally used kindergarten resources. During one teacher's interview, she shared a large planning book that listed materials and manipulatives that existed in her classroom. She used the book to plan for centres and while leafing through the book could articulate the mathematical potential that existed in materials. For example, she noted that the measuring cups, bottles, scoops, and medicine droppers that could be used to measure and compare amounts at the sand and water table. She also noted that many of the games (e.g., Candy Land, Connect 4, Bug Bingo) and fine motor manipulatives (e.g., dominoes, bristle blocks, wooden shapes) lent themselves to mathematical ideas involving counting, shapes, and patterns. Even though she said she was aware of the mathematics, she was not sure how often she interacted with the children to make those ideas explicit.

Several of the teachers referred to the developmental appropriateness of some of their activities. For example, although some of the teachers questioned whether calendar activities were suitable for young children, they felt the need to balance the appropriateness with children's desire to know about upcoming events. One teacher said that the children asked incessant questions about whether the next day was a home day or school day; how many more days until Halloween; or when their birthdays would be. Rather than use a standard calendar, she created a visual alternative by placed small

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

squares in long rows across the bulletin board. Each square represented a day; special events and home days were shown, but dates, months, and days of the week were not included (see Figure 1 below).

Table 1: Mathematical Activity During Preschool Classroom Routines

Classroom Routine	Preschool Teachers' Examples of Mathematical Activity
Arrival/greeting	• Children ask about the numbers of students present/absent based on sign in grid. • Children find matching shoes from the shoe bucket
Circle time	• Count the number of days on the calendar and use popsicle sticks to represent each day to 100 school days. • Taking attendance and counting the number of children present/absent
Centre time (i.e. house - imaginary play, blocks, sand/water, arts/craft/painting, playdough)	• Board and card games • House – buying groceries and exchanging money • In-class hopscotch • Blocks: balance, how many in a tower • Pattern blocks – making puzzles • Number bingo • Fine motor centres include many sorting activities • Crafts involved making snowman with Styrofoam and comparing heights • Filling buckets with snow – full empty, half full, almost empty
Snack time	• Comparing the size of water bottles
Clean up time	• Object and manipulative sorting • Stacking chairs – maximum of three in a stack
Lining up to go outside or to bathroom	• Line up and count how many boys and girls; creates a concrete bar graph • Numbers on the bathroom stalls
Music	• Patterns with actions to music; "jump, jump, jump" three times. • Songs with counting such as "10 in the Bed" and "5 Little Monkeys" • One-to-one correspondence – one word for one beat., on clothing
Getting children's attention	• Action patterns e.g., "head, tummy, head, tummy …" as the children move to the carpet.
Figure 1. Alternative Calendar.

In addition to purposeful planning based on student interests, the teachers identified some opportunities for mathematical interactions during other routines such as arrival/greeting, snack, and clean up. For example, during arrival/greeting in one class, children had to find their matching pair of shoes from the shoe bucket. At snack time, another teacher noticed a pair of children comparing the heights of their water bottles. As a final example, several teachers indicated that students were using sorting rules (e.g., same type of toy or colour) at clean up.

Conclusion

From these initial interviews, the teachers were able to identify a range of mathematical activities. Of interest were the range of opportunities noticed by the teachers. For example, one teacher appeared to emphasize counting and number in many daily activities, but another referred frequently to patterning and measurement. Also, while they purposefully planned for mathematical

activities during circle and centre time, teachers were looking forward to learning about ways to integrate mathematical thinking into other routines.

The next phase in the project to be completed by spring 2016, will be to engage in professional development sessions through collaborative video viewing with the preschool teachers. Through these sessions, we hope to increase participants' and researchers' attention to and awareness of different possibilities for action within preschool routines, and to further consider ways the teacher may make the mathematics explicit through purposeful interactions.

MAKING RESPONSIVENESS EXPLICIT: CONFERRING IN THE ELEMENTARY MATHEMATICS CLASSROOM

Jen Munson
Stanford University
jmunson@stanford.edu

Responsiveness is critical to math learning. This study examines how elementary mathematics teachers use a discourse structure adapted from literacy instruction - the conference - to engage in responsive teaching with students as they grapple with mathematical tasks. Teacher-student interactions from nine lessons in two fourth grade math classrooms were analyzed to define the structure of a math conference. An emergent typology of the pivotal conferring teaching move, the nudge, is presented.

Keywords: Classroom Discourse, Elementary School Education, Instructional Activities and Practices

Responsive teaching is critical to math learning. When teachers use their understanding of student thinking to craft instruction, students can learn with meaning (Carpenter, Fennema, & Franke, 1996). Interactions between teachers and students are one crucial way teachers learn about and respond to student thinking. However, Franke et al. (2009) have shown that while teachers readily learn to ask initial questions of student thinking, asking appropriate follow-up questions and planning the next move is much more challenging. Notably, many elementary teachers, who typically teach multiple disciplines, have a responsive discourse structure in literacy instruction, the *conference* (Calkins, 1986). In this study I examine the practice of conferring when it crosses the disciplinary boundary from literacy to mathematics and how the conference structure can support responsive teaching in mathematics.

Conceptual Framework

Calkins (1986) has defined the architecture of literacy conferences in elementary classrooms as *research-decide-teach*. The teacher's role is to determine what the student needs – moves called *research* and *decide* - and provide differentiated, scaffolded instruction in the model of cognitive apprenticeship, or *teach* (Calkins, 1986). To adapt this structure to mathematics instruction I draw on the *professional noticing of children's mathematical thinking*, defined by Jacobs, Lamb, and Philipp (2010) as three distinct but intertwined processes: *attending to*, *interpreting*, and *deciding how to respond to* student thinking. In conceptualizing what it means to *teach* in the mathematics conference, disciplinary differences suggest that students need opportunities for productive investigation rather than cognitive apprenticeship. In previous work, I termed the *nudge* as the set of moves that teachers use to teach in the math conference and which suggest a productive pathway without dictating a series of steps to follow.

Drawing on these concepts I offer the following framework for the teacher's process for conferring with students, (see Figure 1):

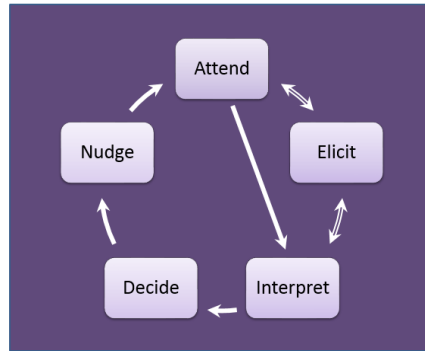
1. Attending to students at work, including student thinking and collaborative behaviors,
2. Eliciting student thinking or the status of the collaboration,
3. Interpreting student actions, words, and representations,
4. Deciding on a key instructional focus and how to shift student attention to this focus,
5. Nudging student thinking forward in partnership with students, and
6. Moving fluidly and iteratively through this process as dialogue unfolds until students are on a productive trajectory.


Figure 1. The teacher's conferring process, beginning with *attending*.

In this study I ask: What is the structure of the discourse in a mathematics conference? What types of mathematics conferences might teachers conduct?

Methods

Context and Data Sources

The study was conducted at a semi-rural elementary school in the southern U.S., which had dedicated efforts to mathematics professional development (PD) over the previous five years. The student population is primarily white (54%) and Latino/a (43%), and the state classifies over 60% of students as "economically disadvantaged." Two fourth grade teachers participated; both had taken part in the ongoing PD, which concentrated on conferring, in the year the study took place. I collected audio recordings of all teacher-student interactions during mathematics work time from nine lessons (six lessons from one teacher and three from the other) for analysis.

Analysis

Interactions (n=330), defined as a string of talk turns between the teacher and a given student(s), were classified by their function (e.g., managing behavior, monitoring, conferring) and conferences (n=97) were identified based on the presence of eliciting student thinking, rather than simple checks on workflow or answers. Conferences which included a nudge and conferences that represented variation in the sample were selected and transcribed for coding. Interactions were segmented in episodes, which were defined as a series of talk turns with a shared discursive purpose (e.g., eliciting, probing). The structure of these episodes within each conference was analyzed to determine shared features and categories.

Analysis then focused on a single episode, the nudge (n=37). The nudges were analyzed to determine their characteristics and develop an emergent typology.

Findings

Conference Structure

Within the conferences identified, two groups emerged. Those with a nudge were coded as *complete conferences* (n=32) and those without a nudge were coded as *approximate conferences* (n=65). Conferences as conceptualized include an instructional push on student thinking or practices, and as such I refer to them as *complete conferences*. Complete conferences shared a common structure with some variation across the sample. The transcript in Figure 2, in which students were grappling with how to move between inches and feet, illustrates this structure. Conferences begin with an initiation, which in this case serves to elicit student thinking (lines 1-4), a nudge (lines 10-17) and a closing (line 18). This conference also includes probing student reasoning (lines 5-9), which 10 of the 32 complete conferences included.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

```
1    Teacher:    Okay. So what kind of ideas have y'all come up with?
2    Student 1:  First, first 'cause there's 12 inches in each foot, I would do, like, 6 feet times 12 inches
3        in each foot would give you 72 inches. Then you add the leftover 5 inches and get 77 inches
4        total.
5    Teacher:   Okay. So what made you think that? How did you know to do that?
6    S1:   I, I was thinking of equal groups of, like, 12 in-, 12, equal groups of 12.
7    Teacher:   Okay… and how come you just added that, uh, 5 in there…        - at the end?
8    S1:                                                                                                                            -
9        Because-              - 6 feet, 5 inches. 5 inches is not a foot, so you have to add that in. It's
10       left over from the 6 feet.
11   Teacher:   Okay. And how would you go and explain that to somebody else? Is there a way to
12       draw a picture or explain it in a way for somebody else to understand?
13   Student 2:   I guess we could draw a picture…somehow. Like we, instead of -
14   S1:    - Oh, yeah, 6 circles [with 12 inches in them…plus the] remainder of 5.
15   S2:                                     [Yeah, yeah, that's what I was thinking!] ...        –
16       Yeah, you could do that -
17   Teacher:   Mmm…
18   S2:                   - To explain it.
     Teacher:   Very interesting. I'm going to come back and check that out.
```

Figure 2. Structural example of a complete conference, with eliciting and nudge indicated. Some conferences also contain probing student reasoning. The final line is a closing.

This example illustrates four key characteristics of a nudge. First, a nudge is initiated by the teacher to advance mathematical thinking, engagement in math practices, or collaboration. In this example, note that advancement of students' thinking occurs in the nudge when the teacher asks students how they might communicate or represent their thinking, two math practices. Second, the nudge is contingent on elicited student thinking. In this case, students demonstrated a conceptual and strategic understanding of their work and could consider how to make it clear to others. Third, students must take up the nudge and co-construct its meaning. Here students ignore the nudge to explain but take up the idea of drawing a picture. Finally, the nudge maintains student sense-making and ownership over the work. While teachers suggest the avenue for productive work, students have the agency and authority to transform what is offered, in this case to decide what picture to create and how it will represent their thinking.

Fully two-thirds of the conferences (n=65 of 97) in this study were *approximate conferences*, in which teachers elicited student thinking, but attempts to push student thinking, when present, lacked the characteristics of the nudge. Over half of the transcribed approximate conferences (14 of 25) included an attempt by the teacher to nudge student thinking that students simply did not take up at all, reflecting the findings of others that responding to student thinking is the most challenging pedagogical move (Franke et al., 2009; Jacobs, Lamb, Philipp, & Schappelle, 2011).

Nudge Typology

Analysis of the 36 nudges in the data revealed that nudges come in five different types, distinguished by their purpose (see Table 1). A key finding is that each type focuses on advancing conceptual or strategic thinking or engagement in mathematical practices.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Typology of nudges

Nudge Type	Description
Conceptual Understanding	• Focuses attention on the underlying meaning of the task and the concepts it represents • May include attending to and reasoning about an error
Developing a Strategy	• Coaches students to develop a strategy for the current problem • Students maintain ownership over the strategy
Communication	• Prompts students to articulate thinking in a cohesive explanation • Often a rehearsal for writing or sharing orally with others
Representation	• Prompts students to develop a way of representing the task, current thinking, or the strategy used • May allow students to communicate more effectively, develop generalizable representations of a concept, identify a strategy, or uncover errors
Collaboration	• Orients students to each other's thinking (Chapin, O'Connor, & Anderson, 2013) and focuses efforts on joint work

Discussion

Identifying teacher-student discourse practices that deepen student thinking and engagement in mathematical practices is of critical importance for the daily work of math classrooms. But interactions cannot be planned in advance. Teachers would benefit from a framework for navigating these intimate moments of instruction. The explicit structure and foci of complete conferences found in this study provide such a framework.

This study demonstrates that conferring is a discursive practice that can be adapted for responsive instruction in the elementary mathematics classroom. The math conference centers on two critical elements, eliciting student thinking and nudging that thinking forward. Advancing mathematical thinking or practices hinges on co-constructing a nudge with students. This co-construction process depends on teachers eliciting enough student thinking to form an accurate interpretation and deciding on an avenue of response that students will take up and own.

Future research is needed to investigate how nudges affect student understanding beyond the interaction itself. In order to further implementation of conferring by practitioners, the field needs an understanding of how teachers might learn to confer and the professional development structures that could support growth of similarly responsive practices.

SIGNIFICADO MOSTRADO AL RESOLVER ECUACIONES LINEALES

THE MEANING DISPLAYED WHEN SOLVING LINEAR EQUATIONS

Carlos R. Paez Paez	María de los Ángeles Cruz	Rocío Gallardo
Navajo Technical University	Universidad Autónoma de Juarez	University of Texas El Paso
cpaez@navajotech.edu	maria.cruz@uacj.mx	regallardo@utep.edu

Esta investigación consistió en tres estudios de caso y fue realizada a alumnos de segundo año de preparatoria. Los datos se recabaron mediante entrevistas y cuestionarios. El estudio estuvo centrado en el análisis de los tratamientos y conversiones de las diferentes representaciones semióticas de sistemas de ecuaciones lineales exhibidas por los alumnos. El análisis se realizó desde el enfoque de la Teoría de los Registros de Representaciones Semióticas (TRSS) de Raymond Duval. Además, el estudio describió las experiencias y reflexiones relatadas por los estudiantes de cuando trabajaron con las ecuaciones lineales en el salón de clases.

Palabras clave: Afecto, Emoción, Creencias y Actitudes; Álgebra y Pensamiento Algebraico; Actividades Y Prácticas De Enseñanza; Educación Bachillerato

Introducción

Las ecuaciones lineales son un tema enseñado como parte de los programas de educación preparatoria en cada país del mundo y México no es la excepción. Schmidt et al. (2001) argumenta en su reporte del análisis del currículum que alrededor del mundo no hay un tema más ampliamente enseñado en preparatoria que el de ecuaciones. Por lo tanto resulta de gran interés el analizar el proceso de enseñanza-aprendizaje involucrado en la didáctica de las ecuaciones lineales desde la perspectiva de los estudiantes.

Cuando un estudiante se enfrenta a un objeto matemático en el salón de clases, empieza a generar hipótesis acerca del objeto matemático en sí, cómo funciona y para qué puede llegar a ser útil. Esto es debido a que intenta darle un significado a lo que está estudiando (Block y Papacostas, 2000). Es interesante este proceso, una vez que el alumno hace sus hipótesis, empieza a encontrar diferencias con lo que realmente es el objeto matemático presentado por el instructor. Una vez que encuentra estas diferencias y le da un nuevo significado al objeto podemos decir que el estudiante ha hecho un trabajo constructivista ya sea gracias a actividades del maestro o actividades del mismo estudiante pero que al final de cuentas producen un conocimiento a partir de la experiencia propia. Sin embargo, la didáctica de algunos maestros ni siquiera genera interés en los alumnos por aprender ciertos objetos matemáticos (Kline, 1989). Es por ello que resulta esencial el interés de los alumnos en el tema para que estén motivados a aprender.

D'Amore (2006) establece que: "en los años 80 y 90 se declaraba que, mientras el matemático puede no interrogarse sobre el sentido de los objetos matemáticos que usa o sobre el sentido que tiene el conocimiento matemático, la didáctica de la matemática no puede obviar dichas cuestiones" (p. 179). Es por ello que resulta importante reflexionar y analizar el proceso de enseñanza- aprendizaje dentro de un salón de clases.

Diversos estudios (e.g., Hiebert et al. 2003; Hollingsworth, Lokan, & McCrae, 2003) han revelado que en la mayoría de los países las actividades matemáticas relacionadas con las ecuaciones lineales en preparatoria tienen la estructura siguiente: revisión, introducción, ejemplo, ejercicio sentado en la banca y resumen de la actividad. Dicha estructura se denominará tradicional en este estudio. Aunque existen variaciones en la didáctica, la estructura básica es en esencia la misma. De hecho, estas investigaciones muestran que no importa el tema que se pretenda enseñar, la estructura en su mayoría es la misma.

Alrededor de la didáctica de las matemáticas, las teorías que se han desarrollado de este campo

son meramente constructivistas. Dichas teorías proponen actividades y situaciones donde los alumnos sean quienes generen el conocimiento a partir de reflexiones de experiencias propias y al final ellos mismos construyan un significado, gracias al razonamiento hecho previamente para solucionar un problema o actividad que sin el nuevo conocimiento adquirido hubiese sido imposible de resolver. Existen prácticas dentro del salón de clases que de acuerdo a la perspectiva de los maestros son "efectivas"; desafortunadamente, las percepciones de los alumnos suelen ser muy distintas a las de los maestros.

En general, durante la historia de la práctica de la enseñanza de las matemáticas el enfoque de la misma ha estado orientado solamente a la enseñanza sin darle el lugar que merece el proceso de aprendizaje. Dicha dualidad debe ser tomada en cuenta con igual importancia ya que sin una de ellas no existe la otra.

Debido a ello es que debe realizarse un estudio a fondo del proceso de enseñanza-aprendizaje llevado a cabo en el salón de clases enfocándose en lo que expresan los alumnos para tener una diferente perspectiva que enriquezca los conocimientos actuales acerca de la enseñanza de las ecuaciones lineales.

Preguntas de Investigación

Este estudio estuvo guiado principalmente por dos preguntas de investigación que son las siguientes:

1. ¿Cómo describen los estudiantes sus experiencias dentro del salón de clases acerca de la enseñanza-aprendizaje de los sistemas de dos ecuaciones lineales con dos incógnitas?
2. ¿Cuáles son los conocimientos mostrados por los alumnos en los tratamientos y conversiones de las diversas representaciones semióticas de los sistemas de dos ecuaciones lineales con dos incógnitas?

Marco Teórico

La Teoría de las Representaciones Semióticas fue desarrollada en los noventas por el francés Raymond Duval. Esta teoría hace énfasis en que los objetos matemáticos únicamente pueden ser manipulados por el hombre a través de sus múltiples representaciones semióticas, ya que los objetos matemáticos son intangibles para el ser humano a diferencia de los objetos físicos. Por lo tanto, es necesario manipularlos a través de sus representaciones. Esta manipulación del objeto matemático en sus diferentes representaciones es llamada tratamiento por Duval (2004).

Esta teoría, se enfoca básicamente en tres características de la semiótica: la representación, el tratamiento y la conversión (D'Amore, 2006). Un objeto tiene distintas representaciones como la verbal, la gráfica, la numérica, la textual, entre otras. El tratamiento no es posible en el objeto en sí, sino que el tratamiento se hace en las representaciones del objeto. La conversión se entiende como el cambio de una representación a otra cuidando no perder de vista cuál es el objeto matemático.

De acuerdo con Duval (1993) la única forma de conseguir una conceptualización auténtica de un objeto matemático es haciendo tratamiento en varias de las representaciones semióticas sin perder el significado del proceso al realizar alguna conversión. Es muy común ver que los estudiantes hacen tratamientos en buena manera dentro de alguna representación dada pero en la conversión pierden el sentido de lo que están realizando. Es por ello que entre más conexiones hagan entre las representaciones y no pierdan el sentido del objeto al hacer conversiones las probabilidades de adquirir una conceptualización del objeto matemático aumentan.

De acuerdo con Segura (2003) "la coordinación de varios registros de representación semiótica resulta fundamental para una asimilación conceptual de un objeto; además, es necesario que el objeto no se confunda con sus representaciones, pero debe ser reconocido en cada una de ellas" (p. 53).

Método

El estudio se desarrolló en Ciudad Juárez, una comunidad al norte del México que colinda con los Estados Unidos. El Colegio Bachilleres de Chihuahua Plante # 6 es la escuela preparatoria de donde se eligió la muestra. Dicha institución cuenta con alumnos de nivel medio socioeconómico. Los profesores en dicho colegio cuentan con al menos licenciatura para poder impartir clases. Los profesores que imparten clases de matemáticas son egresados de licenciaturas en diversas ingenierías. El colegio ofrece dos turnos para sus estudiantes: matutino de 7:00 am a 1:10 pm y vespertino de 1:10 pm a 7:50 pm. En el cuarto semestre los estudiantes pueden elegir de tres diferentes especializaciones: físico-matemático, humanidades y ciencias biomédica. Los estudiantes que forman la muestra provienen de diferentes especializaciones y turnos.

Debido a que el acceso a información de los estudiantes del Colegio como calificaciones requería un trámite especial y tardaban un tiempo considerable en responder a un requerimiento de esa índole, el investigador optó por utilizar el método de selección de muestra denominado 'bola de nieve'. El investigador tenía como conocidos a varios estudiantes dentro del Colegio. Sin embargo ellos no podrían ser sus participantes en el estudio debido a que habría conflicto de intereses, por lo que el investigador solamente les pidió que le identificaran estudiantes que cursaran el cuarto semestre y que se caracterizaran por expresarse de manera natural en las clases y que además vivieran cerca de la escuela y que tuvieran un promedio general mayor al 8.0. Además se solicitó que los participantes tuvieran facilidad de palabra y que tuvieran interés en el tema de investigación de este estudio. Fue así como tres estudiantes fueron sugeridos por otros estudiantes del colegio. Una vez que se determinó quiénes serían los participantes, el investigador se comunicó con ellos. Los tres participantes accedieron a participar en el estudio.

En esta investigación se emplearon dos instrumentos para la colección de información: la entrevista no estructurada y el cuestionario.

Resultados y Conclusiones

De acuerdo con la Teoría de Registros de Representaciones Semióticas, para lograr la conceptualización de un objeto matemático dado, en este caso un sistema de dos ecuaciones lineales con dos incógnitas, es necesario para el estudiante interactuar con diferentes registros de representación semiótica como pueden ser en este ejemplo el registro gráfico, el registro literario y el registro algebraico. Además, se resalta la importancia tanto el tratamiento como de la conversión de cada uno de los registros y así mismo, que no se pierda de vista en las conversiones, en los tratamientos y en sus representaciones el objeto matemático en sí.

En los resultados de la investigación, se pudo observar que la conversión del registro literario al algebraico no representó mayor dificultad para los alumnos participantes. Con respecto a la conversión del registro algebraico al gráfico solamente un participante no pudo realizarlo pero expresó que de haber tenido calculadora lo hubiera hecho. En ambos casos el registro algebraico estuvo presente y los alumnos mostraron habilidad para realizar los tratamientos y conversiones. En la sección 3 de nueva cuenta los participantes realizaron tratamientos al registro algebraico y no mostraron dificultad. Solamente un participante prefirió contestar que no estaba seguro. Al final del cuestionario se le cuestionó su respuesta y el participante mencionó que de haber tenido calculadora lo hubiera hecho sin dificultad. Debido a las respuestas a estas tres secciones pudimos concluir que donde está el registro algebraico presente los estudiantes no muestran dificultad para manipularlo ya sea mediante tratamientos o conversiones. Sin embargo, en la única sección donde no está presenta el registro algebraico, se pudo observar que la dificultad fue mayor. Ninguno de los estudiantes acertó las dos respuesta, solamente un estudiante acertó una de ellas. Con esto pudimos concluir que la representación gráfico representó un problema real para los estudiantes. Además, de acuerdo con lo que comentaron los estudiantes en sus entrevistas, se mencionó que el registro gráfico en el salón de clases no es tan frecuentemente visto como el algebraico.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Es por ello que se pudo deducir con base en las entrevistas y los cuestionarios que las prácticas más comunes dentro del aula de clases es el registro algebraico y por lo tanto el tratamiento de este registro es dominado en su mayoría por los estudiantes. No obstante, el significado mostrado por los participantes careció en general de sentido. Los participantes sabían que se debían utilizar las ecuaciones en la vida diaria; sin embargo, no tuvieron claro ejemplos de donde aplicarlo. Por lo tanto, resultó necesario que las prácticas dentro del salón de clases deben dar igual importancia a los diferentes registros de representación así como a los tratamientos dentro de cada uno de ellos y brindarle vital importancia a las conversiones que representan comúnmente el mayor de los retos para los estudiantes.

Finalmente, de acuerdo con las categorías emergentes, los profesores utilizaron los exámenes como el medio más adecuado para evaluar a los alumnos. Sin embargo, podemos ver que los alumnos no tienen precisamente una idea muy clara de cuál es el uso en la vida diaria de las ecuaciones lineales y no dominaron todos los registros de representación semiótica. Además, las ecuaciones fueron mejor identificadas por los alumnos como método operativo más que una relación entre dos cantidades.

This research consisted of three case studies and it was conducted with high school students. The data was collected by interviews and questionnaires. The study focused on the analysis of the treatments and conversions of the different semiotic representations of linear equations displayed by the students. The analysis was based on the Theory of Register of Semiotic Representation (TRSR) developed by Raymond Duval. In addition, the study describes the experiences and reflections expressed by the students when they were working with linear equations in the classroom.

Keywords: Affect, Emotions, Beliefs, and Attitudes, Algebra and Algebraic Thinking, Instructional Activities and Practices, High School Education

Introduction

Linear equation is a topic taught as part of the high school education program in every country in the world and Mexico is not an exception. Schmidt et al. (2001) established in their curriculum analysis report that around the world there is no topic more broadly taught in high school than linear equations. Therefore, it is interesting to analyze the process involved in the teaching-learning of linear equations from students' perspective.

When a student faces a mathematical object in the classroom, they generate a hypothesis about the mathematical object itself. How does it work? How can it be useful? This happens because the student tries to give a meaning to what he is studying (Block & Papacostas, 2000). This process is interesting, as once the student makes his hypothesis, he begins to find differences with the real mathematical object presented by the instructor. Once the student finds the differences and gives a new meaning to the mathematical object we can say the student has constructed the object. It could be because of the instruction given by the teacher or activities generated by the student himself. However, in the end the student produces knowledge from his or her own experience. Unfortunately, teacher strategies sometimes do not create interest in students to learn certain mathematical objects (Kline, 1989). Thus, students' interest in the topic is crucial to support motivation to learn.

D'Amore (2006) stated: "in the 80's and 90's, while the mathematician might not be asked about the sense of the mathematical objects used or about the sense that the mathematical knowledge has, the mathematics didactics cannot obviate such questions" (p. 179). Therefore, it is essential to analyze and reflect about the teaching-learning process within the classroom.

Many studies (e.g., Hiebert et al. 2003; Hollingsworth, Lokan, & McCrae, 2003) have revealed that in most of the countries, mathematical activities related to linear equations in high school have

the following structure: review, introduction, example, exercises at students' desk and activity summary. Such structure will be called traditional in this research. Even though there are didactic variations, the basic structure is basically the same. In fact, these studies show that the topic being taught does not matter, the lesson structure typically remains the same.

Most of the theories developed in the field of mathematics education are constructivist theories. Such theories propose activities and situations where students should be the ones generating the knowledge from reflections on their own experiences and then they construct their own meaning. This meaning occurs because of students' prior reasoning to solve a problem or activity that without the new knowledge obtained would be impossible to solve. There are many practices in the classroom that according to teachers' perspective are "effective". Unfortunately, student's perceptions are often very different from teachers' perspectives.

In general, in the history of mathematics teaching practice, the focus has been oriented only towards teaching without giving adequate focus to the learning process. The duality of the teaching-learning process should be taken with equal importance because without one of them the other would not exist.

Hence, the importance of a deep research about the teaching-leaning process in the classroom focused on students' perspective. This research can help us to have a better understanding of the teaching-learning process involved in linear equations.

Research Questions

This study was guided mainly by the following two research questions:

1. How do the students describe their experiences in the classroom related to the teaching-learning process involved with systems of two linear equations with two unknowns?
2. What is the knowledge shown by the students in the treatments and conversions of the different semiotic representations of systems of two linear equations with two unknowns?

Theoretical Framework

The French scholar Raymond Duval developed the Theory of Register of Semiotic Representation (TRSR) in the 90's. This theory emphasizes that people can only manipulate mathematical objects through their multiple semiotic representations because mathematical objects are intangibles to human beings, in contrast to physical objects. Therefore, it is necessary to manipulate mathematical objects through their representations. This manipulation of mathematical objects in different representations is called treatment (Duval, 2004).

The TRSR focuses basically in three semiotic characteristics: the representation, the treatment, and the conversion (D'Amore, 2006). An object has multiple representations such as: verbal, graphic, numeric, text, among others. The treatment is not possible on the object itself. The treatment can be done only on the representations of the object. Conversion is the change from one representation to other representation, without changing the meaning of the mathematical object.

According to Duval (1993) the only way to get an authentic conceptualization of a mathematical object is by doing treatments on different semiotic representations without losing the meaning of the process when doing any conversion. It is common to see that students know how to make treatments within one of the representations but in the conversion they lose the meaning of what they are doing. Hence, if there are more connections between the representations and the students do not lose the object's meaning when doing the conversions, the chances of developing a conceptualization of a mathematical object increase.

Segura (2003) states that the coordination of different registers of semiotic representation is fundamental for the conceptual assimilation of an object; in addition, it is necessary that the object

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

should not be confused with its representations. However, the object must be identified in each of its representations.

Methodology

The study was conducted in Ciudad Juarez, a community located in the north of Mexico in the border with the United States. The sample was selected from a high school named Colegio Bachilleres de Chihuahua Plantel # 6. Colegio Bachilleres de Chihuahua Plantel # 6 has students with middle socioeconomic status. The instructors need to have a bachelor's degree in order to teach classes. Most of the instructors that teach mathematics have a bachelor's degree in engineering. The high school has two shifts for students: one in the morning from 7:00 am to 1:00 pm, and one in the evening from 1:10 pm to 7:50 pm. In the fourth semester, the students can choose between three different specializations: physics-mathematics, humanities, or biomedical sciences. The students from the sample reflect different specializations and different shifts.

Since the access to students' data in this high school required a special application that would take some time, the researcher decided to use the sample selection method called "snow ball". The researcher knew some of the high school students. Unfortunately, these students could not be the participants in order to avoid conflicts of interest. However, these students helped the researcher to identify students that were studying in the fourth semester, lived near the school, had a GPA equal or greater to 3.0, and that expressed themselves in a typical manner in the classroom. Once the researcher had the contact information of some students, he contacted them and three of them agreed to participate in the study. An unstructured interview and questionnaire were the two instruments used to collect data from the participants.

Results and Conclusions

According to TRSR, in order to achieve a conceptualization of a mathematical object - in this case a system with two linear equations with two unknowns - is necessary for the student to interact with different registers of semiotic representation such as: the graphic register, the literary register, and the algebraic register. In addition, we highlight the importance of the treatment as well as the conversion of each of the registers. The meaning of the mathematical object should not be lost in the process.

In the results, the conversion from the literary register to algebraic register did not represent difficulties for the participants. In the conversion from the algebraic register to graphic register only one participant could not do it. However, the participant said that if a calculator had been allowed he would have been able to solve it. In both cases the algebraic register was present and the students demonstrated the ability to do the treatments and conversions. In the section about treatment to the algebraic register, the students did not show struggles. Just one student preferred to answer that she was not sure. At the end of the questionnaire the researcher asked her about her answer and the participant mentioned that if a calculator had been allowed she would have been able to solve it without difficulty. From the answers to these sections we concluded that students did not have problems working with the algebraic register, whether it was with treatments or conversions. However, in the only section where there was no algebraic register, the students struggled with treatments and conversions. None of the students answered both questions correctly, and only one student answered one of the questions correctly. This led us to conclude that the graphic register was a real problem for the students. Furthermore, students commented in the interviews that the instructors give lees time to explain the graphic register in the classroom than the algebraic register.

Therefore, from the interviews and questionnaire we determined that the most common practices in the classroom were related to the algebraic register. Thus, the treatment of this register is mastered by most of the students. Overall, the participants demonstrated lack of meaning of the algebraic register. The participants know there are real life applications for linear equations; nonetheless, they

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

could not give examples of these applications. Hence, it is necessary that classroom practices give the same importance to the different registers of semiotic representation as well as the treatments within each of them. Most important would be a focus on the conversions between the different registers because that was the biggest challenge for students in this study.

Finally, according to the emergent categories, the instructors used tests as the better assessment for students. However, the students did not have a clear idea of the real life applications of linear equations, and they did not demonstrate competence with all of the registers of semiotic representation. Furthermore, equations were identified by the students as an operative method rather than a relation between two quantities.

MECANISMOS DE DESARROLLO DE LA CULTURA DE RACIONALIDAD DEL SALÓN DE CLASES DE MATEMÁTICAS

MECHANISMS FOR DEVELOPING A CULTURE OF RATIONALITY IN THE MATHEMATICS CLASSROOM

Mirela Rigo-Lemini
Centro de Investigación y de Estudios
mrigolemini@gmail.com

Sergio G. Rodríguez-Rubio
Avanzados del I.P.N. (Cinvestav) México
rrsergg@yahoo.com.mx

Siguiendo los principios metodológicos de la Teoría Fundamentada y los que Toulmin propone para sistematizar argumentos, y con base en un estudio de caso, en la investigación se identificaron dos mecanismos que inciden en el desarrollo de la Cultura de racionalidad de la clase de matemáticas analizada (de primer grado de secundaria): un mecanismo se refiere a los formatos de interacción presentes en el desarrollo de argumentos y otro, al tipo y funciones de los argumentos, destacando los productivos y los reproductivos. La metodología empleada permite sugerir que estos mecanismos tienen vigencia en aulas de matemáticas de distintas latitudes; por ello, el conocimiento que el profesor posea sobre dichos mecanismos puede serle de gran utilidad para planear la evolución de la Cultura de racionalidad de su clase de matemáticas.

Palabras clave: Razonamientos y Demostraciones, Conocimiento del Profesor

Objetivos del trabajo y Antecedentes

En escritos previos elaborados por los autores se aportaron evidencias de que en el salón de clases de matemáticas existe una Cultura de racionalidad (Rodríguez y Rigo, 2015). En la presente investigación se plantea identificar y explicar el proceso de construcción, evolución y consolidación de la racionalidad real que impera en el aula ordinaria de matemáticas de educación secundaria.

La noción de Cultura de racionalidad tiene filiación con las nociones de cultura y cultura de clase (Bertely, 2000), pero especialmente con la de normas sociomatemáticas (Yackel y Cobb, 1996). Estas normas regulan los argumentos matemáticos que ahí se dan y consisten, por ejemplo, en los acuerdos normativos acerca de las explicaciones matemáticamente aceptables. Sobre el mismo tema versa también el trabajo de Planas y Gorgorió (2001), quienes se centran en averiguar las "posibles interferencias en el aprendizaje que en el aula pueden derivarse de las diferentes interpretaciones de las normas matemáticas" (p. 135).

Marco Teórico

Para el análisis de los argumentos identificados en el estudio de caso se adoptó el Modelo de Toulmin (1974), conforme al cual, un argumento está integrado por una conclusión (C); por una evidencia (E), que aquí coinciden con los sustentos ofrecidos para obtener la conclusión; por una garantía (G), que aparecen descritas en la segunda columna del Cuadro 1, y por un respaldo (R), que ofrece el cimiento teórico, práctico o experimental del argumento. En este estudio se consideran dos clases de respaldo. El primero está relacionado con el tipo de sustento en el que se soporta el argumento. Para caracterizar estos sustentos se acude a los esquemas epistémicos, término que Rigo (2013) definió para hacer referencia a los mecanismos que una persona o una comunidad recurren habitualmente para sustentar los hechos de las matemáticas. La investigadora identifica esquemas epistémicos de tipo matemático y esquemas epistémicos extra-matemáticos. La segunda clase de respaldo alude al nivel de conocimiento sobre la teoría de proporcionalidad (operatoria, intuitiva o formal escolar) que el sujeto pone en juego al argumentar. Así que el respaldo permite distinguir de forma general la racionalidad en la que se inscribe el argumento. En la investigación cuyos resultados

parciales aquí se exponen, la Cultura de racionalidad de una clase de matemáticas está integrada, entre otras cosas por:

Normas de sustentación

Prácticas habituales y más aceptadas de sustentación o de elaboración de argumentos (integrados por una sucesión de esquemas epistémicos) sobre los hechos de las matemáticas, que los agentes de clase llevan a cabo en el aula (cf., normas sociomatemáticas de Yackel y Cobb, 1996).

Normas sociales sobre el reparto de responsabilidades y sobre las formas de interacción

Hace referencia al agente de clase que habitualmente le corresponde argumentar (i.e., dar las conclusiones y las evidencias, y eventualmente las garantías), y al que le toca sancionar los argumentos y las conclusiones dadas, y apunta también hacia las formas de interacción que para argumentar se dan cotidianamente en clase (cf., normas sociales de Planas y Gorgorió, 2001).

La Cultura de racionalidad es la suma de las racionalidades que están presentes en un salón de clase a lo largo de un período de tiempo. Un momento de racionalidad se da cuando se presenta un conjunto de argumentos que tienen en común los mismos respaldos.

Metodología de investigación y técnicas e instrumentos de recogida de datos

La investigación que aquí se reporta fue desarrollada aplicando los principios de la Teoría Fundamentada (Corbin y Strauss, 2015), cuyo objetivo central consiste en construir, a partir de apoyos empíricos, conceptos teóricos que expliquen fenómenos sociales. Las herramientas analíticas de la Teoría Fundamentada (e.g., la codificación axial y el análisis centrado en los procesos) permiten crear relaciones entre conceptos teóricos con base en las cuales es posible dar cuenta del cómo se genera, evoluciona y cambia el fenómeno bajo estudio pero también permite explicar y responder al por qué de algunos aspectos relacionados con él.

Los datos empíricos provienen de un estudio de caso. El caso lo conforma la profesora Noemí y su grupo integrado por 42 alumnos de primer grado de educación secundaria. Para el análisis que aquí se expone se examinó la secuencia didáctica que versa sobre el tema 'Reparto proporcional', impartido por la profesora en seis módulos de 50 minutos cada uno, los cuales fueron videograbados y transcritos. Para este reporte se analizaron 37 episodios y 74 argumentos.

Mecanismos de desarrollo de la Cultura de racionalidad en el salón de clases de matemáticas. Algunas evidencias empíricas

En el apartado se caracterizan e ilustran, con pasajes del caso de estudio, dos mecanismos de construcción y desarrollo de la Cultura de racionalidad de la clase analizada.

Mecanismo "Formatos de interacción para el desarrollo de argumentos"

Este mecanismo descansa en la idea de que los argumentos se construyen en un contexto de interacciones entre los agentes de clase (Krummheuer, 1995). Se identificaron tres patrones relacionados con este mecanismo, pero por cuestiones de espacio se describirá sólo uno.

Patrón sobre el nivel de los argumentos. Dado un primer argumento para una conclusión, los argumentos subsecuentes (para esa misma conclusión) son generalmente de un nivel de complejidad mayor. En el Cuadro 1 se han organizado ascendentemente los argumentos por nivel de complejidad: en la parte inferior se han incluido los de carácter extra-matemático y en la superior los que tienen una base matemática, comenzando por instanciaciones de reglas con bases intuitivas (teoremas en acción, Vergnaud, 1989) hasta llegar a los argumentos en los que se explicitan los procesos matemáticos o éstos se justifican. El patrón al que aquí se hace referencia se puede reconocer en ese Cuadro 1; para la conclusión cuatro por ejemplo, la primera evidencia, dada por un alumno, consistió en una instanciación intuitiva de una regla y en la segunda evidencia la Maestra justificó el proceso. En ese mismo Cuadro 1 es posible detectar estas regularidades; por ejemplo, de los 27 casos donde se

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

identificaron primeras y segundas evidencias para una misma conclusión, en 23 de esos casos (el 85%) el nivel de profundidad de la segunda evidencia fue mayor.

Mecanismo "Tipos y funciones de los argumentos: los reproductivos y los productivos"

Evocando las funciones de la prueba (de Villiers, 1990; y Hanna, 1990), en este trabajo se han distinguido dos tipos de argumentos.

Los 'argumentos reproductivos' que comparten con otros argumentos análogos, evidencias y garantías similares pero respaldos iguales. Los agentes de clase exponen este tipo de argumentos a través de 'intervenciones de consolidación' que tienen como finalidad (explícita o implícita, consciente o no deliberada) fortalecer y arraigar una racionalidad y crear las condiciones sobre las cuales se puedan construir nuevos argumentos, lo que eventualmente dará lugar a una racionalidad modificada quizás más rica en formas de sustentación.

Los 'argumentos productivos' son aquellos cuyos respaldos ofrecen un soporte más enriquecido, en el sentido matemático, en relación a los argumentos precedentes, y comparten con éstos los mismos procedimientos, reglas o tareas por resolver. Los agentes de clase proponen este tipo de argumentos mediante 'intervenciones de cambio', modificando la racionalidad existente y dando eventualmente lugar a una nueva, en el caso en el que ésta se arraigue.

En el Cuadro 1 también se pueden ilustrar los tipos de argumentos y sus funciones. Intervenciones de consolidación de una racionalidad operatoria que involucra a la regla de tres son aquellas en las que se ofrecen los argumentos reproductivos 3, 5, 10, 11, 28, 29, 59, 60, 61 y 62, mismos que comparten igual respaldo; una intervención de cambio es en la que se expone el argumento productivo 63, el cual presenta ya un nuevo respaldo; la mayoría de estos argumentos fue proporcionado por la maestra quien muy posiblemente de forma deliberada ofreció el primer grupo de argumentos con el fin de consolidar una racionalidad, de tipo operatorio, y expuso el 63 con el propósito didáctico de profundizar matemáticamente en la regla involucrada, modificando así la racionalidad previa en torno a esa regla, e introduciendo una racionalidad basada en una teoría de la proporcionalidad formal escolar. Los argumentos productivos, cuando son compartidos y reiterados por el colectivo, pueden reconfigurar una nueva racionalidad, cuya consolidación crea las condiciones para que eventualmente se dé un nuevo ciclo. En la clase analizada, el 85% de los argumentos son reproductivos, y el 15% son productivos (v. Cuadro 1).

Las intervenciones de consolidación tienen como finalidad servir de nutrimento a las intervenciones de cambio. En este mismo sentido, Chevallard, Bosch y Gascón (1997) sostienen que en clase, la producción de técnicas nuevas "se apoya en el dominio robusto de las técnicas básicas" (p. 279) (argumentos reproductivos) y en los "momentos de la justificación de la técnica" (p. 263) (argumentos productivos).

Consideraciones finales

Con base en la metodología de la Teoría Fundamentada, adoptada en este trabajo, se puede suponer razonablemente que los mecanismos antes descritos están presentes en aulas de matemáticas de regiones diversas. Sería importante entonces que los profesores tomen en consideración la Cultura de racionalidad que prevalece en su clase y la dinámica de su desarrollo. En particular, que reflexionen sobre las consecuencias didácticas que puede acarrear el desequilibrio entre argumentos productivos y reproductivos –posiblemente la elaboración conceptual del grupo será bastante raquítica– o el desbalance a favor del profesor entre sus intervenciones y las de los alumnos, lo que les impedirá beneficiarse de los resultados cognitivos que propicia la acción y la interacción en clase, dando lugar otra vez a aprendizajes escasos.

Following the methodological principles of Grounded Theory and those proposed by Toulmin for systematizing arguments and based on a case study, this research identified two mechanisms that have incidence in the development of a Culture of rationality in the mathematics class analyzed (first year of secondary school). One mechanism refers to the interaction formats that occur in development of arguments, and the other to the type and function of the arguments, among which productive and reproductive arguments are the most salient. The methodology employed allows for the suggestion that these mechanisms occur in mathematics classroom at different latitudes. Therefore, the teacher's knowledge on said mechanisms may be very useful in planning the evolution of the Culture of rationality in the mathematics classroom.

Keywords: Reasoning and Proof, Teacher Knowledge

Work Objectives and Background Information

Previous papers produced by the authors provide evidence that there is a Culture of rationality in the mathematics classroom (Rodriguez & Rigo, 2015). This research proposes to identify and explain the process of construction, evolution and consolidation of real rationality that reigns in the ordinary classroom of secondary school mathematics education.

The notion of a Culture of rationality is related to the notions of culture and classroom culture (Bertely, 2000), but specifically with the notion of sociomathematical norms (Yackel & Cobb, 1996). These norms regulate mathematics arguments that occur there and consist, for instance, of normative agreements concerning mathematically acceptable explanations. The work of Planas and Gorgorió

(2001) addresses the same topic, in that they focus on finding the "possible learning interferences that may be derived from different interpretations of mathematical norms in the classroom" (p. 135).

Theoretical Framework

The Toulmin Model (1974) was used to analyze the arguments in the case study, according to which an argument is made up of a conclusion (C); data (D), which in this case coincides with the grounds offered to obtain the conclusion; a warrant (W), which is described in the second column of Table 1; and a backing (B), which offers the theoretical, practical or experimental basis for the argument. This study considers two kinds of backing. The first relates to the type of grounds upon which the argument is backed. Epistemic systems are used to characterize these grounds, a term that Rigo (2013) defined to make reference to mechanisms that a person or community habitually resorts to in order to back mathematical facts. The researcher identifies epistemic schemes of a mathematical and extra-mathematical type. The second type of backing alludes to the level of knowledge concerning proportionality theory (operational, intuitive or formal scholarly) that the subject puts forth when arguing. Hence, the backing allows to distinguish, in general, the rationality on which the argument is built. In the research, of which partial results are presented here, the Culture of rationality of a mathematics classroom is integrated, *inter alia*, by:

Norms of sustentation

Habitual and accepted practices for grounds or development of grounds (integrated by a succession of epistemic schemes) regarding mathematics facts, which the agents of the class (students and teacher) carry out in the classroom (cf., sociomathematical norms by Yackel and Cobb, 1996).

Social norms related to the division of responsibilities and on forms of interaction

These norms make reference to the class agent that habitually argues (i.e., provide conclusions and data, and eventually warrants), and the agent that sanctions the arguments and the conclusions, and points to forms of interaction that routinely arise in class for purposes of stating arguments (cf., social norms of Planas & Gorgorió, 2001).

The Culture of rationality is the sum of rationalities that are present in a classroom throughout a period of time. A moment of rationality occurs when a set of arguments are presented that have the same backings in common.

Research Methodology and Data Collection Techniques and Instruments

The research reported in this paper was developed applying the principles of Grounded Theory (Corbin & Strauss, 2015), whose main purpose is to construct -from empirical support- theoretical concepts that explain social phenomena. The analytical tools of Grounded Theory (e.g., axial coding and process-centered analysis) allow for the creation of relationships amongst theoretical concepts on which basis it is possibly to appreciate how the phenomenon being studied is generated, how it evolves and changes, but it also allows for explanations and reasons as to the why of some aspects related to it.

The empirical evidence came from a case study. The case is composed of teacher Noemi and her group of 42 first year of secondary school students. The didactic sequence on the "Proportional division" topic given by the teacher in six fifty-minute modules was examined for the analysis presented here. This sequence was videotaped and transcribed. 37 episodes and 74 arguments were analyzed for this report.

Mechanisms for the Development of a Culture of Rationality in the Mathematics Classroom. Some Empirical Evidence

The section illustrates and characterizes, using passages from the case study, two mechanisms for

construction and development of the Culture of rationality in the analyzed class.

"Forms of Interaction for Development of Arguments" Mechanism

This mechanism is underpinned by the idea that arguments are constructed within a context of interactions among class agents (Krummheuer, 1995). Three patterns related to this mechanism were identified, but only one will be described due to space constraints.

Pattern on the level of the arguments. Once an argument has been given for a conclusion, subsequent arguments (for the same conclusion) are generally more complex. Table 1 shows arguments sorted in an increasingly complex arrangement: The lower portion includes extra-mathematical arguments and the upper portion includes those with mathematical basis, from instances of a rule with intuitive bases (theorems in action, Vergnaud, 1989) to arguments in which mathematical processes are made explicit or are justified. The pattern in reference can be recognized in Table 1; conclusion 4, for example, the first datum given by a student, is composed of an intuitive instance of a rule and in the second datum the Teacher justifies the process. In that same Table 1 it is possible to detect such regularities; for instance, of the 27 cases where first and second data for the same conclusion were identified, the second datum is deeper in 23 of those cases (85%).

"Type and Function of the Arguments: reproductive and productive" Mechanism

Bringing to mind the functions of the test (de Villiers, 1990; Hanna, 1990), in this work the authors have distinguished two types of arguments.

The 'productive arguments' share with analogous arguments, similar data and warrants but with equivalent backings. The agents of the class present this type of argument through 'consolidation interventions', which have the purpose (explicitly or implicitly, consciously or non deliberately) of strengthening and entrenching a rationality and creating conditions upon which new arguments may be constructed, which will eventually lead to a modified rationality that is perhaps richer in its forms of sustentation.

'Productive arguments' are those whose backings offer richer grounds, in a mathematical sense, in terms of the arguments that precede them, and they share the same procedures, rules or tasks to be solved. The agents of the class propose this type of argument through 'interventions of change,' modifying the existing rationality and eventually leading to a new one, whenever it takes root.

Table 1 also shows the types of arguments and their functions. Interventions aimed at consolidating an operational rationality that involves cross multiplication are those that use reproductive arguments 3, 5, 10, 11, 28, 29, 59, 60, 61, and 62, which also share a backing. An intervention of change is one in which productive argument 63 is expressed, and that argument already presents a new backing. Most of these arguments were provided by the teacher who, possibly deliberately, offered the first group of arguments in order to consolidate an operational-type rationality, and presented 63 with the didactic purpose of deepening mathematical insight concerning the rule involved, modifying thus the previous rationality regarding this rule and introducing a rationality based on a theory of formal scholarly proportionality. When productive arguments are shared and reiterated collectively, they can reconfigure a new rationality, which consolidation can create the conditions for a new cycle to eventually occur. In the class analyzed, 85% of the arguments are reproductive and 15% are productive (see Table 1).

Consolidation interventions serve to nourish interventions of change. In this sense, Chevallard, Bosch, and Gascón (1997) hold that in a class, production of new techniques" is supported by the robust mastery of basic techniques" (p. 279) (reproductive arguments) and in the "moments of the technique justification" (p. 263) (productive arguments).

Final Considerations

Based on the Grounded Theory methodology that was adopted in this work, it can be reasonably assumed that the mechanisms described above take place in the mathematics classrooms of various regions. It would then be important for teachers to take the Culture of rationality that prevails in their class and the dynamics of its development into consideration. In particular, reflecting on the didactic consequences that can entail the imbalance between productive and reproductive arguments –it is possible that the group's conceptual formulation may be fairly weak- or an imbalanced teacher-student participation, favoring the former that prevents them from benefiting from the cognitive results driven by action and interaction in class, once again leading to scarce learning.

Table 1: Trajectories of Arguments and Participation

PA: Productive Arguments; RA: Reproductive Arguments; WC: Warrant supporting the conclusion, AW: Agent providing the warrant: C: Conclusion; AC; Agent providing the conclusion: JE: Empirical Justification of definitions and rules; EPIR: Explicit instance of a rule: RIRAVI: Repetition of explicit instance of a rule to provide institutional endorsement: IR: Instance of a rule (supported by intuitive considerations "I" or formal scholary "EF"; RIROAVI: Repetition of explicit instance of a rule supported by operational considerations to provide institutional endorsement: RP: Instance of a rule supported by operational considerations; RP: Practical Reasons. PIM: Isomorphic property of multiplication; VU: Unit Value; FP: Proportionality Factor; R3: Cross multiplication.

EFFECTS OF TEACHER KNOWLEDGE AND QUALITY OF INSTRUCTION ON LINGUISTICALLY DIVERSE LEARNERS

M. Alejandra Sorto	Rachel S. G. Bower	Teresa Lynn Salazar
Texas State University	Texas State University	Texas State University
sorto@txstate.edu	rsb61@txstate.edu	tls206@txstate.edu

The main goal of this project is to empirically estimate whether and which classroom factors contribute to mathematics gains of English Language Learners in Texas schools. The emphasis is on mathematical knowledge for teaching (MKT), the mathematical quality of instruction (MQI), and language diverse quality of instruction in middle grade classrooms. First round of correlational analysis shows that there are strong associations between teachers' mathematical knowledge for teaching and some elements of MQI such as exposure to rich mathematics and attention to students as learners during instruction. Preliminary regression analysis shows that one of the significant factors that predict student learning is teachers' practices related to knowing their students not just as mathematics learners but affording their linguistic diversity.

Keywords: Mathematical Knowledge for Teaching, Instructional Activities and Practices, Equity and Diversity, Middle School Education

Motivation and Goal

Currently in the United States, significant achievement gaps in mathematics exist between linguistically diverse students and their majority counterparts. Nevertheless, recent mathematics achievement results in the state of Texas show that some districts outperform others despite having large percentages of socio-economically disadvantaged students. Therefore, the main goal of this study is to provide insights and explanations for this phenomenon from the teacher capacity perspective by investigating how teachers' mathematical knowledge, knowledge of students as linguistically diverse learners, and quality of instruction contribute to students' achievement gains. In particular, we explore the relationship between teachers' knowledge and their teaching practices in linguistically diverse middle school classrooms.

Theoretical Framework

Studies in US bilingual mathematics classrooms have at least three different categories of research foci. One deals with the relationship of learning mathematics with cultural issues such as students' households, parents, and communities (Civil, 2007). This perspective does not look at the practice of teaching but instead relates the world of the learners to the classroom. Another deals with the relation of mathematics and 'social activism' (Gutstein, Lipman, Hernandez, & de los Reyes, 1997) and issues of empowering minority students (Celedón-Pattichis, 2004). Gutstein and others looked at the teachers' and principals' beliefs and ideologies in relation to integrating the mathematics with the children's culture, while Celedón-Pattichis investigated the role of parents, educators, and administrators together with school policies and procedures that place English Language Learners (ELLs) in mathematics upon immigration to US schools. Finally, a third category, more pertinent to this study, deals with mathematics practices and language (Civil, 2007; Khisty & Chval, 2002; Moschkovich, 2007). Part of this body of research focuses on the structures of the lesson that provide opportunities for students to talk about mathematics. Civil (2007) explored the learning of mathematics in different settings like regular classrooms, after-school mathematics clubs, out-of-school activities, and with their parents. Moschkovich looks at the use of two languages (code switching) and gestures during mathematical conversations. She provides examples from classroom observations of how the use of two languages can provide resources for mathematical communication, contrary to the view that code switching indicates deficiency. Khisty and colleagues

focus on the mathematical discourse and analyze the role of the teacher. They argue that even students that are proficient in English have difficulty communicating in mathematics discussions because of the difference that exists between 'social language' and 'academic language'. Furthermore, they conclude that the teacher plays a significant role by using her/his own academic talk as a model and support for emerging mathematics discourse. Despite this extensive body of research about the teaching and learning of mathematics for ELLs, there is a lack of detailed understanding of *how* teacher knowledge and classroom instruction affects these students' achievement. Further, there is a lack of empirical evidence about how these variables relate to each other in this population of students. Hence, the two research questions addressed in this study are:

1. To what extent are teachers' knowledge measures and the mathematical quality of instruction in linguistically diverse classrooms associated?
2. What are the effects of teachers' mathematical knowledge, teacher knowledge of students as linguistically diverse learners, and mathematical quality of instruction on student achievement?

Methodology

Measures

The study utilizes established measures for teacher knowledge and mathematical quality of instruction with complementary measures to capture the special knowledge and instruction in linguistically diverse classrooms. The first measure is the Mathematical Knowledge for Teaching (MKT) instrument which includes domains conceived of as pedagogical content knowledge, as well as common content knowledge and specialized content knowledge. One of the main reasons for using this instrument for our study is because MKT has been linked to student achievement gains and to the mathematical quality of instruction (Hill, Ball, & Schilling, 2008). Finally, we capture the classroom practices with the 4-point version of the Mathematical Quality of Instruction (MQI) protocol. This instrument measures several dimensions that characterize the rigor and richness of the mathematics of the lesson, including the presence or absence of mathematical errors, mathematical explanations and justifications, mathematical representations, and related observables. The MQI was augmented by the ELL Mathematical Proficiency rubric developed by the authors based on previous research and validated with a focus group of teachers and a small set of video samples from linguistically diverse classrooms (Sorto, Mejía Colindres, & Wilson, 2014). The elements of this newly develop rubric are 1) Connections of mathematics with students' life experiences, 2) Connections of mathematics with language, 3) Meaning and multiple meanings of words (including gestures, use of two languages, cognates), 4) Use of visual support, 5) Record of written essential ideas and concepts on the board, and 6) Discussion of students' mathematical writing.

Sample and Data Collection

The participants of the study are 34 middle grade mathematic teachers representing all of the 11 middle schools in a large district in south Texas with even distribution among grades 6, 7, and 8. About two thirds of them self-identified as being either advance or high advance in Spanish language proficiency. The average teaching experience is 9.5 years and the majority of them (75%) teach in classrooms with at least half of students classified by the school district as ELLs. About 99% of the students in the district are from low-income homes (qualify for free/reduced lunch).

Teachers responded to the two surveys during a professional development session in summer 2013. The following school year, teachers were videotaped three times (beginning, middle, and end of the school year). A total of 98 lessons were videotaped. Thirty-one teachers were videotaped three times, two teachers were videotaped twice and one teacher was videotaped once.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Data Analysis and Results

Scoring Quality of Instruction and MKT

Videotaped lessons were broken into seven and one half-minute segments which were then coded by two independent raters using the 30 codes designed to represent the elements of mathematical quality (outlined in Table 1) and ELL mathematical proficiency. The codes used a 4-point scale: *not present*, *low*, *medium*, and *high*. Finally, each lesson was assigned a holistic score that ranged from 1(*low*) to 5(*high*) which represents the overall MQI score. The two raters were trained using the MQI training program (http://isites.harvard.edu) prior to independently coding each lesson and reconciling conflicting codes afterwards. Video scores for each teacher in each element and overall lesson scores were computed by averaging all three lesson scores. The MKT pencil-and-paper responses of the 34 teachers were compared with a larger national sample using a two-parameter IRT model. Scale scores for each teacher were computed using parameters estimates for each item derived from the results of the national sample. The distribution of scores for our sample was very similar to the scores for the national sample of teachers.

Data Analysis and Results

To address the first research question, we explored the relationship between teacher knowledge and quality of instruction. Table 1 shows the correlation between the overall elements of mathematical quality and the MKT measure. All of the associations are positive, except for the errors and imprecisions, which indicate that teachers that tend to make fewer mistakes in class have higher levels of mathematical knowledge for teaching. Two elements, Richness of Mathematics and Working with Students and Mathematics have significant positive associations with MKT; the Overall ELL Math Proficiency is tending to significant ($p = 0.078$).

Table 1: Correlation between MQI and MKT Measures

MQI Elements	Correlation with MKT
Richness of the Mathematics	0.482**
Working with Students and Mathematics	0.359*
Errors and Imprecisions	-0.288
ELL Mathematics Proficiency	0.311^
Common Core Aligned Student Practices	0.256
Overall Mathematics Quality of Instruction	0.285

^ Significant at 0.078 level. * Significant at 0.05 level. ** Significant at 0.01 level.

To address the second research question, we performed hierarchical linear model (HLM) analysis with standardized learning gains as the dependent variable and controlling for social economic status and school effects. The factors that explain learning gains for all students are the level of MKT and Overall MQI, their effect is positive and significant. Positive effects on ELL students include teachers' implementation of tasks and activities that develop mathematics ($p = 0.045$) and ELL Mathematics Proficiency ($p = 0.064$).

Conclusions

The present correlational study yields preliminary results that demonstrate strong links between mathematical knowledge for teaching and the exposure of rich mathematics presented to students and the teachers' ability to attend to and remediate students during instruction. Links are moderate between teachers' knowledge and the ability to implement strategies that support the learning of mathematics for linguistically diverse students. Variables that explain or contribute to students' learning gains for English Language Learners are the teachers' practices related to knowing their

THE ROLE OF MATH TEACHERS IN FOSTERING STUDENT GROWTH MINDSET

Kathy Liu Sun
Santa Clara University
ksun@scu.edu

This paper presents on a year long mixed-methods study that investigated how math teachers might contribute to students' beliefs about their own math potential (mindset). The paper shares results from analysis of survey data that examined whether teachers' beliefs predict students' mindset. This paper also presents findings from analysis of classroom observations and artifacts that identified potential instructional practices that may explicitly or implicitly communicate mindset messages to students. This paper has implications for both researchers and practitioners.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Instructional Activities and Practices

Introduction & Relevant Literature

The belief that math ability is innate – some people have it, others do not, and there is little one can do to change their basic math ability – is particularly prevalent in the United States (Stevenson, Chen, & Lee, 1993) and has been linked to maladaptive behavior such as avoiding challenging work and giving up when encountering difficulty (Dweck, 2000). Such beliefs may contribute to the persistent problem of relatively low performance and low interest in mathematics in the U.S. (Boaler, 2009), particularly among female (National Academy of Sciences, 2006), African American, and Latino (Flores, 2007) students. Improving U.S. students' math performance requires a better understanding of the sources of such beliefs. This mixed-methods study investigates the ways in which math teachers may contribute to students' beliefs and ideas about their own math potential.

People's beliefs about math ability tend to fall along a spectrum which ranges from a *fixed mindset*, the belief that one's math ability is innate and limited, to a *growth mindset*, the belief that math ability is something that is malleable and can be developed through hard work and perseverance (Dweck, 2006). Despite evidence suggesting the value of growth mindsets for student achievement (Aronson, Fried, & Good, 2002; Blackwell, Trzesniewski, & Dweck, 2007), little is known about how teachers might influence student mindsets, particularly in relation to mathematics. To further our understanding of math teachers' potential influence on student mindset beliefs, this paper addresses the following research questions: (1) What is the relationship between teacher and student beliefs related to mathematics and mindset? (2) How might teachers communicate mindset messages in the mathematics classrooms?

Methods & Analysis

The study consisted of two parts, a quantitative and a qualitative component. First, I designed a survey study to address the first research question, which sought to understand the relationship between teacher and student beliefs. I designed and tested survey instruments to measure four belief constructs: 1) student and teacher mindset beliefs related to math ability (e.g., You have a certain amount of math intelligence, and you can't really do much to change it; $\alpha= 0.688$), 2) teacher expectations (e.g., In my class(es) students who start the year low performing tend to stay relatively low performing; $\alpha= 0.726$), 3) teacher beliefs about which students should have access to more complex math (e.g., It is important for students to acquire basic skills before engaging in complex conceptual math; $\alpha= 0.836$), and 4) student and teacher beliefs related to the nature of mathematics (e.g., Mathematics involves mostly facts and procedures that have to be learned; $\alpha= 0.650$). All items were rated on a six-point agree-disagree Likert scale. The survey was administered to 40 middle school math teachers and approximately 3400 of their students at the beginning and the end of the

2013-2014 academic school year. All participants came from six middle schools with economically, linguistically, and racially diverse student populations in California. I examined various correlations between the different belief constructs. Using hierarchical linear modeling (HLM) (Raudenbush & Bryk, 2002), I also examined whether teachers' beliefs predicted students' mindsets and related beliefs at the end of the academic year.

To address the second research question, I examined teacher interactions with students to further our understanding of how teachers communicated mindset messages in the context of their math classes and how such interactions might influence students' beliefs. From the 40 surveyed teachers, I purposefully sampled (Marshall, 1996) eight teachers who represented a range of beliefs about math ability. Over the course of one year, I conducted parallel case studies (Yin, 2009) of these eight case teachers. Through the conduct of ethnographic methods (Eisenhart, 1988), such as teacher and student interviews, classroom observations with field notes and analysis of classroom talk and course materials (e.g., feedback on assessments, wall postings, syllabi, etc.), I examined differences in how these case math teachers communicated particular messages about math ability to their students. Building upon existing frameworks (Boaler, 2013), this study identified potential instructional practices that may explicitly or implicitly communicate mindset messages to students.

Findings

Results from this study found that one's perception about the nature of mathematics was correlated with having more of a growth or fixed mindset related to math ability. This was true for both teachers and students ($\beta = 0.313$, $p < 0.05$ and $\beta = 0.218$, $p < 0.01$, respectfully). Teachers and students with more procedural and rules-based (one-dimensional) views of math were more likely to have more of a fixed mindset. Results from the HLM analysis suggests that teacher mindset at the beginning of the year did not predict students' mindsets at the end of the year, while controlling for students' beginning of the year mindsets. Rather, teachers' beliefs about the nature of mathematics predicted student mindset at the end of the year (Coefficient = 0.212, $p < 0.01$, intercept $p < 0.001$). Thus, teachers who ascribed to more multi-dimensional views of mathematics at the beginning of the year, viewing math as more than procedures and rules, tended to have students with more of a growth mindset at the end of the year.

In the case study, I expanded upon the relationship between mindset and nature of math. Through examination of classroom instruction of the case teachers, I developed a framework to analyze math teaching using a mindset lens that I called the *math teaching for mindset framework*. Through triangulation of the qualitative data (Miles & Huberman, 1994), I identified particular teacher practices that had the potential to communicate mindset messages. These practices were initially identified using both a priori codes determined by past literature related to mindset and emergent codes. I then sorted and classified each practice into four dimensions of math teaching from Boaler's (2013) conceptualization of mindset and mathematics: 1) sorting, 2) norm setting, 3) using math tasks and 4) assessing and giving feedback. In total I identified 15 practices that were classified under these four dimensions. For each of the practices, I identified the nature of the mindset message communicated through each teaching practice, as being more fixed, more growth mindset, or more neutral mindset. I also examined how the practice was or was not connected to a multi-dimensional view of mathematics.

Through this process of sorting and classifying teacher practices, I created a continuum by identifying anchor instances for each of the various practices. These anchor instances represented the relative extreme of a particular practices as being more fixed or growth mindset oriented. Table 1 provides an example of an anchor instance for a sorting practice called "grouping strategies," which I elaborate upon in the proceeding sections[1].

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Math Teaching for Mindset Framework

	FIXED MINDSET Math Teaching	GROWTH MINDSET Math Teaching
Dimension #1: Sorting		
Grouping Strategies	Groups based on **one-dimensional** of mathematical success and on **deficit-based** views of students.	Groups based on **multi-dimensional** perspective of mathematics and on **asset-based** views of students.

In classrooms where grouping strategies communicated more fixed mindset messages, teachers intentionally placed a "smart" student in each group who was identified by having a high test score. Such fixed labeling could communicate fixed ability (Dweck, 2006) because some students were viewed as smart and others were not. Additionally, this type of grouping was based on a deficit view (Valencia, 1997) of low achieving students. Students who were considered low performing were viewed as being in need of help and only the "smart" student or the "leader" was capable of helping the student. Under this grouping approach low achieving students felt that they had limited ability to contribute.

In contrast, grouping strategies that were based on a wide range of characteristics, and not solely on perceived math achievement or ability, communicated more growth mindset messages. Teachers who adopted this more growth mindset approach to grouping espoused a more multi-dimensional view of mathematics (Boaler, 1998, 2006) that accounted for multiple ways students could engage each other around mathematical ideas. In these classrooms multiple "smarts" (Cohen, Lotan, Scarloss, & Arellano, 1999) were valued, such as clearly communicating, asking questions, and drawing others out. This type of grouping strategy conveyed that there were multiple ways students could contribute and grow their math ability.

Across the math teaching for mindset framework, a key difference between more fixed and more growth mindset math instruction is the nature of the mathematics that was emphasized. For more growth mindset math instruction across sorting, norm setting, using math tasks and assessing, teachers make explicit connections to the multi-dimensional and open nature of mathematics (Boaler, 2006). Whereas, more fixed mindset math instruction tends to focus on closed (Boaler, 1998) and one-dimensional mathematics with a particular focus on rules and procedures (Boaler, 2002). Thus, as suggested by the survey study, the qualitative analyses also highlight how growth mindset is intricately linked to a multi-dimensional perspective of mathematics.

Ultimately, findings from the survey and case study analyses seem to confirm that having a multi-dimensional view about the nature of math may be an essential component of having a growth mindset towards math ability (Boaler, 2016).

Conclusion

Developing knowledge of the ways teachers might influence student mindset is crucial for leveraging the many benefits of growth mindset for students. Findings suggest that if teachers have closed (Boaler, 1998), highly procedural, or one-dimensional views of math and instruct in these one-dimensional ways, they are likely to communicate fixed mindset messages about math ability to students. In contrast if teachers have more multi-dimensional views of math valuing connection between ideas and multiple strategies and instruct in ways that align with this perspective, they are

more likely to communicate growth mindset messages. In sum, we cannot disentangle having a growth mindset from a multi-dimensional (Boaler, 2006; Cohen et al., 1999) perspective about the nature of mathematics. By empirically identifying opportunities for teachers to convey mindset messages in their math lessons, this study offers authentic examples of growth mindset math instruction. This study can inform best practices for how math teachers can help students develop more of a growth mindset.

EXPLORING THE INSTRUCTIONAL CONSEQUENCES OF A SECONDARY TEACHER'S LEVEL OF ATTENTION TO QUANTITATIVE REASONING

Michael A. Tallman
Oklahoma State University
michael.tallman@okstate.edu

This paper reports findings from a study that explored the effect of a secondary mathematics teacher's level of attention to quantitative reasoning on the quality and coherence of his instruction of angle measure. I analyzed 37 videos of an experienced teacher's instruction of trigonometric functions to characterize the extent to which the teacher attended to supporting students in reasoning quantitatively, and to examine the consequences of this attention (or lack thereof) on the quality and coherence of the meanings the teacher's instruction supported. My analysis revealed that the incoherencies in the teacher's instruction were occasioned by his inattention to quantitative reasoning.

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge, Cognition

Introduction

A growing body of research (e.g., Ellis, 2007; Moore, 2012, 2014; Moore & Carlson, 2012; Oehrtman, Carlson, & Thompson, 2008; Thompson 1994) has identified *quantitative reasoning* (Smith & Thompson, 2007; Thompson, 1990, 2011) as a powerful way of thinking that supports students in constructing a meaningful understanding of a wide variety of mathematics concepts. Several researchers have noted that quantitative reasoning is especially foundational for supporting students' conceptual learning of angle measure and trigonometric functions (Moore, 2012, 2014; Tallman, 2015; Thompson, 2008). However, the instructional consequences of teachers' attention to quantitative reasoning (or lack thereof) are less frequently documented. For this reason, I explored the effect of a secondary teacher's level of attention to quantitative reasoning on the coherence of the meanings of angle measure his instruction supported.

Quantitative Reasoning

I leveraged Smith and Thompson's (2007) and Thompson's (1990, 2011) explicit formalizations of *quantitative reasoning* in the design of this study and in my analysis of its data. Quantitative reasoning is a characterization of the mental actions involved in conceptualizing situations in terms of *quantities* and *quantitative relationships*. A *quantity* is an attribute, or quality, of an object that admits a measurement process (Thompson, 1990). One has conceptualized a quantity when she has identified a particular quality of an object and has in mind a process by which she might assign a numerical value to this quality in an appropriate unit (Thompson, 1994). *Quantification* refers to the mental actions involved in conceptualizing an appropriate unit of measure as well as a measurement process, and results in an understanding of "what it means to measure a quantity, what one measures to do so, and what a measure means after getting one" (Thompson, 2011, p. 38).

The quantities one might construct upon analyzing a situation are not limited to those whose numerical values are attainable from direct measurements. Defining a process by which one might measure a quantity often involves an operation on two or more previously defined quantities. In such situations, we say that the new quantity results from a *quantitative operation*—its conception involved an operation on other quantities. Quantitative operations result in a conception of a single quantity while also defining the relationship between the quantity produced and the quantities operated upon to produce it (Thompson, 1990, p. 12). Arithmetic operations, in contrast, are used to calculate a quantity's value.

Methods

The sole participant for this study was an experienced secondary mathematics teacher, David, who taught Honors Algebra II at a large suburban high school in the Southwestern United States. I collected data throughout David's instruction of trigonometric functions. In this paper, I present only the results of my analysis of David's instruction of angle measure.

David taught two sections of Honors Algebra II every weekday during the spring semester of 2014. I video recorded both classroom sessions over a seven-and-a-half-week period of this semester, which resulted in 37 videos of David's teaching. In addition to the video recordings of David's instruction, I generated field notes during the class sessions that focused on characterizing the extent to which David supported students in reasoning quantitatively, and on documenting the mathematical meanings David's instruction promoted.

The procedures I used to analyze the video data are consistent with Strauss and Corbin's (1990) grounded theory approach. My analysis focused on documenting the degree to which David's instruction supported students in: (1) identifying quantities, (2) attending to units of measure, (3) constructing quantitative relationships, and (4) interpreting mathematical symbols and expressions as representing the values of quantities. I organized the coded segments of video into themes, examined the data within each theme, and characterized the extent to which the quality and coherence of the meanings David's instruction promoted was facilitated/impeded by his level of attention to supporting students in reasoning quantitatively.

Results

Meaningfully assigning numerical values to the "openness" of an angle requires that one has identified a quantity to measure and has specified a unit with which to measure it. David's instruction was often inconsistent with regard to the quantity one measures when assigning numerical values to the "openness" of an angle. On some occasions David supported students in conceptualizing angle measure as the length of an arc the angle subtends, while on other occasions he explained that measuring an angle involves determining the fraction of the circle's circumference subtended by the angle. These meanings are not the same. Understanding the fraction of a circle's circumference that an angle subtends as a measure of subtended arc length involves conceptualizing the circle's circumference as a unit of measure for the length of the subtended arc. Specifically, one must recognize that the resulting fraction represents a multiplicative comparison of an attribute being measured (subtended arc length) and the unit of measure (circumference). For example, to say an angle subtends 59/360[ths] of the circumference of a circle centered at its vertex is to say that the length of the subtended arc has a measure of 59/360 in units of one circumference. The two meanings of angle measure David conveyed were distinct since he did not support students in conceptualizing the circumference of the circle centered at the angle's vertex as a unit of measure for the length of the subtended arc. Due to space limitations, the following paragraphs illustrate only two occasions in which David's instruction supported inconsistent meanings of angle measure (from my perspective). I emphasize that the events discussed here are representative of several instances from David's teaching in which he promoted discrepant meanings.

David began his first lesson by asking a student to draw two angles on the whiteboard. The student drew one angle above the other. David then explained that the measure of the angle on top is larger than the measure of the angle on bottom because, if one were to construct two circles of equal radii respectively centered at the vertex of each angle, the angle on top would subtend an arc that is longer than the arc subtended by the angle on bottom. Immediately following this explanation, David asked the question in the following transcript.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

David: When we measure an angle what are we really measuring? I mean it's not like we're measuring a length, right? How would we describe the thing that I'm measuring when I just look at these two angles? …

Student: The openness of the angle.

David: Yeah. Which is weird. How do you measure openness? … I'm not measuring length. … We have to think about what we are actually measuring.

While David previously compared the openness of two angles by attending to the respective arc lengths these angles subtend, he claimed that quantifying the openness of an angle does *not* involve measuring a length. Following the dialogue above, David explained that two angles have the same measure if "the length of the [subtended] arc is the same, as long as I made the circle have the same radius and it was centered at the vertex." David therefore supported contradictory meanings of angle measure during the first lesson; he pronounced that measuring an angle is not a process of measuring a length and then proceeded to compare the openness of two angles, as well as define what it means for two angles to have the same measure, by attending to the arc lengths the two angles respectively subtend. In other words, when speaking of angle measure David did not consistently reference the same quantity being measured.

A few minutes after David's remarks in the above transcript, he projected the image displayed in Figure 1 on the whiteboard.
Figure 1. Angle measure as a fraction of the circle's circumference.

After acknowledging that the angle in Figure 1 "subtends 1/8th of the circumference of the circle," David exclaimed that the measure of the angle is a value without units. In particular, David explained that if one measured the subtended arc length and circumference in inches, the ratio of these quantities is unit-less because the inches "cancel" as a result of the division. Moreover, by claiming, "I'm not just measuring arc length. What am I measuring? I'm measuring arc length and comparing it to what? … Circumference!" David did not support his students in seeing the ratio of subtended arc length to circumference as the length of the subtended arc measured *in units of the circumference*. Generally speaking, David's instruction did not provide students with an opportunity to interpret the ratio of subtended arc length to circumference as a quantitative operation but rather as an arithmetic operation; that is, he did not communicate the division of these quantities as a measure of subtended arc length in units of circumference but simply as the ratio of two lengths. Such an emphasis is necessary if one is to support students in conceptualizing angle measure quantitatively (i.e., as a measure of some attribute in some unit). Therefore, while David's instruction during the first lesson overtly emphasized angle measure as a fraction of the circle's circumference subtended by the angle—and implicitly conveyed angle measure as the length of the subtended arc—he did not encourage students to see the former meaning as an application of the latter by failing to support them in conceptualizing the ratio of subtended arc length to circumference as a quantity that represents the length of the subtended arc measured in units of the circumference. In fact, David suggested that these meanings were incompatible by continually asserting that the process of measuring an angle is not one of measuring length.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Discussion

The results of this study demonstrate that a secondary mathematics teacher's (David) inattention to quantitative reasoning contributed to his conveying incoherent meanings of angle measure and trigonometric functions. In particular, by not maintaining a consistent emphasis on supporting students in: (1) identifying quantities, (2) attending to units of measure, (3) constructing quantitative relationships, (4) interpreting mathematical symbols and expressions as representing the values of quantities, and (5) performing quantitative—rather than arithmetic—operations, the ways of understanding David's instruction promoted were often inconsistent. Moreover, the meanings David supported varied by context because they were not consistently governed by, or in the service of promoting, a particular way reasoning. Consequently, the results of this study suggest that teacher educators should design instructional experiences that allow pre- and in-service teachers to develop the disposition to support students' identification of quantities and quantitative relationships, particularly in the difficult context of trigonometry.

ACTIVITIES IN CALCULUS I ASSOCIATED WITH STUDENT INTEREST

Derek A. Williams
North Carolina State University
dawilli6@ncsu.edu

Establishing and maintaining students' interest during class has been theorized as vital for learning (e.g., Dewey, 1913) and empirically connected to positive affect (e.g., Bye, Pushkar, & Conway, 2007), information retention (e.g., Siegle, Rubenstein, Pollard, & Romey, 2010), persistence (Hidi, 1990), and academic achievement (e.g., Bye et al., 2007; Koaler, Baumert, & Schnabel, 2001; Siegle et al., 2010). This study reports on a secondary analysis of data collected from the Characteristics of Successful Programs in College Calculus (CSPCC) project (Bressoud, Mesa, & Rasmussen, 2015), where student interest is analyzed using multiple level modeling. Results suggest that college students with more class time for explaining their reasoning, and working individually while taking the course with an experienced instructor tend to be more interested during class, even when controlling for their enjoyment of mathematics.

Keywords: Affect, Emotion, Belief, and Attitudes, Instructional Activities and Practices

Many regard the report by Steen (1988), former president of the Mathematical Association of America (MAA), as the beginning of Calculus reform efforts in the United States. However, following this work, no nationwide study to examine the conditions of college-level, introductory Calculus (calculus) was conducted for nearly 30 years. In 2009, the MAA set in motion a national study to investigate the conditions of college-level calculus and to identify aspects of programs that were consistently experiencing success in this area. The *Characteristics of Successful Programs in College Calculus* (CSPCC) project set out to achieve five goals:

1. To improve our understanding of the demographics of students who enroll in calculus.
2. To measure the impact of the various characteristics of calculus classes that are believed to influence student success.
3. To conduct explanatory case study analysis of exemplary programs in order to identify why and how these programs succeed.
4. To develop a theoretical framework that articulates the factors under which students are likely to succeed in calculus.
5. To use the results of these studies and the influence of the MAA to leverage improvements in calculus instruction across the United States. (Bressoud et al., 2015, p. vi)

To achieve these goals, CSPCC project investigators administered surveys to calculus students, instructors, and department chair persons to a nationally representative stratified random sample of colleges and universities. Additionally, in-depth case studies were conducted to further understand the aspects of successful programs.

Sonnert and colleagues (2014), used hierarchical linear modeling with the survey data to determine characteristics of calculus classrooms, reported by students, associated with students' attitudes towards mathematics. Results of their analysis indicated that, on average, college calculus has a substantial negative effect on students' mathematics attitudes; technology use had non-significant influences; *good teaching* was positively associated with students' attitudes towards mathematics, especially for students who entered college calculus with low attitudes; and *ambitious teaching* was negatively associated with students' attitudes on average, but tended to improve the attitudes of students who entered the course with high attitudes towards mathematics. Good teaching and ambitious teaching were terms coined by these investigators used to describe composites of

variables indicative of each set of pedagogical practices (e.g., listening to students' comments and questions [good] and frequent collaborative work [ambitious]).

The purpose of this paper is to delve deeper into the investigation of students' attitudes and consider their interest in calculus. Hence, this is a report of a secondary analysis of survey data from the CSPCC project. This work can provide further contribution towards the original project's second goal – identifying characteristics of calculus programs associated with student success. Psychologists suggest that interest is an important emotion influencing learning (Bergin, 1999; Dewey, 1913; Hidi, 1990).

Methods

Identifying factors of classroom environments that are positively associated with interest would allow for instructors and departments to make decisions about their practices that enhance the interestingness of their introductory calculus courses. This study conducts a secondary analysis of survey data collected for the CSPCC project in order to empirically describe factors of college calculus classrooms associated with high levels of student interest. Specifically, this analysis aims to address the following research questions: (1) what are the effects of opportunities for students to present, explain their thinking, work collaboratively with their peers, and work individually during class time on students' interest in college calculus when controlling for student enjoyment?, and (2) do these relationships depend on instructors' recent teaching experience with college calculus?

Description of the Data

The CSPCC project administered pre- and post-semester surveys to calculus students and their instructors and a single survey to department chairpersons or calculus coordinators to a stratified random sample of 212 institutions of higher education across the country. This undertaking resulted in survey data from nearly 14,000 students and roughly 700 instructors. However, due to incomplete responses, a subsample of 3,103 students and 308 instructors from 123 institutions are considered for this report. Sonnert and colleagues (2014) utilized the same subsample in their report on the relationship between students' attitude towards mathematics and instructor pedagogical practices. Their report completely describes the sample used here and compares it to the national population of college calculus students. This subsample represents the group of students (nested within instructors, nested within institutions) who have data from all five survey instruments. This dataset possesses a requisite nesting structure – students within instructors within institutions – for which multiple level modeling is appropriate (Raudenbush & Bryk, 2002).

Variables and Centering

One item on the student survey was, "My instructor makes class interesting." Students were instructed to rank their beliefs of this item on a 6 point scale, where 0 represents "Strongly disagree" and 5 corresponds to "Strongly agree." Here, student *interest* (or instructor *interestingness*) will serve as the dependent variable. Additionally, students were asked how often their instructors allowed them class time to collaborate with their peers, present solutions, explain their work, and work individually. Students were also asked to rank their enjoyment of mathematics. Each of these items was also ranked on a 6 point scale, where 0 represents "Not at all" and 5 represents "Very often." These will be used as student-level predictor variables.

Instructors were asked to indicate the number of terms they taught calculus I during the previous five years. This item was reported with a scale of ranged values (e.g., 3-5 times), so a linearized variable was created using the central value from each range. This is the instructor-level predictor variable used in this analysis. All predictor variables were grand-mean centered (Raudenbush & Bryk, 2002) to provide meaningful interpretations of results.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Analysis

To begin, a three-level unconditional model was created to determine the amount of variation in interest located at each level. This model indicated only significant variation at the student and instructor level, so only two-level models were conducted for the remainder of the analysis. Thus a two-level unconditional model was conducted to examine the partitioning of variation.

Next, a completely unconstrained model was conducted (Model 2). This model estimates the extent to which students vary from the sample (average) slopes (or intercept) estimated for each level 1 predictor variable. Third, only the variability around the slopes of the collaboration and explanation slopes were left in the model (Model 3). Finally, a completely constrained model was conducted (Model 4). This model constrains all variability around the slopes of level 1 predictors to be zero. Models 2, 3, and 4 all contained cross-level interaction terms in order to respond to research question 2.

Results

The parameter estimates for all models were computed using PROC MIXED in SAS 9.4. Model 1 indicates that 26% of variation in student interest lies at the instructor-level, while 74% lies at the student-level. These values are significantly different from zero, which justifies the remaining models. Model 2 did not converge, and according to Singer's (1998) method Model 4 is better fitting than Model 3 ($\chi^2(5) = 74.7, p < .001$). Thus, only the estimates from Model 4 are interpreted.

On average, students agreed that their instructors made class time interesting ($\gamma_{00} = 3.17$, $t = 58.22, p < .001$). Frequency of class time to collaborate with peers ($\gamma_{10} = .04, t = 1.81, p = .07$) and to present in class ($\gamma_{20} = .02, t = 1.19, p = .23$) were not associated with student interest. However, students with more opportunities to explain their work ($\gamma_{30} = .36, t = 18.83, p < .001$) and to work individually ($\gamma_{40} = .07, t = 4.23, p < .001$) tended to report higher levels of interest even with enjoyment present in the model. Students who enjoyed mathematics tended to report higher interest ($\gamma_{50} = .21, t = 11.79, p < .001$). Instructors with more than the sample average experience were associated with higher interestingness ($\gamma_{01} = .04$, $t = 2.82, p = .005$). No cross-level interactions yielded statistically significant results. This suggests that the relationships between student interest and the student-level predictors do not depend on instructor experience ($\gamma_{11} = .004, t = .63, p = .53$; $\gamma_{21} = -.005, t = -.74, p = .46$; $\gamma_{31} = -.01, t = -1.94, p = .053$; $\gamma_{41} = -.001, t = -.12, p = .90$; $\gamma_{51} = -.004, t = -.75, p = .45$). Model 4 explains 28% of student-level variation in interest and 38% of instructor-level interestingness (Raudenbush & Bryk, 2002).

Discussion & Conclusion

Establishing and maintaining students' interest during class time has been theorized as paramount for learning (e.g., Dewey, 1913). In fact, research on the role of interest while learning has demonstrated that interest is positively associated with positive affect (e.g., Bye, Pushkar, & Conway, 2007), information retention (e.g., Siegle, Rubenstein, Pollard, & Romey, 2010), persistence (Hidi, 1990), and academic achievement (e.g., Bye et al., 2007; Koaler, Baumert, & Schnabel, 2001; Siegle et al., 2010). Recently, Pantziara & Philippou (2015), concluded that positive self-efficacy beliefs positively influenced students' interest in mathematics, so it is no surprise that student enjoyment of mathematics was positively associated with student interest.

This study provides empirical evidence for the importance of certain classroom activities and their positive associations with student interest. Additionally, this analysis suggests that department heads and decision makers should consider course assignments for instructors over more than one term. For this subsample of the CSPCC survey data, the 308 instructors had an average of 2 terms in the previous five academic years with teaching calculus, and those instructors with higher than average experience tended to be reported as more interesting. Bergin (1999) concluded that interest is reciprocally related to learning, in that, interest sparks a desire to learn, and learning more increases

interest. Thus, aspects of college calculus classrooms that are positively associated with student interest are synonymous with aspects of effective learning environments.

"BIG SQUARE, ROUND CIRCLE": SPATIAL TALK BY EARLY CHILDHOOD EDUCATORS AND IF IT MATTERS

The objectives of the present study were (a) to examine the types and frequency of spatial language that early childhood educators (ECEs) naturally engage in during circle times, and (b) to investigate whether spatial language input predicts children's mathematical knowledge. Twelve ECEs participated in the study. Seventy 3- to 5-year-old children's mathematical abilities were pre- and post-tested with The Test of Early Mathematics Ability (Ginsburg & Baroody, 2003). The circle times in six classrooms were video recorded over a six-week period and were transcribed and coded for the frequency and types of spatial talk in which the ECEs typically engaged. Results revealed that ECEs did not spend a substantial portion of time engaging in spatial input, and as such, the amount of spatial input by ECEs was minimally related to preschooler's mathematical competence.

Keywords: Early Childhood Education, Instructional Activities and Practices, Pre-School Education

Introduction

Children's mathematical knowledge prior to formal schooling has important implications for their future success. Mathematics comprehension in the preschool years remains highly stable until at least the second grade, and children with a high level of competence experience a faster rate of growth in their mathematical development than those that enter school with limited mathematical understanding (e.g., Aunola, Leskinen, Lerkkanen, & Nurmi, 2004).

One mathematical domain that is especially important is geometric and spatial ability. For instance, advanced spatial abilities in adolescence predict engagement and success in science, technology, engineering, and mathematics occupations in later adulthood (STEM) (Shea, Lubinski, & Benbow, 2001).

Adult input has an imperative impact on mathematical development. The amount of overall math talk that preschool teachers use predicts the growth of children's mathematical knowledge over the school year (Klibanoff, Levine, Huttenlocher, Vasilyeva, & Hedges, 2006).

However, no studies thus far have explored the spatial language input preschoolers receive at child care centres and how it is related to their overall mathematical competence. This is important because the spatial input children receive has implications for their overall mathematical ability (Cheng & Mix, 2014). Further, high quality interactions between early childhood educators (ECEs) can act as a buffer against poor cognitive outcomes if there is a lack of verbal input in the child's home (Vernon-Feagans & Bratsch-Hines, 2013). Thus, the objectives of this study were to explore (a) the nature of spatial language input in child care settings and (b) whether such input predicts children's mathematical knowledge.

Method

Data Source

The present study was part of a cross-sectional research project evaluating the effectiveness of an early numeracy program on children's mathematical development in a child care setting. The

program did not have a spatial focus, therefore it was not expected that the program would influence the results of the present study on spatial input.

Participants

Seventy (39 boys) children (M_{age} = 47.49 months, SD = 7.84; $Range$ = 34 months to 70 months) were recruited from six classrooms within four child care centres. Approximately 81% of the children were Caucasian. A total of twelve female early childhood educators from the six classrooms were also recruited for the study. All of the early child educators were Caucasian.

The mother's highest education level was used as a proxy for SES (Catts, Fey, Zhang, & Tomblin, 2001). The highest education level attained by mothers was as follows: 21% of mother's completed highschool, 13% had a college education, 26% had a university degree, and 40% had graduate/professional training.

Materials and Procedure

The Test of Early Mathematics Ability- Version 3 (TEMA-3). The TEMA-3 (Ginsburg & Baroody, 2003) is a standardized, one-on-one test that assesses three- to eight-year-old children's overall mathematical understanding. The TEMA-3 is not timed. Testing stops once a child answers five incorrect questions in a row. Children's TEMA-3 raw scores were converted into standard scores (M = 100, SD =15) for analysis. The TEMA-3 consists of two parallel forms: Form A and Form B to avoid practice effects for pre- and post-test purposes.

The current study was conducted over a ten-week period. The first two weeks of the study consisted of pre-testing children on TEMA-3. The first author conducted all of the testing. The circle times were videotaped over the next six weeks. Circle times were chosen for analysis because they are a period in which ECEs purposefully engage in activities and/or teaching with their preschoolers. Thus, these segments were used as a beginning step to evaluating such input. There was one ECE per circle time that was videotaped .The ECEs were asked to act as naturally as possible and to deliver their typical planned circle time activities, though they were aware that the study had a general math focus. No time constraint was imposed. Once the video tapings were completed, the children were post-tested on the TEMA-3 (form B).

Transcribing and Coding

The data collected consisted of a total of 32 videotapes and 37% (12 observations) were secondary coded for inter-coder reliability (Cohen's Kappa = 0.92, Rho = 0.99).

Spatial Talk. The video recordings were transcribed and coded to examine the total spatial talk per circle time in which the ECEs engaged, using the Noldus Observer XT software (The Observer XT 8.0, 2008). The coding scheme was adopted, with permission, from Cannon, Levine, and Huttenlocher (2007). This scheme categorizes spatial words into eight categories:

1. *Spatial Dimensions*: the size of physical objects, people, and spaces (i.e., big, little, small)
2. *Shapes:* any 2- or 3- dimensional object or space (i.e., circle, triangle, rectangle)
3. *Locations and Directions*: the whereabouts of objects, people, and spaces (i.e., left, under, above, between)
4. *Orientations and Transformations*: an object's or person's orientation or transformation (i.e., turn, flip, rotate)
5. *Continuous Amount*: the amount of continuous quantities such as objects, liquids, and spaces (i.e., half, whole, piece, more)
6. *Deictics*: words that are place deictics/ pro-forms and rely on the context of which they are used to determine whether they are used spatially (i.e., here, there, somewhere)

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

7. *Spatial Features and Properties*: describe 2- and 3- dimensional objects, people, and spaces (i.e., straight, curvy, round)
8. *Pattern:* words used in a spatial pattern (i.e., next, first, repeat)

The present study used a "word-type level analysis" (Cannon et al., 2007). Spatial words from the coding scheme were identified in the transcripts. Then, each word was considered in the context it was used and only words used in a spatial context were coded. The total frequency of spatial words for each classroom was summed and divided by the total time of video recording gathered for that classroom to calculate a spatial talk per minute score for each classroom.

Results

The total time of all 32 observations was 606 minutes ($M = 18.93$ minutes, $SD = 6.14$, *Range* = 7 to 38 minutes). The ECEs produced a total of 3,675 spatial words across the 32 observations ($M = 114.84$, $SD = 51.01$, *Range* = 36 to 209 spatial words). On average, they produced 6.02 spatial words per minute ($SD = 1.80$, *Range* = 3.05 to 9.67 words per minute). The most frequent types of spatial talk were Location and Direction (58%), followed by Spatial Dimensions (15%), Continuous Amount (12%), and Deictics (10%). The least frequent types were Shapes (1%), Orientation and Transformation (1%), and Pattern (less than 1%).

The second objective was to determine whether the amount of spatial talk engaged in by ECEs predicted children's mathematical ability. Due to the children being nested within classrooms, the current analysis used a multilevel model analysis. Because the TEMA-3 post-test standard score was significantly correlated with SES ($r = 0.40$, $p = 0.001$), the TEMA-3 score at pre-test ($r = 0.84$, $p < .001$), and not correlated with gender ($r = -0.15$, $p = 0.22$), the children's pre-test scores and SES were the only covariates entered into the model.

The full model was: $Y_{ij} = \gamma_{00} + \gamma_{01}(\text{SPATIAL}_j) + \gamma_{10}(\text{SES}_{ij}) + \gamma_{20}(\text{Pretest}_{ij}) + \mu_{0j} + \varepsilon_{ij}$.

The MLM analysis revealed that spatial talk was not a significant predictor of the variability in TEMA-3 post-test standard score ($\gamma_{01} = 1.96$, $SE = 1.04$, $p = 0.06$), though this analysis was approaching significance. SES was also not a significant predictor of TEMA-3 post-test standard score. As expected, TEMA-3 pre-test scores significantly predicted TEMA-3 post-test scores ($\gamma_{20} = 0.73$, $SE = 0.07$, $p < .001$).

Discussion

The present study suggests that 3- to 5-year-old children's spatial environment, and in turn, their mathematical development, may not be adequately supported during circle time in child care centers.

Overall, spatial language input was limited. Many spatial words uttered by the ECEs were not explicitly uttered with the purpose of engaging in spatial teaching. One implication of our findings is that there was minimal talk about shapes, and spatial features and properties. Most children are aware of circle, triangle, square, and rectangle prototypes before preschool. However, by the age of five, children are already rigid in their thinking that a square is not a rectangle (Hannibal, 1999). ECEs should be exploring the characteristics of shapes so that children's concepts of shapes and their categories remain flexible (Clements, 2004, p. 285). The ECEs in the present study did not teach children about the characteristics of shapes, at least not during circle times – a period of purposeful teaching – and thus, children did not get opportunities to be exposed to atypical shapes or shape properties.

The limited input of ECEs' spatial talk may explain why it was not related to children's mathematical knowledge. This analysis, however, was approaching significance and may have been due to the small number of classrooms ($N = 6$) at the second level in the MLM model.

The main limitation is that we only analyzed spatial talk engaged in during circle times. However, this time of day was specifically chosen because of the purposeful teaching that occurs

during circle times. Further investigation throughout different activities during the child's day may provide additional insight to more and different types of spatial talk by ECEs.

The importance of providing a spatial environment is evident, given that spatial abilities provide the necessary tools required for success in STEM related occupations (Shea et al., 2001) and in mathematical achievement (e.g., Cheng & Mix, 2014). Further, studies that show that spatial abilities are malleable (Uttal et al., 2013) and that children's spatial abilities decline over the summer from kindergarten to first grade (Huttenlocher, Levine, & Vevea, 1998), point to the fact that the development of young children's spatial abilities strongly depends on adult input. With an appropriate enriched environment, early childhood educators can thus help foster children's success in mathematics and in their spatial abilities.

INVESTIGATING THE QUALITY OF MATHEMATICS OFFERED TO STUDENTS IN POST-SECONDARY CONTEXTS

Mary Beisiegel	Claire Gibbons	Teresa Paul
Oregon State University	Oregon State University	Oregon State University
beisiegm@oregonstate.edu	gibbonsc@oregonstate.edu	pault@oregonstate.edu

Keywords: Post-Secondary Education, Instructional Activities and Practices

Several observational tools have been developed to study and describe elementary school mathematics instruction (see Boston, Bostic, Lesseig, & Sherman, 2015). Some of these tools have been linked to student outcomes (Blazar, 2015) and are being used for professional development purposes (Hill, Beisiegel, & Jacob, 2013). Researchers have begun to develop observational tools that would apply to teaching any discipline at the post-secondary level (Hora & Ferrare, 2014), while others have been designed specifically for post-secondary mathematics (Bergqvist, & Lithner, 2012), but few of these tools focus specifically on the mathematics that is taught to students. Since students rely on and are more likely to learn the mathematics they are taught, we argue that such an observational tool is critical for understanding the mathematics that is presented to students at the post-secondary level.

The specific goal of this study was to investigate and describe the mathematics offered by multiple instructors teaching a College Algebra course. The *Mathematical Quality of Instruction* (MQI) instrument (Hill, Blunk, Charalambous, Lewis, Phelps, Sleep, & Ball, 2008) was chosen as a first step in analyzing the mathematics in lessons because of its honed focus on mathematical content in the dimension the *Richness of the Mathematics*. In particular, this dimension includes the codes *Linking between Representations*, *Multiple Procedures and Solution Methods*, *Explanations*, *Patterns and Generalizations*, and *Mathematical Language*. Each of these codes has multiple score points that describe the varying levels of quality.

Over the course of two years, the lessons of three instructors teaching the same College Algebra course were video recorded. Three researchers watched and scored these lessons with the *Richness* dimension, while also paying attention to meaningful mathematical contributions that were not captured by the MQI. Our findings include: (1) the MQI provided a valuable starting point and we were able to single out, score, and describe some of the mathematics that was taught, and (2) in order to capture more, if not all, of the mathematics taught by the instructors, new dimensions need to be created and tested. These findings as well as exemplars from the lessons will be presented.

According to the PCAST report (2012) increasing the retention rate of the students who enter college intending to major in a STEM field has the potential to significantly decrease the gap between the number of STEM degrees produced and the projected number of STEM degrees needed to sustain the United States position in the global market. While there are many reasons students leave STEM fields, there is a growing body of research that suggests that intending STEM students are switching out of STEM fields due to experiences in their introductory mathematics courses (PCAST, 2012; Rasmussen & Ellis, 2013), including experiencing poor instruction (Bressoud, Mesa, & Rasmussen, 2015; Seymour & Hewitt, 1997). To this end, we seek to better understand student experiences in successful Calculus courses by answering the question, *how do students in successful Calculus programs talk about their instructors?*

The data reported here comes from student focus group interviews undertaken as part of the Characteristics of Successful Programs in College Calculus (CSPCC) project - a five year study focused on Calculus I instruction at colleges and universities across the United States with overarching goals of identifying institutional and departmental factors that contribute to student success. Qualitative analysis was conducted on a subset of questions from the student focus group interviews; this subset of questions helped to identify overarching ways in which students at these institutions talk about their instructors. Our findings include four distinct perceptions students have of calculus instructors and their roles/behaviors in the classroom: (1) Students report instructors concern for their *conceptual understanding* of foundational concepts in calculus; (2) students perceive their instructors as accessible, approachable, and *available* both in the class and out; (3) the instructors promoted an *encouraging atmosphere* in the classroom where students can interact with mathematics; and, (4) students report their instructor as *mathematically diverse*, offering multiple approaches to problems.

SHIRKERS, WORKERS, AND SHOWBOATERS: SHIFTING SOCIAL POSITIONING TO INCREASE EFFECTIVENESS OF MATHEMATICAL DISCOURSE

Claudia M. Bertolone-Smith
University of Nevada, Reno
claudia.bs@charter.net

Keywords: Affect, Emotion, Beliefs and Attitudes

Shirkers, Workers, and Showboaters: Breaking Borders

Student self-selected social positioning is a border- constructed to protect beliefs about our capacity to be a mathematician. Communication in the mathematics classroom can suffer from behaviors oriented towards protecting self-identity, rather than actively engaging in learning (Barron, 2003). In order to break through this border, we asked the students to identify the behaviors they use when acting as a novice (Shirkers) or an expert (Showboaters). This was contrasted with a co-regulation stance, showing a willingness to be influenced by others (Workers). Students knew exactly what it looked like to shirk or showboat (see Table 1). Students were able to describe underlying beliefs when shirking- "afraid that people will find out they can't do it", and showboating- "wanting attention, think it is a way to get people to like them". Additionally, these negative behaviors increased when the mathematics became more challenging.

A Common Language for Change

By distinguishing behaviors from mathematical ability, we were able to increase attentiveness and co-regulation among the class. During the study, Jessica suddenly put her head down on her desk and began crying; she was angry and would not respond to peer or teacher help. Later, she identified her behavior as "shirking", but underneath she was "frustrated". We used the Worker list to identify what she can do when frustrated, she chose to ask questions. Jessica became a regular participant in our mathematical discourse and improved her achievement on assignments. This type of intervention was repeatedly used during the teaching experiment. We found that students were able to participate in a discourse about the mathematics at hand, rather engaging in social positioning.

Table 1: Student Generated List of Behaviors

Shirkers	*Workers*	*Showboaters*
Escape to bathroom, nurse	Get started right away	Brag
Play with things	Work quietly, ask questions	Say, "I told you so"
Get someone else to do their work	Say, "I can do it!"	Won't listen to others' ideas
Whine about the work	Help others	Try to finish first
Take the easy way out	Try to understand other people's ideas	Interrupt the teacher and other kids

Adjusting Sociomathematical Mindset Norms

During the teaching experiment, the research team tracked behaviors of the class which impeded learning. The teacher reported that she usually "ignored the behaviors" during prior math lessons. Calling attention to shirker and showboater behavior adjusted negative sociomathematical mindset norms. The teacher asked students to set positive mindset goals before math lessons. The class was praised for choosing the worker moves they generated on their list. This approach broke through self-protective borders, which allowed for a strong mathematical community to blossom.

TEACHER LEARNING AS A TASK OF TEACHING

Mary Alice Carlson
Montana State University
mary.carlson5@montana.edu

In this poster, I present findings from a qualitative case study that brings boundaries between teaching and learning into question. The literature has many examples of teachers as learners. Teachers are positioned as students, needing knowledge related to content and practice (e.g. Ball, Thames, & Phelps, 2008), or professionals, drawing situated knowledge to select and bring classroom artifacts to a community of practice for continued learning (e.g. Franke & Kazemi, 2001). I posit another conception of "teacher as learner" is needed, wherein learning is framed as a fundamental task of teaching; necessary for carrying out day-to-day work in classrooms.

I analyzed the practice of two teachers who participated in a NSF-funded PD program aimed at helping K-3 teachers develop mathematical knowledge for teaching. A central component of the program was cultivating teacher characteristics thought to be important when teaching in ways that are responsive to students' mathematical ideas. Data analyzed includes observations, transcripts, teacher interviews, and lesson plans.

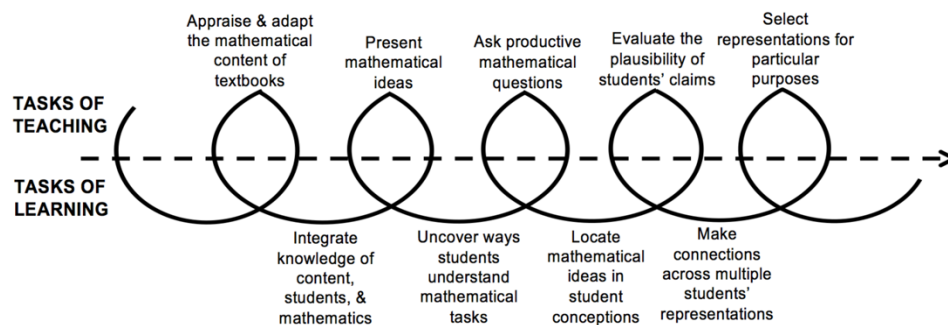
When responding productively to students' mathematical ideas, teachers set up and took advantage of opportunities to learn while teaching. In other words, teachers who used students' mathematical ideas productively transformed their own learning into a task of teaching. Findings suggest tasks of teaching and tasks of learning are cyclical and mutually reinforce one another. Findings also suggest it may be useful to conceptualize lists like Ball, et al.'s "mathematical tasks of teaching" (p. 400) as comprising both tasks of teaching and tasks of learning (Figure 1), and to consider how teachers might develop their capacity for learning while teaching. Implications for teacher education and professional development are explored.


Figure 1. Tasks of teaching and tasks of learning.

Palabras clave: Educación Media Superior, Resolución de Problemas, Creencias de los Maestros

Importancia de las Creencias de Docentes y Estudiantes

Las creencias permiten entender lo que los docentes y alumnos hacen en clase y por qué lo hacen (Lebrija, Flores, & Trejos, 2010). En un estudio realizado en México, De la Peña (2002) encontró que las creencias de los docentes de bachillerato acerca de las matemáticas propician frecuentemente el rechazo de los estudiantes hacia las matemáticas.

Leder, Pehkonen y Töner (2002) plantean que las creencias tienen una gran influencia en cómo aprenden y utilizan las matemáticas los alumnos, que las creencias del profesor regulan sus decisiones, la planificación, el desarrollo y la evaluación de los procesos de enseñanza aprendizaje de las matemáticas, además, que las creencias y las prácticas en la clase forman un círculo difícil de romper. Vila y Callejo (2005) consideran que para destruir este círculo primero es necesario diagnosticar aquellas creencias que no son adecuadas y, después, diseñar actividades dirigidas a los estudiantes que propicien experiencias que puedan desestabilizar esas creencias. Con base en lo anterior el objetivo de este trabajo es identificar las creencias de un grupo de profesores y estudiantes de bachillerato acerca de la enseñanza aprendizaje en la resolución de problemas matemáticos en México. Las preguntas de investigación planteadas son: ¿Cuáles son las creencias predominantes de docentes de bachillerato acerca de la enseñanza de las matemáticas? ¿Cuáles son las características de las creencias de estudiantes de bachillerato acerca del papel del profesor de matemáticas en la enseñanza?

Métodos y Análisis

Participaron en total 730 estudiantes de todos los grados del nivel de bachillerato de escuelas públicas y privadas, y 24 maestros de matemáticas. Las escuelas pertenecen al Estado de Puebla en México. Se aplicó el *Mathematics-Related Beliefs Questionnaire*, a los alumnos, y *Enseñar matemáticas*, a los profesores. Ambos instrumentos son de la autoría de Gómez-Chacón, Op't Eynde, y De Corte (2006).

Las creencias identificadas, tanto en los profesores como en los alumnos, se pueden clasificar en las de etapa ontológica (referentes a qué es la matemática, qué es aprender matemáticas, qué es la resolución de problemas), las de etapa gnoseológica (referidas al aspecto didáctico de las matemáticas) y las de etapa de validativa (que tratan con cuestiones de quién y cómo valida el aprendizaje matemático), tanto en alumnos como en profesores.

Conclusiones

Se destaca que si bien existe una importante dificultad para identificar las creencias y concepciones, entre ellas las referentes a las matemáticas, el uso de instrumentos como los empleados en este trabajo facilita aproximarse a su estudio. Se reflexiona acerca del influjo del tipo de creencias identificadas entre los profesores en aspectos como la búsqueda de estrategias didácticas que les permitan superar las dificultades y las exigencias de enseñanza.

Keywords: High School Education, Problem Solving, Teacher Beliefs

Importance of Beliefs of Teachers and Students

Beliefs allow us to understand what teachers and students do in class and why they do (Lebrija, Flores, & Trejos, 2010). De la Peña (2002) in a study in Mexico found that beliefs of high school teachers about math, often promote the rejection of students towards mathematics.

Leder, Pehkonen, and Töner (2002) argue that beliefs have a strong influence on how students learn and use mathematics, that teachers' beliefs govern their decisions, planning, development and evaluation of the processes of teaching and learning mathematics and that beliefs and classroom practices form a circle that is difficult to break. Vila and Callejo (2005) consider that to change and improve this circle, first it is necessary to diagnose those beliefs that are not appropriate, and then design activities that foster experiences for students that could destabilize those beliefs. The purpose of this work is to identify the beliefs of a group of high school teachers and students about the teaching and learning process toward solving mathematical problems in Mexico. The research questions are: What are the prevailing beliefs of high school teachers about teaching mathematics? What are the characteristics of high school students' beliefs about the mathematics teachers' role in teaching?

Methods and Analysis

Twenty-four math teachers and 730 High school students from public and private schools participated in this study. Schools are located in the state of Puebla in central Mexico. The instruments used to collect the data were *Mathematics-Related Beliefs Questionnaire* to students, and *Teach mathematics* to teachers. Both instruments authored by Gómez-Chacón, Op't Eynde, and De Corte (2006).

The identified beliefs, both in the teachers and in the pupils, can be classified in the ontological stage (concerning what mathematics is, what learning math is, what problem solving is), those of epistemological stage (referring to the math teaching aspect) and the validative stage (dealing with questions of who and how mathematical learning is validated), for students and teachers alike.

Conclusions

Findings suggest that although there is a major difficulty in identifying the beliefs and conceptions, including those relating to mathematics, the use of instruments as used in this paper facilitates approaching to its study. We reflect upon the influence that the type of beliefs identified among teachers' areas such as the search for teaching strategies that allow them to overcome the difficulties and demands of teaching.

IMPLEMENTATION OF AN INTERDISCIPLINARY CO-PLANNING TEAM MODEL AMONG SECONDARY MATHEMATICS AND SCIENCE TEACHERS

Michelle Cetner
North Carolina State University
mcetner@ncsu.edu

Allison W. McCulloch
North Carolina State University
awmccull@ncsu.edu

Academic subjects in school are traditionally isolated, but drawing connections, especially between mathematics and science, may increase student engagement, performance, and critical thinking skills (Becker & Park, 2011). However, obstacles limit widespread implementation of integrated curricula in schools (Vars, 2001). The Interdisciplinary Co-planning Team (ICT) model was created to overcome these obstacles to offer a sustainable interdisciplinary experience for teachers and students. In the model, teachers of different subjects participate in co-planning sessions on a regular basis to discuss connections that can be drawn between their subjects. They then implement their plans in their own classrooms. The ICT model is iterative, so after implementation, the teachers meet to reflect on their lessons and to co-plan future lessons.
Figure 1. The interdisciplinary co-planning team model.

This study uses a qualitative multiple-case intervention design to examine the nature of teachers' planning processes, plans, and beliefs during an 8 week implementation of the ICT model. The conceptual framework, informed by literature regarding teachers' beliefs and planning practices, expresses the reciprocal relationship among the co-planning process, teacher beliefs, and teaching practices. Data includes observations of co-planning sessions, artifacts of planning (i.e., lesson plans, student worksheets, reflective journals), and interviews.

Preliminary findings include that routine is quickly established, teacher experience seems to affect the nature of co-planning discussions, and that pairs are most productive when they discuss specific concepts, processes, or activities. Regarding teacher plans, science teachers tend to use extended labs whereas math teachers tend to use shorter examples to draw connections. Regarding teacher beliefs and dispositions, co-planning seems to result in courage for teachers to leave their comfort zones, and teachers who engaged in co-planning seemed to have an overall positive experience and plan to continue to collaborate with their partners.

EXPLANATION AND ARGUMENTATION: A CASE STUDY

AnnaMarie Conner   Laura M. Singletary
University of Georgia   Lee University
aconner@uga.edu   lsingletary@leeuniversity.edu

Keywords: Teacher Beliefs, Classroom Discourse, Instructional Activities and Practices

One important aspect of mathematical discourse in a classroom environment is collective argumentation. Yackel (2002) suggested that the teacher plays a particularly important role in facilitating collective argumentation. Pedagogical choices about when to press for justification and what norms are negotiated in the classroom have consequences for how and when students engage in mathematical arguments and even what counts as appropriate explanation and justification (Yackel & Cobb, 1996). In our framework for teachers' support for argumentation, we describe specific moves teachers may use to facilitate this type of discourse (Conner, Singletary, Smith, Wagner, & Francisco, 2014). This research uses our framework to describe one teacher's support for argumentation and link that support to her beliefs about mathematics, teaching, and proof to answer the question: What aspects of Kylee's beliefs explain her choices in supporting argumentation in her classroom practice?

Using qualitative methods that align with a situative perspective on learning to teach mathematics (Peressini, Borko, Romagnano, Knuth, & Willis, 2004), we described her beliefs about mathematics, teaching, and proof as well as her actions in support of collective argumentation. Kylee contributed many of the warrants in her class, and her students' warrants were surrounded by her supportive actions (such as repeating or rephrasing her students' contributions). In Toulmin's (1958/2003) model of argumentation, the warrant is crucial in linking the data to the claim, explaining relationships within the argument. Kylee often expressed a belief that explaining was an important part of teaching: "Knowing that your explanation helped somebody to get it really is exciting to me…I love math anyway, and I was excited about explaining things to people." Her beliefs about mathematics and proof were also related to explanation. Kylee believed that explanation was important, and her patterns of support illustrate a belief that she was responsible for the explanations within her classroom.

THIS IS NOT MATHEMATICS

Karla Culligan
University of New Brunswick
kculliga@unb.ca

David Wagner
University of New Brunswick
dwagner@unb.ca

René Magritte's famous painting *The Treachery of Images* depicts a smoker's pipe with writing under it that says "Ceci n'est pas une pipe," which means "This is not a pipe." We apply this play on language to mathematics classroom communication to raise questions about the teaching and learning of mathematics.

When we were mathematics teachers, we generally thought students should be doing mathematics, and we considered them "off task" if they talked about anything else. Perhaps not surprisingly then, our own and many other research analyses of mathematics classroom discourse often distinguish mathematical discourse from nonmathematical discourse (e.g., Setati, 2005). However, drawing on others' work (e.g., Chazan & Ball, 1999) we now explore the storylines intersecting during communication acts expressed by groups of Grade 10 French immersion students, and reflect on the potential for "off task" mathematics for expanding students' language and mathematical repertoires. In one exchange, for example, in a group comprising two males and one female, storylines came together to influence group dynamics and mathematics. The two male students took charge of the mathematics and the communication. Very little "off task" communication occurred but at one point students brought storylines to the table that were seemingly unrelated to the task at hand (discussing their parents). We question how these storylines affected students' communication choices (e.g., choosing to not participate in the case of the female student, a male student choosing to disclose his knowledge of the female student's personal details) and thus the mathematics at hand. Significantly, we wonder if one reason for these bilingual students staying "on task" when doing mathematics is that they are linguistically less equipped to say things "off task" in French.

The classic interpretation of Magritte's painting is that it is not a pipe. It is an image of a pipe. We suggest that being "on task" with mathematics is like an image of mathematics, different from real mathematics used as a tool in complex situations. We call for work that develops ways for engaging students in more complicated situations and explores differences in the way students connect various storylines to their mathematics in schoolwork, especially in additional-language contexts.

"THEY NEVER TAUGHT US THAT": ACCESS TO MATHEMATICS DISCOURSE PRACTICES AMONG PRE-ENGINEERING COLLEGE STUDENTS

Alberto Esquinca
University of Texas at El Paso
aesquinca@utep.edu

Angelica Monarrez
University of Texas at El Paso
amonarrez5@miners.utep.edu

A sociocultural perspective on the specialized ways of thinking, being and using language in mathematics is valuable in order to understand ways in which underrepresented minority groups (URMs), including Latinos and English learners (ELs) develop specialized discourses. URMs acquisition of these discourses may be compromised by a limited access to these discourses. In this paper, we report on an analysis of the discourse practices of pre-engineering students. Part of a larger study in which a college course for freshman pre-engineering students at a Hispanic Serving Institution (HSI) was re-designed, in this study we focus on a teaching and learning activity. Student teams presented a lesson to their fellow students on an assigned precalculus topic. All students in the course were randomly placed into teams of four, resulting in teams that were composed of students with varying levels of math achievement, (as determined by test placement scores). We video recorded all presentations. Data for this study were selected based on feedback from interviews. Three out of five students noted that the presentations on trigonometry (including functions and unit circle) were the most helpful. We asked: How do college students at varying levels of mathematics achievement differ in their mathematical discourse practices? Using discourse analysis (Gee, 1999), we analyzed the use of multimodal resources including oral language, writing and gestures. We identified several mathematical Discourse practices, suggesting differences among students as to their identity.

Results

The first practice, giving definitions, is reading or recalling memorized phrases. Students with the lowest placement scores were limited to the use of this practice. These students spoke the least during the presentation with an average of 85 words for the entire lesson delivery.

The second practice, giving instructions, is giving test-taking tips, memorization strategies and mnemonic devices. Students might engage in this practice by positioning themselves as "a traditional teacher" in the sense that they seemed to assume that mathematics is about answering test items correctly and doing well on exams.

The third practice was constructing meaning. This practice consisted of making connections to audiences by drawing on various meaning-making resources including the use of writing and visual representations on the whiteboard. Students who had been placed in Calculus and above happened to use this practice the most, though they also used other prior practices as well. These students explained and justified their thinking drawing on multiple representations.

In this paper we have shown differences in mathematical discourse practices to argue that differential access to these discourse practices indexes achievement in college mathematics.

CHARACTERISTICS OF EFFECTIVE QUESTIONING FOR MATHEMATICAL MODELING TASKS

Jennifer A. Czocher
Texas State University
czocher.1@txstate.edu

Joshua B. Fagan
Texas State University
jbf51@txstate.edu

Complex modeling tasks on their own may not be sufficient to achieve the desired outcomes of mathematical modeling in the classroom. The literature identifies at least two reasons: the challenges for both the student and the teacher to engage in modeling tasks (Blum & Borromeo Ferri, 2009) and the need for teachers to shift their focus onto students' current knowledge and understanding (Doerr, 2006). Thus there is a need to consider the interactions between student and teacher to harness the potential for mathematical modeling as a learning tool. The strong link between teacher moves (e.g. questioning, scaffolding, or leading discussions) and student outcomes in cognitively demanding mathematical tasks (Drageset, 2014; Henningsen & Stein, 1997) suggests that exploring the ways in which questioning directs students' attention toward the connection between the real world and mathematical aspects of the task would be beneficial. We present a preliminary analysis of the impact of questions posed to 12 high school and middle grades students in task-based, think-aloud interviews. The tasks were mathematical modeling and applications problems. We first analyzed interview transcripts according to a modeling cycle (Czocher, 2016). We then used frameworks for exploring classroom interactions (Drageset, 2014; Henningtsen & Stein, 1997) and qualitative coding techniques to document the impact of interviewers' questions on the students' progress and success. Analysis suggests that any one interviewer question or interaction may not be universally helpful. However, there are ways to scaffold students' mathematical reasoning about real world situations without trivializing the connection between real world assumptions and mathematical constraints. We found that when the interviewer used questioning to initiate parts of the modeling cycle for students it created a collaborative modeling process that led to the student's continued progress within the modeling cycle. For example, the interviewer's questions often became part of the student's validation of her own modeling choices. As Stender and Kaiser (2015) suggested, we also found that asking a student to explain her work gave the interviewer insight into the student's metacognitive process and allowed the student to refocus her thoughts on the task. An emphasis on validating resulted in greater understanding of student thinking, more focused follow-up questions, and sustained student interaction with the modeling cycle.

TRANSLATING RADICAL CONSTRUCTIVIST RESEARCH INTO PRACTICE: FIRST STEPS

Tiffany Friesen
AIMS Center for Math and Science Ed
tfriesen@aimsedu.org

Richard Thiessen
AIMS Center for Math and Science Ed
rthiess@aimsedu.org

Keywords: Elementary School Education, Instructional Activities and Practices, Number Concepts and Operations

The Nation's Report Card (National Center for Educational Statistics, n.d.) makes clear that mathematical proficiency for U.S. students, as a group, is not only shockingly low, but is declining. Lack of proficiency is not evenly distributed: Gaps continue between groups based on gender, ethnicity and socio-economic status, creating borders that limit access for some and generate opposing trajectories for others. The intransigence of these problems in mathematics education may be due to the fact that we continue to organize the mathematics curriculum from the adult's frame of reference (Steffe, 2010), so that the mathematics of children is not capitalized on, but rather suppressed, in favor of more conventional ways and means generated from the adult perspective. Radical constructivist researchers call for teachers to organize their instruction around the mathematics of their students, using the models of children's mathematics that can be built by researchers and teachers. A critical need exists for a translating group that knows the current research on the mathematics of children and the realities of the classroom well enough to bridge the divide.

Inspired by the line of research initiated by Leslie Steffe, we are using research, video, teaching experiments and the extant epistemic subjects developed by researchers to assist teachers in building second-order models of student thinking that may explain and predict the student's mathematics (Steffe, 1991). Having knowledge of epistemic subjects influences the teacher/researchers to understand potential differences among student's understandings and to employ a prescriptive course of action that works within a student's zone of proximal construction and might eventually engender a reorganization in the students' thinking (Ulrich, Tillema, Hackenberg, & Norton, 2014).

By focusing on knowledge translation we are able to weave together research and action in a way that is beneficial to the classroom teacher and different from the pressures felt by either the researcher or the teacher (Bennett & Jessani, 2011). The essential aspects of the mathematics of students must be understood deeply by the teacher so that s/he may seamlessly weave between work with the individual and the class as a whole. Therefore, the translator(s) must maintain the integrity of the research, but make decisions about the language and level of detail to use in order to be accessible to the teacher. The translation of research to classroom practice may well be the missing link to true equity in access.

CHALLENGES OF MAINTAINING COGNITIVE DEMAND DURING LIMIT LESSONS

<u>Dae S. Hong</u>	Kyong Mi Choi
University of Iowa	University of Iowa
dae-hong@uiowa.edu	Kyongmi-choi@uiowa.edu

Keywords: Classroom Discourse, Instructional Activities and Practices

In this study, we examined 10 limit lessons to understand students' opportunities to learn cognitively challenging tasks and maintain cognitive demand during limit lessons. Since our results are based directly on day-to-day instructional practices, we hope our results will have more widespread impact in the actual teaching of calculus. The results show that over 90% of tasks were at a low level and both mathematicians were not able to maintain cognitive demand for most tasks. With our findings, we can suggest the following for Dr. A and Dr. B. For Dr. A, more mathematical questions that require explanations and reasoning are needed because over 80% of her questions only required simple and short answers. These questions often sought only correct answers. In addition, instead of taking over the discussion, Dr. A needs to give her students opportunities to reflect and monitor their work. For Dr. B, it is critical to ask more questions, give them time to think about tasks, and provide students opportunities to explain and monitor their thinking. Dr. B tended to lecture and explain everything and, as a result, his students worked on only a few limit tasks and were asked only a handful of mathematical questions. We also recommended professional development for calculus instructors. Professional development at secondary and elementary levels is common, but not often seen often at the undergraduate level. Reflecting on one's own teaching and changing the concept of one's teaching are keys to successful professional development (Hannah, Stewart & Thomas, 2011; Paterson et al., 2011). Such an approach is "bottom-up" rather than "top-down," meaning that instead of developing a policy to be imposed on faculty members, each faculty member reflects on his/her teaching practices. With self-reflection and collaboration, we should be able to identify and provide class-based individualized feedback for each calculus instructor and take a step toward reforming instructional practices in calculus.

Key words: Classroom Discourse, Instructional Activities and Practices

In this study, we examined 10 integral lessons to observe the quality of instruction in these lessons. The results of this study confirmed the well-known fact that lecture is still the main mode of teaching in Calculus 1. With our findings, the real question is, "How can we use these results to improve calculus teaching?" One way is to collaborate with mathematicians to share our findings, so they can reflect on their teaching. With our findings, we can suggest the following for Dr. A and Dr. B. Both mathematicians should carefully select and implement mathematical tasks with high level cognitive demand and instead of taking over class discussions, ask more novel questions to elicit responses from students. Also, even if many tasks required only low-level cognitive demand, both Dr. A and Dr. B should attempt to access students' prior knowledge to assess understanding, so that students have opportunities to make connections between procedures and concepts. We also suggest professional development for calculus instructors, similar to what previous studies on secondary and elementary mathematics teachers (Boston, 2009; Henningsen & Stein, 1997). As part of professional development and collaboration, calculus instructors can be informed of the Mathematical Tasks Framework, the maintenance of cognitive demand, and more importantly, be provided with opportunities to reflect on their teaching. These suggestions may sound obvious, but mathematicians are often not trained in education, so it is beneficial to collaborate with them and provide professional development opportunities. Reflecting on one's own teaching and changing the perception of one's teaching are keys to successful professional development (Hannah, Stewart & Thomas, 2011; Paterson et al., 2011). With self-reflection and collaboration, we should be able to take a step toward reforming instructional practices in calculus.

TEACHERS' BELIEFS: HOW THEY ARE ENACTED IN THE CLASSROOM

Christa Jackson	Ashley Delaney
Iowa State University	Iowa State University
jacksonc@iastate.edu	delaneya@iastate.edu

One of the essential elements needed to have effective mathematics instruction for all students is a commitment to access and equity (NCTM, 2014). Unfortunately, this commitment has not been fully realized in many U.S. mathematics classrooms. Many African American students are consistently demonstrating low mathematical achievement, and many educators have refused to acknowledge the racial inequities faced by African Americans. Too often, teachers hold beliefs that do not facilitate the academic participation and learning of African American students (Martin, 2007). The purpose of this study was to examine two middle level mathematics teachers' beliefs about African American students and how they learn mathematics. Specifically, we investigated how these beliefs were enacted during mathematics instruction.

In this qualitative study, we analyzed data from three different contexts: (1) teacher interviews, (2) videotaped classroom observations, and (3) classroom artifacts including lesson plans, teacher handouts, and student work. The data were analyzed using a data reduction approach (Miles & Huberman, 1994) and a constant comparative approach (Charmaz, 2006). Coding was used to generalize patterns and find conceptual coherence in the data (Grbich, 2007).

Both teachers articulated that it was important they relate mathematics to their students' lives and provide opportunities for students, especially their African American students, to talk with their peers about the mathematics. One teacher noted that African American students seem "to be more outspoken…they get really excited and kind of get louder" (Initial Interview, 2015). Although the teachers expressed students, particularly African American students, learn mathematics through sharing and discussing the mathematics with their peers, about 65% of the observed instructional time the students were working individually. When the students were given the opportunity to work in groups or with a partner, the teachers spent a considerable amount of time quieting the students, even when the noise level in the classroom was minimal.

The commitment to access and equity centers on teachers having productive beliefs and high expectations of students who have been traditionally marginalized in the mathematics classroom. Most importantly, the commitment must be enacted in teacher's daily practices and classroom instruction in order to ensure all students, including African American students, have access and opportunities to learn and engage in challenging and rigorous mathematics.

STUDENT TEACHERS' AND TEACHER LEADERS' TAKE-UP OF EXPLORATORY ("ROUGH DRAFT") TALK

Amanda Jansen
University of Delaware
jansen@udel.edu

During classroom discussions, some students prefer to wait to share their thinking until they are certain that their ideas or solutions are correct. These students may not recognize that it is helpful to engage in exploratory or "rough draft" talk (Mercer & Hodgkinson, 2008). Rough draft talk is talking about ideas while they are still in progress by using hesitant, imprecise, and bumpy language. Talking is used as a tool to develop thinking. Instead, students may default to presentational or "final draft" talk. Final draft talk aligns with *performing* rather than *learning*.

Promoting rough draft talk in the mathematics classroom has benefits for both students and teachers. Mathematics students may not be aware that they can *continue* to learn during classroom discussions by refining their thinking through rough draft talk. Mathematics teachers benefit from eliciting students' thinking in progress so that they can access and build upon students' thinking during instruction (Leatham, Peterson, Stockero, & Van Zoest, 2015).

How do middle school mathematics student teachers and secondary mathematics teacher leaders take-up exploratory ("rough draft") talk? Data from this study were drawn from two professional development contexts: a pedagogy course during a student teaching semester and a statewide professional development experience for teacher leaders. Participants in both contexts engaged in a semester-long online study group about exploratory talk. They reflected on readings (chapters from Mercer and Hodgkinson (2008)) and discussed self-selected video clips from their classrooms that exemplified exploratory talk. This work parallels others who have studied how teachers take up a construct introduced in professional development (c.f., Herbel-Eisenmann, Drake, & Cirillo, 2009; Turner, Christensen, Kackar-Cam, Tracano, & Fullmer, 2014).

All participants reported that exploratory talk supported students with making connections collaboratively during discourse and reduced risks during whole-class discussions. When reflecting upon ways to create occasions for exploratory talk, student teachers focused more upon eliciting talk generally and teacher leaders focused more upon opportunities for *exploratory* talk in particular. Teacher leaders additionally reported that they explicitly talked with students about how people learn mathematics, especially the role of talk in learning. Teacher leaders also reported using rough draft talk to position more learners as mathematically competent. Although it is unsurprising that these groups of teachers differed, contrasting the ways that teacher leaders' thinking differed from student teachers' thinking suggested a trajectory for teachers' learning.

RIGHTS OF THE LEARNER: A FRAMEWORK FOR PROMOTING EQUITY THROUGH FORMATIVE ASSESSMENT IN MATHEMATICS EDUCATION

Crystal Kalinec-Craig
University of Texas at San Antonio
Crystal.Kalinec-Craig@utsa.edu

Keywords: Equity and Diversity, Elementary School Education, Teacher Education, Instructional Activities and Practice

Despite calls to address the inequitable opportunities for all children to be successful in school (Sleeter & McLaren, 1995), not all students have such an opportunity, specifically in mathematics (U.S. Department of Education & National Center for Education Statistics, 2015). In order to help more students learn mathematics, there are existing frameworks that help teachers leverage students' mathematical, cultural, and linguistic resources while teaching mathematics (Gonzalez, Andrade, Civil, & Moll, 2001; Turner, Drake, McDuffie, Aguirre, Bartell, & Foote, 2012). If as Bob Moses and the Algebra Project argue (Moses & Cobb, 2002) that mathematics education is seen as a civil right, then teachers should provide specific opportunities to validate the mathematical thinking of each student; and as a result, teachers can help more students connect their in-school mathematical learning with how they use mathematics outside of the classroom. This poster describes another framework aimed at helping teachers to promote equity in the mathematics classroom: The Rights of the Learner.

Framed by sociocultural learning theory (Werstch, 1990), the Rights of the Learner (RotL) was first conceived by an elementary mathematics teacher, Olga Torres, and is comprised of four elements: 1) the right to be confused, 2) to make mistakes, 3) to say what makes sense to you, and 4) to write what makes sense to you. The RotL assumes that all students are afforded an equitable opportunity to take explicit ownership of their learning, both in writing and oral communication. Furthermore, teachers (including teacher educators) can use the RotL to help students embrace productive struggle as a part of the learning process and to recognize mathematical misconceptions and mistakes as being an crucial insights into students' mathematical thinking. Finally, the RotL frames formative assessment as a tangible tool that teachers can use when supporting *all* students to learn mathematics while honoring students' diverse mathematical resources (e.g., native language, out-of-school knowledge and experiences). Implications for future research and teacher education will be suggested.

REACHING BEYOND STRUGGLE TO PROMOTE MATHEMATICAL PROFICIENCY IN ALL LEARNERS

Kirsten S. Keels
University of Georgia
ksk06155@uga.edu

Keywords: Elementary School Education, Instructional Activities and Practices

Providing high quality instruction for all students has been a unifying theme in mathematics education for years (NCTM, 2014). However, additional research on instructional supports used to develop mathematical proficiency (Kilpatrick, Swafford, & Findell, 2001) in struggling learners is still needed. While it is expected that students will engage in struggle at some point during instruction, the ways in which teachers and students reach resolutions impact students' opportunities to learn substantive mathematical concepts and practices. Consequently, a systematic investigation of the way teachers support struggling learners in mathematics may offer insight on maintaining rigorous instruction when students grapple with complex ideas.

In this exploratory study, I examined how a first grade teacher assisted students who struggled with differentiated tasks while working in math centers. In this research, I defined struggle as moments when "students expend effort to make sense of mathematics, to figure something out that is not immediately apparent" (Hiebert & Grouws, 2007, p. 387). In particular, instances of struggle were identified when the teacher engaged students in tasks designed to remediate students' lack of understanding demonstrated on an assessment or when a student could not make independent progress toward a solution. I identified instances of struggle across 12 lessons related to number sense and measurement and consulted with a second researcher as I developed codes from the data. Three students who consistently struggled to grasp mathematical ideas were the central focus of the data analysis.

Preliminary findings indicate that the teacher used student struggle as an opportunity to engage students in mathematical practices such as providing justifications, evaluating arguments, and refining solutions to problems. She used probing questions that encouraged students to connect their work to other mathematical representations and provide "proof" for claims they made about content. Using these supports usually allowed students to arrive at a resolution independently, but the findings also reveal circumstances in which teacher-directed resolutions tended to occur. Finally, my findings will illustrate similarities and differences between the instructional supports used in lessons related to number sense and measurement.

PATHWAYS TO LEARNING OPPORTUNITIES FOR CONCEPTUAL DEVELOPMENT: CASE OF KOREAN HIGH SCHOOL CLASSROOMS

Hee-jeong Kim
University of Nebraska – Lincoln
hkim14@unl.edu

Keywords: Classroom Discourse

This study presents a classroom discourse interactional model that enhances development of students' conceptual understanding, in particular of derivations of the formulas for the finite series, $\sum_{k=1}^{n} k^2$ and $\sum_{k=1}^{n} k^3$. Previous research has pointed out that secondary mathematics classrooms in the United States often lack the intellectual engagement of important mathematical ideas or explicit attentions to connections among ideas, procedures and various representations (Hiebert & Grouws, 2007; Hiebert et al., 2003). This study illustrates a classroom model using detailed examples from a Korean high school mathematics classroom where classroom activities ultimately focused on making connections to the core concepts. This model provides an image of mathematically productive learning opportunities for development of conceptual understanding, particularly in secondary mathematics classroom contexts.

The analysis with the mathematical discourse framework (Sfard, 2007, 2012) focused on how the teacher (1) provided mathematical commognitive conflicts for students to explore the patterns of the finite series $\sum_{k=1}^{n} k^2$ and $\sum_{k=1}^{n} k^3$, (2) guided them to make connections between the manipulatives (e.g. unicube blocks) and visual representations, and (3) led them to make explicit connections to the symbolic expressions. The results show that students did not immediately take into account the representations in a traditional mathematical sense but their mathematical understandings emerged and developed in social discourse activity where the participants—teacher and students—supported development of conceptual understanding through discourse. In the poster, the specific features of the teacher's use of words and visual mediators will be provided with detailed examples from the classroom observation data.

This model sheds light on our understanding on the process of teaching-learning interaction as a social activity in a mathematics classroom. This study also methodologically contributes to the potential of the detailed analysis on the development of conceptual understanding in the process of teaching-learning interaction in classroom research. Implications on improving practice such as professional development for concept-focused instruction or curriculum design will be discussed. This study particularly addresses the conference theme, *questioning borders within mathematics education across two countries,* by serving as a tool for understanding on productive learning opportunities for development conceptual understanding using international classroom data.

STUDENT PRESENTATIONS AS A LOCUS FOR DEVELOPING INTELLECTUAL AUTHORITY AND MATHEMATICAL PRACTICES

Hee-jeong Kim
University of Nebraska-Lincoln
hkim14@unl.edu

Kimberly Seashore
San Francisco State University
kimseash@sfsu.edu

Denny Gillingham
UC Berkeley
gillingham@berkeley.edu

Keywords: Instructional Activities and Practices, Standards, Middle School Education, Classroom Discourse

Mathematics reform movements, most recently, the Common Core State Standards for Mathematics (CCSSM, 2011) focuses on the mathematical practices intertwined with mathematical content across grade levels as critical aspects of mathematical learning. In an effort to understand how classrooms can become environments that support students' development of the mathematical practices, we focused our research inquiry toward a particular structure, student presentations. During student presentation time, students are more genuinely responsible for developing their mathematical arguments, having opportunities to present their thinking, learning to analyze other peoples' arguments and reaching agreement on shared understanding (Engle & Conant, 2002; Lampert, 2001). These presentations are both public and place the spot light directly on one or two individual students. Hence, student presentations may have substantial potential to promote students' intellectual authority and to develop their mathematical practices.

In this study, we are investigating pursuing the following questions: (1) In what ways do students engage in the mathematical practices during presentation to their classmates? And (2) In what ways do the student presentations promote the intellectual authority of the student presenters?

The study uses video data of three lessons in two middle school mathematics classrooms, drawn from a larger research project, examining classroom use of lessons specifically developed to support the mathematical practices and formative assessment. Video recordings of the student presentation portions of each of the lessons are transcribed and coded for opportunities for students to engage in reasoning quantitatively and abstractly and development and critiquing mathematical arguments. The interactions between the student presenters and the teacher in preparation for the presentation, during and immediately following the presentation are analyzed based on Engle's (2010) notion of four kinds of intellectual authority: *intellectual agency, authorship, contributorship,* and *local authority*.

Preliminary results indicate substantial differences between the two classes in student engagement with mathematical practices during mathematical presentations. These differences correspond to differences in the intellectual authority afforded to these students. In addition, the analyses reveal strengths in how each teacher prepares for and interacts with the student presentations, as well as suggesting how student presentation can be better leverages to support learning. This study particularly addresses the conference theme, *questioning borders within mathematics education,* by serving as a tool for understanding on development of student authority and of mathematical practices across grade levels.

ADDRESSING DILEMMAS OF SOCIAL JUSTICE MATHEMATICS

Kari Kokka
Harvard University
kari_kokka@mail.harvard.edu

What constitutes student success?

Social Justice Mathematics (SJM) educators explicitly aim to develop students' sociopolitical consciousness in addition to teaching mathematics content (Gutiérrez, 2013; Gutstein, 2006). These multiple goals, create a question of "What constitutes student success?" If a student uses mathematics to save their homes from being demolished through advocacy work with city officials, but the student does not pass the required math exit exam, would this student be considered successful, or vice versa? Critical race scholar William Tate (1995) poses the question, "Is it possible to develop high-level mathematical competence for African American students within a Eurocentric paradigm?" Rochelle Gutiérrez (2013) suggests "playing the game while changing it" to improve students' facility with both *critical* and *dominant* mathematics.

What is the curriculum for SJM instruction?

Second, is the dilemma of the actual SJM curriculum, or the projects and activities to be developed for one's students. Students themselves should propose the social issue(s) they wish to investigate and use mathematics to analyze and take action to solve such problems. This empowers students and fosters a co-constructed classroom space, rather than the teacher choosing and designing a mathematics project around a social issue s/he thinks is relevant to his/her students. Opportunities for collaboration to develop SJM lessons and projects are helpful, with teams of teachers, student advisors, and/or with outside guests from local universities.

How can teachers gain sociopolitical consciousness?

When developing SJM lessons and projects, teachers must have an awareness of students' lives. However, teachers may or may not be from nor live in students' neighborhoods and therefore may or may not possess the sociopolitical consciousness needed to create meaningful SJM projects. Students may be able to help teachers gain sociopolitical consciousness through respectful dialogue between students and teachers and community members and families. This is a great way to cultivate a co-constructed classroom space because students take the lead as experts. These dilemmas of SJM may be addressed through collaboration of students, educators, families, and even university professors and graduate students to empower students to succeed in both critical and dominant mathematics.

THE INFLUENCE OF TEACHER AFFECT ON RETENTION OF URBAN MATH TEACHERS OF COLOR

Kari Kokka
Harvard University
kari_kokka@mail.harvard.edu

Objectives

Urban schools often struggle to find certified math teachers who remain in the classroom. Teachers of color are more likely to work in diverse urban schools (e.g. Ingersoll & May, 2011), making their retention a potential means of reducing math teacher shortages. Studies also indicate that teachers of color produce better academic results for students of color than white teachers (e.g. Achinstein et al., 2010). The present study investigates reasons for longevity of eight math teachers, six teachers of color and two white teachers, in one urban Title I public school with high teacher retention, Beachside High School, or BHS (pseudonym). BHS serves 98.5% students of color with 100% considered economically disadvantaged. I focus on these research questions.

1. What reasons do participants give for job satisfaction (and how might this differ by race)?
2. What conditions, factors, and/or experiences influence participants' longevity in the classroom (and how might this differ by race)?

Methods

All eight math teachers with more than five years' experience at Beachside High School, or BHS, sat for a 60-minute interview. All interviews were audio recorded with participants' consent and transcribed through a transcription service. Interview data was coded and re-coded with Atlas.ti through a grounded theory approach to uncover themes to answer the research questions.

Results

Student Interactions

All teacher participants, both of color and white, enjoy interactions with students. Participants enjoy students' "aha" moments, or when the "lightbulb" goes off. They also enjoy learning from their students. Teachers expressed that they are "learning from students every day," and are "inspired" and "empowered" by students. Third, not surprisingly, participants enjoy gratitude and thank-yous from students.

Meaningful Work in an Urban School

Participants explained that they felt more useful, or more needed, in an urban under-resourced school like BHS and did not express fear of the community. When asked if participants chose to teach at BHS intentionally or by coincidence they affirmed their commitment to teaching in an urban school. Teachers described teaching at BHS because it is "where the most need is," and "where the struggle is." Math teacher longevity in urban schools may be improved by cultivating positive relationships between teachers and students.

Along with other accountability measures, high-stakes teacher evaluation is on the rise in the United States. Although teacher evaluation systems vary district by district and state by state, all fifty states require observation to be part of their evaluation systems (Hull, 2013). This study focuses on the role of subject matter content in various observational instruments used for both instructional improvement and decisions about teacher retention. To study whether and how instrument choice affects outcomes on observational assessments of mathematics teachers, ten videotaped mathematics lessons were coded using six different instruments. The video analysis followed Erickson's "manifest content approach" (2006). Four of the instruments used were mathematics-specific (RTOP; M-SCAN; TRU; MQI); two were not (Danielson; Marzano). In order to compare ratings, nine major constructs present in all six instruments were developed.

For nine of the lessons viewed, the choice of observational instrument made little difference on ratings outcomes. For one lesson, however, the choice of instrument produced different results. Although this only represents 10% of our sample, in a high-stakes environment, this is cause for concern. These difference results can be attributed to the following: a) Instruments vary in density about teaching and learning of mathematics. b) Mathematical content substance varies across mathematics-oriented instruments. c) Some instruments highlight differently the standards of mathematical practices, and other math processes. d) Instruments are sensitive to mathematical content differentially, and lesson types vary.

These findings suggest that observational instruments might be productively employed for establishing shared language for instruction and improving instruction, and instrument choice can be directed towards targeted areas of need. But since a lesson could be rated differentially on different instruments, caution is called for in the use of observation assessments to inform high-stakes teacher retention decisions.

Palabras clave: Actividades y Prácticas De Enseñanza

Antecedentes

El desarrollo de competencias matemáticas en el estudiante implica una serie de retos en los procesos de enseñanza. Una alternativa es el uso de recursos tecnológicos, sin embargo estos deben ir articulados con una estrategia didáctica para alcanzar los propósitos de aprendizaje. Este trabajo aborda el ¿cómo los estudiantes desarrollan competencias matemáticas al aplicar la estrategia de investigación con el apoyo de sensores? Se sustenta en Hitt (2003), para apoyar el uso de los recursos tecnológicos para la visualización así como el manejo de diferentes representaciones semióticas de los conceptos, (Duval, 1993). Los resultados muestran que los estudiantes desarrollan diferentes competencias matemáticas: A partir de lo anterior, se detalla una de éstas experiencias. El salón de matemáticas es un laboratorio permanente para explorar estrategias didácticas. Es así como desde el 2010, en la clase de análisis numérico del sexto semestre de la licenciatura en matemáticas aplicadas, se explora la estrategia didáctica de investigación. La tarea: los estudiantes deberían realizar un trabajo de investigación para aplicar y profundizar los contenidos del semestre. Es así como, al inicio del semestre se les presenta los lineamientos de ese trabajo de investigación: delimitación del tema clara y pertinente, justificación, definición de objetivos, sustento teórico matemático relacionado con los objetivos, ejecución práctica del tema investigado, contrastación entre la teoría y la práctica.

Objetivo, Metodología, Desarrollo y Resultados

El objetivo fue documentar las competencias matemáticas que desarrollan los estudiantes al implantar la estrategia didáctica basada en investigación y con el uso de sensores. La investigación fue cualitativa y la metodología ACODESA Hitt (2007) y Hitt y Cortés (2009), cuyas fases son: 1. El trabajo individual, comprender la tarea, 2. El trabajo en equipo con los procesos de discusión y validación, 3. Debate, 4. Auto reflexión y 5. Institucionalización del conocimiento. La población: un equipo conformado por dos estudiantes de licenciatura. Resultados por fases: 1. Los estudiantes delimitaron su trabajo: comparar los valores del Ph del suelo en diferentes zonas de la ciudad de Durango (Dgo). 2. Identifican y precisan los conceptos matemáticos: interpolación lineal y pruebas de hipótesis. 3. Se genera el debate, en forma de espiral permeando todas las fases.4. Los procesos de auto reflexión se constatan en cada una de las asesorías. 5. La institucionalización de conocimientos se comprueba en tres momentos. El primero, al término de su trabajo semestral, ellas articularon las representaciones gráficas, tabulares y los modelos algebraicos de regresión lineal. El segundo, ellas retoman el problema de la medición del Ph con diseño de experimentos. Tercero, ellas desarrollan su tesis en las zonas agrícolas en la ciudad de Dgo. Las competencias desarrolladas fueron: pensamiento reflexivo, analógico, toma de datos y procesamiento de información (López-Betancourt, 2013). La aprehensión de conceptos matemáticos es una evolución de los procesos mentales de los estudiantes. Al enfrentar la solución de un problema en contexto detona una activación de procesos mentales para acceder a los conceptos matemáticos y darles significado.

Keywords: Instructional Activities and Practices

Background

The development of mathematical skills in a student involves a number of challenges in the teaching processes. An alternative is the use of technological resources; however, these must be articulated with a teaching strategy to achieve the purposes of learning. This paper addresses: How do students develop math skills by applying a research strategy supported by sensors? Based on Hitt (2003), to support the use of technological resources for visualization and handling different semiotic representations of concepts (Duval, 1993). The results show that students develop different mathematical skills: from the above, one of these experiences is detailed. The math classroom is a perpetual laboratory to explore teaching strategies. Thus, since 2010, in the class of numerical analysis of the sixth semester of a degree in applied mathematics, teaching strategy research is explored. The task: students should conduct a research to apply and deepen the contents of the semester. Thus, at the beginning of the semester, they are presented the guidelines of this research: delineation of clear and relevant topic, justification, definition of objectives, mathematical theoretical basis related to the objectives, practical implementation of the research topic, contrasting between theory and practice.

Objective, Methodology, Development and Results

The aim was to document the math skills that students develop to implement a research-based teaching strategy and the use of sensors. The research was qualitative and used the ACODESA methodology Hitt (2007) and Hitt and Cortés (2009), whose phases are: 1. The individual work, understand the task, 2. Teamwork with the processes of discussion and validation, 3. Debate, 4. Self-reflection, and 5. Institutionalization of knowledge. Population: a team made up of two undergraduate students. Results by phases: 1. Students delineated their work: compare soil pH values in different areas in Durango city (Dgo). 2. Identify and acquire mathematical concepts: linear interpolation and hypothesis testing. 3. The debate generated a spiral permeating all phases. 4. Self-reflection processes are detected in each of the devices. 5. The institutionalization of knowledge is checked three times. The first, at the end of its six-month work, they articulated the graphics, tabular and algebraic linear regression models. The second, they retake the problem of measuring pH with design of experiments. Third, they develop their thesis in agricultural areas in Durango city. The skills developed were: reflective thinking, analogic, data and information processing (López-Betancourt, 2013). The apprehension of mathematical concepts is an evolution of the mental processes of students. Facing the solution of a problem in context triggers mental processes activation to access mathematical concepts and give them meaning.

MATHEMATICS AND DIGITAL CITIZENSHIP: BRIDGING CONCEPTS WITH TECHNOLOGY

Ricardo Martinez
Iowa State University
ricardom@iastate.edu

Ashley Delaney
Iowa State University
delaneya@iastate.edu

Keywords: Technology, Instructional Activities and Practices, Teacher Knowledge

Middle school is a tremendous period of change for students. Among notable changes, student interest and self-perception in mathematics declines most in middle school (Holdren, 2010). Additionally, Gonzalez, Andrade, Civil, and Moll (2001) finds individuals are more likely to think of math as a "school" subject with complex algorithms instead of recognizing the mathematical thinking underlying their daily lives. This poster presents how one teacher used the Analyze Design Develop Implementation Evaluate (ADDIE) model to design a technology-based lesson for bridging mathematical reasoning and digital citizenship.

"Technology is an "indispensable feature of [the mathematics] classroom… [T]he platform of the technology is less important than the functionality that it provides" (NCTM, 2014). Koh (2015) argues in order to design a lesson utilizing technology, teachers should incorporate design thinking (ADDIE model). The interactive lesson used for this study embedded mathematical questions in a presentation about digital citizenship and allowed each student the opportunity to answer questions using Nearpod. The use of technology allowed the teacher to monitor and get instant feedback on posed questions.

Student responses highlight which questions sparked the most effective connections between mathematical reasoning and digital citizenship. Question 4, "In 2013 Bruno Mars had his songs illegally download 5,783,556 times. If each time Bruno sells a song he makes a quarter, how much money was stolen from Bruno because of illegal down loads?" and Question 5 "If people were stealing a million dollars from you how would you feel, and what would you do if you were Bruno Mars?" work together to blend mathematics and digital citizenship. Students did not have to accurately complete mathematical computations (question 4) to apply reasoning and problem solving skills (question 5) when evaluating the ideals of good digital citizenship. After evaluating student learning, the teacher returned to the cyclical ADDIE model reanalyzing the lesson goals to redesign the content focus. Redeveloping the lesson using ADDIE created an effective and efficient bridge between digital citizenship and mathematics.

Keywords: Elementary School Education, Problem Solving, Instructional Activities and Practices

Research Purpose

Many research studies have demonstrated a strong correlation between reading and mathematics achievement (e.g. Fuchs, Fuchs, Eaton, Hamlett, & Karns, 2000). Understanding, text and mathematical concepts, are the goal for both literacy and mathematics teachers. Using comprehension skills with mathematics has not kept pace with other disciplines. There is a need for more research that links specific comprehension strategies with specific mathematics content (e.g. algebra, number and number sense, geometry). If such connections exist, mathematics instruction could include specific comprehension strategies. In particular, our research examined released standardized mathematics tests to explore the possibility of this connection.

Methods

Our initial findings come from a larger content analysis (Krippendorf, 2013) study. We used three third grade released standardized tests and our unit of analysis was each test problem. We conducted a qualitative analysis to identify the comprehension strategy or strategies using the constant comparison method (Glaser, 1965) on the first two tests and axial coding on the second set. We conducted inter-rater (two literacy experts) reliability measurement on the third test.

Results/Conclusions

Our inter-reliability measure was .91, outstanding (Landis & Koch, 1977). First, we identified 14 comprehension strategies that we used as codes. Reduced to eight, we created operationalized definitions for each: author and me, clarifying, cognitive flexibility, compare and contrast, fluency, graphics, prior knowledge, think and search. We found that number and number sense may best be supported by the comprehension strategy graphics; computation and estimation by fluency, author and me, and graphics; measurement and geometry by graphics and prior knowledge; probability and statistics by graphics and clarifying; and algebra by clarifying, think and search, and fluency. Currently, we are analyzing three fifth grade state released mathematics tests. Next, in-service teachers will use our codes to identify the comprehension strategy or strategies for each problem using the same tests to validate our findings.

STUDENT MATHEMATICAL CONNECTIONS IN AN INTRODUCTORY LINEAR ALGEBRA COURSE EMPLOYING INQUIRY-ORIENTED TEACHING

Spencer Payton
Washington State University
spayton@math.wsu.edu

Keywords: Instructional Activities and Practices

Linear algebra is a subject that many undergraduate students find difficult for a number of reasons; one such reason is the overwhelming number of mathematical connections students are expected to learn. Many of these connections can be illustrated through theorems like the Invertible Matrix Theorem (IMT), which presents a list of statements logically equivalent to the statement "a square matrix A is invertible" (Lay, 2011). While the IMT is arguably the most famous theorem in introductory linear algebra, it is only applicable to square matrices; however, similar theorems of logical equivalence can be formed for matrices of any size. Viewing logical equivalence as a bidirectional logical implication, many of the connections in linear algebra at an introductory level could be viewed as *connections as logical implications*.

There is currently a growing body of research on inquiry-oriented learning in linear algebra. While such research is an important contribution in providing resources for instructors to implement inquiry-oriented materials in a linear algebra class, factors such as time constraints and class size can make it difficult to foster inquiry in an undergraduate class. Rather than abandoning all hope of implementing inquiry in the face of these challenges, I aim to find areas in linear algebra where inquiry could be implemented in a practical, realistic sense. To that end, I have followed Rasmussen and Kwon's (2007) suggestion of viewing inquiry in a mathematics classroom through Richard's (1991) definition of *mathematical inquiry* as the mathematics of mathematically literate adults; this includes participating in mathematical discussion, solving new mathematical problems, and forming mathematical conjectures. I then define *inquiry-oriented teaching* as a practice of creating opportunities for students to participate in mathematical inquiry. With this definition, I have investigated the following research questions:

- How can a teacher implement inquiry-oriented teaching in an introductory linear algebra course?
- How do students connect linear algebra concepts through logical implications and logical equivalencies when provided with opportunities to engage in mathematical inquiry?

In an attempt to answer these research questions, I have conducted an action research study in which I taught an introductory linear algebra course that implemented both inquiry-oriented teaching and traditional lecture. Preliminary results suggest that while there are both advantages and disadvantages to this hybrid approach, there appears to be important differences in how inquiry-oriented teaching and lecture each provide opportunities for students to form logical implications.

ANALYSIS OF SINGULAR-PLURAL DIALOGUE OF MATHEMATICS TEACHERS

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

Introduction

This presentation reports on the continuing analysis of an empirical comparison of singular-plural usage during lessons by specially chosen mathematics teachers (whose classrooms demonstrated healthy student dialogue) with the usage seen in "typical" American mathematics lessons (Ricks, 2015). One indicator of functional mathematical learning communities is healthy student dialogue (when students talk *to each other* about mathematical ideas); for students to talk to each other about their mathematical ideas—especially in the public space of whole-class discussions—a classroom cultural climate must be carefully cultivated. I hypothesized that in classrooms with such healthy student dialogue, teacher dialogue would manifest lower singular (*me*, *I*, and *my*) usage compared to plural (*us*, *we*, and *our*) usage.

Methods and Results

The teachers demonstrating classrooms with healthy student dialogue participated in *The Mathematics Class as a Complex System* (MCCS) study, described in greater detail elsewhere (Ricks, 2007). For comparison, I chose the four American lessons with publicly available transcripts of classroom dialogue that were highlighted in the 1999 Trends in International Mathematics and Science Study (TIMSS) video study as "typical" classes (NCES, 2003). As reported earlier (Ricks, 2015), previous analysis of classroom dialogue (one lesson per MCCS teacher) demonstrated that the MCCS teachers had similar singular-plural usage with each other (average: .42), which differed significantly from the TIMSS mathematics teachers (average: 1.26). Thus, all the MCCS teachers had low singular-plural usage (using singulars less than half as much)—as hypothesized, while the "typical" American teachers generally had a high singular-plural usage (using singulars more than plurals, some higher than twice as much). Further analysis also revealed similar growth patterns of the ratio of singular-plural usage during lessons for the MCCS teachers. The comparable consistent rise of cumulative usage is a surprising regularity across the MCCS teachers, especially when compared to the irregularities of the ratios for the TIMSS teachers. This presentation focuses on this similar growth pattern over time.

Discussion and Conclusions

These additional findings suggest that an underlying dynamic may be regulating the MCCS teachers' singular-plural usage because their language growth patterns over the course of their lessons were so similar. More research is needed to understand the relationship of singular-plural usage as an indicator of potential healthy student dialogue, and what might encourage its growth.

HOW DO SECONDARY MATHEMATICS TEACHERS MANAGE (APPARENTLY) INCORRECT STUDENT RESPONSES?

Annick Rougée
University of Michigan
arougee@umich.edu

Though there are numerous teaching practices that impact student learning (e.g. facilitating whole class discussions, giving explanations, etc.), one ubiquitous practice embedded within many of these is the mathematics teaching practice of managing students' (apparently) incorrect responses. Enacting this practice skillfully necessitates being "responsive" to student thinking and ideas (Pierson, 2008) which is no small feat. Managing students' responses involves complex cognitive processes and resources utilized by mathematics teachers in-the-moment to hear, interpret (hence, the qualification that responses are *apparently* incorrect), and respond to what a student has said (Jacobs, Lamb, & Philipp, 2010). These needed cognitive resources include both specialized skills and specialized content knowledge, such as mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008), that a teacher must use while simultaneously navigating her obligations to the mathematical discipline, individual students, the class as a whole, and the institution in which she works (Herbst & Chazan, 2012). It is no wonder, given these obligations and this complexity, that this practice can be incredibly stressful and difficult to enact, even for veteran teachers.

Though several lines of research are germane to the practice of managing apparently incorrect student responses, the practice itself is neither well-understood nor described in mathematics teaching. This poster presents preliminary findings from a study that explores this practice by using records from classroom observations of four secondary mathematics teachers across four to five consecutive lessons in each of their classrooms. Pre and post lesson interviews also provided information about what teachers anticipated students might struggle with and how teachers thought about particular instructional moments when students provided an apparently incorrect response. In general, teachers struggle with managing their obligations to help students demonstrate an understanding of the mathematics and creating an environment it is safe for students to publicly make mistakes. There were noticeable patterns in how teachers responded to errors that had anticipated versus those that they had not anticipated. Information about teachers' general anxieties and beliefs about teaching and learning mathematics (Stipek, Givvin, Salmon& MacGyvers, 2001) were also explored to contextualize the classroom findings.

MEASURING ACTIVE LEARNING WITH AN OBSERVATION PROTOCOL IN COLLEGE CALCULUS CLASSROOMS

Vicki Sealey
West Virginia University
sealey@math.wvu.edu

Nicole Infante
West Virginia University
nengelke@math.wvu.edu

Alexis Morrison
West Virginia University
amorri26@mix.wvu.edu

Keywords: Instructional Activities and Practices, Classroom Discourse, Post-Secondary Education

Active learning, defined by Freeman et al. (2014) "engages students in the process of learning" and "emphasizes higher-order thinking." This type of student-centered instruction has been shown to increase learning (e.g. Prince, 2014). The purpose of our research was to determine the extent to which the Mathematics Classroom Observation Protocol for Practices (MCOP^2) (Gleason, 2015) measures active learning in classrooms. The MCOP^2 consists of 16 items scored on a scale of 0 to 3, with 8 items addressing student engagement/active learning and 8 items addressing teacher facilitation (Gleason and Cofer, 2014).

Three college calculus instructors (I1, I2, and I3) were videotaped as they taught the same topic (the Mean Value Theorem), and the MCOP^2 was used to score the lessons. I1 and I2 lectured for the entirety of the lesson with questions frequently posed to the class; in contrast, I3 lectured for about half of the lesson, using a large portion of time for students to work in groups and have a whole class discussion about what the groups found. We observed that I1 and I2 had identical active learning totals of 8/24, while I3 received an active learning sub score of 22/24. Due to the similarities between the active learning sub scores for I1 and I2, we looked for any large, noticeable differences in the class sessions. After analyzing the videos, it became clear that the types of questions asked by I1 and I2 were very different. The researchers used a condensed version of Bloom's Taxonomy (Piggott, 2011) to categorize instructors' questions. This categorization indicated that I2 asked questions that required a higher-level of student thinking.

Although the scores on the MCOP^2 did correlate with the amount of active learning in the classroom, the scores did not accurately reflect the level of difficulty of questions posed, which is an important part of active learning. While the MCOP^2 did capture the levels of questioning in one item, we believe that the differences in scores on this one item did not fully illustrate the vast differences in the quality of the lessons. In summary, we found the MCOP^2 to be a useful tool to quantitatively compare active learning in classrooms, but was not a good tool for comparing the quality of multiple lectures.

CO-TEACHING AND MATH DISCOURSE TO SUPPORT STUDENTS AND TEACHERS IN LINGUISTICALLY DIVERSE ELEMENTARY CLASSROOMS

Mary P. Truxaw   Rebecca D. Eckert
University of Connecticut   University of Connecticut
mary.truxaw@uconn.edu   rebecca.eckert@uconn.edu

There are cognitive advantages to speaking more than one language; yet, linguistic diversity can impact teaching and learning in complex ways (Moschkovich, 2005). For math, all students are expected to develop rigorous understanding of content and math practices (CCSSO & NGA Center, 2010). However, instruction for English learners (ELs) may focus on procedures and vocabulary rather than cognitively demanding activities (Moschkovich, 2005); thus, ELs may not be held to the same high expectations as other students. ELs need opportunities to participate in rich math activities and discussion that take into account their competencies and also provide necessary support. This need may require *innovative educational ideas*. Co-teaching, where both teachers assume the responsibility of planning and implementing instruction (Bacharach, Heck & Dahlberg, 2010), may provide innovation for increasing teacher confidence and flexibility in responding to student needs – thus "questioning borders" (conference theme) of traditional solutions for supporting linguistically diverse mathematics classrooms.

This ongoing, small-scale study investigates how supported, co-teaching practices may enhance engagement with math discourse in linguistically diverse elementary school classrooms. Four co-teaching teams each include one experienced teacher and one master's intern (post-student teaching). The teams participate in professional development (PD) and ongoing collaborative support related to co-teaching and math discourse. Data include: field notes and video and audio recordings (PD and math lessons), co-teaching team reflections, and classroom artifacts. Data collection and qualitative analysis (Creswell, 1998) are ongoing.

Preliminary results suggest that co-teaching models, when accompanied by focused PD and co-planning opportunities, have the potential to increase student-teacher interaction, instructional flexibility, and attention to individual needs – and, thus, may promote more meaningful mathematical discourse and, in turn, positive student learning outcomes. Further, findings suggest benefits and challenges of different co-teaching approaches (e.g., parallel teaching; station teaching; one teach, one assist; and team teaching) (Bacharach, Heck & Dahlberg, 2010) and their relationships to supporting math discourse. The poster will provide greater detail of the findings. This work is significant because it has the potential to identify best practices, strategies, and tools to support teacher education and PD with specific emphasis on the intersection of co-teaching and math discourse to support linguistically diverse classrooms.

EXAMINING WHOLE GROUP MATHEMATICAL DISCOURSE: WHAT IT MEANS TO BE STUDENT-CENTERED

Seanyelle L. Yagi
University of Hawai'i
slyagi@hawaii.edu

Keywords: Classroom Discourse, Elementary School Education

Introduction

Engaging in whole group mathematical discourse affords early elementary students the opportunity to consider and respond to mathematics in discussions, as well as engage in collaborative problem solving (Perry, McConney, Flevares, Mingle & Hamm, 2011). One aspect central to mathematical discourse involves the degree to which interactions are student-centered (Deboer, 2002), where students' thinking drives the discussion and they take agency for their learning (Hufferd-Ackles, Fuson & Sherin, 2004). What does this mean for first grade students for whom mathematics-focused discussions are a new experience? This poster presents an example of a student-centered interaction within a first grade mathematics classroom.

Methods

Utilizing a case study design, classroom observations were video-recorded twice a week for six-week intervals, during November, February, and May. Researcher field notes were taken during observations, with semi-structured teacher interviews audio-recorded once a week. Recordings were transcribed and segments of interactions coded and categorized into themes.

Findings & Discussion

Open-ended problems were regularly posed to students in a way that allowed them to make sense of the tasks and resolve any questions they might have. After working through the problem in small groups, a whole group discussion ensued in which up to four students presented their solution methods to the class. Through regularly engaging in this type of activity, the norm of explaining one's mathematical thinking was established, and afforded opportunities for the rest of the students to examine each other's thinking.

One interaction highlights the student-centered nature of mathematical discussions that might develop over time. Two first graders were provided with the opportunity, tools and facilitation to explain their solution method to the class, thereby making their mathematical thinking explicit. A classmate then asked several key questions which pushed the discussion forward, bringing forth an opportunity for the examination of a numerical pattern by the entire group. With the teacher's facilitation, students' thinking became central to the discussion. They explained, questioned each other, found relationships, and determined the direction of the discussion, all aspects that constitute what it means to engage in student-centered mathematical discourse.

Se reportan y analizan diferentes tipos de preguntas y problemas planteados por futuros profesores de educación media superior durante el proceso de reconstruir configuraciones dinámicas de una figura dada en el enunciado de un problema geométrico. ¿En qué medida el uso de un Sistema de Geometría Dinámica (SGD) ayuda a los participantes para implementar actividades de planteamiento de problemas durante todas las fases de la resolución de problemas que incluyen la construcción de modelos dinámicos, la búsqueda de distintas soluciones y la extensión de la tarea inicial? Los participantes exhibieron estrategias que involucran el arrastre, deslizadores, medición y lugares geométricos para construir configuraciones dinámicas que los llevó a formular y explorar diversos problemas.

Palabras clave: Resolución de Problemas, Tecnología, Geometría y Pensamiento Geométrico y Especial, Maestros en Formación

Introducción

En los últimos treinta años, la resolución de problemas ha sido un dominio o área de investigación en educación matemática que relaciona el quehacer de la disciplina con el aprendizaje de los estudiantes (Santos-Trigo, 2014). Un principio fundamental en la resolución de problemas es la importancia de formular preguntas relevantes como medio para de entender, representar, explorar y resolver problemas (Polya, 1965). Así, estas preguntas son el medio para explorar conceptos y para desarrollar habilidades de resolución de problemas. Misfeldt y Johansen (2015) resaltan que la actividad de formular preguntas y problemas es un aspecto crucial y no trivial de la práctica profesional de los matemáticos. También, se reconoce que el avance científico y tecnológico generalmente se origina y relaciona con del planteamiento y seguimiento de preguntas o problemas novedosos. Einstein e Infield (1938) argumentan:

> La formulación de un problema es generalmente más importante que su solución, la cual puede ser simplemente una cuestión de habilidades matemáticas o experimentales. Para generar nuevas preguntas y nuevas posibilidades, para revisar viejas preguntas desde nuevos ángulos y para lograr avance real en la ciencia se requiere de imaginación creativa. (citado en Ellerton & Clarkson, 1996, p.1010).

En este contexto, un aspecto central en los ambientes de aprendizaje es que los estudiantes tengan la oportunidad de participar en actividades de planteamiento de problemas para profundizar en conceptos matemáticos durante todo el proceso de la resolución de problemas (Cai, Hwang, Jiang & Silber, 2015). Para este fin, resulta importante investigar en qué medida el uso de distintas herramientas, en particular el uso de SGD, permite a los participantes involucrarse en actividades de planteamiento de problemas a partir de interrogantes que surgen en ambientes de resolución de problemas. En este camino, la pregunta de investigación que guió el desarrollo de este estudio es: ¿Cómo y en que medida el uso de un SGD (GeoGebra) ofrece a los participantes estrategias para formular y dar seguimiento a preguntas o problemas durante las fases de resolución de problemas que

incluyen la construcción de modelos dinámicos, búsqueda de distintas soluciones, extender las tareas iniciales y comunicar resultados?

Marco Conceptual

Planteamiento de problemas y el uso de la tecnología

El planteamiento de problemas se puede caracterizar a partir de tres actividades: (1) generación de un problema original a partir de una situación dada, (2) reformulación de un problema que se está resolviendo o (3) formulación de un problema nuevo modificando los objetivos o condiciones de un problema que ya ha sido resuelto (Rosli et al., 2015). Kılıç (2013) menciona que el planteamiento de problemas "involucra la generación de nuevos problemas y preguntas con el objetivo de explorar una situación dada así como a la reformulación de un problema durante el proceso de resolverlo" (p. 145). En esta perspectiva, el proceso de planteamiento de problemas puede ocurrir en cualquier fase de la resolución de problemas.

Actualmente se reconoce que el uso de tecnologías como GeoGebra genera oportunidades para desarrollar conocimiento matemático, pero también permite transformar escenarios de enseñanza alrededor de la resolución de problemas (Santos-Trigo, Reyes-Martínez & Aguilar-Magallón, 2015). En esta dirección, resulta necesario investigar cómo el uso de distintas herramientas digitales ofrece a los estudiantes caminos y oportunidades para representar, explorar, entender, resolver, generalizar y extender problemas. Algunos estudios reportan que las herramientas tecnológicas liberan al individuo de trabajo técnico relacionado con cálculos o gráficas y le permiten concentrarse en el análisis y el sentido de las relaciones o conceptos matemáticos (Lavy, 2015). Abramovich y Cho (2015) afirman que "El uso apropiado de herramientas tecnológicas digitales comúnmente disponibles pueden motivar y soportar actividades de planteamiento de problemas" (p. 71).

Lavy (2015) argumenta que el uso de un SGD puede jugar un papel importante en el planteamiento de problemas, pues permite de forma sencilla manipular, mover y deformar objetos geométricos, pero además facilita conjeturar y explorar relaciones matemáticas a partir de distintas representaciones. Leikin (2015) menciona que una forma de plantear problemas con ayuda de un SGD es mediante tareas de investigación; donde se formulan interrogantes y problemas a partir de la exploración de configuraciones dinámicas que surgen al resolver problemas geométricos de demostración. Una idea fundamental en el trabajo de Leikin (2015) son las tareas o actividades para favorecer o promover episodios de resolución y planteamiento de problemas. Imaoka et al. (2015) consideran algunos elementos fundamentales de este tipo de tareas donde se usa un SGD. Por un lado, las tareas deben tener características que el estudiante pueda usar para plantear problemas; por ejemplo, los problemas deben motivar múltiples representaciones o deben involucrar la medición de atributos, como áreas, perímetros o longitudes. Por otro lado, las tareas deben estar pensadas para trabajarse dentro del SGD, en otras palabras, que la solución a las tareas pueda encontrarse por medio de la formulación y exploración de conjeturas más que por la aplicación de algoritmos conocidos.

Metodología

En este estudio participaron nueve estudiantes de una Maestría en Educación Matemática a lo largo de catorce sesiones de trabajo semanal con duración de tres horas cada una. Las sesiones se desarrollaron en un laboratorio de cómputo donde cada participante tuvo acceso a una computadora. En cuanto a la forma de trabajo, se intentó crear una comunidad de aprendizaje donde los participantes tuvieran la oportunidad de enfrentarse a tareas de resolución y formulación de problemas con el apoyo de diversas herramientas digitales (GeoGebra). Esencialmente se diseñaron e implementaron tres tipos de problemas: problemas de investigación, problemas de demostración y problemas de construcción. Siguiendo las ideas de Leikin (2015), en los problemas de investigación

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

los participantes analizaron y exploraron configuraciones geométricas dinámicas prediseñadas dentro del SGD con el objetivo de formular problemas. Otro tipo de tarea fue la resolución de problemas geométricos de demostración. Por último, en los problemas de construcción el objetivo fue construir figuras o elementos geométricos básicos (rombos, tangentes, triángulos, rectángulos, cónicas, entre otros) a partir de condiciones iniciales dadas.

El trabajo durante las sesiones estuvo dividido en dos etapas. En una primera etapa los participantes trabajaron de manera individual. En la segunda etapa se generaron discusiones plenarias donde los participantes presentaban sus ideas y había una retroalimentación directa del grupo y de los coordinadores del grupo.

Resultados

En esta sección se discutirán algunos episodios que muestran cómo los participantes se involucraron en actividades de planteamiento de problemas durante el proceso de resolver un problema tradicional de geometría. En particular, el análisis se centra en cómo el uso de GeoGebra ayudó a los participantes para plantear problemas novedosos como resultado de reconstruir figuras presentes en el enunciado del problema.

Planteamiento de problemas antes de la resolución de un problema

Existe una gran variedad de problemas geométricos en los cuales la información o condiciones son presentados por medio de figuras o configuraciones geométricas. Por ejemplo, la Figura 1 es parte del enunciado de un problema donde se solicita probar cierta relación entre los objetos matemáticos involucrados. Comúnmente, cuando se resuelven problemas de forma tradicional (con papel y lápiz) el estudiante no se plantea la tarea de reconstruir las figuras que aparecen en el enunciado del problema. Cuando se trabaja el problema dentro de un SGD, resulta esencial pensar en las formas de obtener una representación dinámica que generalmente involucra el enunciado del problema. Por ejemplo, durante una de las sesiones se pidió a los participantes que trabajaran con el siguiente problema:

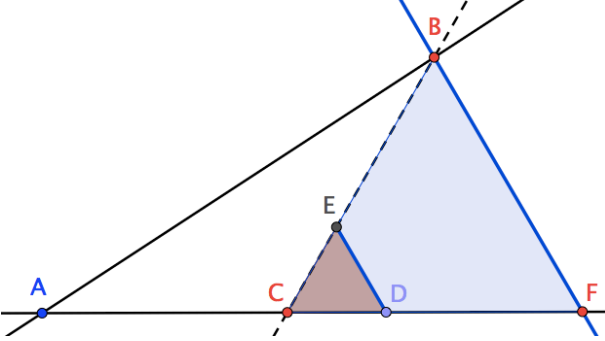
Problema 1. La Figura 1 muestra dos círculos, un ángulo y un triángulo equilátero. Demuestre que la suma de los radios de las circunferencias es igual a la altura del triángulo. (adaptado de Leikin, 2007).
Figura 1. Probar que la suma de los radios de las circunferencias es la altura del triángulo.

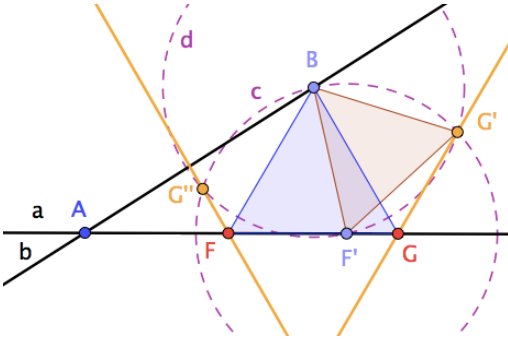
¿Cómo reconstruir una representación dinámica del problema? Los participantes observaron que la figura del problema incluía cuatro elementos (un ángulo, dos circunferencias y un triángulo) y formularon la siguiente pregunta: ¿con qué elemento comenzar? Esta pregunta los condujo a plantear problemas asociados con diferentes caminos para reconstruir la configuración geométrica. La Tabla 1 muestra algunas rutas sugeridas por los participantes y los problemas formulados. Los participantes identificaron seis formas distintas de obtener la configuración dinámica del problema (en total existen 18 formas de construirla). En algunos casos, obtener la representación del problema inicial se redujo a formular y resolver problemas similares o idénticos. Por ejemplo para la primera y tercera

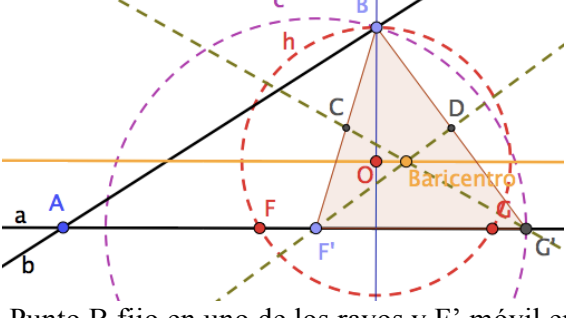
Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

opción, al final se requirió construir las circunferencias tangentes a los rayos del ángulo y al triángulo equilátero.

Tabla 1: Algunas rutas identificadas por los participantes para obtener la configuración geométrica del problema

Opción	Orden de la construcción	Problemas formulados
1	Ángulo Triángulo equilátero Circunferencias	1.1 Trazar el triángulo equilátero, a partir del ángulo formado por dos rectas. 1.2 Trazar las circunferencias tangentes, a partir del ángulo y el triángulo.
2	Circunferencias Ángulo Triángulo equilátero	1.3 Trazar el ángulo, partiendo de las dos circunferencias. 1.4 Trazar el triángulo equilátero, a partir del ángulo y las circunferencias.
3	Circunferencia Ángulo Triángulo equilátero Circunferencia	1.5 Trazar el ángulo, teniendo una circunferencia. 1.6 Construir el triángulo equilátero, teniendo el ángulo y una circunferencia. 1.7 Trazar la circunferencia tangente a los rayos del ángulo y al lado del triángulo.






Después de identificar distintos caminos para construir la configuración geométrica del problema 1 los participantes resolvieron algunos de los problemas formulados. En la siguiente sección se describen algunas soluciones obtenidas para el problema 1.1.

Planteamiento de problemas durante la resolución del problema

Durante la resolución del problema 1 se exhibieron actividades de planteamiento de problemas. Por ejemplo, los participantes formularon y exploraron diferentes formas de reconstruir la figura involucrada en el enunciado del problema. Para este fin, fueron útiles algunas heurísticas de resolución de problemas vinculadas directamente con estrategias de reformulación; por ejemplo relajar las condiciones del problema, resolver un problema similar o más simple, descomponer el problema en problemas subsidiarios, analizar casos particulares o extremos, entre otras (Cai et al., 2013).

Considerar trazos auxiliares y lugares geométricos como estrategia de resolución y planteamiento de problemas. En una sesión posterior se discutieron, de forma plenaria, distintas rutas para obtener la configuración dinámica del problema inicial. En esta discusión, se resaltaron estrategias de reformulación basadas en la heurística de relajar las condiciones del problema para simplificarlo. Por ejemplo para resolver el problema 1.1 se discutieron tres soluciones distintas. En la Tabla 2 se muestra la descripción de las construcciones, el proceso de reformulación y las estrategias de solución del problema 1.1.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Tabla 2: Procesos de reformulación y estrategias de solución del problema 1.1

Construcción	Proceso de reformulación	Estrategia de solución
1. Punto C fijo sobre un rayo del ángulo. Triángulo CDE equilátero. Punto de intersección B de la recta CE con el rayo del ángulo. Recta BF paralela a ED.	Problema: construir un triángulo equilátero CDE que tenga su base CD en un rayo del ángulo. Condición relajada: el vértice E no está en el otro rayo del ángulo.	Una vez obtenido el triángulo CDE equilátero, trazar un triángulo CFB semejante (equilátero) por medio de una recta paralela.
2. Punto B fijo en uno de los rayos y F' móvil en el otro. Triángulo BF'G' equilátero.	Problema: Construir un triángulo equilátero BF'G' que tenga sus vértices B y F' sobre los rayos del ángulo. Condición relajada: la base del triángulo equilátero no está sobre uno de los rayos del ángulo.	Visualización del lugar geométrico que genera el vértice G' del triángulo equilátero BF'G' cuando se mueve el vértice F'. Solución cuando el vértice G' está sobre el rayo del ángulo.
3. Punto B fijo en uno de los rayos y F' móvil en el otro. Triángulo isósceles BF'G' tal que BF'=F'G'. Baricentro del triángulo BF'G'. Altura de triángulo BF'G' asociada al vértice B.	Problema: construir un triángulo isósceles BF'G' que tenga un lado sobre un rayo del ángulo y un vértice sobre el otro. Condición relajada: el triángulo no es equilátero.	Visualización del lugar geométrico descrito por el baricentro del triángulo BF'G' cuando se mueve el punto F'. Solución cuando el baricentro está sobre la altura (en un triángulo equilátero baricentro, ortocentro, circuncentro e incentro coinciden; punto O).

Durante la construcción del triángulo equilátero, los participantes formularon preguntas acerca del comportamiento o propiedades de algunos objetos usados para construir dicho triángulo. Por ejemplo, en el acercamiento que involucra la construcción del baricentro del triángulo plantearon: ¿qué propiedades tiene el lugar geométrico descrito por el baricentro del triángulo? ¿es una línea

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

paralela a la base? ¿en qué proporción divide el punto O a la altura del triángulo BF'G' (asociada con el vértice B)? ¿la proporción es 2/3?

Planteamiento de problemas después de la resolución del problema

Resolver el problema 1.1 condujo a resolver el problema 1.2, es decir, trazar las circunferencias tangentes a las rectas y al triángulo equilátero. En la discusión plenaria, los participantes resolvieron el problema 1.2 por medio del trazado de las bisectrices de los ángulos externos del triángulo y la bisectriz del ángulo formado por las dos rectas (Figura 2). Finalmente, el problema inicial (Problema 1) se resolvió de diversas maneras; en las Figuras 2 y 3 se muestran dos de ellas. La primera solución involucra el Teorema de Viviani que menciona que para cualquier punto sobre un triángulo equilátero se cumple que la suma de las distancias de dicho punto a los lados del triángulo es igual a su altura. La segunda solución implica construir un rectángulo ELHI con EH=IL igual a uno de los radios, para después demostrar que el cuadrilátero FGIC (donde FG es igual al otro radio) es un paralelogramo, como se observa en la Figura 3.
Figura 2. Solución probando que FJ=JI y LE=IL para aplicar teorema de Viviani.
Figura 3. Solución probando que el cuadrilátero FGIC es un paralelogramo.

¿Qué preguntas o problemas formularon los participantes después de resolver el problema inicial? En general, los participantes se centraron en formas de generalizar y extender los métodos usados para resolver el problema como plataforma para plantear nuevos problemas. Algunos problemas planteados por los participantes fueron los siguientes:

- Problema 1.8. Teniendo dos rectas que se intersecan y dos circunferencias tangentes a ellas ¿siempre es posible construir un triángulo equilátero entre las dos circunferencias como en la Figura 1? ¿Qué relación debe existir entre la posición de las circunferencias para que sea posible construir el triángulo equilátero?
- Problema 1.9. Teniendo dos rectas que se intersecan y dos circunferencias tangentes a ellas ¿es posible construir un triángulo isósceles entre las dos circunferencias?
- Problema 1.10. ¿Si el triángulo es isósceles se cumple que la suma de los radios es igual a la altura del triángulo?

Los participantes examinaron el modelo dinámico construido para explorar el problema 1.8 y concluyeron que no siempre es posible construir un triángulo equilátero dados el ángulo y las circunferencias tangentes. Más aún, descubrieron que dados el ángulo y las circunferencias siempre es posible trazar un triángulo isósceles entre las dos circunferencias y tangente a ellas. Un vértice del triángulo es la intersección de un rayo del ángulo con la mediatriz del segmento que une los centros

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

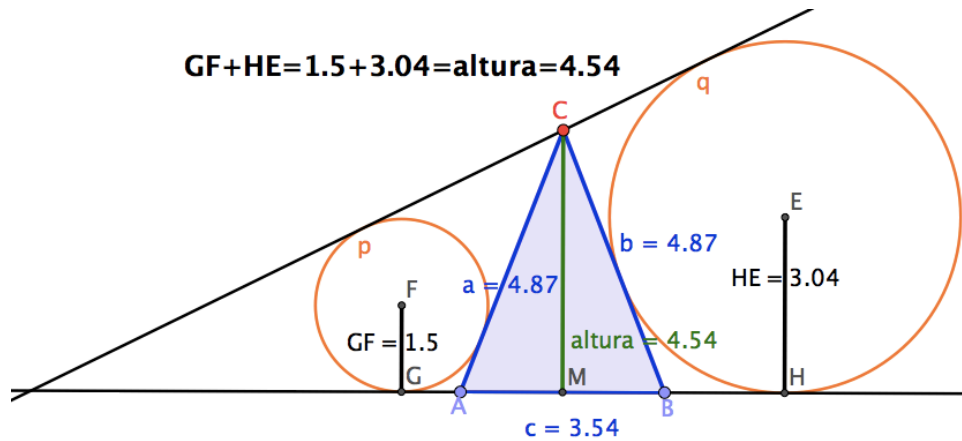
de las circunferencias. La configuración dinámica mostrada en la Figura 4 se usó para mostrar que la suma de los radios de los círculos es igual a la altura del triángulo isósceles ABC.


Figura 4. La proposición del problema 1 se cumple cuando el triángulo es isósceles**.**

Discusión de resultados

Normalmente, cuando se resuelven problemas la atención se enfoca principalmente en obtener un resultado. El uso de GeoGebra permitió a los participantes poner atención en otros aspectos de la resolución de problemas. Uno de estos aspectos fue considerar distintas maneras de representar una situación problemática lo cual motivó un episodio de planteamiento de problemas. El reflexionar sobre los posibles caminos para obtener una representación dinámica del problema 1 permitió a los participantes problematizar y conectar diversas propiedades de figuras básicas como triángulos, circunferencias y rectas tangentes. Además, los participantes identificaron un conjunto de relaciones que surgieron a partir de la exploración del modelo dinámico. Por ejemplo, encontraron que para obtener la configuración dinámica del problema inicial el ángulo definido por las dos rectas debe ser menor de 60º.

Gracias a las herramientas que ofrece el SGD para dar movimiento a objetos matemáticos, los participantes lograron implementar procesos de reformulación de problemas. En este camino, el uso de la heurística "relajar las condiciones del problema" fue fundamental. Construir trazos auxiliares y visualizar lugares geométricos fueron estrategias usadas por los participantes no solo para resolver problemas de formas novedosas, sino también como plataforma para plantear problemas. Después de visualizar lugares geométricos, una actividad recurrente de formulación de problemas, fue explorarlo y describirlo en términos de sus propiedades.

Conclusiones

¿Qué tipo de preguntas o problemas plantean futuros profesores cuando se apoyan de herramientas digitales para representar y explorar problemas matemáticos? En este estudio se documentó que futuros profesores pueden involucrarse en actividades de planteamiento de problemas durante todas las fases presentes al resolver un problema. Para este fin, el objetivo de reconstruir una figura dada (que involucra dos circunferencias, un ángulo y un triángulo equilátero) en un problema tradicional, fue el punto de partida para formular problemas relacionados con el orden para obtener dicha configuración. Después, identificaron e implementaron diferentes formas de construir objetos particulares, como un triángulo equilátero, a partir de ciertas condiciones. De forma similar, la exploración del modelo dinámico del problema inicial no solo les ayudó a formular nuevas preguntas, sino también a buscar argumentos para soportar resultados matemáticos. Al final, los participantes se enfocaron en las condiciones necesarias para construir un modelo consistente y robusto del problema; lo que los condujo a encontrar que la medida del ángulo tiene que ser menor

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

que 60º y también les permitió concluir que siempre es posible construir un triángulo isósceles en medio de los círculos tangentes. Varias estrategias de resolución de problemas les ayudaron a examinar casos particulares (relajando las condiciones iniciales) para explorar el comportamiento de objetos e identificar relaciones matemáticas. En particular, algunas permisibilidades de la herramienta (GeoGebra) como el arrastre de objetos, lugares geométricos, medición de atributos y el uso de deslizadores fueron importantes para encontrar y soportar conjeturas. Inicialmente, estas conjeturas fueron soportadas por medio de argumentos empíricos; pero después los participantes presentaron argumentos geométricos y algebraicos.

We analyze and discuss ways in which prospective high school teachers pose and pursue questions or problems during the process of reconstructing dynamic configurations of figures given in problem statements. To what extent does the systematic use of a Dynamic Geometry System (DGS) help the participants engage in problem posing activities throughout problem solving phases that include the construction of dynamic models, the search for different solutions methods and the process of extending initial statements? The participants relied on technology affordances such as dragging objects, using sliders, quantifying relations, and drawing loci to construct dynamic configurations that led them formulate and pursue different problems.

Keywords: Problem Solving, Technology, Geometry and Geometrical and Spatial Thinking, Teacher Education-Preservice

Introduction

In the last thirty years, problem solving has been a research domain in mathematics education, which relates the practicing or development of mathematics and the ways in which students learn the discipline (Santos-Trigo, 2014). A fundamental principle in a problem solving approach is that learners engage in an inquiring process as a means to understand, represent, explore, and solve mathematical tasks (Polya, 1965). Thus, questions are the vehicle for learners to explore concepts and to formulate and develop problem solving competencies. Misfeldt and Johansen (2015) pointed out that the activity of formulating problems is a crucial aspect that distinguishes the work and professional practice of mathematicians. Indeed, it is also recognized that progress and developments in scientific and technological fields involve both the formulation of questions and the process to follow up those questions. Einstein and Infield (1938) argue that:

> The formulation of a problem is often more essential than its solution, which may be merely a matter of mathematical or experimental skills. To raise new questions, new possibilities, to regard old questions from new angle, require creative imagination and marks real advance in science. (Cited in Ellerton & Clarkson, 1996, p.1010).

In this context, a central aspect in learning environments is that students have an opportunity to engage in problem posing activities in order to delve into mathematical concepts and during the entire process of solving problems. (Cai, Hwang, Jiang & Silber, 2015). To this end, it becomes important to investigate the extent to which the students' use of different digital technologies and in particular the use of a DGS provides opportunities to engage them in problem posing activities and ways to follow up related questions in problem solving environments. Thus, the research question that guides the development of the study is: How and to what extent does the systematic use of a Dynamic Geometry System (GeoGebra) provide the participants the affordances to formulate and pursue questions or problems during problem solving phases that include construction or reconstruction of dynamic models, thinking of and implementing various solution methods, extending mathematical tasks and communication of results or solutions?

Conceptual Framework

Problem posing and the use of digital technology

Learners can engage in problem posing activities in contexts and situations that involve: (1) the generation of an original problem from a given information or data (2) the reformulation of a problem such as solving a simpler or related problem as a means to delve and solve an initial problem or (3) the formulation of a new problem by modifying the objectives or conditions of a given problem (Rosli et al., 2015). Kılıç (2013) mentions that the problem posing "is defined as the creation of new problems or the reformulation of a given problem" (p. 145). In this perspective, the process of problem posing might occur during or at any stage of the solution process.

It is now recognized that the use of digital technologies such as GeoGebra provides learners an opportunity to extend ways of reasoning about problems and learning environments need to encourage students to rely and value the use of several digital technologies in their problem solving experiences (Santos-Trigo, Reyes-Martínez, & Aguilar-Magallón, 2015). In this direction, it is necessary to investigate how the use of different digital tools offers students ways and opportunities to represent, explore, understand, solve, generalize and extend problems. Some studies report that the use of technological tools releases the individual technical work that involves calculations or graphs and helps students to concentrate on the analysis and making sense of relationships or mathematical concepts (Lavy, 2015). Abramovich and Cho (2015) state that "the appropriate use of commonly available digital technology tools can motivate and support problem posing activities" (p. 71).

Lavy (2015) argues that the use of a DGS can play an important role in the problem posing, which allows a simple way to manipulate, move and deform geometric objects, but also facilitates the formulation of conjectures and the exploration of mathematical relationships from different representations.

Leikin (2015) mentions that one way to pose problems with the help of a DGS is through investigation tasks; where questions and problems are formulated from exploring dynamic configurations that arise when geometric problems are solved. A fundamental idea in the work of Leikin is to ask learners to work on tasks or activities to facilitate or promote both the formulation and solution of problems. Imaoka, Shimomura, and Kanno (2015) consider some fundamental elements of these tasks where a DGS is used. Tasks should have features that students can use to pose problems; for example, problems should encourage multiple representations or should involve the measurement of attributes, such as areas, perimeters and lengths. Also, tasks must be designed to be worked within the DGS, in other words, the solution to the tasks should be found through the development and exploration of conjectures rather than the application of known algorithms.

Methodology

In this study, nine students participated in a Problem Solving course as part of a Master program in Mathematics Education over fourteen weekly working sessions lasting three hours each. The sessions were developed in a computer lab where each participant had access to a computer. As for the way they work, we tried to create a learning community where participants had the opportunity to face posing and solving problems with the support of digital tools (GeoGebra). Essentially three types of task were designed and implemented: investigation problems, demonstration problems and construction problems. Following the ideas of Leikin (2015), in investigation problems, the participants discussed and explored dynamic geometric configurations through the use of GeoGebra with the aim of formulating problems. Another type of task was to solve geometric demonstration problems. Finally, in the construction problems the objective was to draw or represent simple mathematical objects (rhombus, tangents, triangles, rectangles, conics, etc.) dynamically in order to find, formulate, and support mathematical relations.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

The dynamic of the session involved two main activities: In the first stage the participants worked individually and later discussed his/her ideas with another participant (pair work). In the second stage there was collective or plenary discussion where they presented their ideas and received direct feedback from the group and the group course coordinators.

Results

In this section, we present and discuss some episodes that show how the participants engaged in problem posing activities during the process of solving a traditional geometry problem. In particular, we focus on analyzing how the use of GeoGebra opened up novel ways for the participants to formulate problems as a result of reconstructing figures associated with problem statements.

Problem posing before solving a problem

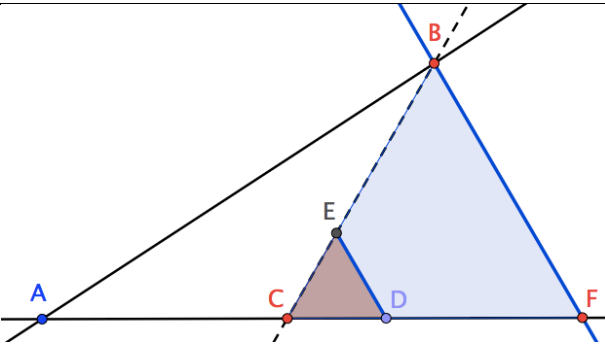
There is a variety of geometric problems for which the information or conditions are given through figures or geometric configurations. For instance, Figure 1 is part of a statement in which learners are asked to prove a certain relation of involved objects. Usually, when problems are solved in a traditional way (with paper and pencil) students do not ask themselves how to reconstruct the figures shown in the problem statement. However, with the use of GeoGebra it is natural to ask about ways to reconstruct the figure(s) involved in problem solving statements. For example, during one of the sessions, the participants were asked to work on the following task:

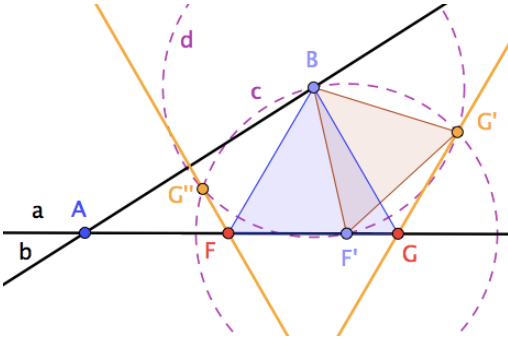
Problem 1. The Figure 1 shows two circumferences, an angle and an equilateral triangle. Prove that the sum of the circles' radii is equal to the height of the triangle (adapted from Leikin, 2007).
Figure 1. Prove that the sum of the circles radius is equal to the height of the triangle.

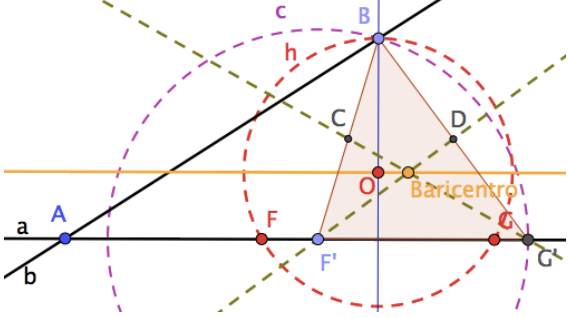
How to draw a dynamic representation of the problem? Participants noted that the figure of the problem included four elements (an angle, two circles and a triangle) and formulated the following question: with which elements do we begin? This question led the participants to select and pursue different ways to reconstruct the geometry configuration. Table 1 shows some approaches suggested by the participants and the problems they formulated to construct the figure. Participants identified six different ways to get the dynamic configuration of the problem (in total there are 18 ways to get it). In some cases, representing the initial problem consisted of formulating and solving similar or identical problems. For example, for the first and third option, in the end it was required to construct the circumferences that are tangent to the ray and to the equilateral triangle.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Approaches identified by the participants to draw the geometric configuration of the problem

Option	Order of the Construction	Formulated problems
1	Angle Equilateral triangle Circle	1.1 Draw an angle formed by two straight lines and construct the equilateral triangle. 1.2 Draw tangent circles to an angle and the triangle.
2	Angle, tangent circles Equilateral triangle	1.3 Get the angle. Draw two tangent circles to the angle. 1.4 Construct the equilateral triangle tangent to the angle and the circles.
3	Circle, Angle Equilateral triangle Circle	1.5 Draw a circle and construct the angle whit two tangent lines. 1.6 Construct the equilateral triangle, having the circle and the angle. 1.7 Construct tangent circle to the sides of the angle and the side of the triangle.






After identifying various ways to construct the geometrical configuration of the problem 1 the participants solved some of the formulated problems. The following section provides some solutions obtained for the problem 1.1.

Problem posing during the resolution of the problem

Problem posing activities were shown during the process of solving problem 1. For instance, the participants formulated and explored different ways to draw the figure in the problem. To this end, some problem solving heuristics helped them pursue some ways to draw a dynamic model of the figure. These heuristic involve: relaxing the task conditions of the problem, solving a similar or simpler problem, decomposing the problem in simpler problems, analyzing particular or extreme cases, etc. (Cai et al., 2013).

Considering auxiliary objects and geometric loci as a strategy for posing and solving problems. In a later session the participants discussed as a whole group ways to draw a dynamic model of figure 1. The heuristic that involves relaxing the initial conditions to simplify the problem was implemented. Thus, the participants showed three different routes to construct an equilateral triangle (problem 1.1). Table 2 shows the main ideas associated with the constructions, the process of reformulation, and solution strategies.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 2: Reformulation process and solution strategies of problem 1.1

Construction	Reformulation process	Solution strategy
1. Fix point C on a ray of the angle and draw an equilateral triangle CDE. Identify the intersection point B of line EC and ray AB (side of angle) and draw line BF parallel to ED.	Problem: Draw an equilateral triangle CDE having its base CD on a ray of the angle. Relaxed condition: the vertex E does not belong to the other ray of the angle.	Once the equilateral triangle CDE is obtained, draw a similar triangle CFB (equilateral) through a parallel line.
2. Let point B be a fixed point on one of the rays of the angle and F a mobile point on the other ray. BF'G' equilateral triangle.	Problem: Draw an equilateral triangle BF'G' whose vertices B and F' are on the rays of the angle respectively. Relaxed condition: the base of the equilateral triangle is not necessary on the ray of the angle.	Draw the locus generated by the vertex G' of the equilateral triangle BF'G' when the point F' is moved along one ray of the angle. The solution is achieved when vertex G' is on the ray of the angle.
3. Let point B be a fixed point on one of the rays and F' a mobile point on the other ray. Draw an isosceles triangle BF'G' such that BF' = F'G'; centroid of triangle BF'G'. Draw the height of triangle BF'G' that passes through vertex B.	Problem: draw an isosceles triangle BF'G' having a side on one ray of the angle and a vertex on the other side. Relaxed condition: the triangle is not equilateral.	Draw the locus generated by the centroid of the isosceles triangle BF'G' when the point F' moves along the side of the angle. Solution is achieved when the centroid is on the height (in an equilateral triangle centroid, orthocenter, circumcenter and incenter all coincide; point O).

During the construction of an equilateral triangle, the participants formulated questions about properties or behaviors of objects that appeared or were used to draw the triangle. For example, in the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

approach that involved the construction of the triangle centroid, they posed: What are the properties of the locus described by the centroid of the triangle? Is it a line parallel to the base? In which proportion does point O divide the height of the triangle BF'G' (associated with the vertex B)? Is it a ratio of 2/3?

Problem posing after the resolution of a problem

Solving problem 1.1 led the participant to solve problem 1.2, i.e. they traced the tangent circles to the angle and equilateral triangle. In the whole group discussion, participants solved the problem 1.2 by drawing the bisectors of the exterior angles of the triangle and bisecting the angle formed by the two rays of the angle (Figure 2). Finally, the initial problem (Problem 1) was solved in various ways; Figures 2 and 3 show two of the ways. The first solution involves Viviani's Theorem which states that for any interior point on an equilateral triangle it is true that the sum of the distances from that point to the sides of the triangle is equal to its height. The second solution involves building a rectangle EHLI (EH = IL equal to one of the radii) to demonstrate that the quadrilateral FGIC (where FG is equal to the other radius) is a parallelogram, as shown in Figure 3.
Figure 2. Solution proving FJ = JI and LE = IL to apply Viviani's theorem.
Figure 3. Solution proving that the quadrilateral FGIC is a parallelogram.

What questions or problems did the participants formulate after solving the initial task? In general, the participants focused on ways to generalize and extend the methods they used to solve the task as a means to propose new questions. Some examples of problem that the participants formulated included:

- Problem 1.8: Given two intersecting lines and two circles that are tangent to them is it always possible to construct an equilateral triangle between the two circumferences as shown in Figure 1? What relationship should exist between the positions of the circumferences to make it possible to construct the equilateral triangle?
- Problem 1.9: Given two intersecting lines and two circles that are tangent to them is it possible to construct an isosceles triangle between the two circles?
- Problem 1.10: If the given triangle is isosceles, instead of equilateral, does it hold that the sum of the radius is equal to the height of the triangle?

The participants examined the dynamic model that they had constructed of the task (problem 1.8) and concluded that it was not always possible to draw and equilateral triangle from a given angle and tangent circles. Indeed, they found that given an angle and the tangent circles it is always possible to draw an isosceles triangle between the circles that is tangent to them. A vertex of this triangle is the intersection of the perpendicular bisector of the segment that joins the centers of the circle and one ray of the angle. Figure 4 was used to show that the sum of the radii of the tangent circles is equal to the height of the isosceles triangle ABC.

Figure 4. The sum of the radii of the tangent circles is equal to the height of the isosceles triangle.

Discussion of Results

In general, when learners are asked to solve problems they mainly focus on getting a solution to the problem. The use of GeoGebra allowed participants to pay attention to other aspects of problem solving. One of these aspects was to consider different ways to represent the given situation, which led them to formulate and pursue new problems. Focusing on possible ways to construct a dynamic representation of the problem 1 enabled the participants to problematize and connect various properties, concepts and results associated with triangles, circles and tangents. In addition, the participants identified a set of relations that emerged during the dynamic exploration of the model. For instance, they found that in order to construct the model of the problem, the angle defined by the two lines must be less than 60 degrees.

The affordances provided by the DGS allowed the participants to move objects within the model and to constantly pose questions about the objects' behaviors. "Relaxing the initial conditions of the problem" became an important heuristic. Similarly, the participants used strategies such as introducing auxiliary objects and visualizing geometric loci not only to solve problems in new ways, but also to pose new problems. After visualizing geometric loci, a recurrent activity in the formulation of problems, exploring and describing in terms of its properties also happened.

Conclusions

What types of questions or problems do prospective high teachers pose when they rely on digital technology affordances to represent and explore mathematical problems? In this study, we document that prospective teachers can engage in problem solving activities throughout all problem solving stages. To this end, the goal of reconstructing a given figure (that involved an angle, two tangent circles and an equilateral triangle) in a traditional problem became a point of departure to formulate problems related to the order to draw the elements involved in the figure. Later, focusing on ways to draw a particular object, an equilateral triangle, led them to identify and implement several ways to achieve this task. Similarly, the exploration of the dynamic model of the task not only helped them formulate new questions; but also to look for arguments to support mathematical results. At the end, the participants asked about conditions to construct a consistent model of the task and this led them to find out that the measure of the angle must be less than 60 degrees and also that it was always possible to draw an isosceles triangle between the tangent circles. In addition, several problem solving strategies helped them to examine particular cases (relaxing initial conditions) to explore objects' behaviors and to identify mathematical relations. In particular, GeoGebra software affordances that include dragging objects, finding loci, quantifying attributes and using sliders

became important to find and support conjectures. These conjectures were initially supported through empirical arguments; but later the participants gave geometric and algebraic arguments.

This paper explores the use of animations as an approximation of practice to provide a transformational technology experience for elementary mathematics preservice teachers. Preservice teachers in mathematics methods courses at six universities (n=126) engaged in a practice of decomposing and approximating components of a fraction lesson. Data analysis focused on the extent to which preservice teachers were specific or general with respect to mathematics in written and animated accounts of noticing. Findings illuminate preservice teachers' degrees of specificity, with most preservice teachers being more specific about mathematics in their animations, showing promise for animation as a tool for communicating what is noticed. Further, preservice teachers perceived the use of animations a transformational experience, meaning the technological medium provided learning and access beyond what could have been accomplished without the technological support.

Keywords: Teacher Education-Preservice, Technology, Instructional Activities and Practices

As technology changes, new advances permeate teacher education programs and traditional methods of teacher preparation. These recent developments have "made feasible the rich presentation of classroom processes in a way that can capture much of the complexity inherent in education" (Miller & Zhou, 2007, p. 332). For example, showing video of classroom scenarios provides an opportunity for preservice teachers (PSTs) to view a setting they otherwise may not have observed. These technologies afford PSTs growth in learning from the technology and in learning how to use the technology. As teacher educators consider how they will teach their methods courses, they must recognize the role of technology in the process and maintain cognizance about the affordances and constraints of such innovations. The purpose of our study was to analyze the role technology played to support the specificity of PST noticing. We analyzed PST noticing to gain an understanding of affordances and constraints for the incorporation of technology within a mathematics methods course and answered the following questions: (1) How does the technological medium of animation as an approximation of practice enable specific communication of PST noticing?, and (2) Based on these findings, does the animation technology replace, amplify, transform or hinder written processes? We use the term *methods courses* to refer to university or college courses that prepare future teachers on the pedagogical approaches for teaching a specific content area. In this paper, we specifically focus on elementary mathematics methods courses, meaning those courses designed to prepare future elementary teachers with research-based methods for teaching mathematics.

Theoretical Framework

As teacher educators prepare courses and consider the incorporation of technology, it is important they are aware of the function of technology in their courses. Cognizance of the intent of technology integration is integral for positive outcomes for PSTs (Amador, Kimmons, Miller, Desjardins, & Hall, 2015; Hughes, Thomas, & Scharber, 2006). Teacher educators should consider how technology infused into the course functions, meaning the extent to which it is replacing (R),

amplifying (A), or transforming (T) current methodological practices (Hughes et al., 2006). If a technology takes the place of a process currently performed without technology, it is considered replacement (R). When a technology adds to a current practice in a methods course, amplification (A) occurs. Finally, when a technology provides opportunities that could otherwise not be accomplished without the given technology, transformation (T) takes place. Coupled with this framework of replace, amplify, and transform (RAT), some researchers have proposed hindrance (H) as a fourth technology function, claiming that not all technology incorporation is positive (Amador et al., 2015). Consequently, we frame our work theoretically with the Hughes et al. (2006) RAT (replace, amplify, transform) model with the addition of H (hindrance) as a lens for understanding the role of technology in supporting PSTs' development of research-based practices.

Related Literature

A variety of techniques, ranging from traditional drawings to GIF environments, can be used to produce an animation that depicts the phenomenon of movement. For this research, animation refers to the use of a digital medium in which a sprite (Amador & Soule, 2015) is manipulated and speaks audible utterances and the sequence of interactions is playable. Animation can be used to generate fictional interactions, such as classroom episodes, or can be produced by the teacher educator and provide straightforward depictions of a concept or practice, which can be productive when helping novices learn (Chazan & Herbst, 2012). For example, Chen (2012) had PSTs create comic-based lesson depictions to describe the nature of teaching. Similarly, Herbst, Chazan, Chen, Chieu, and Weiss (2011) argued for the use of Lesson*Sketch*, a comic-based representation, as a way to support PSTs in making decisions about teaching. As Hoban and Nielsen (2013) indicated, "animations could provide a motivation for engaging with content if learners became the designers and creators rather than consumers of information as in expert-generated animations" (p.121). Although our focus was not to explore PST motivation and engagement, we were interested in exploring how the use of PST-generated animations could provide a window into PST noticing to support communication about what they notice.

Professional noticing is fundamental to the work of teaching (Sherin, Jacobs & Philipp, 2011), and many instances simultaneously demand teachers' attention and impact teachers' decisions (Star, Lynch, & Perova, 2011). Research indicates that differences exist between novice and expert teachers' noticing skills, where veterans are more adept at interpreting a situation and novices tend to be descriptive and miss key elements (Huang & Li, 2012). Research also indicates that it is possible to improve PST noticing with support (Schack et al. 2013). As a result of studying the development of noticing among PSTs, Star et al. (2011) argued that teacher education programs should explicitly teach PSTs to notice. We were interested in studying what the use of PST-generated animations could enable in regards to their noticing, so that we as teacher educators could better support PST development of this complex skill.

Within practice-based teacher education, the primary goal of a methods course is to develop PSTs' professional practices in a specified content area, meaning the focus is on PSTs learning to do the work of teaching (Grossman, Hammerness, & McDonald, 2009). Grossman and colleagues (2009) developed a framework for pedagogies of professional practice to conceptualize processes that support teachers' development of professional skills. This framework includes three elements: representations, decompositions, and approximations of practice. Approximations of practice are opportunities for PSTs to enact one or some practices of teaching themselves with scaffolding. Turning again to technology, various technological mediums have been used as a way to approximate practices with the aim of enhancing PSTs' development of professional practices. One example of this is the use of simulations, including SimSchool, which is an on-line teaching application (Gibson, 2007) as well as the TeachLive program (Dieker, Rodríguez, Lignugaris, Hynes, & Hughes, 2014). These technological features, including animation, provide an advantageous way for PSTs to engage

in an approximation of practice and simultaneously provide us, as teacher educators, insight into their noticing.

Method

PSTs (n=126) from mathematics methods courses at six universities in the United States participated in a task involving the use of animation. Data for this study come from a larger study, and were analyzed to measure PST noticing to further understand the specificity of noticing that existed across the different mediums employed, namely written records and animations. To design and implement the task, we built on previous literature of professional noticing in the context of methods courses (e.g., Star et al., 2011) by using video, and added the use of PST-generated animations. The project design involved three phases.

Phase One: Task Design

In Phase One, we created a task to provide insight into PSTs' noticing that could be administered in each of the six methods courses. We showed the PSTs a video clip from a mathematics classroom that featured a student-centered classroom and included segments of elementary students sharing their mathematical thinking. We used the publicly available video, *Cookies to Share*, (http://www.learner.org/resources/series32.html). The PSTs were required to watch the clip (beginning to 13:45) in class, identify a pivotal moment of student(s)' mathematical thinking specific to mathematical learning or teaching, and then record this moment in writing. After writing about what they noticed, preservice teaches created their own scenes of the most pivotal moment they noticed using the website, goanimate.com. Goanimate is a cloud-based platform for generating and disseminating animated videos. Figure 1 is a screenshot of an animation. The intent of this design was to provide opportunities for PSTs to communicate what they noticed from the video through written and animated mediums.

Figure 1. Goanimate screenshot example.

Phase Two: Task Implementation

For Phase Two, the task was administered in one section of an elementary mathematics methods course at each of six different universities during the fall 2013 semester. The exact timing of project implementation within the semester schedule was left to the discretion of the individual methods course instructors. The methods instructor of the respective methods course administered the project him or herself. The data set included all of the PSTs' written responses, animations, and transcriptions of the animations: 126 written documents and 106 animated videos in all. It should be noted that due to limited access to technology PSTs in one teacher educator's class did not animate the written medium, thus accounting for the difference between the written and animation data.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Phase Three: Data Analysis

In Phase Three data were analyzed to measure PST noticing and further understand the specificity of noticing that existed across the different sections of the elementary mathematics courses and the different mediums employed. First, we analyzed each written account and animation with a focus of whom and what PSTs noticed, using the coding framework in Figure 2, adapted from (DeAraujo et al., 2015). Each data item was coded as one of the following: Teacher General Noticing, Teacher Specific Noticing, Student General Noticing, or Student Specific Noticing.

WHO	Teacher		Student	
	Attend to the Teacher		Attend to Whole Class Attend to a Group of Students or Attend to a Student	
WHAT	**GENERAL** Focus on General Teaching Strategies, Pedagogy, Content of a Lesson, Context of a Problem	**SPECIFIC** Focus on a connection between the teacher and another person(s) or aspect (e.g. pedagogical strategies interactions	**GENERAL** Focus on general actions, aspects, ideas, topics, lesson structure or contextual features (e.g. physical environment, home environment, dispositions, etc.)	**SPECIFIC** Focus on a connection between a student and another person(s) or aspect (e.g. his/her mathematical thinking, his/her interactions with others, or specific teaching strategies)

Figure 2. Framework for Level One coding, general or specific.

Following the Level One coding, we were interested in knowing more about the content of the data items coded as specific to understand what the PSTs were identifying as pivotal. We coded these data using a Level Two Coding Framework that included the following codes: 1) Addition, 2) Slope, 3) Fair Sharing, 4) Justification, 5) Procedural Explanation, 6) Written Notation, 7) Clarification, and 8) Meaning of Equal. All written and animated data deemed as *specific* in Level One coding were then coded again based on these Level Two themes.

To analyze data, we built on the aforementioned data analysis with a focus on the specificity of PSTs as they noticed. We took all codes that were general or specific (Level One coding) and the codes of content (Level Two coding) and analyzed the data by examining changes from the written to animated mediums. We analyzed for one of the following four scenarios: General in Writing to General in Animation, General in Writing to Specific in Animation, Specific in Writing to Specific in Animation, or Specific in Writing to General in Animation. We then analyzed for the extent to which the change occurred, meaning the quantity of specific and general comments, such as changing from one specific focus in the written account to two specific foci in the animation (see Table 1). Following this analysis, four of the researchers discussed major themes across the data set. This information resulted in discussion about: (a) the type of change that occurred (i.e. specific to general), and (b) the content of the change each ultimately informing the role animation played in replacing, adding, transforming or hindering PST noticing.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Codes for Level of Specificity in Communication

Code Number	Change Description	Animation Content Compared with Written Content. Animation has…
Code 1	Specific to Specific	Same Content
Code 2	General to General	Same Content
Code 3	Specific to Specific	Same Content with Additional Specificity
Code 4	Specific to Specific	Specific Content is Different
Code 5	General to Specific	One Specific Focus
Code 6	General to Specific	More than One Specific Focus
Code 7	General to General	Different General Focus
Code 8	Specific to Specific	Different Specific Codes and Written Account had more than one Specific Focus
Code 9	Specific to General	General Stemming from one Specific Focus in Animation
Code 10	General to Specific	Specific stemming from more than one General Code
Code 11	General to Specific	More than one General Code shifted to more than one specific code

Findings

Based on analysis of the written versus animated accounts of PST noticing, four main categories of data were present when comparing PSTs' levels of specificity: general to general, general to specific, specific to specific, and specific to general. We describe the change with respect to specificity from the written account to the animated account, both intended to capture the salient moment of PST noticing. Figure 3 shows the distribution of the categories of change for the PSTs.

N = 106

5	53	46	2
General → General	General → Specific	Specific → Specific	Specific → General
Figure 3. Distribution of change from written to animated noticing based on degree of specificity.

Chi-Square for type of change was 80.94 (df=3, $p < .001$). Therefore, changes from the written to animated noticings towards general occurred less than expected by chance, and moves toward specific occurred more than expected by chance. The two main categories that occurred more than expected by chance and represented the greatest number of PSTs were general to specific (n=53) and specific to specific (n=46). Consequently, we focus our results on these two categories because they represent the greatest number of PSTs and are statistically distinguished from the other two categories.

Following analysis of the overall categories, we analyzed additional details about the changes that were occurring across mediums to further recognize how PSTs were expressing their noticing both through the written and animated mediums. For example, Code 10 states, "Two general to one specific" this indicates that in the written record of noticing, the data from the PST in this category had two general topics that were present and when the PST animated, the animation had one specific topic included (see Table 1). Similarly, as another example, in data coded with Code 4, the PSTs' written data were each coded with one specific code and when they animated, they focused on a different specific code.

After recognizing the various paths taken by the PSTs, we sought understanding for the changes that occurred from the written to animated mediums that would provide insight to mathematics teacher educators about how PSTs' thinking was communicated differently across the two mediums.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

The most common scenarios for PSTs who transitioned from written general accounts to specifics in their animations were to transition from one general aspect in the written noticing to one specific focus in the animated noticing (code 5, n=29) or to transition from one general aspect to more than one specific focus when animating (code 6, n=20). Analysis of those who were specific in their written accounts and maintained specificity in their animations showed that it was common for PSTs to write about one specific topic and then animate that same aspect (code 1, n=18). Additionally, many PSTs began with one specific focus and then animated that topic along with at least one more specific topic (code 3, n=11). There were also PSTs who wrote about one specific topic and then animated a different specific topic (code 4, n=16). These five cases were further distinguished in the data set because they represented the majority of the PSTs and posed interesting situations about how the PSTs were maintaining or adjusting their noticing with the use of different mediums.

General to Specific Noticing Across Mediums

The PSTs who had general descriptions of what was noticed in their written analysis and then included a specific connection between the teacher or student and another person or aspect in the animation accounted for 49 of the 106 cases, being the most common change noted across the data set. Within these cases, 29 PSTs shifted their noticing to one specific aspect while 20 focused on two or more aspects in their animation.

One general to one specific. There were 29 PSTs who focused on one general aspect in their written account and one specific aspect in their animation. As the shift from general to specific occurred, two main features were identified. First, most PSTs introduced additional people into the animation who were not mentioned in the written account of noticing. For example, one PST focused on students when describing her pivotal moment in writing, "When the student expressed that everyone (all 8 people) will have the same amount of cookies and none left over." When the same PST animated the pivotal moment (see animation at https://youtu.be/ZUGf1x8FOkQ), she included the teacher and had the teacher prompt a student (named Grinch) to explain an equal sharing problem and justify his thinking. As seen in this example, a shift from a general account in the written medium typically involved the addition of other people in the animated medium. Second, as the PSTs shifted from a general focus in their written accounts to specific connections in their animations they increased the frequency comments related to mathematics. In the animations, the PSTs most notably included fair sharing, the explanation of a method, or the meaning of equal or equal parts.

One general to more than one specific. There were 20 PSTs who focused on multiple aspects within their animations. Nineteen of the 20 PSTs focused on the use of justification or explanation as one of their paired aspects which was often not noted in the written noticing across these cases. For example, one student wrote, "I chose the moment when the teacher asked the students if ½ a cookie would work." In the animation of this moment, the PST connected this action to the notion of student explanation or justification. The second theme among these 20 PSTs was the specific use of justification or explanation to support student mathematical understanding of fair share within the animated video. This occurred in 80% of the cases. The final theme across these cases was the use of *anchor* questions within animations to support the PST noticing. A majority of the students had the teacher asking questions such as, "How do you know you are right? What did you come up with? What did you guys do?" These questions served as an entry point and focus of conversation within the animated video, but were rarely mentioned in the written reflection.

Analysis across all 49 cases of PSTs who wrote about general aspects and animated specific aspects indicates: (a) an increased quantity of people present, (b) an increased mathematical focus, especially with fair sharing, (c) the inclusion of explanation and justification, and (d) the inclusion of anchor questions embedded in dialogue in their animations. These findings indicate that when the PSTs animated their noticings, they were more specific and included elements of effective mathematics teaching and learning that were not present in their written accounts.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Discussion and Implications

We argue that the practice of implementing the animation platform as a mechanism for PSTs to communicate their noticing was transformative (Hughes et al., 2006) because the medium afforded opportunities for PSTs to convey their thoughts about classroom interactions in a way that was not afforded through the written medium alone. We support this claim with the increased specificity that was apparent in the animations as compared to the written records. Further, we consider this practice of animating, as a transformational experience, to serve as an approximation of practice for teaching; the transformational features of the animation enabled PSTs to engage in approximating actual teaching practice (Grossman et al., 2009).

According to Grossman et al. (2009) approximations of practice engage participants in practices that are proximal to the practices of a profession, meaning closely related to teaching in this case. As previously mentioned, current research has examined approximations of practice in multiple forms, including through technological mediums and other avenues (e.g. Herbst et al., 2014). In fact, Herbst et al. (2014) focused on media rich, web-authoring tools for PSTs to create scenarios as an approximation of practice. We argue that our use of animation provides similar opportunities for approximating teaching as does their platform, *LessonSketch*. The ability to manipulate audio and visual components of figures (i.e. student(s) and teacher) in a scene in the present study further increases the opportunities for proximal practice through transformational means. More specifically, when considered in combination with the literature on professional noticing, this medium afforded opportunities for PSTs to approximate their practice as they communicated what they professionally noticed.

Further, in the present study, animation was used in the context of a mathematics methods course. We recognize the affordances of this medium for providing PSTs with opportunities to communicate their noticing about a mathematics scenario. However, future research should examine how the platform could be used in other disciplines and contexts to provide proximal practices that closely mirror actual teaching (Grossman et al., 2009). These opportunities are essential for teacher development because they provide opportunities for deliberate practice, allow for elaborations of practice, and highlight PST considerations about the profession—all key components for learning to teach.

THE USE OF STUDENT-CREATED DYNAMIC MODELS TO EXPLORE CALCULUS CONCEPTS

Ryan Gertenbach
University of Texas, Austin
gertenrawk@gmail.com

Beth Bos
Texas State University
bb33@txstate.edu

Multiple representations, multiple modalities, and technology can be helpful in the understanding of mathematical concepts when used in an appropriate manner (Shah & Freedman, 2003; Goldman, 2003), but this alone does not account for the student benefits of creating and using dynamic models over teacher generated graphs to construct connections between representations. By uncovering the dynamic nature of mathematics, calculus becomes more transparent as relationships and patterns emerge. The struggle to understand becomes worthwhile and rewarding for students as they create and observe the action of a dynamic mathematical object. This study shows an improvement in attitude, and academic achievement when students develop dynamic mathematical object to understand calculus and poses new questions to explore.

Keywords: Technology, Curriculum, High School Education, Learning Theory

Introduction

Mathematics students across all ages and subtopics are encouraged to explore multiple representations of mathematical relationships (e.g., graphical, symbolic, tabular) using a variety of appropriate tools (National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010; National Council of Teachers of Mathematics [NCTM], 2000). The use of tools ranging from pencil, paper, and rulers to calculators, computer algebra systems, and dynamic geometry software are encouraged to aid in the solution and exploration of mathematical problems and concepts. Since the invention of the computer in the mid-twentieth century, computers have decreased considerably in size, increased tremendously in processing power, and have become inexpensive enough to permeate private and public sectors, including education. The increasing availability of technology in education has led to digital textbooks, advanced handheld calculators, and one-to-one technology initiatives. New technologies such as these lead to new questions and studies regarding the efficacy of technology in the classroom, and the results have varied greatly (Bebell & Kay, 2010; Donovan, Hartley, & Strudler, 2007; Maninger & Holden, 2009). The opportunity to explore the affordances of effective practices is expanding as the technologies evolve, and more studies must be done in order to identify these affordances to help maximize learning in a mathematics classroom.

Although computers grant access to the Internet, powerful dynamic software, and the ability to collaborate in new ways, it is necessary that teachers thoroughly explore the multitude of options and determine what methods are effective and beneficial to teaching and learning. Studies of effectiveness should parallel the teachers' and students' explorations to confirm whether particular methods are beneficial, or possibly detrimental, to learning objectives and also strive to identify the particular affordances of the experience. This process will refine educators' understanding of the usefulness of technology and may help to evolve current methods of instruction by identifying the affordances of useful procedures. In this paper, these matters of efficacy and affordances will be explored by examining the use of software to create dynamic representations of functions, referred to as dynamic models, in a secondary calculus classroom. Specifically, this paper will address the question: does student creation of, and interaction with, dynamic models using Wolfram *Mathematica* increase performance on calculus assessments composed of a variety of subtopics (i.e., derivatives, tangent lines, relative extrema)? And, does this experience have an effect on student

attitudes toward mathematics? First, the Literature Review section will provide context for the various tools that were utilized during the experiment. Then, the Design and Methods section will describe the quasi-experimental design and provide details about the intervention that took place during the experiment. Finally, sections will explore certain affordances of the learning activity and make suggestions for further clarifying research.

Literature Review

Dynamic mathematic learning environments allow students and teachers to explore and uncover relationships by manipulating aspects of a particular concept. These dynamic learning environments can be applied in a variety of ways to a diverse assortment of topics. Students can use dynamic geometry software (e.g., Geometer's Sketchpad, GeoGebra) to construct geometric figures and explore properties of the figures by clicking and dragging components to investigate patterns, make conjectures, and verify relationships. Bu and Haciomeroglu (2010) explore the specific use of sliders (see figure 1) in dynamic learning environments. A slider acts as a single mathematical object that has two representations. Algebraically, a slider acts as a variable within a defined interval that can be conceptualized as a constant in certain settings. "Graphically, a slider appears as a segment which allows the user to adjust the value of the corresponding variable through dragging" (Bu & Haciomeroglu, 2010, p. 214). The presentation of both graphical and algebraic representations gives learners the ability to make abstractions more visible and the opportunity to make connections between representations (Martinovic & Karadag, 2012). When sliders are used to represent a constant or a constant variable that acts as a parameter of a function, learners can explore multiple cases of a function without having to change the function definition (Bu & Haciomeroglu, 2010). By comparison, graphing multiple of cases of a function using pencil and paper, or even a traditional graphing calculator (e.g., the TI-84+), would invariably take more time. Among the various studies that examine the benefits of dynamic and interactive mathematics environments, there still exists a need to explore the importance of having learners generate dynamic representations as opposed to having them generated for them (Goldman & Petrosino, 1999; Schwartz & Bransford, 1998).

Design and Methods

During the course of a two-year period, assessments were collected from two introductory level calculus classes consisting of high school seniors at a midsized, rural high school in Texas. As seniors, students in this course had taken an advanced algebra course and a precalculus course prior to entering the introductory level calculus course. At the beginning of the experiment, the teacher had about four years of teaching experience and had taught the course multiple times before. During the 2013-2014 school year, the course content was taught to a class of 29 high school seniors in a traditional manner. The first semester of the course was designed to review algebra concepts while the second semester focused on connecting precalculus concepts to topics of differential calculus. Multiple representations were explored using pencil and paper. Graphing calculators (e.g., TI-84+) were used on occasion to verify relationships and check the reasonableness of solutions. The teacher often used graphical representations during instruction. Although graphical representations were an emphasis of the course, symbolic manipulation and interpretation were largely the primary foci, and the graphs that were explored were not dynamic. During the 2014-2015 school year, the same teacher taught course content to 25 high school seniors. Periodically throughout the second half of the year, the teacher guided students to create dynamic models that utilized sliders using Wolfram *Mathematica,* after which the teacher would formatively assess the students' understandings of the concept under investigation through the lens of the dynamic applet. All other instruction, assessments, and assignments were unchanged.

An Overview of the Tasks

The students were first introduced to *Mathematica* as a replacement of the graphing calculator in order to gain familiarity with the software. By making use of *Mathematica's* freeform input, which essentially allows the user to input commands using English phrases and basic math notations, students could easily plot functions and note how *Mathematica* reformats the input into formal code. With this feature and varying amounts of support and guidance from the teacher and the Wolfram website, the students programmed an applet that accounted for the effect of one parameter of a sinusoidal function (e.g., amplitude). Then, the students were challenged to explore and manipulate the families of trigonometric functions by creating an applet in which all parameters of the functions could be changed (see figure 1). Upon completion, the teacher checked for understanding by asking questions about the effects of changing each parameter and by challenging the students to create sinusoidal functions that had certain attributes (e.g., a period of π, an amplitude of 4).
Figure 1. Screenshot of student created exploration of tangent lines.

Data, Analysis, and Results

All assessments were collected from the two senior classes during the 2013-2014 (Group1) and 2014-2015 (Group 2) school years. The formal assessment that occurred after the final use of *Mathematica* was chosen as the dependent measure to be compared in the quasi-experimental design. The assessment covered topics that aligned with the goals of the final applet-creation activity including the understanding of tangent lines and relative extrema. This assessment will be referred to as the post-test. The comprehensive semester exam (covering a review and extension of algebra topics) was chosen as a covariate to act as a control for the variability in math skills and experience between the two groups. The semester exam was graded on a traditional 100-point scale. The post test included an opportunity to score five bonus points for a maximum score of 105. As seen in table 1, the means and ranges of the scores on the semester exam vary between the groups, and it appears that the means of the post-test scores vary considerably. The Attitudes Toward Mathematics Inventory (ATMI) was given to each group, at the same time each year, after the post-test was given (see Tapia & Marsh, 2004). The ATMI is a brief survey consisting of 40 questions that is designed to measure high school and college students' attitudes toward mathematics.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Descriptive Statistics

		Minimum	Maximum	Mean	Std. Deviation
Group 1 N = 29	Semester Exam	49.00	101.00	75.93	12.23
	Post Test	46.00	99.00	69.48	16.40
Group 2 N = 25	Semester Exam	41.00	95.00	70.08	15.99
	Post Test	58.00	103.00	80.56	11.90

Results

A One-way ANCOVA revealed a statistically significant difference between the post-test scores of each group controlling for prior mathematical skill level and inconsistencies using the semester exam scores, $F(1, 51) = 14.075$, $p < 0.001$. It is important to note that the results were also significant when other prior assessments were used as a covariate. A partial eta-squared value of about 0.185 indicates that approximately 18.5% of the variance in the post test scores is attributable to the independent group variable (i.e., group 1 as the control group, group 2 as the post-intervention group).

A chi-square test of independence revealed a significant difference between the reported attitudes of group 1 and group 2, $\chi_2(2, N = 50) = 680.835$, $p < .001$. Students from group 2 reported a higher proportion of neutral and positive responses and reported fewer negative responses. Figure 3 shows the frequencies of responses for each group and level of response. The responses utilized a Likert scale from which the students chose the extent to which they agreed or disagreed with a statement involving mathematics. A response of rating one (1) corresponds to a choice that reflects the most negative attitude toward mathematics (e.g., Strongly Agree to the statement: "Mathematics makes me uncomfortable."; Strongly Disagree to the statement: "I think studying advanced mathematics is useful."). A response of rating three (3) corresponds to a selection of "neutral," and a response of rating five (5) corresponds to a choice that reflects the most positive attitude toward mathematics. Ratings of four (4) and two (2) correspond to intermediate responses, such as "Agree" or "Disagree."

Discussion and Conclusion

The significant difference in post test scores and reported attitudes suggests that the experience of creating and interacting with dynamic spaces did indeed aid the students in their quest to understand the nuances of calculus. This section will aim to explore some of the constructive aspects of this experience that may have implications for creating effective technological learning experiences in mathematics instruction. First and most obvious, the use of sliders allows for more time for productive discourse (Bu & Haciomeroglu, 2010). Once students learn how to operate the more advanced technology (i.e., *Mathematica*), students and teachers are enabled to spend more class time talking about the concept under investigation. As employed by the teacher in this study, discourse can evolve and move beyond addressing procedural features of a task (e.g., graphing multiple functions to identify a pattern) to attend to the qualities of the concept in a shorter amount of time while also granting more opportunities for feedback, revision, and reflection—a vital aspect of technology use in education (National Research Council [NRC], 2000). For example, during the task, questions (e.g., how can you use this model to find the where the lowest point on the function occurs?) used the dynamic aspect of the model to quickly make connections to concepts (e.g., relative extrema, concavity) while providing immediate feedback to each student. The efficiency of the dynamic models allows students and teachers to address broader conceptual qualities with less of an opportunity for students to lose interest or get distracted from the goal of the lesson.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

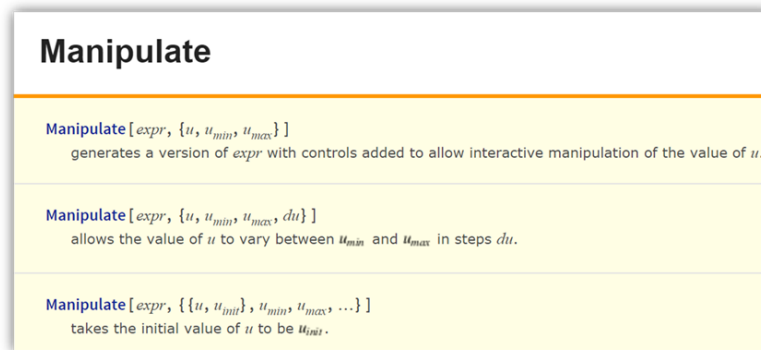
The act of modeling and programming dynamic spaces can parallel the construction of underlying mathematics (Tall,1991). On the surface, the students are mirroring the common task of constructing tangent lines when they define a function and situate the correct values in position (e.g., $f''(u)$ as the slope, $f(u)$ as the y-intercept) (see figure 1). In this particular activity, several students initially programmed incorrectly by positioning functions (e.g., $f'' x$ as the slope) rather than functions evaluated at a point (e.g., $f'' u$ where u represents a constant). This mistake was quickly realized when the student's output returned graphs that clearly did not represent a tangent line which, in turn, led to conversations between the students and the teacher about the difference between a variable and a variable that represents a constant—an example of an opportunity for revision and reflection. While other software (e.g., GeoGebra, Geometer's Sketchpad) can construct similar dynamic spaces, programming using *Mathematica* introduce a practical application of a function. Specifically, by using the "Plot" and "Manipulate" functions of Mathematica, students gain experience with functions of multiple arguments (see figure **2**). At a deeper level, when students embed a function into another function (e.g., Manipulate [Plot[{f(x),…), they are reintroduced to the concept of function composition, a crucial topic in the understanding of the chain rule.


Figure 2. Screenshot showing multiple arguments of the Manipulate function.

The positive results are also consistent with NCTM Standards (2000) suggesting that the exploration of multiple representations is beneficial to the understanding of mathematical concepts. Since it is believed that "student difficulties in understanding calculus concepts result from an inadequate understanding of graphic and algebraic aspects of these concepts" (Haciomeroglu & Andreasen, 2013, p. 7), it is plausible that the experience with the dynamic graphical representations, the algebraic nature of coding *Mathematica,* and the use of a slider that acts as a medium between representations contributed to the easing of such difficulties and increased understanding evident in the results. For example, when using derivatives to determine relative extrema (i.e., a maximum or minimum value of a function) the analytic procedures employed align with a graphical interpretation. Specifically, to determine possible relative extrema, or critical points, of a single variable function f analytically, one may compute the derivative of the function f' and solve for the values at which the derivative evaluates to zero (i.e., solve for c such that $f' c = 0$). This process aligns with the graphical interpretation of finding the points along the function at which the line tangent to the point has a slope of zero (figure 3).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Graphical Process

Analytical Process

Given   –   –
$f(x) = 1/2\ x^2 + 1/4\ x^4 - 6x,$
Compute $f'(x)$,
$f'(x) = x4 + x - 6$
$= (x - 2)(x + 3)$
Let $f'(x) = 0$, solve for x,
$x4 + x - 6 = 0$
$(x - 2)(x + 3) = 0$
$x = 2, -3$

Conclude that f may have relative extrema at
$x = 2$ and/or $x = -3$.

Figure 3. Relationship between graphical interpretation and analytic.

The visualization of the graphical interpretation can act as a reference when selecting the appropriate analytic method to employ. In this case, by visualizing an example function, one can deduce that because the extrema occur where the tangent line has a slope of zero and the derivative of the function at a point can be interpreted as the slope of the tangent line, then the analytic process to find the extrema begins by setting the derivative equal to zero because that is the point where the slope is horizontal. When students fail to make this connection between the graphical and analytic procedures through visualization, many students haphazardly resort to analytic procedures without fully understanding what to use or why they are using them (Haciomeroglu & Andreasen, 2013).

Multiple representations, multiple modalities, and technology can be helpful in the understanding of mathematical concepts when used in an appropriate manner (Shah & Freedman, 2003; Goldman, 2003), but this alone does not account for the benefits of creating and using dynamic models over teacher generated graphs to construct connections between representations. One benefit of the dynamic feature of the models used is that they provide an external representation of tangent lines at various points on a function. Consequently, students do not have to maintain or mentally transform a mental representation of the model which may reduce the cognitive load required to comprehend the new concept being presented (Shah & Freedman, 2003). As Tall (1991) suggests,

> A computer can also give much-needed meaning to mathematical concepts that students may feel are not of the physical world but in the mind, or in some ideal world. It is generally agreed that ideas are easier to understand when they are made more "concrete" and less "abstract". When an abstract idea is implemented or represented in a computer, then it is concrete in the mind, at least in the sense that it exists (electro-magnetically, if not physically). Not only can the computer construct be used to perform processes represented by the abstract idea, but it can itself be manipulated, things can be done to it. (Tall, 1991, p. 235)

Tall's (1991) explanation may help shed light on how the dynamic model involving tangent lines aids in a concrete understanding of the abstract idea that a derivative of a function is, in many cases, a function itself. That is, the derivative of a function is more than just a slope at a single point, but

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

rather a sort of formula that contains enough information for the practicing mathematician to find a slope, or rate of change, at any point along a curve (granted the derivative is defined at each point on the curve). Also, Tall (1991) posits that it is often true that "whenever a person constructs something on a computer, a corresponding construction is made in the person's mind" (p. 235). Although this is a very bold remark, it is suggestive of constructivist learning theory in the sense that what is being learned is inextricably tied to how it is learned. Thus, by using animated (i.e., dynamic) visuals to decrease the cognitive load of the learner at the time of conceptualization (Shah & Freedman, 2003), students are enabled to make connections between graphical and analytic procedures through previously unrealized dynamic visualization and avoid haphazardly resorting to analytic procedures without a deep understanding of the reasoning behind them.

Finally, Shah and Freedman (2003) suggest that students' attention is drawn to electronic visual displays, that students are more apt to study electronically delivered content for longer periods of time, and that visualizations in electronic learning environments can be attractive and motivating. These ideas help to explain the increase in positive responses on the mathematical attitude survey.

The implications of this research align with the current trend and push to integrate technology in the mathematics classroom. Although it may be detrimental to assume that the use of technology automatically implies learning, it is evident that effective use of technology in the classroom by both teachers and students can have substantially beneficial impacts. The affordances involved with the effective use of technology should be identified, and this technology should continue enhancing learning opportunities in mathematics classrooms by taking "advantage of what technology can do efficiently and well - graphing, visualizing, and computing" (NCTM, 2000, p. 26).

Limitations

This study highlights the beneficial aspects of incorporating technology into the calculus classroom but has many limitations and leads to more questions about maximizing learning through the use of student-created explorative spaces. The study was primarily limited by the small sample sizes involved. The sample sizes could be expanded to include a more diverse population by including other schools and classes. This could also help eliminate the possibility that the positive results were due to teacher engagement or an excitement about using "new" technology, rather than the actual exploration of concepts and representations.

Opportunities for Future Research

Although the large effect size implies that the applet-creation and exploration was substantially valuable, from this study alone, it is unclear to what extent each aspect of the creative and investigative processes was beneficial to student learning. For this reason, among others, this study raises many more questions to be explored. Would the results have been different if the dynamic models were to be created and supplied by the teacher rather than created by the students? Would the results differ if another program were to be used? To distinguish between the benefits of investigating student-created dynamic spaces versus teacher supplied dynamic spaces, multiple groups could be included in a study. Particularly, the control group could be taught traditionally, a second group could explore concepts using teacher supplied dynamic spaces, while a third group could explore concepts using student-created dynamic spaces. This design need not be limited to concepts of calculus. Rather, it could be expanded to explore other statistical models and spaces used for real-world problem solving tasks. A similar three-group design could be used to distinguish between benefits of one program over another, given a particular topic, which might aid in determining if there is a strong benefit to the programming language employed by *Mathematica* over a more elementary software program. Although current popular programs used to explore mathematical concepts and create dynamic spaces (e.g., *Desmos, GeoGebra, Geometer's Sketchpad, Mathematic*a, *Matlab*) share some overlapping features of their functionality (e.g., the ability to

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

create sliders) and user interfaces (e.g., programming language, inputting geometric figures by clicking and dragging), certain programs may be more appropriate for certain levels of development and age groups and may also vary among particular concepts and explorations. As Tall (1991) posits, it is important to note "the principal aim of the programming system of *Mathematica* is predominantly for doing mathematics, rather than learning mathematics" (p. 242). Since the technology that is used as an instructional tool develops over time due to updates in software, it could prove beneficial to identify the affordances of common features that aid in the development of mathematical skills in order to maximize the advantages of using technological tools in education. The future of technology in the classroom is promising; there are many questions left to explore.

EXAMINING PRESERVICE TEACHER THINKING ABOUT TECHNOLOGY-BASED TRIGONOMETRIC EXPLORATIONS THROUGH A REPLACING, AMPLIFYING, AND TRANSFORMING FRAMEWORK

Aaron Brakoniecki
Boston University
brak@bu.edu

David Glassmeyer
Kennesaw State University
dglassme@kennesaw.edu

Julie Amador
University of Idaho
jamador@uidaho.edu

Researchers promoting the inclusion of technology for teaching and learning have recently called for the integration of mathematical technologies into the preparation of future teachers. This report analyzes the dynamic geometry sketches produced by preservice secondary mathematics teachers when investigating trigonometric relationships. We analyzed preservice teachers' approaches to a particular task based on the extent to which the technology replaced, amplified, or transformed learning opportunities about tangent. We highlight the prominent aspects of the diagrams produced and discuss technological affordances these diagrams present for supporting preservice teachers' development of content knowledge and pedagogical approaches related to trigonometry.

Keywords: Technology, Teacher Education – Preservice, Geometry and Geometrical and Spatial Thinking

There have been recent pushes to incorporate technology into the teaching and learning of K-12 mathematics (National Council of Teachers of Mathematics, 2000; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). As Lee and Hollenbrands (2008) point out, "Whether technology will enhance or hinder students' learning depends on teachers' decisions when using technology tools, decisions that are often based on knowledge gained during a teacher preparation program" (p. 326). Subsequently pre-service teachers (PSTs) need opportunities to incorporate technology to learn and teach mathematics (Association of Mathematics Teacher Educators, 2006; International Society for Technology in Education, 2008). Incorporating technological tools into mathematics content courses allows conversations about new ways in which mathematical topics can be explored and new mathematical investigations that were not previously possible with more traditional tools (Hughes, Thomas, & Scharber, 2006).

One mathematical topic PSTs particularly struggle with is trigonometry (Moore, 2009), which spans both geometric and algebraic perspectives where an algebraic approach uses the unit circle as the object of study and a geometric approach uses right triangles as the object of study. Although researchers advocate for students to make connections between these two approaches, teachers often have difficulty coherently understanding trigonometric relationships (Moore, Paoletti, & Musgrave, 2014; Weber, 2005). This paper examines a set of activities used to develop 20 secondary preservice mathematics teachers' thinking about trigonometric relationships. These tasks required teachers to create dynamic geometry sketches in Geogebra or Geometer's Sketchpad to create multiple representations of trigonometric relationships and make connections between these representations. Specifically, the activity asked the PSTs to examine the slopes of lines, the slope-triangles created on these lines, the ratios of side lengths within these triangles, and the angles within these slope triangles. This research examines the following question: How does the production of dynamic geometry sketches by preservice teachers support their understandings of tangent, and what is the role of technology (i.e. *replace*, *amplify*, *transform*) in supporting their content knowledge about the tangent relationship?

Frameworks

The Technological Pedagogical Content Knowledge (TPACK) framework, described by Koehler and Mishra (2009) unpacks the unique kinds of knowledge that go into the effective teaching of

content (in this case mathematics) with technology. The framework identifies ways in which pedagogical, technological, and content knowledge interact with each other in a given context. The emergent forms of knowledge are "the basis of effective teaching with technology, requiring an understanding of the representation of concepts using technologies" (p. 66). This framework is also a useful lens for examining the technological artifacts that teachers create and use to explore mathematical content. Through these artifacts, mathematical, pedagogical, and technological issues are highlighted and minimized when they are used as tool to illustrate and investigate mathematics. By investigating the technological tools created by PSTs, we gain insight into their understanding of the complex interactions between technology, pedagogy, and content.

As new technologies are developed and utilized in mathematics classrooms their effects commonly *replace*, *amplify*, or *transform* non-technological means of teaching the same content (Hughes et al., 2006). New technological features (e.g. dynamic presentations, simultaneous representations, communication, etc.) offer the potential to change the mathematical explorations and discussions that occur in classrooms. However, this is only possible if the technology is used in ways that make use of this potential. The Replacing, Amplifying, and Transforming (RAT) framework provides a lens for analysis of the mode of technology integration into an activity (Hughes et al., 2006). This framework draws attention to whether the technology *replaces* a similar presentation without the technology, *amplifies* the learning process that was present in the non-technology version, or *transforms* the learning experiences to provide possibilities that were otherwise not possible without the technology. This framework has been a useful tool for analyzing the integration of technology into teacher preparation courses as a means for understanding how teacher educators can improve instruction (Glassmeyer, Brakoniecki, & Amador, 2016a, 2016b). The RAT framework allows for the analysis of technology and the range of ways it is used in tasks to advance learning outcomes.

The tasks used with these PSTs were focused on exploring mathematical content, namely the tangent relationship (as these tasks were given in a mathematics content course for beginning teachers). In our study, the TPACK framework is a theoretical lens for understanding how PSTs conceptualized the tangent relationship while using technology tools and considering their future careers as secondary mathematics teachers. The RAT framework functions as an analytic lens to describe how the PSTs used sketches when exploring this relationship and how the technology provided for learning opportunities. Together, these frameworks for technology integration provided understanding about how PST-generated dynamic geometry sketches supported their understandings of tangent as technology was integrated into a given task.

Method

This study took place at a large Southern university within a content course for prospective secondary teachers. In the course, PSTs regularly engaged in learner-centered instruction incorporating collaborative learning and technology such as graphing calculators, Geometer's Sketch Pad, Geogebra, and Desmos. Approximately half of the course meetings were devoted to having PSTs explore trigonometric relationships to support their quantitative reasoning and ultimately their conceptual understanding of mathematical topics, with secondary attention going to enhancing their pedagogical content knowledge by considering how they would teach this material to their own students.

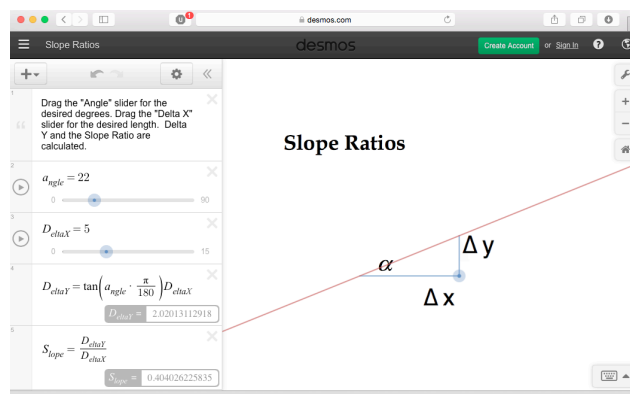
The study focuses on a three-day lesson where the 20 PSTs investigated the tangent relationship. The task was modified from the CPM Core Connections Geometry textbook (Kysh, Dietiker, Sallee, Hamada, & Hoey, 2013) by requiring teachers to create dynamic geometry sketches to answer parts of the lesson. The lesson has teachers explore connections between the slope-ratio triangle (a right triangle produced by a line and it's vertical-to-horizontal change) and the base angle of that slope triangle angle. (See figure 1 for an example of a slope ratio triangle in a pre-constructed applet).


Figure 1. Screenshot of an app that can be used to explore relationships of slope and angle.

Near the beginning of this exploration, the PSTs determined (with a paper and pencil task) that for a slope-ratio triangle with an 11º base angle, the slope ratio is approximately 1/5. Additionally, for a triangle with a 22º base angle, the slope ratio is approximately 2/5. These beginning teachers were asked to construct their own dynamic geometry sketches to explore this supposed fact from their pencil and paper sketches.

Data for this study include PST homework and subsequent class discussions in which they used the dynamic geometry software to explore the tangent relationship. The preservice teachers were explicitly asked to create dynamic geometry sketches where they could "click and drag a point to get different slope triangles." The PST then met in class and presented their sketches to their peers. These whole class discussions were audio recorded as well as conversation of three small groups of 3-4 PSTs as they worked through the task. The series of tasks lasted three days, resulting in a total of nine transcripts, three small group recordings a day for three days. As a part of a larger project, the transcripts were initially read by all three researchers of the project, one being the instructor of record for the course in which the data were collected. The data were originally open coded using Strauss and Corbin (Corbin & Strauss, 2007) constant comparative methods by each of the researchers. The researchers then met and identified technology as an emergent theme in the data as a way to support the PSTs' understanding. Following this, cognizant of the theoretical framing of TPACK (Koehler & Mishra, 2009) and the analytic framework for RAT (Hughes et al., 2006) the three researchers each independently recoded the entire data set with a focus on the role of technology in supporting PSTs' understandings of the tangent relationship. The identified chunks in the data that related to technology and assigned a code of *replace*, *amplify*, or *transform*. The three researchers then met and compared codes of the data. Themes related to technology use were then derived and agreed upon. The researchers then collectively generated themes around the *replace*, *amplify*, and *transform* uses of the technology as related to learning tangent to describe the PSTs' use of the dynamic geometry software for exploring the tangent relationship. An emphasis was on understanding variations of technology use to support understanding. Finally, the dynamic geometry sketches were analyzed to corroborate findings to further understand how PSTs were using technology to understand the tangent relationship.

Findings

This section describes several of the variations among the multiple sketches produced by the PSTs. Each variation is discussed including its mathematical, pedagogical and technological implications, with specific emphasis on the role of technology to *replace*, *amplify*, or *transform* learning processes.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Static vs. Dynamic

One of the features of dynamic geometric software is the ability to drag objects in a sketch and observe what happens to the relationships among lengths, angles, and the connected shapes. This provides an *amplification* over static sketches where multiple sketches must usually be created in order to observe a change in various relationships. In this study, some of the sketches produced by the PSTs contained no dynamically moving parts. Either this was because all pieces of the sketch were "locked" together (any attempt to move a single aspect of the sketch actually moved the entire sketch), or there was no dynamic and relational aspects included in a picture (e.g. lengths of sides were written in, not linked to actual lengths, there were no preserved aspects of the diagram evident such as lines remaining horizontal or vertical)—in other words, these uses *replaced* traditional methods for learning. Here, PSTs treated their sketch the same as a regular pencil and paper sketch, only done on a computer, choosing not to utilize one of the key advantages of dynamic geometry software. This choice may have come from a lack of technological knowledge around how to display these measures or construct these relationships within their sketches. Additionally, their understanding of the activity may have centered on producing a sketch that displayed the relationship as opposed to exploring the relationship.
Figure 2. Screenshot of PST-created sketch with multiple slope triangles.

Multiple Overlapping Triangles

When using dynamic geometry software, the dragging of points and lines often allows the user to, in essence, see multiple different arrangements of figures within quick succession of each other. While at any given time, only one version of the figure is visible, the moving of one aspect allows users to visualize patterns and relationships in the figure and explore what may vary or remain invariant. With paper and pencil static sketches, often multiple versions of the figure will be included in a single diagram, with appropriate aspects labeled, in an attempt to "illustrate" these relationships. Some of the PSTs in the study created dynamic sketches and also included multiple slope triangles in their diagrams (see figure 2). While it was possible to dynamically manipulate their sketches to see relationships, the existence of multiple triangles made this interaction unnecessary as the relationships for consideration were already displayed upon opening the sketch. Here, again, the sketches seemed to be digital representations of static diagrams *replacing* a sketch of a similar representation, and the pedagogical advantage of exploration with dynamic geometry software was no longer a key feature of these sketches.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Right Angle

When creating dynamic sketches, the objects are often created in a parent-child relationship. For example, when creating a line segment, two points are first placed (the parents) then the line segment (the child) connects the two points. Whenever a parent is moved, objects that are dependent on the parent are adjusted accordingly. With many digital sketches, there are often aspects of a diagram that users would like to vary, and other aspects of a diagram that creators may wish to remain invariant. For example, when investigating parallelograms, a learner may wish to have the side lengths and angles be modifiable, but always have the opposite sides of this quadrilateral be parallel and congruent in length. For the activity in our task, one of the crucial elements of a slope triangle is comparing the "rise" to the "run" of the triangle, which must be at right angles to each other. In many of the PST-generated sketches, the sketch of the slope triangle initially showed a right triangle. However, when vertices of the triangle were moved with the technology, their triangles no longer remained right triangles (see figure 3 for a sketch before and after manipulation). When these PSTs created their triangles in the software, the right angle was not an invariant part of the diagram. When the right angle was set to be invariant, the sketch *amplified* what might have been presented in other static representations, making it clearer for those looking at the sketch the relationships that exist in the diagram. It is possible that these PSTs did not know how to arrange the parent-child relationships among the aspects of their, diagram which would ensure that the angle of the slope-ratio triangle always remained at 90º. Additionally, they might not have understood the importance of this feature of their diagram. Consequentially, they may have felt that by closely approximating a right angle in their diagram through the manipulations of multiple points, you could still see the relationship between side lengths, and the base angle of the slope-ratio triangle. However, this introduced a potential source of error in measurements and the conclusions based off of those measurements, in addition to being a less efficient way of moving vertices and preserving the right angle.
Figure 3. Screenshot of PST-created sketch with a non-preserved right angle.

Fixed Angle vs. Fixed Slope

In this activity, PSTs were asked to explore the relationship between the degree of the base angle in the slope-ratio triangle and the slope-ratio of that triangle. To create these slope-ratio triangles, there were two approaches PSTs used. One approach was to use a horizontal base for the triangle, and construct a line off of that base at a given angle for the hypotenuse of the triangle. In these sketches, the exploration allowed PSTs to see, given a particular degree measure, approximately what slope-ratio results exists in that triangle? A second approach in constructing these triangles was to again, begin with a horizontal base length. To create the hypotenuse, a line defined by a function with a given slope was created.

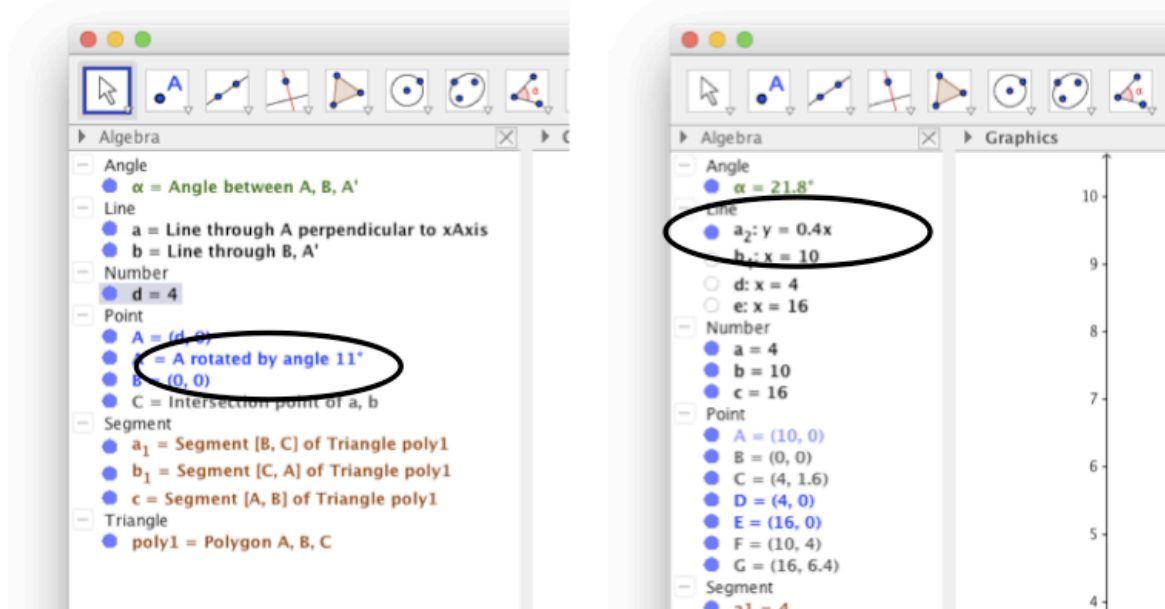
Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.


Figure 4. Screenshot of PST-created sketches with triangle created by angle, and by linear function with slope.

With these diagrams, the exploration allowed PSTs to see, given a triangle with a particular slope ratio, what is the base angle of that slope ratio triangle? Figure 4 provides an example of each approach used by the same PST in different sketches. The circled aspect of each diagram highlights how they defined their slope-ratio triangle. One of the key features to note with this different approach to constructing the triangles is that it actually enabled different mathematical explorations, in essence *transforming* the learning process in mathematics by allowing users to retrace exactly how a sketch was created. Furthermore, these different approaches emerged from the same activity around exploring the relationship. It's unclear whether the PSTs were aware of how their constructions impact the mathematics that they were investigating, or how these two approaches are complementary and can work together to support the investigation of the same relationship.

Unit Circle

This overall activity focuses on investigating right triangle trigonometry (relationships between the angles and side lengths in a right triangle). In addition to this perspective, trigonometry can also be investigated with the unit circle (a circle of radius 1 unit). In this approach, often times triangles are drawn inside of these unit circles, with the hypotenuse of each triangle extending from the origin to the circle, and the triangle is drawn connecting the point on the hypotenuse/unit circle to the x-axis so it intersects perpendicularly. In these unit circle triangles, the vertical length of this triangle is the sine of the angle, and the horizontal length of this triangle is the cosine of the angle. In some of the sketches produced by the PSTs, there appeared to be some efforts made to merge these perspectives of trigonometry. Figure 5 provides one instance of this approach by a PST. In these sketches, the slope-ratio triangle was embedded in circles centered at the origin (although not always unit circles). This attempt at merging was important for several reasons. First, it was an attempt to bridge mathematics content, usually presented differently in two domains (algebra and geometry), in essence *transforming* the learning process in mathematics. While there are mathematical similarities in these perspectives, the differences shape the range of relationship explorations.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 5. Screenshot of PST-created sketches with slope triangles and circles.

Right triangle trigonometry is limited to exploring angles between 0º and 90º while unit circle trigonometry is presented only with triangles with a hypotenuse of 1 unit. Additionally, the sketches that merge the right triangle and unit circle approaches have the potential for helping PSTs understand the strengths and limitations of each perspective and also offer ways that PSTs can simultaneously draw upon both perspectives when reasoning through a problem.

Discussion

Through this task of exploring the slope ratio triangle and its angles using dynamic geometry software, the PSTs were exposed to different approaches for thinking about trigonometric content and the tangent function and had opportunities to use technology in ways that would *replace*, *amplify*, or *transform* their previous experiences (Hughes et al., 2006). The activity was designed to engage these beginning teachers in mathematical explorations, but to also encourage them to think about the use of this task with their own students, and use technology to explore and explain some of the conjectures they were making. In analyzing the diagrams produced by the PSTs, we uncovered the variety of approaches used in their constructions, the role of the diagram with the activity, and the mathematical, pedagogical, and technological choices made by these PSTs. Specifically, they were able to recognize the role of technology in affording opportunities to *transform* their previous experiences through technological manipulation that otherwise would not have occurred with a pencil and paper drawing.

This study raises points about our work with, and study around, the role of technology and dynamic geometry programs with PSTs. As teacher educators, we need to be more explicit with PSTs about the strategic advantages that individual technologies offer (e.g. dynamic movement, simultaneous changes in representation, etc.) and how they may transform learning for their students in ways analogous to the transformations that occurred within the context of this secondary content course. One aim is to ensure that PSTs doing work to incorporate technology in their teaching are aware of the ways that the technology is best suited to enhance their instruction, albeit through replacement, amplification, or transformation of learning processes (Hughes et al., 2006). This may involve explicitly focusing different forms of TPACK knowledge (Koehler & Mishra, 2005) PSTs might be drawing upon when they create and use these sketches or other technologies. As we look toward supporting future teachers' uses of technology for their own teaching and learning, we recognize the complex interactions of mathematics content, the incorporation of technology into practice, and the attention to the ways in which learners will interact with that technology. By understanding how PSTs are currently making sense of these interactions, we hope to better support their future efforts.

ASSESSING MATHEMATICAL ARGUMENTATION THROUGH AUTOMATED CONVERSATION

Gabrielle A. Cayton-Hodges
Educational Testing Service
gcayton-hodges@ets.org

Mathematical Argumentation skills have historically been overlooked in assessment, but the inclusion of Mathematical Argumentation in the Common Core State Standards (CCSS) as one of the Standards of Mathematical Practice challenges assessment developers to assess this mathematical practice. Explanation and justification of one's own thinking to a specific audience is considered a fundamental part of this mathematical practice. Based on student demonstration of argumentation skills when engaging with peers, we have developed automated conversations with virtual teachers and peers to investigate how alternative conversational patterns influence types of student responses. This technology allows assessment developers an innovative avenue for exploring new task designs that adapt to individual users and produce additional data not found in traditional measures. Preliminary findings from this investigation are presented.

Keywords: Assessment and Evaluation, Classroom Discourse, Elementary School Education, Technology

Defining Mathematical Argumentation

Mathematical Argumentation has been defined most generally as "understanding relationships to make connections to new ideas" (Mueller & Maher, 2009). Hunter (2007) defines argumentation in the classroom as collaborative argumentation in which students work together through mathematics discourse "to critically explore and resolve issues which they all expect to reach agreement on ultimately." (Hunter, 2007, p. 3-18). More specifically, argumentation includes making a conjecture, proving a proposition, justifying an inference, or explaining a point. Students have been found to demonstrate argumentation skills when arguing with and asking questions of peers. In addition, explanation and justification of one's own thinking such that it can be understood by a specific audience is considered a fundamental part of this mathematical practice.

Conversation-Based Assessment

To address the challenge of assessing mathematical argumentation, we turned to the prospects of using Conversation-Based Assessment (CBA). Such automated conversations with virtual agents have been widely used to support student learning in intelligent tutoring systems (ITS) (e.g., Graesser et al., 2004; Halpern, Millis, Graesser, Butler, Forsyth, & Cai, 2012; Millis, Forsyth, Butler, Wallace, Graesser, & Halpern, 2011). Students' interactions with these agents can be used to gather evidence about their knowledge and skills, and provide them with appropriate help (e.g., feedback, scaffolding). The use of CBA, and more specifically, "trialogues" (three-party conversations among a human student and two virtual agents) for assessment is more recent (see Yang & Zapata-Rivera, 2010), but this area of application is a natural fit for assessment purposes due to the underlying requirement for ITSs to assess relevant skills that will enable intelligent and adaptive responses. Leveraging this requirement allows assessment developers an innovative avenue for exploring new task designs that adapt to individual users and include additional data not found in traditional measures (i.e., conversational responses related to specific scaffolding).

Trialogues are one way to create learning environments that can be used to simulate particular learning strategies or social interactions (Butler, Forsyth, Halpern, Graesser and Millis, 2011). This makes this type of environment an ideal one for the assessment of argumentation skills since we are

able to recreate not only the mathematical content learned in the classroom, but also the interactions that accompany them.

In the development of the task that serves as the basis for our automated conversation, we looked at what design principles could be used to structure tasks so that students' collaboration, and their discourse in particular, will be "thought-revealing" (Kelly & Lesh, 2000). Hoover, Hole, Kelly and Post (2000) proposed a set of principles for developing thought-revealing activities: 1. The model construction principle, 2. The reality principle, 3. The construct documentation principle, 4. The construct shareability and reusability principle, and 5. The effective prototype principle.

These principles suggest that a thought revealing task should require the development of "an explicit construction, description, explanation or justified prediction;" (p. 609) involve a situation that requires students to engage in meaningful mathematics; result in the creation of a product that itself provides information about student understanding; require students to produce explanations of process and not just a final product/answer; and result in the creation of an idea that can be referred back to in another context. We developed not only our underlying task, but also structured our conversations around these principles.

Figure 5: Screenshot of CBA prototype.

We developed a CBA that involves students engaging in an automated trialogue with a virtual teacher and virtual peer agents. The trialogue occurs in a simple chat-like interface as the student is led through solving a problem that involves both linear algebra and mathematical argumentation (Figure 1 shows a screenshot of the prototype, including the problem the students were asked to solve). We found that students are able to showcase their skills with mathematical argumentation through explanation, refutation, evidence, and position-taking just as would be the case in a classroom setting. Further, by utilizing automated scoring engines already integrated into the design of the CBA, we were able to come up with scores for mathematical argumentation that are more objective than the subjective scores of classroom observation or teacher rating.

Researchers have explored how best to support students' skills to support deep conversations and question-asking (see Graesser, Ozuru & Sullins, 2010). We aimed to build on this body of literature by continuing onto the next step in the development process, the framing of the questions and prompts to provide the continued support of thought-revealing responses and therefore student

argumentation contained within. For instance, do students provide the most information when countering misconceptions or when responding to direct questioning? Do students respond differently when the question comes from a virtual teacher as opposed to a virtual student? These are the design questions we aimed to better understand through this study.

The Problem Statement

In drafting the structure of automated conversations, just as in a real-life classroom situation, we must make multiple decisions as to how to query a student to elicit certain information. Sometimes, a very small change in wording of a query may elicit more, less, or different information. However, unlike a real-life situation, we do not have the opportunity to listen to nuances in the student response and ask the question again in a different way. This study looks at small changes to automated questions at three important points in the mathematical argumentation conversation to determine what impact these changes have on student responses.

Main Research Question: How do alternative conversational prompts influence the types of math responses gathered from students in the math prototype?

Sub-questions:

1. Do students respond differently in a situation where they are first asked to explain in their own words or when they are responding to another student's ideas? [Manipulation 1]
2. Do students respond differently to a question asked by a virtual student versus a virtual teacher? [Manipulation 2]
3. Do students provide a more complete argument when prompted to respond to an unlikely answer or a likely answer? [Manipulation 3]

Study Design and Procedure

Sample

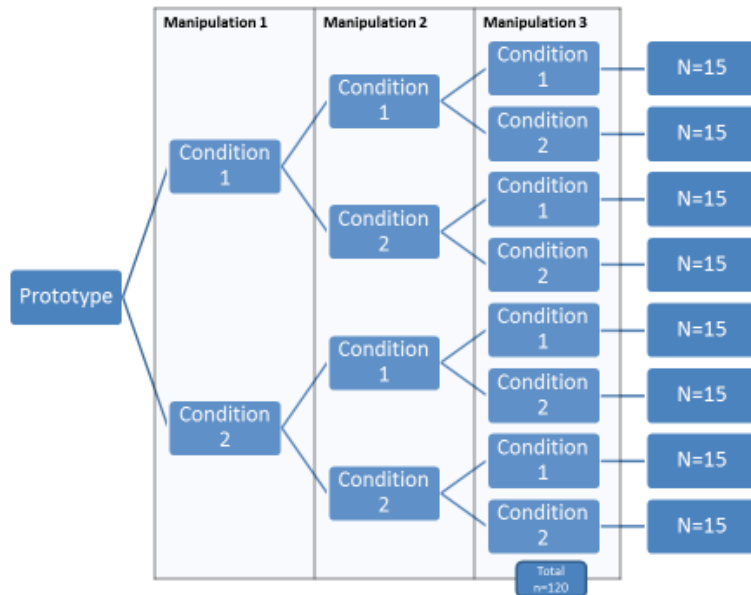
The study was conducted with students in 8th-grade algebra at four schools in different regions of the U.S.A. We investigated the three research sub-questions simultaneously, using the same sample of students. Students were randomly assigned to one of the eight possible conditions as shown in Figure 2 (numbers shown were planned). We had aimed for a total of 120 students but due to technical difficulties at one school that caused them to end before all students were complete, we ended with 123 records for Manipulation 1, 107 for Manipulation 2, and 74 for Manipulation 3.


Figure 6: Study design.

Instruments

Students were administered a short pretest focusing on linear algebra skills as a baseline measure. They then engaged in the automated conversation on a computer, with random assignment to one of eight conditions, as described above. They then answered a short post survey about their perceptions of the activity.

Data Analysis

Scoring and Analysis. The pretest items were all automatically scored. Most of the analyses of the conversation data were also automatically scored with the exception of one longer argumentation item (Manipulation 3), which had to be scored by human raters.

Analysis. Each of the three manipulations has two discrete conditions that are being compared in their outcomes. Each of those manipulations was analyzed using Chi Squared Tests of Independence.

Results

Manipulation 1

Manipulation 1 varied by whether the initial response by the student was in reaction to a misunderstanding by the virtual student, Pat (Condition 1), or whether it was in reaction to a direct question by the virtual teacher, Ms. Turner (Condition 2). In both conditions, we were looking for the student to answer that y is the dependent variable and represents the total cost. In Condition 1, Pat offers an incorrect answer where y is the independent variable and is the cost per shirt. Figure 3 shows the conversation diagram for the first cycle of Condition 1. Condition 2 differs in the opening such that Pat does not offer an [incorrect] answer and instead Ms. Turner directs her question directly to the student.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Opening			Cycle1	
Ms. Turner	X (Student)	Pat	Ms. Turner	X (Student)
Let's think about graphing the information about all three companies. To begin with think about the axes and their scale. Pat, how should you label the y-axis?		I think that y-axis is the independent variable, and here it is the cost for each shirt.	Let me restate what you just said. Y is the independent variable. Y represents the cost per shirt. _X_, do you agree with Pat? Why or why not?	A. Correct answer with full correct explanation of dependent variable: y=dependent y=total cost
				B. Correct Answer with incorrect explanation of dependent variable: y=dependent y=total cost
				C. Correct answer, no additional information: y=dependent y=total cost
				D. Misunderstanding: y=dependent; y=cost per shirt (agrees with Pat)
				E. Misunderstanding: y=independent (agrees with Pat); y=total cost
				F. Misunderstanding: y=dependent y=amount of shirts (confuses x and y axes)
				G. Incorrect answer: y=independent y=cost per shirt; or anything else
				H. Irrelevant response
				I. No response
				J. I don't know; I have no idea; I don't understand what you mean.

Figure 7: Conversation Diagram for Manipulation 1, Condition 1.

First, we looked directly at how the CBA system evaluated the student responses to the manipulated question. The results are shown in Table 1, where A is a completely correct response that leads directly to the end of the conversation, and C-F are variations of which components were correct or partially correct (B is missing as no one went down that path). G is the completely incorrect, but relevant response where the student states the same thing as Pat, that y is independent and the cost per shirt (or other relevant but incorrect labels for *y*). Other represents a path that the system computed as irrelevant, blank (i.e., no response provided by the student), or metacognitive (e.g., "I don't know") (H, I, or J).

Table 1: Manipulation 1 Cycle 1 Response

	Student Response Evaluation								Pretest Score
	A	C	D	E	F	G	Other	*Total*	% correct
Condition 1 (misunderstanding)	1	2	5	5	2	29	16	*60*	66%
Condition 2 (direct question)	1	0	8	0	6	5	43	*63*	69%
Total	2	2	13	5	8	34	59	*123*	68%

Students in Condition 1 were most likely to have both parts of the response incorrect (*G*) while students in Condition 2 were most likely to have a response that was interpreted as irrelevant or blank (*Other*; χ^2=38.9, *p*<.001). This result was interesting as the misunderstanding by Pat was intentionally built into the script to make it clear which pieces of information were relevant to the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

question while allowing the student to correct the information with their own response. This approach may have backfired as it indicates that the students given the response by Pat initially were likely to agree with him. On the other hand, more than half of the students that were directly questioned by the teacher with "how should you label the *y*-axis" did not produce any relevant response, indicating that both groups may have been lacking this basic knowledge of how to contextualize linear functions. Students in Condition 1, however, had Pat's answer to copy or restate while the other group did not have any information to use.

To explore this further, we looked at student responses to follow-up questions posed after this initial response in Cycle 1 to see which students eventually arrived at the correct answer through further questioning (Table 2).

Table 2: Manipulation 1 Final Answer

	Correct	Incorrect	Other	*Total*
Condition 1 (misunderstanding)	23	21	16	*60*
Condition 2 (direct question)	9	11	43	*63*

None of the students who began down the "Other" paths were able to eventually reach the correct answer. Of the remaining students, approximately half in each conditional eventually reached the correct answer (23/44 students in Condition 1 and 9/20 students in Condition 2), demonstrating that it was only the direct response to the manipulated prompt that caused student differences, there was no further chain reaction to this manipulation.

Manipulation 2

For Manipulation 2, the original version of the manipulated question (Condition 1) has Ms. Turner explicitly telling the students to use $y=mx+b$ and asks what m and b represent. In Condition 2, Pat says "I know we're supposed to use $y=mx+b$ for the equations. But I'm not really sure what m and b stand for. [Student], can you help me? What do you think m and b stand for?" This is similar to Manipulation 1 in that the student is responding to either Pat or Ms. Turner, but it also differs from that manipulation in that the question in this case is near-identical. There is no misconception introduced, and in both conditions the student is explicitly asked to define m and b in $y=mx+b$. In this particular instance, the flow chart is nonlinear, that is, the students are expected to say that m is the slope (or cost-per-shirt) and b is the y-intercept (or set-up fee) but there is no prescribed order to those two events. As shown in Table 3, there were more respondents in Condition 2 who met both expectations (defined both m and b), but the difference between the groups was not statistically significant ($\chi^2=3.13$, $p=0.37$).

Table 1: Manipulation 2 Results

	Only *m* is defined	Only *b* is defined	*m* and *b* are defined	Neither	*Total*	Pretest
Condition 1 (Ms. Turner)	11	5	17	17	*50*	65%
Condition 2 (Pat)	10	4	29	14	*57*	70%
Total	*21*	*9*	*46*	*31*	*107*	68%

After the manipulated question in Manipulation 2, all students were asked to write the equation for one of the companies, which was posed in an identical manner for all students. We investigated whether students' initial responses to the manipulated question led to response differences on this new, non-manipulated question. The results are shown in Table 4. No statistically significant difference in performance was found between the groups ($\chi^2=0.81$, $p=0.27$).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 2: Manipulation 2 and Later Prompts

	Full Equation Written Correctly	Incorrect	*Total*
Condition 1 (Ms. Turner)	30	20	*50*
Condition 2 (Pat)	40	17	*57*
Total	*70*	*37*	*107*

Manipulation 3

The focus of Manipulation 3 was on the final mathematical argument. This manipulated question asks students to develop an argument for which company should be used for the school fundraiser. They do this by responding to an email from the student council stating they will go with either EZ Tees (Condition 1) or Perfect Printing (Condition 2). We chose these two conditions based on evidence from preliminary data of human trialogue interactions (teacher and two students). In the human trialogues, most triads arrived at the conclusion that Perfect Printing was the best choice of the three companies because it is the cheapest for the greatest range of shirts ordered. Thus, we intended to compare an argument for/against an unlikely choice with an argument for/against a likely choice. However, as can be seen in Table 5, most students in both conditions chose Shirts for Less (SfL), the third company, as the best choice. Therefore, the two conditions were each prompting students to respond to a choice that most thought unideal and, we did not have a condition with the most common choice.

Table 3: Manipulation 3 Final Argument

	EZ Tees	SfL	Perfect Printing	Other	*Total*	*Pretest*
Condition 1 (unlikely choice)	9	16	10	2	*37*	*67%*
Condition 2 (likely choice)	4	23	9	1	*37*	*68%*

The data seem to indicate that students in Condition 2 (Perfect Printing prompt) were more likely to choose Shirts for Less than those in Condition 1 (EZ Tees prompt), but the difference was not statistically significant ($\chi^2=3.22$, $p=0.19$).

We then scored student arguments along a rubric that was designed to align with an Argumentation Learning Progression (Cayton-Hodges et. al., 2014). The argument was scored 1-5, with 5 being the most complete and convincing argument. Results are shown in Table 6.

Table 4: Manipulation 3 Argumentation Score

Argument Score	**1**	**2**	**3**	**4**	**5**	**Total**
Condition 1 (unlikely choice)	10	14	8	3	2	*37*
Condition 2 (likely choice)	13	8	4	7	4	*36*

The results indicate that students in Condition 1 may have been writing slightly more proficient arguments than those in Condition 2. However, we achieved only 61% reliability (exact score matches) over multiple scorers in the rubric, so we did not perform inferential statistics on this data. It is clear that, as a whole, the sample did not perform well on the final argument. We see this as indicating a weak performing population, which was also shown in Manipulation 1, which could also be one reason for the discrepancy with the human trialogues, as that population of students was overall quite strong. We plan to investigate this question further using a sample of 9th and 10th grade students to see how the findings compare.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Conclusion

This study aimed at better understanding the design choices made when developing CBA questions, which could also translate to choices made when encouraging argumentation in the classroom. We found that introducing misconceptions, a common approach to encourage argument in CBA, could actually lead students to repeat the misconceptions later in the assessment as opposed to argue against them. Meanwhile, other changes such as a direct question by a virtual teacher versus a virtual student had little, if any, effect responses from students in our sample.

Finally, we were unable to test the premise of responding to a likely versus unlikely answer since a majority of students in both cases chose a different answer than intended by the problem. This was overwhelmingly true in Condition 2, which was supposed to be the "likely" answer.

Further research on this prototype is ongoing, including increasing sample sizes and assessing students in later grades who should have more command of the material, to see if the results change with a stronger population.

THE RHYTHM OF TOUCHCOUNTS: COUNTING ON TECHNOLOGY

Sean Chorney
Simon Fraser University
sean_chorney@sfu.ca

This research reports on a class of grade one students engaging with number concepts using the iPad application TouchCounts. It is theorized that students develop understandings of number based on a materially engagement with both social and material resources. Rhythm is the fundamental unit of analysis used to attend to student engagement with TouchCounts. A class activity as well as three students working together will be analyzed in terms of emerging rhythms. It is concluded that rhythm is an emergence of form, modeling and aligning with the mathematical notions of number.

Keywords: Technology, Elementary Education, Number Concepts and Operations

Early learning of number is significant for future success in mathematics (Libertus, Feigenson & Halberda, 2011). Concepts, ranging from counting and subitising to skip counting, are important in early development of number sense as a foundation for higher development. Students, however, find number concepts difficult (Lockwood, 2012) partly because they often do not have many ways of engaging with number. For example, when children learn to count, they often learn a song in the form of the audible sounds, 'one', 'two', 'three', and so on. While this method can be a good starting point for learning counting, it is linear and only supports an audible approach to counting. New technologies provide new opportunities for students to become more closely engaged with mathematical concepts.

New technologies such as the iPad, including the numerous applications that can be used on this platform, provide new and unique ways of engagement for students. Multi-modal approaches that include embodied actions such as gestures can help support the learning of number by allowing different ways to interact. In this study, the application *TouchCounts* (Sinclair & Jackiw, 2011) is used because it provides an open-ended experiential approach to interacting with number. Pappert (1980) drew on this notion of learning with expressive technologies in his development of Logo. In Logo, a turtle, which was controlled by student's programmed instructions, drew shapes on a computer screen. Pappert argued that when students created these shapes they 'were' the turtle and 'felt' the movements and turns in creating shapes. *TouchCounts* is similar in that it provides a new form of engagement where number is understood in multiple visual, audible, and gestural modalities among others.

Research with new technologies is still a new field as research is striving to keep up with new technology. There are frameworks that have been implemented but the overall number of studies is still very small. Since technology is changing so fast and new applications are being created everyday, different approaches are needed for new insights in learning mathematics, particularly with digital technology, since it is so new. In this study, the construct of rhythm is used as a unit of analysis when students engage with number in a grade one classroom, rhythm being a way to attend to what occurs during interaction rather than framing the human mastering the tool. Rhythm itself is a way to embrace the fusing of tool and user because it is a clearly material and easily identifiable result of an activity. While many frameworks identify the user of technology as the central figure in an interaction, this study adopts a new materialist approach that sees the user and the technology as being fused together, thus expanding the boundaries and consequently the potential of user and technology as one. Rhythm has been implemented in mathematics education (Roth, 2011; Radford et al., 2007). Moreover, rhythm can be seen as an aspect of learning number in how children learn to count. There is a temporal component in how children are introduced to the 'one', 'two', 'three'

song. As an expression of interaction we are familiar with in music, rhythm shifts attention to the material. It is evident that rhythm aligns new forms of engagement with multi modal technology. This research report explores what rhythmic variations occur in different approaches to learning number, particularly with the use of the iPad app *TouchCounts*? [For information on TouchCounts see: http://www.touchcounts.ca/]

Theoretical Framework

New materialist scholars (de Freitas & Sinclair, 2014; Barad, 2007) are challenging the duality and binary components of Cartesianism which separates mind and body. Consequently, one can approach the activity of a student working with technology as a material engagement and not rely on black boxed phenomenon such as thinking or mental construction. Critics of the immateriality of mathematics challenge the idea of what mathematics is and whether ideas can exist independent of physical materiality such as the body, the social collective, or even spoken words. de Freitas and Sinclair have developed a monist framework they term inclusive materialism that does not distinguish between digital tool and user thereby expanding the boundary of thinking subject as both technology and user as one material. This is important in this study because using a digital technology does not depend on mental contemplation and intention since that centralizes the 'thinking' in the student. de Freitas and Sinclair criticize representationalism because it assumes a mediation of knowledge that is based on the immaterial. According to Roth (2011), thinking is spontaneous and is not interrupted by constant mediation of interpretation and intent. The mediating aspect of representation is aligned with a computer model approach in which input is stored and operated on. Real life engagements do not seem to follow such a constantly interrupted flow of living forces. Roth argues that thinking is improvised in-the-now, particularly when engaged in a new activity.

New approaches in theory demand new considerations of methods. In this study, rhythm is taken to be the unit of analysis because it is its own unique phenomenon and yet something we are quite familiar with. Rhythm can be identified as a repeated action within a temporal consistency. It is not mechanical nor metronomic (Ingold, 2011) but has variance making it both organic and structured. It is fully material since what is seen and heard and felt contributes to our adoption of the construct. While rhythm is discounted as something extraneous or epiphenomenal, Ingold asserts that it is part of the development of knowledge and helps us understand learning. It is a significant part of the in-the-moment. However, it is also develops familiarity with patterns. Thus, it can be evaluated at the present time and it can also be used to predict what is to come.

It is the form of rhythm and how it aligns with the form of mathematics that makes it so significant. Rhythm provides evidence of the structuring of a human engagement with a mathematical idea. For example, ordinal numbers can be counted, rhythmically as 1, 2, 3. In that counting there is form, a structure of consistent beat and of always being able to add 1. These forms fuse together in practice, the rhythm emerging from their fusing so that the rhythm becomes a leader or guide to the structure. It takes over, and one becomes a part of its flow indicating that the social adoption of rhythm is where meaning begins and becomes.

Radford et al. (2007) describe rhythm as an indicator of generalizing. They position rhythm as a semiotic resource that is mobilized by students in their apprehending of a pattern and its subsequent generalization to convey a sense of generality. However, rhythm can be considered less as emanating from within students or as a constructed resource but more as an emerging engagement between student and tool. Rhythm need not necessarily be viewed as a choice or a personal expression but as a expression of material interaction. Radford et al. also draw on a notion of form in expressing rhythm. They describe two levels of rhythm when students express 'one, one, plus three', 'two, two, plus three' and 'three, three, plus three'. They describe the first rhythm as the verbal expression of the four beats of one, one, plus, three, where single syllable words one, one, plus, three, repeated in the

next two expressions, indicate a level of rhythm in each single set of words. They refer as well to a rhythm of expression. That is, one, one plus three could be seen as beat one, two, two plus three as beat 2 and this beat 1, 2, 3 indicates a rhythm that can go on. While the first rhythm with words draws attention to repetition and to slight changes in that repetition, the second rhythm is about continuation and how each expression in its length, cadence and expression is the same, continuing with no end.

Roth (2011) has also explored rhythm, basing his critical approach on the concept of material body and metaphysical mind being distinct. He asserts that both are modalities of the flesh. His analysis is based not upon using new tools but upon focusing on people speaking and listening to each other. He argues that periodic features such as rhythm are produced and reproduced in interactions of verbal dialogues and that rhythm of speech is integral to the expression and recognition of knowing (p. 160). He identifies pauses in speech as important because they are part of speaking, the pauses giving temporal structure to the speech event. Roth further proposes that rhythmic phenomenon is not merely evident with individuals speaking or listening but that is also manifested collectively.

As a unit of analysis, rhythm, initiates a research practice that moves away from representationalism and pays attention to material force as a way to notice how and when it is expressed, how to account for changes, and how to highlight forms of knowing. In this study, rhythm is advocated as an emergence of form and structure when students engage in varying modalities of interacting. From this, further questions arise: What do we notice about the change in rhythms in an activity? How do rhythms begin, how do they end, and how do they connect to the meaning making practices in mathematics learning?

Methods

The research took place in a multi cultural grade 1 classroom with 26 students in a French speaking school in Western Canada. Grade 1 was selected for observation because the curriculum centered on number sense, particularly on one to one correspondence, skip counting, numbers in depth as well as addition & subtraction to 20. It was on this foundation and curricular outline *TouchCounts* was introduced. The teacher had been teaching for 7 years and had not used *TouchCounts* before. *TouchCounts* was subsequently used in addition to some other techniques that the teacher was familiar with such as using hundred charts, Gattengo charts as well as using her hands.

Two researchers, including myself, visited the class approximately once a week for three months. We videotaped the classes which were taught both by the teacher and by one of the researchers. The videotaping focused at time on the whole class and at other times when students worked together in pairs or triplets. Notes were taken during the research by one of the researchers, noting relevant events. Videos were analyzed later, focusing upon rhythms of sound and movement.

Data

Two episodes present different activities in which students are engaged. Not only is the organization of the activity different but the content is also different. The first sequence covering skip counting draws from a collective class activity using *TouchCounts*. The second is drawn from a group of three girls sharing an iPad using *TouchCounts* to create herds of five. What these two episodes contrast is the variations of rhythm that emerge in each scenario. While the rhythms need not be contrasted they do highlight how rhythms are unique in each context and how each rhythm has its own unique connection to mathematics.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Episode 1: Skip counting

With *TouchCounts* set up on the front projector and students sitting on the floor, one of the researchers was teaching the class and introduced skip counting (Figure 1). *TouchCounts* supports skip counting in a very rhythmical way because one successively touches above the shelf, below the shelf, above the shelf, below the shelf and so on. In this way, rhythm is established not only in a spatial and temporal way both above and below but also hints toward continuation. The researcher modeled how to create even numbers on the shelf by saying 'one down here,' touching below the shelf, 'one up here,' touching about the shelf, and so on until 2, 4, 6, 8, 10 were on the shelf. She then asked the students to verbally repeat the numbers and the students said 'two,' 'four,' 'six,' 'eight,' 'ten' in a very consistent beat. While the students were uttering the numbers, the researcher, turning slightly to point at the screen, was moving her hand toward each number when it was said and then moving her hand back as if she were pulling away from *TouchCounts* (Figure 2). The researcher could have just moved her hand horizontally, pointing at each number as her hand moved, but instead seemed to let the movement on the iPad affect her movements in the air as she pointed. After resetting *TouchCounts*, the researcher called up a volunteer from the class to put 2, 4, 6, 8, 10 on the shelf. As a student was going up to the iPad, a girl beside the researcher side lifted one hand to mimic the iPad, used her other hand to point towards the tops of her fingers and said, "one on the top" and pointed lower down towards her hand, saying, "one on the bottom.". It did not seem like a question but a confirmation that she would be able to do it.

Figure 1. Children sitting on floor.

Figure 2. Pointing at numbers.

The student who came up to the iPad put the numbers on the shelf in the exact consistent beat that the researcher had put the numbers on. The researcher asked the students to state the numbers again and the same rhythm and pointing of the researcher was enacted. Two more students came up

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

to put the even numbers on the shelf and followed steady, consistent, and in flow, in the exact rhythm. Each time the researcher asked the students to put one extra even number on the shelf. Each time the students read the numbers.

At one point a student was asked to point to the numbers as they were repeated. The pointing was as if she were using *TouchCounts*. She pointed and pulled away, pointed and pulled away, just like the researcher had done in the same timing as before.

When the fourth student was asked to put the even numbers on the shelf, the student put the number 2 in middle of the shelf. He matched the rhythm for his first two touches but then sped up for 3, 4, 5, 6, 7, 8 and then stopped because he was at the edge of the screen of the iPad. The class was quiet. After about 10 seconds, he fit 10 on by touching 9 below and 10 above in the same constant rhythm that had been established earlier. The researcher at this point indicated that he could put discs on the other side of the shelf. When moving to the left of the screen, he touched above the shelf and 11 landed on the shelf, the researcher asking if this was even. The student shook his arm in the air, back and forth, rhythmically, while the rest of the class, said no.

Episode 2: Making 5s in *TouchCounts*

After a class activity took place in which students sat on the floor and the teacher performed 'friends of five', which entailed holding up a number of fingers. Raising two fingers, she then asked how many fingers on her other hand should be held up to make five. After this activity, students moved to work with *TouchCounts*. A group of three girls could be seen making 'friends of five' in this episode. The first girl touched the screen with two fingers, a herd of two being instantly created. She looked at her fingers, making three, and touched the screen creating a herd of three. Combining the two herds, a herd of 5 had been created. A second girl then moved the herd to the right and then moved her hands back towards her body. After adjusting her hair, she touched the screen with one finger, creating a herd of one and then touched with four fingers creating a herd of four, she then combined them and moved the 5 to the right of the screen under the first 5 (Figure 3).
Figure 3. Second girl making herds.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figure 4. Third girl making herds.

These two girls established a rhythm. The timing of the movement was identical: touch once, look at fingers, touch again, combine, move to the side. The actions of the girls occurred in exact temporal alignment. The movement of their arms, the turning of the fingers, and the timing were all aligned thereby setting up a improvised but rhythmically negotiated approach to the activity. The third girl, however, did not match the rhythm of the previous two girls because she was interrupted. She touched the screen with two fingers and, as soon as she did that, the first girl moved her body toward the iPad, saying, 'You can't do the same as I did,' causing the third girl to not let go of the 'two' and just waited. An observing researcher attempting to prompt her with a question, asked, 'What can you add to two to make five?' She then touches three, combines the two numbers very slowly somewhat unsure of what may happen (Figure 4). The slowness is a new rhythm, possibly brought about by the interruption. As soon as a third girl created a five, the second girl from the previous turn-taking moved the five to the side and continued to repeat the same rhythm as before with the same timing and the same pattern of looking at her fingers.

Discussion

In the first episode, the mathematics was based upon skip counting. The rhythms that emerged were consistent among the researcher and the students. The consistent gestures that appeared, both in the touching of *TouchCounts* and the pointing at the numbers on the projector screen, remained within a very specific rhythmic pattern. Almost all the touching and pointing approximated the beat of the second hand on a clock. This rhythm addresses the notion of the social collective and how both the technology and social engagement with the technology had remained similar throughout the whole activity. It could be assumed that each student who participated in touching *TouchCounts* was mimicking what the researcher had done but this would imply that a mental intention is present as opposed to the improvisation alluded to by Roth (2011). Furthermore, if we see the student using technology to accomplish a goal, we lose sight of the central thinker in the interaction. While it might seem that the student is placing the numbers on the shelf in a very controlled way, this puts all important activity in the mind of the student. However, by seeing rhythm as a result of social becoming and as evidence of material engagement of a student-digital tool, we begin to see the importance of how rhythm carries students along. Rhythm seems to convey that a certain collectivity precedes knowledge.

As a researcher, I differentiate two different rhythms in this activity like Radford et al. (2007). The constant timing and movement of the above, below, above, below touching was a rhythm of repetition. As previously noted, this is important because it identifies a connection between social rhythm and personal rhythms. There is, however, also the unit of repetition that repeats which exists when the researcher, then one student after another, all express the same repetitive rhythm which has become a rhythm of continuity. This higher level rhythm gives a structure to the idea that the skip

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

counting can continue onward. Each student who was observed was requested to put one more even number on the shelf. Consequently, there were slight differences, not found either in the constant rhythm of touching the screen nor in their movements in how they touched the screen. The last boy who did not fulfill the task did not follow the rhythm of the previous students. He sped up, he stopped, and then moved to the left side of the screen of the iPad. This is evidence that there is room for variation of engagement leading to different expression of rhythm, thus highlighting the significant of the same rhythm set by the researcher and three students who followed her.

In the pointing at the numbers on the shelf, both the researcher and the student pointed in a unique way, one that had been established in using *TouchCounts*. Here we see how rhythm establishes itself in the activity. For the fourth student, spacing became important when we saw rhythm develop or breakdown. The student's rhythm had been interrupted so that a new negotiation with the technology was needed. However, the previous rhythm did not seem to want to provide any more time and so he touched with 11 and was incorrect.

In the second episode, the rhythm established by the first two girls indicated an alignment of meaning making. The fingers, making the 2, then the 3, then combining the 2 and the 3 and then moving 5 to the side, created a form of engagement that is mathematical. Although moving 5 to the side could be argued to be extraneous, the movement of the 5 as an object was an action that was not present in whole class activities. However, this movement in the rhythm, as a repeated step and within a temporal framing, was afforded by *TouchCounts* so that in moving the five as a step in the activity, the girls legitimized the herd of 5 as a mathematical object, demanding its own gesture and it own space. There is an important aspect here of how rhythm, improvised as it was, creates an opportunity of understanding the mathematical symbol as being more than something to look at or say its name. The rhythm creates an opportunity for the object 5 to be touched and moved, just as any material object could be. While this may happen without rhythm, one still wants to know how this could occur. Without being told by a teacher and without a reason to touch 5 and move it, one wonders if an activity could be thought up to support this new form of engagement. However, in the social negotiation of creating 5s, there was a need for space, and there is a strong argument in the rhythm of 2, 3, combine, move, and 1, 4, combine, move, that the repetition and the exact temporality plays a part in the creation of number beyond sight and sound.

The result for all three girls was the same. Each created a herd of five. However, the third girl had a unique rhythm after having been interrupted. After the interruption, each movement was unique. She touched the screen quickly but kept her hand on the screen, later combining 2 and 3 very slowly. Her rhythm did not match the previous rhythms but became an attempt to renew a form of engagement. The important point is that each student ended up with a herd of five but the differences in how the first two were achieved, compared with the third creation, draws attention to process as opposed to product. If rhythm is the process of engagement, the third girl had a different 'understanding' of combining 2 and 3 than the first two girls.

Conclusion

Mathematics can be seen as a set of propositions that can be acquired, stored and applied to different situations. This supports the idea of representation which raises the question as to whether this approach to learning and knowing is too dependent on interpretative mediation. Life and movement, according to critics of representationalism, do not reflect such stop-and-reflect kinds of practices. Inclusive materialism, a new materialism established in mathematics education, privileges material interactions as knowing. With new digital technologies, methods that align with theoretical materialist approaches are needed to understand mathematical classroom practices. In the present study, rhythm was formulated as a correlative between new technologies and the social and the personal.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

In early education, counting is very much rooted in a rhythmic expression. However, new technologies support new rhythms. More specifically, the use of TouchCounts, both in a whole class activity and in a smaller group, enables the creation of a rhythm which provides an opportunity to experience mathematics within the context of an improvised and unique structure. In conformity with inclusive materialism, rhythm as an unfolding emergence is an expression of living forces and materials. In this study, we have seen TouchCounts provide new ways of engaging with skip counting. A gestural approach attends students both to the skip counting pattern and to the numbers that are skipped as well as to the temporal aspect of developing a sense of sequence. In adding 2 and 3, a new engagement with the number 5 emerges, not solely because of the affordances of the technology but because of the emergent improvised rhythms that create a need for such an interaction. Rhythm can help anticipate what is to come. Teachers may use emergent rhythms as a way of understanding collectivity or individuality, noticing as well how the in-the-now rhythm structures affect the rhythm that is to come.

This research report presents the results of a STEM summer program on robotics and game design. The program was part of a three-year study funded by the National Science Foundation. Children in grades four through six participated in a two-week summer camp in 2015 to learn STEM by engaging in LEGO® EV3 robotics and computer-based games using Scalable Game Design. Twenty-eight students participated in the study that took place in a small urban community in the Rocky Mountain West. This paper reports on the results of this part of the study, specifically, how children's computational thinking skills developed and how their self-efficacy in technology, attitude toward engineering and technology, and 21st century skills changed as a result of their participation.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Informal Education

According to the Bureau of Labor Statistics, U.S. Department of Labor (2016), the need for mathematicians, computer systems analysts, and biomedical engineers is projected to grow from 21-23% by 2024. Preparing students to succeed in mathematics and technology is crucial to ensuring access to these and other STEM occupations of the future. Moreover, the number of engineering students is not increasing and in some instances is declining while the demand for engineers is expected to continue to grow (Hirsch, Carpinelli, Kimmel, Rockland, & Bloom, 2007). One reason that students are not choosing to study engineering is lack of information about the field, what it entails, and what engineers do (Hirsch et al., 2007). Exposing underrepresented students to pre-engineering skills through robotics and game design has the potential to increase their interest and to provide them with the skills needed to broaden participation to create a diverse STEM workforce (National Research Council (NRC), 2011).

To address this need in STEM education, a student- and teacher-focused project funded by the National Science Foundation was implemented in Wyoming. The goals of the three-year quasi-experimental study were to examine how spatial reasoning, computational thinking, children's self-efficacy in technology, and attitudes toward STEM and STEM careers changed as a result of participation and how well teachers implemented the STEM program. Specifically, we provided students with access to LEGO® EV3 robots, its accompanying software MINDSTORMS®, and Scalable Game Design software and protocols (Repenning, Webb, & Ioannidou, 2010; Webb, Repenning, & Koh, 2012). Teachers received training to deliver the instruction through an online professional development course.

The purpose of the two-week summer program was to field test the double effect of teaching both gaming and robotics to improve students' spatial visualization and computational thinking skills. Robotics and game design have not only been extolled for their role in learning but have also been identified as pathways to broaden participation in STEM and STEM-related careers (Caron, 2010; Sheridan, Clark, & Williams, 2013). We implemented the summer program to inform Year 3 deliverables. In Year 1, we piloted the instruments and the iterative project model. In Year 2, teachers taught robotics in the fall and game design in the spring to measure the effect of a single treatment. The research questions that guided this part of the study were as follows:

1. How did students' self-efficacy in technology, attitudes toward engineering and technology, and 21st century skills change as a result of engagement in robotics and game design?
2. How did children's computational thinking (CT) compare and contrast on Maze Craze, Frogger, and Pac Man games?
3. What learning preferences and STEM interests did students report during focus group interviews?

Theoretical Framework

The framework that undergirds this study is Learning-for-Use (LfU) (Edelson, 2001). LfU is a technology design framework that is based on four principles: (a) knowledge construction is incremental in nature, (b) learning is goal directed, (c) knowledge is situated, and (d) procedural knowledge needs to support knowledge construction (Edelson, 2001). These principles inform robotics applications and game design and lend themselves to the interventions implemented in this study.

The first and fourth principles of the LfU model are the incremental development of new knowledge and procedures. The goal behind the progression of two intervention components—robotics and game design— is to engage students in an incremental process. This idea allows students to incrementally add new concepts to memory, while subdividing existing concepts or making new connections between concepts. Procedural strategies for supporting and reinforcing incremental learning include observation, discussion, reflection, and application. New knowledge informs and empowers students to become proactive in their own learning. In its second and third principles, LfU recognizes that acquisition of knowledge is goal directed and situated. The realization of gaps in one's knowledge, perhaps as the result of an elicited curiosity or external demand, can be used as a motivational goal for acquiring new knowledge. The intervention was designed to encourage goal-directed tasks as students created computer games to learn and apply spatial reasoning and computational thinking skills, which are needed for computer science and information and communications technology (ICT) careers.

Literature Review

The bodies of literature that support this study are robotics and digital gaming. The literature that support this study is presented below.

Robotics

Robotics programs have resulted in an increase in students' comfort level with applications of STEM, development of 21st century skills, and increased interest in pursuing STEM-related programs beyond high school (Brand, Collver, & Kasarda, 2008). LEGO® robotics, specifically, is widely used in K-8 settings as an authentic and kinesthetic way to improve children's problem-solving skills, reinforce science applications and concepts, and build upon informal learning activities often done at home (Karp & Maloney, 2013). Informal STEM experiences in robotics extend students' experiences into alternative spaces where there is greater potential for learning to be "...self-motivated, voluntary, and guided by the learner's needs and interests" (Dierking, Falk, Rennie, Anderson, & Ellenbogen, 2003, p. 109). In this study, robotics provided students with opportunities to engage in authentic learning, inquiry, and scientific processes such as observing and recording data, evaluating and providing feedback, and using evidence to revise thinking, planning, and actions.

Digital Gaming

Digital game playing has also been used successfully to teach mathematics problem solving (Chang, Wu, Weng, & Sung, 2012) and can be used as a social practice to support the development of "strategic thinking, planning, communication, application of numbers, negotiating skills, group

decision-making, and data-handling" (Li, 2010, p. 429). Studies revealed that children showed considerable improvement in regard to developing positive attitudes toward learning mathematics through gaming (Kebritchi, Hirumi, & Bai, 2010). Using digital games in mathematics classrooms has led to favorable attitudes toward learning mathematics and to increases in mathematics achievement and student success. Several studies explore the use of games to improve student learning and computational thinking (Li, 2010; Repenning et al., 2010; Webb et al., 2012). For example, Scalable Game Design (SGD) project consists of instructional units to support game computational thinking through the use of game designs such as AgentSheets and AgentCubes (Repenning et al., 2010).

Methodology

Participants and Setting

Twenty-eight students (23 males; 5 females; 4 underrepresented minorities; and 4 students with disabilities) were recruited into the program. The two-week summer camp was held in August 2015 at the Starbase facility (Starbase is a Department of Defense program that seeks to motivate fifth-grade students to explore STEM through inquiry-based curriculum) in Cheyenne from 9 a.m. – 3 p.m., Monday – Friday with morning and afternoon breaks and a 1-hour lunch and recess. We ran two concurrent classes—one on robotics and the other on game design—with 14 students each. Students switched classes in the afternoon to receive four hours of instruction on robotics and game design each day.

The main instructor for the robotics class was an engineer at Starbase. The principal investigator was the main instructor for the game design class. Lesson plans in the robotics course focused on using MINDSTORMS® to engage in basic programming to incorporate ultrasonic sensors, color sensors, and touch sensors. Students used LEGO® EV3 robotic kits while working in pairs to make the basic car, two- and three-wheeled rovers, and a sumo bot that were programmed to traverse a color-coded map, race on a simulated track, or bot fight in a ring, respectively. Lesson plans in the game design class focused on guiding students to create Maze Craze, Frogger, and Pac Man games using Scalable Game Design.

Data Analyses and Data Sources

Mixed methods were used to analyze quantitative and qualitative data in this phase of the study. The Self-Efficacy in Technology and Science instrument (SETS) developed by Ketelhut (2010) was used in this study. Self-efficacy as defined by Bandura (1977) is the belief that one can successfully perform specific tasks. We administered three of the SETS subscales to measure students' self-efficacy in technology: videogaming (8 items), computer gaming (5 items), and using the computer to solve problems (5 items). Cronbach alpha reliability ratings ranged from 0.79 to 0.93, which were in the acceptable range. The Student Attitudes toward STEM survey developed by the Friday Institute (2012) was modified to include two subscales: engineering and technology (9 items) and 21st century skills (11 items). Cronbach alpha coefficients were in the acceptable range ($\alpha > 0.83$). A 5-point Likert scale that ranged from 1 (strongly disagree) to 5 (strongly agree) was used to rate items on the SETS and the Student Attitudes toward STEM surveys. The T-statistic was used to analyze pre-post scores on these surveys. The confidence interval was .95, and statistical significance was established at $\alpha = .05$.

Computational thinking (CT) was analyzed using a rubric developed by the principal investigator to rate students' games. A three-point rubric was established with an interrater reliability of 86%. Scores on the rubric ranged from 1 for emerging, 2 for moderate, and 3 for substantive evidence of CT. Focus group data were collected the final week of the summer camp during an interview with several randomly selected students. These data were analyzed using the constant comparative method

(Strauss & Corbin, 1990) to identify emergent themes and patterns related to the participants' learning and interest in STEM. Finally, two members of the research team collected field notes and conducted classroom observations.

Results

Self-Efficacy, Engineering/Technology Attitude, and 21st Century Skills

Twenty-one students completed the pre-post surveys. The data (see Table 1) reveal no significant differences on the SETS for computer gaming and computer use. However, there was a significant decline on the videogaming subscale: ($t = 2.126$; $p = 0.046$; Cohen's $d = 0.477$). Cohen's d shows a moderate effect size for this decline. While pre-post scores increased on Attitudes toward Engineering and Technology (M = pre: 3.87 (Std. Dev.: 0.80); post: 3.93 (Std. Dev.: 0.72)) and 21st Century Skills (M = pre: 4.12 (Std. Dev.: 0.72); post: 4.24 (Std. Dev.: 0.65)), results of a paired t-test show no statistically significant differences on either subscale.

Table 1: Results of Self-Efficacy in Technology Scale by Cohort

Construct (n=21)	Pre-Survey Mean	Standard Deviation	Post-Survey	Standard Deviation
Videogaming	4.32	0.59	4.20*	0.65
Computer gaming	4.08	0.76	4.04	0.68
Using the Computer	4.05	0.99	4.04	0.80

* $p < 0.05$

Computational Thinking

Descriptive statistics were also used to rate students' games for computational thinking using a 3-point rubric. Students were taught how to design three different types of games: Maze Craze, Frogger, and Pac Man. To analyze students' games, we evaluated the students' code, worksheets, and game functionality using the six International Society for Technology in Education (ISTE) definition for CT (i.e., problem formulation; abstraction; logical thinking; algorithms; analysis and implementation; and generalization and transfer). The majority of students completed the Pac Man game, which was the most difficult of the three games.

The results of analyzing the Pac Man game show that four students exhibited emerging CT strategies (threshold from 1 – 1.5), nine students exhibited moderate CT strategies (threshold from 1.6 to 2.5), and five exhibited substantive CT strategies (threshold from 2.6 to 3.0). Thus, the majority of students exhibited moderate or substantial CT strategies on one of the most difficult games. To further understand CT on all of the games, we completed additional analysis on four focal students (all names pseudonyms) using the same rubric described above. They were randomly selected from among eight students who completed all three of the games. The descriptive data are shown in Figure 1.

Figure 1. Focal Students' Computational Thinking Scores by Game Type**.**

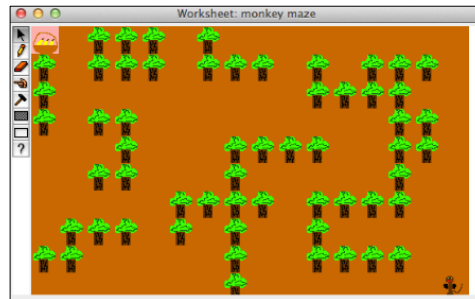
Interestingly, Kate and Latrice, who were underrepresented females in a class that was predominantly male, showed greater levels of computational thinking than their male counterparts on two of the games. Latrice, who was also a student with disabilities, had the highest average CT score. When these data are analyzed by game type, the Pac Man game had the highest average CT rating (M = 2.00) compared to Maze Craze (M=1.92) and Frogger (M=1.92). Overall, mean scores support the finding that the CT scores of students in the summer cohort fell into the moderate range. Screenshots of each type of game are shown in Figures 2-4.


Figure 2. Maze Craze Screenshot (Kate).
Figure 3. Frogger Screenshot (Latrice).

Figure 4. Pac Man Screenshot (Devon).

Qualitative data included excerpts from a questionnaire during focus group interviews with seven randomly selected student participants. The focus group interview with two girls and five boys was transcribed verbatim. Portions of the transcribed interview are presented below:

Interviewer: What one or two things did you think were cool about participating in robotics?

Student 1: What I thought was cool about…robotics was that we got to build our own robots and try out different things with our sensors, and we got to activate our robots….

Student 2: I liked building the robots, and I also liked programming the robots and finding out how far you could make the thing go.

Student 3: I liked it so much I have been to Starbase three times…two camps and once at school.

Student 4: I like building robots and putting on the sensors.

Interviewer: What one or two things did you think were not so cool about robotics?

Student 1: What I did not think was so cool about the robots was that we had to do certain steps, like we struggled through, and it was hard. I think they should make it easier.

Student 4: They should try to bring in people that have jobs with robots to help us out. That would be helpful.

Interviewer: How many of you are doing robotics for the first time? Oh, one. How many for the second time? Three. And how many are pros? What! Oh, all of the rest of you.

Interviewer: What one or two things did you think was cool about gaming?

Student 3: What I liked about the gaming was that we learned how to make our own avatar thing out the little pixels, and programming was fun, too.

Student 4: I get to create my own game. Just creativity, and you can actually play the game.

Student 6: I like what we are doing right now with Pac Man. My favorite game was my first game. I made snakes, and it was really fun. I think snakes are cool.

Student 7: I like how you can make it impossible for people to beat your game and that the teacher told me she never tried [a game like mine] before.

Student 2: I don't really like doing gaming. I like putting things together. It was really hard for me. The computer did not work very well. This is the first time [doing gaming].

Interviewer: How many of you are doing gaming for the first time. (Hands raised.) Oh, all of you are doing this for the first time.

Student 7: Gaming was not as easy as robotics. It's hard to follow the instructions. You can easily get confused and can do something wrong….

Themes and patterns were found in the qualitative data. The first theme—*building* robots—emerged among three of the seven students. Two students mentioned enjoying the sensors. A second theme that emerged from the transcribed data was *creating* or *programming* robots or games. Three students mentioned *creating* or *programming* explicitly, while two others were implicit in their references to creativity: *"I made snakes, and it was really fun; I like how you can make it impossible to beat your game."* The third emergent theme was the level of difficulty involved in programming

either robots or designing games. Three students stated "*it was hard*" and that specific steps had to be followed to make the robot move or to create games. The final theme that emerged was *prior knowledge* and *experience* with robots. However, none of the students had prior experience with game design. The novelty and high learning curve for developing computer games influenced students' attitudes toward videogaming and computer gaming, even though most of the students mentioned they enjoyed playing several off-shelf computer games (i.e., Mario, Minecraft, etc.) before participating in the study. While only one student mentioned the importance of having *STEM professionals* as guest speakers, this was a good suggestion in terms of helping students understand different aspects of engineering and technology and could improve their aspirations to pursue a STEM career.

Discussion

The results of this study reveal a great deal about student efficacy, computational thinking, and student interest in robotics and game design. The data suggest these children self-selected the summer camp because they had a high interest in robotics, gaming, or both. Their pre-scores on the surveys were high, indicating that results may have been impacted by a ceiling effect. While non-significant, STEM attitude scores in engineering and technology increased slightly along with 21st century skills. The highest score on the SETS survey was videogaming, but the scores declined significantly from pretest to posttest. Focus group data suggest some reasons for the decline, including a preference for robotics over game design, the difficulty in following directions to make the game, and making games that were impossible to win. One of the survey questions on the videogaming subscale specifically addressed students' efficacy as it related to winning a game. Most of the students' scores declined on this item after participating in the program. While the sample is small, we noticed that some girls were active gamers, and one female student with Asperger's Syndrome enjoyed game design and benefited from the step-by-step process. Moreover, an examination of her code revealed a departure from the SGD protocol to include her own nuances. Her game (see Figure 3 above) was judged as one of the most creative by her peers during a showcase on the final day of the camp.

In terms of developing computational thinking, focus group data suggest CT scores may be correlated with interest, enjoyment, and exposure to game design. None of the students had participated in game design before the summer program while almost all of them had prior experience in robotics. Field notes and classroom observations revealed most of the students in the program enjoyed working on robotics and playing each other's games. Engagement in robotics and gaming provides opportunities for students to engage in STEM content and creates pathways to STEM careers (Caron, 2010; Sheridan et al., 2013).

Significance

The findings presented in this research report informed the project team about the importance of combining the treatments of robotics and game design to increase students' spatial reasoning and computational thinking skills prior to implementing the Year 3 study. Instruction in both robotics and game design courses should be made more explicit (to be addressed during professional development). While minorities, females, and students with disabilities had high engagement, they were underrepresented in the program. This is an important finding that needs to be explored further. Recruiting females and other underrepresented students has been difficult in informal STEM programs (Leonard, J. Buss, A., Gamboa, R., Mitchell, M., Fashola, O. S., Hubert, T., et al., in press; Repenning et al., 2010), particularly in rural settings. This study is no exception. Perhaps using intact classrooms, as suggested by Webb et al. (2012) is one important mechanism for broadening participation. Our work is ongoing and will culminate in 2017.

ESCENARIOS DE APRENDIZAJE Y EL USO SISTEMÁTICO DE TECNOLOGÍAS DIGITALES EN AMBIENTES DE RESOLUCIÓN DE PROBLEMAS

LEARNING SCENARIOS AND THE SYSTEMATIC USE OF DIGITAL TECHNOLOGIES IN PROBLEM SOLVING ENVIRONMENTS

aguilarm@cinvestav.mx

Existing technologies pose challenges for the education system related to what contents, strategies and skills students should learn and what types of teaching scenarios should be considered in learning. In this study, prospective high school teachers were encouraged to systematic use various digital technologies in a problem solving course during one semester. Results indicate that the participants developed and implemented a set of strategies and ways of thinking that complement and extend the approaches based on the use of pencil and paper. In addition, the use of technology allowed the participants extend mathematical discussion beyond formal settings.

Palabras clave: Resolución de Problemas, Tecnología, Maestros en Formación

Introducción

En los últimos diez años, el rápido desarrollo y disponibilidad de tecnologías digitales han cambiado sustancialmente la manera de interactuar de los individuos, las formas de comunicarse, obtener información y de realizar varias actividades cotidianas. Por ejemplo, con un dispositivo móvil (tableta o teléfono inteligente) es posible consultar información en línea, leer un periódico o, por medio de una aplicación, contratar los servicios de un taxi, reservar una habitación de hotel o conocer la ruta más eficiente para viajar de un lugar a otro. Las tecnologías existentes plantean retos para el sistema educativo relacionados con los contenidos, estrategias y habilidades que los estudiantes deben aprender y sobre qué tipos de escenarios de enseñanza se deben considerar en el aprendizaje. En este estudio interesa analizar y documentar los elementos de un escenario de aprendizaje donde los participantes utilizan diversas tecnologías digitales en un ambiente de resolución de problemas que promueve la interacción entre pares, el trabajo colaborativo y la extensión y solución de los problemas matemáticos planteados.

Para guiar este estudio se planteó la siguiente pregunta de investigación: ¿Qué formas de razonamiento construyen y exhiben un grupo de profesores de Bachillerato en formación cuando utilizan diversas herramientas (GeoGebra, Google Classroom, Padlet) en un ambiente de resolución de problemas? En particular, existe interés por documentar en qué medida el uso de herramientas para compartir información en línea (Padlet) puede ayudar a los estudiantes a modificar sus acercamientos iniciales de solución y desarrollar nuevas formas de explorar y extender los problemas a partir de trabajarlos con el Sistema de Geometría Dinámica (SGD) GeoGebra.

Marco conceptual

El estudio se sustenta y estructura a partir de tres áreas o dominios relacionados: (i) la idea de problematizar el aprendizaje de las matemáticas como principio básico en la resolución de problemas, (ii) el uso sistemático y coordinado de diversas tecnologías digitales en los procesos de representación y exploración de los conceptos matemáticos, y (iii) el diseño de las tareas como vehículos para organizar y promover el desarrollo del conocimiento matemático de los estudiantes.

La resolución de problemas y la actividad de interrogar o cuestionar

Un principio básico en una perspectiva de resolución de problemas es que los estudiantes desarrollen un enfoque inquisitivo para desarrollar y utilizar los conocimientos matemáticos. En este proceso, el aprendizaje de las matemáticas se concibe como una actividad de búsqueda de sentido en la que los estudiantes constantemente formulan y responden preguntas como una manera de representar, explorar, comprender y resolver situaciones matemáticas. Este principio es consistente con lo que Hiebert, et al. (1996) refiere como permitir que los estudiantes problematicen los temas o contenidos como una manera de profundizar y reflexionar sobre los conceptos matemáticos, esto significa "permitir que los estudiantes se pregunten porqué las cosas suceden, para indagar, para buscar soluciones, y para resolver las incongruencias" (p. 12), los autores utilizan el término problematizar en el sentido de que a los estudiantes se les debe permitir y alentar a problematizar lo que estudian, para definir los problemas que provocan sus curiosidades y habilidades para crear sentido. Por su parte Postman y Weingartner (1969), argumentan:

El conocimiento se produce en respuesta a preguntas. [...] Una vez que ha aprendido cómo preguntar -preguntas relevantes, apropiadas y sustanciosas- el estudiante ha aprendido cómo aprender y ya nadie lo puede detener en el camino de seguir aprendiendo lo que necesite y quiera conocer (p. 23).

El uso coordinado de herramientas digitales en la resolución de problemas matemáticos

Santos (2007) reconoce la importancia de que los estudiantes problematicen el estudio de la disciplina. Es decir, resulta esencial que los estudiantes formulen preguntas cuando se encuentran resolviendo problemas o intentan comprender ideas matemáticas, que utilicen distintas representaciones, busquen conjeturas y relaciones y donde el uso de distintas herramientas digitales les ayude a explorar y sustentar sus argumentos con acercamientos que pueden ir desde aspectos empíricos hasta acercamientos formales. El uso coordinado de varias herramientas digitales ofrece a los estudiantes diversas maneras de identificar, formular, representar, explorar y resolver problemas desde varias perspectivas (Santos-Trigo y Reyes-Martínez, 2016). El amplio desarrollo de tecnologías digitales implica decidir cuáles y cómo utilizarlas en los ambientes de aprendizaje con el objetivo de que los estudiantes comprendan conceptos matemáticos y resuelvan problemas. Santos (2007) sostiene que el uso sistemático de herramientas digitales en la construcción del conocimiento matemático de los estudiantes no sólo influye en la manera de presentar y explorar con las ideas matemáticas sino también en las formas de razonar, sustentar y presentar relaciones o propiedades matemáticas. También, Santos-Trigo y Ortega-Moreno (2013) documentan que las tecnologías digitales no solo extienden las representaciones y estrategias que aparecen en acercamientos basados en el uso de lápiz y el papel sino que generan nuevas formas de razonamiento para desarrollar conocimiento matemático.

Así, el uso de varias herramientas digitales ofrece diferentes oportunidades para que los estudiantes formulen y discutan preguntas que puedan guiarlos hacia la representación y exploración de las tareas matemáticas desde perspectivas distintas y complementarias pero también ofrecen a los profesores nuevas formas de organizar el trabajo el clase, para gestionar las tareas y materiales con mayor eficiencia, para mantenerse en constante comunicación con sus estudiantes y para crear ambientes que permitan extender la discusión de los problemas más allá del aula. En esta perspectiva, los problemas y el ambiente que se genere al resolverlos son aspectos cruciales para guiar y promover el desarrollo del conocimiento matemático y el aprendizaje de los estudiantes.

La importancia de las tareas matemáticas

En el marco de la resolución de problemas, las tareas o problemas representan un punto de partida y una oportunidad para que los alumnos busquen diferentes representaciones y formas de

resolverlas y ampliarlas, son un ingrediente fundamental para que los profesores guíen, fomenten y analicen los procesos que realizan los estudiantes en la construcción o desarrollo de un pensamiento matemático. Hiebert y Wearne (1993) afirman que "lo que los estudiantes aprenden se define en gran medida por las tareas que se les dan" (p. 395). Para Mason y Johnston-Wilder (2006), el objetivo de las tareas es hacer que los estudiantes participen de manera activa en la creación de sentido y en el desarrollo de sus habilidades matemáticas. Por lo tanto, las tareas son el vehículo para que los estudiantes comprendan los conceptos y desarrollen formas de pensamiento consistentes con el quehacer de la disciplina.

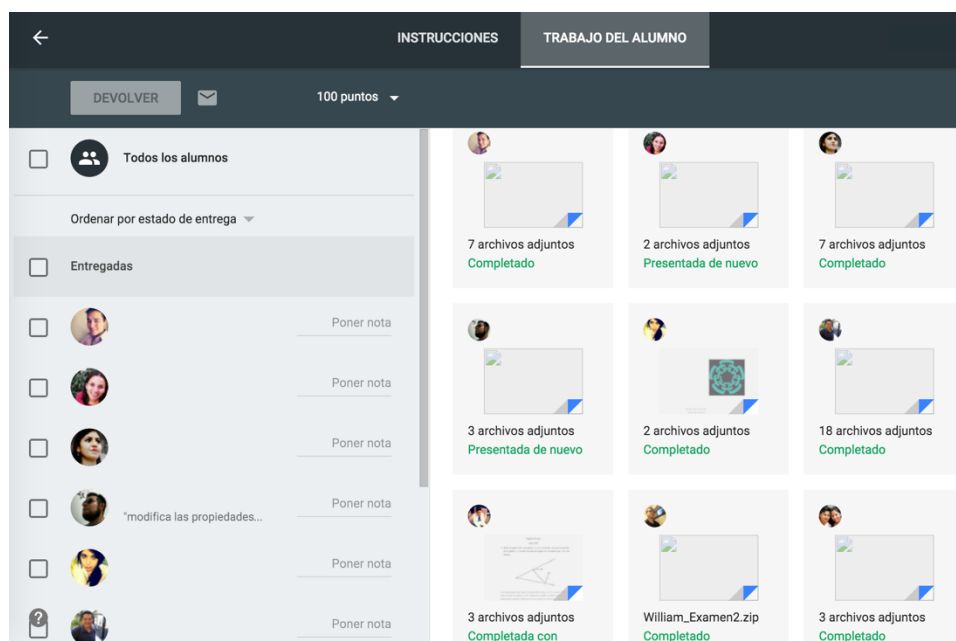
Se argumenta que el uso coordinado de diversas herramientas digitales ofrece a los estudiantes la oportunidad de ampliar las formas de razonar y trabajar los problemas y brindan la posibilidad de organizar, identificar y acceder a cierta información relevante en línea en todas las etapas de la resolución de problemas.


Figura 1. La plataforma se utilizó para enviar notificaciones a los estudiantes, compartir materiales y retroalimentar las tareas.

Participantes, problemas y procedimientos

En este trabajo se describen los elementos de un entorno de aprendizaje que busca extender las interacciones que ocurren en una aula tradicional de matemáticas. En este nuevo escenario se busca que los participantes usen de forma sistemática y coordinada un conjunto de tecnologías digitales en la resolución de problemas matemáticos. Tecnologías como: un SGD (GeoGebra) para explorar y representar los problemas de forma dinámica, una plataforma para administrar los contenidos y gestionar las tareas (Google Classroom, Figura 1), un muro digital (Padlet) para compartir ideas y nuevos acercamientos de solución y hacerlos accesibles durante el proceso de resolver problemas, servicios de Internet (Wikipedia, WolframAlpha, YouTube, KhanAcademy) para acceder, seleccionar y discriminar información relevante durante todas las etapas de resolución de problemas, una tableta (iPad) como principal medio de comunicación y acceso a información y contenidos interactivos (iBooks) y un servicio de mensajería instantánea (Google Hangouts) para comunicar y compartir información de forma eficiente con sus compañeros así como participar en una comunidad de aprendizaje en donde se discutan y compartan ideas y estrategias que les permitan resolver las tareas matemáticas.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Para esta investigación participaron nueve profesores en formación inscritos en un curso de un semestre de resolución de problemas que formaba parte de un programa de maestría en educación matemática. Todos los participantes tenían un grado universitario en el área de matemáticas y se encontraban cursando el segundo semestre del programa. El curso incluía dos sesiones de tres horas cada una durante un semestre. En el desarrollo de las actividades se intentó que los participantes desarrollaran una actitud inquisitiva, la cual consiste, fundamentalmente, en el hábito de formular y discutir constantemente preguntas acerca de una situación y que siempre se buscaran diferentes formas de explorar y resolver los problemas con el uso sistemático de un conjunto de herramientas digitales.

En este contexto los problemas representaron un punto de partida para que los estudiantes se involucraran en una reflexión matemática que se extendiera más allá del aula y que les permitiera, inicialmente, resolver el problema y posteriormente buscar otras relaciones o resultados. En este sentido, el uso de herramientas digitales ofrece a los estudiantes oportunidades de participar en situaciones que los involucren en la formulación de conjeturas, la exploración de relaciones matemáticas, la creación de nuevos problemas, la extensión y generalización de las condiciones iniciales (Autores, 2015). Para este reporte, nos enfocamos en la discusión de un problema implementado a la mitad del semestre.

El problema. Dada una circunferencia *c* y un segmento *a*, construir un rombo de lado *a* de tal manera que la circunferencia *c* quede inscrita en ese rombo.

Este problema se planteó a los profesores como parte de una evaluación que consistió en tres etapas. En la primera etapa los estudiantes trabajaron de forma individual durante tres horas, durante este periodo utilizaron diferentes herramientas digitales para explorar el problema. Todos los participantes utilizaron GeoGebra para construir sus modelos dinámicos, esto resultó crucial para representar y explorar los objetos matemáticos involucrados en la construcción del rombo. Otra de las herramientas que fue utilizada por todos los participantes fue Wikipedia, mediante esta enciclopedia en línea pudieron consultar información (como definiciones, teoremas, propiedades y formulas: https://es.wikipedia.org/wiki/Rombo) que contribuyó a que los participantes comprendieran y le dieran sentido a la tarea. En la segunda etapa de la actividad se pidió a los estudiantes que compartieran en Padlet las ideas que utilizaron en sus exploraciones individuales, esto con el objetivo de crear un repositorio de ideas que pudieran ser utilizadas posteriormente por los demás participantes para explorar el problema. Por último, se pidió a los estudiantes que exploraran el problema a partir de las ideas compartidas por sus compañeros en el muro, con esa información los participantes se volvieron a enganchar en la exploración del problema, esta actividad la realizaron durante una semana.

Primera etapa. Trabajo individual. Al término de la sesión de trabajo individual, se reportaron 14 soluciones diferentes, que incluyen acercamientos empíricos, algebraicos, trigonométricos y geométricos. En esta sección se muestra el acercamiento más representativo que surgió durante esta sesión.

Cinco participantes construyeron el mismo modelo dinámico trabajando de forma independiente, para ello utilizaron la heurística de *relajar las condiciones iniciales del problema*, de esta manera construyeron un rombo cuyos lados tuvieran longitud *a* y luego hicieron que los lados fueran tangentes a la circunferencia *c*. Ubicaron el punto E sobre el eje *y* y trazaron una circunferencia de radio *a* que interseca al eje *x* en los puntos F y G, después reflejaron E respecto a A para encontrar el punto E', de esta manera se consigue una representación parcial de a solución (Figura), el rombo de vértices EFE'G tiene los 4 lados congruentes (de longitud igual al segmento *a*), al mover el punto E es posible visualizar una posición en la que la circunferencia *c* esté inscrita al rombo EFE'G, para que eso ocurra los lados del rombo deben ser tangentes a la circunferencia *c*. ¿Cómo se logra esta construcción?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figura 2. El rombo EGE'F es una representación parcial.
Figura 3. En naranja se muestra el lugar geométrico de los puntos H, T, I y U.

Al trazar rectas perpendiculares a los segmentos *e* y *b* por el punto A, éstas se intersecan con los lados del rombo se obtienen los puntos H, T, I y U (Figura 3). El lugar geométrico que describen los cuatro puntos cuando se mueve el punto E sobre el eje *y* se muestra en color naranja. Las intersecciones del lugar geométrico y la circunferencia *c* marcan las posiciones en las que los segmentos del rombo serán tangentes a la circunferencia *c*. Debido a la simetría del rombo y la circunferencia, este problema se puede simplificar y explorar solo en uno de los cuatro cuadrantes. Si centramos la atención en el primer cuadrante, se puede observar que el lugar geométrico que describe I interseca a la circunferencia *c* en dos posiciones, marcando así las dos soluciones del problema (Figura 4 y Figura 5).
Figura 4. Primera solución**.**
Figura 5. Segunda solución**.**

Segunda etapa. Ideas compartidas en Padlet. Después de trabajar de forma individual en la construcción del rombo, se pidió a los participantes que compartieran en Padlet las ideas medulares de sus exploraciones individuales. Se hizo hincapié en que no compartieran las soluciones sino las ideas que los llevaron a construir los modelos dinámicos. En la Figura 6 se muestra una parte del muro digital en el que se compartieron las ideas que se utilizaron para resolver el problema del rombo.

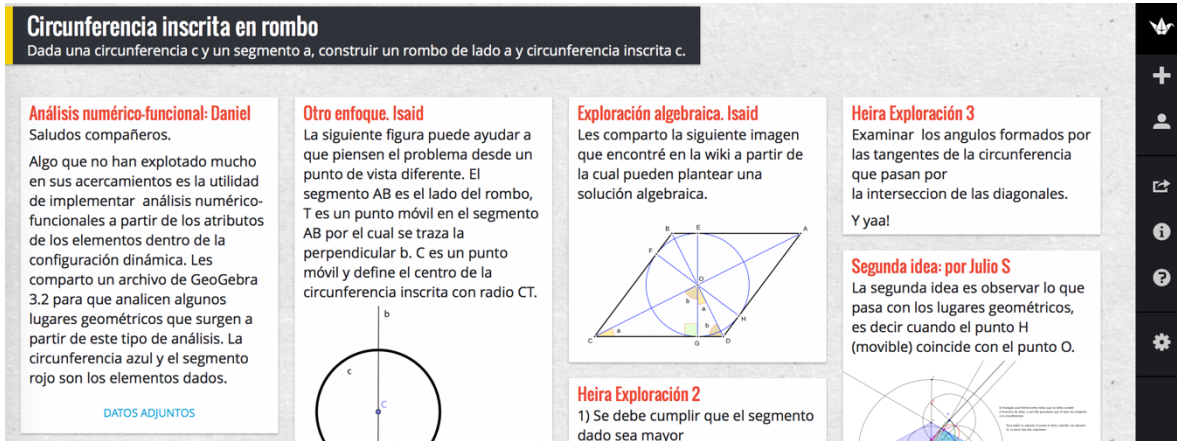
Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.


Figura 6. Muro que contiene todas las aportaciones hechas para el problema del rombo.

En total se compartieron 25 ideas en el muro (http://es.padlet.com/isaid/rombo). Se pidió a los participantes que seleccionaran algunas de las ideas de sus compañeros y que volvieran a explorar el problema a partir de esas ideas.

Tercera etapa. Exploraciones a partir de las ideas compartidas en el muro. Tres de los 9 participantes no lograron construir un modelo dinámico, fue hasta que tuvieron acceso a las ideas de sus compañeros que lograron resolver el problema. A continuación se muestra una solución que parte de una idea que se compartió en el muro. La Figura 7 hace referencia a una propiedad importante de los rombos: *La altura del rombo es igual al diámetro de la circunferencia inscrita*. Esta idea fue recuperada por una de las participantes que no había conseguido resolver el problema durante la primera etapa. En la Figura 8 se obtienen de forma algebraica los vértices y el centro del rombo a partir de construir un triángulo rectángulo de atura *2r*, base *x* e hipotenusa *a*. La participante utilizó deslizadores para variar los valores de *r* y *a*, esto le permitió definir el valor mínimo de *a* como *2r*, de esta manera siempre es posible construir el rombo.

Figura 7. Idea compartida por Karen.
Figura 8. Solución algebraica a partir de considerar la idea compartida por Karen.

Todos los participantes mostraron una marcada participación respecto al número de soluciones que reportaron después de la exploración de las ideas del muro, en especial los que no habían podido resolver el problema por si solos. Resalta el caso de una participante que durante la primera etapa (trabajo individual) presentó 4 exploraciones en las que no pudo obtener una solución, tras explorar el problema a partir de las ideas del muro presenta quince exploraciones que incluyen dos soluciones que no surgieron durante la primera etapa.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Comentarios. Durante esta actividad se resalta el caso de una participante que durante la sesión de trabajo individual no logró resolver el problema, después de realizar 4 intentos, pero despés de tener acceso al muro consigue presentar 15 exploraciones exitosas que incluyen dos soluciones que no se presentaron durante la sesión de trabajo individual. En este sentido, el muro digital le permitió a la participante recuperarse de intentos no exitosos y retomar ideas del muro que la llevaron a presentar varias soluciones al problema.

Conclusiones

Durante este reporte se ha argumentado que el uso de un SGD (GeoGebra) por parte de los profesores en formación puede depender de las *affordances* de la herramienta para construir y explorar los modelos dinámicos de las tareas matemáticas. Esta exploración los llevó a observar invariantes, patrones y relaciones entre los elementos de los modelos. Del mismo modo, el uso de las tecnologías de comunicación permiten que los participantes extiendan y continúen con las discusiones matemáticas más allá del salón de clases. De esta manera las discusiones pueden ocurrir prácticamente en cualquier lugar, sin limitaciones de tiempo y espacio.

Con el uso de las tecnologías digitales es posible restructurar y extender los ambientes tradicionales de los salones de clase, promoviendo que los estudiantes continúen trabajando, explorando, interactuando y reflexionando de forma continua virtualmente desde cualquier sitio sin limitaciones de tiempo y espacio. Para ello es importante que los estudiantes desarrollen formas de pensar y trabajar en esos ambientes que les permite el desarrollo de habilidades para utilizar de manera coordinada un conjunto de herramientas digitales.

De esta manera, el uso coordinado de diversas herramientas digitales fue esencial para que los participantes lograran identificar y apoyar las relaciones matemáticas y para crear un ambiente de aprendizaje que favoreciera y promoviera las interacciones de los participantes dentro y fuera del aula. En este contexto, el uso de Google Classroom permitió a los participantes acceder a los materiales del curso desde cualquier lugar y recibir retroalimentación de otros participantes. El uso de GeoGebra fue importante para la construcción de los modelos dinámicos que les ayudaron a identificar y examinar relaciones matemáticas. El uso de Internet les dio la oportunidad de obtener información en línea que les permitió aclarar o ampliar información sobre los conceptos involucrados en las tareas. Del mismo modo. El uso de Mathematica les ayudó a realizar cálculo matemáticos complejos y de esta forma concentrarse en el significado de los resultados. Compartir sus ideas en Padlet y utilizar Hangouts favoreció la interacción con los demás, ya que fue importante para buscar diferentes maneras de cómo resolver las tareas matemáticas. El uso de Padlet resultó transcendental durante esta actividad ya que impactó en todas las fases de la resolución de un problema (Polya, 1973) al permitirles:

1. Tener claridad acerca de lo que trataba el problema (Fase de comprensión del problema).
2. Considerar varias formas de resolver el problema y seleccionar un método particular a partir de una evaluación en relación con su utilidad (Fase de diseño de un plan).
3. Monitorear el proceso de solución y decidir cuando abandonar algún camino que no estuviera produciendo resultados (Fase de implementación).
4. Revisar el proceso de solución y evaluar la respuesta obtenida (visión retrospectiva).

Existing technologies pose challenges for the educational systems related to what contents, strategies and skills students should learn and what types of teaching scenarios should be considered in learning. In this study, prospective high school teachers were encouraged to systematic use various digital technologies in a problem solving course during one semester. Results indicate that the

---

participants developed and implemented a set of strategies and ways of thinking that complement and extend the approaches based on the use of pencil and paper. In addition, the use of technology allowed the participants extend mathematical discussion beyond formal settings.

Keywords: Problem Solving, Technology, Teacher Education-Preservice

Introduction

In the last ten years, the rapid developments and availability of digital technologies are substantially changing ways in which individuals interact, communicate, access and get information to perform daily activities. For example, with a mobile device (tablet or smartphone) you can look for online information, read a newspaper or, through an application, request the services of a taxi, book a hotel room or make the most efficient route for going from one place to another. This study aims at analyzing and documenting the extent to which the use of digital technologies helps prospective high school teachers represent and explore mathematical tasks and to foster pairs' interaction, collaborative work and to extend mathematical discussions beyond formal settings.

To guide this study, the following research question was posed: What forms of reasoning do prospective high school teachers construct as a result of using different digital tools (GeoGebra, Google Classroom, Padlet) in a problem-solving environment? In particular, there is interest in documenting the extent to which the use of tools in sharing information online (Padlet) can help students to change their initial problem solving approaches and to develop new ways to explore and extend initial tasks by working on them with the Dynamic Geometry System (DGS) GeoGebra.

Conceptual framework

The study is based and structured around three areas or related domains: (i) the idea of problematize the learning of mathematics as a basic principle to learn mathematics and develop problem solving competencies (ii) the systematic and coordinated use of various digital technologies in the processes of representing and exploring of mathematical concepts, and (iii) the design of the tasks as vehicles to organize and promote the development of students' mathematical knowledge.

Problem solving and the problematizing activity

A basic principle in a problem-solving perspective is that students develop an inquisitive approach to develop and use mathematical knowledge. In this process, learning mathematics is conceived as a search for meaning activity in which students constantly ask and answer questions as a way to represent, explore, understand and solve mathematical situations (Santos-Trigo, 2014). This principle is consistent with what Hiebert et al. (1996) refers to as allowing students to problematize topics or content as a way to deepen and reflect on mathematical concepts, this means "allow students to ask why things happen, to investigate, to find solutions, and to resolve the incongruities" (p. 12), the authors use the term problematize in the sense that students should be allowed and encouraged to problematize what they study to define the problems that cause their curiosity and skills to create sense. Postman and Weingartner (1969), argue:

> Knowledge is produced in response to questions. [...] Once you've learned how to ask- relevant questions, appropriate and with substance- the student has learned how to learn and nobody can stop them to continue learning what they need and wants to know (p. 23).

The coordinated use of digital tools in solving mathematical problems

Santos (2007) recognizes the importance for students to problematize the study of discipline. That is, it is essential for students to ask questions when they are solving problems or try to understand mathematical ideas using different representations, to look for conjectures and relationships and where the use of different digital tools help them explore and support their

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

arguments with approaches that can go from empirical reasoning to formal approaches. The coordinated use of various digital tools offers students different ways to identify, formulate, represent, explore and solve problems from various perspectives (Santos-Trigo & Reyes-Martínez, 2016). The extensive development of digital technologies involves deciding what and how to use them in learning environments with the objective that students understand mathematical concepts and solve problems. Santos (2007) argues that the systematic use of digital tools in the construction of students' mathematical knowledge not only influences the way to present and explore mathematical ideas but also the ways of reasoning, supporting and presenting relationships or mathematical properties. Also, Santos-Trigo and Ortega-Moreno (2013) pointed out that digital technologies not only extend the representations and strategies that appear in approaches based in the use pencil and paper but also generate new ways of thinking to develop mathematical knowledge.

Thus, the use of various digital tools offers different opportunities for students to develop and discuss questions that can lead them to represent and explore mathematical tasks from different and complementary perspectives, and also offer teachers new ways of organizing and managing the class work and class materials more efficiently. Similarly, teachers can keep constant communication with their students and create environments to extend the discussion of problems beyond the classroom. In this perspective, the problems and the teaching atmosphere are crucial aspects to guide and promote the development of mathematical knowledge and student learning.

The importance of mathematics tasks

In the context of problem solving, tasks or problems represent a starting point and an opportunity for students to find different representations and ways to solve and extend them. Mathematical tasks are essential tools for teachers to guide, promote and analyze their students' processes to construct, develop, and use mathematical knowledge. Hiebert and Wearne (1993) state that "what students learn is defined largely by the tasks they are given" (p. 395). For Mason and Johnston-Wilder (2006), the objective of the tasks is to make students participate actively in the creation of meaning and develop their mathematics skills. Therefore, the tasks are the vehicle for students to understand concepts and develop ways of thinking that are consistent with mathematical practices.

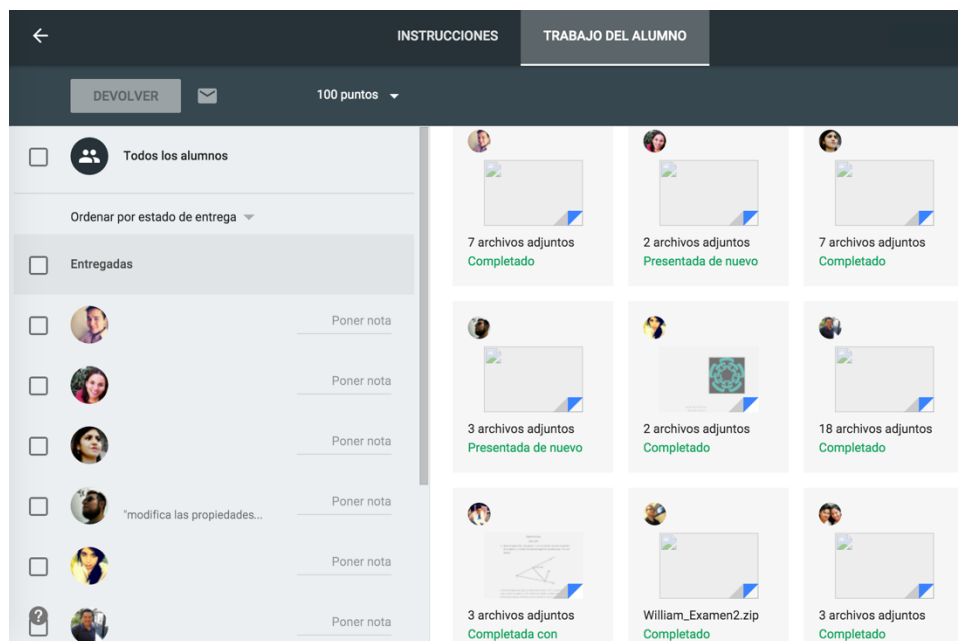
We argue that the coordinated use of various digital tools offers students an opportunity to expand the ways of thinking involved in solving problems and to organize, identify and access some relevant online information at all problem solving phases


Figure 1. The platform that was used to send notifications to students, share materials and to provide feedback to students**.**

Participants, problems and procedures

In this paper we describe aspects of a learning environment that seeks to expand the interactions that take place in a traditional mathematics classroom. In this new environment the goal is that participants use in a systematic way a collection of digital technologies when solving mathematical problems. These digital technologies included: A DGS (GeoGebra) to explore and represent problems dynamically, a platform for managing content and manage tasks (Google Classroom, Figure 1), a digital wall (Padlet) to share ideas and new approaches to solve the tasks that were available during the problem solving process, Internet services (Wikipedia, Wolfram Alpha, YouTube, Khan Academy) to access, select and discriminate relevant information during all stages of problem solving, a tablet (iPad) as a primary means of communicating and accessing information and interactive content (iBooks) and instant messaging (Google Hangouts) to communicate and share information efficiently with their peers and participate in a learning community where they discuss and share ideas and strategies to solve mathematical tasks.

This study involved nine prospective high school teachers who were taking a semester long problem solving course that was part of a master's program in mathematics education. All participants had a bachelor's degree with a mathematics major and were enrolled in the second semester of the program. The course included two sessions of three hours each. During the development of sessions, all participants were encouraged to engage and develop an enquiring approach, which consists mainly in the habit of formulating and constantly discuss questions about a situation and different ways to explore and solve problems with the systematic use of a set of digital tools.

In general terms, all tasks or problems that were given to the participants represented a starting point for them to engage in mathematical thinking that could extend beyond the classroom and that would allow them to first solve the problem and then look for other connections and solutions. In this sense, the use of digital tools offers the participants an opportunity to share their ideas or conjectures, the exploration of mathematical relationships, the creation of new problems, the extension and generalization of initial conditions (Santos-Trigo, Reyes-Martínez, & Ortega-Moreno, 2015). For this report, we focus on the discussion of a problem implemented in the middle of the semester.

The problem. Given a circle *c* and a segment *a*, construct a rhombus with side *a* such that the circle *c* remains inscribed in the rhombus.

This problem was posed as part of the participants' assessment and consisted of three stages. In the first stage students worked individually for three hours, using different digital tools to explore the problem. All participants used GeoGebra to construct a dynamic model of the task. This model became a key source for the participants to identify, represent, and explore mathematical objects involved in the construction of the rhombus. Another tool that was used by all participants was the encyclopedia Wikipedia in which they looked for information (such as definitions, theorems, properties and formulas: https://es.wikipedia.org/wiki/Rombo) that helped them understand and give meaning to the task. In the second stage, the students were asked to share in the Padlet board the ideas they used in their individual explorations. That is, they created a repository of ideas which later could be used by other participants to explore the problem. Finally, the participants were asked to explore the problem using their colleagues' ideas; with that information, participants were again engaged in the exploration of the problem; this activity was conducted for a week.

First stage. Individual work. At the end of the individual work session, 14 different solutions, including empirical, algebraic, trigonometric and geometric approaches were reported. In this section the most representative approaches that emerged during this session are presented.

Five participants proposed the same dynamic model working independently, to this end they relied on the heuristic to *relax the initial conditions of the problem,* so they drew a rhombus whose sides have length *a* and then they made the sides tangent to the circumference *c*. They placed the point E on the *y* axis and drew a circle of radius *a* that intersects the *x* axis at points F and G, then reflected E with respect to A to find the point E ', so a partial representation of the solution is achieved (Figure 2); the rhombus with vertices EFE'G has 4 congruent sides (of length equal to segment *a*); if you move the point E it is possible to find a position where the circumference *c* is inside rhombus EFE'G, for this to occur the sides of the rhombus should be tangent to the circle *c*. How is this construction achieved?
Figure 2. The rhombus EGE'F is a partial representation.
Figure 3. The geometric locus of the points H, T, I and U is shown in orange.

When drawing perpendicular lines to the segments *e* and *b* through point *A*, these perpendicular lines intersect the sides of the rhombus at the points H, T, I and U (Figure 3). The locus of the four points when point E moves on the *y* axis is displayed in orange. The intersections of the loci and the circumference *c* identify the positions in which the segments of the rhombus will be tangent to the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

circumference *c*. Due to the symmetry of the rhombus and the circumference, this problem can be simplified and explored by only looking at one of the four quadrants. If we focus on the first quadrant, we can see that the locus described by I intersects the circumference *c* in two positions, showing the two solutions of the problem (Figure 4 and Figure 5).
Figure 4. First solution.
Figure 5. Second solution.

Second stage. Padlet shared ideas. After working individually in the construction of the rhombus, participants were asked to share via Padlet the core ideas of their individual approaches. It was emphasized that they should not share the solutions, but the ideas that led them to build the dynamic models. Figure 6 shows part of the digital wall where the participants shared the ideas that later were used to solve the problem.

Figure 6. Digital wall that contains all participants' contributions made to the rhombus problem.

In total 25 contributions were shared on the wall (http://es.padlet.com/isaid/rombo). The participants were asked to select some of their peers' ideas and to pursue them to explore the problem again.

Third stage. Explorations that consider shared ideas from the wall. Three of the 9 participants failed to initially build a dynamic model, but they were able to construct such a model later on based on the ideas that were shared at the wall. In what follows we show a solution that emerged from one idea that was shared in the wall. Figure 7 refers to an important property of the rhombus: *The height of the rhombus is equal to* the *diameter of the inscribed circle.* This idea was

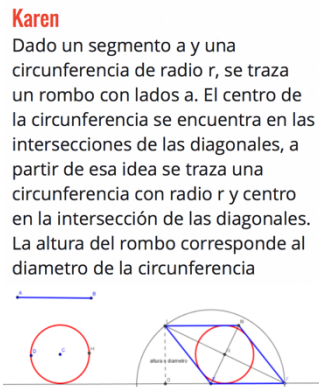
recovered by one of the participants who had failed to solve the problem during the first stage. Figure 8 shows an algebraic approach that involves the vertices and the center of the rhombus and a right triangle with height *2r*, base *x* and hypotenuse *a*. The participant used sliders to change the values of *r* and *a,* this allowed her to set the minimum value of *a* as *2r,* so it is always possible to build the rhombus.


Figure 7. Idea shared by Karen.
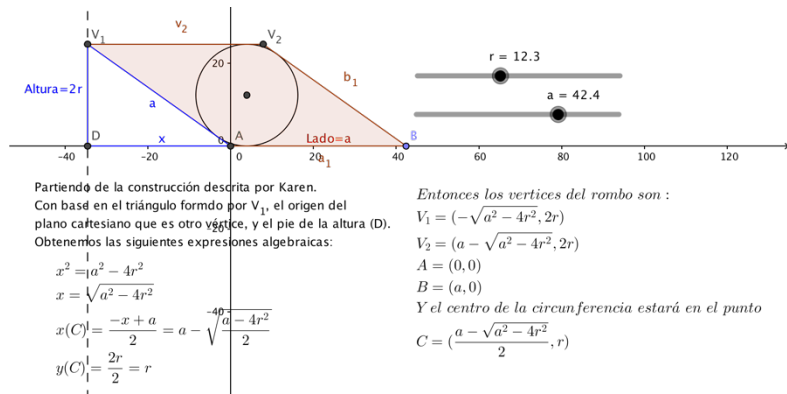

Figure 8. Algebraic solution from considering the idea shared by Karen.

All participants showed a marked participation regarding the number of solutions that were reported after exploring the ideas that were shared through the wall, especially those who had not been able to solve the problem by themselves. It is highlighted the case of a participant that during the first stage (individual work) presented four explorations in which she could not obtain a solution, after exploring the problem from the ideas of the wall, she presented fifteen explorations including two solutions that did not emerge during the first stage.

 Comments. One participant experienced difficulties during the individual work time and could not solve the problem after 4 attempts; however, after having access to the wall, she was able to present 15 successful explorations that included two solutions that were not presented during the individual work session. In this sense, the digital wall allowed the participant to recover from unsuccessful attempts and take into account ideas that led her to present several solutions to the problem.

Conclusions

Throughout this report we have argued that the use of a DGS (GeoGebra) by the prospective high school teachers can depend on the tool affordances to construct and explore dynamic models of mathematical tasks. This exploration led them to observe invariances, patterns and relationships among elements of the model. Similarly, the use of communication technologies allows the participants to extend and continue mathematical discussions beyond formal settings. This task discussion can happen virtually anywhere without limitations of time and space.

With the use of digital technologies, it is possible to restructure and extend the traditional classroom environments, promoting that students keep working, exploring, interacting, and reflecting from any place without limitations of time or space. To this end, it is important that students develop forms of thinking and working in these environments so that they can develop the ability to use in a coordinated way the digital tools.

Thus the coordinated use of various digital tools was essential for the participant to identify and support mathematical relations and to create a learning environment that favored and fostered interactions among participants inside and outside the classroom. In this context, the use of Google Classroom allowed the participants to access course materials from anywhere and receive feedback

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

from others participants. The use of GeoGebra was important to construct dynamic models that helped them identify and examine mathematical relationships. The use of Internet gave them the opportunity to obtain online information that helped them clarify or extend what they recall from concepts involved in the tasks. Similarly, using Mathematica helped them to perform complex calculations and focus on the meaning of the results. Sharing their ideas via Padlet and using Hangouts favored the interaction with others, and accessing others' ideas was important to look for distinct task paths solution. The use of Padlet was essential for the participants during the process and problem solving phases during this activity (Polya, 1973) by allowing:

1. To fully understand the problem (Problem understanding phase).
2. To consider several ways to solve the problem and selecting a particular method from an assessment regarding its usefulness (Design of a plan phase).
3. To monitor the solution process and decide when to abandon a path that was not producing results (Implementation phase).
4. To review the solution process and evaluate the results (Review/extend phase).

TRADEOFFS OF SITUATEDNESS: ICONICITY CONSTRAINS
THE DEVELOPMENT OF CONTENT-ORIENTED SENSORIMOTOR SCHEMES

Mathematics education practitioners and researchers have long debated best pedagogical practices for introducing new concepts. Our design-based research project evaluated a heuristic framework, whereby students first develop acontextual sensorimotor schemes and only then extend these schemes to incorporate both concrete narratives (grounding) and formal mathematical rules (generalizing). We compared student performance under conditions of working with stark (acontextual) vs. iconic (situated) manipulatives. We summarize findings from analyzing 20 individually administered task-based semi-structured clinical interviews with Grade 4 – 6 participant students. We found tradeoffs of situatedness: Whereas iconic objects elicit richer narratives than stark objects, these narratives may detrimentally constrain the scope of potential sensorimotor schemes students develop in attempt to solve manipulation problems.

Introduction: Forging an Embodiment Middle Ground
Between Formalisms-First and Progressive Formalization

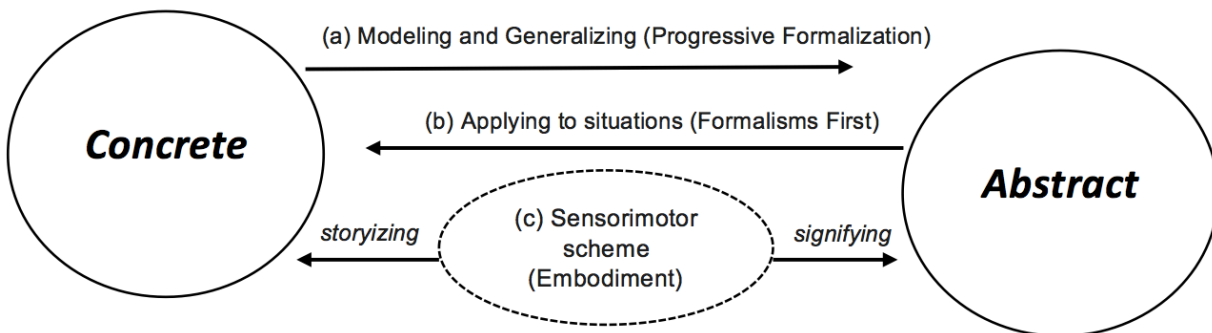
Scholars of mathematics education tend to hold two diametrically opposed positions on best pedagogical practices for introducing new mathematical concepts (Nathan, 2012). The formalisms-first approach (e.g., Baird, 2004; Kaminski et al., 2008; Sloutsky et al, 2005; Stokes, 1997; Uttal, Scudder, & DeLoache, 1997) posits that students should first learn symbolical representations of a new concept and only then apply their formal strategies to situated contexts. The progressive-formalization approach (e.g., Goldstone et al., 2005, 2008; Harnad, 1990) posits that students should begin from concrete situations and then progressively formalize their understandings of the situations towards normative abstract representations.


Figure 8. Positioning the (c) Embodiment approach with respect to the
(a) Progressive-Formalization approach and the (b) Formalisms-First approach.

And yet in between these two oppositional stances there may be a third position (see Figure 1). Inspired by the embodiment approach (Campbell, 2003; Chemero, 2009; Clark, 2013; Nemirovsky, 2003; Varela, Thompson, &, Rosch, 1991), this position implicates sensorimotor schemes as the epistemological core of mathematical learning and knowing. We conjectured that students could encounter new mathematical concepts by first developing sensorimotor schemes and then both grounding these schemes in concrete situations (storyizing) and signifying the whereas we embrace

the proposal to ground mathematical meaning in "our direct physical and perceptual experiences" (Nathan, 2012, p. 139), we decompose this idea by foregrounding and differentiating its two inherent phenomenological dimensions, sensorimotor schemes and situatedness (contextuality). We argue that these two dimensions have been conflated in historical debates (e.g., Barab et al., 2007; Bruner, 1986; Burton, 1999). That is, we maintain that learning activities can be created such that sensorimotor schemes are fostered either in contextual or acontextual situations. We hypothesized that different levels of contextuality would have different effects on learning, and we assumed that sensorimotor schemes would mediate this effect. We believed that students would develop different sensorimotor schemes in low- vs. high-context activities, and that the low-context condition would prove advantageous.

To evaluate this hypothesis, we designed and implemented a learning activity complete with materials, tasks, and facilitation techniques based on the embodied-design framework (Abrahamson, 2006, 2009, 2014). In the empirical study reported herein, we varied the contextuality of a manipulation problem by either incorporating or not incorporating iconic information that would cue narrative framings of the situation, and we measured for effects of this experimental variation on qualities of students' behaviors as they engaged in solving the problem. Our study thus aimed to empirically evaluate this in-between embodiment position with respect to the ongoing debate of formalisms-first vs. progressive formalization.

Theoretical Background

Nathan (2012) has characterized two opposing approaches to mathematics education as follows:

- *progressive formalization* proposes that students should encounter new concepts in the context of meaningful concrete situations and then abstract toward formal models of these situations by progressively adopting mathematical forms and nomenclature (Goldstone, Landy, & Son, 2008; Harnad, 1990); and
- *formalism first* proposes that students should encounter concepts through abstract procedures and then map formalisms to concrete situations via application problems (Baird, 2004; Kaminski et al., 2008; Sloutsky et al., 2005; Stokes, 1997).

The *embodiment approach* put forth in this article borrows the progressive-formalization epistemological position that abstract notions are grounded in concrete situations yet also partially subscribes to the formalism-first ontological position that mathematical concepts should be grounded in generic images. On the one hand, as per *progressive formalization*, *embodiment* learning materials are pre-symbolic and informal. On the other hand, per *formalisms first*, the materials are generic or stark, that is, highly economical on any situated or narrative content.

Affordances and Constraints of Stark (Acontextual) vs. Rich (Situated) Manipulatives

Pedagogical approaches inspired by embodiment theory champion the principle of fostering opportunities for students to build new sensorimotor schemes prior to signifying the schemes in a discipline's semiotic register (Abrahamson, 2006; Nemirovsky, 2003). Our study considered from an embodiment perspective the effect of situatedness on the development of sensorimotor schemes. We thus sought a theory of situated perception and action that would enable us to model, anticipate, and analyze for effects of experimentally varying an activity's situatedness.

Our focus on the relationship between the properties of objects that students manipulate and their actions on these objects led us to consider the theoretical notions of affordances and constraints as relevant to the goals of this study. *Ecological psychology* (Gibson, 1977) theorizes an agent's potential actions on the environment as contingent on the agent–environment relations. An agent (e.g., a mathematics student) perceives opportunities for acting on objects in the environment (e.g.,

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

classroom manipulatives) in accord to these objects' subjective cues; the agent tacitly perceives the object as *affording*, that is, privileging certain forms of goal-oriented engagement. Importing Gibson's interactionist views into educational research, Greeno (1994) modeled student learning as the process of attuning to constraints and affordances in recurring situations. Araújo and Davids (2004) further offer that an instructor can "channel" students' engagement in goal-oriented activity by controlling environmental constraints.

Still, to the extent that one subscribes to the constructivist thesis underlying this research, namely that sensorimotor learning mediates conceptual learning, *why might different degrees of the learning materials' contextuality afford different sensorimotor learning?* The answer, we believe, lies in the nature of these sensorimotor schemes vis-à-vis the particular features of the learning materials that the students mentally construct in the course of developing the materials' new perceived affordances. That is, a given situation may lend itself to different goal-oriented sensorimotor schemes. And whereas a variety of schemes may accomplish the prescribed task, some of these schemes may be more important than others for the pedagogical purposes of the activity. We hypothesize that *the situatedness (contextuality) of learning materials constrains which sensorimotor schemes the materials might come to afford*. Where particular contextual cues unwittingly constrain student development of pedagogically desirable affordances, the students' conceptual learning will thus be delimited.

In evaluating this hypothesis pertaining to the nature and quality of situated learning, we needed a theoretical construct that would both cohere with the embodiment perspective and enable us to implicate in our data which sensorimotor schemes students were developing. We realized we were searching for a means of determining how the students are mentally constructing the materials; what specifically they were looking at that mediated their successful manipulation. Such a theoretical construct already existed: an attentional anchor (see below).

An *attentional anchor* is a dynamical structure or pattern of real and/or projected features that an agent perceives in the environment as their means of facilitating the enactment of motor-action coordination (Hutto & Sánchez–García, 2015). Abrahamson and Sánchez–García (2016) demonstrated the utility of the construct, which originated in sports science, in the context of mathematics educational research. Abrahamson et al. (2016) studied the role that visual attention plays in the emergence of new sensorimotor schemes underlying the concept of proportion. They overlaid data of participants' eye-movement patterns onto concurrent data of their hand-movements. They found that the participants' enactment of a new bimanual coordination coincided with a shift from unstructured gazing at salient figural contours to structured gazing at new *non*-salient figural features. The participants' speech and gesture confirmed that they had just constructed a new attentional anchor as mediating their control of the environment.

For this study, we adopted the construct of an attentional anchor as a key component of our methods. We sought to characterize what attentional anchors students developed during their attempts to solve a motor-action manipulation task. By so doing we hoped to gauge for effects of varying the contextuality of learning materials (iconic vs. stark) on student development of the sensorimotor scheme mediating an activity's learning goal. We hypothesized that richer manipulatives would constrain the scope of attentional anchors students develop.

Methods: Designing Constraints on Sensorimotor Engagement of a Technological System

The Mathematics Imagery Trainer for Proportion (MIT-P; see Figure 2) sets the empirical context for this study. Students working with the MIT-P are asked to move two cursors along vertical axes so as to make the screen green and keep it green. Unknown to the students, the screen will become green only if the cursors' respective heights along the screen relate by a particular ratio, otherwise the screen will be red. For instance, for a ratio of 1:2, the screen will be green only when

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

the right hand is twice as high along the monitor as the left hand. Students develop a variety of motor-action strategies to satisfy the task demand (Howison et al., 2011).
Figure 2. The Mathematical Imagery Trainer for Proportion (MIT-P) set at a 1:2 Ratio. Compare 2b and 2d to note the different vertical intervals between the hands and, correspondingly, the different vertical (or diagonal) intervals between the virtual objects. Noticing this difference is crucial to experiencing, then resolving a key cognitive conflict.

In the current study, images appear at students' fingertips when they touch the screen. These images are either stark crosshair targets (see Figure 3a) or iconic images (e.g., hot air balloons; Figure 3b).
Figure 3. Experimental conditions and hypothesized attentional anchors: (a) stark crosshair targets cue the vertical or diagonal interval between the hands; and (b) iconic images (hot-air balloons) that cue the interval from each object to the bottom of the screen. In the actual experiments we used large touchscreens where the hands are on the interface.

In both experimental conditions (stark and iconic) students are led through a task-based semi-structured clinical interview. Following an unstructured orientation phase, in which the participants find several green locations, they are asked to maintain green while moving both hands from the bottom of the screen to the top. The interviewer and student then engage in a coordination challenge, where the interviewer manipulates the left image and the student manipulates the right image. The student is asked to predict the green locations. All along, the students are prompted to articulate rules for making the screen green.

We wished to investigate for attentional anchors that emerge during children's interactions with the technology. We reasoned that the attentional anchors would indicate what sensorimotor schemes the students developed. More specifically, we explored for an effect of experimental condition (stark vs. iconic cursors) on the types of attentional anchors students construct and articulate (via speech and/or gesture). We also looked at the effect of condition sequence.

Twenty-five Grade 4 – 6 students participated individually in the interviews, 14 in the "stark-then-iconic" condition and 11 in the "iconic-then-stark" condition. We exclusively interviewed students around the numerical item of a 1:2 ratio. These sessions were audio–video recorded for subsequent analysis. As our primary methodological approach, the laboratory researchers engaged in a micro-genetic analysis of selected episodes from the data corpus, focusing on the study

participants' range of physical actions and multimodal utterance around the available media (Ferrara, 2014). Our working hypothesis, to iterate, was that the virtual objects' figural elements may cue (afford) particular sensorimotor orientations and thus "filter" the child's potential scope of interactions with the device. Namely, we analysed for effects of the manipulatives' perceived affordances on participants' scope of interaction.

Results: Perceived Affordances of Stark vs. Iconic Situations Mediate Student Strategies
A main effect was found. Below, we report our findings in each experimental condition by first describing participants' typical strategies and then illustrating these behaviors through brief vignettes. The section ends with comparing observed student strategies under the two conditions.

Stark Targets Afford the "Distance Between the Hands" Attentional Anchor
In the trials where participants interacted with stark targets first, they began the activity by placing their left-hand- and right-hand fingertips on a blank touchscreen. Immediately they noticed crosshairs appear at the locations of their fingertips. In an attempt to make the screen green, the participants began moving their hands all over the screen with no apparent strategy, "freezing" their fingers as soon as the screen turned green. Eventually, participants oriented toward the spatial interval between their fingers, soon discovering that their fingers have to be a certain distance from each other at different heights along the screen. Finally they determined a dynamical covariation between the interval's size and height: the higher the hands, the bigger the interval must be (and vice versa). We turn to several vignettes (all names are pseudonyms). As we shall see, both participants will refer to an imaginary diagonal line connecting the cursors.

Luke (age 10). As he found various green-generating screen location, Luke commented about the space between his hands at these various locations: "It's the same angle. Well, I mean the line connecting them is the same direction" [4:53]. Later, he noted that the "[angle] is changing because my right hand is getting faster, so when this goes up that much (moves left hand approximately 2 in. on the screen) this one goes up at this much (moves right hand approximately 4 in. on the screen)" [11:10].

Amy (age 9). Amy reported her observation: "The diagonal [between the hands] at the top is different than [at] the bottom" [7:15]. Then later during the iconic challenge, she said: "You have to make them different diagonally from each other to make it change color" [7:42].

Thus during the stark-target trials the participants not only noticed that the interval between their hands was changing in size, they came to see this interval as an imaginary line between their hands. In turn, this imaginary line—its size, angularity, and elevation along the screen—apparently served the participants in finding and keeping green, ultimately enabling them to articulate a strategy for doing so. This imaginary line along with attributed properties is an attentional anchor: it is crafted out of negative space to mediate the situated coordination of motor intentionality; subsequently this mentally constructed object serves to craft proto-proportional logico–mathematical propositions. This spontaneous appearance of a self-constraint that facilitated the enactment of a challenging motor-action coordination is in line with dynamical-systems theory (Kelso & Engstrøm, 2006).

Of the 14 students in this stark-then-iconic experimental condition, 10 spoke about the interval between the hands still within the "stark" phase of their interview, with eight of them referring explicitly to its magnitude. Then during the "iconic" phase of the interview, 2 of these 10 students began to speak about the icons as separate entities, focusing on the speed of each respective icon, or reverting to a focus on the color feedback of the screen to determine where to place the hands. The remaining 8 of these 10 students continued to use the interval line between their hands as a guide for making the screen green. These students' attention to the diagonal line was consistent, suggesting that this imaginary "steering wheel" had become perceptually stable in their sensorimotor engagement with this technological system.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Iconic Images Afford the "Distance From the Bottom" Attentional Anchor

Similar to the stark-then-iconic condition, in the trials where students interacted with rich icons first, they began the activity by placing their left-hand- and right-hand fingers on a blank touchscreen. However, in this condition they immediately saw hot-air balloon icons (not stark targets) appear on the screen. Thus, the virtual manipulatives in this condition are situational and not stark, even as the tasks are otherwise identical. Recall that these students worked first with the iconic images and then with the stark images. As we will now explain, beginning with the iconic images cued a narrative-based strategy that was based on a frame of reference that did not attend to the interval between the images but instead to each of these hot-air balloons vertical distance above the "earth" (the bottom of the screen). As we will see, this alternative sensorimotor orientation was so strong that it carried over to the stark condition, so that by-and-large these participants were less likely to attend to the interval and thus were less likely to benefit from its potential contribution to their problem-solving strategy.

Leah (age 11). Having generated green for the first time, Leah noticed that when she moves one hand, the greenness dulls out toward red. Later, she described her strategy for making the screen green referring gesturally to the hand's distance from bottom of the screen: "I would say what I said before, where one hand chooses a place and the other hand chooses a color based on where the hand is, and you can adjust it to keep it green. Once you find that, you just need to keep it the same height [from the bottom]" [8:40]. Then in the next task, she maintains her strategy, saying: "When you move one hand up you need to move the other hand up so it's the same distance [from the bottom], but higher" [12:22].

Jake (age 11). Jake described his initial strategy: "Try putting your hands together in the middle and then try moving one down or the other one up. One of the balloons should stay in the middle while the other moves" [4:47]. Note how "middle" refers to that balloon's location along a vertical axis irrespective of the other balloon. Jake perseverates with this strategy throughout the set of challenges, moving his hands up along the screen sequentially rather than simultaneously. When later tasked to make the screen green with the stark targets, he appeared disoriented, noting, "This is harder because I don't have a starting point" [24:12]. Jake refers to the absence of an "earth" as a grounding frame of reference for the cursors' vertical motion.

Of the 11 students who encountered the rich images first, 4 began to speak about the interval between the hands still during the rich condition, however these students did not elaborate about the line between the hands, and rather focused on each hand as a separate entity (e.g., stating that one hand controls color and the other controls brightness). During the second phase, in which they encountered the stark images, 2 of these 4 students as well as 3 of the 7 who had not attended to the interval demonstrated the emergence of this attentional anchor. The remaining students treated each of the two icons as separate entities throughout the entire interview, and hardly spoke about the interval between the hands. Collectively, these students were more inclined to treat the two objects on the screen as separate entities, focusing on the changing height of each object and the differing speeds of the two objects as they move upward.

In summary, participants who began in the stark condition oriented toward the distance between their hands as their attentional anchor, whereas participants who began in the iconic condition tended to treat the manipulatives as independent, untethered entities. It would appear that participants who began in the stark condition generated the interval as their attentional anchor because no other frame of reference was cued. Participants who began in the iconic condition, on the other hand, followed the cued narrative implicit to the familiar images and tended rather to visualize the two balloons as launching up from the ground.

It thus appears that objects bearing rich associative content introduce a new layer of baggage onto an interaction task, including forms, dynamics, hierarchies, and social conventions that guide the students' perception of the action space (on framing, see Fillmore, 1968; Fillmore & Atkins, 1992).

For instance, we typically think of hot-air balloons as "starting" at a point, such as the ground at takeoff, and these evoked frames implicitly constrain the scope of possible attentional orientations to a situation by privileging the interval from each object down to the bottom of the screen, at the expense of the interval between the hands. In contrast, when manipulating stark cursors, there is no "starting point" as such, enabling the possibility for students to attend to the interval between the hands.

Supporting our study's hypothesis, the findings suggest an effect of situatedness on the construction of sensorimotor schemes. The finding is relevant to mathematics pedagogy, because sensorimotor schemes mediate conceptual learning. It follows that situatedness of instructional materials is liable to impede mathematical learning by precluding the emergence of sensorimotor schemes pertinent to a cognitive sequence toward the generalization of rules. Future iterations of this intervention would avail of eye-tracking (e.g., Abrahamson et al., 2016) to corroborate students' verbal and deictic report of attentional anchors.

Conclusion

Mathematics education researchers have long debated the question of whether concepts best develop from rich or stark learning materials. We contributed to the debate by offering that the focus of such research should be not on the learning materials per se but on the sensorimotor schemes they may afford (cf. Day, Motz, & Goldstone, 2015, for a competing position). Richer materials, we demonstrated, constrain the scope of sensorimotor schemes students may develop through engaging with the materials. In particular, richer materials may diminish opportunities for conceptual development, because they draw students' attention toward less mathematically relevant ways of thinking about the situations. Students might even miss out on opportunities to think about the situation in ways that are critical for an instructional sequence.

Students, that is to say children, are highly imaginative. They readily engage in pretense with stark objects, visualizing them one way and then another way. It is the *low* situativity of stark manipulatives that lends them to a greater variety of narratives and consequently a greater variety of sensorimotor orientations. And so we agree with Uttal, Scudder, and DeLoache (1997) that sensory richness of manipulatives may derail certain forms of mathematics learning. But we stress that the issue here is not so much about sensory overload distracting from intended forms of engaging the objects. It is not about manipulatives but about *manipulation*—it is about task-oriented sensorimotor schemes students should develop in solving challenging bimanual motor-action problems. So the issue at hand is the hands' motion. Learning is moving in new ways, and we should ensure that the tasks we create facilitate this motion. Sometimes the objects children manipulate might be so perceptually stark that there are no objects at all—just imagined objects. One might speak of mathematics students' right to bare arms.

somin84@uga.edu

Our mathematics cognitive technology noticing framework is based on professional noticing and curricular noticing frameworks and data collected in a study that explored how secondary mathematics teachers evaluate technology. Our participants displayed three categories of noticing: attention to features of technology, interpretation of the features, and response to these features. We believe this framework can potentially allow researchers to document the evolution of teachers' evaluation of mathematical cognitive technologies and examine how the inclusion or exclusion of particular features of technology influences their evaluation and subsequent selection of technology.

Keywords: Technology, Curriculum Analysis

As technology is an essential tool for learning mathematics in the 21st century (NCTM, 2014) and is becoming more ubiquitous in the classroom, mathematics teachers are being asked to evaluate, select and implement quality technological tools to use with their students. However, little is known about how teachers select technology, particularly mathematical cognitive technologies (MCTs), digital technological tools that can be used to teach and learn mathematical concepts "that [help] transcend the limitations of the mind (e.g., attention to goals, short-term memory span) in thinking, learning, and problem-solving activities" (Pea, 1987, p. 91). The purpose of this paper is to propose a framework for thinking about what teachers notice when they evaluate, select, and modify technology to use in their mathematics classrooms.

Background

As an everyday term, *noticing* is used to refer to particular observations that one makes (Sherin, Jacobs, & Philipp, 2011). In the field of mathematics education, researchers specifically use the phrase *teacher noticing* to refer to what teachers attend to in a classroom situation and how they make sense of what is observed using their knowledge of mathematics teaching and learning and the context being observed (Blomberg, Stürmer, & Seidel, 2011; Dreher & Kuntze, 2015; van Es & Sherin, 2002). Jacobs, Lamb, and Philipp (2010) and McDuffie et al. (2013) extended previous views of noticing to include instructional responses teachers make. Jacobs et al. conceptualized *professional noticing of children's mathematical thinking* as three interrelated and cyclic components: attending to students' thinking, interpreting their thinking, and deciding how to respond based on their understanding. Researchers in mathematics education extended Jacobs et al.'s noticing framework to connect to equity (Wager, 2014) and curricular materials (Males, Earnest, Dietiker, & Amador, 2015).

By drawing upon constructs of the study of Jacobs et al. (2010) for professional noticing of children's mathematical thinking, Males et al. (2015) developed the *curricular noticing* framework to provide support for examining what teachers notice in curriculum materials, how they make sense of what they attend to, and what actions they make based on their observation of curriculum materials. Providing findings of four exploratory studies by prospective elementary and secondary teachers, Males and colleagues demonstrated that mathematics method courses could support prospective teachers in developing noticing skills of curriculum materials. They claimed that the curricular noticing framework might provide a lens for describing the mechanisms for teacher decision-making with curricular materials.

Once considered an add-on to the curriculum, technology has a strong presence in many of

today's mathematics classrooms and teachers are being asked to regularly evaluate technology and integrate it into the curriculum. Previous research on teachers' evaluation of technology to teach mathematics has focused on the criteria created and analysis performed by prospective elementary teachers (e.g., Battey, Kafai, & Franke, 2005). Battey et al. (2005) studied prospective elementary teachers' criteria for evaluating rational number software. The researchers found the prospective teachers' criteria focused more on surface features of the software (e.g., clarity of directions, clear visual presentation, and ease of use) than on specific mathematics content or how technology could support students' learning. Johnston and Suh (2009) studied prospective elementary teachers' planning for mathematics instruction with technology. They found that only a few of their participants selected MCTs to use in their lesson plans and they considered technology to be a beneficial tool for developing students' conceptual learning or providing a visual representation. The prospective elementary teachers who selected review games or non-MCTs (e.g., digital cameras or Smart Boards) indicated that a benefit of using technology is that it is a fun, engaging, or motivating tool. The studies by Johnston and Suh and Battey et al. indicated that, in general, prospective elementary teachers seem to select and use technology based on student engagement, surface features of the software, and motivation rather than developing students' understanding of mathematical content. Although these studies provide evidence of the criteria prospective elementary teaches use to select technology and what the teachers believe to be the main benefits of using technology, the authors of the studies did not provide much insight into how the teachers actually evaluated these technologies to teach mathematics. In particular, what features did the teachers attend to? How did they interpret these features? What were their responses? We believe our framework builds upon and extends the actions that other researchers have identified in a way that specifically characterizes what teachers notice when evaluating MCTs as an important subset of their curricular noticing.

The Mathematical Cognitive Technology Noticing Framework

The framework is based heavily on the work of Jacobs et al. (2010) in professional noticing and the work of Males et al. (2015) in curricular noticing. In both works, the authors focus on three categories of teachers' action: Attending, Interpreting, and Responding. If we can agree the evaluating technology is a subset of curricular noticing, then it seems natural to use these same categories. However, the codes would be slightly different from those proposed by Males et al. because we focus specifically on the evaluation of MCTs while they provide a more general framework on curricular noticing. To develop the codes, we observed and analyzed four trios of teachers as they evaluated and compared four MCTs to use to teach the triangle inequality theorem to eighth grade students. Each of the four MCTs was an online pre-constructed dynamic geometry sketch. In the transcript, we noted when the teachers seemed to be attending, interpreting, and responding and created codes based on their words and actions within each of these categories. As we continued our analysis, we modified and collapsed codes in order to have meaningful codes and categories. The three categories of noticing, along with the codes of each, constitute the mathematical cognitive technology noticing framework (see Table 1).

Table 1: Mathematical Cognitive Technology Noticing Framework

	Attending		Interpreting		Responding
Interaction	Attends to the ways in which one can engage with the MCT	*Student Thinking*	Interprets how students' uses of the MCT may influence their thinking	*Choose*	Considers whether he/she would select the MCT to use in his/her classroom
Supportive Features	Attends to features that assist in operating the MCT or provide help with the content	*Student Engagement*	Interprets whether the MCT enhances or distracts from students' learning	*Redesign*	Considers how he/she may change the MCT to better fit his/her instruction
Instructions and Questions	Attends to questions or instructions included in the MCT or website	*Value*	Interprets whether a feature of the MCT is beneficial or a drawback	*Adapt*	Considers how he/she would adjust the given activity but not changing the MCT
Mathematical Features	Attends to the mathematical ideas displayed on the screen	*Design*	Interprets how the layout of the MCT influences student interaction and learning	*Incorporate*	Considers how the MCT could be included as part of the activities in the classroom without modification
Aesthetics	Attends to the layout of the MCT	*Differentiation*	Interprets whether all students would be able to use the MCT productively		
		Mathematics	Interprets the display and ways students interact with mathematical objects		

As an example, consider the following analysis performed by Mary, Abby, and Bob (all names are pseudonyms) who had earned undergraduate degrees in secondary mathematics education and were pursuing Masters degrees in mathematics education. All were currently in their first year of teaching mathematics at a middle school or a high school. In this example, Mary, Abby, and Bob were evaluating an internet-based pre-constructed sketch (Garrison, n.d.) that students could use to develop the triangle inequality theorem (see Figure 1). The website provides brief directions on how to use the applet and a question asks users to generalize a theorem based on their experiences using the applet. Two sets of objects are displayed at all times: a set of sliders (pink, green, and yellow) and a set of segments whose lengths and colors are linked to the corresponding sliders. Users are able to change the length of segments by using sliders that range from 0 to 10 with 0.5 increments. The applet's appearance is very different depending on whether a triangle can be formed with a given set of segment lengths. When a triangle can be formed, two additional objects appear: a smiley face and a tan triangle (see Figure 1a). The tan triangle shows the user where the pink and green segments would need to be dragged in order for the triangle to be created. The user can drag each endpoint of

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

the two segments (pink and green) to make the triangle. The tan triangle also has markings of the interior angles of the triangle which are named angles alpha, beta, and gamma. However, the measures of these angles are not displayed and the user cannot measure them. If the conditions for a triangle are not satisfied, the applet does not make the tan triangle and the smiley face is not displayed (see Figure 1b). Users can drag each endpoint of the two segments to check the fact that a triangle cannot be formed. The applet's website does not provide any further assistance or directions other than the name of the applet's creator and a link to the Geogebra website.
(a)   (b)

Figure 1: MCT Analyzed by Mary, Abby, and Bob when the length of the segments do (a) and do not (b) form a triangle.

Mary, Bob, and Abby spent over 12 minutes evaluating this applet. Given the space limitations, it is impossible for us to provide the transcript in its entirety. Instead, we provide the following narrative with direct quotations used as much as possible. Opening the website, Abby read the instructions aloud and Bob pointed out that the triangle is present and the angles are marked with Greek letters. Bob briefly dragged the sliders and said, "It gives you the awesome smiley face. It would be better if it gave you a frowny face if it didn't work." As they determined whether the applet engages students in meaningful ways, Abby said, "it's pretty straightforward, except for the smiley face and we'll just drag {it}." Bob responded, "Well it's unnecessary that it [instruction] tells you to move the line segments, since it already creates it, so it's kind of unnecessary." Bob continued to explore the applet and supported his previous claims stating,

> *Bob*: [Dragging segments] See here when they're the same, it does, it shows you if you move your triangle, and then it shows point C as, well, so it shows that. But then there's still no new, I guess, to see that you'd move it here.
> *Mary*: Yeah.
> *Bob*: But with the ones that actually make triangles, there's no need to move anywhere. It's very obvious.
> *Mary*: It's very lame.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Changing the foci of the conversation to the specific benefits and limitations of the applet, Abby said, "Okay, yes the use of three colors distinguishes the different segments. Um, when a triangle is formed a smiley face appears encouraging students, encouraging students that they achieved a triangle. They create a triangle." Mary stated a benefit is that it provides instructions on how to use the applet. Abby considered whether the angle markings are beneficial. She said, "In terms of the mathematics. I think that in this case with the angle measures, since we're not really concerned with angle measures, it could potentially distract [from the triangle inequality theorem]." She continued, "They [Angle markings] are not, they are not essential for the development of this theorem."

Next, the teachers discussed whether the applet allows students to develop an appropriate conception of the triangle inequality theorem.

Mary: And I guess, this question down here at the bottom does make them [students] think about it [triangle inequality theorem], but unless I require that they submit some kind of answer for that, they're just going to ignore that.
Bob: Mm hmm.
Mary: And they're going to be like, ooh smiley, not smiley.
Bob: Yeah. There's going to be, yeah, they're going to see the smiley face or the no.
Abby: Yeah.
Mary: So we could say, if the questions at the bottom are required, and emphasized,
Abby: then the program
Bob: emphasis is placed on, on the end questions.
Mary: Yeah.
Abby: If the questions on the end are required and emphasized, then the tool does
Mary: could
Abby: could, yeah, provide
Mary: an appropriate thought process.

The teachers also stated that if these questions are ignored, the students will think very little about the theorem.

The teachers then considered the mathematics of the applet focusing on the restrictions on the segments lengths and the types of triangles can be formed. Abby asked, "Does it provide all cases? Yes." Mary responded, "The slider can be manipulated to any length." Bob interjected, Well, between zero and ten." Abby then asked, "Can it be an obtuse angle?" Bob responded, "Yeah, we can have an obtuse. Within. Yeah". As Bob created an obtuse triangle, the teachers discussed the merits of the segment lengths ranging from 0 to 10, specifically the length of a segment being zero. Abby said, "Um, yes the slider can be moved to any length from zero to ten. Students could potentially find a problem with side length of zero." She continued, "However, a discussion could be had about this issue." Mary and Bob agreed.

The teachers discussed whether the applet has a balanced difficulty level; whether all students would be able to use the applet to make appropriate meanings of the applet. Abby asked, "Does it have a balanced difficulty level?" Mary responded, "Yes, it's not too easy." Abby stated "Yes, not too easy not too hard."

When considering which applet they might select to use with students, the teachers compared the affordances and limitations of each of the four online applets.

Bob: If we were going to use an applet, we would use, what was it, the sec, the third one, the one that created the triangle for you. Even though it created the [tan] triangle for you, you could still discover the [triangle] inequality [theorem].
Abby: Overall if we wanted our students to develop the inequality on their own, tool three would allow, um, would, um, would allow

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Mary: for

Abby: freedom?

Mary: freedom in knowing when triangles can and cannot be created. And then possibly talking about why.

Abby: Alright, what'd you, I'm sorry. Okay.

Mary: Uh, knowing when triangles can and cannot be created, then a discussion could be had about why this is.

When asked which applet they would use with eighth grade students, Mary, Bob, and Abby strongly considered selecting this applet but chose to use a different applet.

Examples and Analysis

In the subsequent paragraphs, we provide examples of each of the framework's codes using Bob, Mary, and Abby's evaluation of the online applet and a brief analysis of their evaluation using the framework.

Attending

When evaluating the technology, teachers attend to particular features of the technology. We categorized these features into five codes (see Table 1). Upon opening the website, Abby attended to the instruction included in the applet by reading it aloud, and Bob continued to attend to it by saying, "Well it's unnecessary that it [instruction] tells you to move the line segments..." Mary, Bob, and Abby also attended to a given question. Abby said, "And I guess, this question down here at the bottom does make them [students] think about it [triangle inequality theorem]... " We coded these actions of attention as *instructions and questions* because the focus was on these particular features. At times, Mary, Bob, and Abby attended to *mathematical features* displayed in the applet such as angles and side lengths of the triangle. For example, Abby said, "In terms of the mathematics. I think that in this case with the angle measures... " Abby also attended to *aesthetics* when she noticed segments' color of the triangle by stating, "Okay, yes the use of three colors..." In addition, the teachers would attend to *interaction* by dragging or clicking as they explored the abilities and limitations of the applet. For example, dragging segments in the applet, Bob said, "See here when they're the same, it does, it shows you if you move your triangle, and then it shows point C as, well, so it shows that..." Attending to the *interaction* is unique to this particular framework because in other noticing studies, the analysis of teacher attending was mostly based on the teachers' verbal or written comments (e.g., Jacobs et al., 2010; Wager, 2014). In their evaluation, the teachers did not attend to *supportive features*, which is likely due to the fact that these features were not present in the applet. Other applets they evaluated included these kinds of features (e.g., a video demonstration) and the trio did attend to those features when they were present. While evaluating this particular applet, other trios did take note that the applet lacked supportive features.

Interpreting

When teachers provide their thoughts and ideas about features of the technology and the technology as a whole, we refer to these actions and statements as *Interpreting*. In this category, teachers reflect on their own uses of technology, consider how students may use the technology and anticipate how that affects students' learning of key mathematical concepts. Our analysis generated 6 codes for interpreting (see Table 1). Abby interpreted *student engagement*, when she said the angle markings could distract students from learning the theorem "because they are not essential to the development of the theorem." She wanted students to be engaged in learning the triangle inequality theorem and thought the angle markings may distract students from staying focused on the goal of the activity. Often Mary, Abby, and Bob would interpret whether a feature had *value*. When Bob realized there was no reason to move the segments because the tan triangle appeared, Mary said, "It's

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

very lame." Mary was interpreting the value of the tan triangle or, in this case, the lack thereof. There were times when Mary, Abby, and Bob interpreted the *mathematics* of the technology including the display of mathematics and how students could interact with mathematical ideas. For example, Abby noted the lengths of the segments could range from 0 to 10 and "students could potentially find a problem with side length of zero." Abby was anticipating students' difficulty with this mathematical issue. In one instance, Mary and Abby interpreted whether the technology could be used for *differentiation*, when they were attempting to determine whether the technology had "a balanced difficulty level". Abby also interpreted the technology's *design* when she noted the use of color and the smiley face as features that could positively influence student learning. Finally, Mary, Abby, and Bob interpreted *student thinking* when Abby and Mary discussed whether they would select this applet. Abby said, "Overall if we wanted our students to develop the inequality on their own, tool three would allow, um, would, um, would allow…" Mary continued, "freedom in knowing when triangles can and cannot be created." Abby and Mary considered how students could develop conjectures related to theorem based on their uses of the tool.

Responding

Based on their interpretation about features of the technology, teachers make possible or potential curricular decisions. We refer to these actions as *Responding*. In this phase, we defined 4 codes for the activities in which teachers might engage: Choose, Incorporate, Redesign, and Adapt (see Table 1). When comparing four applets, Bob argued he would *choose* this applet to use with eighth grade students. He said, "If we were going to use an applet, we would use, what was it, the sec, the third one, the one that created the triangle for you. Even though it created the [tan] triangle for you, you could still discover the [triangle] inequality [theorem]." When playing with the applet, Mary, Abby, and Bob found that a smiley face appears when the segments formed a triangle. Bob said, "It would be better if it gave you a frowny face if it didn't work." We coded his idea as *Redesign* because Bob considered how he could change the tool itself. When Mary, Abby, and Bob discussed whether the applet helps students develop an appropriate mathematical conception of the triangle inequality theorem, Mary said teachers need to emphasize the bottom questions in order to facilitate students' deeper understanding of the theorem. Mary's decision to emphasize the question did not change the applet itself; rather she was attempting to *adapt* it by placing greater emphasis on the question in order to best meet the needs of her students and meet her goals as the teacher. Finally, when Abby discussed the feature that allows students to adjust the sliders such that lengths could be zero, Abby considered how she could *incorporate* the applet into her teaching. Abby said, "Students could potentially find a problem with side length of zero." She continued, "However, a discussion could be had about this issue." By including a discussion, Abby did not want to redesign the applet or adapt particular features to meet her or her students' needs. Rather, she wanted to incorporate the applet as it stands, but she recognized the need to have a discussion about this particular feature.

Analysis

Using the framework in our analysis of Mary, Abby, and Bob's evaluation of the applet, we noticed that the trio attended mostly to mathematical features, instructions and questions, and how they interacted with the applet. They seemed to initially focus on the features the stood out the most (e.g., the smiley face and the tan triangle) but progressed to less noticeable features such as the range of the segment lengths. The teachers' initial interpretations were the design of the applet in which they focus on how the layout and features of the tool would influence students' interaction and learning. Their interpretations evolved into anticipating and interpreting how students would think when engaging with the applet. Finally, when we coded a response as adapt or incorporate, we noticed that we had also coded the teachers' interpretations as student thinking. It seems when the

teachers were considering how to use the applet in their own classroom, they were taking into account how students may think when using the technology.

Conclusion

We propose this framework as a device that allows researchers to examine how teachers evaluate and select MCTs to use in their classroom. In our evaluation of our data, we have been able to use the framework to document the evolution of teachers' evaluation beginning with their initial attentions and ending with the selection, rejection, or modification of the tool. We believe this framework can potentially allow researchers to examine how the inclusion or exclusion of particular features of technology influences teachers' evaluation and subsequent selection of technology. By conducting such an analysis with this framework, mathematics education researchers would be able to provide a clearer understanding of the processes teachers employ to select MCTs to use with their students.

EXPLORING STUDENTS' UNDERSTANDING OF THE LIMIT OF A SEQUENCE THROUGH DIGITAL AND PHYSICAL MODALITIES

Matthew Voigt
San Diego State University / University of California San Diego
MKVOIGT@gmail.com

The purpose of this study was to investigate how a set of physical and digital instructional activities can serve as an example space to help further develop a concept image that is aligned with the formal concept definition for the limit of a sequence. In addition, the unique affordances and constraints allowed by using either a physical or digital modality in understanding the convergence of a sequence was analyzed. Results suggest that both of these activities served to help students conceptualize the arbitrary nature of the error bound, and for some students it further illustrated the relationship between an arbitrarily small error bound, the limit value, and the index of the sequence. The physical activity constrained students to think of the sequence as a finite terminating set of numbers whereas the digital activity provided additional information that student used in subsequent problem solving.

Keywords: Technology, Post-Secondary Education, Instructional Activities and Practices

Students' misconceptions of limits and infinity are a well-documented and researched area in math education literature (e.g., Cory & Garofalo, 2011; Roh, 2008; Tall & Vinner, 1981). Students often have difficulty advancing from an intuitive dynamic conception of limit to the more formal limit conception, and often fail to understand the relationship between a given epsilon error range and the index of the sequence (Roh, 2010; Tall & Vinner, 1981). Students may resort to memorization tactics and often confuse the formal definition of the limit of a sequence with the limit of a function or other limit ideas.

Roh (2010) developed instructional materials that utilize visualization to support student understanding of the formal definition of the limit of a sequence based on the vast amount of misconception literature on limits and calls for the increased role of visualization in calculus (Dreyfus, 1990). Using an instructional activity referred to as the epsilon-strip task, Roh was able to categorize and support student understanding of the logical structure between epsilon and the index of a sequence. Roh has also shown how students' understanding of the definition of the limit of a sequence are influenced by their images of limits as asymptotes, cluster points, or true limit points using the same instructional activities (Roh, 2008).

This research project was driven by the conjecture that a technologically enhanced epsilon-strip instructional activity would make the instructional materials more accessible and promote deeper engagement by the user. Research shows that technology can be utilized to help students make sense of calculus concepts by using multiple representations (Tall, 1994) and that when technology uses dynamic versus static visualizations there is an overall benefit for student learning (Hoffler & Leutner, 2007). In a recent study with preservice teachers, dynamic sketches for sequence convergence were utilized to help strengthen their understandings of formal limit ideas as they integrated the visual representation with the symbolic definition (Cory & Garofalo, 2011). In this study, I seek to address how physical and digital epsilon-strip activities relate to students' understanding of limits of sequences. Furthermore, I investigate what constraints and affordances are provided in using either the physical or the digital epsilon-strip activity.

Theoretical Framework

Tall and Vinner (1981) examined student understanding of limits and developed the constructs of *concept image* and *concept definition* to describe the cognitive process of learning mathematics.

Concept image refers to the "total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes," whereas the *formal concept definition* is the form of words which are accepted by the mathematical community to describe the concept (Tall & Vinner, 1981). Often times a student's *evoked concept image*, which is the image generated given a certain context or prompt, may not be globally coherent and may deviate considerably from the formal concept definition. In the context of this study the formal concept definition for the limit of a sequence is referred to as the ε-N definition presented in Figure 1.

$\epsilon - N\ definition$: A sequence $\{a_n\}_{n=1}^{\infty}$ convergeges to L if,
for any $\epsilon > 0$ there exists $N \in \mathbf{N}$ such that for all $n > N, |a_n - L| < \epsilon$

Figure 1. Definition for the limit of a sequence referred to as the ε-N definition.

In addition to drawing on the concept image and concept definition framing, in this study I utilizes gesture theory from the field of embodied cognition as a means for illustrating student understanding through non-verbal communication. Preliminary research suggests that using dynamic visual environments can evoke metaphoric gestures to convey the temporal relationship in calculus concepts and are an essential element to effective mathematical communication (Ng, in press; Núñez, 2004). In this study I seek to answer the following research questions: In what ways do these instructional activities produce an evoked concepts image consistent with the concept definition for the limit of a sequence? Are there unique affordances or constraints in using either the digital versus the physical instructional activity?

Methods

The participants in this study were three undergraduate mathematics majors recruited from a Vector Calculus course at a 4-year public research university. At the time of the study, each student had completed a sequence of single-variable calculus and a course in analytic geometry and multivariable calculus. Additionally, each had previously been exposed to the definition of limit of a sequence and the concepts of convergence and divergence. The 45-60 minute semi-structured, individual interviews were video recorded and interview tasks were based on a modified sequence of instructional activities drawn from Roh (2010). Students were told they would explore a concept in calculus in a non-evaluative problem solving interview and were encouraged to think aloud as much as possible as they worked on each of the tasks.

In order to gain insight into each student's initial evoked concept image for the limit of sequence they were asked about their prior experience with limits of sequences and how they thought about of the convergence of a sequence. To further explore student conceptions of convergence they were asked to represent the sequence $\left\{\frac{n^3}{2^n}\right\}_{n=1}^{\infty}$ numerically in a table and prompted to determine what would happen to the sequence as the index *n* gets larger. After assessing students reasoning and prior background regarding the convergence of a sequence they were presented with the following digital and physical epsilon-strip activities.

The digital epsilon-strip activities were created with the design heuristic principles of manipulation of content and guided discovery (Plass, Homer, & Hayward, 2009). The *manipulation of content* principle asserts that student learning is improved if the learner is able to manipulate the content of a dynamic visualization and the *guided discovery* principle suggests students learn better when guidance is used in discovery-based learning in multimedia contexts. Using these principles I created digital activities using Desmos[©] online graphing utility as shown in Figure 2. A link to the resources and graphs used in this study are available at the following web address (goo.gl/Bm31eD). Students were given a brief tutorial explaining the onscreen graphs and the epsilon-strip. In

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

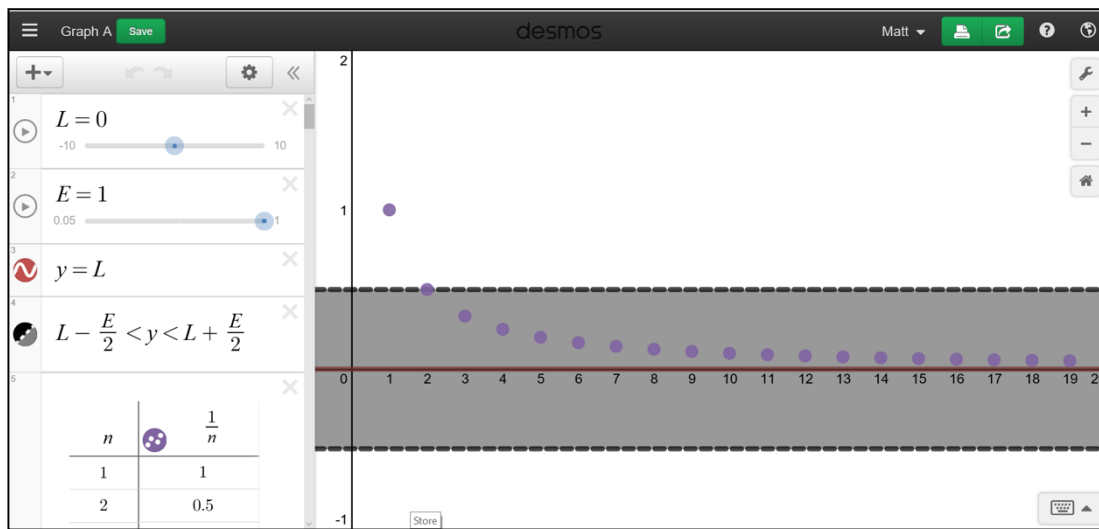
particular, they were shown how to manipulate where the epsilon-strip was centered and how to adjust its width through the use of sliders, which provide dynamic changes of the values, or by manually entering a desired value. Based on the principle of guided discovery, students were given an activity sheet that instructed them where to center the epsilon-strip, and had them iterate through three decreasing values for the width of the epsilon-strip. For each given epsilon width, students filled out a table where they counted the number of terms inside the epsilon-strip and the number of terms outside the epsilon-strip, which is referred to as the *counting process*. Student were then asked to repeat the same procedure and counting process but with the epsilon-strip centered at a different value. There were a total of three graphs explored, each selected to illustrate a different type of sequence convergence or divergence: monotonically convergent $\left\{\frac{1}{n}\right\}_{n=1}^{\infty}$, oscillating convergent $\{(-.75)^n\}_{n=1}^{\infty}$, and oscillating divergent $\{(-1)^n\}_{n=1}^{\infty}$.


Figure 2. Digital epsilon-strip graph for monotonically convergent sequence.

The physical activity consisted of printed graphs of a sequence and strips of rectangular transparencies that represented the error bounds of a limit of a sequence, as shown in Figure 3. In accordance with the guidelines presented in Roh (2008) the strips had a constant width and each were marked through the center with a red line. The same procedure and counting process as described for the digital activity were used with the physical activity. There were a total of three graphs explored with this exact process: monotonically convergent $\begin{cases} \frac{1}{n}, & n \le 10 \\ .1, & n > 10 \end{cases}$, oscillating convergent $\left\{\frac{(-1)^n}{n}\right\}_{n=1}^{\infty}$, and oscillating divergent $\left\{(-1)^n \left(1+\frac{1}{n}\right)\right\}_{n=1}^{\infty}$.

Figure 3. Physical epsilon-strip activity for monotonically convergent sequence.

After the digital and physical epsilon-strip activities, students were asked to evaluate the validity of two "student" generated definitions for the limit of a sequence, called ε-strip definition A and the ε-strip definition B:

- ε-strip definition A**:** *L* is a limit of a sequence when infinitely many points on the graph of the sequence are covered by any ε-strip as long as the ε-strip is centered a *L.*
- ε-strip definition B: *L* is a limit of a sequence when only finitely many points on the graph of the sequence are NOT covered by any ε-strip as long as the ε-strip is centered a *L.*

After evaluating these definitions students were given the formal ε-N definition and asked to explain each of the components of the definition and how they made sense of this definition. In the last part of the interview students were asked to explain how they saw the formal definition in relation to the ε-strip activities.

Results

Students' evolving concept image

Pedro's (all names are pseudonyms) initial concept image for the limit of a sequence was based on discrete representations, pattern recognition, and procedural computations. He recalled computing values for the limit of a sequence in prior mathematical classes, but was unable to provide a definition. When he was asked about the end behavior of the sequence $\left\{\frac{n^3}{2^n}\right\}$ he said it would depend on the relationship between the numerator and denominator. He stated that he would need to "plug in numbers and see the pattern" of values and then visualize those values to determine the limit. Pedro appeared to draw on a discrete representation of the sequence and pattern recognition to determine what the sequence was approaching as the index increased.

After the completion of the epsilon-strip activities Pedro was able to articulate several additional components related to his concept image for the limit of a sequence. He stated expressly the importance of where the epsilon-strip was centered, L, as crucial in determining if the sequence had a limit. He then linked the dependence on L with the idea that epsilon was allowed to vary and that for any epsilon there could only be finitely many terms outside of the strip. Although he didn't formalize the directional relationship between any given epsilon and the existence of some index *n*, he did articulate a relationship between the arbitrary epsilon and the finite number of terms outside

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

the epsilon error range, and used this reasoning in rejecting ε-strip definition A. In describing the formal definition, he used the physical transparency showing how the sequence will be contained using gesture to show a motion like pattern in the strip, and then pointed to the digital epsilon-strip activity to show that it has to be bounded in that range. Although the activities elicited further components related to the limit of sequences, he was still unable to explain how definition B was valid, or articulate how each of the components in the formal definition related to the limit of a sequence.

Nick's initial concept image of the limit of a sequence was the most robust of all three students. Nick initially drew on the limit as an asymptote concept and descried convergence as "it hitting a particular number as the index n approaches infinity." When computing the limit of the sequence $\left\{\frac{n^3}{2^n}\right\}$, Nick used a graphing calculator to plot the sequence as a continuous function and used the visualization to assert that the function was converging to zero. Nick's initial evoked concept image of the limit of sequence drew heavily from ideas of continuous functions and asymptotes versus the discrete representation conception evoked by Pedro.

After the completion of the epsilon-strip activities Nick's evoked concept image was similar to Pedro's yet contained further refinement regarding the relationship of the index n in the formal definition. Nick expressed that epsilon was "arbitrarily small" and you could, "pick any one" that you wanted, and that the limit value L was crucial in determining if the sequence converged to that particular value. Nick was the only student to explain the importance of the index n after picking an epsilon-strip, explaining that n is important because "we can always find an $n+1$ such that it is inside our strip." Nick first rejected both definition A and definition B, using an oscillating divergent sequence as a counterexample to definition A. Nick further argued that definition B was an invalid definition because it was possible to have a finite terminating sequence and thus there would be finite number inside and a finite number outside the epsilon-strip. When invited to consider an infinite sequence, Nick utilized the physical graphs, and then stated that definition B would be valid.

Heng's initial evoked concept image for the limit of a sequence included categorization and computational techniques. When discussing the limit of a sequence he drew on ideas of divergence as infinity and convergence as "related to some sort of range" of values. When computing the limit of the particular sequence$\left\{\frac{n^3}{2^n}\right\}$, Heng said it would go to infinity because he used the ratio tests to compare the "values of a_{n+1} and a_n." However, since he only compared the first two values of the sequence he failed to see that the sequence increases for the first few terms and then converges to zero.

During the physical epsilon-strip activity Heng viewed the oscillating convergent sequence as divergent since it alternated between positive and negative values. However, when working through the digital epsilon-strip activity he stated that the oscillating convergent sequence did converge since it was getting closer to the value of zero. Heng had one of the least developed concept images prior to the activity, and in addition expressed difficulty as an English language learner in engaging with the definition-provoking-activities that followed the digital and physical epsilon-strip activities. Heng initially asserted that definition A and B were correct, but after being asked to explain them in relation to the oscillating divergent sequence, he stated that A didn't fulfill the requirement and thus we "need both definitions for the limit" to exist. He did articulate that the epsilon-strip in the formal definition was arbitrary and that for "anyone that I pick" we can bound the sequence. He did not express the epsilon as arbitrarily small, nor was he able to express a relationship between epsilon and the index n. Heng, although acknowledging that they were different, wrote out the formal delta epsilon definition for continuous functions to try and make sense of the ε-N definition for convergence.

Affordances and Constraints

In addition to examining how the overall activities helped the development of student concept images related to the limit of a sequence, I analyzed the unique affordances and constraints provided by either using the digital or the physical modality for the epsilon-strip activity. During this study there were two prevalent constraints observed in using the physical modality related to the finite nature and imprecision of the epsilon-strips. Due to the nature of the static paper, both Pedro and Heng conceived of the graphs as a terminating sequence with only a finite number of terms and therefore had to be instructed to think of them as infinitely long. Although Nick did not evoke this misconception, he did use the example of a terminating sequence as a counter example to definition B, arguing that you could have finitely many inside and outside the strip. The imprecision of the epsilon-strips also lead each of the students to have questions about the ambiguity of terms lying on the epsilon-strip during the paper activity. This could have been a result of human cutting error regarding strip width uniformity or difficulties with the physical act of aligning and using strips. I speculate that the latter is more probable, since the strips were measured and cut using a guillotine style paper cutter and were observably uniform.

The digital modality offered several unique interactions that were not observed during the physical epsilon activity, including students using ancillary information provided by the digital modality and an increase in the use of gestures. Both Heng and Nick used the ancillary information that was located in the graphing utility on the left hand panel to reason and complete the activities. Heng, when working on the digital activities, first computed the epsilon error range given the width and center, and then used this range of numbers to compare against the table of sequence values in order to determine which terms were outside and inside the strip. Heng used this information to correctly identify the convergence for each of the digital activities, yet he failed to do so for the physical oscillating convergent sequence. Although this strategy was accurate, it is still unclear how this may have impacted his visualization of limits as it relates to the formal definition. Nick also drew on the additional information and argued that since the function was programmed in as $\{1/n\}$, he knew from prior experience that this sequence would converge to zero. It should be noted that the same ancillary information could have been included in the physical graphs, but they were an automatic result of using the digital technology.

Both Pedro and Nick increased their use of gestures when interacting with the digital modality and during the definition activity, as illustrated in Figure 4. I attended to the use of gestures in this study since the prior research from Roh's studies have failed to address the role of gesture in mathematical learning. Moreover, using the dynamic digital modality one might expect an increase in the use of gestures because the visual movement parallels the movement of the gesture. Pedro utilized his thumb and index finger in a collapsing motion when highlighting the arbitrarily small nature of epsilon while using the digital modality. Nick used a similar gesture when talking about the arbitrary nature of epsilon but used his thumb and all of his remaining fingers to show a collapsing dynamic motion. While neither Nick nor Pedro explicitly stated the concept that epsilon values tend toward zero, their gestures indicate an understanding of this very relationship. Nick also utilized his left forearm and right hand in an up and down motion when discussing the importance of where the epsilon-strip was centered in determining the limit while interacting with the physical modality, suggesting that the tangible movement of the strip was more salient given the physical context.

Conclusion

This study was driven by a desire to take existing innovative instructional materials and utilize technology in a controlled setting to ascertain how they may jointly help develop students' concepts images for convergence, and furthermore provide insight into the affordances and constraints in using the two different modalities. Both the physical and digital activities helped to illicit a more detailed evoked concept images regarding the limit of a sequence from all three of the participants. All of the students after the activity expressed the limit in relation to the arbitrary nature of the epsilon-strip, and two of the students conceived of epsilon as getting arbitrarily small. Students still had issues explaining the formal ε-N definition of the limit of a sequence, with only one student articulating the importance of the index *n* as it related to the chosen epsilon error range. Although students didn't have a globally aligned concept image with the formal concept definition, each expressed how the nature of these activities helped them think and reason about the formal ε-N definition of the limit of sequence.

In comparing the two types of modalities, it appears that the physical activity seemed to constrain students into thinking of the sequences presented as finite and terminating. In addition there were issues of ambiguity related to when a given term was located inside the epsilon-strip either because they were not cut uniformly or because they were not centered level to the x-axis. The digital activity provided students with a dynamic representation which may have resulted in the increased presence of gestures in describing the definitions. In addition, the ancillary information was used in unique ways during the counting processes in unanticipated ways, such as the formal examination of the table of values. Future research studies may examine each of these activities with a larger range of students and determine if the gestures used by students is a unique affordance of the dynamic nature of the digital representation of the epsilon-strip activity and address the effect of the ancillary information (i.e. table of values or programmed function) on students understanding.

There is clearly more room for the examination of innovative and improved curriculum even though mathematics education literature abounds with research on student misconceptions of limits and infinity. In this study, a technologically enhanced epsilon-strip activity proved beneficial to promote student understanding of the limit of sequence. It provided a dynamic visualization of the epsilon-strip as an arbitrary small error range for a sequence that appeared to continue on ad infinitum. It is the hope that as these instructional materials and technology further develop, they will serve to broaden the example space that students draw upon in order to understand the formal mathematical definition of the limit of a sequence.

TEACHING WITH VIDEOGAMES: AN EXPLORATION OF EXPERIENCE

Amanda Bell
Vanderbilt University
amanda.m.bell@vanderbilt.edu

Melissa Gresalfi
Vanderbilt University
melissa.gresalfi@vanderbilt.edu

Digital games have demonstrated great potential for supporting students' learning across disciplines. But integrating games into instruction is challenging. One factor that contributes to the successful use of games in a classroom is teachers' experience implementing the technologies. We explored this idea by comparing years 1 and 2 of a middle-school mathematics teacher's use of Boone's Meadow, a digital problem-solving game around ratio and proportion, in her classroom. While the two implementations were quite similar, the teacher was able to use students' gameplay time more productively in the second year, both for mathematical engagement and for immersing students in the narrative of the game.

Keywords: Instructional Activities and Practices, Middle School Education, Technology

Introduction

It is difficult to claim at a large scale that technology integration is associated with increased learning (Penuel, 2006). However, digital games in particular have demonstrated potential for supporting student learning across disciplines (Gresalfi & Barnes, 2016; Pareto et al., 2011; Squire, 2006). Much has been said about the potential of games to capture student attention (Dickey, 2007; Garris, Ahlers, & Driskell, 2002; Lepper & Malone, 1987), to situate disciplinary learning in realistic contexts (Barab et al., 2005; Clarke & Dede, 2009), and to offer consistent and substantive feedback (Gresalfi & Barnes, 2016; Mayer & Johnson, 2010; Nelson, 2007).

Despite their potential, integrating digital games into instruction also creates new challenges and requires a shift from current pedagogical practices to those afforded (or demanded) by new technologies (Ertmer, 2005; Straub, 2009). It is not simply a matter of making the tools available (Ertmer et al., 2012; Ertmer, Ottenbreit-Leftwich, & Tondeur, 2014). Instead, like every reform that has the potential to change classroom practice, it is important to develop a model of what successful integration looks like in that particular context. In particular, one factor that contributes to the successful integration of games is teachers' experience with the technology, which affects teacher practice in a number of ways (Ertmer & Ottenbreit-Leftwich, 2010; Mumtaz, 2000; Sheingold & Hadley, 1990). As with any new classroom technology, the more teachers use it, the more they understand how students interact with the technology and what aspects are difficult for students to understand, which can lead to more organized and focused classroom discussions based on students' needs.

This paper focuses on a videogame that was designed to incorporate teacher-student interactions rather than replace instruction. In this context, the teacher's role is central to implementing the game successfully. We explore how one teacher uses the game across two years and how integration of the game changes with her experience with the technology.

The Game

Boone's Meadow is an interactive problem solving experience that involves mathematical ideas of ratio and proportion. In the game, a veterinarian recruits players to help save an injured eagle using an ultralight (a small plane). Players must choose between three different ultralights to use based on fuel efficiency, speed, and payload. Players must also plan the route to pick up the eagle and safely return her to the veterinary clinic in time, choosing whether or not to stop for gas. Players have two attempts to save the eagle, and they can use the second try to find a more optimal solution (taking less time, using less gas, and spending less money) or test another route.

Methods

Setting/Participants

This paper focuses on Ms. Lynn, a 7th grade mathematics teacher at a school with 92% free and reduced lunch and 30% English language learners in a southeastern U.S. city. Ms. Lynn used the game in her classroom for 4 days during the fall of both years 1 and 2.

Data Collection

Data includes videos of gameplay and whole class discussions, and students' pre and post-tests about ratio and proportion. We also interviewed Ms. Lynn informally after the game implementations, and we use her responses to triangulate our findings.

Analysis

The teacher's talk was coded by utterance. We coded the teacher's talk for four different types of mathematical engagement (from Gresalfi & Barab, 2011): (1) procedural – following procedures, (2) conceptual – conceptual explanations of procedures, (3) consequential – examining how procedures relate to outcomes, and (4) critical – questioning why one procedure should be used over another. We also categorized talk as defining terms from the game or narrative immersion (when the teacher makes explicit connections to the story).

Findings

Table 1: Average Pre and Post Test Scores for Years 1 and 2 in Ms. Lynn's Classes

Year	Average Pre Score	Average Post Score	Significance (p value)
1	3.46	6.77	p<0.004
2	11.17	12.39	p<0.04

We first analyzed the pre and post-test changes for Ms. Lynn's classes (Table 1). The year 2 scores start out higher because items were added to the tests. Both years showed significant pre to post-test change, with a larger gain occurring in the first year. However, Ms. Lynn devoted much more time to the implementation in year 2 (262 minutes total of gameplay and discussion time in year 1 versus 404 minutes in year 2), taking less time to transition between classes or talk about other issues unrelated to the content of the game (like field trips).

The number of utterances coded as conceptual, consequential, or critical mathematical engagement was similar in both years, with less than 30 utterances in each of those categories. Most of Ms. Lynn's math talk with her students afforded procedural engagement. While the overall counts are similar, more of the procedural engagement occurred during gameplay (and less in discussion time) in year 2 (see Figure 1). Similarly, the amount of teacher talk involving narrative immersion increased during gameplay time in year 2 (see Figure 2). The amount of talk around defining terms from the game (such as fuel capacity or endangered) also increased.

Figure 1. Graph of number of utterances coded as procedural engagement during discussions versus gameplay in years 1 and 2.
Figure 2. Graph of number of utterances coded as narrative immersion during discussions versus gameplay in years 1 and 2.

Discussion and Conclusions

In this paper, we examined changes in Ms. Lynn's math and game talk during discussion and gameplay time in her first two years of implementing Boone's Meadow. In our informal interview with Ms. Lynn after year 2, she reported her that the second year went much better, specifically because students were much more engaged in the game and the mathematics in year 2. "That's one thing that I liked this year versus last year…they would come in and they were working and trying to understand and very rarely did they need an adult."

The biggest differences in teacher talk between years 1 and 2 can be seen in the context of the talk, that is, whether it occurred during class discussions or gameplay time. Much more of the mathematical discourse took place while students were actually playing the game in year 2. Similarly, Ms. Lynn engaged her students in much more narrative immersion during gameplay in year 2. This might be due to her increased familiarity with the game or with her increased value of the narrative, which she felt created an important context for her students' mathematical thinking. We believe this shift in the context of discourse reflects Ms. Lynn's increased experience with integrating the technology into her classroom.

The case we examined in this paper was unique in a number of ways. First, the students in Ms. Lynn's class were far below grade level in their mathematics achievement; most students had very little multiplicative reasoning. This might help to account for the time spent on procedural engagement. However, it is interesting that the teacher saved her procedural mathematics talk for

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

gameplay times, rather than "pre-teaching" before game play commenced. Second, the teacher was strongly committed to providing her students with an opportunity to engage in mathematical problem solving. She saw the game as an important and unusual opportunity for her students, despite comments she received from the mathematics coordinator that the game had caused her class to fall behind schedule: "…to me, I feel like the experience is so valuable, that it is worth the time, and we will skip something else that is less valuable."

STUDENTS' USE OF A COMPUTER PROGRAMMING ENVIRONMENT TO REPRESENT DISTANCE AS A FUNCTION OF TIME

Anna F. DeJarnette
University of Cincinnati
dejarnaa@ucmail.uc.edu

I used the framework of Realistic Mathematics Education to examine students' reinvention of representations of distance through the use of a visual programming environment. With the resources of the environment, most students initially created pictoral or pseudo-symbolic representations of the distance traveled by a moving car. Although students struggled to create graphs, their use of variables foreshadowed connections between the motion of the car and a graphical representation. This study is part of a design experiment aimed at privileging students as active creators of mathematics through the use of technology, while also scaffolding connections between different representations of function in algebra.

Keywords: Algebra and Algebraic Thinking, Technology, Middle School Education

Education within STEM fields often reveals boundaries between different subjects, driven in part by subject-specific content standards that students are expected to learn. Computing and programming technologies support the work of doing mathematics professionally in the 21st century (Lockwood, Asay, DeJarnette, & Thomas, 2016); and the increasing relevance of computer science instruction for students in secondary grades makes it necessary to consider how computing may be used as a resource for learning mathematics (Grover & Pea, 2013). This creates an opportunity to identify openings in the boundaries between mathematics and technology education, specifically in the use of computer-programming technologies.

I report on the first phase of a design research project aimed at using computer-programming technologies to support students' conceptual understanding of linear functions. I examined students' creation of representations of distance as a function of time through the use of a visual programming environment. I considered two research questions: (1) What representations did students create through their use of a visual programming environment to represent distance traveled by an object? (2) How might students' creation of representations be scaffolded so that students can discover connections between these representations? The findings of this study have implications for the design of a learning experience to support students to make connections between representations of function in algebra through the use of programming technologies.

Theoretical Framework

The approach of Realistic Mathematics Education (RME) places students at the center of recreating mathematics through explorations of relevant contexts (Freudenthal, 1973; Gravemeijer & Doorman, 1999). This principle, known as *guided reinvention*, posits that students should be able to participate in the process through which mathematical ideas and procedures were created, thus foregrounding mathematics as an ongoing human activity (Freudenthal, 1973; Gravemeijer, 2004a). To take as an example the case of multiple representations in algebra, this means that students should have the opportunity to conceive of the use of tables, graphs, and symbolic representations of a function, rather than being presented with these representations as predetermined techniques or resources for particular problems. In fact, there is evidence from prior research of students using a Logo-like environment to program real-life motion and inventing graphing as a way to keep track of that motion (DiSessa, Hammer, Sherin, & Kolpakowski, 1991). Students' use of programming–environments provide a setting for students to recreate mathematics as they formulate and solve problems through the concrete representations afforded by the environment.

An important aspect of the principle of guided reinvention is that the instructional environment plays a critical role in providing the conditions for students to recreate mathematical ideas and activity (Kaput, 1994; Gravemeijer, 2004a, 2004b). To support students in actively reinventing important mathematics, teachers need instructional activities that have been designed and revised through empirical evidence of student work (Gravemeijer, 2004a). Design research allows for instructional activities to be developed through a cyclical process of instructional experiments that home in on students' learning processes (e.g., Gravemeijer & Doorman, 1999; Rasmussen & King, 2000). This study reports on the first phase of a design experiment intended to understand students' thinking about multiple representations through the use of a programming environment. I report on students' work on a task of representing distance a moving car has traveled as a function of time within the environment.

Data and Methods

I conducted this study as part of an after-school club in a large suburban junior high school serving grades 7–8. During the club, students used Scratch (http://scratch.mit.edu) to learn about computer-programming techniques such as the use of if-then statements and loops. Scratch is a visual programming environment, which means that users are able to program objects through a collection of drag-and-drop tiles, rather than through the inputting of a programming syntax. In this study I focus specifically on weeks 3-4 of the club. During this time students needed to program a car to race another car around a track, and then they needed to create dynamic representations of their car's distance traveled and speed as functions of time. For the analysis, I include only pairs for which at least one student in the pair was present each of the two weeks. This includes data from 11 pairs of students, each pair working together at one computer. I recorded students' work on the computer through the use of screen capturing software. The software continuously recorded all activity happening on the computer screen while recording audio, producing a video of students' work.

Following the data collection each week, members of the research team used video recordings to produce timelines of students' work at the computer. Using the timelines, I identified increments during which students worked on the task of creating a representation of the distance traveled by their car. I used a coding template to identify the types of representations proposed by students and how the representations students created were connected to the motion of the car. Finally, because there were times when students proposed representations that they did not create, I noted any barriers that students came across in their attempts to create a specific representation.

Findings

Table 1 summarizes pairs of students who created different types of representations in Scratch. In cases where students were satisfied with their creation of an initial representation, the instructor encouraged them to try to create a second representation of distance traveled. Given the different paces at which different pairs worked, not all students worked on a second representation. Pictoral and pseudo-symbolic representations (described further below) were the most common among students' choices. Some pairs attempted to create graphs and tables, although these were more common in in students' second representations.

Table 1: Students' Creation of Different Representations of Distance

	Picture	Pseudo-Symbolic	Graph	Table	Measurement
1st Representation	5	4	1	0	1
2nd Representation	0	3	3	2	0

The most prevalent initial representation was the pictoral representation (included on the left of Figure 1). Scratch is equipped with a collection of drag-and-drop tiles that can be used to program a

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

moving object to trace its path. In the picture in Figure 1, students programmed the red car to trace its path with a blue curve. With the pictoral representations, students seemed to view the curves drawn by the moving cars as an artifact of the distances those cars had covered. The tracing commands could be used independently of how the car's motion had been programmed, which made this representation an accessible entry point in students' work.

   I use the term "pseudo-symbolic" to describe those representations in which students created a variable to keep track of the total distance their car had traveled. For example, the students whose work is pictured on the right side of Figure 1 created a variable in Scratch called "distance (number of steps)", which increased by 10 each time the car moved 10 steps. To create this representation, students used a variable to represent total distance and implicitly made use of the formula *distance = rate×time*, where the rate was measured in number of steps the car moved per iteration of the loop, and time was measured in the number of iterations of the loop. The representation was pseudo-symbolic in that it required the creation of a variable and some explicit connection between that variable and the motion of the car, but the representation did not require any explicit connection with symbols to represent rate or time.
Figure 1. Pictoral (left) and pseudo-symbolic (right) representations of distance.

   Although graphical and tabular representations were less common among students, they became more common after students had produced a pseudo-symbolic representation. Consider one example of this, from the work of Nick and Greg, who controlled the speed of their car by a variable labeled "speed". After creating a pseudo-symbolic representation of distance by aggregating the car's rate over time, Nick and Greg used their speed variable in an effort to produce a graph of the distance the red car had traveled as a function of time (Figure 2). Although Nick and Greg's graph contained errors, their solution used their pseudo-symbolic representation as a precursor to graphically representing distance traveled as a function of time. Students' use of symbolic tiles provided a concrete way to connect the speed of the moving object with a dynamically created graph representing that object. In a future iteration of the design research project, these connections will be made explicit to guide students towards the reinvention of graphical and tabular representations of distance as a function of time.
Figure 2. Nick and Greg's graphical representation of distance as a function of time.

Discussion and Conclusion

This study has provided the foundation for a sequence of instructional activities designed to support students' guided reinvention of representations of function through the use of a computer–programming environment. Findings from students' work indicate that an environment such as Scratch provides the resources to create pseudo-symbolic representations with explicit connections between the motion of an object and the total distance it has traveled. Although graphical representations may require more explicit guidance from an instructor (DiSessa et al., 1991), pseudo-symbolic representations can serve as a link between a physical phenomenon (created or modeled through the use of Scratch) and a dynamic representation of that phenomenon. In the next iteration of this work, students' creation of pictoral and pseudo-symbolic representations will be used to scaffold the introduction of graphs and tables.

The use of Scratch for creating physical motion through the use of a computer program, and then representing the distance that object travels over time, represents a blurring of the distinction between computer science and mathematics education. The use of a computer-programming environment, which provides a concrete, experientially real context for students to explore, provide a setting for their guided reinvention of mathematical ideas and processes. Thus, guided reinvention can be inspired not only by the ways that mathematics has been done historically (e.g., Gravemeijer & Doorman, 1999), but also by the ways that mathematics can be done through the use of increasingly robust and accessible technology tools.

OPTIMIZING TEACHER AND STUDENT AGENCY IN MINECRAFT-MEDIATED MATHEMATICAL ACTIVITY

This brief research report describes a project we undertook to design and implement mathematical tasks for use in Minecraft. At several points in the implementation of these tasks we were mindful that what we refer to as teachers' and students' spheres of agency were in interference, with teachers' agency to pursue instructional goals in competition with students' agency to pursue self-directed activity. By acknowledging that agency is a powerful force that should be honored but perhaps also negotiated, we sought to identify the essential elements of the design and implementation of tasks that generate a space for mathematical activity in which both teachers and students are afforded agency and have the capacity to exercise it. In this report we present excerpts from the data that illustrate varied enactments of agency by teachers and students that point to a way forward in identifying a productive balance between the two.

Keywords: Technology, Design Experiments, Affect, Emotion, Beliefs, and Attitudes

There has been a recent surge of interest in the potential of video games as immersive, interactive, and creative spaces for students to learn mathematics. For students, video games offer the promise of familiar and enjoyable modes of creative play; for teachers, they offer the promise of an opportunity to leverage that play in pursuit of the advancement of mathematical knowledge. Unfortunately, classroom teachers have historically found it difficult to implement these environments in their own classrooms due to what seem to be inevitable conflicts that arise between the objects of students' self-directed activity and teachers' own instructional goals (Jenkins, 2014). Our research seeks to produce a framework that teachers can use to implement gaming environments that sustain the joy and creativity of gaming, while emphasizing the purpose and utility of mathematics (Ainley, Pratt & Hansen, 2006) and harnessing the potential for students to act as agents of their own learning (Stroup, Ares & Hurford, 2005). Recognizing that what we refer to as teachers' and students' *spheres of agency* must be negotiated and are bound to intersect, we sought to identify the essential elements of the design and implementation of tasks that generate a space for mathematical activity in which both teachers and students are afforded agency and have the capacity to exercise it.

Theoretical Framework

Our vision of Minecraft as a tool for learning is informed Vygotsky's (1978) notion of mediated activity and Verillon and Rabardel's notion of instrumental genesis (1995), each of which express the dialectic relationship between tools and sense-making. Minecraft is a sandbox-style video game in which players explore and build within a world that looks similar to our own. Players assume an individual, first-person view of the world and experience it through the eyes of their avatar. The graphics are purposefully "blocky" and provide a "visual allusion to LEGO™" that "suggests a space in which the player is given free rein to create whatever he or she wishes from the pieces provided" (Duncan, 2011, p. 4). Indeed, as Kuhn (2015) suggests, agency is the unique affordance of sandbox-style games like Minecraft, which generate a space of possibilities in which users can exercise this agency to craft their own narratives.

Our perspective on Minecraft-mediated mathematical activity (MMMA) is informed by Resnick's (2014) approach to Constructionist design, which features four core elements of creative learning: meaningful projects, peer collaboration, a passion for the work, and playful

experimentation. We designed mathematical tasks with a "Freirean intention" of generating a space for MMMA characterized by an environment of mutuality and trust among students and teachers that encourages students to assume active roles (Freire, 1970). Within that space, "willing and doing are unified. Students are central to what expressive artifacts and insights are produced" (Stroup, Ares, & Hurford, 2005, p. 192). They decide not just "to play along, but also to play a part in what the activity is about [and] what matters" (p. 192). Accordingly, we focused on agency as a significant feature of MMMA and explored it by taking a socially situated perspective that views learning as legitimate participation (Lave & Wenger, 1991) in communities where students' collaborative activity involves them in shaping classroom practice. As a consequence of that involvement, students come to feel powerful and engaged. Their sense of ownership is advanced and they gain legitimacy by exercising the agency afforded to them.

Mindful of the conflicts that have been seen to arise between the objects of students' self-directed activity and teachers' own instructional goals when gaming environments are introduced classrooms, we sought to answer the question: How might a teacher implement a gaming environment in a mathematics instructional setting so that both teachers' and students' agency are honored and leveraged in the development of mathematical knowledge?

Methods

We took a design experiment approach (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) to determining principles for the design of tasks that generate a learning ecology wherein students engage in enjoyable, agentive, and productive mathematical work that could engender changes in their mathematical knowledge. Two of the authors assumed the roles of teacher-researchers engaged in systematic inquiry in relation to developing a framework for the design and implementation of agentive MMMA tasks. Three students in grades 4 and 5 who were enrolled in a STEM summer camp that took place at our university participated in the study. We chose these students because they had worked with Minecraft before and were familiar with the environment.

We collected video data of classroom discourse and computer interactions in addition to reflective journals in which we recorded observations on students' mathematical work at the conclusion of each of the five class meetings. We conducted a thematic analysis (Braun & Clarke, 2006) by transcribing the video data and looking for relationships that emerged from an iterative re-reading of that data by each of the authors. Specifically, we sought to identify interactions between the design of tasks, their implementation, and their generated spaces of agency. As our findings are preliminary, the instances of negotiated and intersecting spaces of agency that we identified from the video data formed the basis of the analysis that is presented here.

Preliminary Findings

The theme across all of the tasks was that the students played the role of town developers who were being asked to renovate and build structures in a Minecraft environment called CraftLand. In the first of these tasks, we pre-installed a pile of stone blocks in the shape of a rectangular prism (Figure 1, Stone Pile task) and challenged the students to find the number of blocks in the pile. Our goal for this task was to engage students in the experience of volume measurement in three dimensions and they did so by leveraging the inherent agentive nature of Minecraft and also the space of agency generated by a task featuring multiple pathways and an agreed upon endpoint (Stroup, Ares, & Hurford, 2004). We saw a diversity of approaches to finding the volume, ranging from simply counting the blocks on one level and multiplying by the height, to digging inside the pile to confirm that it was solid, to building additional nearby structures that allowed students to gain a perspective on the pile from above.
Figure 1. (left to right) Stone Pile, House Design, and Staircase tasks.

The Stone Pile task also called on students to obtain a set of tools with which to build a mine cart and a track that would carry the demolished stones to another location. The outcomes of this task were not as we envisioned. As there was just one set of hidden tools to be found, students were expected to share those tools in collaboration with each other. However, when one student found the tools, he was reluctant to share them with the others. The teacher then assumed her obligations not just to the target mathematical content but to her commitment that every student engage in agentive and collaborative MMMA by intervening to alert them that the task required collaboration, not the kind of competition-style gaming they were used to in Minecraft. In traditional gaming environments, such competition for resources is to be expected and this expectation seems to have been the rationale for the student's behavior.

The House Design task (see Figure 1) called on students to build a house with a base that has a perimeter of exactly 36 blocks. This task was generative (Stroup, Ares, Hurford, 2004) in that students had free reign with respect to how they would accomplish it to satisfy the single constraint. Students were afforded agency that they could exercise in the completion of the task, but the boundaries of that agency were not well understood. When the teacher exercised agency to initiate a discussion in which students would share their strategies, not all students were interested in participating. Doing so would require that they give up what they perceived as their own Minecraft time, something that the students could be reluctant or unwilling to do. At one point when the teacher asked "Jacob" how he determined that the perimeter of his house was 36, he responded, "Let me show you after." The teacher's request came at a time when Jacob was engaged in a task he had set out for himself.

A similar conflict occurred during the Staircase task (see Figure 1). Students were given the opportunity to either work together or on their own as they constructed staircases to fit each of the four levels of a building. One student was intent on exploring another area of the world, climbing in and out of the gardens and chopping down any bushes he encountered. The teacher noticed what this student was up to and insisted, "This isn't where you're supposed to be. You're supposed to go find this building and work with Jacob." Ignoring the teacher's redirection, the student continued to go about his business. In response, the teacher used Minecraft's admin tools to teleport the student to the building where he was meant to be working. He was rattled by the interruption of his play when his screen darkened and his avatar was suddenly transported from the gardens to the building. With respect to both of these conflicts, we were cognizant of our need as teachers to assume our obligations to instructional goals, but nonetheless we were dismayed by the felt need to interfere in activity that students assumed they had been afforded more agency over.

Conclusion

Throughout the implementations of the tasks of the design experiment, we witnessed the negotiations and interactions that were provoked between the instructional goals of the teacher and the desire of students to be agents of their own activity. At ideal points, such as when students exercised self-directed activity in the completion of a given task, teachers were able to leverage that agency toward the development of mathematical knowledge. The Minecraft environment proved to be a suitable space wherein students could construct "objects to think with" (Papert, 1980), thereby

providing them opportunities to explore and advance that knowledge. In contrast, when teachers' and students' spheres of agency were in interference, such as when students exercised the agency afforded to them in the pursuit of their own task-irrelevant goals, teachers exercised their own agency in the pursuit of instructional goals by shutting down students' activity and redirecting them to the task at hand. At these points, the environment proved to be well suited to students' intentions as they leveraged their agency toward game-based play but ill-suited to teachers' intentions to leverage their own agency in the support of mathematical learning.

Regardless of the nature of the ways that teachers and students exercised the agency afforded to them, their actions were reasonable with respect to their expectations for Minecraft play and the target goals of that play. We hope that the task design and implementation framework for Minecraft-mediated mathematical activity we are constructing will honor both teachers' and students' intentions to the extent that they align with and support learning. We believe that such a framework will be beneficial to teachers who wish to engage their students in game-based mathematical activity and also to the developers of such gaming environments who wish to support it.

ROLLY'S ADVENTURE: DESIGNING A FRACTIONS GAME

Caroline Williams-Pierce
University at Albany, SUNY
cwilliamspierce@albany.edu

New digital medias, such as games, provide the opportunity for radically re-envisioned mathematics representation and engagement in both formal and informal contexts. This paper aims to present a game, Rolly's Adventure, that was specifically designed for and built on the PlayStation 3 platform LittleBigPlanet 2, and combines best practices for game design, research on supporting fractions learning, and the affordances of this unique platform.

Keywords: Technology, Design Experiments, Number Concepts and Operations

"I claim that using video games is the way Euclid would have taught basic mathematics had that technology been around in ancient Greece" (Devlin, 2011, p. 47).

New digital medias provide new opportunities for mathematics education, but – perhaps most importantly – new challenges. This paper proposes an investigation of some of those challenges that aligns with the PME-NA theme of *Sin Fronteras: Questioning Borders with(in) Mathematics Education*, by presenting a game built at the intersection of mathematics education and videogame design. From with(in) this intersection, *Rolly's Adventure* (Williams, 2015) was designed to take full advantage of these new interactive spaces, instead of following the unfortunate trend of creating digital versions of flash cards, worksheets, and activities where the mathematics is disconnected from the context. In particular, the author combined the learning affordances of videogames (e.g., Salen & Zimmerman, 2003; Schell, 2008) with the ways that students best learn particular mathematics concepts (in this case, fractions), as identified by leading mathematics education researchers (e.g., Hackenberg 2007, 2010; Steffe & Olive, 2010; Tzur, 1999). This process of *combining* is by no means simple, as game design principles, mathematics learning research, and even the vagaries of chosen digital platforms are occasionally prone to irreconcilable differences. However, digital media such as videogames provide the opportunity to design new representations and interactions for learning mathematics in powerful ways, and such a border is worth investigating.

Mathematics Learning Games

A considerable number of games ostensibly intended to teach mathematics concepts have recently flooded the market, and many of them are merely digital duplications of non-digital mathematics activities, such as flashcards and other skill-and-drill activities. Other math games have richer digital worlds, but the in-game activity and the mathematical activity are often deeply disconnected. For example, Gillispie (2008) describes *DimensionM*, a rich game world designed to support mathematics learning, in which the players are stranded on a beautifully rendered desert island. A nearby gate must be unlocked by finding nearby nautilus shells that have prime numbers on them. In other words, the task (unlocking a gate) requires the very unrealistic task of identifying prime numbers on objects that do not normally have prime numbers on them, requiring the player to engage in non-authentic mathematical activities.

Other math games are designed by learning scientists or math educators and researchers, and strive for a more organic design that pairs the activity and the mathematics more deeply. For example, the virtual world *Quest Atlantis* has a mission that uses the theory of transformational play to position player, content, and context together for powerful statistics learning (Barab, Gresalfi, & Ingram-Goble, 2010). *Candy Factory* (see, for example, Norton et al., 2014) is a fractions game with deep roots in research and theory, designed to assist the player in progressing through five schemes

(Steffe & Olive, 2010). Both games offer legitimate engagement with mathematical concepts that are naturally embedded within mathematical activities, amid game structures to support engaged learning.

However, few math games are able to take full advantage of the new opportunities by re-envisioning what doing mathematics can *look like*. This partially due to the constraints of participating in a field where a considerable amount of design for mathematical activities are conducted within formal educational environments that have their own limits in terms of time and technology access, and partially because the field of videogames – and educational videogames in particular – is still nascent. It is difficult to simultaneously invent new digital contexts for mathematics learning *and* invent new representations within those digital contexts.

Learning and Design Goals

Fractions

Smith (2002) declares that "No area of elementary school mathematics is as mathematically rich, cognitively complicated, and difficult to teach as fractions, ratios, and proportionality" (p. 3). The *Common Core State Standards for Mathematics* (CCSSM) (National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010) in the United States also recognize fractions as a complex and important area of mathematical learning. For the purposes of this paper, I define fractions as "a *relationship* or multiplicative comparison between two quantities" (Lobato & Ellis, 2010, p. 58, italics original). Quantities are characteristics of objects that can be measured prior to any actual measuring, or even a determination of *how* such a characteristic could be measured (Thompson, 1995, 2010).

Of particular importance is that quantities, even prior to measuring, can still represent a fraction – in other words, a glass half full is always half full, even when the liquid or glass have not been measured or numerically labeled. I highlight this because Thompson (1995) warns us to be on our guard when using notation: "...it is easy to confuse convention and principle unthinkingly. There is nothing principled about standard algorithms. They are standard only because they have become customary within a community" (p. 201). Thus, the familiar notation of ½ is a convention designed to abstract from, for example, a glass half full – but both ½ and the glass half full legitimately represent a fractional relationship.

Game Design Learning Principles

The field of games studies regularly discusses possible definitions of *game*, but has yet to settle on a single overarching definition. My definition is one of the many outlined by Schell (2008): *a problem-solving activity approached with a playful attitude*. In short, I developed a problem-solving activity using quantitative representations of fractions, and relied upon the game context to support players approaching it with a playful attitude. In doing so, I relied upon learning principles commonly used in games (e.g., see Gee, 2005), but given space constraints, I share only one here: the opportunity for failure.

The term *failure* nicely illustrates the contrast between mathematics classrooms and mathematics games. In classrooms, the word is associated with a variety of high stakes issues that may result in a student re-taking a class or possibly staying back a grade – there is nothing positive about failure. In well-designed games, however, players learn *through* failure: as they enter this new imaginary world and begin testing ideas, the game indicates an incorrect hypothesis about how to behave through failing the player. The player then revises her hypotheses and ideas in response, and tries again. As Gee (2005) notes, a good game "makes failure part of the fun and central to learning" (p. 13). Mathematics games have the opportunity to incorporate the useful parts of failure in a way that

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

classrooms may not, given the negative associations with the term (and the experience of *failing*) in formal education.

LittleBigPlanet 2

LittleBigPlanet 2 (LBP) is simultaneously a *game* and a *platform*: the disc comes with a game to play, and provides the opportunity to unlock the tools used to design and build the same game, or one of the player's own devising. After creating their own game, players can hit "publish" to share with the entire LBP community via the PlayStation Network – and millions of levels have been created and shared in this fashion, including *Rolly's Adventure*. LBP provides sophisticated tools that allow for complex design with only an understanding of logic, requiring no background in programming, and its own coherent aesthetic approach. However, LBP also has its own peculiar and unique constraints – for example, it is impossible to design a game using LBP which supports the concept of multiplication as scaling, because there is no way to design the game such that players can transform the attributes of quantities in such a way.

Game Design

In the following section, I highlight some of the main design elements in *Rolly's Adventure*. First, however, I must highlight that as this game was designed to be played *in the wild*, the goal was to create a *provocative object* (Williams-Pierce, accepted) that caused player-learners to discover the mathematical content and relationships on their own, with no instruction or guidance other than the game itself. Furthermore, the game never states what the (digital) objects are, what the relationship of those objects are to each other, or what the goal of the game is. Rather, unlike most traditional mathematics learning contexts, player-learners must test, hypothesize, and discover those elements themselves directly through interaction and failure.

Figure 1, on the left, shows the very first puzzle presented to the player-learners. They must discover their goal (to get Rolly, the blue circular character at the top left, across the hole), and endeavor to determine what the secret relationship is between the buttons (green and gold circles on the ground), the button labels (blue and black underneath the buttons), and the gold bar in the hole. Through testing and failure, player-learners quickly discover that activating the button labeled with two black dots results in two gold bars filling the hole, and Rolly is able to continue.
Figure 1: The first (left) and the last (right) puzzles in *Rolly's Adventure*.

As the player-learners progress through the game, traditional fraction notation begins to be introduced, as is apparent in the final puzzle (Figure 1, on the right). However, long before such notation appears, player-learners have to determine the relationship between the button labels and the resulting number of gold blocks: the presented gold block is the unit, and the circles are the number of those units that result. While the first puzzle is a gentle introduction, later puzzles that present – for example – a gold block that is three-fourths of the hole, requires the player-learner to mentally partition the gold block in relationship to the amount missing from the hole, in order to realize that the correct choice is one and one-third of the unit in order to fill the hole.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

The difficulty present in such complex activity – without paper and pencil, or any way to otherwise quantify the relationship – was intentionally designed throughout the game trajectory, in order to use the limitations of visual perception to provoke a desire for the accuracy and efficiency of traditional notation. As the gold blocks become smaller or more complicated (as in Figure 1, on the right), and player-learners can no longer rely upon their visual perception, the fraction notation is immediately useful, aligning both with Harel's (2007) necessity principle and Gee's (2005) info-just-in-time principle.

Conclusion

The goal of this paper is to present a new game, *Rolly's Adventure*, that was designed specifically to provoke fractions learning. Although analysis of gameplay and interview data is ongoing, preliminary results indicate that player-learners produced mathematical language during gameplay that reflected their own growing understanding of fractions knowledge. The final results of analysis will be briefly presented at the conference, alongside discussion of the design process and final game.

SUPPORTING EMBODIED GAMES FOR MATH LEARNING WITH WEARABLE TECHNOLOGY

Ivon Arroyo	Wendy Leigh Rountree	Yuting Liu
Worcester Polytechnic Inst.	Worcester Polytechnic Inst.	Worcester Polytechnic Inst.
iarroyo@wpi.edu	wlrountree@wpi.edu	yliu3@wpi.edu

Keywords: Technology, Problem Solving, Measurement, Geometry and Geometrical and Spatial Thinking

We had students use cell phones and watches use on their wrist that act as "wearable tutors", that provide instructions and support while playing math games. Students search for objects such as geometric pieces with identifying tags. Students physically manipulate shapes and measurement tools to complete tasks, receiving feedback and hints/scaffolds via a display, buzzers and lights, learning while interacting with artifacts and students (Arroyo et al., in press).

The TANGRAMS RACE is a team-based game for 3rd grade, a relay race where students take turns to run and retrieve shapes out of a basket at the end of the room as indicated by the watch (Liu, 2014). The final goal is to construct a Tangram puzzle, at the starting line. Children run one at a time to find a basket full of shapes, and need to discern which geometric shape fits the description on their watch (e.g. "*I am a quadrilateral with two sets of parallel sides*").

ESTIMATE IT! is a measurement estimation and number sense game for 4th–6th grade students (Rountree, 2015). Children search for objects around a physical space. For example, the display may show the following: *"Find a cube with a 6" edge"*. Hint 1 may say: *"Use your 12" dowel to measure"*. Students are given unmarked measurement tools to encourage estimation.

The results presented in Tables 1 and 2 suggest that students learn and improve their expectation of personal success in math, as well as their appreciation of mathematics.

Table 1: Cognitive and Affective Outcomes, Before and After Playing the *Tangrams Race*

Variable (N=15)	Pretest	Posttest	% Increase
MCAS Standardized 7-item Test	0.65 (0.13)	0.74 (0.14)*	+9%
Self-concept in ability to do math (min=1; max=5)	4.2 (0.80)	4.9 (0.36)*	+14%
Liking of Mathematics (min=1; max=5)	4.5 (0.94)	4.8 (0.42)	+6%

a. * Significant paired-samples t-test difference, $p<0.05$

Table 2: Cognitive and Affective Outcomes, Before and After Playing *Estimate IT!*

Variable (N=13)	Pretest	Posttest	% Increase
MCAS Standardized 7-item Test	0.65 (0.22)	0.70 (0.23)	+7%
Self-concept in ability to do math (min=1; max=5)	4.37 (0.50)	4.67 (0.41)**	+6%
Liking of Mathematics (min=1; max=5)	4.55 (0.89)	4.64 (1.15)	+2%

a. ** Significant paired-samples t-test difference, $p<0.005$

MATHEMATICS STUDENTS' EXPERIENCES WITH PROGRAMMING

Laura Broley
Concordia University
l_brole@live.concordia.ca

Keywords: Technology, Research Methods, Post-Secondary Education

For many topics in mathematics, the use of computer programs is essential or, at the very least, may enhance student experience. While teaching such university-level topics, the mathematicians I interviewed (Broley, 2015) all faced the same question: "To what extent will my students develop, examine, and operate the programs?" Our analysis of the interviews shows that professors choose to address this issue in significantly different ways. A qualitative approach allowed us to identify *six kinds of programming interactions* they may have offered to their students:

L0: Strict observation of the results of a computer program, often directed by the professor;
L1: (Extracurricular) manipulation of an interface of an existing program;
L2: Observation (and perhaps interpretation) of the code of a program;
L3: Modification of an existing code to accomplish something new;
L4: Construction of code, with aspects (e.g., the algorithm) specified by the professor; and
L5: Creation of a program, including algorithm development, coding, and validation.

Each of our participants seemed to favour a subset of these interactions. Philippe, for example, perceived his use of programs (L0) in teaching probability as an effective way to challenge students' intuitions about important theorems; after his illustrations, he posts his programs online and encourages students to play with them (L1) with the hope that they become more active in observing the phenomena and gain a better understanding of the material. He avoids other interactions because, in his view, they require programming skills that are not related to his course. Paul, also a probability professor, agrees that "The purpose of the programming is to help [students] learn probability." Nonetheless, he's convinced that "If they're doing it themselves, they learn it way better." His students interact with programming in the form of L4 or L5.

Bearing witness to such debates, I am led to wonder about (a) the affordances of each interaction type, and (b) the opportunities taken and obstacles faced by students who actually engage in them. To address these issues, I propose a case study approach (Yin, 2013). For (a), I will construct a reference model of affordances, building on previous findings reported in the literature (e.g., Marshall et al., 2014). I will then solicit characterizations from professors (information-rich cases) who offer programming interactions to their students. Finally, to gain an in-depth understanding of (b), I will follow the journey of some of these students.

At my poster, I expect to discuss and receive feedback on my proposed research direction. Focussing on pertinent issues such as the variables I should consider when choosing my cases or the methods I could use to collect and analyse rich data, I hope to advance in my pursuit of a reliable and meaningful study of mathematics students' experiences with programming.

Palabras clave: Álgebra y Pensamiento Algebraico, Educación Media Superior, Resolución de Problemas, Tecnología

El objetivo de esta investigación es analizar a qué nivel el uso de herramientas como YouTube y Padlet ayudan a los estudiantes a discutir y compartir ideas matemáticas en un ambiente de resolución de problemas fuera del salón de clases. Las preguntas que guían está investigación son ¿cómo extender y promover la discusión matemática fuera del salón de clases con el muro digital Padlet y los videos educativos de YouTube? ¿De qué manera impacta el uso coordinado de videos que explican y promueven la comprensión conceptual de contenidos matemáticos seleccionados de YouTube y muros digitales de Padlet en las discusiones matemáticas fuera del salón de clases?

Marco conceptual

En necesario tener presente que un aspecto importante para aprender matemáticas en un ambiente de resolución de problemas es "identificar y promover las formas de razonar que los estudiantes pueden construir a partir del empleo sistemático de varias herramientas digitales como enciclopedias, software, tabletas electrónicas, etcétera" (Santos, 2014, p.24). Dentro de la caracterización de la cognición de los individuos al atender situaciones problemáticas que demanden el uso de estrategias y conocimiento matemático, Schoenfeld (1985) propone un modelo de análisis el cual se caracteriza por cuatro elementos: recursos, heurísticas, control y sistema de creencias.

Resultados

Los estudiantes resuelven de forma correcta los problemas planteados (Véase Figura 1), sólo con ayuda de los videos sugeridos, la información e ideas compartidas en Padlet.

Figura 1. Comentarios de los estudiantes en el muro de Padlet.

Con el uso de las tecnologías digitales es posible extender las discusiones matemáticas más allá del salón de clase; sin embargo, el papel del profesor es fundamental para guiar las discusiones que permitan llegar a la reflexión y solución de los problemas. Esto abre la oportunidad de hacer nuevos cuestionamientos: ¿Cómo seleccionar material audiovisual que presenten información relevante e incentive al estudiante a cuestionarse sobre el contenido matemático? Y ¿cómo elaborar material que promueva la resolución de problemas?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Keywords: Algebra and Algebraic Thinking, Higher Secondary Education, Problem Solving, Technology

The purpose of this research is to analyze to what degree the usage of tools such as YouTube and Padlet helps students discuss and share mathematical ideas within a problem-solving environment outside the classroom. The questions that guide this research are these: How can we extend and promote mathematical discussion outside the classroom using the Padlet digital wall and the YouTube educational videos? How are mathematical discussions outside the classroom impacted by the coordinated usage of videos selected from YouTube and the Padlet digital walls that explain and promote conceptual understanding of mathematical content?

Conceptual Framework

It is necessary to keep in mind that an important factor to learn mathematics in a problem-solving environment is "to identify and promote the ways of reasoning that students can construct from the systematic use of various digital tools, such as encyclopedias, software, tablets, etcetera" (Santos, 2014, p.24). Within the characterization of an individual's cognition when addressing problematic situations that require the use of mathematical strategies and knowledge, Schoenfeld (1985) proposes a model of analysis characterized by four elements: resources, heuristics, control and beliefs system.

Results

The students correctly solve the presented problems (See Figure 1) only using the help from the suggested videos and the information and ideas shared on Padlet.

By using digital technologies, it is possible to extend mathematical discussions beyond the classroom; nevertheless, the teacher's role is fundamental to guide such discussions to promote reflection and solving problems. This opens up the opportunity to generate new questions, how to select audiovisual material that presents relevant information and encourages the student to question mathematical content? Moreover, how to elaborate material that promotes problems solving?

TECHNOLOGY PROFESSIONAL DEVELOPMENT: MATHEMATICS TEACHERS IN THE STATES

Elif N. Gokbel
Duquesne University
karalie@duq.edu

Ahmet O. Akcay
Duquesne University
akcaya@duq.edu

Rachel A. Ayieko
Duquesne University
ayiekor@duq.edu

Keywords: Teacher Education-Inservice/Professional development, Technology, Teacher Knowledge

The professional development (PD) of teachers has been studied in various ways. Avalos (2011) stated, "at the core of such endeavors there is the understanding that professional development is about teachers learning, learning how to learn, and transforming their knowledge into practice for the benefit of their students' growth" (p.10). The United States Department of Education's 2010 National Education Technology Plan underlines the importance of teacher development in technology integration in the classroom by stating that, "technology can help us better prepare effective educators and increase their competencies throughout their careers while building the capacity of our education system to deliver effective teaching." (p.39). Although the Common Core and the International Society for Technology in Education (ISTE) Standards emphasize technology-supported pedagogy in mathematics classrooms, there are differences in state policies about teacher's professional growth regarding technology use in mathematics instruction. Also, there is scant documentation on the differences in math teachers' technology professional development (TPD) activities across the states.

The purpose of this study is to highlight the variations in teachers' PD in technology use in mathematics instruction across nine states in the United States. Those states are the benchmark states in the Trends in Mathematics and Science Studies (TIMSS) 2011. The National Assessment of Educational Progress (NAEP) secondary data was used. The items were selected from the teacher questionnaire. The question guiding the study was: What are the differences in fourth grade students' teachers PD participation to learn technology integration into their mathematics classes across the selected states from the years 2005 to 2015? The NAEP Data Explorer was used to examine the differences in teacher TPD for mathematics instruction.

The results highlighted the disparities of the teacher TPD participation rates over the years and across the states. Specifically, in 2005, 32% of the fourth grade math teachers reported that they never participated in TPD in the last two years. By 2015, the participation to the TPD increased relatively as the percent of the teachers who reported that they never participated in a TPD decreased to 24%. Furthermore, 8% of the teachers in 2005 reported large extent participation in using technology for math instruction compared to 10% in 2015. As access improved overtime, there was a slight increase in teachers' attempts to learn how to use technology in their math instructions. In particular, the teachers in Florida, Alabama, Indiana, and Minnesota continually exceeded the national average in their participation in PD activities for teaching math using technology. Further investigation will be conducted to examine the relationship between teacher TPD and fourth grade students' algebra achievement.

COMMON CORE MATHEMATICS BECOMES A POP CULTURE ENTITY

Jessica James Hale
Georgia State University
jhale8@student.gsu.edu

It is not often the Fox News and MTV agree on something, but in the case of Common Core Mathematics the two media outlets have found common ground; Common Core math is something to be ridiculed. This commonality is demonstrated in both outlets' coverage of Doug Herrmann's, now famous (infamous to some), "common core check" posted on Facebook. The message said: "Wrote a check to Melridge Elementary using common core numbers. I wonder if they'll take it? #YouFigureItOut" (Herrmann, 2015). The check depicted the amount to be paid using a ten-frame. For days following his post the headline "Frustrated dad writes hilarious Common Core check to child's school" was shared, reshared, tweeted and retweeted by countless media sources and individuals. Facebook and Twitter feeds were filled with parents and teachers sharing these articles. Has mathematics curriculum became part of popular culture? The media frenzy around Herrmann's check, the creation of twitter accounts like @thankscommoncore, and now even a beer commercial mocking common core mathematics make it clear this is a conversation happening in social and mass media, as much as at the dinner table. What does this mean for the teaching and learning of mathematics? How is this impacting the work that we do as mathematics teachers, mathematics teacher educators, and young mathematicians engaging in learning and doing of mathematics in schools?

A Discourse Analysis

Utilizing discourse analysis to guide my work this poster will look at how these conversations are being shaped both in the mass media and in social media, looking critically at who (and what) is privileged by discourses created as common core mathematics has found its place in popular culture. While complexities and nuances exist my analysis shows that many of the same power structure that benefited from previous discourses about mathematics continue to benefit from these newly created discourses. That in many ways we are watching the "math wars" of our past be played out in commercials and comedy sketches. But now that this has been taken up outside of the mathematics education community even more voices are being silenced, especially those of teachers and students.

Questioning Borders With(in) Mathematics Education

As Common Core mathematics is taken up in popular culture we as mathematics educators can choose to let our voices be silenced by not participating in the conversation, or we can take this opportunity to engage with those outside of the mathematics community. In this poster I advocate for the later, that we use this opportunity to dismantle the borders that have existed between mathematics educators (and mathematics education researchers) and come together. To work together to simultaneously critique and find the benefits of common core mathematics. To take this time that mathematic curriculum is so widely being acknowledged to open the conversation to parents and students. If ever there was a time to take on a revolution in mathematics education, it is when Stephen Colbert is taking about mathematics curriculum!

EXAMINING THE QUALITY OF INTEGER "PINS" ON PINTEREST

Joshua T. Hertel
University of Wisconsin-La Crosse
jhertel@uwlax.edu

Nicole M. Wessman-Enzinger
George Fox University
nenzinger@georgefox.edu

Keywords: Number Concepts and Operations, Technology

In this poster we report results from a research study examining negative integer resources available on the social media site Pinterest. Pinterest is a virtual space similar to a real-life bulletin board. The site allows users to organize and share online content (webpages, images, videos, links, etc.) by creating "pins" that link to specific resources. Once created, pins can be discovered by other users using keyword searches, "repined" (i.e., reshared), collected onto "boards," and "liked." The ease of finding content on Pinterest means that teachers, both preservice and inservice, can use the site to find ideas for activities, projects, and lessons. Use of Pinterest in this way is akin to a kind of border crossing in that individuals leave traditional sources (e.g., books, colleagues) and journey a into a new space in search of resources.

Although pins are easily accessible, they represent an educational resource of unknown quality. Pins are created by users without review or scrutiny from peers. Once created, the only data provided related to a specific pin are the number of repins and the number of likes it has accumulated. At the same time, a recent survey by Darleen, Kaufman, and Thompson (2016) found that 87% of elementary and 62% of secondary teachers reported using Pinterest as a source for instructional materials. In our own classrooms, we have seen a trend of preservice teachers using Pinterest as a primary source for mathematical lessons, activities, and projects.

To take some initial steps in investigating pins as an educational resource, we conducted a project focusing on negative integers, which are a challenging topic for students of all ages (Piaget, 1948; Stephan & Akyuz, 2012). Our investigation focused on the following questions:

1. What is the scope of mathematical content in pins related to negative integers?
2. What is the accuracy of mathematical ideas in pins related to negative integers?
3. What patterns are present in the source material of pins related to negative integers?

Using these questions as an analytical lens, we created a coding scheme that considered a variety of topics including mathematical operations, mathematical language, mathematical notation, use of manipulatives, use of real-world context, and source material. We then gathered a dataset of 200 pins using keyword searches and analyzed it using the coding scheme.

Results indicated mathematical errors in more than one-third of pins, a dominance of addition over other operations, strong connections to the MathTwitterBlogosphere for source material, and infrequent use of real-world context. Additionally, results raised questions about the appropriateness of using repins or likes as a measure of quality. We will provide a breakdown of results and highlight implications for use of pins as an educational resource.

EPISTEMOLOGICAL AND DIDACTICAL VALIDITY ISSUES OF ONLINE TEACHING AND LEARNING OF MATHEMATICS

Veronica Hoyos-Aguilar
National Pedagogical University, Mexico
vhoyosa@upn.mx

Keywords: Post-Secondary Education, Teacher Education-Inservice/Professional Development, Technology

Here (see more information in Hoyos, 2016) it is proposed a discussion about main characteristics of new online educational applications for the learning and teaching of mathematics, namely MOOCs (Massive Open Online Courses) and how it could affect the teaching and learning of mathematics. It was based in revisiting and applying the theoretical notions of epistemological and didactical validity of learning computational environments, now to the case of distance teaching and learning of mathematics mediated by ICT. This discussion is supported by the analysis of new data on the resolution of mathematical complex tasks accomplished by in-service secondary teachers enrolled in an online program for professional development, both on mathematics content and the use of digital technology in teaching.

First discussion on the epistemological and didactical validity issues of computational environments was due to N. Balacheff and R. Sutherland (see Balacheff 1994, 1999, 2004; Balacheff and Sutherland, 1994; and Sutherland and Balacheff, 1999), to illustrate different contributions that bring the use of certain software when they are incorporated in particular computational learning environments. Now the time is ripe to revise what could be the potential of new MOOCs (see, for example, http: //www.coursera.org), what this type of online courses are bringing to the field of mathematics education, to describe and analyze their characteristics under the light of the theoretical constructs from Balacheff & Sutherland.

While using computational environments for the teaching and learning of mathematics raises questions of complex character from an educational point of view, particularly focusing in the active role of the student and the teacher as an administrator or manager of these media in learning situations (Sutherland & Balacheff, 1999), new educational trends now materialized in the massive open online courses (MOOC) may call for free online education without any tutorial intervention, occurring outside of school and when perhaps pedagogical means are automatically managed, for example by digital tutorials. Also through these courses, users are expected to assume the responsibility of their own appropriation of knowledge, and their learning and possible development is promoted primarily through a series of opinion exchanges among peers. All this considered, in this work it is shown and discussed by data obtained from an online course for the professional development of teachers, which in fact simulate some MOOC characteristics, how it is not enough to have free access to mathematics digital technology and/or Internet free resources to achieve expertise on a complex mathematical content that is online being addressed.

Fully online courses have become more widespread for graduate programs that are designed for in-service teachers due to the flexibility of the time commitment. In this environment most interaction among students, and between students and instructors occur on discussion forums. That is why there is a growing interest researching the nature of this interaction and how it contributes (or does not contribute) to individual knowledge construction.

Using Weinberger and Fischer's (2006) framework, we analyzed three in-service mathematics teachers' knowledge construction in a fully online graduate level geometry course. We purposely selected Kevin, Dana, and Helen since they showed high presence on the discussion board and they were along the spectrum of course grade levels (low, average, and high, respectively). We focused on the participants' discussion board engagement. Weinberger and Fischer's framework to provide us four dimensions that may "extend and refine our understanding of what kind of student discourse contributes to individual knowledge acquisition" (p. 73): participation, epistemic, argumentative, and social mode of co-construction.

Our preliminary results reveal that in the participation dimension all three participants' statistics of course content and discussion board access were consistently above class average throughout the semester. However, Kevin stood out when we run the statistics for discussion board posts read and posted. Unlike Dana and Helen who *read* all 789 posts, Kevin read only 72 posts. Additionally, Kevin posted 10, Dana posted 26 and Helen posted 16 threads. These threads were coded under the epistemic dimension. Kevin and Dana had all, but one, *construction of conceptual space (CCS)* posts and another one was coded as *construction of adequate relationship between conceptual and problem space (CARC-P)*. Helen, on the other hand, presented more diverse threads with 10 *CCS*, 5 *CARC-P* and 1 *construction of inadequate relation between conceptual and problem space (CIRC-P)*. In argumentative dimension, Kevin only had 9, Dana had 33, and Helen had 22 threads posted. Unlike Kevin, Dana and Helen had all, but one, threads as valid claims. Kevin, on the other hand, posted only 3 valid claims. Lastly, within social mode of co-construction dimension, all three participants' main mode of interaction was externalization (Kevin=16, Dana=33 and Helen=25). However, Helen (7) and Dana (5) also utilized elicitation much more than Kevin (2), and Helen utilized non-argumentative moves significantly more than Kevin and Dana (23 vs 8 and 8, respectively).

Based on our findings, we argue that although the quantity of the time spent on discussion board is important, the "quality" of the time spent must be closely monitored. Also, it has been reconfirmed that discussion board engagement plays a significant role in knowledge construction. Lastly, developing a discussion board engagement rubric based on Weinberger and Fischer's framework might potentially increase meaningful engagement and a stronger knowledge acquisition in an online environment.

DESIGN OF A VIDEO GAME FOR PROMOTING EMBODIED MATHEMATICAL REASONING

Mitchell J. Nathan
University of Wisconsin, Madison
mnathan@wisc.edu

Candace Walkington
Southern Methodist University
cwalkington@smu.edu

Keywords: Cognition, Geometry and Geometrical and Spatial Thinking, Technology

An emerging literature on embodied cognition (Wilson, 2002) shows that mathematical ideas can be learned through action-based interventions that ground understanding of abstract principles in concrete, perceptual and motor experiences. As theoretical perspectives like embodied cognition emerge in education, so do alternative ways of using technology to support teaching and learning. Our video game, *The Hidden Village,* utilizes *directed motions*, which embody the geometric relations that form the basis of players' proofs and justifications for subsequent geometry conjectures. The game tracks players' movements using rapid visual processing of images through the built-in camera found in common laptop computers and uses no other specialized hardware (see Figure 1).

Justification and proof are central in mathematics education (Stylianides, 2007). Yet students struggle to construct viable and convincing mathematical arguments and valid generalizations of mathematical ideas (e.g., Healy & Hoyles, 2000). Past research (Nathan, Walkington, Boncoddo, Pier, Williams, & Alibali, 2014) showed that directing undergraduates to perform actions where they modeled triangles and turning gears with their bodies aided generation of correct insights and valid proofs. Notably, successful participants were largely unaware the beneficial actions were related to their subsequent math performance. In a recent pilot study, proof success for a range of geometric conjectures was correlated ($r = 0.348$) with learners' production of spontaneous *dynamic gestures*, which are hand movements that reveal learners' abstract and generalizable thinking about imaginary mathematical entities as though they were real objects.

In this newest study, grade 6-11 students ($n = 18$) played *The Hidden Village* for 6 geometry conjectures. Performance was initially lower than for college students, but increased significantly ($p = 0.02$) after pedagogically directed hints relating the game directed actions to the conjectures. Video analyses show use of spontaneous gestures illustrating how the directed motions from the game left a *legacy* in the dynamic gestures learners made that contributed to their proofs. Having established a viable platform for introducing embodied forms of mathematical reasoning through game play we plan to study the effect of this game on proof practices in high school classrooms.

If one angle of a triangle is larger than a second angle, then the side opposite the first angle is longer than the side opposite the second angle. **[TRUE]**

Figure 1. An example conjecture that is first acted out by *The Hidden Village* game characters and copied by players is more apt to elicit a valid proof.

A FRAMEWORK FOR HOMEWORK IN FLIPPED MATHEMATICS CLASSES

Samuel Otten
University of Missouri
ottensa@missouri.edu

Zandra de Araujo
University of Missouri
dearaujoz@missouri.edu

Salih Birisci
University of Missouri
biriscis@missouri.edu

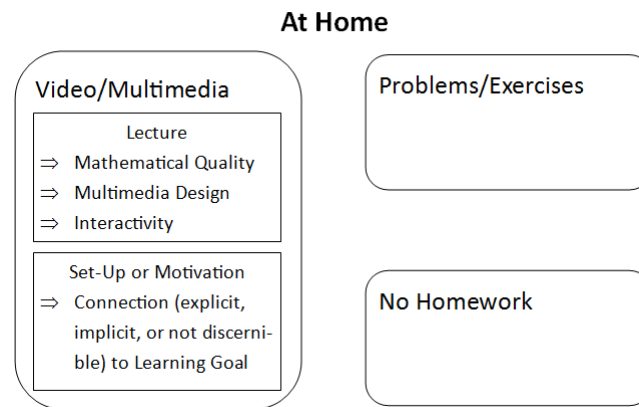
One defining characteristic of flipped instruction is the homework teachers assign, which typically consists of an instructional video rather than problem sets (Bergmann & Sams, 2012). We present a framework for flipped homework that categorizes types of homework and draws on existing literature to discern quality for each type (see Figure 1). This framework allows for the distinction between different implementations of flipped instruction with respect to the homework assigned, thus moving away from the assumption of flipped and non-flipped teaching as a binary distinction as in past studies (Clark, 2015; DeSantis et al., 2015).


Figure 1. A framework for "homework" in flipped mathematics classrooms.

Video/multimedia homework is separated into *lecture* and *set-up or motivation* categories based on the purpose of the homework, and for each category we provide illustrative examples from a study of flipped mathematics classes. We show how the quality of instructional videos can vary according to specific criteria. We also discuss how, in our study, teachers seldom included interactive features in their lecture videos and the teachers more frequently assigned lecture videos than set-up/motivation videos. Looking beyond homework, it is likely that the in-class implementation of flipped instruction is just as (or more) important than the homework.

This poster presents results of the first stage of a larger project aimed to contribute to the recent ongoing research on the potentialities of integrating dynamic geometry environments and multi-touch technologies in the strand K-2 to foster young children's geometrical thinking. The goal of the first stage of the study was to design a sequence of seven mathematical activities in a learning environment that combines Geometer's Sketchpad® (Jackwic, 2009) and the iPad to help children informally understand congruence and similarity in dynamic ways. Grounded on prior research on the early implementation of dynamic geometry (Hegedus, 2013; Sinclair & Moss, 2012) and on the development of shape (Clements & Sarama, 2014), it is conjectured that young learners could link properties of congruence and similarity to continuous motion and multiple representations of triangles in different positions and orientations and to informal measuring actions. The use of iPads could improve gestural expressivity and collaboration in small teams (Hegedus, 2013). The main goal of the second stage of the study was to implement the learning sequence with second-grade students to examine the ways in which they can develop intuitive understandings of congruence and similarity while collaboratively working in small groups with the technologies. The poster is focused on the first stage related to activity design, but examples of children's forms of reasoning illustrate the learning potentialities of the tasks.

The sequence of activities was designed following a student-centered, inquiry-based approach from a sociocultural view and design principles for the use of dynamic geometry software and multi-touch interfaces with young children such as: continuous motion, connectivity and communication (Sinclair & Crespo, 2006) and, executability of multiple representations, co-action and multiple manipulation and interaction (Hegedus, 2013). The sequence includes two exploratory activities and one problem-solving situation for congruence and, three exploratory activities and one-problem solving situation for similarity. The Cognitive Task Analysis of the activities includes the description of the tasks, mathematical structure, cognitive demand, learning goals and ways of reasoning that they could potentially promote.

Palabras clave: Educación Secundaria, Tecnología

El objeto de estudio de esta investigación es la interpretación de las gráficas en 3D de ecuaciones paramétricas usando los recursos figurales asociados a éstas, para ello proponemos a los estudiantes *dispositivos gráficos* para usarlos como herramientas en la construcción del conocimiento y dar sentido a incidencias sobre ellas. Estos dispositivos pueden ser puntos, curvas o planos adecuadamente proyectados sobre los planos *xy. yz* y *xz* los que permitirán interpretar las propiedades gráficas de la forma en 3D en términos de la gráfica en 2D, tales como concavidad, continuidad, puntos críticos entre otros.

El procedimiento de proyección paralela se apoya en un uso inicial de lápiz y papel para luego usar la computadora con fines de exploración. Las propiedades figurales pueden ser visualizadas matemáticamente (Duval, 1998) y con apoyo de herramientas histórica y culturalmente determinadas (Radford, 2014) podremos anticipar y dar sentido a las gráficas 3D con dispositivos particulares en 2D.

Por ejemplo, podríamos usar una parábola en 3D como la de la figura 1, la que será proyectada convenientemente sobre el plano *xy* en 2D que nos sugiere continuidad, puntos mínimos, concavidad, entre otras propiedades de la primera. Además, si asociamos una recta sobre la superficie que hace las veces de dispositivo gráfico que se desplaza a lo largo de la proyección, recuperamos la gráfica en 3D. Tanto la parábola proyectada como la recta desplazada por esta pueden ser dispositivos gráficos usados para dar sentido a las gráficas mencionadas.

Las aproximaciones figurales pueden permitir incrementar la dificultad tanto de las curvas estudiadas como de los dispositivos gráficos adecuados para analizarlas.
Figura 1. Parábola en 3D con su dispositivo gráfico en 2D.

Keywords: High School Education, Technology

The object of study of this research is the interpretation of graphs in 3D of parametric equations using the figural resources associated to these; to do so, we propose *graphics devices* to students so they can use them as tools in the construction of knowledge, and to give a sense to incidences about the graphs. These devices can be points, curves or planes, adequately projected on the planes *xy, yz*

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

and *xz*, which will allow to interpret the graphic properties in 3D shape in terms of the graph in 2D shape, such as, concavity, continuity, critical points, among others.

The process of parallel projection is supported by an initial use of pencil and paper, to proceed later with the use the computer to be able to explore. The figural properties can be visualized mathematically (Duval, 1998), and with the support of historical and culturally determined tools (Radford, 2014), we can anticipate and make sense to 3d graphs, with particular devices in 2D.

As an example we could use a parabola in 3D, like the one in Figure 1, which will be conveniently projected on the *xy* plane in 2D, which suggests continuity, minimal points, concavity, among other properties of the first one. Moreover, if we associate a straight line on the surface, which sometimes acts as a graphic device that moves along the projection, we recover the graph in 3D. Both, the projected parabola, and the associated straight line may be graphic devices used to make sense of the mentioned graphs.

The figural approaches may allow to increase the difficulty of the curves under study, as well as of the appropriate graphic devices used to analyze them.

PRAXES PROXIES: REVISITING EDUCATIONAL MANIPULATIVES FROM AN ECOLOGICAL DYNAMICS PERSPECTIVE

Dor Abrahamson	Raúl Sánchez-García	Dragan Trninic
UC Berkeley	European University, Madrid	National Inst. of Ed., Singapore
dor@berkeley.edu	raulsangar@gmail.com	trninic.dragan@gmail.com

The recent proliferation of technological devices with natural user interfaces (e.g., touchscreen tablets) is regenerating scholarship on the role of sensorimotor interaction in conceptual learning. Some researchers of mathematical education have adopted views from constructivism, phenomenology, enactivism, and ecological dynamics to interpret implicit sensorimotor schemes as both forming and manifesting disciplinary competence. Drawing on these views, this theoretical paper returns to the enduring question of what it means to develop a new skill by way of task-oriented interaction with objects. Beginning with sports then moving to mathematics, we focus on a subcategory of pedagogical artifacts that serve students only during training activities yet constitute proxies for developing target schemes toward normative application. We argue for the contribution of these views to conceptualizing the design of effective mathematics instruction.

Keywords: Instructional Activities and Practices, Learning Theory, Technology

Background and Motivation: Teaching for Learning Mathematics as an Activity

Hans Freudenthal (1971, p. 435) once remarked that learning mathematics is better understood as learning how to swim. This remark could be understood as metaphorical, that is, Freudenthal is indicating that learning mathematics is an *activity*, rather than something passively done to the student. And yet one way to teach mathematics as an activity is to have students *physically* engage in the mathematical process, much like swimming necessarily involves an initial period of flailing one's arms and legs in water.

This theoretical paper is based on the speculative premise that learning mathematics is literally, not only metaphorically, much like learning to swim. Accordingly, we will be devoting the first portion of this paper to introducing, from the sports science, a framework for modeling how people learn to perform physical techniques, such as martial-arts maneuvers. Only once we have established this analytical model will we then turn to discuss the case of mathematics, which we perceive as significantly analogous.

To allay the reader's concern, let us stress that this project is not construed naively: We are well aware of patent differences between sports and mathematics. To an onlooker, freestyle swimming appears quite different from solving for *x*. The overt physical actions, tasks, goals, media, and semiotic register and tenor across these disparate cultural practices are indeed incongruous. And yet we submit that these apparent differences need not undermine a project to investigate for meaningful similarities across the activities.

A comprehensive comparison of sports and mathematics is probably beyond the scope of this modest paper. And so our tack here will be to carry out the comparison by way of selecting a particular prism as a means of narrowing and focusing the comparison. We have chosen to examine what it means to learn a skill with the aid of an object, what is often referred to in the mathematics-education literature as a manipulative. We are thus proposing here an inter-disciplinary comparative analysis of the didactical function of manipulatives in sports and in mathematics, because we believe that this comparison bears potential rewards for the theory, design, and practice of mathematics education more generally.

Praxes Proxies: Pedagogical Artifacts for Practicing Novices

To even further hone this paper, we will look at an exclusive class of manipulatives, those that are used not in enacting an actual goal practice in its normative trappings but only in training toward enacting that goal practice. For example, a soccer player might develop prowess by way of dribbling in slalom path along a line of cones, even though there would never be cones on the field during an actual game. Here the cones are standing in for people, and they are positioned in a form that exaggerates and distils the core coordination challenge facing the novice.

We are tentatively calling this class of objects *praxes proxies*, because we believe they do not quite fall squarely under any current definition of materials or activities that are employed in the service of learning a new skill. For example, one might think of this specialized class of artifacts as scaffolds, in the sense that they constitute auxiliary elements or structure temporarily deployed into a learning environment and then later removed (faded) once the learners are prepared to engage in normative practice, as in the case of bicycle trainer wheels (Bakker, Smit, & Wegerif, 2015). And yet our artifacts of interest are not really scaffolds, because they are used not only to support the student's physical execution of otherwise overwhelming actions but also at times to simulate ecologically authentic environmental features actually encountered in normative experiences—our artifacts of interest might *pose* rather than preempt problems. One might therefore think of our artifacts of interest as enabling what Kirsh (2010) would view as a form of rehearsal, in the sense that they support practitioners in reducing, decomposing, or schematizing a complex practice by way of focusing on some circumscribed aspect. And yet these artifacts actually supplement structure onto the activity—structure that does not exist in the goal activity. Moreover, the student has not yet experienced the goal practice and thus cannot have any agency in decomposing it. One might therefore think of these artifacts as enabling a form of simulation of the goal activity that is less dangerous, costly, or otherwise resource consuming (Schwartz, 2007). And yet we are looking at cases where the learner need not or even cannot be aware of how the performance of these unique exercises is related to the goal practice, so that it does not make sense to call them simulations, at least not in view of the student's own phenomenology.

By calling our focal class of pedagogical objects *praxes proxies* we are considering them as basic-training substitutes for critical aspects of "the real thing." As we will be arguing, praxes proxies serve to entrain learners toward operating effectively within target activity contexts by way of creating for the students opportunities to develop sensorimotor coordinations relevant to, and applicable in enacting the goal practice. These new sensorimotor coordinations are elicited from students as they attempt to overcome performance challenges that emerge in the course of satisfying a task objective. From the systemic perspective that we will be evaluating, learning is developing new sensorimotor coordination oriented on newly constructed aspects of the environment: As they practice, students reconfigure the environment to afford new interactions.

Our focus herein on praxes proxies could be instrumental in considering educational phenomena. Namely, praxes proxies are quite unique in that they have been historically designed or selected explicitly for teaching and learning a skill, not for actually performing the skill in its goal contexts. The very existence of this class of objects should be interesting to educational researchers, because it helps us isolate and thus examine "purely" pedagogical affordances of cultural practice as they relate to the target skills they foster. The sections below clarify and demonstrate our thesis, arguing for its broad utility.

Theoretical Framework

Why might researchers of mathematics education care how people learn to perform sports techniques? This intellectual orientation warrants some explaining.

We grant that the learning of physical skills is often seen as substantially different from the learning of conceptual notions. Yet we ask the reader to keep an open mind, as looking to physical

disciplines for inspiration may not be as radical as it appears at first glance. Indeed, over thirty years ago, in his address to the International Group for the Psychology of Mathematics Education, when von Glasersfeld (1983) criticized research in mathematics education for having under-delivered, he added,

> this disappointment—I want to emphasize this—is not restricted to mathematics education but has come to involve teaching and the didactic methods in virtually all disciplines….There is only one exception that forms a remarkable contrast: the teaching of physical and, especially, athletic skills. There is no cause for disappointment in that area. (p. 42)

von Glasersfeld argued that we ought to learn from those physical domains that have been exceptional, because

> the primary goal of mathematics instruction has to be the students' conscious understanding of what he or she is doing and why it is being done…[W]hat the mathematics teacher is striving to instill into the student is ultimately the awareness of a dynamic program and its execution—and that awareness is in principle similar to what the athlete is able to glean….from his or her performance. (pp. 51-52)

We agree with von Glasersfeld that analogizing competence in sports and mathematics might go more than skin deep. Our work has been an attempt to implement this radical-constructivist epistemological position in the form of pedagogical activities designed for mathematics students to ground targeted curricular content in new forms of physical activity they learn to enact. Accordingly, in this paper we consider content learning as sprouting from 'dynamic programs' then maturing via guided reflection into 'conscious understanding.' The heart of this paper is on artifacts that both elicit and shape said dynamic programs. Yet just before we focus on these artifacts, we explain how our epistemological position on grounded mathematics is not as arcane as might at first appear.

This paper is situated within a current turn in mathematics-education research toward theorizing conceptual knowledge as grounded in sensorimotor schemes. Per this view, learning new concepts requires the development of new spatial–dynamical motor-action coordinations. This notion, which is shared by cognitive developmental psychology (Piaget, 1968), enactivism (Varela, Thompson, & Rosch, 1991), and neuro-educational research (Norton & Deater-Deckard, 2014), orients mathematics education researchers on the action patterns themselves—how a physical task is accomplished—equally or perhaps more so than on the material or semiotic products of these actions (Nemirovsky, 2003). We hope with this paper to contribute to the field's discourse specifically around designing activities that foster targeted action patterns.

Several reasons account for our somewhat unusual program of research that has led us to collaborate with scientists who specialize in modeling how people develop and control motor action. To begin with, converging reports from empirical research studies in diverse branches of the cognitive sciences have been putting forth claims to the effect that cognitive activity is grounded in the tacit enactment of perceptually guided physical motor action, even when no overt corporeal action is manifest to the on-looking observer (Barsalou, 2010). In fact, it has been claimed that sports psychology is essential for understanding cognition (Beilock, 2008). It thus stands to reason, at least per our judgment, that researchers of mathematical cognition should have a firm grasp of the relation between sensorimotor and mathematical activity (see Nemirovsky, 2003).

Granted, the thesis that concepts are grounded in sensorimotor action is foundational to constructivism (Piaget, 1968) and carries through to neo-Piagetian scholarship (Kalchman, Moss, & Case, 2000; Norton & Deater-Deckard, 2014). And yet, by-and-large the community of mathematics-education researchers is not equipped to capture, document, analyze, and model these sensory perceptions and physical motor actions in which concepts are allegedly grounded (Abrahamson & Sánchez–García, 2015, in press). For example, research articles on mathematics learning process

rarely offer micro-ethnographic analyses of the minute sensorimotor schemes students develop via solving interaction problems. When articles do offer these analyses, we witness careful transcriptions of multimodal activity that include descriptions of students' and teachers' instrumental and representational gestures (Nemirovsky & Ferrara, 2009). However, these descriptions are not framed by, and therefore do not attend to, kinesiological properties of these actions. That is, the studies might espouse an embodied-cognition framework to explain why a concept is challenging and how teachers and students interact with artifacts to construct and elucidate the inherent mathematical notions, yet the studies are not founded on the premise that *the physical actions themselves are challenging and that this challenge is explanatory of the conceptual challenge of grasping and applying the new notions*.

To be sure, lifting a fist-sized red block and placing it on a nearby blue block is certainly within the motor skills of normally developing kindergarten students. For this population, the physical motor operation of re-positioning a block is not designed in and of itself to be challenging, and so performing this rudimentary isolated physical operation per se is not conceived as fostering the development of a new sensorimotor scheme. Rather, to the extent that we view mathematics learning as contingent on overcoming sensorimotor challenges, this view is situated in a relatively new design genre for STEM education, namely in technologically enhanced embodied learning environments (TEELE, see Lindgren & Johnson-Glenberg, 2013).

Pioneered by Nemirovsky and his collaborators (e.g., Nemirovsky, Tierney, & Wright, 1998), TEELE involve a dynamical interaction task that turns out to demand a challenging sensorimotor coordination. Performing the task is enacting a new form of reasoning. Further classroom discourse on the solution, which may elicit reflection, description, representation, interpretation, and argumentation, makes to consolidate the new form of reasoning in normative semiotic registers, such as vocabulary, diagrams, graphs, and symbolic notation (Abrahamson & Lindgren, 2014). It is these environments—and in particular their central focus on dynamical solutions to sensorimotor coordination problems—that have been motivating our research program to step aside from mainstream mathematics-education scholarship and seek the wisdom and practice of disciplines dedicated to the investigation of motor-action learning and control.

In sum, we are interested in a class of cultural artifacts we call praxes proxies. Unique about these artifacts is that they are not used in performing some goal practice per se, but rather to *train* towards performing this goal practice. For example, consider the speedbag used in boxing. This artifact is viewed as invaluable for training boxers yet is clearly *unlike* what is enountered in an actual boxing match. As von Glasersfeld stipulates, the pedagogical utility of these artifacts is that through training students become aware of, or attuned to, some aspect of practice. We argue that mathematics education, particularly the design of manipulatives, stands to benefit from leveraging what other fields have discovered about the pedagogical utility of these artifacts.

In the remainder of this paper we turn directly to an emerging theoretical framework from sports sciences, ecological dynamics, so as better to understand the contribution of praxes proxies to students' development of competence in a physical activity. We will then illustrate an analogous case from mathematics education.

Ecological Dynamics & Non-Linear Pedagogies: Introducing Adequate Constraints

Relations between student, task, and available artifacts can be modeled after an ecological-dynamics perspective (Abrahamson & Sánchez–García, 2015). From this view, the student, task, and artifacts comprise a system. As the student attempts to perform some goal task, we say that the artifacts constitute productive constraints on these efforts. By "productive constraints" we mean just that—the artifacts usefully negate a vast spectrum of possible yet culturally irrelevant routes of action (degrees of freedom) leaving only a narrow range of possible ways to go about completing the task, where these ways are in line with the pedagogical intention of the activity. A child building a

castle from interlocking plastic blocks will learn through exploration to adjoin the blocks according to the designer's intention: For this child, the blocks will come to privilege (afford) particular modes of interacting. As researchers, we look to understand, build, and evaluate learning environments that foster new dynamical interaction patterns by productively constraining how a learner might engage an activity in seeking to satisfy some task objective.

Ecological dynamics originates in the sports sciences. The application of dynamical systems to ecological psychology enables sports scientists to explain the learning of physical activities as the complex self-organizing of subject–environment dynamical systems (Vilar, Araújo, Davids, & Travassos, 2012). In this systemic approach, learning is modeled not as generating a sequence of disembodied symbolical propositions, such as abstracted inferences and decisions, but as intrinsically emergent from and tuned to the agent's embedded action structures within a non-linear system (Araújo, Davids, Chow, Passos, & Raab, 2009). Thus, the unit of analysis is not the isolated individual but the indissoluble pair of individual–environment in interaction.

The self-organizing behavior of this agent–environment system can be affected or "channeled" by different kinds of constraints. Newell (1996) identified three sources of constraints affecting the behavior of the system: organismic (biochemical, biomechanical, neurological), environmental (gravity, temperature, light), and task (goals and rules). In this paper we are theorizing the role of supplementary artifacts as introducing task constraints appropriate to the pedagogical objectives. Notably, the introduction of praxis-proxy artifacts changes the task, and so we may consider them as task constraints.

From a didactical point of view, the introduction of adequate constraints becomes a paramount issue. Non-linear pedagogy (Chow et al., 2011) is based on supplementing and modifying constraints in the learning environment. Coaches, similar to constructivist mathematics educators, adopt a strategy of discovery-based learning, where students' learning process is constrained in deliberate ways. By assigning what should be done and constraining how it might be accomplished, instructors generate "fields of promoted action" (Reed & Bril, 1996). Therein, learners are encouraged to engage in explorative behavior by which to find personal solutions to the task at hand. Such constraints can be introduced either by changing the game's rules/conditions, changing/restricting physical space, modifying equipment, increasing gradually the complexity of the task, or simplifying it (Davids et al., 2008, pp. 161-167). The main aim of this cluster of activities is to foster self-discovery by providing enough variability for individual learners to find their own solutions to varying situations that bear for the learners emergent contingency (Bernstein, 1967).

The introduction of constraints must always follow the principle of "representative design" (Brunswik, 1956): Activities created specifically for training purposes should not distort or change some key information of the environment that learners would find in the actual conditions of the real game (Renshaw, Davids, Shuttleworth & Chow, 2009). Rather, learners are to engage in behaviors that foster attunement towards the key perceptual information sources pertaining to the ultimate physical performance in the authentic goal context. Chow et al. (2009) stress that practice activities must be representative of performance demands so as to lead to transfer of skills between practice and performance environments.

Artifacts that create representative-design task constraints might be either complex or simple and even mundane familiar objects. Consider a well-familiar object: a wall (see Figure 1).
Figure 1. In Systema, a Russian self-defense method, a wall serves in an exercise, per the principle of representative design. Stand opposite a wall. Lay your hands on it. Now "walk" your hands down the wall, one hand at a time. All the while, your feet, too, must walk backwards so as to maintain a more-or-less straight body. Once low, you would walk your hands into a push-up position on the floor. You would then reverse the sequence back up to the starting position.

The introduction of this simple artifact (a wall) channels your activity into dynamically maintaining a corporeal structure able of sustaining a line of force transmitted from feet to hands, thus resulting in a constant pushing-forward action. Such performance is crucial when facing a fighting opponent who pushes you backwards with her attack. Thus, the wall exercise fosters the student's attunement to key information coming from the haptic (dynamic touch) sense. The wall acts as a praxis proxy, substituting an opponent yet maintaining representative-design principles.

We thus view praxes proxies in terms of their systemic role. As students attempt to perform the given task under the constraints poised by the artifact, the students learn to move in new ways. That is, the environment comes to afford new ways of moving, namely new motor-action coordinations. (By way of cultural reference, the reader might remincise about the Karate Kid.)

Praxes proxies are a unique class of pedagogical artifacts in the sense that they serve students in the deliberate absence of actual goal contexts, creating intact worlds that idealize or essentialize specified aspects of the normative tasks. Various gym devices serve in this capacity by way of demarcating a space and dedicated equipment for engaging in an activity that, to the naked eye, bears little to no ecological authenticity (e.g., we rarely waddle down a wall). Yet this activity nevertheless focuses attention and effort on developing and exercising a targeted corpus of motor action highly relevant and environmentally attuned to ecologically authentic tasks.

As we turn from sports to math, we stress that across these domains praxis proxies

foster not only local skill development per se, that is, becoming better at some particular movement, but are methods for gaining insight into disciplinary knowledge. In other words, the central argument is that, through their practice, these routines serve as *methods* of developing disciplinary knowledge. [They are]….not practiced for their own sake, but for what is gained through practice. (Trninic, 2015, p. 24)

Praxis Proxies in Mathematics Education: The Mathematical Imagery Trainer

From the epistemological perspective of embodiment theories, we have argued, learning mathematical and athletic skills is similar, in that both require the construction of new sensorimotor schemes as a condition for competent performance. Creating representative design for mathematics learning hinges on determining, perhaps inventing, particular sensorimotor schemes that arguably capture the dynamical cognitive substrate of reasoning about and toward a target concept. Thus, if we the designers wish to create praxes proxies for proportional reasoning, we must first account for what proportional reasoning looks like, feels like, moves like for us—we must 'phenomenalize' (Pratt & Noss, 2010) proportional reasoning in the form of a sensorimotor coordination and then build embodied-interaction tasks that foster the development of these very coordinations by way of solving some performance challenge.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

a.   b.   c.   d.
Figure 2. The Mathematical Imagery Trainer for Proportion (MIT-P) set at a 1:2 ratio, so that the favorable sensory feedback (a green background) is activated only when the right hand is twice as high from the monitor's bottom line as the left hand. This figure sketches out our Grade 4 – 6 study participants' paradigmatic interaction sequence toward discovering and then practicing an effective operatory scheme: (a) while exploring, the student first positions the hands incorrectly (red feedback); (b) stumbles upon a correct position (green); (c) raises hands maintaining a fixed interval between them (red); and (d) corrects position (green). Compare 1b and 1d to note the different vertical intervals between the hands and, correspondingly, between the virtual objects.

An example for a mathematics praxis proxy is the Mathematical Imagery Trainer for Proportion (see Figure 2; Abrahamson & Howison, 2010). We first designed a bimanual motor-action scheme that enacts proportional equivalence, and then we engineered conditions for students to move in a new way that would require developing this scheme. Our two-step activity plan was for students to: (1) develop a target motor-action scheme as a dynamical solution to a situated problem bearing no mathematical symbolism; and (2) describe these schemes mathematically, using semiotic means we then interpolate into the action problem space.

Empirical evaluation of the design, including the integrated micro-genetic analysis of clinical, electronic, and eye-tracking data, suggests that indeed students are devising target sensorimotor schemes in solving the interaction problems (Abrahamson et al., 2016).

Conclusion

We are only just beginning to understand the relation between bimanual coordination and mathematical cognition. Researching the emergence of this digital-cum-digital prowess, from manual action to symbolic notation, is contingent upon thinking out of the curricular box to design opportunities for witnessing and investigating this emergence. And yet for all these efforts ultimately to contribute to education in its authentic ecology, we must strive to remove borders between research and practice. Per the PME-NA 38 call, "We see borders as potentially productive as well as potentially problematic." We agree: We seek partners across the border to engage in productive, synergistic discourse so that mathematics learning can move in new ways.

DUAL ANALYSES EXAMINING PROVING PROCESS: GROUNDED THEORY AND KNOWLEDGE ANALYSIS

Aditya P. Adiredja
University of Arizona
adiredja@math.arizona.edu

Shiv Smith Karunakaran
Washington State University
shiv.karunakaran@wsu.edu

This report presents dual analyses of an undergraduate student, Cassie, whose work provides nice contrasts between Grounded Theory (GT) analysis and Knowledge Analysis (KA). The analyses highlight particular methodological differences, such as grain size of findings, positioning of novices and more general implications about expert–novice studies. The combination of the two methods results in a more complete and nuanced description of Cassie as a prover, while mediating many of the methodological concerns from the individual analysis.

Keywords: Cognition, Equity and Diversity, Reasoning and Proof, Research Methods

At the higher academic levels (graduate and professional mathematics), proving can be considered to be a way in which the truth of a claim is established or realized (Hanna, 2000; Weber, Inglis, & Mejia–Ramos, 2014). Proving, and more generally, justifying is a process by which mathematical knowledge can be furthered throughout the K–12 grades and in higher mathematics education. Selden, McKee, and Selden (2010) stated that the proving *process* "play[s] a significant role in both learning and teaching many tertiary mathematical topics, such as abstract algebra or real analysis" (p. 128). Various empirical studies have ventured to provide insight into the process of proving separate from the product of proof. For instance, previous work involving the comparing of expert and novice productions of proof have examined issues such as differences in strategic knowledge in the construction of proofs in abstract algebra (Weber, 2001), private and public aspects of proof (Mejia–Ramos & Tall, 2005; Raman, 2002), and use of examples by doctoral students in evaluating mathematical statements (Alcock & Inglis, 2008). This current work adds to this corpus of literature in order to better understand the process of proving, without necessarily associating the process to the finished product of proof.

The study of the process of proving as an unfamiliar phenomenon benefits from the use of qualitative methods that focus on explaining the phenomenon being studied instead of validating existing theory about the phenomenon. Grounded Theory (GT) research is a qualitative research method that is defined by the generation of theory that is inductively derived from the study of data (Glaser & Strauss, 1967). GT research can be used to investigate how individuals go through a process and to identify the different steps in that process (Charmaz, 2000, 2006; Creswell, 2007). More specifically the types of questions routinely investigated using GT methods are of the type: "What was the process?; …What was central to the process? (core phenomenon); … What strategies were employed during the process? (strategies); [and] What effect occurred? (consequences)" (Creswell, 2007, p. 66).

The goal of a GT analysis is to develop a substantive theory based on categories that are generated from iteratively gathering and examining data until the categories generated have been sufficiently saturated. This often implies that any theory developed through GT analysis is expected to be coarser and may necessarily sacrifice details and nuances about the phenomenon. Parnafes and diSessa (2013) asserted that claims about cognitive processes using GT typically use "time–scale and meaning–resolution [that] are rather large and indefinite" compared to other types of analyses of learning that are more microgenetic in nature (p. 15).

One such method is Knowledge Analysis (KA) (diSessa, Sherin, & Levin, 2016; Parnafes and diSessa 2013). KA is a methodological approach associated with the Knowledge in Pieces (KiP)

theoretical framework (diSessa, 1993) to "study the content and form of knowledge for the purpose of understanding learning" (diSessa et al., 2016). KA aims to describe details of models for mental representations of students' knowledge through micro–assessments and tracking of an individual's learning in real time. In principle, KA explicitly rejects the notion that novices' knowledge is a subset of experts' knowledge, and thus prioritizes the investigation of how mathematical knowledge emerges out of naïve thoughts.

In this paper, we employ both GT analysis and KA to explore the proving process of Cassie (a pseudonym), a "novice" prover. We anticipate that the two methods to complement each other in some aspects but to diverge in others. The goal is to provide a more complete and nuanced account of Cassie's proving process with the two methods, and to simultaneously contribute to the more general discussion about combined methods in qualitative research.

Methods

Data Source

Data was drawn from a larger study (Karunakaran, 2014), which examined the similarities and differences in the usage of knowledge by expert and novice provers of mathematics. The larger study involved individual semi–structured interviews where 5 undergraduate mathematics students and 5 mathematics Ph.D. students validated or refuted the truth of five mathematical statements. At the time of data collection for the larger study, Cassie was a female undergraduate student majoring in mathematics. Cassie was selected because her work offers a palpable illustration of the affordances of using the individual methods of GT and KA. Cassie's proving work was not unique compared to that of others within the novice prover group. In fact, the use of the GT analysis necessitated that the resultant claims about Cassie were consistent with her peers. Five mathematical statements were presented to Cassie over the course of two 90-minute interviews, which were audio and video recorded for subsequent transcription and analysis. The analysis in this paper focuses on Cassie's engagement with the first task.

Grounded Theory Analysis

GT analysis uses methods such as *constant comparison*, and coding strategies such as *open coding*, *axial coding* and *selective coding* (Charmaz, 2000, 2001, 2006; Straus & Corbin, 2008). These phases of coding can be described as examining the data in order to develop categories of information (open coding), examining these categories to develop them further and to interconnect them (axial coding), and using these developed categories and their interconnections to build a theory that explains the existence of the categories (selective coding).

To instantiate this coding and analysis process, consider the following excerpt from Cassie's first interview, where she was addressing the task shown in Figure 1. For space considerations, the transcript has been abridged to exclude non–mathematical language and probing questions from the interviewer.

Cassie: Let's see. So if a_n were 1, uh a_1 were 1 then that would have to be less than or equal to a_2, a_3 um so and then that would have to be um that would have to be less than or equal to a_4 plus a_5 plus a_6 plus a_7 /…/ Ok. (Pause) um I'm inclined to say that it's false. /…/ Because the, I mean the only constraint is like in the future so the a_{2n}. a_{2n+1} can grow arbitrarily large and like all that matters is that the next two, like the next a_{2n} and a_{2n+1} are bigger than that. … So like a_n is only constrained by a_{2n} and a_{2n+1}. But uh nothing before it so my initial inclination is to say that it's false.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 1: The task statement for Task 1 and Cassie's counterexample to the statement.

The first level of coding involved the identification of the mathematical objects used by Cassie (*resources*) and the acts performed on or with them (*actions*). For instance, the inequality condition from the task statement was identified as a resource to perform the action of generating an example sequence. The second level of coding was to infer the intention behind Cassie's use of the resources and actions. In the above transcript, all the identified actions and resources seemed to be expressly used with the intention of generating an example sequence to refute the statement. Thus, the second level of coding generated *bundles* of actions and resources based on their common intention. This was done iteratively for every task worked on by every participant. The final level of coding involved comparing the bundles identified across every task for each single participant and across every participant for each single task. For more details about data collection and of the GT phases of analysis see Karunakaran (2014).

Like typical GT studies, the claims generated for the expert and novice groups in this study were solely derived and supported by the data. This was achieved by constant and repeated examinations of the data for confirming and for disconfirming evidence. Since the emergent claims during the GT process were constantly evolving based on the confirming or disconfirming evidence found with continuing analyses, the final claims put forth by this method were necessarily consistent with the corpus of data collected within each group.

Knowledge in Pieces (KiP) and Knowledge Analysis (KA)

KiP models knowledge as a system of diverse elements and complex connections. One of the main principles of KiP is that knowledge is context sensitive (Smith, diSessa and Roschelle, 1993). This means that the productivity of a piece of knowledge is highly influenced by the context in which it is used. In contrast to studies that focus on identifying students' misconceptions, KiP focuses on the ways that students build new knowledge onto their prior knowledge. Adopting this theoretical framework implies that one analysis in this paper focuses on ways that Cassie builds on her prior ideas while suspending judgment about her correctness.

There are different types of KA studies. *Microanalytic* studies are a type of KA studies, which focuses on identifying knowledge elements/resources and how they are used in real–time reasoning. Knowledge resources considered in KA do not have to be mathematical, and can be intuitive in nature. KA tends to focus on a short segment of thinking, and document moment–by–moment changes in the process by which different ideas develop in students' engagement with the topic. The KA in this paper segmented Cassie's engagement with the task into thematic episodes. It exploited any relevant data (e.g., gestures, other parts of transcripts) to optimally understand the activation of knowledge resources in various contexts. The analysis then generated multiple models (interpretations) of Cassie's argument in each episode, and put these models in competition with one another. This process of *competitive argumentation* (VanLehn, Brown, & Greeno, 1984) was used to refine interpretations of Cassie's thinking. In this paper, we illustrate the use of the counter models with the first episode of Cassie's engagement with task 1. For the rest of the episodes we only present the final model from the analysis due to space constraint.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Analysis

Grounded Theory Analysis

The GT analysis found, through comparison of bundles across the tasks and students, that if the novice provers (NPs) searched for a counterexample to invalidate a given task statement then they seemed to require an earlier rationale (intuitive, inductive, deductive, or otherwise) for the invalidity of the statement. That is, the NPs needed to already believe that a statement is invalid, before they searched for a counterexample. An alternative to this would be the strategy of using the search for a counterexample as an investigative tool, without any earlier rationale for the invalidity of the statement. This alternative strategy was more descriptive of the expert provers in the larger study.

For instance, when given the statement in Task 1 (see Figure 1), Cassie stated that, "with sequences I usually start just by like counting numbers and then seeing if it seems like it's gonna converge or not." She then assigned the first term of the sequence to be 1. Cassie went on to realize that since the inequality condition presented in the task statement did not place a strict upper bound on the terms of the sequence. She justified this by stating, "the only constraint is like in the future so a_{2n} and a_{2n+1} can grow arbitrarily large and like all that matters is that the next two, like the next a_{2n} and a_{2n+1} are bigger than that." She then made her initial conclusion that the statement of Task 1 was invalid. Cassie then explicitly expressed her intention of finding a counterexample. She proceeded to generate the sequence $a_n = \{n\}_{n=1}^{\infty}$ (where n is a positive integer) as a valid counterexample to the statement of Task 1. That is, the sequence $a_n = \{n\}_{n=1}^{\infty}$ satisfies the inequality condition $0 < a_n \leq a_{2n} + a_{2n+1}$, but the corresponding series diverges.

Cassie also routinely used examples that were generated only by using the constraints or assumptions present within the task statements. These types of examples are termed as *constructed examples*. For instance, when Cassie contended with a modified version of the statement in Task 1, she used only the constraints within the task statement to generate more examples. The modified task statement was identical to the original statement, except for the last word changed from "converges" to "diverges." Cassie seemed to focus on constructing an example of a sequence that expressly satisfied the inequality condition $0 < a_n \leq a_{2n} + a_{2n+1}$. She successfully did this by generating the sequence {1, ½, ½, ¼, ¼, ¼, ¼, … } with the goal of constructing a sequence with converging terms, and where the corresponding series diverges.

The previously described instances are exemplars of Cassie's proving behavior. This behavior was consistent with the proving behavior of other members of the greater NP group. In the next section, we present the KA of Cassie's proving process separate from her group. We analyzed Cassie's engagement with Task 1, which was split into three episodes. The analysis was organized chronologically.

Knowledge Analysis

In episode 1, Cassie came up with the sequence $\{n\}_{n=1}^{\infty}$ as a counterexample for the statement in Task 1. She relied on a transitive property of inequalities and inferred the strictness of the problem's constraint.

> *Cassie:* So if a_n were 1, uh a_1 were 1 then that would have to be less than or equal to a_2, a_3. So and then that would have to be, that would have to be less than or equal to a_4 plus a_5 plus a_6 plus a_7, a triangle inequality.

Cassie started by plugging in numbers for n and described the nature of the sequence based on the inequality, $a_n \leq a_{2n} + a_{2n+1}$. She immediately saw that if the terms of the sequence satisfied the inequality for all integers n, then $a_1 \leq a_2 + a_3$ meant that $a_1 \leq a_2 + a_3 \leq a_4 + a_5 + a_6 + a_7$. She called this a triangle inequality. We posit that she mistakenly referred to the transitivity property of inequality as a triangle inequality.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Cassie: I'm inclined to say that it's false because the, I mean the only constraint is in the future. So the a_{2n}, a_{2n+1} can grow arbitrarily large and all that matters is that the next two, like the next a_{2n} and a_{2n+1} are bigger than that. So. /.../ So like a_n is only constrained by a_{2n} and a_{2n+1}, but nothing before it. So my initial inclination is to say that it's false.

At this point Cassie saw that each term of the sequence could grow to become arbitrarily large insofar as it was smaller than its associated $a_{2n} + a_{2n+1}$. Her use of the phrase "in the future," "all that matters," and "nothing before" suggests that Cassie did not see the constraint as particularly strict, or as immediately affecting the terms of the sequence. The inequality only required that the sum of the future terms of the sequence had to be larger than the current term. Thus, given that the sequence could grow to become arbitrarily large, and there was not an immediate constraint on the rate of growth, Cassie posited that a sequence that satisfied the inequality could diverge, and thus the statement was false.

Cassie: So let's see (pause) um (pause) yeah I mean it, it seems like the sequence just a_n equals n wouldn't converge because obviously we have the n's less than or equal to $2n$ plus $2n+1$. So that meets the criteria but /.../ which means the a_n's are going to infinity. So the sum wouldn't converge.

Cassie used the sequence a_n as a counterexample to disprove the claim in task 1.

Model. By plugging in values for n, Cassie immediately recognized the behavior of the terms of the series. Applying the transitive property, she concluded that $a_1 \le a_2 + a_3 \le a_4 + a_5 + a_6 + a_7 \le \cdots$. This seemingly "nested" quality of the terms did not play a major role in the process of coming up with the counterexample. Cassie asserted that the terms of the sequence could grow to become arbitrarily large, and she deemed the constraint of the terms' needing to be smaller than a sum of two consecutive future terms to be relevant, but not immediately consequential to the growth of the terms. With this she came up with the sequence $a_n = \{n\}_{n=1}^{\infty}$ as a counterexample to disprove the claim in Task 1.

Counter Model. Cassie initially considered the sequence $a_n = 1$ ("if a_1 were 1,"), which she would return to later. However, she noticed that the terms were only constrained by a_{2n} and a_{2n+1}, but "nothing before it", and so any a_i's before a_{2n} could behave without constraint. Thus, the unpredictability of the terms before a_{2n} and a_{2n+1} led her to believe that it could diverge. So she came up with the $a_n = \{n\}_{n=1}^{\infty}$ as a counterexample because it satisfied her initial thought of $a_1 = 1$ and a_n grew to become really large before it reached a_{2n}.

We posit that students' taking $a_1 = 1$ is a common practice. After that, Cassie worked with an arbitrary sequence a_n, and did not revisit $a_1 = 1$. She later came up with the sequence $a_n = 1$, but only after she recognized the lack of strict inequality in the constraint. The counter model suggests that Cassie did not treat the sum of a_{2n} and a_{2n+1} as the bound, but instead the individual terms. Her acknowledgement that $n \le 2n + 2n + 1$ with her counterexample refutes the counter model. Cassie understood that the inequality constrained the terms, but attributed the looseness of the constraint to the possibility of the terms diverging, which motivated her counterexample.

In episode 2, Cassie constructed an example of a sequence that satisfied the inequality, and where the corresponding series diverges, by recognizing and utilizing the lack of strict inequality in $a_n \le a_{2n} + a_{2n+1}$. Using the transitive property from earlier, she constructed a sequence $\{a_n\}$ where $a_1 = 1$, $a_2 = a_3 = \frac{1}{2}$, and $a_4 = a_5 = a_6 = a_7 = \frac{1}{4}$ and so on, such that $1 = a_1 = a_2 + a_3 = a_4 + a_5 + a_6 + a_7$. She generalized the pattern associated with this example, where the 1's were made of 2^{n-1} many terms of $(\frac{1}{2})^{n-1}$. She effectively used a sequence $b_n = 1$ as a counterexample, where b_n followed the pattern $b_1 = a_1$, $b_2 = a_2 + a_3$, $b_3 = a_3 + a_4 + a_5 + a_6$, etc. Cassie asserted that her example was a defining example for the claim that any series satisfying the task's criteria must always diverge.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

In episode 3, Cassie justified that claim by arguing that it was not possible for any series that satisfied the given criteria to be convergent. Cassie explained that with two general related sequences (say, a_n and b_n), if b_n was a strictly increasing sequence, then $\sum b_n$ (and thus, $\sum a_n$) would be infinity (The Divergence Theorem), and therefore the series would not be convergent. Cassie asserted that the best–case scenario for the series to be convergent would be if all the b_n's were equal, like with her counter example. Cassie proved the statement by using her example as a boundary case.

In summary, Cassie's engagement with the task and the modified task is sophisticated. She productively inferred the implication of the loose constraint of the inequality to the rate of growth of the sequence, and used it to find the first counterexample. She attended to relevant details about the task, like the lack of strict inequality to construct her example. She recognized $\sum 1$ as an example, and using the transitive property constructed and generalized the sequence $1, \frac{1}{2}, \frac{1}{2}, \frac{1}{4}, \frac{1}{4}, \frac{1}{4}, \frac{1}{4}, \dots$. She recognized her example as a boundary case and worked with two different, albeit related sequences, a_n and b_n to prove the modified statement.

Discussion and Implication

The results from the two analyses provide insights into Cassie's proving process, albeit at different grain sizes. The Grounded theory (GT) analysis provided broader patterns about Cassie's process as a representative of the novice prover (NP) group across the five tasks. Particularly pertaining to the need to find a counterexample to disprove a statement, Cassie needed prior conviction (grounded in a particular rationale) about the fallacy of the statement. To then construct it, Cassie solely focused on the explicit constraints set in the problem statement.

Knowledge Analysis (KA) focused on the details of Cassie's engagement with one task to identify knowledge resources that were influential in her proofs. While the GT analysis also started with identifying actions and resources, albeit strictly mathematical, the ultimate result of that analysis necessarily removed details that do not apply across the NP population. KA remained at that level of detail in providing specific insights about Cassie's proving process.

KA also highlights the power of Cassie's productive inferences in constructing a counterexample, and to generalize from an example. Cassie did need the prior conviction before constructing a counterexample. However, that prior conviction came from a productive inference she made about the loose constraints of the inequality on the growth rate of the terms of the sequence. In addition to providing the prior conviction, her attention to task constraints (lack of strict inequality) also allowed her to construct a counter example ($b_n = 1$). She then productively inferred that a sequence satisfying the equation, $a_n = a_{2n} + a_{2n+1}$, was a boundary case, and used her example to prove the modified claim. KA confirms the findings from the GT analysis, but allows us to observe Cassie's sophistication through the details of her proving process.

These two analyses together provide a more complete picture of Cassie's proving process. On the one hand, this is common sense. Employing complementary methods results in richer analysis. On the other hand, to our knowledge this might be one of the first studies that uses GT analysis in concert with KA, thereby crossing the boundaries between the two methods set out in Parnafes & diSessa (2012). We now discuss the importance of considering these two methods together, and the danger of privileging only one of the analyses.

Combining the two methods provides a more accurate positioning of Cassie as a prover. The result of the GT analysis positioned Cassie as a consistent member of the novice prover group, whereas KA was able to uncover Cassie's sophistication. Adiredja (2015) has argued that theoretical perspectives of cognition hold the power in determining *what* counts as productive mathematical practice, and who are deemed as "successful" learners, highlighting the connection between cognition and equity issues. While KA and KiP value and prioritize knowledge and sense making of novice learners, and are against treating novices' knowledge as a subset of that of experts, GT is not tied to any such particular theoretical perspectives. In fact, the GT analysis in this paper was

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

particularly mindful of the danger of positioning the novice group in a deficit way. However, by grouping students a priori as novices and experts, the study was in danger of beginning with a particular positioning of students before the analysis even started. This discussion highlights the importance of framing for GT studies, and how framing, in addition to theoretical perspectives also contribute to students' positioning. We were able to mediate that concern by combining the two methods.

Combining the two methods also mediates some generalizability concerns of KA and problematizes the common novice–expert dichotomy. By favoring depth and richness of analysis of cognition, one of the potential limitations of the findings from the KA done in this paper is the lack of immediate generalizability of its findings to other subjects. In a typical microanalytical KA study, the analysis would continue to identify particular kinds of resources or knowledge elements that Cassie used. Then it would examine the generalizability of those theoretical entities with other students. As is, in this paper, while KA was able to show Cassie's sophistication in her proving process, that sophistication is unique to Cassie. Little can be said about how undergraduates generally prove or construct counterexamples.

The GT analysis grounds Cassie's sophistication in her membership in the NP group as implicated by her proving process. Without the GT analysis, any resemblance of Cassie's proving process to those of an expert, or any sophistication could be attributed to her being an exception. The fact that Cassie's proving processes were consistent with those of the NP group, allows her sophistication to challenge the novice–expert dichotomy. Researchers have argued against the over–privileging of experts' knowledge, and suggested the shift in focus to understanding novices' knowledge in their own terms (diSessa et al., 2016; Smith, diSessa & Roschelle, 1993). In fact, Weber et al. (2014) have shown the continuity between novice and experts proving behaviors.

In summary, putting the two methods in communication with each other proved productive. The varying grain sizes in the results of the analyses provide a more complete reporting of the patterns we observed about Cassie's proving process. Mindful of the role of cognitive studies in positioning students, the two methods together also provide a more accurate positioning Cassie as a student. Related to that point, we problematize the common expert–novice framing of studies. Our dual analyses highlight how framing, independent from methods and theory, also contribute to the positioning of students. At the same time, the analyses also highlight the power in combining the two methods in challenging the subset model of novices' knowledge to that of experts.' By only focusing on Cassie, we were able to see the power of her proving process and the important inferences she was able to make.

In this paper we examine the application of Tzur's (2007) fine-grained assessment to the design of an assessment measure of a particular multiplicative scheme so that non-interview, good enough data can be obtained (on a large scale) to infer into elementary students' reasoning. We outline three design principles that surfaced through our recent effort to devise a sequence of items to assess at which stage—participatory or anticipatory—a child might have constructed the multiplicative double counting (mDC) scheme (Tzur et al., 2013). These principles include the nature and sequencing of prompts, number choice, and authenticity of responses.

Keywords: Number Concepts and Operations, Assessment and Evaluation

Introduction

In this paper we articulate a design process, focusing on assessing upper-elementary students' mathematical reasoning through a written instrument to develop an assessment tool sensitive to students' multiplicative reasoning. Through our project[1], we intended to assess over a 1,000 students, with future follow-ups likely to scale-up. Therefore, an immediate challenge presented itself: how to gain a trustworthy inference into a child's reasoning without conducting interviews with each participating student.

Following the approach of Norton and colleagues (e.g. Norton & Wilkins, 2009), we decided to try producing a written, pencil-and-paper assessment tool[2]. The written format would have to reflect the theoretical distinctions—schemes and stages in students' multiplicative reasoning—that we intend to measure. Our project team decided to assess two of the six schemes articulated by Tzur et al. (2013). In this paper, we focus on the design process, and design principles gleaned from the production of assessment items for the first of those six schemes (further explained in the next section), which marks a child's conceptual leap from additive to multiplicative reasoning. As this is not an empirical study, sections of the paper do not follow a canonical format of a research report.

We contribute an important elaboration on the work of Norton and colleagues (e.g. Norton & Wilkins 2009)—the need to distinguish a stage at which a learner's scheme might be constructed. Their work demonstrated how written assessments could provide a good enough substitute to inferences made from data collected in time-consuming, effort-intensive interview settings. A written assessment constrains and/or complicates the possibility for a researcher (or teacher) to make inferences about students' reasoning, because data obtained from written items hardly indicate language and actions the child might be using (e.g., moving fingers, counting to oneself). To overcome these challenges, assessment items Norton & Wilkins (2009) created for children's fractional schemes were highly correlated with interview-based inferences. Norton & Wilkins (2009)

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

tested a correlation against the underlying schemes a child might be using while successfully solving assessment items—first written and then through interviewing. The premise of their correlation seems to be that a child's ability or inability to solve certain items reflects having or not having constructed the underlying scheme, respectively.

In our project, we take a compatible, yet more nuanced approach. We premise our project on the recognition of gradation in successful solution to assessment items that is contingent upon the stage at which a learner has constructed the measured (inferred) scheme. Specifically, we articulate our design process and posit design principles that attempt to distinguish children who constructed a new scheme only at the participatory stage, which limits a learner's use of an evolving scheme to items only if somehow being prompted (Simon, Placa, & Avitzur, 2016; Tzur & Simon, 2004).

Conceptual Framework

We ground our conceptual framework in constructivist scheme theory (Piaget, 1985; von Glasersfeld, 1995), meaning that we define learning as a conceptual change brought forth through a learner's own goal directed activity (Simon, Tzur, Heinz, & Kinzel, 2004). We use "scheme" to indicate a three-part conceptual 'building block': a situation ("assimilatory template") that sets the learner's goal, an activity triggered to accomplish that goal, and a result that can turn into a prediction. We distinguish two stages in a learner's development of a new scheme: participatory and anticipatory (Tzur & Simon, 2004). Broadly, we classify a learner as "participatory" if she needs a prompt to elicit a new scheme, and "anticipatory" if she does not need a prompt to elicit a new scheme. In the context of assessment, we use "prompt" to refer to a written statement or diagram used to elicit the use of a new scheme that, otherwise, would not be brought forth.

Tzur and Simon (2004) proposed the participatory/anticipatory stage distinction to explain the "next day" phenomenon, which entails the inconsistent accessibility learners seem to have to an evolving, new way of reasoning. Initially, a learner might connect the last two parts of a scheme, as she might notice novel effects that the activity brings about. While the activity and its effect(s) are enacted, the learner can anticipate future 'mental runs' of the activity to yield the same effects. However, at the participatory stage the newly noticed activity-effect is yet to be linked with the situation/goal. Thus, at a later time ("next day"), if/when the activity has not been triggered and 'ran' to bring the newly noticed effects—the learner is likely to 'revert back' to using previously established, anticipatory schemes (Tzur & Lambert, 2011).

To distinguish between participatory and anticipatory stages, our assessment of a learner's way of reasoning needs to be sensitive to a learner's independence (or lack thereof) in using a newly constructed scheme (Tzur, 2007). To make participatory/anticipatory stage distinctions, we follow his recommendation to use fine grain assessment that proceeds from prompt-less items indicative of the anticipatory stage to prompt-dependent items indicative of the participatory stage of a new scheme. We provide a twofold reason for our choice, First, when/if prompted, a learner at the participatory stage can solve assessment tasks in ways that provide 'false positive' data—as if the learner is properly using the new scheme. Therefore, providing prompts too early may prohibit distinguishing a learner at a participatory stage from a learner at an anticipatory stage of the same scheme. Second, if assessment items avoid prompting for an evolving scheme altogether, then the learner's prompt-independent schemes (anticipatory stage) are expected to trump the use of prompt-dependent schemes (participatory stage) (Tzur & Lambert, 2011). In such a case, the learner's responses to assessment items will provide 'false negative' data—as if unable to use the newly constructed scheme, whereas she can actually reactivate and properly use the new scheme once prompted. This possibility for a 'false negative is a key aspect of our elaboration on Norton & Wilkins (2009) work.

Our assessment draws on findings about students' constructions of six schemes for multiplicative reasoning (Tzur et al., 2013). A core goal of our assessment is to identify stages in learners'

transition from additive to multiplicative reasoning. We use learners' coordination of composite units—single "things" a learner can conceive of as being made up of sub-parts (Steffe & von Glasersfeld, 1985) —to distinguish between additive and multiplicative reasoning (Clark & Kamii, 1996; Steffe & Cobb, 1998). Consider the problem: *Maria is making treat bags for her 3 friends; each treat bag will have 8 candies; how many candies does Maria need in all?* A child using additive reasoning preserves the type of composite unit (e.g., 8 candies + 8 candies + 8 candies = 24 candies). In contrast, a child using multiplicative reasoning transforms the type of composite unit, and for the candy bag problem there would be two types of composite units (8 candies per bag; 3 bags). A child using multiplicative reasoning coordinates two different types of composite units by distributing items of one composite unit over the items of another composite unit; the result of this distribution is a third, different kind of unit (e.g., 8 *candies per bag* distributed into each of 3 *bags* = 24 *candies*). Tzur et al. (2013) termed this scheme of multiplicative reasoning *multiplicative double counting* (mDC), to reflect the way a child determines the total number of 1s in the coordinated quantity by operating simultaneously on two counting sequences (e.g., 1-is-8, 2-is-16, 3-is-24).

Design Process and Principles

In this section, we articulate our process for designing a written assessment distinguishing between participatory and anticipatory stages of the mDC scheme. We chose the mDC scheme because it reflects a child's crucial conceptual leap from additive to multiplicative reasoning. A minimum of 3 items on a written assessment is considered necessary to provide a valid and reliable score of a theoretically grounded construct (Hinkin, Tracey, & Enz, 1997; Raubenheimer, 2004). To play it safe, our team decided to begin by developing five items – up to 2 of which could later be eliminated. This paper focuses on the creation of one item—a sequence of questions—the design of which proved most challenging. This item, initially asking (with drawing like Fig. 1) "How many small, gray boxes are needed to fill the large box?", required most of our effort and recurrent revisions, which assisted in our explication of design principles.

The goal we set for each assessment item was to provide data to distinguish the stage, participatory or anticipatory (Simon et al., 2016; Tzur & Simon, 2004), at which a child had constructed the mDC scheme. Following the fine-grained assessment rationale (Tzur, 2007), each item had to progress from prompt independent ("hard") to prompt dependent ("easy") questions, so that a child at the anticipatory stage can demonstrate reasoning without any prompts at the start of each item. The assessment item on which we focus here was created as a task of figuring out, in a context of two-dimensional shapes (here rectangles – see Figure 1), how many small units fit into an entire larger unit[3].

Figure 1. A small and a large rectangle providing a context for mDC.

For this item, we took caution to counteract giving a lower-level solution to a child already at the commencing, prompt independent version. For example, a child may simply draw all small rectangles and then count them one by one, which gives no information about a child's mDC scheme. We identified the need for this caution through informal interviews that one of our team members had conducted with her 7- and 9-year old daughters. The girls' use of this "easy-way-out" strategy made us realize that such a solution can yield the correct answer even for a child who is still operating on units of one (1s) and is yet to construct numbers as composite units—let alone

coordinate such units multiplicatively.

During an interview, an interviewer could present and monitor constraints to make "easy way out" strategies less likely. Furthermore, an interviewer could also probe (or avoid probing) to figure out if the child would spontaneously supply, say, columns (here, a composite unit of 7) and rows (here, a composite unit of 4) to organize and then execute a simultaneous count of the items that constitute each of those units (e.g., 1-has-4, 2-have-8, etc.). However, how might a written format steer students away from the "easy-way-out" strategy, and instead elicit data indicating an anticipatory, simultaneous operation on (coordination of) composite units?

Our tentative solution, which at the time of writing this paper is yet to be tested with more children, brought us face-to-face with the reading and writing capabilities, as well as known or unknown multiples of particular numbers (e.g., 5s vs. 7s), of 3rd and 4th grade students whose reasoning we intend to assess. Thus, on one hand, we strive to reduce the number of words in each assessment item as much as possible, and use active-voice phrases with simple-yet-precise mathematical terminology (e.g., the drawing is of rectangles, not of a cube or a box – which we initially used). We also want to allow a student to present her or his solution (answer + reasoning) while having to write as little as possible. On the other hand, we must provide clear directions about constraints we might have introduced in an interview (e.g., use numbers for which a child does not have a memorized sequence of multiples, such as 7). Several rounds of comments and suggested revisions from our project team members, led to changing the item's first question into: "How many small, gray rectangles fill the big rectangle? To find the answer, do NOT draw small rectangles." A drawing like in Figure 1 is presented below this revised question, and below that drawing three more probes are provided in large font:

A: Do you understand the question? (circle one)   Yes   No

B: Your Answer (fill in the blank): It takes _____ small rectangles to fill the big rectangle.

C: Show how you got your answer. Do NOT draw small rectangles.

With this first question to assess if a child has an anticipatory stage of the mDC scheme, we turned to creating subsequent questions that provide prompts for solving the problem by identifying and coordinating units a child may not yet be able to bring forth spontaneously. For each of those questions, we presented a drawing of the two original rectangles with some changes (see Fig. 2a-b-c), each figure followed by three probes like the ones above.

As our team discussed how to sequence the follow-up questions/drawings, we took notice of three design principles:

1. Sequencing gradually more explicit prompting for the mathematical reasoning at hand (here – units coordination);
2. Selecting "non easy" numbers to mitigate students' use of memorized facts and to engineer opportunities for students to simultaneously use composite units;
3. Eliciting authentic student responses under the given constraints.

To address the first design principle, we created the first of three prompts (Fig. 2a) for this assessment item to possibly elicit a child's organization of the rectangular space into two kinds of composite units. To this end, we drew (not fully!) 7 columns and just one row, using the same size as the small rectangle's dimensions. We considered this as the least explicit prompt of all three, because the child has not only to notice the dimension compatibility but also supply the organization of a unit of four 1s, and then coordinate the accrual of 7 units of 4 units of 1.

The second of three prompts further explicated 4 small units of 1 that would constitute a single, 4-unit 'column' (Fig. 2b), to possibly trigger the child's constitution of an anticipated, similar

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

composite unit for each of the 6 other columns. Because adding those 4 small rectangles could confuse children about the reference in the written question, we ended up extending it as follows: "Maria drew four (4) small gray rectangles in the big rectangle. How many small, gray rectangles fill the big rectangle? To find the answer, you can draw up to 6 more small rectangles."

As seen in Fig. 2c, the third of three prompts explicated almost all small units of four 1s, while still leaving two columns for the child to supply such units and successfully complete the "filling" task. Here, we wanted to ensure a majority of the students would be successful in solving the problem while still having to anticipate the interjection of a composite unit of 4 into the two empty columns, hence showing at least a rudimentary form of an assimilatory scheme for such a unit. For students who may still be unable to solve the problem, this last prompt of the assessment item could provide an indication that, perhaps, they are yet to construct number (e.g., 4) as a composite unit.

The three prompts shown in Figures 2a-c illustrate our second design principle. For each assessment item we produce, we strategically choose numbers to mitigate students' use of memorized facts and engineer opportunities for students to use composite units. First, we chose "non-easy numbers" (4 and 7) for which many students may not have a memorized sequence of multiples that can mitigate the need to keep track of the simultaneous accrual of composite units and 1s that constitute them. Second, we chose to introduce the first 4 rectangles and allow drawing up to 6 more, so the child is still constrained to not drawing each and every unit of 1 (small rectangles) while having a possibility of producing a "mental marker" for the two sets of composite units (4 along the 'width' and 7 along the 'length').

Figure 2a. First prompt   Figure 2b. Second prompt   Figure 2c. Second prompt
Figure 2. Three, diagram-based prompts for simultaneously coordinating 7 units of 4 (1s).

To address the third design principle, we faced a challenge of how to encourage children to express to others, with only a pencil and paper available, what they did in their mind to solve the item. In an interview, the child's bodily motions (e.g., fingers, head, eyes) provide an interviewer with hints as to follow-up probing questions to ask about the reasoning that took place. In a paper-and-pencil format, while trying to eliminate the need for the child to produce written, linguistic explanations, we instead guided the child as openly as possible ("Show how you got your answer") while maintaining the initial constraint ("Do NOT draw small rectangles"). We presumed that a child's drawing of some sort, likely using the figure provided as a basis, could provide a window onto the mental units and operations she or he used. It should be noted that administration of the assessment would include an explicit request to use drawing as a way to help us understand the student's thinking, as if she or he "shows it." We also decided to administer each assessment item, with its gradual-prompting versions, one question at a time. This way enables to invite the child to show how she solved a problem by approaching the person who administers the assessment. That person would document, in an abbreviated form, what the child said (e.g., "Used fingers; counted 4 and 4 = 8; then 8+8 = 16; + 8 = 24; +4 = 28). As soon as the assessment is over, that person would then select and record a code developed for conceptually distinct solutions.

Discussion
Guided by Tzur's (2007) constructivist notion of fine grain assessment, we identified three

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

design principles that can guide the design of a written assessment for distinguishing, without conducting an interview, between a participatory and an anticipatory stage in students' reasoning (Simon et al., 2016). The principles we identified included (a) gradual sequencing of prompt-less to prompt-heavy assessment items, (b) selecting "non easy" numbers, and (c) eliciting authentic student responses. We illustrated how each of these principles was applied to the creation and refinement of items for assessing the stage at which a child might have constructed a particular mathematical idea—the multiplicative double counting (mDC) scheme (Tzur et al., 2013). In this section, we discuss two main contributions the paper can make.

First, we assert that providing guidance for assessing if a student is at the participatory or anticipatory stage in the construction of a new way of reasoning (scheme) seems complementary to the design of instruction so that a classroom zone of proximal development (ZPD) can be promoted (Murata & Fuson, 2006). We root our assertion in Jin & Tzur (2011) and Tzur & Lambert's (2011) postulation of a theoretical linkage between the participatory/ anticipatory stage distinction and Vygotsky's (1986) core notions of ZPD/ZAD (zone of actual development), respectively. Written assessments that allow such a distinction seem key to effectively selecting (a) goals for what each student should learn next based on what they already know and (b) instructional activities that may facilitate such learning. Specifically, instructional activities would attempt to foster two types of reflective processes proposed by Tzur (2011) as suitable for promoting the construction of each stage. Simply put, the design process and principles depicted in this paper explicate important considerations for assessing cognitive correlates of ZPD.

Second, this paper also contributes to the ongoing efforts in the field to figure out ways to both infer into and promote key developmental understandings (KDUs, Simon, 2006) in students. Specifically, our paper focused on the work devoted to creating a stage-sensitive assessment of the first scheme (mDC) a child may construct when embarking on the conceptual leap required to transform one's additive into multiplicative reasoning about whole numbers. As noted in the Conceptual Framework, such a shift in reasoning is considered central to children's mathematical progression (e.g., to fractions and later to algebra). Illustrating how a scalable assessment can help identify students whose initial way of reasoning multiplicatively is still prompt-dependent, and thus prone to being left behind if instruction moves along prematurely, may provide a model for creating such an assessment for other KDUs.

Endnotes

[1]This research was supported by the US National Science Foundation under grant DRL 1503206. The opinions expressed do not necessarily reflect the views of the Foundation.

[2]Testing the tool for validity and reliability would involve a sequence of steps that includes administering the assessment items in a written format and a follow-up interview format to a sample of ~25 students, and figuring out the correlation between each student's work on each item in both format.

[3]Andy Norton suggested this item to us, based on his use of a similar item to assess, without the stage distinction, a fraction scheme.

Computer scientists have reported on "computational thinking," which Aho (2012) defines as "the thought process involved in formulating problems so their solutions can be represented as computational steps and algorithms" (p. 832). We wanted to investigate such thinking in mathematics. To study this, we interviewed five mathematicians about the role of computation in their work, and the notion of "algorithmic thinking" developed from these interviews. We found that mathematicians value this thinking, and in this paper we define algorithmic thinking and present a number of applications and affordances of such thinking.

Keywords: Post-Secondary Education, Cognition, Reasoning and Proof

Introduction and Motivation

Suppose we asked you how many ways there are to arrange the letters in the word COMPUTER, and, even more, we asked you to sketch out an algorithm that would enumerate an organized list of all the arrangements. Or, considering other contexts, suppose we asked you to write a program to compute the standard deviation of a data set or to shift a graph of the function $y = sin(x)$ to the right by π radians. Is there a certain way of thinking, a type of knowledge, or a set of skills that you would use to successfully complete such tasks?

These kinds of questions motivate our work, and broadly we seek to explore the ways that technological tools shape the way that people think about and do mathematics. One component of this is to consider the role of procedures and algorithms in doing mathematics, as well as the kinds of thinking that might underpin the design and implementation of such procedures. In the literature, there are ongoing conversations about the nature of procedural knowledge (e.g., Hiebert & Lefevre, 1981; Baroody, et al., 2007; Star 2005, 2007), and there have been explicit calls to foreground the study of procedural knowledge so that it may be better understood (Star, 2007). As a preliminary step toward understanding such thinking, we interviewed mathematicians about the role of computation and algorithms in their work, whether they think there are certain ways of thinking or activity to help students learn and successfully implement computation, and whether or not such thinking is important. By interviewing mathematicians, our goal is to provide evidence that members of the mathematical community value such thinking and that it may be beneficial to foster such thinking among students. We consider these findings a proof of concept, supporting the idea that such thinking is of value to members of the mathematical community and is worthy of further investigation. Specifically, our research questions are: a) How do mathematicians characterize the kind of thinking that facilitates computation in their work, and b) what are applications and affordances of such thinking?

Background Literature

In computer science, there is a construct called *computational thinking* (CT) (Grover & Pea, 2013; Wing, 2006; 2008), which Wing initially described as "taking an approach to solving problems, designing systems and understanding human behaviour that draws on concepts

fundamental to computer science" (2006, p. 33). Wing went on to characterize CT broadly and as encompassing many kinds of thinking and activity, such as "thinking recursively" (p. 33), "using abstraction and decomposition when attacking a large complex task or designing a large complex system" (p. 33), "using heuristic reasoning to discover a solution" (p. 34), and "making trade-offs between time and space and between processing power and storage capacity" (p. 34). This broad characterization makes it difficult to pin down a precise definition, but it provides a start for identifying common threads among computational activity, suggesting that perhaps there are common ways of thinking that underlie reasoning about computation and algorithms. Aho (2012) built on these definitions, and he considered "computational thinking to be the thought process involved in formulating problems so their solutions can be represented as computational steps and algorithms" (p. 832). These computer scientists seem to be articulating a way of thinking that they view as essential to the kind of work they do in their field, and these initial definitions of computational thinking as inspiring this study. There has also been some work in STEM education related to computational thinking (e.g., Weintrop, Beheshti, Horn, Orton, Trouille, Jona, & Wilensky, 2014; Wilensky & Reisman, 2006). We are motivated to understand whether there is some version of computational thinking that might be applied in a mathematical context.

Theoretical Framework

Conceptual and Procedural Knowledge

Hiebert and Lefevre (1981) elaborate an important distinction between conceptual knowledge and procedural knowledge, and since then many more mathematics education researchers have contributed to the discussion on the topic (e.g., Baroody, Feil, & Johnson, 2007; Star, 2005, 2007). Hiebert and Lefevre characterize *conceptual knowledge* as "knowledge that is rich in relationships. It can be thought of as a connected web of knowledge, a network in which the linking relationships are as prominent as the discrete pieces of information" (p. 3-4). They define *procedural knowledge* as being made up of two parts: "One part is composed of the formal language, or symbolic representation, of mathematics. The other part consists of the algorithms, or rules, for completing mathematical tasks" (p. 6). Hiebert and Lefevre (1986) also made a distinction between meaningful and rote learning. They claim that "meaning is generated as relationships between units of knowledge are organized or created," (p. 8) and noted that by their definition, conceptual knowledge must be learned meaningfully (p. 8). Rote learning "produces knowledge that is notably absent in relationships and is tied closely to the context in which it is learned" (p. 8), and they state that conceptual knowledge cannot be developed by rote learning, while procedural knowledge can. Although procedural knowledge and rote knowledge ought not to be conflated, there has been a tendency to characterize procedural knowledge as being shallow. As Star (2005) points out, Hiebert and Lefevre characterize the sequential nature of relationships in procedural knowledge, and "by this definition, procedural knowledge is superficial; it is not rich in connections" (p. 407). Star (2005, 2007) argues that this characterization, in part, has contributed to perhaps a devaluing of procedural knowledge and resulted in a lack of empirical research on procedural knowledge.

We acknowledge that there is some debate as to the nature of procedural knowledge, and that procedure knowledge has typically been related to students' implementation of known procedures. The mathematicians we interviewed talked about not just the implementation of procedures, but also the development and designing of procedures and algorithms. We are interested in studying the kind of thinking and knowledge involved in designing procedures, and we wonder whether such knowledge is related to (or is an extension of) procedural knowledge as it is currently characterized. With these ideas in mind, the constructs of conceptual and procedural knowledge helped to frame our study. We hope that our findings can contribute to Star's narrative that procedural knowledge can be deep and important, ultimately providing insight about why and how such thinking might develop.

Methods

To accomplish these goals, we interviewed five mathematicians in single 60-90 minute semi-structured interviews. Four of the mathematicians were professors in mathematics departments (M1 was a mathematical biologist, M2 an applied mathematician who specialized in modeling, M3 a numerical analyst, and M4 a geometer), all holding PhDs in mathematics, and one worked in industry and had a Master's degree in statistics. All interviews were audio-recorded. We were motivated by the literature on computational thinking (Wing, 2006, 2008), and we initially framed the interviews in terms of better understanding the role of computation. Thus, we asked the mathematicians to reflect upon various aspects of computation, including computation in their own work, the value of computation for themselves and for students, how they might teach computation, and whether there were particular kinds of thought that might support computation. Because terms like "computational thinking" or "algorithmic thinking" were not likely to carry much meaning with the mathematicians initially, and because of the various areas of mathematical expertise, we sought to establish some common language for each interviewee.

The first half of the interview was thus spent asking mathematicians about their own particular work, and especially for examples of computation in their own work. The interviewer could then follow up with appropriate questions that could target particular questions about (what we now term as) algorithmic thinking. For example, after asking some preliminary demographic questions, we asked the following: *Do you use computation in the work that you do? How so? How are you defining 'computation'?* and *What are some specific ways (or contexts) in which you use computation in your work?* This enabled us to get a sense of how they viewed and might use computation. When we had an example, we could ask questions such as *Is there a certain type of thinking/behavior/activity that needs to be carried out when performing such a mathematical computation?* This was the crux of what we wanted to study in the interview, and we could adapt this question based on specific examples a certain mathematician would give. Once this kind of language and discussion was established, we could ask them for preliminary definitions of "computational thinking" and "algorithmic thinking." We also asked whether they thought computation is important for mathematicians to learn, and why or why not. We concluded with discussions about whether and how they had taught computation before, and for them to weigh in on how students might learn computation.

To analyze the data, we transcribed the interviews, and members of the research team organized responses to the various questions. Then, using a constant comparative method (Strauss & Corbin, 1998), we generated categories of relevant phenomena that emerged from passes through the transcripts, resulting in themes that shaped a narrative to describe the results.

Results

We remind the reader that our main research question was to investigate how mathematicians characterize the kind of thinking that facilitates computation in their work, and we were especially interested in studying whether or not *computational thinking* might be a meaningful term for mathematicians. Throughout the interviews, though, it became clear that the mathematicians found computational thinking to be too broad to characterize meaningfully, but that the term *algorithmic thinking* provided more appropriate language to describe the kind of thinking we targeted in the interviews. It is important to emphasize that the term algorithmic thinking is something that emerged from, and seemed to resonate with, the interviewees. In this results section, we first define and characterize algorithmic thinking and describe how it emerged from the interviews with the mathematicians. Then, we outline two reasons why mathematicians seem to value such thinking: first, because it has a variety of practical applications that they use in their work, and second, because such thinking offers broader implicit affordances that are desirable for doing mathematics. With

these findings, we hope to convince the reader that algorithmic thinking is a specific, useful construct that is worth trying to engender in students.

Algorithmic Thinking

As noted in the methods, in each interview there was some effort required in getting on the same page with the mathematicians, having them articulate the kinds of computation they do in their work and the kind of knowledge, skills, or training might be necessary for such work. These conversations gave rise to the following preliminary, working definition of algorithmic thinking: *A logical, organized way of thinking used to break down a complicated goal into a series of (ordered) steps using available tools*. We note that our definition has similarities with Aho's (2012) characterization of computational thinking, although we emphasize using procedural steps to solve a given goal, and he emphasizes formulating problems so they may be solved with computational steps. To see how this definition emerged from the data and to elaborate various aspects of this definition, we highlight some of the mathematicians' responses. Due to space constraints, we report on M1's response in detail and only briefly mention comments from some of the other mathematicians.

The term "algorithmic thinking" first emerged in our interview with M1, whose work involves analyzing biological data. In describing how computation arises in his work, he noted that after familiarizing himself with data, he will ask himself a question like "Okay, what sort of math tools or what sort of algorithmic approaches would be fit for this approach?" Then, after implementation on test data, he might engage in an iterative process, asking himself "Okay, how can we modify this algorithm to make it work a little bit better?" M1's work involved not just computation, but in particular the development, implementing, and refining of algorithms.

We eventually asked M1 if he could define computational thinking or algorithmic thinking. He said, "computational thinking makes me think of somebody that has an eye to computation" and went on to say that, "algorithmic thinking is something I think that I could try to describe a little bit more." He gave the following definition of algorithmic thinking: "Yeah, so, I have only just today verbally articulated, but really like, the idea of how to practically solve a goal by breaking it down from a series of steps that consist only of the tools that you have at hand."

To clarify what he meant by "only the tools you have at hand," he noted that there are some restrictions depending on the context or environment in which one is creating an algorithm. In one context, like Matlab, there may be powerful packages that one can evoke, whereas in Mathematica the commands might need to be more specific. Thus, the algorithm must be created given whatever restricted set of tools is available. We have incorporated some of his ideas into our definition above, highlighting the notion of a "break down" and the idea "available tools" from M1's definition. Prior to our interview with M1, the term "algorithmic thinking" had not been something we were necessarily targeting (rather, we were interested in "computational thinking"). Through his interview, however, we realized that this might be an appropriate and meaningful term for the mathematicians. Because a working definition of "algorithmic thinking" emerged from the first interview, we subsequently asked about it in the remaining interviews.

M3 highlighted two features of algorithmic thinking – compartmentalization and order. He talked about compartmentalization as being able to "see the big picture but also recognize the smaller blocks." He went on to say, "It's the same thing when you're looking at code. It might be written linearly, but each chunk does different things." He also emphasized the importance of putting things in the proper order. He said, "The big picture has maybe three blocks. Those obviously have to be in the proper order, but the farther you zoom in, you still need to make sure each subsequent subsection is in the proper order." M5 also articulated the series of steps and the compartmentalization that M3 alluded to.

M5: I guess the algorithmic thinking is something I can relate to, based on the conversations we just had. Is that you have an idea of the series of steps that you need to go through to analyze a data set. And each one of those steps could then be decomposed into more steps.

The language of "ordered steps" in our statement is meant to convey the structured process that M3 and M5 articulate, and M3's compartmentalization echoes M2's "break down" language.

In our interview with M4, we were discussing the activity of writing code (specifically designing, as opposed to simply implementing, a package in Geometer's Sketchpad). We asked him, "What does writing the package bring that is beneficial?" and he responded, "So one of the things that it brings is these general critical thinking for programming skills." We then pressed him on what "critical thinking for programming" might mean, and he said, "Um, it's a very linear structure, a linear representation that I'll let, for the lack of a better name I'll call coding, um, that requires a particular form of creative, logical reasoning." Later, when discussing what the term "algorithmic thinking" might mean, M4 noted that such thinking was closely tied in to his notation of critical thinking for programming. We interpret then that his sense of algorithmic thinking involves a linear structure that requires logical reasoning.

The mathematicians also indicated that algorithmic thinking transcended particular programming environments or particular contexts. For example, M1 said, "Yeah, I want them to gain the skills, and I don't really care what the language is. Because once—it's really surprising. So once you've steeped yourself in one language and really understand the process of algorithm design and approximating mathematical quantities and practically implementing it, those same skill sets transfer over real quickly to some other language." M4 had a similar sentiment about the overarching nature of algorithmic thinking: "What I care about is that they develop both an appreciation for, and an ability with, interacting with a machine to problem-solve. And that they learn how to write some code, not just ask one-line questions, so that they have an experience with debugging code. Once they've done that for any language, they can build on that in any context they need it later." We feel that these comments are important because they highlight algorithmic thinking as a way of thinking that may be used and applied in a variety of contexts. They also underscore the fact that there is some kind of broader way of thinking that may be associated with engagement with designing and implementing procedures and algorithms.

To summarize, the mathematicians articulated some key features of the kind of thinking that might be involved in computation that entails writing, implementing, and checking algorithms. We address further issues related to the nature of algorithmic thinking in the Discussion section.

Practical Applications of Algorithmic Thinking

In the interviews, the mathematicians articulated several of the ways that they use computation and algorithms in their work. In this section, we use the term computation to mean the kind of computation that occurs in conjunction with algorithmic thinking (i.e., computation involving the design and implementation of procedures and algorithms). Without exception, the mathematicians saw algorithmic thinking as being useful. The following comments by M1 are representative of the opinions of a number of the mathematicians, which are that the ability to design and implement algorithms is a vital part of being a mathematician:

M1: Honestly with how data-driven [it] is and [is] increasingly becoming, and how everything Is electronics- and computer-based. I think it's pretty vital to have that, even if you're going to be some totally pure mathematician or field—like number theory or something like that— eventually there will be a real-world application. … Even being aware and having a little bit of exposure and practice of that sort of theory to practice algorithmic implementation and computationally thinking is, I think, critical and/or it would be an incomplete education without having it.

On the whole, the mathematicians articulated that such computation is useful because it allows them to accomplish some things that cannot be done efficiently by hand. Here we briefly mention examples of practical applications of thinking that emerged in the interviews.

First, some of the mathematicians seemed to frame such computation as a tool allowing them to do mathematics, which is perhaps not surprising. Here, computation is framed as a means to an end, something that facilitates the exploration of a conjecture or the generation of examples that ultimately serve the purpose of informing a theoretical mathematical exploration. M4 discussed his use of Mathematica, and he said, "the more Mathematica I have learned, the easier it has been to perform the complicated computations. But all of that elegance in programming is just to make my life easier. There's nothing inherently, um, there's, there's no direct contribution to the research project or the results that comes from my ability to program in Mathematica, beyond the fact that there is a way for me to check these difficult computations." His comment that the "elegance in programming is just to make my life easier" suggests a perspective of programming as a tool to streamline the mathematical exploration he needs to conduct. He then made the following comment, which again highlights the relationship between the role of computation and how it relates to his mathematical work.

> *M4*: So it's an interaction. I'm, I'm using Mathematica as a crutch to do my computations for me as I am thinking through which calculations to do…So I try things and see what happens. And Mathematica gives me a way to tell what's happening. And sometimes it's productive and sometimes it isn't. Um, there's a little bit of each. There are times when I know the answer and I'm just checking that it's true.

M1 and M5 offered a different kind of practical application, one in which the algorithm is itself an integral part of the work of analyzing data. M1 described a practical application of needing to refine a particular algorithm for the purpose of analyzing biological data: "Yeah, yeah, so basically there's this math quantity that I want to compute, called the earth-mover's distance, and there exists algorithms to compute it exactly, but they're too slow. So I'm going to approximate that actual metric in a heuristic, algorithmic fashion." Here the act of developing an algorithm is not just for facilitating mathematical exploration, but rather it itself is a fundamental aspect of the mathematical activity. M5 similarly used algorithms in order to analyze data statistically: "Well, yeah, I do use computation in that I analyze data for a living. And most of that is through a series of algorithms that I'll run on a set of data that can range from doing simple statistics to executing predictive models to graphics." We consider these examples as practical ways that algorithmic thinking can be used in both pure and applied mathematics, highlighting that mathematicians do draw upon such thinking that allows for a variety of applications across a number of contexts.

Implicit Affordances of Algorithmic Thinking

In addition to the practical applications for which algorithmic thinking might be useful, the mathematicians also suggested a number of other potential benefits of algorithmic thinking. This emerged through explicitly asking the mathematicians about whether and why students should develop this kind of thinking and why such computation is important for students to learn. There are three major affordances that emerged from the interviews.

First, algorithmic thinking seems related to mathematical practices such as proving and problem solving. For example, M1 said the following of algorithmic thinking: "It's problem solving. And it's, at its core, the same problem solving that mathematicians do all the time, which is "Here are the constraints, my assumptions. This is the goal, my theorem. Now what steps can I break it down to get over there?" And mathematicians do this all the time. It's just that the set of tools that they have are totally different than when you want to apply that same process to a computational problem." We infer that M1 is suggesting that the kind of thinking involved in designing and implementing an

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

algorithm is closely aligned with mathematical problem solving, and thus that reinforcing algorithmic thinking could help to strengthen problem solving.

Second, M3 made interesting comments about the relationship between algorithmic thinking and communicating mathematical ideas with others. He said, "you couldn't make clear arguments to convince people of other types of conclusions that you're trying to make if you didn't take your arguments through logical steps. So if you're trying to convince anybody of something, you need to tell them that your solution, or your idea, does what you think it does and nothing else. And that's exactly what a code is supposed to do, too." He went on to say, "I'm saying that it, it not only helps with doing math. It also helps with communicating math." For his students, then, he saw that beyond whatever mathematical insight they were gaining, such thinking could help improve their mathematical communication skills.

Finally, a number of the mathematicians also talked about the importance of having a certain disposition toward being wrong and fixing mistakes, and they suggested a relationship between this idea and algorithmic thinking. For example, M2 said, "Well, of course, and there is the other ability of being able to recover from mistakes. Which, in computing, is fundamental. And not being too frustrated and just keep going back and forth. And trying to morph something that you know worked to something you know should work." Other mathematicians also suggested that debugging code is a key activity in working with algorithms, and we contend that debugging may help to engender the ability to recover from mistakes that M2 thinks is important.

In sum, the mathematicians articulated a number of affordances of algorithmic thinking that extend beyond practical applications. These results provide additional reasons for why mathematicians value such thinking and believe it is important for students to develop.

Discussion

An important note about our definition of algorithmic thinking is that in some ways it is similar to the kind of procedural knowledge that Hiebert and Lefevre define, as they highlight procedural knowledge as involving a sequential nature of steps: "A key feature of procedures is that they are executed in a predetermined linear sequence. It is the clearly sequential nature of procedures that probably sets them most apart from other forms of knowledge" (p. 6). However, our definition of algorithmic thinking goes beyond just the implementation of a procedure, or even the explanation of why a procedure works as it does. It involves planning and designing the steps, and having an overall sense of what the algorithm can do, as well as having the details in place to successfully implement the algorithm.

In this way, the mathematicians' characterization of algorithmic thinking may be related to Star's (2005) definition of deep procedural knowledge, which involves "knowledge of procedures that is associated with comprehension, flexibility, and critical judgment" (p. 408). In particular, algorithmic thinking seems to involve a decision-making process about what tools to use and how to organize them, and this necessarily involves a flexible way of thinking. We suppose, then, that this notion of algorithmic thinking may be conceived of as overlapping with procedural knowledge. Indeed, we argue that an understanding of how to design (and not just implement) an algorithm may be a hallmark of procedural knowledge that could be considered to be more than just superficial. We also see our work as contributing because we highlight what might be entailed in algorithmic thinking at a more advanced level and as a disciplinary mathematical practice. This offers another perspective on procedural knowledge, allowing another perspective to flesh out nuances of this important construct.

Conclusion and Avenues for Future Research

Although this work is preliminary, we believe that the mathematicians' responses suggest that it may be promising to pursue and refine this idea of algorithmic thinking and what it might entail, as mathematicians seem to believe that algorithmic thinking is a valuable component of the practice of

doing mathematics. In light of this, it is important for researchers to think through how we might help students develop this way of thinking. In terms of next steps, we hope to continue to investigate the nature of algorithmic thinking. In particular, we want to gather more evidence about algorithmic thinking from both mathematicians and students at a variety of levels, with the ultimate goal of better understanding the relationship between (deep) procedural knowledge and algorithmic thinking as well as how to engender such thinking among students.

(IR)REVERSABILITY IN MATHEMATICS

Anderson Norton
Virginia Tech
norton3@vt.edu

In this theoretical paper, I consider reversibility as a defining characteristic of mathematics. Inverse pairs of formalized operations, such as multiplication and division, provide obvious examples of this reversibility. However, there are exceptions, such as multiplying by 0. If we are to follow Piaget's lead in defining mathematics as the science of reversible mental actions, such exceptions must be examined. We consider the case of multiplying by 0 by adopting Davydov's model of multiplication as a transformation of units and by investigating the underlying mental actions. Results of this investigation have implications for breaking down the barriers between various domains of mathematics.

Keywords: Cognition, Learning Theory

As mathematics educators, our ultimate goal is to support students' development of mathematical knowledge. We can define this body of knowledge culturally, as the processes and products in which mathematical communities engage (cf., Harel, 2008), but this definition is circular (how do we recognize these communities as mathematical?). Dictionaries define mathematics as "a group of related sciences, including algebra, geometry, and calculus"; or the like ('mathematics', 2016). Such definitions defy the unity of mathematics and the emersion of new branches of mathematics, such as algebraic topology and game theory. Compare those definitions to the definition of biology: "the study of living organisms" ('biology', 2016). Like mathematics, biology has numerous branches, but those branches are unified under the umbrella of living organisms. If mathematics is a science, we should be able to define its objects of study in a unified manner—one that crosses the boundaries of its various branches.

Piaget (1970) defined mathematical objects as products of coordinated mental actions. In particular, logico-mathematical actions (operations) are characterized by their composability and reversibility. Composability empowers mathematical reasoning with the possibility of combining chains of mental actions. For example, students who *count on* can take a result from counting and combine it with further acts of counting to reach a new result. Reversibility guarantees perfect reliability in mathematics: "Because every operation is reversible, an 'erroneous result' is simply not an element of the system" (p. 15). Indeed, mathematics education researchers have studied reversibility as a critical aspect of students' development of mathematical reasoning (Greer, 2011; Hackenberg, 2010; Simon, Kara, Placa, & Sandir, 2016). By inverting mental actions, such as those involved in counting, students can return to the previous result, from which they can count on, again, with assurance that they will reach the new result again. Note that no other science has perfect reliability because the objects of study (e.g., living organisms) are derived from experimental observations (rather than mental actions)—experiments that cannot be repeated with perfect precision.

As examples of mathematical objects, consider the cube and the number 5. According to many definitions of mathematics, these objects are categorically different (shape and number), but Piagetian theory demonstrates that both arise from the coordination of composable and reversible mental actions. No one has ever seen a cube; what we see are two-dimensional projections. However, we know the three-dimensional object perfectly, through coordinated mental actions, such as rotations (Piaget & Inhelder, 1967; Roth & Thom, 2009). "Children are able to recognize and especially to represent, only those shapes which they can actually reconstruct through their own

actions. Hence, the 'abstraction' of shape is achieved on the basis of co-ordination of the child's actions and not, or at least not entirely, from the object direct" (Piaget & Inhelder, 1967, p. 43).

Mental rotations are composable and reversible, and by coordinating them, we can imagine the whole cube at once. Likewise, 5 arises through the coordinated activity of pointing and reciting a verbal number sequence, "one, two, three, four, five" (Piaget, 1942). This activity generates a one-to-one correspondence between items that are taken as units of 1 and elements of the verbal number sequence. On that basis, students develop the mental action of iterating a unit of 1 "five" times—a mental action that can be reversed by partitioning the collection into the constituent five units of 1 (Steffe, 1992).

As mathematical objects, students can act on the cube and the number 5 in new ways—ways that might not be possible with physical objects. For example, they can reflect a cube about a plane through its center (see Figure 1). This action is an involution; it reverses itself. Acting on mathematical objects in new ways provides the basis for constructing new mathematical objects, at a higher level, and this is the sense in which mathematics builds upon itself.

Consider the number 5 again. As a unit containing five units of 1, 5 is an object that can be acted upon through mental actions associated with multiplication (Steffe, 1992). By coordinating these mental actions, products of two numbers can become objects in themselves.
Figure 1. Reflecting the Cube about a Plane through its Center.

When we consider formalized operations, such as addition and multiplication, it may seem obvious that mathematical operations are reversible (via subtraction and division, respectively). However, reversibility does not refer to formalized operations but, rather, to the mental actions that undergird them. Moreover, some formalized operations are not reversible; consider non-invertible matrix transformations, constant functions, and multiplying by zero. If we are to define mathematical objects—including matrices and functions—as the coordination of reversible mental actions, these examples must be examined. Here, we consider the simplest example: multiplying by zero.

The purpose of this paper is to investigate the apparent irreversibility in the case of multiplying by 0. We use that example to consider other cases of apparent irreversibility. Finally, we consider the educational implications of Piaget's definition of mathematical objects. As such, we address the conference theme of questioning "borders between mathematical content areas" and how those borders "limit access to mathematical content."

Multiplying by 0

Multiplying any real number by 0 yields a product of 0. From that product, we cannot uniquely

determine the real number with which we began. In this sense, multiplying by 0 is an irreversible formalized operation. We investigate this example further by considering the mental actions that undergird the formalized operation. We begin by defining multiplication as a transformation of units. Then, we relate that definition to the mental actions involved in units coordination. Thus, our investigation involves examining the mental actions associated with units coordination and the roles they play in transforming units.

Multiplication as a Transformation of Units

Davydov (1992) defined multiplication as a transformation from one unit of measure to another. Building from this definition, Boulet (1998) too sought to break down boundaries—boundaries between the various contexts in which multiplication arises. She demonstrated that, by defining multiplication as a transformation of units, researchers could understand the principal commonality in multiplying whole numbers, integers, rational numbers, and irrational numbers. Whereas repeated addition fits concrete models often used to introduce multiplication, the transformation of units explains what distinguishes multiplicative reasoning from additive reasoning.

Consider the product, B×A=C, as illustrated in Figure 2. We know that C is B measures of the unit A, but we want to transform the relationship to determine C as measured in units of 1 (Davydov, 1992). Thus, we are interested in a transformation of units, from units of A to units of 1. This model explains the efficacy of repeated addition when A and B are whole numbers, but the transformation also highlights what is essentially multiplicative about multiplication. Namely, to reason multiplicatively, students need to coordinate three different *levels* of units (C in units of A, and A in units of 1), not just two levels (A as A 1s) being repeated at level of 1s. Research on students' development of units coordination helps us to understand the distinction, as well as the mental actions associated with transforming units.
Figure 2. Davydov's Model of Multiplication.

Units Coordination

Units coordination refers to the number of levels of units that a student maintains when acting in a numerical situation (Steffe, 1992). Levels refer to the way numbers are embedded within each other. At the lowest level, there are 1s, from which all other numbers are constructed, primarily through counting. From units of 1, students can construct composite units—units containing other units. For example, students who coordinate two levels of units can consider 5 as a composite unit, made up of five 1s, any of which can be iterated (repeated) five times to produce 5. As a composite unit, 5 as five 1s is immediately available to the student in conceptualizing 5. Furthermore, students

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

can act on 5 as an object. For example, students can iterate the composite unit, 5, to produce a unit of units of units.

A student who has constructed composite units can also determine the number of 5s in 35 without relying on memorized facts and without having to start from 1s. She can iterate 5 seven times, simultaneously keeping track of these iterations as iterations of 5 and iterations of five 1s— two different levels of units—while building up the third level (35 as seven 5s). As such, she knows that when she has produced seven 5s, she has also produced 35 1s (see Figure 3). Thus, by iterating the composite unit, 5, she has produced 35 as a unit of seven units of 5, each of which contains five 1s—three levels of units.

Figure 3. 35 as a Unit of Seven Units of Five 1s.

Mental actions that support units coordination include unitizing, disembedding, partitioning, iterating, and distributing (Steffe, 1992). *Unitizing* refers to the mental action of taking an item, or collection of items, as a whole unit that can be further acted upon. *Disembedding* refers to the mental action of taking a sub-collection of items without destroying the whole; the sub-collection exists simultaneously as part of the whole and as a part out of the whole. As such, unitizing and disembedding can be organized as inverse actions within a structure for assimilating and coordinating units: a collection of parts can be unitized as composite unit and, inversely, any number of those parts can be disembedded from the composite unit while maintaining a part-whole relationship.

Partitioning and iterating from another pair of reversible operations (Wilkins & Norton, 2011). *Partitioning* refers to breaking a whole into equally sized parts; *iterating* refers to making connected copies of a part. These operations are inverses because iterating a part can reproduce the whole, and partitioning an iterated part reproduces that part.

Distributing refers to inserting the units within one composite unit, into each of the units in another composite unit (Steffe, 1992). With regard to Figure 3, the five units of 1 within 5 are inserted into each of the seven 1s within 7. This can involve iterating the composite unit, 5, seven times, or recursively partitioning each of the seven parts (1s) within 7 into five new parts. Either way, distributing relates to Davydov's definition of multiplication, as illustrated in Figure 4.

Figure 4. Coordinating Units of Measure.

When A and B are positive integers, we can consider the yellow bar as a composite unit containing A units of the blue bar, and we can consider the red bar as B iterations of that composite unit. Thus, there are three levels of units to consider: the blue bar as a unit of 1; the yellow bar as a composite unit; and the red bar as the result of iterating that composite unit. As such, the yellow bar

acts as an intermediate unit for measuring the red bar. We know the measure of the red bar in units of the yellow bar, but we want to know its measure in units of the red bar. To determine this measure, we can transform the yellow bar as the unit of measure into the blue bar as the unit of measure by partitioning each iteration of the yellow bar into A units of the blue bar. If the partitioning were done sequentially, it would amount to nothing more than repeated addition. However, if the partitioning occurs across all of the yellow bars at once, we have a multiplicative transformation of units.

Mental Actions that Comprise Multiplying by 0

In Davydov's (1992) definition of multiplication, commutativity is not taken for granted. Thus, the case of multiplying by zero occurs as two subcases: $0 \times A$, where 0 is the multiplier; and $B \times 0$, where 0 is the multiplicand (see Figure 5). We consider these subcases separately.
Figure 5. Zero as Multiplier (left) and Multiplicand (right).

When 0 is the multiplier, the transformation of units (between units of 1 and units of A) is reversible. This reversibility relates to partitioning and iterating as inverse mental actions: the composite unit, A, is A iterations of 1, which can be partitioned into A parts to reproduce 1. Whether we iterate A zero times or iterate 1 zero times, we produce the same result (0). This kind of many-to-one mapping is the root cause for irreversibility of formalized operations, in general, and we return to that issue in the discussion section. However, in the subcase under consideration, the transformation of units itself is reversible.

When 0 is the multiplicand, the transformation of units is irreversible because a unit is lost; the unit of 1 cannot be recovered from 0. In fact, strictly speaking, there is no transformation of units because 0 is not a unit of measure; it has no quantity, measure, or extent. We must rely upon other forms of logico-mathematical reasoning to determine the product, thus completing the formalized system of multiplying two non-negative integers. We know that C is B units of 0 and, from that, we deduce that C is 0 units of 1. Here, reversibility takes the form of reciprocity, rather than inversion.

Piaget (1970) distinguished two forms of reversibility: inversion and reciprocity. The integration of these two forms undergirds children's construction of number (Piaget, 1942). Up to this point, we have been considering inversion alone, wherein one mental action undoes another (or itself, in the case of involution). Reciprocity constitutes a form of reversibility wherein one mental action compensates for another. For example, among ordering relations, "5 succeeds 4" is reversed by way of reciprocity, in the form, "4 precedes 5." In the subcase at hand, reciprocity demands that $B \times 0 = 0$ because $B \times 0$ must map 1 to 0 again in order to compensate for the unit lost in the initial transformation. The mental action represented by each mapping/transformation is *projection*, which

generally conflates units but also can annihilate them. Thus, in the second subcase, we do not have a transformation of units, but an annihilation of units, by way of projection.

Discussion

According to Piagetian theory, mathematical objects arise through coordinated mental actions, and actions on mathematical objects can become coordinated as new objects (Piaget, 1970). This is the sense in which mathematics builds upon itself. Composite units become objects for students, through coordinated mental actions of unitizing, disembedding, partitioning, and iterating (Steffe, 1992). Once students have constructed composite units, they can act on those objects through new mental actions, such as distributing. By transforming units, this mental action supports the construction of a formalized operation for multiplication, as well as its products (Davydov, 1992).

A key aspect of coordinating mental actions is the reversibility of those actions. Reversibility provides for perfect reliability in mathematics (Piaget, 1970). In some cases, this reversibility is apparent in the formalized operation. However, in cases like multiplying by 0, the formalized operation is irreversible. Nonetheless, when we consider the underlying mental actions in one of the subcases (0×A), the transformation of units is reversible, through inversion of partitioning and iterating. In the other subcase (B×0) there is no corresponding transformation of units. Rather, we must rely on a different form of reversibility—reciprocity—to generate the product.

Determining Bx0 without a transformation of units is a means of completing the formal system of multiplication for non-negative integers. The system can be further extended to all integers, and even complex numbers, by considering directed quantities (Boulet, 1998). In the subcase of B×0, the trouble in transforming units arises from the fact that the primary unit of measure, 1, is lost. Geometrically, we can think about this subcase as a projection of the entire continuum to a single point, 0. This is precisely what happens in the case of non-invertible matrix transformations and constant functions; an independent unit is lost by way of projection. In fact, the same projection can be represented by the 1×1 matrix, $[0]$, or the constant function, $f(x)=0$.

When we consider how projection affects units and values based on those units, the result is irreversible, as it is for any many-to-one relation, because there is no way to uniquely recover any of the many values from the one value. However, the mental action of projection, itself, is reversible. In geometry, we see the inverse action in the form of sweeps: A point (P) can be swept to produce a line segment (l); that line segment can be swept in another direction (l'), to produce a square area; and that square area can be swept in yet another direction to produce a cubic volume (see Figure 6). Inversely, projections in those directions collapse the cube into a square; the square into a line segment; and the line segment into a point.

Implications

Borders between content domains limit access to mathematical content by focusing students' attention on superficial features within each domain, rather than supporting students' development of mental actions that cross those domains. As the study of reversible mental actions, mathematics is a unified science, and we can teach it as such. For example, units coordination involves the coordination of several mental actions that undergird students' knowledge of whole number (Steffe, 1992), fractions (Steffe, 2002), integers (Ulrich, 2012), algebra (Hackenberg & Lee, 2015), and geometry (Battista & Clements, 1996; Wheatley, 1992). Moreover, we can support students' construction of higher levels of units within various domains (Boyce & Norton, in press; Norton & Boyce, 2015). In the case of multiplying by 0, we find further connections to projections in geometry.

If reversible mental actions are the objects of study in mathematics, then students' mental actions need to be the focus of research within mathematics education. What mental actions are available to students? What activities will help students to reverse those actions and to compose them in new ways, in order to construct mathematical objects? Conveying mathematics as a unified science to students can support their creativity, as it has for professional mathematicians. Many of the intractable problems in mathematics have been solved by crossing domains. Specifically, proofs concerning the geometric construction problems of antiquity (e.g., the impossibility of trisecting angles with compass and straightedge) came millennia later, in the form of Galois theory, within abstract algebra.

This qualitative study sought to understand the practices (actions) enacted by mathematics middle school teachers in Mexico during mathematics instruction. We explore the "knowing-to act" of the teachers. According to Mason (1998), Knowing-to act refers to "the kind of knowledge which enables people to act freshly and creatively." (p.245). A case study was conducted with two participating teachers. Classroom observations were performed to identify the "knowing-to act" of these teachers. Mainly teachers' actions identified were asking for student's justification, revealing students' mistakes, and providing an explanation. Individual interviews with the participants allow them to describe and justify the way he or she acts. These actions and reasons to act in certain way are relevant to know in order to become aware of the factors that influence their teaching, and how it might impact on student learning.

Keywords: Teacher Knowledge, Teacher Education-Inservice/Professional Development, Mathematical Knowledge for Teaching, Instructional Activities and Practices

Introduction

Since considering what knowledge or knowing have a direct influence on teaching practices that could be used to enhance teacher education programs and teaching practices, a growing number of studies focusing on teacher knowledge has been conducted (e.g. Shulman, 1986; Tchoshanov, Cruz, Huereca, Shakirova, Shakirova, & Ibragimova, 2015). This study aimed to provide insights that will provide awareness to teacher education programs and policy makers to make important decisions in regards of what teachers need to do to know how to act desirably during teaching mathematics.

This study focused on "knowing-to act" which is the process where "knowledge [that] enables people to act creatively rather than merely react to stimuli with trained or habituated behavior" (Mason and Spence, 1999, p.136). According to Mason and Spence (1999), there is an absence of "knowing-to act" that leads mathematics teachers not to be able to respond creatively in the moment even when they possess mathematical and pedagogical content knowledge. Consequently, this absence may limit the learning opportunities that teachers can offer. Research on this kind of knowing may help teachers develop the active knowledge needed to respond creatively in the moment. The following questions guided the research: how do the teachers act in the KtA situations occurring in mathematics classroom? And how do middle school mathematics teachers describe and justify their knowing-to-act?

Theoretical Framework

This paper analyzed the teachers' "knowing-to act" (Mason & Spence, 1999) possessed by in-service teachers in mathematics classrooms at the middle school level in Mexico. Following Mason and Spence (1999), in this research "knowing-to act" refers to "active knowledge which is present in the moment when it is required" (p.135). They mentioned that this construct depends on the structure of attention in the moment, thus, "knowing-to act" depends on what one is aware of (Mason & Spence, 1999). Also, Mason and Spence (1999) identified different forms of knowing which

composed knowing-about: factual knowledge, which is the knowing-that; knowing-how, which refers to knowing the technique and skills; and knowing-why, to be able to have a story to "account for phenomena and actions" (Mason & Spence, 1999, p.137).

More specifically, "knowing-that" refers to the factual knowing, to know about facts, topics, among others. "Knowing-how" means to know how to do something, techniques or skills utilized in accomplishing a particular task. "Knowing-why" is about having an argument in order to structure actions and from which to reconstruct actions (Mason & Spence, 1999). Jong and Ferguson-Hessler (1996) categorize these kinds of knowing as: situational knowledge, conceptual knowledge, procedural knowledge, and strategic knowledge. Mason and Spence (1999) recognize that "knowing-about" is immersed in the Shulman's categories (1987). However, they considered that more than these categories are necessary to enable a teacher to act at the moment required. "Knowing-about" is considered as static knowledge possessed by a person, but it does not mean that she/he is able to act creatively in a particular situation. Mason et al. (1999) refers to the term of "knowing-to act" (KtA) as "knowledge that enables people to act creatively rather than merely react to stimuli with trained or habituated behavior" (p.136).

According to Skemp (1979b), "knowing-to act" is to be able to use the knowledge or technique in a novel situation. This type of knowing implies more than possessing ability or knowledge. The essence of "knowing-to act" is the use or call of the knowledge when required. In Rowland, Huckstep and Thwaites (2005) a categorization of the kinds of knowledge needed to teach mathematics is provided. This framework is called "knowledge quartet". One of its components is contingency, which is similar to "knowing-to act". This component is concerned about how the teachers perform when students ask questions in a particular way. According to Mason and Spence (1999) the absence of "knowing-to act" blocks students and teachers to respond creatively in the moment, thus, there is a need for distinguishing "knowing-to act" from "knowing-about" and their elements. Studies that focus on how teachers act during their instruction in the mathematical classroom is critical considering "knowing-to act" as a fundamental part of teacher knowledge, professional development activities could be implemented to promote and help in-service teachers to develop this kind of knowledge.

Methodology

This qualitative study sought to understand the practices (actions) enacted by mathematics middle school teachers in Mexico during mathematics instruction. Qualitative research places a holistic emphasis (Jackson & Verberg, 2007) on the phenomena under study. It means to conduct the research of mathematics middle school teachers in natural settings where their "knowing-to act" is enacted. As Marshall and Rossman (2011) state a particular setting influences the human actions performed in it. Therefore, to study the participating teachers' actions during instruction in the mathematics classroom was crucial in order to understand and describe the "knowing-to act" of mathematics middle school teachers.

The "knowing-to act" of the teachers was captured through face-to-face interactions with the participant and the natural setting where the actions were enacted. We were in the middle schools in Mexico where the mathematics teachers teach every day. Since the purpose of this study was to understand and explore the teachers' performance during mathematics instruction in which their "knowing-to act" was involved, the observation and analysis of teachers' "knowing-to act" was ensured. A case study method was performed to understand the "knowing-to act". To achieve this purpose and answer the research questions of the study, three classroom observations and a video-recorded interview were conducted for each participant. Another data source consisted of field notes taken during the observations. The observations were conducted using a designed protocol that focused on classroom situations (KtA situations) where the knowing-to act can be enacted, and the actions performed in those situations. Each classroom observation lasted 45 minutes. An hour-long

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

interview was later conducted with each participant to allow describing and justifying their actions. Fragments of videos from the observations were shown to them during the interview.

Participants

The case study included two participants: Omar and Maria (pseudonyms). Omar was a middle-aged teacher at the eighth and ninth grade. He had 27 years of teaching experience in mathematics. He went through a Normal School preparation. The most advanced mathematics course that he took was Integral Calculus. Omar's middle school has an enrollment of 401 students for the current academic year. This school has a dropout rate of 11.6%. However, more alarming is the fail grade rate which is 38.9%-- meaning that 38.9% of the students in this school do not pass at least one course (SNIEE, 2013b). There are approximately 25 students per classroom. Maria has 7 years of teaching experience. She holds a bachelor's degree in engineering. She taught mathematics at the eighth grade, and science at that time. The student population of the middle school where Maria worked was 845. There was a dropout rate of 9.95%. The fail grades rate is 13.31% (SNIEE, 2013b) in this school. Her class was large with 40 students.

Data analysis

The data collection process started with the classroom observations, field notes, and video recordings of the classroom observations. The observation protocol was designed with classroom situations classified as student misconceptions (Shulman, 1986; An, Kulm, & Wu, 2004); student difficulties (Fennema & Franke, 1992; Ball et al., 2008); situations that are a challenge for the teacher (Mason & Spence, 1998; Rowland et al., 2005); and emerging situations (Mason & Spence, 1998; Rowland et al., 2005). The situations included are KtA situations. The interview was designed to allow getting insights about teachers´ thinking in that situations.

 Subsequently, the analysis of these data was performed using a coding process that was developed to identify the teachers' actions as based on the data sources. The analysis of the classroom observations informed the design of the interview questions. The interview was video recorded and transcribed for further analysis. Triangulation analysis of the observations, field notes, and video recordings yielded themes that described the teacher's reasons for acting in certain ways in given situations during mathematic instruction.

Findings and Discussions

During the observations, there were four KtA situations that were common among the participants. One situation was *when a student solves a particular mathematical problem and asks if the answer or steps are correct*. In this situation, Omar and Maria acted most of the time asking for student's justification. Another KtA situation was *when a student makes a mistake.* In this situation, Omar acted reveling the students' mistakes several time while Maria was asking for students' justification of their mistaken task. *When a student is unable to see an obvious pattern in the problem was a situation that took place in Omar and Maria´s classrooms*. During this situation Omar was providing hint to their students to identify the pattern. Maria revealed the students´ mistakes when they were trying to identify the obvious pattern as well as she asked some students to keep trying. Additionally, she was also providing an explanation when she was on this last KtA situation. Another KtA situation that we focused on was *when students were having hard time completing an assigned activity/task.* When Maria and Omar were on this situation, they were providing explanations to their students to help them to complete their tasks.

During the interviews, the teachers described their actions and provided their reasons to act as they did. We found that teachers' actions are influenced by several factors such as the curriculum, class activity, students (Student's attitude; student's mistake; learning expectation; students' capabilities; student's answer), time, content, and teaching practice.

Exploring the Knowing-to act of these mathematics teachers allows understanding the teacher actions undoubtedly have an impact on student learning. The knowledge added by this study may help to restructure mathematics teacher education programs, engaging pre-service teachers to focus on the "knowing-to act" during the observations and activities that pre-service teachers are asked to do in their preparation as well as during their teaching practice. And hopefully it impacts the teaching and learning process in Mexican middle schools. Educators need to educate in-service and pre-service teachers about the "knowing-to act" processes that characterize their teaching in mathematics classrooms. This could be achieved through the implementation of professional development that includes activities that allow teachers to identify their "knowing-to act" and reflect about their actions enacted in "knowing-to act" situations. Teachers need to pay attention in particular situations that arise in their classroom that either limit or promote critical thinking.

In this theoretical paper, we discuss fairly novel conceptual tools for thinking about and carrying out equity-oriented work in mathematics education. Specifically we discuss the framing of an equitable mathematical system, and the role of three key features in this system: access, agency, and allies. In doing so, we also problematize their use and frame the tensions that arise as we have begun to use them in our research. We intend to re-examine and challenge these three core features by using specific concepts from race-critical theories (e.g., interest convergence, centrality of race and difference) as well philosophical perspectives and theories of justice, social contracts, and epistemic injustice. We conclude by discussing implications for our related research and professional development in an urban school district.

Keywords: Teacher Education-Inservice/Professional Development, Equity and Diversity

In recent years, equity has emerged as a "legitimate object of study for mathematics educators [that] can potentially move the field into new and significant directions" (NCTM Research Committee, 2005, p. 94). Yet, despite the increased attentiveness to issues of equity (and inequity) in the field, there have been very few efforts to revisit and rearticulate goals, agendas, or new conceptual tools for equity-oriented scholarship, policy, and practice. The purpose of this paper is to challenge the boundaries of how the conceptualization of new tools for thinking about and carrying out our work in mathematics education as researchers and practitioners can occur with deep and renewed attention to equity.

According to Atweh (2011), "concerns about equity are about who is excluded from the opportunity to participate and achieve in mathematics within our *current practices and systems*, and about how to alleviate their disadvantage" (p. 65). Typically these current practices and systems include a focus on the achievement gap or testing. As an alternative to this view, we suggest that the disparities should be re-framed in terms of the unfair distribution of opportunities to learn (OTL) (Gresalfi & Cobb, 2006). We argue that addressing equity in mathematics education as a function of OTL shifts the focus of mathematics education reform away from the remediation of particular groups of students towards ensuring powerful mathematics learning for these groups within classrooms, schools, and districts (Martin, 2009; Moschkovich, 2010).

Theoretical Framework and Concepts

In the proposed framework, we define an equitable system as the qualities of mathematics education that empirical studies have shown afford opportunities for groups of people who have experienced longstanding marginalization to participate powerfully in mathematics teaching and learning. We introduce and elaborate three features of equitable systems in mathematics education: *access, agency,* and *allies*. Drawing on a framework developed by Gutiérrez (2012) that emphasizes the importance of access and agency in equitable mathematics teaching and learning, the framework is augmented by research from Tatum and colleagues (1994) and others (e.g., Katsarou, Picower, & Stovall, 2010; Swalwell, 2012) on the role of allies in disrupting systems of privilege and oppression in education.

Access

Access relates to the resources (tangible and otherwise) and practices that enable students and teachers to participate in ways that are viewed as competent by standards shared within the same community of teachers and students and influences of the community at large (Gutiérrez, 2007). Access for *students* relates to, for instance, opportunities to engage in "high level" tasks (Stein & Smith, 1998) that have multiple entry points (e.g., Boaler, 2006) and support students to use mathematical practices of explaining, reasoning, justifying, and arguing in multiple "communication contexts" (Herbel-Eisenmann, Steele, & Cirillo, 2013). Access for *mathematics teachers* requires opportunities to learn in relationship to problems and dilemmas that are real within the context of their practice (Lampert, 2001).

Agency

Agency in mathematics learning relates to the ability for individuals to take action or operate upon objects (tangible or otherwise) in a mathematical learning environment (Boaler & Greeno, 2000; Gresalfi, Martin, Hand, & Greeno, 2008). Agency for *students* involves being able to utilize mathematical concepts and procedures to solve problems in sensible ways (Gresalfi & Cobb, 2006), as well as being able to participate in mathematics learning in ways that are meaningful to them (Nasir & Hand, 2008). Agency for *mathematics teachers* involves having teachers define (real) problems of practice in order to generate solutions to these problems that result in productive learning for students.

Allies

Our view of an equitable mathematical system also requires collaboration among allies who are invested in negotiating a locally situated sense of what equity means for their contexts. An ally is a person who helps, supports, or acts in solidarity with another in a particular effort. In the case of racism in the U.S., for example, Tatum (1994) notes, "there is a history of white protest against racism. A history of whites who have resisted the role of oppressor and who have been allies to people of color" (p. 470) and who have "support[ed] their efforts to swim against the tide of cultural and institutional racism" (p. 472).

Challenging Boundaries of Theoretical Perspectives on Access, Agency, and Allies

Although we see promise in incorporating new conceptualizations of access, agency, and allies within a reframing of equity, we also see a continual need to raise critical questions. For instance, what does it really mean to focus on developing and sustaining an equitable mathematics system with a focus on these three concepts? And as this work progresses, what does it mean for equity-oriented discourse to move from the margins toward the center? Who will benefit most? What are the tradeoffs?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

As a challenging framework, we draw on race-critical theories, philosophical perspectives on justice (Rawls, 2009; Mills, 1997), and recent perspectives on the nature of epistemic injustice (Fricker, 2007). Critical Race Theory is perhaps the most comprehensive of the broader collection of race-critical theories (see Essed & Goldberg, 2002), and we draw particularly on the centrality of race, the salience of counter-narrative and voice, and interest convergence. From the broader constellation of race-critical theories, we also draw on aspects of everyday racism, racial formation theory, and the intersections of racialization, class, and gender. In an effort to continue to strengthen the framing of equitable mathematical systems, we will continue to interrogate our framing to challenge the boundaries where tensions arise. Toward locating tensions that may also emerge from the enactment of our framework, we explore the following questions in relation to the three major concepts in the presentation:

Access: Access for whom and for what purposes? In what ways does access for one group of stakeholders converge with and possibly conflict with the interests of other stakeholders? Does access guarantee agency? What is the relationship between access and agency?

Agency: What is agency and who decides? Can one enact agency without access to resources and practices? Drawing on race-critical theories and recent scholarship in in philosophy regarding epistemic injustices, one might conceptualize agency as the capacity for individuals to counter supposed credibility deficits and assert their own counternarratives and testimonies (e.g., Fricker, 2007).

Allies: What does it mean to co-negotiate a social contract for change? Who benefits from the alliance? How will the alliance function such that the voices of those with the least relative privilege to enact are amplified? How will the idea of alliance intersect with the principle of interest convergence, such that the interests of white allies do not outweigh the strategic interests of allies of color?

Discussion and Implications for Future Work

The framing of an equitable mathematical system—and particularly, the triad of access, agency, and allies—is positioned as an attempt to reframe of equity discourse in mathematics education, but it is also the theoretical basis for a new project in which we aim to co-construct a more equitable mathematical system in an urban school district. In the presentation, the implications of this framing for that ongoing work will also be discussed.

BACK TO THE DRAWING BOARD: ON STUDYING INTERACTION WITH MECHANICAL DESIGN

Leah F. Rosenbaum   Dor Abrahamson
University of California, Berkeley   University of California, Berkeley
leahr@berkeley.edu   dor@berkeley.edu

In a pilot study of an experimental calculus activity centered on the CalcMachine—a concrete manipulative—subjects visually "projected" the anticipated results of their actions before executing them. From these empirical findings, we tentatively argue for integrating two theoretical models: distributed cognition (Kirsh, 2009) and instrumental genesis (Vérillon & Rabardel, 1995). Emerging from a study in the concrete domain, this theoretical development may bear implications also for digital interactive educational technologies.

Keywords: Cognition, Design Experiments, Learning Theory, Technology

Education technology research in the 21st century increasingly focuses on electronic media (Hourcade, 2015), particularly in mathematics education (e.g., see Confrey et al., 2010). Yet this research draws on educational theory often based on interactions with now-antiquated media. We assert that new forms of interaction warrant re-conceptualization of learning, teaching, and educational design (Papert, 2004). In this paper, we take a step back in hopes of taking a few steps forward, turning our attention away from virtual manipulatives and toward concrete ones (Sarama & Clements, 2009). From studying how students learn to operate tangible devices within a concrete context, we hope to contribute to digital realms of interactive technology.

Reporting on a modest study from a design-based research practicum, we first explain the design problem that inspired this project. We then propose a theoretical contribution of the pilot study and introduce two case studies as applications. We end by reframing the study as a case of our larger argument for the value of dabbling in "low tech" to inform innovation in "high tech."

A Pilot Study

The problematic role of calculus as an academic gatekeeper (Steen, 1988) motivated us to improve students' first encounters with calculus. Inspired by arguments for the inherently embodied nature of mathematics (Nemirovsky, 2003), we created an embodied learning environment (Abrahamson, 2014) to motivate and steer students' goal-oriented actions and descriptions thereof toward normative disciplinary practices (Abrahamson & Trninic, 2015).

Design

We designed, built, and pilot-tested the CalcMachine (see Figure 1a, next page), a 1-foot square frame containing: (I) a metal curve approximating a parabola; (II) a drawing bar; and (III) two magnetic points attaching the drawing bar to the curve. The points slide along a slit in the drawing bar, allowing it to be adjusted along the curve at various locations and angles. Users trace against the bar to draw secant and tangent lines to the curve.

Students' activity with CalcMachine centers on a set of target images (see Figure 1b, next page). Students are asked to recreate these images with the device. For each image, they are to set the drawing bar at an appropriate location on the curve and then use a pencil so as to trace a line on a sheet of paper placed under the device. The images were designed to promote motor-action schemes presumed as relevant to reasoning about secants and tangents. The rationale was to orient subjects toward relationships between the curve, action schemes, and resulting shapes.

Methods

The subjects, one mid-20s male and one mid-60s female, do not reflect the ultimate target population but were auspicious for this paper, as they could articulately reflect on their work. Interviews began by introducing the CalcMachine, demonstrating how to draw, and then inviting the subject to explore. Once subjects drew comfortably, the target images (Figure 1b) were introduced. Subjects were asked to draw a target image of interest and explain his/her process.
Figure 1. a. CalcMachine prototype. b. Target Images. c. Diagram for theoretical integration of IAS (bold font) & Distributed Cognition (italicized font).

Theory Interlude: Toward Integrating Seminal Frameworks

Subjects spent significant time orienting themselves toward operating the CalcMachine and applying it as a drawing tool. We believe this orienting work profoundly shaped their learning. Here we present two relevant theoretical frameworks as well as a proposed integration thereof.

Instrumental Genesis

Vérillon and Rabardel's (1995) *instrumented activity situations (IASs)* capture the multi-directional interactions among a Subject who learns to use an Artifact to facilitate an Objective (see Figure 1c, above). Examples for IASs include using an abacus to do sums or using written words to communicate. As the subject learns to operate the artifact, the artifact **instruments** the subject, limiting the subject's actions to those within the artifact's constraints. As the subject learns to use the artifact toward the objective, the artifact is **instrumentalized**, becoming a tool for the task. Feedback from the objective during instrumentalization surfaces new capabilities and constraints of the artifact, further instrumenting the subject. Through instrumented action and in keeping with cultural norms, subjects develop **utilization schemes** (USs) through which they interact with and imagine the objective. USs reflect instrumentation and instrumentalization, narrowing the subject's actions and perceptions to those afforded by the artifact. We use the IAS framework to analyze how subjects: (1) learn to operate the CalcMachine; (2) instrumentalize it to achieve the drawing objective; and (3) become instrumented as users of the CalcMachine.

Distributed Cognition

In addition to the system-level IAS framework, we also seek a perspective on moment-to-moment work. We observed nonstandard instrumentalizations of the CalcMachine that suggested the subjects' thinking to be distributed through the artifact onto the task environment. Kirsh's (2009) construct of 'projection' helps us clarify such subject–environment interactions.

Projection captures features of the environment that we visualize despite their not being physically present. For example, when solving a geometry problem, we might visualize a line bisecting an angle even though such a line is not yet physically in the environment. Projection is often paired with *creation*, either by gesturing or constructing something in the environment to materialize a projection. The former projection now perceptible, the freed cognitive resources can be put to other uses, allowing iterated projection perhaps by visualizing greater detail (as in the geometry problem). In social settings, creation may occur as much, or more, for an observer as for

the subject him/herself, transforming a private projection into a shared discursive element.

A Proposed Integration

We propose integrating project–create into the IAS triangle (see Figure 1c, previous page). We offer that 'project' and 'create' illuminate particular instances of sensorimotor feedback that shape broader instrumentation, instrumentalization, and utilization schemes. Thus subjects can project–create onto the Object, either via the Artifact, thus further instrumentalizing it, or directly onto the Object. In the latter case, implicit utilization schemes likely mediate the direct projection–creation. We find support for this theoretical integration in the task-based interviews.

Findings

In these excerpts project–create seems to co-occur with, and serve, novel instrumentalization. We also interpret moments of project–create as suggesting nascent utilization schemes.

Projected Parabolas
Figure 2. a. Traced parabola against the curve. b. Gestured parabola on Target Image F.

Working on Target Image F, Karen traced a parabola against the curve (Figure 2a) and then indicated an analogous parabola on Target Image F (Figure 2b), where drawing curves thus was a novel instrumentalization of the CalcMachine. Karen's drawn and gestured creation of parabolas not present in the environment suggests she had projected them and also indicates a utilization scheme; Karen may view the target images as things in which to recognize parabolas.

Projected Tangents
Figure 3. a. Gestured tangent. b. Marker as tangent. c. Drawing bar as tangent. d. Drawing bar itself utilized spontaneously as constituting a tangent line at various locations.

Drew considered moving the drawing bar with the points adjacent. He gestured a line roughly tangent to the curve (Figure 3a), indicating a line projected there, then materialized this projection with the marker (Figure 3b). This direct creation suggests a conception of the space as comprising such lines, a utilization scheme in step with Drew's academic background in calculus. He also recreated his projection and achieved novel instrumentalization by placing the drawing bar along the formerly gestured path (Figure 3c) and other tangent locations (Figure 3d).

Summary

From these pilot cases, we tentatively advance two propositions integrating project–create into

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

IASs. First, project–create cycles may facilitate novel instrumentalization. The temporal link between actions/utterance indicating both project-create and novel instrumentalization suggests that such instrumentalization may be a specific case of project–create, where an intended action with the artifact (or an intended product of that action) is projected before it is materialized by using (elements of) the artifact. Second, direct projection–creation onto the environment carries subjects' developing conceptions of legitimate Subject–Objective interactions in that space—a utilization scheme for both artifact and environment. These tentative conjectures require further evaluation, particularly in capturing novel instrumentalizations and nascent utilization schemes.

Based on these proposals, we submit that projection, from cognitive science, can contribute to education research, specifically to micro-analytic investigations of mathematics learning.

Conclusions

Calculus's role as an academic gatekeeper (Steen, 1988) motivated us to undertake a design-based research study using embodied learning. We designed, built, and pilot-tested the CalcMachine, a dynamic tangible device for exploring derivatives. Pilot study observations prompted us to integrate theories of instrumental genesis (Vérillon & Rabardel, 1995) and distributed cognition (Kirsh, 2009) to better understand subjects' work to operate a novel artifact.

We submit that our insights from this project emerged because we stepped back into the concrete. We likely would not have included in a virtual CalcMachine any function for tracing against the curve or using the marker as a line rather than a drawing tool, actions that—in the task context— represent failures. Yet these very failed attempts at normative operation rendered transparent the artifact's embedded functionalities, in turn offering us glimpses into authentic and ultimately productive learning processes en route to normative actions. Even as we advance with the innovations of interaction technology, we also pause to consider interaction affordances of physical artifacts—exploration and transparency among them—that we risk leaving behind. These affordances, in turn, also enabled us to step back and integrate theoretical models.

MATHEMATICAL GESTURES: MULTITOUCH TECHNOLOGY AND THE INDEXICAL SIGN

Nathalie Sinclair
Simon Fraser University
nathsinc@sfu.ca

Elizabeth de Freitas
Manchester Metropolitan University
L.de-freitas@mmu.ac.uk

This paper is about the threshold between gesture and touch in mathematical activity, focusing on the role of multitouch technology. Drawing on the work of gesture theorist Jürgen Streek, we discuss the notion of indexical gestures, in the context of young children's mathematical explorations with a multitouch iPad environment designed to promote counting on and with the fingers.

Keywords: Technology, Cognition, Number Concepts and Operations

With the advent of multitouch technologies, new media gestures have become an essential feature of user interface. The *Touch gesture reference guide* (Villamor, Willis, & Wroblewski, 2010) shows the basic actions needed for screen interaction; core gestures are listed as tap, double tap, drag, flip, pinch, spread, press and rotate. In this paper, we draw attention to the distinctive gestures new media elicit and the way these new manual activities are changing the way we perform mathematics. We also interrogate the taken-for-granted distinction between the touchscreen gestures common in the technology world and the in-the-air gestures that have been the focus of much study in mathematics education research over the past decade. At first blush, they may seem quite distinct— albeit having the same name—but we follow Streeck (2009) in treating all these gestures as part of a continuum, which allows us to study gestures as "media events" in mathematics learning (de Freitas, 2016). We thus seek to expand definitions of gesture so as to address the changing ways in which hand and media interact in contemporary digital culture. In order to illustrate how these new media gestures operate as expressions of numeracy, we draw on research involving a novel multitouch App in which fingers and gestures are used to count (Jackiw & Sinclair, 2014).

Gesture as movement

Researchers often distinguish between hand movements *in the air* and hand movements *that make graphic marks*, where the former is deemed a gesture and the latter an act of inscription. However, such distinctions become fuzzy when we study the movement of the hand across and through media, where 'media' can be more or less receptive of trace or mark. In other words, all hand movements traverse and incorporate media. We see a trace in certain media, and not in others. Since the logic of new media is to break with current conventions of perception, this distinction is provisional. New media allow for new kinds of traces. This insight allows for new ways of studying numeracy and mathematical sign-making in relation to multitouch technologies.

The predominant line of research in gesture studies focuses on movements of the body (especially the hand) and their interactions (i.e. correlations) with speech in communication (Kendon, 2004). Researchers have identified different categories of gestures (iconic, metaphoric, deictic and beat) so as to distinguish different relations between gesture and speech. McNeill has drawn on Peirce's (1994) semiotics in which signs (icons, symbols, and indices) differ in terms of the nature of the relationships between the signifying sign and the signified. Much of this research focuses on the *linguistic* potential of gestures, and tends to overlook the physicality of the hand movement, except insofar as such movement contributes to or obscures linguistic meaning (Kita, 2003; Rossini, 2012). As Streeck (2009) indicates, "it is common to treat gesture as a medium of expression, which meets both informational and pragmatic or social-interactional needs, but whose "manuality" is accidental and irrelevant" (p. 39). Instead, Streeck (2009) defines gesture:

… not as a code or symbolic system or (part of) language, but as a constantly evolving set of largely improvised, heterogeneous, partly conventional, partly idiosyncratic, and partly culture-specific, partly universal practices of using the hands to produce situated understandings. (p.5).

Thus Streek studies gesture for how it is "communicative action of the hands", with emphasis on the term *action* (p.4). This focus on action allows him to show how gesture couples with and intervenes in the material world, and indeed how gesture reconfigures the matter-meaning relationship. Peirce's indexical signs are relevant here, as they emphasize the *material* link between signifier and signified. Unlike icons and symbols, indexical signs are bound to the context in important ways, or in Peirce's words they "show something about things, on account of their being physically connected with them" (Peirce, 1894/1998, p. 5). As in the case of smoke billowing from a chimney indicating that the fireplace is in use, the smoke *indexes* the fire. In other words, smoke is *produced by and contiguous with* the fire. What is distinctive about the indexical sign is that it is a sign that is materially linked or coupled to "its object". According to Peirce (1932), an index "refers to its object not so much because of any similarity or analogy with it, (…) as because it is in dynamical (including spatial) connection both with the individual object, on the one hand, and with the senses or memory of the person for whom it serves as a sign, on the other" (2.305). In this paper, we are particularly interested in the role that indexical signs play in mathematics. For instance, the chalk drawing of a parallelogram on a blackboard is often considered to be an *iconic* reference to a Platonic conception of parallelogram, but it is (also) an *indexical* sign that refers to the prior movement of the chalk. This latter indexical dimension emphasizes the manual labour that produced the sign or trace. This focus on the indexical resonates with our work on inclusive materialism in attending to the material activity of the body in mathematical activity (de Freitas & Sinclair, 2014).

A case study

In this case study, the hand actually operates very close to the surface of a screen: pointing to objects on the screen by tapping them; sliding objects along on the screen so as to leave visual and aural traces of the finger's path; pinching objects together in order to make new ones. These gestures of pinching and pointing both communicate meaning and inscribe marks. *TouchCounts* is an iPad application that permits young learners to coordinate simultaneously various forms of number: number names like 'three', number of taps on the screen, number of discs on the screen and number symbols like 3. It enacts a multimodal correspondence between finger touching, numeral seeing and number-word hearing (a one-to-one-to-one correspondence of touch, sight and sound). The App has two worlds: the Enumerating and the Operating worlds. In this paper, we focus on the Enumerating world, which is the one that children usually first experience.

In this example, a five-year-old girl named Katy is interacting with *TouchCounts* for the first time. The room is quiet. Without prompting, Katy's hand approaches the screen, and her finger touches the top of it and slides down to the bottom. A yellow disc appears under her finger with the numeral '1' on it and the sound 'one' is made. The index finger moves back to the top of the screen, slowly swimming downwards. A chorus of 'two' comes both from her mouth and the iPad. This happens repeatedly, although sometimes only the iPad can be heard announcing the new numbered disc while Katy's lips move in synchrony (see Figure 1a). The appearance of '10' on the tenth yellow disc attracts attention, perhaps because of its double digits, and Katy bends over to look closely. Now only the iPad counts the numbers (see Figure 1b). After 'seventeen', several fingers fall on the screen at once, and then 'twenty-one' is heard. This produces a pause in the action, and Katy's lips spread into a smile. All but the index finger are tucked away, as the rhythmic tapping continues along with the chorus of named numbers. At 'twenty-seven' Katy looks up, no longer watching the screen (see Figure 1c), and she continues swiping and saying numbers. This continues until a finger seems to accidentally land on the Reset button.

Katy's finger – as the main organ of touch in this encounter –takes on new capacities through the reset button. No longer the organ that can only move or drag the yellow circle, it now becomes a finger that resets. The power of the reset button to recalibrate the tempo and rhythm of this encounter, becomes part of the finger's potentiality, thereby redefining what is currently entailed in the sense of touch.
Figure 1. (a) Katy swiping; (b) Following the yellow disc; (c) Tapping while looking up.

Discussion

Katy's hand actions change over the course of the episode, not only in the particular muscular form they take, first sliding down the screen as if lingering on the yellow discs to produce or partake in their falling off the screen, and then tapping impetuously so that each new touching of the screen follows the end of the sounds of the voiced numerical. The swiping gesture seems more exploratory while the tapping gesture seems to concatenate into a unit the touch-see-hear bundle of sensations involved in making a new disc-numeral-name. As Streeck writes, tapping is also "characteristic of ritualized behavior" (p. 76), which suggests that Katy has moved from exploration to practice. In both the swiping and the tapping, the finger can be seen as making an indexical gesture, with the trace being both visible and audible, not to mention tangible for Katy. Although the initial movement and touch of her finger is what produces the disc, it is the disc that drives the swiping movement of her finger. Indeed, both her finger and her eyes *follow* the yellow disc as it heads down the screen. In shepherding the numbered disc off the screen, Katy is able to see when it's time to lift her finger and start making a new disc. But with the tapping, the eyes attend to the numerical sign on the disc— indeed, when "10" appears, Katy notices the change from the previous one-digit numerals. In this sense, the eye and the finger do very similar things in the swiping, the visible trace is followed closely by Katy's eyes as the swiping takes place, so that the hand is subordinated to the watchful eye. With the tapping, the hand seems less subordinated, with the eye only interested when a novel situation comes up. When Katy looks up, the hand is no longer subordinate at all. Finally, when Katy's eyes close, her fingers do the seeing and touching as they repetitively tap.

One might question whether Katy's actions on the screen, which we might think of as touch-pointing, can really be thought of as gestures. Streeck argues that such touch-pointing gestures (and indeed all gestures) emerge from the touching and handling of things—the tracing (or other "data-gathering devices" such as caressing, probing, cupping) of objects that allows one to discover its texture and temperature (and, for young children, for instance, the difference between a cylinder and a pyramid). When the hand has done its exploring of the object, which fulfills an epistemic function in gathering information, it may then be lifted off the object and inclined to repeat the same movements 'in the air': "the hands' data-gathering methods are used as the basis for gestural communication" (p. 69). Streeck identifies such gestures as being communicative, which for him is the characteristic feature of a gesture. So perhaps Katy's touch-pointing becomes a gesture once she lifts her hand form the screen to do her tapping.

However, distinguishing hand movements that explore from ones that communicate is problematic. As Streeck writes, exploratory actions can become communicative when they are made visible to others, who may join in the action or infer tactile properties. If we look at Katy's swiping

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

and tapping gestures, we might say that they are both exploratory, with the swiping gestures involving prolonged tactile contact that enables her to discover what would happen when her finger touches the glass—that a yellow disc would appear, with a numeral on it; that the disc would move down the screen; that the iPad would speak the numeral's name aloud, and that this could all be repeated as often as she wished. But Katy's swiping and, later, her tapping, are also communicative inasmuch as they tell *TouchCounts* what to do and say. The same might be said for clicks of the mouse or key presses of the keyboard, with the difference that the touchscreen is acted upon by direct hand motions. Instead of disentangling the tracing from the pointing (the exploration from the communication), we suggest that re-assembling them into an indexical enables us to see how Katy's hand movements can tap into the potentiality of the body by reconfiguring the relationships between sensations of touch, sight and sound that are at play. This potentiality mobilizes new mathematical meanings as Katy uses her fingers to count on, to count with and to count out one by one and indefinitely. Streeck recognises that hand-gestures "enable translations between the senses" (p. 70) as tactile discoveries provide visual information for interlocutors. With Katy though, the tactile discoveries provide visual and auditory information to herself. She is her own interlocutor.

Conclusion

We have shown that the gestures made by Katy in *TouchCounts* entail ritual and inventive movements of the hand. Streeck (2009) argues that hand-gestures cannot be taken only as components of a language system, which are cast apart from the material world, and used only to communicate about the world. Rather, they are *of* the world, and part of how we *feel* the world around us. This perspective requires us to see the moving hand as "environmentally coupled" (Goodwin, 2007), that is, as indexical and inextricable from the things it touches and engages with. Like Streeck (2009) who suggests a link between the exploratory hand action and the communicative hand-gesture, our case study reveals how the hand becomes part of a ritual production of ordinal numeracy in a new media event. This new kind of gesture is possible in large part because of the feedback mechanism of digital technologies, which can talk, push and show back, but also significant is that the fingers are gesturing and materially bringing into existence a new concept of number. With the touchscreen interface, and particularly the multitouch interface, the hand is involved in a process of communicating that is also a process of inventing new forms of numeracy.

PRESSING METHODOLOGICAL BOUNDARIES: ANALYZING PCK USING FRAME ALIGNMENT PROCESSES

Fran Arbaugh	Nicole Bannister	Amber Simpson
The Pennsylvania State University	Clemson University	Indiana University
arbaugh@psu.edu	nbannis@clemson.edu	ambmsimp@iu.edu

Conceptual tools from frame analysis (Benford & Snow, 2000; Goffman, 1974; Snow & Benford, 1988) have been empirically linked with productive analyses of a situated model of teacher learning (Bannister, 2015) in a community of practice (Wenger, 1998). However, a limitation of this work is that is does not make claims about individual teacher learning, though some scholars question the utility of an individualist approach (Barab, Barnett, & Squire, 2002). This paper builds upon and extends this prior work using literature linking frame alignment processes (Snow, Rochford, Worden, & Benford, 1986) with teacher development of pedagogical content knowledge (Bannister, 2015). By pressing upon established boundaries for understanding the "black box" of teacher learning (Little, 2003), this papers opens up the scholarly mathematics education community to a novel theory for studying teacher learning.

Keywords: Learning Theory, Mathematical Knowledge for Teaching, Research Methods

Pedagogical content knowledge (PCK) refers to a "special amalgam of content and pedagogy" that teachers use in their professional work (Shulman, 1986, p. 226). PCK for mathematics teachers includes knowledge of subject matter, curriculum, teaching strategies, and how these facets work together to support student understanding (An, Kulm, & Wu, 2004; Hill, Ball, & Shilling, 2008; Marks, 1990). PCK is a widely used heuristic in studies of mathematics teacher learning, likely due to strong empirical evidence linking teacher PCK development with improved student outcomes (Depaepe, Verschaffel, & Kelchtermans, 2013). Despite its utility and broad reach, there is disagreement among scholars about whether or not PCK is a static entity—stemming from a cognitivist theoretical perspective—or if PCK is a dynamic classroom-based process, a perspective based upon a situated cognition framework. What is more, while the (mostly agreed upon) components of PCK have been identified, we do not yet understand fully how novice mathematics teachers develop PCK (Ball, Thames, & Phelps, 2008).

The consequences of a nuanced debate about the definition of PCK—"Where is the Mind?" (Cobb, 1994)—unintentionally leave room for unclear theoretical foundations and inconsistencies within research studies on mathematics teacher PCK development (Depaepe, Verschaffel, & Kelchtermans, 2013). This paper addresses these problems in part with a proposed method for analyzing PCK using conceptual tools from frame analysis literature. We argue in our paper that frame alignment processes (Snow, Rochford, Worden, & Benford, 1986) provide productive conceptual tools for explaining mathematics teacher PCK development, thereby contributing new theoretical insights capable of extending current methodological boundaries for analyzing individual teacher learning.

Where is the Mind?

Studies in which PCK is grounded in a cognitivist perspective tend to describe a fixed set of components that compose a category system for teacher knowledge that can differentiate PCK from other categories such as content knowledge or pedagogical knowledge. On the other hand, proponents of a situated perspective of PCK "acknowledge that the act of teaching is multi-dimensional in nature and that teachers' choices simultaneously reflect mathematical and pedagogical deliberations" (Depaepe et al., 2013, p. 22). These perspectives are consequential on the way PCK is empirically investigated:

> Advocates of a cognitive perspective on PCK believe it can be measured independently from the classroom context in which it is used, most often through a test. They typically focus on gaps in individual teachers' PCK, on how PCK is related to and distinguished from other categories of teachers' knowledge base, on how PCK is related to students' (cognitive) learning outcomes, and on how PCK can be improved through a training. Adherents of a situated perspective on PCK, on the contrary, typically assume that investigating PCK only makes sense within the context in which it is enacted. Therefore, they often rely on classroom observations…and typically aim at unraveling the nature of PCK within a particular context, as well as its development through reflection on one's own classroom practices and through participation within professional communities (e.g., discussion groups, mentoring). (Depaepe et al., 2013, p. 22)

While different theoretical perspectives necessarily influence empirical research on PCK, we—like Cobb (1994)—question assumptions that force a choice between perspectives. Rather than "adjudicating a dispute between opposing perspectives" (p. 13), Cobb (1994) instead made a case for the coordination of complementary perspectives because "sociocultural analyses involve implicit cognitive commitments, and vice versa. It is as if one perspective constitutes the background against which the other comes to the fore" (p. 18). However, even we make the blanket assumption that different theoretical perspectives for PCK are complementary, questions remain about how this assumption translates into empirical methods for studying teacher development of PCK.

Table 1: Types of Frame Alignment

Frame Bridging	"linkage of two or more ideologically congruent but structurally unconnected frames regarding a particular issue or problem" (p. 468)
Frame Amplification	"clarification and invigoration of an interpretive frame that bears on a particular issue, problem or set of events" (p. 469)
Frame Extension	extend "boundaries of its primary framework so as to encompass interests or points of view that are incidental to its primary objectives but of considerable salience to potential adherents" (p. 472)
Frame Transformation	redefine "activities, events, and biographies that are already meaningful from the standpoint of some primary framework, in terms of another framework" (p. 474)

Frame Alignment Types as a Means for Capturing Components of PCK

We rely on borrowed frame alignment concepts from the frame analysis literature for this work. Snow, Rochford, Worden, and Benford (1986) define frame alignment as the linkage between individual and larger interpretive frameworks, such as the linkage between individual teacher perspectives on practice and PCK. The authors proposed four types of frame alignment processes, including: (a) frame bridging, (b) frame amplification, (c) frame extension, and (d) frame transformation (see Table 1). "The underlying premise is that frame alignment, of one variety or another, is a necessary condition for movement participation, whatever its nature or intensity, and that it is typically an interactional accomplishment" (p. 464). In keeping with this reasoning, and by extension through Bannister's (2015) prior research, we propose studying shifts in the varying components of PCK using these frame alignment processes. In so doing, we theorize that these processes provide a method for analyzing and generating empirical evidence of individual teacher PCK development, thereby documenting empirical evidences of teacher learning.

Research Strategies

We conducted a meta-analysis of data collected as a part of a 5-year funded research study of novice mathematics teacher PCK development. After taking a grand tour of the data, we began our inquiry of teacher learning with analysis of how beginning mathematics teachers orientations toward and professional visions for teaching shift over time. The data archive includes 4 years of data about novice mathematics teacher participants, beginning with their pre-service phase and then

---

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

transitioning to the teacher induction phase. In this study, teachers in the pre-service phase were enrolled in a 1-year graduate-level teacher-training program, while teachers in the induction phase had a teaching job and up to 3 years of experience as a teacher. More specifically, the data set includes:

1. Pre-service mathematics teacher responses to an instructional planning task upon their entry and exit to their teacher-training program (Van Der Valk & Broekman, 1999). Participants were interviewed after completing the task, where researchers asked participants questions specific to four PCK categories to document participant knowledge of students' understandings, instructional strategies, assessment, and curriculum.
4. Pre-service and induction classroom observation cycles, conducted twice for each participant per year—once in the fall and again in the spring. These 2-day observation cycles produced the following data: (a) 2 days of consecutive mathematics lesson plans; (b) a pre-observation interview in which participants discussed the mathematics lessons, the knowledge they drew on when designing these two lessons, their mathematics teaching orientations, their knowledge of learners, instructional strategies, assessment, and curriculum; (c) observations, video recordings, and field notes for the two consecutive lessons taught to the same class; and (d) two stimulated recall interviews conducted after each day of observation (Pirie, 1996; Schempp, 1995) in which participant knowledge was probed via playback of critical parts of the lesson.

The archival dataset, however, focused on the individual learners rather than the grain-size of teacher community inherent to Bannister's (2015) prior work, and as such, extended this line of research to include frame alignment processes in an effort to conceptualize our inquiry of individual teacher learning from a situative perspective (Collins & Greeno, 2010). We take cues from analogous research in social movement theory that links together "social psychological and structural/ organizational factors and perspectives in a theoretically informed and empirically grounded fashion" (Snow et al., 1986, p. 464). So conceptualized, Snow and colleagues argue that frame alignment is a necessary condition for movement participation, and by extension through Bannister's (2015) prior research, a necessary condition for learning (Wenger, 1998).

Initial Conclusions

After selecting a case of teacher learning that would allow our team to investigate related research questions about teacher learning in context of our proposed theory for analyzing teacher learning, we reduced our dataset using the different components of PCK. From there, we examined our data for evidence of frame alignment processes, which included the teacher's continued alignment with her own framework or movement toward the frameworks build upon the bedrock of the National Council of Teachers of Mathematics (NCTM, 2000) vision. Preliminary findings suggest that the beginning teacher is making sense of her new role and reform-oriented perspective on teaching through her existing framings of teaching. As she learned more effective methods in her teacher training program, she also gained awareness around the absence of sensemaking her prior learning and teaching experiences. As a beginner, she struggles to move beyond her perspective of herself as a learner, and seems less able to take on the perspective of a student, making it hard for her to help students gain entry to and support their learning of this kind of work. Overall, she is struggling with getting her emergent framing of teaching and learning to align with her practice of teaching and learning. For the purposes of this paper, our ongoing analysis of teacher learning allowed us to further refine our theory as a method that effectively links PCK and frame alignment processes.

Importance

This research proposes novel methods for analyzing beginning mathematics teacher learning using processes of frame alignment. In so doing, this work presses existing methodological boundaries and opens up our scholarly community to novel interpretive frameworks for understanding teacher learning.

A HYPOTHETICAL LEARNING TRAJECTORY FOR LOGARITHMS

Ángel M. Carreras-Jusino
University of Georgia
amcarr@uga.edu

Keywords: Learning Trajectories (or Progressions)

Logarithms plays an important role in the high school curricula, particularly as a foundation for further studies in the fields of science, technology, engineering, and mathematics. Unfortunately, the logarithm concept gives students considerable difficulty. Researchers and educators alike have recognized that traditional instructional methods used to teach logarithms do not lead to a productive understanding of logarithms (Weber, 2002; Wood, 2005).

In this poster, I propose a hypothetical learning trajectory (HLT) for logarithms, based on a view of logarithms as an arithmetic operation independent from exponentials. A learning trajectory consists of: (1) a mathematical learning goal, (2) a hypothesized model of students' thinking and learning, and (3) an instructional sequence. I made use of APOS Theory as a framework for the design of the HLT. I found this theory to be useful because it is "principally a model for describing how mathematical concepts can be learned; it is a framework used to explain how individuals mentally construct their understandings of mathematical concepts" (Arnon et al., 2014, p. 17). The poster will also display a series of proposed activities specifically designed to move learners through the HLT.

The main learning goal of the HLT is for students to understand $\log_b m$ as the number of factors of b that are in the number m. Other goals are for students to correctly use and understand logarithmic notation, evaluate logarithmic expressions in which the result are whole numbers, estimate between which two whole numbers the logarithm of a number is, derive the addition and subtraction laws of logarithms, and derive the identities $\log_b 1 = 0$ and $\log_b b = 1$. It is **not** a goal of the HLT for students to find the exact value of a logarithm expression when the result is not a whole number. It is **neither** a goal of the HLT for students to make a connection between logarithms and exponentials.

In line with APOS Theory, I argue that students need to develop and move from an Action, to a Process, to an Object understanding of logarithms in order to have a productive understanding of logarithms. An Action understanding of logarithms would allow students to solve problems that implicitly call for repeated division by the same factor as a solution method, in which the number of repetitions would be the answer. With a Process understanding of logarithms, students can make generalizations about logarithms by deriving and making sense of some of their properties. An Object understanding of logarithms allow students to conceive a logarithmic expression as static, not as an instruction to do something. This particular type understanding is essential for the manipulation of operations with logarithms and generalizations about the laws that these operations entail.

DEVELOPING A HYPOTHETICAL LEARNING TRAJECTORY FOR MULTIPLICATIVE STRUCTURE

Ziv Feldman   Benjamin Dickman
Boston University   Boston University
zfeld@bu.edu   bdickman@bu.edu

Keywords: Learning Trajectories (or Progressions), Number Concepts and Operations, Teacher Education-Preservice

This study presents a hypothetical learning trajectory (HLT) for prospective elementary teachers' (PTs') understanding of multiplicative structure. Simon (1995) describes an HLT as consisting of a learning goal, instructional activities, and the ways in which students' thinking may evolve. Zazkis and Campbell (1996a) define multiplicative structure as "conceptual attributes and relations pertaining to and implied by the decomposition of natural numbers as unique products of prime factors" (p. 541). Research shows that an understanding of multiplicative structure can facilitate the transition from arithmetic to algebra and support work with divisibility, fractions, and decimals (Campbell, 2006; Brown, Thomas, & Tolias, 2002).

Methodology

Qualitative analysis of classroom video transcripts from a mathematics content course for PTs was conducted. The focus of analysis was the interactions of one small group of five PTs during a three-week number theory unit focused on factors, prime factorization, and divisibility. Analysis of the video transcripts consisted of partitioning each lesson into *pedagogical episodes*. Each pedagogical episode was then analyzed for "subtle shifting in thinking" as characterized by Simon and colleagues (2010). Once these shifts were identified, an HLT for PTs' understanding of multiplicative structure was constructed using Simon's (1995) three components.

Hypothetical Learning Trajectory

The *learning goal* is that PTs will understand the relationship between the multiplicative structure of a natural number and its factors, and will be able to use this relationship to identify divisibility and indivisibility. The *instructional activities* consist of three lessons: factors, prime factorization, and divisibility. Analysis resulted in the identification of four mathematical constructs that describe *the ways in which PTs' thinking may evolve*: 1) Magnitude-divisor count relationships; 2) uniqueness of prime factorization; 3) divisibility; and 4) indivisibility.

LATINX CRITICAL THEORY IN MATHEMATICS EDUCATION

Jessica James Hale
Georgia State University
jhale8@student.gsu.edu

Keywords: Research Methods, Equity and Diversity

History

LatCrit's roots are closely tied to Critical Race Theory (CRT). Both LatCrit and CRT began as critical legal studies that "challenge dominant liberal ideas such as colorblindness and meritocracy and show how these ideas operate to disadvantage people of color and further advantage whites" (Bernal, 2002, p. 108). Most, if not all, of the law professors involved with the creation of LatCrit identified as Critical Race Theorists. These intertwined histories leave many to mistake LatCrit for a subset of CRT, when in fact LatCrit was born from the tension many of its founder held with CRT. From these tensions the three guiding principle of LatCrit were born (Valdes, 1996):

1. The possibility to exist as a theoretical genre that focuses Latinxs as both the creators and subjects of scholarship.
2. The possibility of being rooted in both the individual and shared lived experiences of Latinxs, utilizing modern and post-modern theories together to move away from the essentialism that divides Latinxs while also purposefully working to challenge the oppression Latinxs face via social constructs.
3. The possibility of commitment to collaborative work amongst scholars who identify as members of communities traditionally dehumanized by the majoritarian status quo.

Just as many other OutCrit theories have, LatCrit's theoretical frame has begun to be applied to scholarship outside of legal studies. At the turn of the 21st century scholars such as Bernal, and Solorzano brought LatCrit to education research. And since then scholars such as Gutiérrez have brought it to the sociopolitical turn in mathematics education.

Borderlands

Gloria E. Anzaldúa's (2007) teaches us that borderlands are the places where la mezcla is most likely to occur. The border of LatCrit and Mathematics Education being a prime example of this. Many still feel LatCrit (and other theories like it) do not have a place in mathematics education, but when we allow the two to meet conceptions of who can be a mathematician, and what it means to do mathematics are allowed to grow. In this poster I will share examples from my work with young emergent bilingual mathematicians, sharing their testimonios using a LatCrit lens to honor their stories.

USING NARRATIVES ALONGSIDE CULTURAL HISTORICAL ACTIVITY THEORY: A DOCTORAL PROJECT IN THE MAKING

Sarah Mathieu-Soucy
Concordia University
sarah.msoucy@gmail.com

Keyword: Research Methods

In the context of a doctoral project, this poster presents a work in progress that examines how one could use narratives alongside Cultural Historical Activity Theory (CHAT) in a project that aims to understand phenomena in a particular institution. First, I present a description of the theoretical framework and the methodology as they are used in the associated project. The second part consists of explaining how those two concepts can blend together, both internally and practically, using epistemological and pragmatic arguments.

Cultural Historical Activity Theory (CHAT) is used to frame human thinking and behaviour as parts of an activity system (LaCroix, 2010). The participants of activity systems are seen as constantly being transformed through interactions with other individuals and with their natural and social environment. CHAT emphasizes that every transformation is socially, culturally and historically situated and caused by some tensions, that an individual is trying to resolve. Hence, the best way to understand an activity system through a period of time is to study the tensions (Cole & Engeström, 1993).

Narrative inquiry is interested in relating or giving meaning to one's life experiences. Rooted in Dewey's vision of the nature of experience (social and individual, along with the notion of continuity), the history of any experience and the continuous state of change in any situation are at the center of a narrative endeavor (Clandinin & Connelly, 2000). In my project, I am particularly interested in Desgagnés' (2005) view of narratives, where teachers tell stories about problems they solved and the researcher creates an associated narrative. Desgagnés' stories are motivated by the need to account for the internal complexity inherent to the professional practice of teaching.

The connection between the theory and the methodology presented above is rooted in their emphasis on *significant events*, *tensions* for the former, *problems to solve* for the latter. Both conceptions consider these significant events as very useful tools to accurately understand experiences and changes in a specific social, cultural and historical context, *activity system* for the former or the *professional practice* for the latter. Therefore, we hypothesize that CHAT and Desgagné's narratives are internally compatible, as both emphasize the importance of crucial events and see the individuals in similar manners, and practically compatible, as they allow the researcher to focus on significant events in real life to understand a phenomenon. This poster will present more thoroughly both conceptions and the connections and differences between them.

MATHEMATICAL ACTS AND THE RAL FRAMEWORK: UNDERSTANDING ENGLISH LEARNERS' PARTICIPATION IN MATHEMATICAL DISCOURSE

Lindsay M. Merrill
Brigham Young University
bolton.lindsay@gmail.com

Keywords: Classroom Discourse, Equity and Diversity, Research Methods

To provide adequate support for ELs in mathematics classes, educators must help ELs become fluent in *mathematical Discourse* (Merrill 2015). A "big D" Discourse (Gee, 1996) focus attends to the language use *necessary for* authentic (Brown, Collings, and Duguid 1989) mathematical activity, and situates its learning *within* authentic mathematical activity. Based on a study of college-aged ELs with basic English fluency and their work on secondary-level mathematics tasks in pairs (Merrill 2015), I suggest two ways to improve and focus research on ELs' participation in mathematical Discourse.

First, researchers should study ELs' participation in mathematical Discourse by studying their mathematical acts. A *mathematical act* consists of 1) the use of symbol systems such as spoken English, and written equations or gestures; 2) the meaning associated with that use; and 3) the purpose(s) the EL engaged in with the symbol use. This unit of analysis attends to the crucial elements for participation in mathematical Discourse. I will describe how attending to each component improves understanding of ELs' participation in mathematical Discourse.

Second, researches should study how ELs are able to use many symbol systems that do not rely heavily on English (*non-English language (NEL) symbol systems*) to participate meaningfully in mathematical Discourse. My research shows that ELs use NEL symbol systems to compensate for lower literacy with spoken English; ELs use NEL symbol systems to *replace* spoken English, to *augment* spoken English, and to *learn* spoken English. These categories of moves make up the Replace Augment Learn (RAL) Framework, shown in Table 1.

Table 1: RAL Framework

REPLACE	AUGMENT	LEARN
Predominantly use symbols	Use symbol systems as referents	Use own symbol use to improve
Symbol replaces operation	Correctly represent something being said incorrectly	Interpret another's symbol use to improve English
	Legitimize non-standard uses of English	
	Illustrate words or phrases	

Studying ELs' mathematical acts and analyzing how ELs use NEL symbol systems to support spoken English augments the field's understanding of how ELs should be supported in mathematics classes by developing a more thorough understanding of how ELs participate in mathematical Discourse. I will also discuss possible implications these research methods have for classroom practice, such as presenting problems using multiple symbol systems.

USING A TEACHING SIMULATION TO EXPLORE HOW TEACHERS RESPOND TO STUDENT THINKING

Annick Rougée
University of Michigan
arougee@umich.edu

Keywords: Research Methods, Teacher Knowledge, Affect, Emotion, Beliefs, and Attitudes

Though there are numerous teaching practices that impact student learning (e.g. facilitating whole class discussions, giving explanations, etc.), one ubiquitous practice embedded within many of these is the mathematics teaching practice of managing students' (apparently) incorrect responses. Enacting this practice skillfully necessitates being "responsive" to student thinking and ideas (Pierson, 2008) which is no small feat. Managing students' responses involves complex cognitive processes and resources utilized by mathematics teachers in-the-moment to hear, interpret (hence, the qualification that responses are *apparently* incorrect), and respond to what a student has said (Jacobs, Lamb,&Philipp, 2010). These needed cognitive resources include both specialized skills and specialized content knowledge, such as mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008), that a teacher must use while simultaneously navigating her obligations to the mathematical discipline, individual students, the class as a whole, and the institution in which she works (Herbst & Chazan, 2012). It is no wonder, given these obligations and this complexity, that this practice can be incredibly stressful, even for veteran teachers. But how does stress really impact this practice and how might stress be mitigated by various factors (such as teaching experience, MKT, and beliefs)?

To explore answers to these questions, I have designed a teaching simulation that asks participants to place themselves in a 6th grade mathematics classroom, teaching a lesson on solving equations using fact families. I present participants with a series of student responses and ask them to respond to each student as if they were the teacher in the classroom. All of the student responses contain some incorrect thinking as well as elements of sense making. In this design, I have also incorporated the collection of physiological data (electrodermal activity) that has been used in other fields as a measure of stress (Boucsein, 2012). Prior to the teaching simulation, participants also fill out questionnaires about their teaching experience, trait anxiety, and beliefs about teaching and learning mathematics (Stipek, Givvin, Salmon, & MacGyvers, 2001) and answer some MKT items about relevant algebraic content. This poster will present the simulation design and preliminary results from the analysis of the physiological data and participant responses in the simulation and on the questionnaires.

WRITTEN ASSESSMENT OF UNITS COORDINATION IN WHOLE NUMBER CONTINUOUS CONTEXTS

Catherine Ulrich
Virginia Tech
culrich@vt.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

Keywords: Assessment and Evaluation, Cognition, Number Concepts and Operations

Units coordination (Steffe, 1992) is a scheme in which a student distributes the elements of one composite unit (whole number greater than one) across the elements of another composite unit in order to carry out, for example, multiplication. Units coordination (UC) can take place in a variety of contexts, including fractional and whole number continuous contexts. UC has been studied in teaching experiments and been determined to serve as a constraint in developing key ideas in secondary mathematics (e.g., Hackenberg & Tillema, 2009). Written assessments of UC would allow larger-scale data generation. Current written assessments measure UC indirectly in fractional contexts (e.g., Wilkins, Norton, & Boyce, 2013). We are developing a written assessment that includes a series of units coordination tasks (the bars tasks) in whole number continuous contexts. The first iteration of our assessment was administered to 93 sixth-grade students. We had five bars tasks that require the following, in order of increasing hypothesized difficulty: iteration of a small composite unit with the number of iterations shown as partitions (B1), iteration of a large composite with partitions shown (B2), iteration of a composite without partitions shown (B3), the reverse of B2 (B4), and the reverse of B3 (B5). We hypothesized the following correspondences between the bars tasks and other tasks assessing three stages of students' unit construction and coordination (referred to as S1 to S3; Ulrich, 2016): B1 would be possible for some students who had not yet constructed composite units (S1), B2 would be possible for students who had constructed composite units (S2), B3 and B4 would be possible for students who could assimilate using composite units (advanced S2), and B5 would be possible for students who had constructed iterable units (S3).

The data supported the hierarchy of task difficulty we had hypothesized; the overall percentages correct were as follows: B1, 82%; B2, 72%; B3, 71%; B4, 55%; B5, 46%. However, B1 corresponded in difficulty to the tasks that identify S2, and B2 corresponded in difficulty to tasks to identify advanced S2. While we thought that students would be able to construct a composite unit in activity to iterate, it appears that assimilation with composite units is necessary to recognize a single partition as representing a composite. Because students develop the ability to anticipate using small composite units before developing a general assimilatory composite unit construct, B1 was equivalent to easier S2 tasks, while all other UC tasks were at least as hard as advanced S2 tasks. The presence of visible partitions did not decrease the difficulty. We have utilized our findings from the first administration of the assessment to revise our bars tasks.

The second meeting of this Working Group continues to explore questions about the connections between abstract algebra and school mathematics. Our goal is to focus in on questions around the way in which teachers' practice might be influenced based on their understanding of such connections. In particular, we will gather interested individuals in an effort to deepen our understanding of existing connections between abstract algebra and secondary mathematics and which of these connections are important for secondary teachers to know and understand. Moreover, we aim to further research in this area by first considering connections between abstract algebra and school mathematics present in tasks and curricular materials. Second, we will discuss efforts to design and implement professional development focused on these connections. Through our working group meetings, we plan to develop on-going collaborations to further research around the mathematical content preparation of teachers.

Keywords: Advanced Mathematical Thinking, Teacher Education-Preservice, Teacher Education-Inservice/Professional Development, Teacher Knowledge

Brief History of the Working Group

The first working group on connections between advanced and secondary mathematics was held during PME-NA 37 (Bartell, Bieda, Putnam, Bradfield, & Dominguez, 2015). During this working group, facilitators shared definitions of connections, and presented current work about important connections between abstract algebra and secondary mathematics. Through facilitator presentations and whole and small group discussions, the working group addressed the following questions: (1) What are the important connections between abstract algebra and secondary mathematics? (2) How does knowledge of connections between advanced and secondary content impact instruction in secondary classrooms? (3) How can we better support teachers to understand connections between advanced and secondary content and to use pedagogy that employs these connections? (4) How do we determine the depth of teacher knowledge of the connections between abstract algebra and secondary mathematics? (5) What are indicators that teachers have gained particular understandings? (6) What do we want teachers to be able to do with this knowledge?

After considering these questions, the group identified concrete next directions for collaboration. These include both examining tasks or curricular materials and designing and implementing professional development with secondary teachers around connections between abstract algebra and secondary mathematics. These projects were born from participants' interests in next steps as well as the group's desire to better understand teachers' knowledge of connections, how this knowledge could be assessed, and how mathematics teacher educators and teacher leaders might be able to support secondary teachers' knowledge of connections.

To ensure that our work was immediately beneficial to the community as well as of sustained duration, our initial working group proposal contained three primary follow-up activities: (1) submitting an article to the Notices of the American Mathematical Society, the most widely-read journal by professional mathematicians; (2) preparing an entry for the American Mathematical

Society's blog on the Teaching and Learning of Mathematics; and (3) longer-term work via continued meetings at other conferences and establishing a collective research agenda. We are actively working to write an article for the Notices, and we anticipate its completion by the end of the Spring 2016 semester. We completed our blog entry, which focused on providing several examples of connections between abstract algebra and high school mathematics, and it appeared in December 2015 (Baldinger, Broderick, Murray, Wasserman, & White, 2015). Due to its ongoing nature, we are continually working on the third item. Thus far various subgroups have met virtually, via regular email correspondence, and in person at the Joint Math Meetings and the Association of Mathematics Teacher Educators Annual Meeting.

Background and Theoretical Perspective

Connecting Abstract Algebra and High School Algebra

This working group explores connections between advanced mathematics content (in particular, abstract algebra) and secondary mathematics content. We are particularly interested in considering those connections that influence in some way a teacher's instructional practice. Recent policy documents (e.g., Conference Board of the Mathematical Sciences, 2012) advocate for including abstract algebra as a fundamental part of secondary teacher preparation. This provides motivation for better unpacking the connections between this advanced mathematics and school mathematics. Research focused on these connections has begun to gain traction in the mathematics education community. Such research addresses (a) the connections that exist between particular advanced content courses and secondary mathematics (e.g., Baldinger, 2014; Cofer & Findell, 2007; Suominen, 2015; Usiskin, 2001; Wasserman, 2014) and (b) the impact learning connections between advanced and secondary content has on teachers and their instruction (e.g., Baldinger, 2013; Wasserman, 2014).

Researchers have identified and listed connections between abstract algebra and school mathematics using a variety of approaches. For example, using the Common Core State Standards to represent the school mathematics curriculum, Wasserman (2015) considers teachers' potential practices for teaching specific elementary, middle, and secondary topics, before and after learning about introductory concepts in abstract algebra. He developed a framework that considered the K-12 content areas for which teaching might be influenced by teachers' knowledge of abstract algebra. This provides a different perspective than the traditional listing of connections between abstract algebra and secondary mathematics (e.g., $(Z, +)$ is a group). Suominen (2015), in contrast, considered connections by analyzing commonly used abstract algebra textbooks and interviewing abstract algebra professors. She found that the connections made in textbooks could be categorized in different types of connections (e.g., generalizations, real-world applications). After developing a list of connections, she found that the mathematicians interviewed prioritized different connections. Baldinger (2015) took yet another approach, and explored connections as they related to pre-service teacher engagement in mathematical practices. She found that in an abstract algebra course designed for pre-service secondary teachers, participants had opportunities to learn about and engage in mathematical practices such as justification, attending to precision, and communicating mathematical ideas. Following the course, participants were able to better engage in these practices while solving high school algebra tasks.

Influencing Instructional Practice

The connections identified through previous research are particularly important to the extent that they influence teachers' instructional practice. For example, Hill (2003) describes how a secondary teacher was able to build on the axiomatic approach to abstract algebra in a unit on complex numbers for her secondary students. Wasserman (2014) investigated teachers who studied abstract algebra

topics from a perspective emphasizing algebraic structures and their connections to school mathematics. He found that they began to change their beliefs and practices around teaching content such as number operations and solving equations. Cofer (2015) explored how pre-service secondary teachers were able to incorporate ideas from abstract algebra when explaining topics in school mathematics. She found that some participants were able to give explanations that incorporated an "advanced mathematical argument" and clearly drew on their abstract algebra knowledge. In other cases, participants relied on analogy or rules in their explanations, showing a lack of integration of abstract algebra knowledge. Cofer's framework provides a lens for investigating how knowledge of connections might be manifested during instructional practice.

Supporting Teachers to Learn about Connections

Building on the importance of connections between school algebra and abstract algebra, the question comes up about how we can support teachers to learn about such connections. Research suggests that pre-service teachers struggle in traditional abstract algebra courses, and these courses tend to feel disconnected from school algebra (Clark, Hemenway, St. John, Tolias, & Vakil, 1999; Zazkis & Leikin, 2010). Additionally, many do not understand the purpose of taking advanced mathematics courses (e.g., Cuoco, 2001), especially the relevance to teaching secondary mathematics (e.g., Cuoco & Rotman, 2013). For example, Broderick (2013) interviewed prospective secondary teachers about the usefulness of their college math courses. He found their comments were consistent with the literature (e.g., Cuoco, 2001; Hill, 2003), with one caveat. One participant had not passed abstract algebra the first time and went through it again. She found more relevance the second time through and was more satisfied with taking the course. Such findings have led to several efforts to make abstract algebra more accessible and applicable.

At the pre-service level, researchers have documented different strategies for better supporting teachers to learn about these connections (Murray & Star, 2013). Some courses, for example, intentionally utilize cooperative learning environments (Barbut, 1987; Cnop & Grandsard, 1998; Grassl & Mingus, 2007) or include a component of technology (Clark et al., 1999; Leron & Dubinsky, 1995). Through emphasizing non-traditional pedagogy, these courses provide pre-service teachers with a new model of teaching mathematics. Such courses support learning connections by helping pre-service teachers more deeply understand the abstract algebra content, and their non-traditional pedagogical approach may support changes in practice. However, the connections across abstract algebra content and school mathematics are largely implicit. Other courses intentionally address connections with school mathematics (e.g., Baldinger, 2013; Cuoco & Rotman, 2013; Wasserman, 2014). In these cases, the connections are an intentional part of the course design, and pre-service teachers are supported to learn about connections alongside learning about abstract algebra content.

For in-service teachers, research suggests that professional development driven by a focus on mathematics content tends to have a stronger impact on practice than professional development with, for example, an activity focus (Garet, Porter, Desimone, Birman, & Yoon, 2001; Marra et al., 2011). Furthermore, Sowder and colleagues (1998) found that increasing teachers' content knowledge could have impact on teachers' practice. This helps motivate a need to focus explicitly on connections between abstract algebra and school mathematics within professional development, as doing so helps make the content more relevant to classroom practice. This can help mitigate the tension teachers feel when professional development is disconnected from their work with students (Nipper et al., 2011).

Taken together, this research suggests important starting points in considering how to support teacher learning around connections between school algebra and abstract algebra. In this working group, we plan to build on this research to discuss strategies to support teacher learning of these connections in ways that help teachers to make positive changes in their practice based on their deepened understanding.

Theoretical Perspectives

We view teacher knowledge of the connections between school algebra and high school algebra as part of their mathematical knowledge for teaching. We build on the work of other scholars (Ball, Thames, & Phelps, 2008; McCrory, Floden, Ferrini-Mundy, Reckase, & Senk, 2012) in taking a practice-based approach to conceptualizing teacher knowledge, since we are interested in connections that have an impact on instructional practice. Though there is debate about whether some of the categories of mathematical knowledge for teaching identified by Ball and colleagues (specialized content knowledge, in particular) can be appropriately transferred to secondary level mathematical knowledge for teaching (Speer, King, & Howell, 2015), we draw on the approach of considering knowledge in practice. In thinking about connections, we are particularly interested in what Ball and colleagues call "horizon content knowledge". Wasserman and Stockton (2013) unpack this category of knowledge, and explore how it can be applied to the work of teaching.

In considering how teachers develop mathematical knowledge for teaching, and horizon content knowledge around connections in particular, we are guided by the construct of "key developmental understandings (KDUs)" (Simon, 2006). A KDU is a "conceptual advance that is important to the development of a concept" (Simon, 2006, p. 365). Silverman and Thompson (2008) use this construct in their framing of teachers' mathematical knowledge, by proposing that teachers develop mathematical knowledge for teaching of a topic if: (a) they have achieved a KDU that encompasses mathematical understanding of the topic; and (b) they have an understanding of how the topic may evolve instructionally in support of students' reasoning in the K-12 classroom. We apply this notion to understanding of connections, by investigating in particular how understanding those connections contributes to teacher practice.

Connections to PME-NA

For many teachers, the border between high school algebra and abstract algebra is significant. However, the connections between these two content areas that we focus on here serve as key bridges across that border. Our working group this year seeks to address questions that support teachers in questioning this border themselves—beyond just identifying connections between the two areas, we want to support teachers to apply knowledge of these borders to their classroom practice.

Working Group Goals

A long-term collective goal is to fundamentally reconsider the teaching of more advanced content courses for teachers in ways that are useful both generally for the teaching of all mathematics majors and also specifically for the unique considerations and professional practices of secondary teachers.

The goals for the second meeting of the working group are to share the work done for the two projects begun at PME-NA 37, to discuss next steps for these projects, and to consider new research that could advance our collective understanding of connections between advanced and secondary content and the role of connections in secondary mathematics teaching and learning.

The overall goal for this working group remains to strengthen our collective understanding of connections between advanced and secondary content and their role in secondary mathematics teaching and learning. We focus on abstract algebra as an entry into this domain, particularly for its rich connection to secondary mathematics topics such as algebra and functions, while also anticipating that the impact of these conversations will prompt research into other content areas (e.g., calculus, linear algebra, and analysis).

Plan for Working Group

Across the three sessions, participants will have the opportunity to interrogate the current state of the research through brief presentations and guided discussions.

Session 1: Examination of Tasks and Curricula

In the first session, group members will present work about the analysis of tasks and curriculum around the connection between abstract algebra and secondary mathematics. Leading up to the 2016 working group, a subset of participants from the previous year have been exploring this idea from two perspectives. The first perspective is to interrogate mathematics courses taught for prospective secondary teachers (e.g., capstone courses; content courses; content-focused methods courses) for connections, including where the connections are located, which ones are addressed, and how they are addressed. The intent of this analysis is to inform what is going on currently in mathematics teacher preparation and compare the nature of these connections to those that are highlighted in mathematics courses.

The second perspective is to merge the frameworks developed by Wasserman (2015) and Suominen (2015) discussed above. The goal of this work is to see if there are commonalities in the connections noted in both the Common Core State Standards and higher education textbooks. Moreover, the group is interested in determining how meaningful the connections are to instruction in secondary school, particularly those connections that are less commonly noted in the literature. By merging these two approaches, the group is attempting to narrow down what to look for in tasks and curricular materials for secondary mathematics. This attempt will further the group's understanding of what sections, courses, and topics in secondary mathematics could be further explored for connections.

After the presentation, facilitators will lead small group discussions so that participants can provide their own input on connections embedded in current tasks for secondary mathematics students, regardless of whether these tasks are being used for high school students or prospective teachers. At the end of this session, the facilitators will create a summary of important connections and tasks discussed to help organize and motivate the final session.

Session 2: Designing Professional Development

In the second session, group members will present work regarding the design and implementation of professional development with secondary teachers around connections between abstract algebra and secondary mathematics. Based on ongoing discussions among participants of the original working group and others at various professional meetings, the professional development is being planned to have a strong pedagogical component, which involves using classroom-based scenarios or vignettes that highlighted some aspect of high school mathematics connected to abstract algebra. As we design this professional development, we consider the following questions: (1) What are the objectives, goals, and outcomes of professional development focused on the connections between abstract algebra and secondary mathematics? (2) How we can use the professional development to examine curricula and tasks and to solicit teachers' ideas about the connections?

In the second part of this session, we will engage in small group discussions of this particular professional development design. Through this conversation, we will collect ideas and feedback for further professional development workshops and consider the following questions: What are the research questions aligned with this professional development? How do we answer these questions, or measure what we are interested in? How might the internalization of connections between abstract algebra and secondary mathematics changes teachers? At the end of this session, the facilitators will create a summary of ideas generated during the discussions to help organize and motivate the final session.

Session 3: Determining Concrete Next Steps

In the final session of this working group, we will begin by sharing our summaries from the previous two sessions. We will engage in a whole group discussion of possible research questions

that were generated in previous conversations. We will conclude the session by splitting up into groups, based on interest, to begin planning next steps.

Anticipated Follow-up Activities

We will actively continue our work together beyond the working group meetings at PME-NA 38. The formation of new connections among scholars, as well the deepening of the current connections, will positively impact post-conference activities. Our two subgroups (the tasks and curriculum subgroup and the professional development subgroup), along with any new subgroups arising out of the meetings at PME-NA 38 will work on specific research questions generated through our meetings at PME-NA. We also plan to collaborate on grant and journal submissions; an NSF DRK-12 grant is a likely starting point. In addition, the subgroup focused on professional development will take direct action-steps toward producing, testing, and investigating professional development focused on connections between abstract algebra and school mathematics. Through participation in the working group, several members are already sharing and providing feedback on the work of other members, and we will expand and deepen these efforts. We anticipate that these connections among scholars can be maintained and potentially lead to collaboration on related research.

We anticipate that members of this working group will continue to meet virtually, correspond regularly about the work via email, and meet in person at various professional meetings.

The purpose of this working group is to bring together scholars with an interest in examining the research on quantitative tools and measures for gathering meaningful data, and to spark conversations and collaboration across individuals and groups with an interest in synthesizing the literature on large-scale tools used to measure student- and teacher-related outcomes. While syntheses of measures for use in mathematics education can be found in the literature, few can be described as a comprehensive analysis. The working group session will focus on (1) defining terms identified as critical (e.g., large-scale, quantitative, and validity evidence) for bounding the focus of the group, (2) initial development of a document of available tools and their associated validity evidence, and (3) identification of potential follow-up activities to continue the work to identify tools and developed related synthesis documents (e.g., the formation of sub-groups around potential topics of interest). The efforts of the group will be summarized and extended through both social media tools (e.g., creating a Facebook group) and online collaboration tools (e.g., Google hangouts and documents) to further promote this work.

Keywords: Assessment and Evaluation, Research Methods

Introduction

There is value in the knowledge that large-scale quantitative research can bring to the field in terms of generalizability to educational practice when appropriately conducted (American Statistical Association, 2007; Hill & Shih, 2009). The American Statistical Association's report (2007) on *Use of Statistics in Mathematics Education Research* states:

> If research in mathematics education is to provide an effective influence on practice, it must become more cumulative in nature. New research needs to build on existing research to produce a more coherent body of work… Studies cannot be linked together well unless researchers are consistent in their use of interventions; observation and measurement tools; and techniques of data collection, data analysis, and reporting. (pp. 4-5).

As education has shifted more towards data driven policy and research initiatives in the last 25 years (Carney, Brendefur, Thiede, Hughes, & Sutton, 2016; Hill & Shih, 2009), the data for policy-related aspects are often expected to be quantitative in nature (e.g., end-of-course assessments and numerical value of reform-oriented teaching). Funding agencies encouraging research (i.e., National Science Foundation and Institute of Education Sciences) often request proposals to employ quantitative measures with sufficient validity evidence (see http://ies.ed.gov/ and http://www.nsf.gov/).

Measure (instrument) quality strongly influences the quality of data collected and relatedly, findings of a research study (Gall, Gall, & Borg, 2007). Measures with a clearly defined purpose and supporting validity evidence are foundational to conducting high quality large-scale quantitative work (Newcomer, 2009). There are few syntheses of quantitative tools for mathematics educators to employ and even fewer discussions of the validity evidence necessary to support the use of measures in a particular context. Syntheses of measures for use in mathematics education can be found in the literature but these are typically not intended as a comprehensive analysis. For example, Carney et al.

(2015) conducted a brief review of self-report instructional practice survey scales applicable to mathematics education. Boston, Bostic, Lesseig, & Sherman (2015) conducted a review of three widely known classroom observation protocols to assist mathematics educators in determining the appropriate tool for their particular research question and context. Both reviews provided a background on existing measures and their associated validity evidence in relation to a new measure under development. It is important that this type of work continues and is encouraged by the field. Thus, this working group aims to increase conversation around quantitative tools for use on a large-scale with this working group. We share three goals for this proposed working group: (a) To bring together scholars with an interest in examining the research on quantitative tools and measures for gathering meaningful data; (b) To spark conversations and collaboration across individuals and groups with an interest in large-scale tools and those conducting research on student- and teacher-related outcomes; (c) To generate products to disseminate widely across the field of mathematics education scholars.

Related Literature

Historical Context, Terms, and Rationale for Working Group

The National Mathematics Advisory Panel (2008) found that only a "small proportion of those [reviewed] studies have met methodological standards. Most ….failed to meet standards of quality because they do not permit strong inferences about causation or causal mechanisms" (pp. 2-7). Sound methodology is guided by appropriate measure or instrument choice. Good research takes on quantitative, qualitative, and at times both methodologies to become mixed-methodologies (Hill & Shih, 2009; Cresswell, 2012). Our focus for this proposal is quantitative-inclusive methodologies, specifically focusing on measures and tools associated with them, to support mathematics educators use of and need for quantitative tools that may be used in large-scale studies.

Near the core of any methodology is the measure or instrument used to collect data (Newcomer, 2009). The American Psychological Association, National Council on Measurement Education, and American Educational Research Association ([APA, NCME, AERA] 2014; 1999) provide clear guidelines regarding measurement validity and reliability. At a minimum, sufficient evidence for five variables must be shared related to validity: (1) content evidence, (2) evidence for relationship to other variables, (3) evidence from internal structure, (4) evidence from response processes, and (5) evidence from consequences of testing (AERA, APA, & NCME, 1999, 2014; Gall et al., 2007). Unfortunately, "evidence of instrument validity and reliability is woefully lacking" (Ziebarth, Fonger, & Kratky, 2014, p. 115) in the literature. Validation studies of quantitative measures are noticeably absent from mathematics education journals, which present the challenge of determining whether an instrument is appropriate for a given study much less whether it will generate valid and reliable data for analysis (Hill & Shih, 2009). Hill and Shih (2009) reported that eight of 47 studies published in the *Journal for Research in Mathematics Education* provided any evidence related to validity and the majority provided only psychometric evidence. Our goal for this literature review is to present a need for a working group at PME-NA 38 that will bring individuals from around North America to conduct more syntheses and further explore needed areas of tools that can be used to study both student- and teacher- related measures in large-scale research by mathematics educators.

Examining Student-focused Measures

Quantitative measures of student's mathematics content knowledge, problem solving, beliefs, and other factors have been employed across various contexts. We share an initial set of literature to frame the thinking for working group participants. Moreover, we welcome those that have interests not necessarily listed in this section.

Mathematics content knowledge. Students' mathematics content knowledge has been assessed in large-scale studies using end-of-course (high-stakes) measures during the last decade, Trends in Mathematics and Science Study (TIMSS), and National Assessment for Educational Progress (NAEP). Researchers who developed the PISA and NAEP report the validation process; however, the end-of-course measures are often shrouded by commercial entities (e.g., American Institutes of Research and Pearson). The latter group makes examining the quality of the measures for content knowledge problematic. Broadly speaking, it is challenging for researchers aiming to make decisions regarding use of items (or previously used measures) without syntheses describing measure qualities as well as similarities and differences across measures. Thus, a measure may claim to measure students' (at one grade- or developmental-level) content knowledge but how is content knowledge defined for each measure?

Beliefs. Students' beliefs of mathematics, mathematics teaching, and usefulness of mathematics for the real world have been examined in various ways. Students taking the NAEP assessment also responded to questions designed to measure their perceptions of mathematics (Dossey, Mullis, Lindquist, & Chambers, 1988). In the survey created by Dossey and colleagues, students responded to several Likert scale items regarding their attitudes and beliefs about mathematics. Similarly, Lazim, Osman, and Salihin (2004) created a mathematics belief questionnaire that had four belief dimensions: "[about] the nature of mathematics, about the role of teachers, about teaching and learning mathematics, and about their competency in mathematics" (p. 5). Again, the instrument consisted of Likert scale items self-reported by the students. The authors claim they achieved high reliability after the development of the survey but it was not reported. Hence, greater examination of these instruments is needed to benefit mathematics education research.

Examining Teacher-focused Measures

A couple articles have provided syntheses of the literature related to quantitative teacher-focused measures. We explore three sets here: observation protocols (of instruction), teachers' content knowledge, and teachers' beliefs. Again, we use this as a starting point and welcome interests within teacher-focused measures that are not necessarily represented within this frame.

Observation protocols. In 2015, Boston and colleagues compared the Reformed Teaching Observation Protocol, Mathematical Quality of Instruction, and Instructional Quality Assessment. A key finding of the study was that these three unique large-scale teacher-related observation protocols provided three unique lenses into teachers' instruction (Boston et al., 2015). The authors encouraged the field of mathematics education to execute further work to closely examine other observation tools and share syntheses of relevant literature.

Teachers' content knowledge. The components of the Mathematical Knowledge for Teaching (MKT) construct (Ball, Thames, & Phelps, 2008) can serve as a useful tool for exploring and examining quantitative measures of teachers' knowledge. Quantitative measures designed for teacher certification purposes (e.g., the Praxis series) tend to focus on the component of common content knowledge, ignoring other important components of the MKT framework often deemed important to mathematics educators. Other assessments are designed specifically with the intent of measuring teachers' knowledge of particular content areas (e.g., Knowledge of Algebra for Teaching measure, McCrory, Floden, Ferrini-Mundy, Reckase, & Senk, 2012) or grade bands (e.g., Diagnostic Teacher Assessment in Mathematics and Science, Saderholm, Ronau, Brown, & Collins, 2010). The most commonly used quantitative measures for teachers' content knowledge in mathematics come from the Learning Mathematics for Teaching (LMT) project (2005). The LMT assessments aims to measure teachers' content and pedagogical knowledge for teaching and are parsed into different content areas (e.g., K-6 geometry, 6-8 Number and Operations, and 4-8 proportional reasoning; LMT, 2005). A review of the NSF database for measures of teachers' math content knowledge for teaching (a) generating quantitative data, (b) with reliability and validity evidence, and (c) could be

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

used in large-scale studies resulted in 16 measures, 11 of which were part of the set from the LMT series. While tools such as the NSF database or the National Council for Teachers of Mathematics Handbook Chapter "*Assessing teachers' mathematical knowledge: What knowledge matters and what evidence counts*" (Hill, Sleep, Lewis, & Ball, 2007) provide a brief summary of some potential measures a mathematics education researcher could use to examine teachers' knowledge, it does not provide a comprehensive synthesis that might aid in determining which measure to use for a given research question, much less describe the validity evidence associated with the measure. Again, there is no available synthesis of available tools to measure teachers' knowledge of mathematics.

Beliefs. Philipp (2007) defines beliefs as "held understandings, premises, or propositions about the world that are thought to be true. …Beliefs, unlike knowledge, may be held with varying degrees of conviction and are not consensual" (p. 259). Beliefs and attitudes are different; they are related and at times have been discussed synonymously in the literature (Philipp, 2007). One of the oldest and still used measures is the Fennema-Sherman Mathematics Attitude scale (see Fennema & Sherman, 1976). This measure uses a Likert-scale to assess respondents' attitudes towards several domains. The study describes four Likert-scale self-report measures and accurately suggests the limited scope of self-report measures with regards to validity evidence. The Integrating Mathematics and Pedagogy (IMAP, 2004; see also Ambrose, Clement, Philipp, & Chauvot, 2004) is a web-based survey with open-ended items. This measure overcame the challenges of Likert scales, the lack of context for an overall score, and that respondents may give an opinion when one is not naturally held (Ambrose et al., 2004). A search of academic journals for measures of mathematics teachers' beliefs provided numerous hits but few are found in mathematics education journals, much less a synthesis of those available with validity and reliability evidence to be used in studies with large data samples. Put simply, no syntheses of measures in this are shared.

Session Organization and Plan for Engagement

The purpose of this working group is to gather individuals across North America interested in synthesizing the literature on quantitative tools in mathematics education that can be used in studies with large samples to examine student- and teacher-related outcomes. When considering the process for conducting a synthesis of quantitative tools and measures, it may be helpful to think of identifying and compiling tools and measures and their associated evidence separately from summarizing and evaluating the quality of the evidence. A synthesis includes both compilation and evaluation. The sequencing of the activities for the purposes of a working group will begin with compilation followed by evaluation in subsequent follow-up activities. It is important for the group to come to consensus on the parameters and frameworks for the synthesis. We recognize that the scope of the working group sessions proposed for PME-NA 2016 must be greatly narrowed. Therefore, we primarily focus on our first two of the three goals for the conference, which are shared here:

1. Bring together scholars with an interest in examining the research on quantitative tools and measures for gathering meaningful data.
2. Spark conversations and collaboration across individuals and groups with an interest in tools for large-scale studies and those conducting research on student- and teacher-related outcomes.

Prior Work

The idea for this working group proposal started at PME-NA 2015. We explored interest across the field from potential attendees before writing this proposal. We sought feedback from colleagues using the Association Mathematics Teacher Educators' (AMTE) bulletin board feature as well as the Service, Teaching, and Research (STaR) list-serv. An interest survey was shared broadly with both groups (i.e., AMTE and STaR members) to gather an idea of the level of interest in this idea.

Twenty-six people expressed interest, including from individuals who could not attend AMTE's 2016 annual meeting. We held a follow-up meeting at AMTE to meet with fourteen individuals who expressed interest and were attending AMTE's annual meeting. A majority of those at the AMTE follow-up meeting shared that they planned to attend the working group if accepted for PME-NA 2016. To that end, we plan on organizing the sessions in the following manner to address our two primary goals for the PME-NA 2016 working group session.

Session 1

The first session will begin with introductions, in conjunction with discerning the interests and areas of expertise of those in attendance. This will be followed by a group discussion about the stated purpose and aims of the group and the following guiding questions: (a) What do we mean by the term quantitative tools? (b) What do we mean by the term 'large-scale'? (c) How will we define these terms within the working group? We anticipate this discussion will elicit several additional topics that can be further explored during session 1 and potentially sessions 2 and/or 3. Ideally we will conclude by summarizing the discussion from session 1 including potential definitions for the terms identified as critical (e.g., at-scale, large-scale studies, and quantitative) that will be necessary for bounding the subsequent discussion of currently available tools. At the conclusion of session 1, we will present a tentative framework (see table 1 below) for organizing our subsequent discussions around quantitative tools that can be used with large samples to examine student- and teacher-related outcomes. We will request that session participants return to sessions 2 and 3 with ideas for tools that potentially fit within different areas of the framework.

Session 2

The second session will begin with a discussion on current perspectives in validity related to the argument-based approach (e.g., Kane 2001, 2016). Finbarr Sloane, an NSF-program officer with expertise in mathematics education, measurement, and evaluation has offered to provide a brief overview and facilitate discussion regarding the argument-based approach to validity. Following Dr. Sloane's presentation, the remaining part of session 2 will involve whole-group discussion around potential measures that address the identified areas using the organizational framework for student- and teacher-related outcomes. A brief overview of the organizational framework will be used to ignite the discussion of specific instruments. Table 1 presents the initial organizational framework that will be presented with the full expectation that the group may modify it during sessions 1 and 2. Group facilitators and attendees may begin by placing some relatively well-known tools within the framework to ensure we have a common understanding of the process.

Table 1: Initial Organizational framework for discussion of measures

	Knowledge	Beliefs	Practice
Teachers			
Students			

Session 3

The third session will primarily focus on placing tools within the organizational framework including any associated citations related to publically available or published validity evidence. Depending upon the size of the group, this work may be conducted in small-groups with a whole-group share-out towards the end of session 3. While a long-term aim is to develop syntheses of the literature related to available tools, we see the primary aim of the working group's meeting at PME-NA 2016 as bringing together individuals interested in this conversation and working together on

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

future collaborative efforts in this area. By the end of the third session, we intend to have an initial draft document of some available tools and their associated validity evidence but we do not anticipate this will be a comprehensive document. We will conclude session 3 with a discussion of anticipated follow-up activities to determine the level of interest and commitment from the group in continuing with this work.

Anticipated Follow-up Activities

As a result of our working group discussion and document development, we anticipate several potential follow-up activities. Participants will greatly influence the specific follow-up activities; however, we outline a potential progression of activities to guide discussion of potential 'next-steps'.

One outcome of the working group sessions is a draft document outlining some of the available tools and their associated validity evidence. An anticipated outcome will be to determine how this document should be further refined and later distributed. This will include explicit discussion of next steps to develop a comprehensive synthesis of the literature for wide dissemination to the mathematics education community.

We see several possible venues for further conversations and work related to developing syntheses of the literature on quantitative tools in mathematics education that can be used with studies of large-scale samples to examine student- and teacher-related outcomes. First, we anticipate using both social media tools (e.g., creating a Facebook group) and online collaboration tools (e.g., Google hangouts and documents) to promote these syntheses. Second, we anticipate using mathematics education conferences venues to further the conversations and synthesis work around the project. More specifically, we plan on proposing to continue the PME-NA working group at the 2017 conference. In addition, we anticipate submitting for a symposium at either the 2017 or 2018 conference of the Association of Mathematics Teacher Educators. Lastly, there is potential to apply for grant funding through a NSF CORE Research proposal to support a conference with a focused outcome of a monograph synthesizing the research literature within a particular area.

Modeling has received a great deal of attention from mathematics educators in recent years: for example, the Common Core State Standards for Mathematics have identified it as one of eight core mathematical practices, and the 2016 APME yearbook is dedicated to the theme of modeling. The Models and Modeling Working Group has provided a venue for discussing and collaborating to execute research fundamental to this area since the first PME-NA conference in 1978. In convening this Working Group at PME-NA 38 we propose to lay the groundwork for a shared writing project, producing an edited volume on the research questions and opportunities around learning through modeling over extended (course-length) time periods.

Keywords: Modeling, Problem Solving, Design Experiments

The Models and Modeling Working Group has been a significant presence at PME-NA since the Conference was inaugurated in 1978. It has supported substantive research efforts, and it has acted as a vehicle for convening a diverse set of researchers to work collaboratively on larger projects and research problems. An important historical purpose of the Working Group has been to discuss and extend the ways in which a focus on models and modeling can be used both to support learning in mathematics, science and engineering, and to study such learning processes in action. Early in its history, the Group focused heavily on particular activities, elaborating design principles for these activities as learning environments and documenting the idea development they promoted. Gradually, however, researchers associated with the Group have expanded their perspective to consider larger curricular sequences, organized around such activities. Moreover, researchers affiliated with the group have connected in a variety of ways with other lines of inquiry in mathematics education. These broader perspectives open both exciting opportunities and significant challenges for research.

We propose convening the Group at PME-NA 38 as a springboard for articulating and clarifying a shared research agenda to study learning and idea development through modeling at these larger timescales. As described in detail below, the three sessions at the conference will frame a shared writing project on the subject, exploring a range of research themes that have been identified as this proposal has emerged and been framed.

The Models and Modeling Perspective (M&MP)

For nearly forty years, M&MP researchers and educators have engaged in design research directed at understanding the development of mathematical ideas. A fundamental principle underlying this work has been that learners' ideas develop through, and in relation to conceptual entities called *models*, which we define as follows:

> conceptual systems (consisting of elements, relations, operations, and rules governing interactions) that are expressed using external notation systems, and that are used to construct, describe, or explain the behaviors of other system(s)—perhaps so that the other system can be manipulated or predicted intelligently (Lesh & Doerr, 2003, p. 10)

As conceptual systems expressed through representational media, models can provide illumination into how students, teachers, and researchers learn, develop, and apply relevant mathematical concepts (Lesh, Doerr, Carmona, & Hjalmarson, 2003). Further, under appropriate conditions, these models can be evoked and expressed: in such settings, they can become objects of reflection by learners and collaborative groups, and they can form the basis for rich communication. In particular, when individuals and groups encounter problem situations with specifications that demand a model-rich response, their models are observed to grow through relatively rapid cycles of development toward solutions that satisfy these specifications. A focus on learners' models can therefore provide an impetus for design and a lens for research focused on assessment and/or on the fine-grained texture of learning processes.

Originally, the M&MP tradition was focused squarely on local conceptual development: that is, on investigating the micro-evolution of ideas and knowledge in teachers and students. Thus, the resources and tools produced were first and foremost designed to *study* idea development (as opposed to serving teaching or curricular goals). However, by producing materials that fostered the rapid development of ideas, M&MP designers also laid the foundation for extremely effective instructional sequences addressing big ideas in important mathematical domains. Over time, however, the M&MP community has refined its techniques for creating situations that provoke students to express and improve their models. The results of this work include a body of *Model-Eliciting Activities* (MEAs), in which students are presented with authentic, real-world situations where they repeatedly express, test, and refine or revise their current ways of thinking as they endeavor to generate a structurally significant product—that is, a model, comprising conceptual structures for solving the given problem. These activities differ markedly from some "problem-solving" settings, which emphasize applications. In contrast, MEAs give students the opportunity to create, apply and adapt scientific and mathematical models in interpreting, explaining, and predicting the behavior of real-world systems (Zawojewski, 2013). Extensive research with MEAs has produced accounts of learning in these environments (Lesh, Hoover, Hole, Kelly, & Post 2000; Lesh & Doerr, 2003), design principles to guide MEA development (Hjalmarson & Lesh, 2007; Doerr & English, 2006; Lesh, et. al., 2000; Lesh, Hoover, & Kelly, 1992) and accounts and reflections on the design process of MEAs (Zawojewski, Hjalmarson, Bowman, & Lesh, 2008).

Example MEA: the Volleyball Problem

Students are usually introduced to the Volleyball Problem by reading a "math rich newspaper article" that describes a summer sports camp specializing in girls' volleyball. The newspaper article explains how issues arose in the past because it was difficult for the camp councilors to form fair teams that could remain together throughout two weeks of camp. The students' challenge in the volleyball problem is to develop a procedure that the camp councilors can use to form teams that are as equivalent as possible—based on information that is gathered during try-out activities that occur during the first day of the camp. After breaking into groups, students are presented with the problem statement below (Figure 1).

Along with the introduction and statement of the problem, student groups are given tryout data for a sample of 18 players. This data includes some information that is easily represented in tabular form (player's height, measured vertical leap, 40-meter dash time, etc.), as well as some that is not (players' performance in a spiking trial, and brief summative comments about their strengths and weaknesses from the coach of their home team). These data elements are chosen so as to present fundamental challenges to students, involving the nature of data (categorical versus numerical); scaling (e.g., the vertical leap where "large is good" versus the 40-meter dash where "small is good"); units (vertical leap is given in raw inches; height in feet-and-inches); and so on.

> **The Volleyball Problem.** Organizers of the volleyball camp need a way to divide the campers into fair teams. They have decided to get information from the girls' coaches – and to use information from try-out activities that will be given on the first day of the camp. The table below shows a sample of the kind of information that will be gathered from the try-out activities. Your task is to write a letter to the organizers where you: (1) describe a procedure for using information like the kind that is given below to divide more that 200 players into teams that will be fair, and (2) show how your procedures works by using it to divide these 18 girls into three fair teams.

Figure 1. The Volleyball Problem.

Student groups iteratively develop solutions to this problem in the time allotted—usually 50-60 minutes for this MEA. Afterwards, the teacher may choose to organize a structured "poster session" event. In one version of this activity structure, one member of each 3-person group hosts a poster presentation showing the results of their group. The other two students use a Quality Assurance Guide to assess the quality of the results produced by other groups in the class. These instruments are submitted to the teacher and contribute to assessment in various ways, providing evidence for the achievements of both individuals and groups.

A key outcome of the discussion unpacking this and other MEAs is the notion that when a construct such as "volleyball-playing ability" is operationally defined, a variety of reasonable definitions may be possible. Though none of these are objectively "correct," all of them involve different assumptions and may lead to markedly different conclusions or judgments. In particular, in real life situations where statistics procedures are useful, results often vary significantly depending on how the various types of data are quantified and combined. On the other hand, it is also quite possible for solutions to be "incorrect" – either through miscalculation or other errors, or by not adequately addressing the Client's problem or needs.

MEAs like the Volleyball problem present learners with situations in which familiar procedures and constructs are both applicable and insufficient. That is, on the one hand such problems are accessible to learners from a wide range of levels of ability, experiences, or knowledge (from upper elementary school through graduate school). On the other hand, learners encountering these problems find that they have no ready-made solution they can apply to address the client's needs. As a result, learners engage in solution-construction processes that put them off balance in comparison to typical school-mathematics tasks. Indeed, this uncertainty is part of the design of the MEA, illuminating fundamental conceptual issues associated with the core mathematical structures involved.

MEA Design Principles

Historically, as individual modeling activities emerged, an intense period of design research ensued to establish MEAs as a compelling genre of learning tasks that would (a) stimulate mathematical thinking representative of that which occurs in contexts outside of artificial school settings (Lesh, Caylor, & Gupta, 2007; Lesh & Caylor, 2007); (b) enable the growth of productive solutions through rapid modeling cycles; and (c) leave behind researchable traces of learners' ways of thinking during the process. This line of work produced the notion of Thought-Revealing Artifacts and Model-Eliciting Activities (MEAs) (Kelly & Lesh, 2000; English et al., 2008; Kelly, Lesh & Baec, 2008). The success of MEAs as research tools was both enabled by and illustrated through the articulation of a set of six design principles for such activities (Lesh & Harel, 2003; Lesh et al., 2000; Hjalmarson & Lesh, 2007); these principles indicate the key structural and dynamical elements in MEAs as contexts for problem solving. Table 1, below, also indicates "touchstone" tests for whether each of these six principles has been realized in a given implementation setting.

Table 5: Six Design Principles for MEAs

Principle	Touchstone Test for its Presence
Reality Principle	Students are able to make sense of the task and perceive it as meaningful, based on their own real-life experiences.
Model Construction Principle	To solve the problem, students must articulate an explicit and definite conceptual system (model).
Self-Evaluation Principle	Students are able to judge the adequacy of their in-process solution on their own, without recourse to the teacher or other "authority figure".
Model Generalizability Principle	Students' solutions are applicable to a whole range of problems, similar to the particular situation faced by the "client" in the MEA.
Model-Documentation Principle	Students generate external representations of their thinking during the problem-solving process.
Simplest Prototype Principle	The problem serves as a memorable representative of a kind of mathematical structure, which can be invoked by groups and by individuals in future problem solving.

Multi-Tiered Design Research

In parallel with learner-focused research using MEAs, researchers also have observed that teachers' efforts to understand their students' thinking involve yet another process of modeling: In this case, teachers engage in building models of student understanding. Although these teacher-level models are of a different category from student-level models, students' work while engaged in MEAs does provide a particularly rich context for teachers' modeling processes. Following this line of inquiry, the M&MP community has also produced tools and frameworks that can be useful to teachers in making full use of MEAs in classroom settings, while also providing *researchers* with insights into *teachers'* thinking.

Finally, at a third level of inquiry, researchers' own understandings of the actions and interactions in curricular activity systems (Roschelle, Knudsen, & Hegedus, 2010) involving students, teachers, and other participants in the educational process can also be studied through the lens of model development. Multi-tier design experiments in the M&MP tradition have done precisely this, involving researcher teams in self-reflection and iterative development as well (Lesh, 2002). Therefore, multi-tier design research involves three levels of investigators— students, teachers, and researchers—all of whom are engaged in developing models that can be used to describe, explain, and evaluate their own situations, including real-life contexts, students' modeling activities, and teachers' and students' modeling behaviors, respectively.

From Single Activities to Curricular Materials Supporting Modeling at Larger Timescales

Over the past 10 years, M&MP researchers have continued this direction of work in their own teaching and in partnerships with K-12 classroom teachers. Within the domain of statistical thinking in particular, this effort has produced resources and tools sufficient to support *entire courses* in several versions and including accompanying materials related to learning and assessment aimed at both student and teacher levels. Because the courses supported by these materials were designed explicitly to be used as research sites for investigating the interacting development of students' and teachers' ways of thinking, the materials were modularized so that important components could be easily modified or rearranged for a variety of purposes in different implementations. In particular, by selecting from and adapting *the same basic bank of materials*, parallel versions of the course have been developed for: (a) middle- or high-school students, (b) college-level elementary or secondary education students, and (c) workshops for in-service teachers. When these courses have been taught

by M&MP researchers familiar with the underlying theory, they have produced "six sigma" gains (Lesh, Carmona, & Moore, 2009).

One Approach to Longer-Timescale Modeling Research: Model Development Sequences

In the process of developing such curricular materials to focus on modeling, research in the M&MP has investigated ways in which MEAs can be integrated within larger instructional sequences or Model Development Sequences or *MDSs* (Lesh, Cramer, Doerr, Post, & Zawojewski, 2003; Brady, Lesh, & Sevis, 2015; Brady, Eames, & Lesh, 2015). MDSs offer classroom groups opportunities to unpack, analyze, and extend the models they have produced in MEAs, as well as to connect their ideas with formal constructs and conventional terminology. This unpacking work helps to ensure the lasting retention of concepts at a level of generality required for flexible use and application in novel situations. It also sets the stage for the critical connection between conceptual development (the centerpiece and focus of MEAs), and procedural knowledge that is also required for students to achieve well-rounded competence in any subject area.

Within an MDS, **reflection tools** support students in stepping back from their modeling processes and reflecting on this work as critical observers of both individual and group modeling behavior. We consider these tasks to be core to the learning processes in MEAs: when students interpret situations mathematically, M&MP research expects that they don't simply engage interpretation systems that are purely logical or mathematical in nature. Their interpretations also involve attitudes, values, beliefs, dispositions, and metacognitive processes. Moreover, the M&MP does not treat group roles and functioning as if they were fixed characteristics that determined students' behaviors. Instead, students are expected to develop a suite of problem-solving personae or profiles they themselves can learn to apply as the situation demands. Reflection tool activities encourage groups of learners to turn their attention to describing individual- and group-level processes, functions, roles, conceptions, and beliefs. Tools to support these activities include Ways of Thinking Sheets, various surveys and questionnaires, Concept Maps, Observation Sheets, Self-Reflection Guides, and Quality Assurance Guides for the products created in MEAs.

In **product classification** and **toolkit inventory** activities students continue the work of abstraction, characterizing and classifying the thinking they have done and identifying links among their solutions to different MEAs and between these solutions and the "big ideas" of the course. **Model exploration** or **Model extension activities** (MXAs) provide model-rich environments for introducing core concepts and skills from the broader curriculum that students need in order to formulate sophisticated models and present them to a mathematical community. In addition, these activities provide students with a vital opportunity to unpack the work they have done in the MEAs. These may use a combination of pointed YouTube videos and interactive simulations in dynamic mathematics software. Finally, **model adaptation activities** (MAAs) allow students to transfer ideas and techniques developed in MEAs to situations calling for similar performances. These MAA activities also provide smaller-timescale modeling scenarios that exercise concepts they have explored in other components of the MDS. They may be pursued individually or in small groups, depending on the nature of the task and the teacher's instructional or assessment goals. All of these elements of an MDS are designed to be highly modular, to accommodate (as well as to reveal) the needs and intentions of the teacher as they appropriate and adapt the materials for their own use. An example of how this variety of activity types might be laid out in a given unit is shown in Figure 2, below.

Figure 2. Example Structure of a Model Development Sequence (MDS). MEAs and other activities represent modular, re-orderable blocks of instructional time.

A Course-Sized Resource Repository for Research in Data Modeling and Quantification

Early successes in teaching entire courses with MDS units (e.g., Lesh, Carmona, & Moore, 2009) also demonstrated that these MDSs themselves were highly reconfigurable and re-orderable. The "big ideas" in statistics, data modeling, and quantification could be foregrounded in different orders, leading to a variety of possible longer-term modeling experiences for the students and teacher. In light of these findings, a course-sized repository becomes an important enabler for design research on modeling over more extended timeframes. The shared writing project of the Working Group will thus also provide research rationale to support the ongoing construction of this repository.

Thematic Clusters for Ongoing M&MP Research at Larger Timescales

In clarifying a shared research agenda, participants in the Models and Modeling Working Group have identified an initial set of ten thematic clusters that they feel would need to be addressed in an edited volume describing this work. For each cluster, we imagine that two to four short chapters would be dedicated to articulating perspectives on the associated research issues. These tentative clusters are as follows:

1. **What is the Models and Modeling Perspective?** Chapters in this cluster will provide a nuanced description of the main theoretical and philosophical thrusts of M&MP research, along with examples of extended projects in the tradition, with an emphasis on current work and findings. These chapters will also identify the key questions that have motivated and continue to motivate M&MP research.

2. **How do we situate the M&MP tradition within the broader field of education research?** This cluster will describe potential relationships and relevance of M&MP work to important non-M&MP research traditions in Mathematics Education (cf., Kaiser & Sriraman, 2006). Thus, it not only will seek to distinguish M&MP research from other work via contrast and counterpoint; it will also identify commonalities and affinities, along with examples of fruitful connections made across traditions in prior and ongoing work.

3. **Teaching Practice, Teacher Preparation, and Professional Development.** These chapters will describe work to understand the forms of expertise and the practices of teachers that make them successful in the kinds of learning environments demanded by the M&MP approach. An important outcome of research in this area is the elaboration and description of

approaches to professional preparation and professional development that can support sustained communities of teachers in their practice.

4. **Assessment & Measurement.** This cluster will focus on the use of MEAs and other modeling activities as environments for producing evidence to tell a rich and compelling story of what learners know and can do (Katims & Lesh, 1994; Eames, Brady, & Lesh, 2016). In particular, students' work in modeling activities can be used to augment the assessment picture of learners and groups of learners, with evidence of growth and change in conceptual understandings. This cluster will also work to identify the connection between (measures of) conceptual understanding and (measures of) procedural competency.

5. **Intuitions and Other Resources.** Chapters in this cluster may explore how modeling activities provide a medium in which intuitive understandings can build toward more formalized learning (Ferri & Lesh, 2013; Lesh, Haines, Galbraith, & Hurford, 2010). They may also work to demonstrate the value of activity design and assessment design that is sensitive to the ways in which learners recruit intuitions and other tacit/personal learning resources in their modeling work.

6. **Affect, Feelings and Beliefs.** Modeling work invokes more than simply logical/analytical thought. Often, important insights or aspects of students' solutions are rooted in empathic moves, feelings, or beliefs that they hold about the problem situation. Chapters in this cluster would investigate how to document and support the affective dimension of this form of learning.

7. **Learning Beyond School and Learning that does not look or feel like "Doing School."** This cluster will explore connections between the learning in MEAs and other modeling environments to mathematical thinking and acting as it appears beyond school. These chapters will engage the challenge of supporting students in *real-world* problem solving as a vibrant part of their *in-school* experience of mathematics. This is related to the challenge of providing school encounters with mathematics that demand the kind of creative interpretation and "seeing-as" work that is required by creative mathematical work in the real world.

8. **Methodology.** This cluster will deal with various methodological issues and questions associated with new directions and work in the M&MP tradition. Authors of these chapters will outline the need for methodological expansion and/or specialization of frameworks from the broader field of design research to approach questions central to the M&MP tradition, especially as we attempt to characterize idea development at longer timescales.

9. **Representations, Representational Competencies, and Thinking with Representations.** This cluster will investigate the role of representations and the construction (and/or design and invention) of representations in the M&MP tradition. One facet of this question has to do with the role and value of *computational* models and computational modeling activity, including the role of simulation, computational thinking, and even 'programming' of various kinds in the modeling toolkit that we want learners to have.

10. **The Situated-ness of Models and Modeling Research.** In this cluster, chapters investigate the variety of ways in which M&MP research and learning designs must be sensitive to the learning context. This might include discipline specificity (e.g., similarities and differences among math, science, engineering contexts); age or grade-level specificity (e.g., similarities and differences among elementary, middle-school, high-school, college, and graduate level models and modeling); or cultural specificity (e.g., Borba, 1990; and also the impact of institutional or cultural factors on the kinds of practices that are observed or encouraged).

Working Group Session Outline: Advancing the Agenda while Building Capacity

The concrete research product that this Working Group aims to present is a shared writing project consisting of a variety of empirical and theoretical pieces organized under the thematic clusters listed

above (or an iterative refinement of this set of clusters). In addition, however, Working Group meetings generally attract newcomers to the Models and Modeling Perspective, and it is essential to provide the means for these newcomers to engage productively in the sessions. In this way, the working group not only succeeds in setting and advancing a shared research agenda; it also serves to build capacity among junior researchers, paving the way for future work and collaborations.

The working group will meet in three sessions over the course of the conference. As preparatory work continues, the precise contents of each of these sessions will be more clearly defined, but the broad outlines are as follows:

Session One. The capacity-building objective for this session is to introduce the M&MP tradition and its approach to research. Newcomers to the Group will thus act as an authentic audience for a first iteration of material that would form part of Cluster #1, above. The Working Group facilitators will present on this topic, also in the process communicating and 'field testing' the logic of the cluster-based organization of the proposed edited volume.

The agenda-advancing objective of this session is to identify areas for collaborative breakout-group work. Because not all of the important voices to the M&MP may be present at the conference, it is not the objective of the Working Group to "cover" all of the thematic clusters in face-to-face discussions during PME-NA 2016. Instead, the goal will be to identify topics and themes where the participants exhibit diverse or contrasting perspectives. These participants will be grouped to allow them to engage in intense but still open-forum discussions in Session 2. Newcomers will also have the opportunity during this period to identify which breakout group they wish to affiliate with on Day 2. Finally, to support newcomers in preparing for Day 2, facilitators will provide two examples of MEAs, along with transcripts of students' small-group work on these problems, as well as related MDS activities that illustrate how follow-on work after an MEA can serve to "unpack" the thinking that emerged in the course of the MEA.

Session two. The capacity-building objective for Day 2 involves newcomers and junior researchers in frank and open discussions of key issues in the thematic clusters that they identify as personally interesting. The agenda-advancing work of this session involves pairs or small groups of experienced researchers in a thematic cluster in presenting their own research and in reacting to the research of others engaged with the themes of that cluster.

Based on the discussion that ensues, the breakout groups will formulate recommendations for the structure and contents of the cluster in the edited volume, identifying additional questions or topics that should be included, and generating a first-draft plan for the cluster. Each breakout group will also document their discussion, to enable them to report back to the whole Working Group at the end of Day 3. Based on past experience, it is expected that the discussions and debates of Day 2 will continue beyond the time limit of the session.

Session three. The first component of this session will give the breakout groups time to re-assemble and revise their accounts of their thematic clusters, based on discussions that have occurred between the two sessions. Then, the whole Working Group will come back together for the breakout groups to present. Discussion will allow commentary and questions across breakout groups, as well as reflections on next steps for refining ideas both within and across thematic clusters.

A subset of the facilitators for the Working Group will be the Editors of the proposed volume, and the third session will close with an outline of work to develop the thematic clusters into publishable chapter sequences. In the wake of the Conference, a wider set of researchers from the M&MP tradition will be involved in extending the work done in the in-person setting of PME-NA to all of the thematic clusters. It is anticipated that a full first draft of the volume can be produced within the year following the conference, providing a rich basis for discussion at a future iteration of the Working Group, at PME-NA 39.

This Working Group has a dual focus on issues of mathematics teaching and learning and issues of equity and diversity. Following on the topics discussed at the Working Group in 2009–2013 and 2015, this year's focus is on three lingering "borders" in mathematics education research: the achievement gap, the "Where's the math?" question, and the hegemony of psychological approaches to investigating mathematics learning. Each session will consist of a "fish bowl" among scholar-experts followed by breakout discussions among participants and ending with a large-group discussion of the focal issue.

Keywords: Equity and Diversity, Gender

Brief History

This Working Group builds on and extends the work of the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME scholars graduated from one of three major universities (University of Wisconsin-Madison, University of California-Berkeley, and UCLA) that comprised the DiME Center. The Center was dedicated to creating a community of scholars poised to address critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).

The DiME Group (as well as subsets of that group) has engaged in important scholarly activities, including the publication of a chapter in the *Handbook of Research on Mathematics Teaching and Learning* which examined issues of culture, race, and power in mathematics education (DiME Group, 2007), a one-day AERA Professional Development session examining equity and diversity issues in mathematics education (2008), a book on research of professional development that attends to both equity and mathematics issues with chapters by many DiME members and other scholars (Foote, 2010), and a book on teaching mathematics for social justice (Wager & Stinson, 2012) that also included contributions from several DiME members. In addition, several DiME members have published manuscripts in a myriad of leading mathematics education journals on equity in mathematics education. This working group provides a space for continued collaboration among DiME members and other colleagues.

The authors desire to continue DiME's tradition of discussing current work, hearing from leading scholars in the emerging field of equity and diversity in mathematics education, and opening up this space beyond DiME members in this Working Group. Specifically, the Center historically held DiME conferences each summer. These conferences provided a place for fellows and faculty to discuss their current work as well as to hear from leaders in the emerging field of equity and diversity issues in mathematics education. Beginning in the summer of 2008, the DiME Conference opened to non-DiME graduate students and new faculty with similar research interests from other CLTs such as the Center for the Mathematics Education of Latinos/as (CEMELA), as well as some not affiliated with an NSF CLT. This was initially an attempt to bring together a larger group of emerging scholars whose research focuses on issues of equity and diversity in mathematics education. In addition,

DiME graduates, as they have moved to other universities, have begun to work with scholars and graduate students including those with connections to other NSF CLTs such as MetroMath and the Urban Case Studies Project in MAC-MTL whose projects also incorporate issues of equity and diversity in mathematics education. Funding for the DiME project has ceased and the PMENA Working Group has become a major way in which to keep the conversation going.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Theoretically we have been building on the work of such scholars as Marta Civil (Civil, 2007; Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Eric Gutstein (Gutstein, 2003, 2006; Gutstein & Peterson, 2013), Jacqueline Leonard (Leonard, 2007; Leonard & Martin, 2013), Danny Martin (Martin, 2000, 2009, 2013), Judit Moschkovitch (Moschkovich, 2002), Rochelle Gutiérrez (2002, 2003, 2008, 2012, 2013) and Na'ilah Nasir (Nasir, 2002, 2011, 2013; Nasir, Hand & Taylor, 2008; Nasir & Shah, 2011). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), and Megan Franke (Kazemi & Franke, 2004), as well as many others outside of the field of mathematics education.

Previous iterations of this Working Group at PMENA 2009–2013, and 2015 have provided opportunities for participants to continue working together as well as to expand the group to include other interested scholars with similar research interests. Experience has shown that collaboration is a critical component to this work. These efforts to expand participation and collaboration were well received; more than 40 scholars from a wide variety of universities and other educational organizations took part in the Working Group each of the past five years.

Focal Issues

Under the umbrella of attending to equity and diversity issues in mathematics education, researchers are currently focusing on such issues as teaching and classroom interactions, professional development, prospective teacher education (primarily in mathematics methods classes), factors impacting student learning (including the learning of particular sub-groups of students such as African American students or English learners), and parent perspectives. Much of the work attempts to contextualize the teaching and learning of mathematics within the local contexts in which it happens, as well as to examine the structures within which this teaching and learning occurs (e.g. large urban, suburban, or rural districts; under-resourced or well-resourced schools; and high-stakes testing environments). How the greater contexts and policies at the national, state, and district level impact the teaching and learning of mathematics at specific local sites is an important issue, as is how issues of culture, race, and power intersect with issues of student achievement and learning in mathematics. There continues to be too great a divide between research on mathematics teaching and learning and concerns for equity.

The Working Group has begun and will continue to focus on analyzing what counts as mathematics learning, in whose eyes (and for whose benefit), and how these culturally bound distinctions afford and constrain opportunities for traditionally marginalized students to have access to mathematical trajectories in school and beyond. Further, asking questions about systematic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This research begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Some of the research questions the Working Group will continue to consider are:

- What are the characteristics, dispositions, etc. of successful mathematics teachers for *all* students across a variety of local contexts and schools? How do they convey a sense of purpose for learning mathematical content through their instruction?
- How do beginning mathematics teachers perceive and negotiate the multiple challenges of the school context? How do they talk about the challenges and supports for their work in achieving equitable mathematics pedagogy?
- What impediments do teachers face in teaching mathematics for understanding?
- How can mathematics teachers learn to teach mathematics with a culturally relevant approach?
- What does teaching mathematics for social justice look like in a variety of local contexts?
- What are the complexities inherent in teacher learning about equity pedagogy when students come from a variety of cultural and/or linguistic backgrounds all of which may differ from the teacher's background?
- What are dominant discourses of mathematics teachers?
- What ways do we have (or can we develop) of measuring equitable mathematics instruction?
- How do students' out-of-school experiences influence their learning of school mathematics?
- What is the role of perceived/historical opportunity on student participation in mathematics?

Specific to this year's Working Group focus, we will interrogate three existing borders in mathematics education research:

- The achievement gap: Questioning its framing, interpretations, and responses
- "Where's the math?": Questioning what constitutes mathematics education research
- Defining mathematics learning: Questioning the hegemony of psychological approaches

Plan for Working Group

The overarching goal of the group continues to be to facilitate collaboration within the growing community of scholars and practitioners concerned with understanding and addressing the challenges of attending to issues of equity and diversity in mathematics education. The PMENA Working Group provides an important forum for these scholars to come together with other interested researchers who identify their work as attending to equity and diversity issues within mathematics education in order to develop plans for future research. The main goal for this year is utilize the conference theme, "Sin Fronteras," as a means to interrogate lingering tensions in key areas of mathematics education research. We will do this by bringing together scholars to share their perspectives on the field, and then provide space and time for smaller groups to discuss, reflect on, and amplify ideas from the presentation.

Our plans for PMENA 2016 will proceed as follows. Each session will follow a similar format, beginning with a facilitated conversation around the session's central theme. The format for all 3 sessions will include:

- A fishbowl conversation with 4 experts on the focal topic
- 4 break-out groups with audience members and 1 expert to continue the conversation
- Panel discussion on the 4 main questions that emerged during the break-out conversations

Session 1 Focal Topic: "The Mathematics-Achievement Gap"

Session 2 Focal Topic: "Where's the Math?" New Perspective and Possibilities from Emerging Scholars

Session 3 Focal Topic: "Defining Mathematics Learning: Who Decides?"

Previous Work of the Group

The Working Group met for six productive sessions at PMENA 2009–2013, and 2015. In 2009, participants identified areas of interest within the broad area of equity and diversity issues in mathematics education. Much fruitful discussion was had as areas were identified and examined. Over the past five years subgroups met to consider potential collaborative efforts and provide support. Within these sub-groups, rich conversations ensued regarding theoretical and practical considerations of the topics. In addition, graduate students had the opportunity to share research plans and get feedback. The following were topics covered in the subgroups:

- Teacher Education that Frames Mathematics Education as a Social and Political Activity
- Culturally Relevant and Responsive Mathematics Education
- Creating Observation Protocols around Instructional Practices
- Language and Discourse Group: Issues around Supporting Mathematical Discourse in Linguistically Diverse Classrooms
- A Critical Examination of Student Experiences

As part of the work of these subgroups, scholars have been able to develop networks of colleagues with whom they have been able to collaborate on research, manuscripts and conference presentations.

As a result of the growing understanding of the interests of participants (with regard both to the time spent in the working group and to intersections with their research), we began to include focus topics for whole group discussion and consideration and continued to provide space for people to share their own questions, concerns, and struggles. With respect to the latter, participants have continually expressed their need for a space to talk about these issues with others facing similar dilemmas, often because they do not have colleagues at their institutions doing such work or, worse yet, because they are oppressed or marginalized for the work they are doing. These concerns, in part, informed the focus topics for whole group discussion and consideration. For example, in 2009 research protocols (e.g., protocols for classroom observation, video analysis and interviewing) were shared to foster discussions of possible cross-site collaboration. In 2012, the Working Group explicitly took up marginalization in the field of mathematics education with a discussion about the negotiation of equity language often necessary for getting published; this was done in the context of the 'Where's the mathematics in mathematics education' debate (see Heid, 2010; Martin, Gholson, & Leonard, 2010). Dr. Amy Parks was invited to join Working Group organizers to share reflections on their experiences. In 2013 the Working Group hosted its first panel in which scholars (Dr. Beatriz D'Ambrosio, Dr. Corey Drake, Dr. Danny Martin) shared their perspectives on the state of and new directions for mathematics education research with an equity focus. The success of prior panel discussions have encouraged us to use that format as a launching point for deepening conversations on lingering tensions in the field. We see this working group as questioning critical borders that persist within mathematics education.

Anticipated Follow-up Activities

As has happened following previous years of this working group, it is anticipated that scholars who make connections at the working group sessions will maintain contact and at least in some cases, this will lead to collaboration on research questions, conference presentations, manuscripts or research projects.

Pedagogies of teacher education centered on opportunities for rehearsal and enactment provide a promising way to support pre-service and practicing teachers in developing skill with a core set of instructional practices. These practices then support each student's engagement with a set of authentic disciplinary practices—what has been referred to as ambitious and equitable goals for instruction. The focus on these pedagogies of teacher education has grown, and efforts to build on and expand work at the elementary level have raised questions and challenges of using and researching these pedagogies with secondary mathematics teachers. A consortium of teacher educators and researchers who have worked and collaborated in this area leads this working group. This group will provide opportunities to engage the group leaders and other participants in discussions to frame the state of these efforts, identify challenges, develop common language, and establish plans to move forward in research on rehearsal and enactment with secondary mathematics teachers.

Keywords: Instructional Activities and Practices, Teacher Education-Preservice, Teacher Education-Inservice/Professional Development

Brief History of the Group

This is a new working group intended to advance the use and study of "pedagogies of enactment" (Grossman, Hammerness, & McDonald, 2009). Specifically, we study the use of rehearsals of instructional activities (Kazemi, Ghousseini, Cunard, & Turrou, 2016; Lampert et al., 2013) toward the development of core or high-leverage practices (Ball & Forzani, 2009; McDonald, Kazemi, & Kavanagh, 2013). We focus on this in the context of secondary mathematics teacher education and professional development (PD). For more than five years, a group of secondary mathematics teacher educators and researchers (represented, in part, by the leaders of this working group) have collaborated to consider the work of secondary teacher preparation in relation to recommendations from Grossman and her colleagues for teacher education and the work of Lampert, Kazemi, Franke and their colleagues in the area of elementary mathematics education. In addition to numerous calls

and in-person meetings at conferences, members of the group have come together to lead other conference sessions and, in the past year, subsets of the group have engaged in more focused data collection and inquiry. As the group has grown and evolved and the work has continued, the challenges and questions tied to doing this work in secondary mathematics teacher education and to collaborating with other teacher educators and across institutions have also grown and evolved. How do secondary mathematics teachers (and their students) and the setting of secondary mathematics classrooms make this work different or unique? What, exactly, gets rehearsed by teachers, and toward what end? How would this work, primarily discussed in the context of initial teacher preparation, extend to work in PD settings for practicing teachers? Given the increasing interest in the field (as is apparent in conference programs and journal articles) in the use of pedagogies of enactment with a focus on developing core practices, we see now as a crucial time to establish this work, answer foundational questions, and make plans for future collaborations and products.

Relevance to PME-NA

At PME-NA there has been a recent history of other working and discussion groups (and, likely, countless individual papers and posters) looking at the approaches to and content of preparing prospective mathematics teachers and supporting practicing teachers through PD. For example, Kastberg, Sanchez, Edenfield, Tyminski, and Stump (2012) led a group looking at the content and activities of mathematics methods courses. This group continued the next year (Kastberg, Sanchez, Tyminski, Lischka, & Lim, 2013) and also resulted in an NSF-funded conference on inquiry and practice of mathematics methods courses held in 2015. Winsor and colleagues (2013) focused specifically on research on the preparation and development of prospective secondary mathematics teachers, as we do in this work. We extend upon this developing history with a specific focus on a set of activities used in settings of teacher development toward the development of "skilled practice" (Grossman & McDonald, 2008) among prospective and practicing secondary mathematics teachers.

The focus of this working group also provides a contribution in the context of the theme of this year's conference: "Sin Fronteras: Questioning Borders with(in) Mathematics Education." We see the work we are engaged in with secondary mathematics teachers (and each other) as highlighting, questioning, and transforming various borders in mathematics education. Primarily, we see teacher development—whether the preparation of teacher candidates or the continued support of practicing mathematics teachers—as inherently cross-setting work. This may refer to multiple physical settings but, at the very least, the work of teacher development involves the intersection of settings with different cultures and histories that inform the practices in each. Researchers have put forth ideas for teacher development—from "practice based" (Ball & Cohen, 1999) approaches, such as the use of student work, classroom video, and written cases; to "practice focused" approaches as have recently been conceptualized by Ball & Forzani (2009) and McDonald and colleagues (2013), among others—that reframe (though not completely remove) that border. The work of our group continues on this trajectory, not only with approaches designed to better prepare teachers across settings, but with the consideration of how theory and research methods can help acknowledge, negotiate, and appreciate the cross-setting nature of teacher development. This and numerous other borders we discuss below serve as ways for us to focus this working group, as many of the questions that have emerged in this work are a product of coming up against areas of tension, divide, and differences.

Focal Issues

In order to increase student mathematics learning, secondary students need opportunities to productively engage with mathematical content and secondary teachers need to develop skill with instructional practices that provide students with those opportunities. In this section we first frame the focal issues of this working group by specifying what is meant by "ambitious and equitable mathematics instruction" and providing an overview of practice-based and practice-focused

approaches to teacher education and PD, specifically the use of "cycles of investigations and enactment" as a pedagogy for teacher development with a focus on rehearsal and enactment We then present emerging issues, challenges, and questions for conducting and researching this work in secondary mathematics teacher education and PD.

Ambitious and equitable mathematics instruction

Teachers must ensure that each student has access to rigorous academic work to develop mathematical proficiency and meet the demands of an increasing mathematically, statistically, and technologically complex society (Kilpatrick, Swafford, & Findell, 2001; National Council of Teachers of Mathematics [NCTM], 2014). These expectations are summed up, in part, by the way in which students must engage with and develop a set of mathematical practices (NGA & CCSSO, 2010). These practices represent the skills individuals in mathematics-related fields utilize in their work and the way in which all individuals make sense of, reason about, and make decisions regarding mathematical and quantitative situations. These opportunities must deliberately be made available to all students, drawing upon students' diverse cultural and linguistic resources in the mathematics classroom and positioning mathematics as a human practice and a tool for social change (Gutiérrez, 2011).

To be able to support these "ambitious and equitable" goals (Jackson & Cobb, 2010), mathematics teachers must not only hold particular beliefs, values, and knowledge around the teaching and learning of mathematics, but also "skilled practice" (Grossman & McDonald, 2008) to actually carry out the work out in the classroom. Specifically, teachers need skill with a set of core practices (e.g., Grossman et al., 2009; Forzani, 2014) that represent what is known in the fields of mathematics teaching and teacher education as integral aspects of ambitious and equitable mathematics teaching. These instructional practices include leading whole class discussions (Boerst, Sleep, Ball, & Bass, 2011; Chapin, O'Connor, & Anderson, 2009), eliciting and responding to students' reasoning through tasks and questioning (Lampert et al., 2013; Stein, Engle, Smith, & Hughes, 2008), and steering instruction toward a clear and worthwhile mathematical point (Baldinger, Selling, & Virmani, in press; Sleep, 2012). Teachers' capacities with these instructional practices have the potential to engage students in key practices of the discipline of mathematics. Efforts have been made to capture a set of core practices for teaching, such as the "high leverage practices" from TeachingWorks (2016) or the eight essential Mathematics Teaching Practices from NCTM's (2014) *Principles to Actions: Ensuring Mathematical Success for All.* This working group focuses on a set of tools and approaches of teacher education and PD experiences that support teachers' development of these skills.

Practice-based approaches to teacher learning and pedagogies of practice

There has been an increased focused on practice-based approaches to supporting teachers' professional learning. A practice-based approach uses "practice as a site of inquiry in order to center professional learning in practice" (Ball & Cohen, 1999, p. 19), and creates opportunities for teachers to examine the everyday aspects of teaching. Grossman and colleagues (2009) have called for the need to organize practice-based approaches to professional education around what they call representations, decompositions, and approximations of practice, with the latter referring, "to opportunities for novices to engage in practices that are more or less proximal to the practices of a profession" (p. 2058). One form of approximation of practice is what Lampert & Graziani (2009) call rehearsals of "instructional activities," or IAs, which serve as containers of core practices, pedagogical tools, and principles of high-quality teaching (Kazemi et al., 2009). Toward this end, IAs are designed to structure the relationship between the teacher, students, and content in order to put a teacher in position to engage in and develop skill with interactive practices around facilitating rich discussions about mathematics. IAs and the practices that they contain serve as a focus of a set of

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Tucson, AZ: The University of Arizona.

activities that provide teachers the opportunity to both investigate and enact the work of teaching (Lampert et al., 2013; McDonald et al., 2013), often referred to as a "cycle of investigation and enactment". This consists of observing, decomposing, and planning the IA; rehearsing the IA in the teacher education setting with in-the-moment coaching from a teacher educator; enacting the IA in a K-12 classroom setting; and using artifacts of practice such as video and student work to analyze instruction and make connections between teaching practices, student learning, and a broader vision of ambitious and equitable mathematics teaching. In this working group, we focus on the "enactment" elements of this cycle—both the coached rehearsals of IAs in a teacher education or PD setting and the enactments done in classrooms with students.

Emerging issues and challenges in this work

Much of the research around pedagogies of practice in mathematics education has tended to focus on elementary mathematics instruction (e.g., Lampert et al., 2013), but a number of scholars from different institutions and contexts (including members of the working group) have been working to extend this work to the secondary level, both in teacher education and PD (e.g. Aaron & Elliott, 2013; Baldinger, Selling, & Virmani, in press; Campbell & Elliott, 2015; Elliott, Aaron, & Maluangont, 2015; Ghousseini & Herbst, 2016). As we work to design, implement, and research pedagogies of rehearsal and enactment at the secondary level, a number of questions and challenges have emerged that could be explored and addressed through the types of collective work afforded by a working group. We see three main sets of challenges and questions to frame the proposed working group's foci—(1) issues of language around instruction and mathematics, (2) theoretical and methodological choices, and (3) considering multiple settings and boundaries.

Issues of common language around practice, practices, IAs, and mathematics. The first challenge emerges in the language used to communicate practice-focused work—among researchers and teacher educators, and in those stakeholders' interactions and collaborations with teacher candidates, teachers, and school administrators across settings. This includes different language for naming and decomposing instructional practices (Grossman et al., 2009) in ways that could be worked on by teachers and embedded within pedagogies of rehearsal and enactment. Issues of language also emerge when a language developed by teacher educators and researchers interacts with language about the work of teaching as defined in policy used by university and school-based stakeholders. One persistent issues is that of "grain size" (Boerst et al., 2011; Campbell & Elliott, 2015)—with some focusing on a practice of leading a whole class discussion (Baldinger, Selling, & Virmani, in press; Ghousseini & Herbst, 2016), while others focus on a smaller grain size, such as using particular questioning techniques (e.g., Arbaugh, Freeburn, Graysay, & Konuk, 2016). Challenges emerge among teacher education researchers and practitioners about what counts as an IA and how those decisions might be different in secondary contexts as compared to elementary. This is influenced, in part, by differences in the contexts of elementary and secondary classrooms and the mathematical demands of each of those settings as teacher educators work to be responsive to the work of the settings for which teachers are being prepared (Campbell & Elliott, 2015). What are the implications of the different names and decompositions of practice for helping teachers develop their skills—both instructionally as well as their mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008)? How could we build common language for practice or shared meanings from particular terms to describe practice, develop skilled practice, and communicate across settings? Answering these questions is important given the developing appeal of using pedagogies of rehearsal and enactment and other practice-based approaches.

Theoretical and methodological choices. A second set of challenges arises when thinking about how to conceptualize and track teachers' development through the enactment cycle, across cycles, and across settings. Past research on pedagogies of rehearsal and enactment has made use of theoretical lenses such as activity theory (Campbell, 2014; Campbell & Elliott, 2015) or theories of

knowing in practice (Cook & Brown, 1999; Lampert et al., 2013). How might we use different theories of teacher learning to help us define and explore a range of potential ways that teachers might learn in the context of the enactment cycles? For example, we might look to see changes in how teachers enact a particular instructional practice or we might examine the impact on teachers' noticing of student thinking or instruction (Sherin, Jacobs, & Philipp, 2010). Attention must also be paid to other outcomes of teacher development that are important to the various stakeholders invested in this work. Without explicit discussion of the theoretical constructs we employ we run the risk of leaving our goals unspecified, of designing instruments misaligned to our goals, and to make claims that are unwarranted given our research designs. A related challenge is identifying methodological tools that build on different theoretical framings that could allow us to systematically document evidence of change or growth in a range of data sources. As we and others look to make claims about the impact of pedagogies of rehearsal and enactment on teachers' practice, there needs to be more explicit discussion about the theoretical and methodological choices that contribute to research and development.

Crossing settings and boundaries. A final set of challenges and questions arise when considering that work on secondary enactments necessarily crosses a number of boundaries. The first boundary is between professional education settings, such as methods courses or PD workshops, and K-12 learning environments such as field placement classrooms, teachers' own classrooms, or on-site professional learning opportunities. How might the work in the enactment cycle be responsive to the contexts for which teachers are learning to teach or growing their practice? For example, Campbell and Elliott (2015) have highlighted the ways in which secondary mathematics classrooms pose unique structures and expectations to which teacher educators and researchers need to be responsive, resulting in designs that look to simultaneously build on these activity structures and provide students in those classroom settings with increased opportunities to reason mathematically. By designing and using IAs that are responsive to the "normal" workings of secondary mathematics classrooms they hope to be able to support teacher candidates in developing skills that they see as relevant to the work that they will be asked to do in the future and skills that align with what we, as a field, know about effective teaching. Striking a balance between responsive teacher education designs and promoting instructional change in mathematics classrooms is an important area of consideration in this work.

Another cross-setting challenge is to consider how work on pedagogies of rehearsal and enactment might look different for practicing teachers. Much of the work on practice-focused pedagogies has focused on teacher education, but recent efforts are extending this to PD with practicing teachers (e.g., Aaron & Elliott, 2013; Wilson, Webb, Martin, & Duggan, 2016). What aspects of the work might need to be different for in-service teachers and how might it influence the ways in which we study these efforts? Finally, a number of important questions have emerged around the relationship between pedagogies of rehearsal and enactment and efforts to help teachers develop more equitable instructional practices (Jackson & Cobb, 2010). How might situating teacher learning more directly into schools (e.g., methods course held in schools) provide opportunities to think about context and power dynamics in relation to instructional practices (Kazemi et al., 2016)? Kazemi and colleagues also highlight an area for further investigation around how pedagogies of rehearsal and enactment can provide a way to connect to "foundations" courses where issues of inequities in schooling are primarily addressed. How can we work to more explicitly link this body of research to other important efforts to focus on equity and justice in mathematics education?

Plan for Engagement of the Working Group

The three sessions of the proposed working group are structured around sets of focus questions that address these issues and challenges. We first focus on the core ideas of the work and the different language we are using to describe ideas about pedagogies of rehearsal and enactment. Next we consider theoretical and methodological issues involved in researching these ideas. Finally, we

will take up questions about the varied purposes and contexts for work by pursuing more focused interests in small groups. We describe each of the sessions in detail below.

Session 1. Enactments of what? Examining choices about instructional practice and content

The first session will open with opportunities for introductions and to briefly frame the purposes and the structure of the working group. The remainder of this first session will be comprised of two interactive panels, each exploring one of two questions: (1) How can practice be decomposed in different ways for the purpose of rehearsal and enactment and what are the implications for how practice is parsed in this work?, and (2) What mathematics do we work on when we work on instructional practice? The first interactive panel will take up some of the issues around language and terminology for describing instructional practice and work on enactments to help build shared meaning of different terms that are commonly used in our work, such as "core practice", "teaching move", "instructional activity", "rehearsal", and "enactment". Two leaders of the working group will provide short presentations highlighting their respective work on pedagogies of rehearsal and enactment, specifically about the distinct approaches to naming and parsing practice for the purpose of developing teachers' skill. Participants will then have opportunities to discuss different choices in decomposing practice and alignment to purposes and goals. This part of the session will provide key opportunities to develop shared understanding of the different language and terminology used by different groups in this work. The second interactive panel will take up some of the issues about mathematics content and practice in the context of pedagogies of rehearsal and enactment with secondary mathematics teachers. Two perspectives from leaders of the working group will be presented and discussed. Participants will then have opportunities to discuss the types of strategic choices that might be made around different ways to work on mathematics. In sum, the first session will establish shared understanding (or, at least, an understanding of the issues and questions) around decisions to be made in the work of secondary pedagogies of rehearsal and enactment.

Session 2. What constitutes evidence of "skilled practice" and its development?

The second session will build on the previous day's work to consider how we might conceptualize and trace teacher development as they participate in pedagogies of rehearsal and enactment. This session will focus on two main questions: (1) What theoretical and methodological tools are being used and what needs to be developed to track evidence of development within a cycle, across cycles, and across settings and institutions?; and (2) What are the conceptual/theoretical frameworks researchers are using to guide research on instructional practice? These questions are particularly complex to investigate as pedagogies of enactment and investigation cross borders between university coursework or PD and other settings for teacher learning. First, a panel of researchers who have previously published or otherwise shared findings that include claims of teacher learning will share how they are conceptualizing teacher learning and development and the methodological approaches they are using for identifying and characterizing this development in their research. We will then open discussion for other participants to ask further questions about challenges and strategies for researching teacher learning in this type of work. Next we will spend time in small groups that are organized around certain theory-methods perspectives to come up with takeaways about each perspective, including what kinds of research questions could be pursued, what types of data to collect, and what kinds of claims could be made. Participants will be invited to bring their own data about rehearsals and enactments to these small group conversations. We will leave time at the end of this session for the groups to report out about the nature of the discussions.

Session 3. Moving forward with a research and development agenda

The final working group session will provide opportunities for small groups to continue discussing collective takeaways of the first two days, to delve into particular areas of interest for

attendees, and to plan next steps for the working group. For example, some groups might choose to discuss how researching rehearsal and enactments might be different in teacher education or PD contexts. Another group might choose to discuss how pedagogies of enactment and investigation, and specifically choices about what practices to work on and why, allow for work on issues of access and equity. We will invite each group to record the different ideas discussed during this time to better inform the subsequent discussion of next steps. The final part of this session will be used to consider and discuss possible follow-up activities that could build on the work begun during the working group. We will offer a set of potential follow-up activities (see below) and invite participants to suggest additional activities that would build on the work begun at PME. Then we will discuss the group's interest in moving forward with on more more of these ideas and determine a possible work-plan for next steps. We will then ask for volunteers to take the lead in facilitating the next steps for follow-up work.

Anticipated Follow-Up Activities

There are a number of potential follow-up activities to build on the work that will begin during the proposed sessions. One possible activity is engaging in collective dissemination of the ideas that are shared and created through the working group. For example, submitting a set of papers to a journal like *Mathematics Teacher Educator* that address similar or contrasting ideas around secondary level enactments could provide an appropriate forum and audience for these ideas. Alternatively, collectively writing a research commentary would allow us to focus on theoretical or methodological challenges in researching teacher development in practice-based activities. This could be submitted to a venue such as the *Journal for Research in Mathematics Education* that publishes commentaries. Another set of follow-up activities is designing and studying new work around secondary rehearsals and enactments. Participants will have the opportunity to collaborate on projects that investigate one or more of the questions that emerge from the working group. For example, a group of researchers from different projects might choose to examine their data (or collect new data) using the same theoretical and methodological approach to compare ideas across contexts. The members of the working group have explored the conceptualization and preparation of a grant proposal to fund new collaborative research projects. The outcomes from the working group would further support this effort. We will also pursue options for funding future conferences for continued opportunities to bring together scholars for focused work around pedagogies of rehearsal and enactment. To support these collaborations, we will establish ways to communicate about our individual and collective work. In the past, we have used shared Dropbox folders, regular video calls, and in-person meetings at conferences. These strategies would likely be used to support future work.

This Working Group will continue the work of last year's Working Group in considering multiple aspects of research and practice related to mathematics learning and teaching with English Learners. Our goals include: (1) developing further the collaborative endeavors that began during the 2015 meeting and (2) fostering new collaborations and supporting further connections among researchers and research projects in the future. In Session 1, the organizers will present brief reports on the work that resulted from the 2015 Working Group and preview the schedule for this year's Working Group. During Sessions 2 and 3 we will provide the smaller groups time to collaborate and continue their work. We will close Session 3 with time to review group progress and discuss next steps and products of our work.

Keywords: Equity and Diversity, Teacher Education-Pre-service, Teacher Education-Inservice/Professional Development, Research Methods

Brief History

The facilitators of this Working Group initially came to work together through the NSF-funded Center for the Mathematics Education of Latinas/os (CEMELA). CEMELA brought together researchers from across the country to collaborate on research focused specifically on critical issues related to Latinos/as in mathematics. Prior to CEMELA, researchers interested in such a focus worked mostly in isolation. The overarching framework for CEMELA included an examination of language, culture, and mathematics. In considering issues related to Latinos/as in US schools, the issues of language and English Learners (ELs) are closely related. While not all Latinos/as are English Learners, and not all ELs are Latinos/as, these two groups have significant overlap. For example, about 80% of ELs speak Spanish as a first language, and Spanish-speaking ELs appear to struggle on measures of academic achievement (Goldenberg, 2008).

CEMELA expanded the field's knowledge of ELs in mathematics by conducting studies in interdisciplinary teams. CEMELA focused on research in teacher education, research with parents, and research on student learning, resulting in well over 50 publications and presentations. Several of these studies involved the investigation of questions related to the interplay of language, culture, and mathematics education.

Following the conclusion of CEMELA's funding, Zandra de Araujo, Sarah Roberts, Craig Willey, and Bill Zahner continued to meet regularly. These meetings focused on examining intersections among these early career scholars' work related to the mathematics education of ELs. To date these meetings have resulted in a number of national presentations at the annual meetings of the National Council of Teachers of Mathematics, the American Educational Research Association, and PME-NA. Currently, this group is working on several manuscripts and follow-up studies related to the preparation of teachers to work with ELs.

The Mathematics Education and ELs Working Group met for the first time at PME-NA 2015 (de Araujo et al., 2015). At that meeting, we brought together a diverse group of about 20 researchers who started collaborating on several projects related to the mathematics education of ELs (see descriptions of these projects in the section titled *Prior Work*). Our aim for the 2016 Working Group is to provide a space for these scholars to continue their work and to bring new scholars into the fold.

Focal Issues

ELs are the fastest growing group of U.S. students (Verplaeste & Migliacci, 2008). In fact, U.S. schools have seen an increase of 152% in EL students over the past 20 years (National Clearinghouse for English Language Acquisition, 2008). The growing number of ELs across the country induces the need for teachers from all states to be prepared to attend to the needs of ELs in their mathematics classrooms. Considerations of how to support ELs in mathematics is no longer a concern for only states, like Arizona, Texas and California, with traditionally high numbers of EL students. Instead, with all but ten states across the country seeing increases in their EL populations between 2002-03 and 2011-12 (National Center for Educational Statistics (NCES), 2014), there is increasing pressure for support in addressing the needs of these students.

Despite the rise in the number and proportion of ELs, teacher preparation has not kept up with this trend. In 2002, the NCES reported that out of the 41% of teachers who worked with ELs in their classrooms, only 13% received EL-specific professional development. In 2008, Ballantyne, Sanderman, and Levy found that it was "likely that a majority of teachers have at least one English language learner in their classroom," although "only 29.5% of teachers with ELs in their classes have the training to do so effectively" (p. 9). This misalignment of the realities of today's classrooms and teacher preparation necessitates research into effective means for supporting current teachers and for preparing prospective teachers to meet the needs of linguistically diverse learners.

The implementation of the Common Core State Standards for Mathematics (National Governors Association Center for Best Practices (NGA Center) and the Council of Chief State School Officers (CCSSO), 2010) is putting additional pressure on teachers of students who are still gaining proficiency in English. Teaching aligned with the CCSSM's content standards and the standards of mathematical practice will increase the language demands required to engage in mathematical discourse, which is typically in English (Moschkovich, 2012). Providing ELs with quality educational experiences is no longer relegated to only language specialists; it is a "mainstream" issue for which all mathematics teachers must be prepared (Bunch, 2013).

Many ELs or their families have literal experience crossing international borders. Issues related to educating ELs are also connected to metaphorical borders. This year, our Working Group aims to examine critically the borders with(in) mathematics education that hinder quality educational experience for bilingual and emergent bilingual students in mathematics. In particular, we will examine the artificial borders between research and practice, linguistic and mathematical resources, teacher preparation and practice, research with monolingual and bilingual learners, and research in mathematics education at large and research on the mathematics learning of ELs. To do this work, we will bring together researchers from diverse contexts to examine current and past research on ELs in mathematics education while also supporting burgeoning collaborations to establish future, imperative research directions.

Previous Work of the Group

The 2015 Working Group (de Araujo et al., 2015) began with whole group discussions aimed at examining a number of aspects related to the mathematics education of ELs including: a) Student Learning; b) Preservice & Inservice Teacher Education; c) Family and Community Resources; d) Curriculum; and e) Language Perspectives. In the following sections we briefly summarize our discussions of these areas.

Student Learning

Building upon situated and sociocultural perspectives (Moschkovich, 2002), we started from the premise that ELs, like all students, learn mathematics through participating in and appropriating discourse practices, tool use, and perspectives of mathematics. There exists a need to understand better how research in mathematics education at large is connected with research on the learning of ELs; much of the content-focused work in mathematics education is isolated from research on how ELs develop specific mathematical understandings. This has resulted in a gap in the literature and so we need to develop more linkages between mathematics education research on student learning of specific topics, and the mathematics education research on student learning of ELs. We also need to develop more connections among research with monolingual, bilingual, and multilingual mathematics learners or settings. Some results may apply across learners and settings, while other results may be specific to one population or setting. Researchers need to explore both these intersections and differences. Members of this group were involved in research that critically examines issues at the borders of learning mathematics and learning language.

Teacher Education

Despite findings that suggest ELs develop academic language in the content areas over a period of about 5-7 years, many ELs are mainstreamed within two years. Thus, it is essential that teachers support ELs in learning content in mainstream mathematics classes while also providing support to develop their academic language. Most inservice teachers have had few, if any, professional learning experiences around working with ELs in mathematics classrooms (Ballantyne et al., 2008). In fact, many mathematics teachers struggle to understand their role in supporting ELs' mathematics language development (Willey, 2013).

Preservice teachers typically have few opportunities to think specifically about how they will work with ELs in their mathematics classrooms. Preparation programs often include coursework on teaching ELs that is not specific to the content areas in which preservice teachers will work. Meanwhile, the content courses for preservice teacher often focus solely on content, devoid of exploring how to support ELs in mathematics classrooms. There is a need for much more content specific support for mathematics teachers of ELs. Recently researchers have shared strategies for engaging preservice teachers in working with ELs in mathematics classrooms. For example, Fernandes (2012) suggested a series of mathematics task-based interviews to engage preservice teachers in the process of noticing the linguistic challenges that ELs face and the resources these students bring to their mathematical communication. Additionally, the TEACH MATH (Drake et al., 2010) research team is using tasks in their content courses to support preservice teachers in drawing on students' funds of knowledge (Turner, Drake, Roth McDuffie, Aguirre, Bartell & Foote, 2012).

Much of the prior work on teacher education related to ELs has focused on more general strategies (e.g., sheltered instruction, as in Echevarria & Graves, 1998), such as using visuals, modifying texts or assignments, and using slower speech. At our previous meeting, we explored ways to support teachers, both preservice and inservice, in learning to better address the needs of ELs in the mathematics classroom.

Family and Community Resources

Families and communities can serve as resources for ELs in their mathematics learning in myriad ways. Families can advocate for their children and provide and support learning experiences both in and out of the classroom. Communities can also provide a wealth of support mechanisms and learning possibilities. Moll and colleagues (1992) described how students studied candy making and selling within their neighborhood to explore mathematics within this context, such as discussing and analyzing production and consumption. In doing so, the teachers and students acknowledged the value of these community experiences. Additionally, Civil and Bernier (2006) explored the

challenges and possibilities of involving parents in facilitating workshops for other parents around key mathematical topics. These studies and others like them illustrate the promising impact of family and community resources in fostering ELs' mathematics learning. At our prior meeting, we discussed the implications of different language policies on parental engagement and how teacher educators can draw on family and cultural resources in support of ELs.

Curriculum

Curriculum plays a key role in the teaching and learning of mathematics and teachers play a pivotal role in selecting and enacting curriculum materials for students. The choice of curriculum materials impacts students' opportunities for learning in the mathematics classroom (Kloosterman & Walcott, 2010). Early work on curriculum and English learners focused specifically on the challenges ELs encounter when completing or interpreting word problems (Téllez, Moschkovich, & Civil, 2011). More recent work that centers on both ELs and curriculum has focused on culturally relevant curricula. A subset of mathematics education, called ethnomathematics, focuses on this area (e.g., D'Ambrosio, 2006). Other studies have focused on the development of curriculum materials for ELs (e.g., Freeman & Crawford, 2008) or the evaluation of a curriculum's appropriateness for ELs (e.g., Khisty & Radosavljevic, 2010; Lipka et al., 2005). More recently, work related to ELs and curriculum has begun to look at teachers' use of curriculum (e.g., de Araujo, 2012). At our prior meeting, we investigated the intersection of teachers, curriculum, and ELs in discussing how curricula addresses (or not) the needs of ELs.

Language Perspectives

Teachers' and researchers' conceptions of language, second language acquisition, and bilingualism impact teaching and learning mathematics for ELs. At our prior meeting, we considered how perspectives of language, second language acquisition, and bilingualism appear in both theory and practice. We also contemplated, in particular, how work focused on ELs can draw on current work on language and communication in mathematics classrooms, classroom discourse, and linguistics. Looking for these intersections and connections was crucial because it ensures that work in mathematics education is both theoretically and empirically grounded in relevant research, and it will prevent researchers from reinventing wheels, and it can inform crucial research-based guidelines for curriculum, instruction, and assessment.

Aims for the 2016 Working Group

Following the Working Group's discussions of student learning, teacher education, family and community resources, curriculum, and language perspectives, three smaller groups formed to explore subsets of these ideas in depth. Since the conclusion of the 2015 Working Group, these smaller subgroups have continued the work they started in the Working Group. The aim of the 2016 Working Group is to provide updates on the work of these subgroups and continue to move the groups' research agendas forward. In the following section we provide an overview of each of these subgroups and the goals for the groups moving forward.

Group 1 (Curriculum)

In 2015, the curriculum subgroup focused on the role of textbooks, specifically teachers' guides and student work pages, in demonstrating how one might approach supporting ELs in building mathematical understanding and developing mathematics language. We inquired about the process publishers undergo to incorporate and offer support to teachers. What assumptions do they make? Who do they consult? What motivates them to invest in serving ELs better? What is/are their end goal(s)? The group decided to conduct an analysis of various middle grades curriculum to ascertain what supports and guidance are offered to teachers. It was suggested that we might build on the work

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

of Pitvorec, Willey, and Khisty (2011), who explored the features of Finding Out/Descubrimiento (FO/D) that proved to be successful with bilingual children of migrant families in the 1980's (see Neves, 1997) and partially contributed to the development of complex instruction (Cohen, Lotan, Scarloss, & Arellano, 1999).

For the 2016 meeting, this group will continue to examine textbooks to understand better the supports they provide for ELs. The subgroup will will also consider language issues in mathematics texts for ELs, especially as related to word problems and assessment items. We will first share a short literature review of relevant research on linguistic complexity and vocabulary for mathematics word problems. Based on that research, we will summarize recommendations for addressing language complexity and vocabulary in designing word problems for instruction, curriculum, or assessment. We will then use examples of released sample Smarter Balanced Assessment Consortium items to illustrate how to apply those recommendations to designing word problems and to designing supports for ELs to work with word problems.

The subgroup will consider how to provide instructional support at three different levels for mathematical texts in terms of a) language issues: Light Support, Medium Support, and Strong Support, and b) the mathematical content. These three levels address the differing needs of students at differing English proficiency levels, but rather than working with a static student label, which is not consistent, dependable, or useful across settings, these labels refer to the level of support as the focus of instruction. For example, students who are newcomers may need strong support for language but differing support for mathematical content, and those need to be assessed separately but addressed concurrently. Students who are at an intermediate level of Academic English may need Medium Support for language and differing support for the math content. Students who are not immigrants, are native English speakers who belong to bilingual communities, or who speak an on-standard variety of English, or are labeled "long term ELs," may need strong support for reading comprehension in their first language (English) and differing support for mathematical content depending on their mathematics course taking experiences.

We will consider, in particular, how this subgroup can draw on current work on scaffolding in English Language Arts (ELA) to develop supports for comprehension of what ELA experts call "complex text." The following questions will guide the group's work related to this theme:

- What do we know from research regarding the linguistic complexity of mathematics texts, especially word problems and assessment items?
- How can instruction address these issues with mathematics texts?
- What are research based recommendations for designing word problems, revising text, and designing glossaries?

Group 2 (Student Learning)

During the 2015 working group meeting, the student learning sub group discussed multiple ongoing research projects that examine the intersection(s) of research on student learning of mathematics and research on learning language(s). Moschkovich shared examples from her past work that has illustrated the mediation of language and Discourses in students' mathematics learning (2007, 2008, 2015). For example, in one study Moschkovich traced the evolution of the phrase "went by" in reference to the intervals and scales on graphs. Zahner also shared results from an analysis of how assessment pressures shaped whole class discourse practices and opportunities for student learning in one ninth grade algebra classroom (Zahner, 2015). Zahner also shared a preliminary analysis of how teachers and students use formal and informal language about rates of change during classroom discussions (this work will be presented formally at ICME). The working group also discussed ideas for future analyses that build on and extend the prior work in this area.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

The collaborations started at the PME working group in 2015 have directly influenced work on two projects by Zahner that he will share at the working group. Zahner has also invited his collaborators on these projects to join the working group in 2016. In one study led by Phil Vahey at SRI International and Tracy Nobel at TERC, working group member Zahner is contributing to developing a coding scheme that captures EL's participation in the CCSSM Practice Standard "Reason Abstractly and Quantitatively." This coding scheme is being developed specifically to focus on interactions among trios of ELs solving problems about rates of change. The coding scheme builds on and extends prior work by members of the working group who have examined how ELs and their teachers use words, symbols, gestures, and discourse practices to engage in mathematical reasoning (Shein, 2012; Turner, Domínguez, Maldonado, & Empson, 2013; Zahner & Willey, 2014). The work with the team from SRI also includes developing dynamic representational technology for fostering abstract and quantitative reasoning among ELs in mathematics classrooms. Members of this project team will come to the working group in 2016 to share an update on progress and to present preliminary analyses of abstract and quantitative reasoning among ELs.

In a distinct study, Zahner is initiating a new project that has the goal of developing specialized learning trajectories that combine development students' mathematical reasoning and development of students' use of academic language related to specific mathematical topics. This development is occurring in collaboration with a working with a group of three high school teachers in in a Southwest high school, along with a research team including graduate and undergraduate students. The final goal is to design and develop curriculum materials related to linear and exponential growth that account for the special needs of ELs in secondary mathematics classrooms. At the working group Zahner and team members will share preliminary data and updates on this project. The working group will also function as a site where participants can offer feedback and build collaborations around these key ideas.

Group 3 (Teacher Education)

The teacher education subgroup focused on the primary issues that arise in the preparation of teachers to teach ELs at the various institutions. As a group we recognized that there were few attempts to include the teaching and learning of mathematics to ELs beyond the states where there was a high population of ELs. Given that some of the group members were meeting for the first time, a significant portion of the allotted time was spent sharing the details of our research we did and our interest in being part of this particular subgroup. One of the members shared a survey about examining preservice teachers conceptions about teaching mathematics to ELs and the other members agreed to administer the survey at their locations. Together, the responses will provide us with some insight about possible teacher conceptions that need to change and the steps we can take to make that happen. The group decided to stay in touch online and continue the discussions about potential collaborations. This subgroup aims to continue this line of work at the 2016 meeting. In particular, they seek to develop a multi-institution study that will investigate the issues raised at the 2015 meeting.

Plan for the Working Group

During the three sessions, participants will continue the work of the subgroups and bring new members up to date on the group's prior activities. In participating in the three sessions, participants will work to: a) clarify research questions, b) refine research tools, methods, and analyses, c) explore connections among different projects and studies, and d) discuss further collaborations and research on learning and teaching mathematics in classroom with ELs.

In Session 1, the organizers will present brief reports on the work that resulted from the 2015 Working Group and preview the schedule for this year's Working Group. During Sessions 2 and 3 we will provide the smaller groups time to collaborate and continue their work. We will close

Session 3 with time to review group progress and discuss next steps for our work as shown in Table 1. Meeting notes, work, and documents will continue to be shared and distributed via our Google Community (https://plus.google.com/communities/104376842129206334879) and corresponding Google Drive folder (https://goo.gl/EXhUVm). The use of Google Community allows members to create an institutional memory of activities during the Working Group that we have continued to use and add to following the 2015 Working Group. In addition to the Google Community and Drive resources, anticipated follow-up activities include planning for a continuation of the Working Group at PME-NA in 2017 and organizing collaborative writing projects on this topic.

Table 1: Overview of Proposed Working Group Sessions

	INTRODUCTIONS, UPDATES, & CLARIFYING AIMS	
	ACTIVITIES	GUIDING QUESTIONS
SESSION 1	1. Introduction and overview of the Working Group including introduction to the Google Community. 2. Brief presentations by panel members from each of the subgroups providing overviews of research projects with specific examples of how researchers have designed the studies. The purpose is to provide an overview and update of scholarly activities that were initiated at the 2015 Working Group. 3. Following the presentations, participants will discuss specific questions posed by the subgroups and aims for the subgroups' work at the 2016 meeting.	1. What research is being done in relation to each of the subgroups? 2. Which aspects of studies focusing on English learners do you find most puzzling? Most useful? Most misunderstood? 3. What goals do participants have for the 2016 conference?
	SUBGROUP WORK TIME	
	ACTIVITIES	GUIDING QUESTIONS
SESSION 2	1. Subgroups will work to establish goals and work toward those goals. 2. The second session will close with an allotment of time for subgroups to give brief updates on their work and pose questions for the whole group.	1. What theories and theoretical frameworks have informed the design of your research project(s)? 2. How might your work inform theory in mathematics learning and teaching? How can work on this student population expand our theoretical lenses? 3. What issues and challenges have you faced in designing studies?
	SUBGROUP WORK TIME & NEXT STEPS	
	ACTIVITIES	GUIDING QUESTIONS
SESSION 3	1. Work time for the subgroups to discuss directions for continued collaboration. Subgroups will also develop next steps as they plan for continued work. 2. Whole group discussion in which subgroups share goals and next steps developed by the subgroups. 3. Establish next steps for continued collaboration, including the Google Community.	1. How might other researchers pursue research projects on this topic and what can they learn from the work done so far? 2. What are the next steps in continuing this work? 3. How will your subgroups' work be disseminated?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Follow-up Activities

We anticipate that this Working Group will attract other researchers interested in issues related to the mathematics education of ELs. Therefore, an important component of this second meeting of the Working Group will be to continue to establish connections with other interested researchers and to build opportunities for future collaborations. We will provide space for new researchers to contribute to our work, to suggest new directions, and to add to the growing body of research on mathematics and ELs. At the first session of our Working Group, we will share our ongoing online Google Community, which uses Google applications (Plus, Hangout, Groups, Drive, etc.). Google's applications are freely available and allow for a number of collaborative opportunities, including video conferencing, group messaging, collaborative document development, and shared web and social media space. Through this collaborative Google Community, we have organized follow up meetings both virtually and at conferences such as TODOS and the NCTM Research Conference. These meetings, both face-to-face and virtual, allow us to set concrete goals in preparation for the creation of a Working Group proposal for PME-NA 2017 to continue our work.

In addition to these short-term goals, we have several longer-term goals for this Working Group. First, we would like to seek funding for a conference where we can share the results of our work with other researchers and practitioners. A number of the facilitators will attend and present at the TODOS: Mathematics for All Conference in Summer 2016. The TODOS conference brings together practitioners and researchers and provides a venue for the dissemination and discussion of ideas and issues related to the mathematics education of diverse groups of learners. A related conference specifically focused on ELs, which we would organize, would be of great benefit to a multitude of stakeholders as we continue to examine how to best support ELs. In addition to the conference, we will also propose a special edition of a journal focused on issues related to mathematics education and ELs. This would allow the broader mathematics educational research audience access to current work being done in this area.

EXAMINING SECONDARY MATHEMATICS TEACHERS' MATHEMATICAL MODELING KNOWLEDGE FOR TEACHING

Kimberly Groshong
The Ohio State University
groshong.4@osu.edu

Joo Young Park
Florida Institute of Technology
jpark@fit.edu

This working group is in its second year and was formed to address the following research question: What knowledge do secondary teachers need to possess to advance and foster mathematical modeling abilities in students? A task analysis framework with three distinct features – openness, authenticity, and complexity – was created to probe the differences between mathematical modeling tasks and other mathematics or modeling problems to clearly define mathematical modeling and modeling with mathematics. Using this task analysis framework, the group identified mathematical knowledge, modeling knowledge, and pedagogical knowledge as categories in a potential mathematical modeling knowledge for teaching (MMKT) framework. Recognizing that there are many types of mathematical models, e.g. empirical, deterministic, discrete, descriptive, analytical, etc., participants will consider the types of knowledge teachers' exhibit while implementing these different tasks in their classrooms. This session will focus on clearly defining features of these knowledge categories and refining research questions for study throughout the year. A well-defined MMKT framework built from theoretical, qualitative, and quantitative research can inform teacher training programs. Ongoing virtual discussions will continue, and the findings of the working group will be reported.

Keywords: Modeling, Mathematical Knowledge for Teaching, Teacher Knowledge, Teacher Education-Inservice/Professional Development

The Common Core State Standards for Mathematics (CCSSM) include modeling mathematics as a content standard and a mathematical practice in mathematics education and refers specifically to mathematical modeling in grades 9-12 (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). The topics of modeling with mathematics and mathematical modeling differ in the problem context and the degree of openness in the task. Modeling with mathematics activities rely on student generated representations of the either mathematical or real life context situations. These tasks are less open problem statements reducing the number of assumptions and decisions needed by the modeler to simplify the problem, choose variables, and identify relationships. The variety of mathematical approaches available to the solver is also limited resulting in students generating the same model and solution.

Mathematical models are products of an established mathematical modeling process that goes beyond detailing patterns and relationships to use equations, logical arguments, or computer code to explain the behavior of system that is authentic in real-world contexts. The success of the model is closely related to the selection and application of assumptions made by the modeler. These open decision-making problems require the modeler to interpret the ill-posed and less structured task situations, make assumptions, identify variables, develop a mathematical model, manipulate and solve the model, identify limitations, and interpret the solution in the problem's context to determine if the solutions is reasonable (Jensen, 2007). This problem solving process yields multiple solution paths dependent upon the modeler's experiences (Confrey & Maloney, 2007).

Secondary teachers' have limited experiences as learners and teachers of mathematical modeling, which makes implementation of standards and practices challenging (Goos, 2014). Preparing teachers to understand the complexity inherent in mathematical modeling situations and the pedagogical difficulties associated with facilitating and assessing mathematical modeling learning

poses a challenge for mathematics educators. There are few resources available specifically addressing secondary teachers' modeling cognition or pedagogical needs. The proposed working group will build upon its previous work addressing these research needs and increasing the body of research, focusing on the mathematical content knowledge, modeling content knowledge, and pedagogical knowledge that secondary mathematics' teachers need to facilitate rich learning opportunities for students.

Since the term *knowledge* is used repeatedly throughout this paper, it is important to establish a definition. According to the Oxford University Press (2016), knowledge can be defined as the "facts, information, and skills acquired by a person through experience or education; the theoretical or practical understanding of a subject; [and] awareness or familiarity gained by experience of a fact or situation". Research indicates that there are many types of mathematical knowledge called upon to solve mathematical problems, and mathematical knowledge can be increased through exposure to a variety of modeling types and activities (Doerr, 2007).

The fundamental research question for this working group asks "*what knowledge do secondary teachers need to possess in order to foster and advance mathematical modeling in their classrooms?*" In the previous working group sessions, participants, comprised of mathematics education graduate students, educators, and researchers, applied a mathematical modeling task analysis framework, discussed in detail later in this paper, to six distinct modeling tasks published in research journals and mathematics education textbook in order to explore facets of their own mathematical, pedagogical, and modeling knowledge. A groundwork was established defining mathematical modeling and examining distinctions in modeling mathematics, modeling with mathematics, and mathematical modeling tasks. Through the task analysis activity, discussions probed what information, facts, skills, and experiences were needed by teachers to engage students in mathematical modeling situations.

Mathematical Modeling Knowledge for Teaching Framework

The current framework, used by this working group to define mathematical modeling knowledge for teaching, is adapted from research in mathematical modeling competencies with competence defined as a "readiness to act in response to the challenges of a given situation" (Jensen, 2007, p. 142). Jensen's definition suggests that features of mathematical modeling knowledge in three dimensions can be demonstrated by the modeler and observed by educators. The *Degree of coverage* dimension describes the level of independence exhibited by the modeler while working with a mathematical modeling task. *Radius of action* is observed in the breadth of mathematical topics and modeling approaches accessible to the modeler. *Technical level* describes the extent of mathematical sophistication employed in the model.

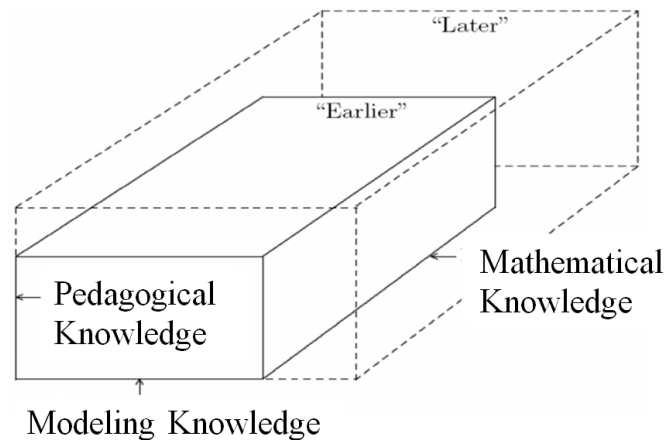
In the initial research, Groshong, Gomez, and Manouchehri (2015) expanded and adapted Jensen's multi-dimensional approach and suggested that *modeling knowledge, mathematical knowledge,* and *pedagogical knowledge* are key elements of mathematical modeling knowledge for teaching framework (Figure 1). In this working group, the components of mathematical modeling knowledge for teaching are defined as follows: *Mathematical Knowledge* includes the breadth of mathematical content and skills as well as the application of necessary mathematics needed to solve mathematical modeling tasks; *Modeling Knowledge* includes the scope of extra-mathematical knowledge (e.g. contextual knowledge) required to solve mathematical modeling tasks, the understanding need to monitor progression through the various modeling sub-processes, and the awareness of various mathematical modeling approaches; and *Pedagogical Knowledge* includes the information and skills needed to plan and implement modeling lessons and to guide and assess student learning in mathematical modeling content.


Figure 1. Mathematical modeling knowledge for teaching framework (Groshong, Gomez, & Manouchehri, 2015; Groshong & Park, 2015).

In the previous working group's task analysis, researchers noticed that when teachers' struggled in one dimension this impacted their performance in other areas. During the discussion of the "bending steel" modeling problem, participants sought to determine how high off the ground a railroad track would rise due to the expansion of the metal from winter to summer. Participants commented that from their perspectives, first as a modeler then as a teacher of modeling, there seems to be a continuum between providing too little supporting situational and modeling information and too much information (Groshong & Park, 2015). With too little information, participants lacked sufficient contextual background to understand the task and they lacked the necessary modeling skills to acquire the needed information, so they abandoned the task. Understanding of real life context, which is contextual knowledge, appears to be a necessary feature of modeling knowledge. The teachers' limited modeling knowledge impacted their pedagogical knowledge needed to prepare, implement, guide, and assess student learning with this task (Groshong & Park, 2015).

Mathematical knowledge for teaching

Mathematical knowledge for teaching (MKT) separates teachers' mathematical content knowledge from their pedagogical knowledge and further breaks each area into sub-categories (Ball, Thames, & Phelps, 2008). The working group is in the early stages of connecting an extensive literature review, task analysis discussions, Jensen's observable modeling competencies, and the MKT framework to gain insight into differences that may exist in a mathematical modeling knowledge for teaching framework and the knowledge needed for teaching other mathematics topics.

In the MKT framework, the *knowledge of content* (CK) has three subcategories of interest to aid in identifying a mathematical modeling knowledge for teaching framework. *Common content knowledge* (CCK) includes the mathematical knowledge that educated adults use in their daily lives, which provides modelers entry to mathematical modeling using less sophisticated but readily accessible daily mathematics. *Specialized content knowledge* (SCK) is specific to mathematics teaching and describes the mathematical knowledge teachers employ when predicting student errors, representing mathematical ideas, providing explanations, and recognizing different solution paths. This area identifies the knowledge that teachers use when presenting the mathematical modeling cycle and describing the problem-solving process.

Horizon content knowledge (HCK) refers to teachers' understanding of how mathematics is connected to other subjects, disciplines, and academic grade levels. Since mathematical modeling tasks arise from messy real-world situations, HCK includes the knowledge of how mathematics is applied in everyday life and in the world of work. Contextual understanding of the world is needed

for working with mathematical modeling tasks and consists of academic knowledge of various subject areas, encyclopedic and factual knowledge, and episodic knowledge arising from life experiences (Stillman, 2000). This knowledge area needs extensive research to identify features of HCK to determine if the broad knowledge of the world, extensive mathematical knowledge, organizational expertise, and communication skills used to make sense relevant information represent a type of knowledge that sets mathematical modeling learning apart from the learning other mathematics subjects (Jensen, 2007; Galbraith & Stillman, 2001). In secondary mathematics classrooms, many different types modeling tasks are used, and these tasks vary in their degree of authenticity as simulations of real life. The relationship between the task's authenticity and modeling teaching and learning is another area rich in research opportunities.

Ball, Thames, and Phelps' (2008) *pedagogical content knowledge* (PCK) also has three subcategories, which may be of interest to defining a MMKT framework. Distinguishing it from mathematical subject knowledge, *knowledge of content and students* (KCS) combines a teachers' knowledge about mathematics with knowing about students to anticipate what students think about topic and whether they will find the material difficult. Identifying barriers to students' progression in working with mathematical modeling activities, e.g. translating the real world context into mathematics and identifying relevant relationships, would demonstrate this type of knowledge. Teachers selecting examples and problems to explore, evaluating the advantages and disadvantages of representations, deciding when to wait or ask for student clarification, and posing new tasks to extend student thinking are all examples of *knowledge of content and teaching* (KCT). These knowledge examples are also relevant to the teaching of mathematical modeling. Due to the openness and complexity of mathematical modeling situations, sequencing mathematical modeling activities by content poses a challenge as each student may make different assumptions and identify different relationships resulting in different mathematical models being created. The *knowledge of curriculum* (KC) includes teachers' knowledge of their course curriculum, the curriculum of courses preceding and following their current course, and the curriculum of non-mathematics subjects the students study. This area also describes teachers' familiarity with and ability to critique available instructional materials. Given the real world contexts of mathematical modeling tasks, understanding the curricular topics studied in other subjects provides insight into the types of episodic and encyclopedic knowledge presented to students.

Secondary Teachers' Mathematical Modeling Knowledge Working Group

This working group will follow a similar path as previously established. The mathematical modeling task analysis framework (Figure 2) will be applied to very distinct mathematical modeling situations. The framework provides a means to encourage working group member participation, probe the differences in types of mathematical modeling approaches found in literature, and discuss the nature of the knowledge needed to solve various types of modeling situations.
Figure 2. Mathematical modeling task analysis framework (Groshong & Park, 2015).

The operational definitions used in this framework are drawn from research. *Authentic* implies that the modeling problem serves more than just educational needs; the task is genuine in a subject area outside mathematics, and the task originates from reality outside classroom (Vos, 2011). Authenticity also refers to the degree of parallelism between the classroom experience and the research field of mathematical modeling including aspects of the problem solving approach, sources of data, modeling software, and modeling environment (Vos, 2011). *Complexity* has two components. Modeling complexity is contingent upon how much assistance is given to students, how many choices of techniques are available, and how many modeling techniques are required (Stillman, 2000). Mathematical complexity refers to the degree of mathematical sophistication incorporated in mathematical modeling process (Jensen, 2007). *Openness* refers to problem situations that permit multiple solutions, multiple interpretations and answers, and even multiple new questions (Abrams, 2001, p.18).

In distinguishing mathematical modeling from other types of modeling experiences, it is also important to identify the many different types of mathematical models found in mathematics education literature, educational standards and curriculum, and instructional materials. The differences identified in each of these taxonomies can provide more insight into the types of knowledge needed to develop, implement, and facilitate mathematical modeling as a standard and a practice in the classroom.

Different types of mathematical models

Since there are many different types of mathematical models which can be created, researching teachers' interactions with this broad field can reveal gaps in understanding teachers' knowledge and guide future teacher training programs (Groshong, 2016). For instance, some mathematical modeling types may be more accessible for students suggesting a sequencing in the types of tasks needed to increase mathematical modeling competencies as these modeling situations may vary in their degree of openness, authenticity, and complexity.

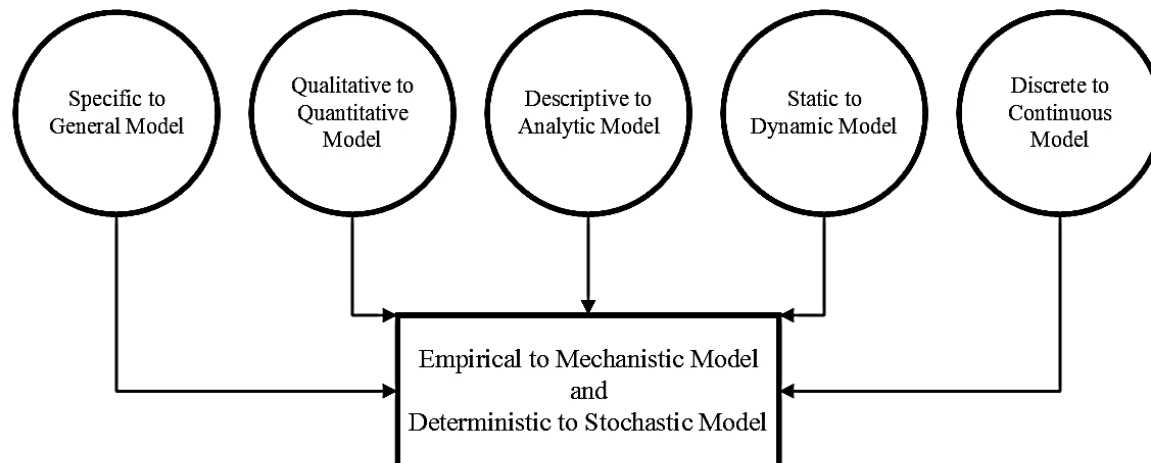
Mathematical models can be classified according to their general characteristics, e.g. the modeling situation and solution form, and mathematical features, e.g. the treatment of data and variability in the solution (Groshong, 2016). Many terms are used to describe different types of mathematical models in mathematics education literature. In addition, a single mathematical modeling activity can be described using several terms (Figure 3). *Empirical* models rely on data whereas *mechanistic* models are rooted in theoretical statements. *Deterministic* models are nonrandom and *stochastic* models include randomness in the model output. Combining these concepts suggests that empirical-deterministic models are built from regression relations; empirical-stochastic models may use analysis of variances techniques; mechanistic-deterministic models arise from theoretical equations; and mechanistic-stochastic models yield probabilistic equations (Edwards & Hamson, 2007).


Figure 3. Different types of mathematical models (Groshong, 2016).

Solutions that address a single situation are *specific models*, and those addressing multiple versions of the situation are *general models*. When examining the overall model, *quantitative models* produce mathematical expressions that can predict or explain responses, and *qualitative models* are frequently use logical arguments to describe patterns and trends. In the initial modeling stages, *descriptive models* are often narratives or representations that include assumptions, define variables, and detail real-life issues (Tam, 2011). Mathematical methods are applied to yield exact answers from *analytical models*. *Static models* take a "snapshot" of time in an equilibrium condition. *Dynamic models* examine how the situation changes with the passage of time. Number values used in modeling my yield *continuous models* with all values between two endpoints acceptable, and *discrete models* treat variables as countable numbers.

Working group plan

The working group has begun and will continue the discussion of mapping the subcategories outlined by Ball, Thames, and Phelps (2008) to mathematical, modeling, and pedagogical content areas in hopes of more clearly defining mathematical modeling knowledge for teaching. Possible discussion topics in these MMKT dimensions include the following:

1. What mathematical knowledge is needed for working with different types of mathematical modeling tasks?
2. What modeling knowledge is needed for working with different types of mathematical modeling tasks?
    o How can modeling knowledge for working with different types of mathematical modeling tasks be identified?
    o How much contextual knowledge of the real world is needed to work with different types of mathematical modeling situations?
3. What pedagogical knowledge is needed for working with different types of mathematical modeling tasks?

Working Group Plan for Active Engagement of Participants

Participants are eagerly invited to join this working group to actively participate in defining this important research area. To continue examining this research question, we propose that members of the working group will divide into smaller groups providing an intellectual support system to critique the definitions, taxonomies, and framework as currently detailed, discuss the suggested focus

questions, and generate new research questions. The working group is committed to the goals of PME-NA while emphasizing collective reflection and collaborative inquiry, addressing challenges, and expanding the field of research. The working group will meet three times during the conference and virtually during the course of one year.

Session 1: Foundation

The first session will discuss common definitions in modeling research, summarize the previous year's working sessions, detail the progress made during the year, and outline the goals for the up-coming year. This will lay a common foundation for all participants to fully engage in the session discussions needed to define a mathematical modeling knowledge for teaching framework. Using the types of mathematical models' taxonomy and the mathematical modeling task analysis framework, sample mathematical modeling tasks will be provided to promote discussion, critique definitions and categorizations, and identify mathematical, modeling, and pedagogical knowledge needed by teachers for implementing these tasks in secondary mathematics lessons. Since it has shown to be successful for eliciting participation within this working group, members will again be invited to share mathematical modeling tasks with the group and generate research questions. The final part of the session will include sharing contact information and encouraging the formation of research groups based on the interests of the participants.

Session 2: Mathematical modeling knowledge for teaching framework

The second session will continue the work from the previous session to further define mathematical knowledge, modeling knowledge, and pedagogical knowledge. Employing the task analysis as a vehicle to elicit understanding of the different knowledge types, participants will discuss a mapping between Ball, Thames, and Phelp's (2008) MKT and a potential MMKT framework more clearly defining the content and pedagogical knowledge subcategories and providing specific exemplars. Participants will revisit last year's lively discussion about the influence of the real world contextual knowledge and experiences in modeling and, then, consider the placement of the knowledge of the real world in the MMKT framework.

Session 3: Modeling Knowledge

The last session will summarize the previous days' findings, articulate research goals, and outline a working plan for designing research projects to be conducted during the upcoming year. Participants will be encouraged to join the ongoing research discussions virtually.

Post-conference

To promote the working group's efforts, the results of all sessions and meetings will be documented and disseminated to all members. Following the conference, participants will be invited to continue discussing research interests in this area through a web-based discussion forum, which will continue to offer an environment for suggesting and reviewing research, posing and critiquing mathematical modeling tasks, posting and discussing teacher and student solutions, and developing an archive of useful and productive mathematical modeling tasks. Working group members will continue to participate in digital meetings throughout the year to review progress on scholarship. Findings of the working group and subsequent discussions will be summarized and reported.

Conclusion

While this working group is still in its infancy, considerable in-roads have been made in establishing a theoretical foundation built upon research principles. This groundwork has yielded operational definitions for distinguishing between the confusing yet often interchanged phrases of mathematical modeling, modeling mathematics, and modeling with mathematics. Drawing upon the theoretical research classifying different mathematical models by their mathematical features and

general characteristics provides another tool for revealing facets of mathematical modeling knowledge for teaching. On-going research is needed to validate the working group's current thinking and refine the proposed MMKT framework. This research can expand our understanding of teaching knowledge and advice teacher training programs.

Embodied cognition is growing in theoretical importance and as a driving set of design principles for curriculum activities and technology innovations for mathematics education. The central aim of the EMIC (Embodied Mathematical Imagination and Cognition) Working Group is to attract engaged and inspired colleagues into a growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education. A thriving, informed, and interconnected community of scholars organized around embodied mathematical cognition will broaden the range of activities, practices, and emerging technologies that count as mathematical. EMIC builds upon our 2015 working group, and investigations in formal and informal education and workplace settings to bolster and refine the theoretical underpinnings of an embodied view of mathematical thinking and teaching, while reaching educational practitioners at all levels of administration and across the lifespan.

Keywords: Classroom Discourse, Cognition, Informal Education, Learning Theory

Motivations for This Working Group

Recent empirical, theoretical and methodological developments in embodied cognition and gesture studies provide a solid and generative foundation for the establishment of **an Embodied Mathematical Imagination and Cognition (EMIC) Working Group** for PME-NA. The central aim of EMIC is to attract engaged and inspired colleagues into a growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education, including, but not limited to, studies of mathematical reasoning, instruction, the design and use of technological innovations, learning in and outside of formal educational settings, and across the lifespan.

The interplay of multiple perspectives and intellectual trajectories is vital for the study of embodied mathematical cognition to flourish. Partial confluences and differences have to be maintained throughout the conversations; this is because instead of being oriented towards a single and unified theory of mathematical cognition, EMIC strives to establish a philosophical/educational "salon" in which entrenched dualisms, such as mind/body, language/materiality, or signifier/signified are subject to an ongoing and stirring criticism. A thriving, informed, and interconnected community of scholars organized around embodied mathematical cognition will broaden the range of activities and emerging technologies that count as mathematical, and envision alternative forms of engagement with mathematical ideas and practices (e.g., De Freitas & Sinclair, 2014). This broadening is particularly important at a time when schools and communities in North America face persistent achievement gaps between groups of students from many ethnic backgrounds, geographic regions, and socioeconomic circumstances (Ladson-Billings, 1995; Moses & Cobb, 2001; Rosebery, Warren, Ballenger & Ogonowski, 2005). There also is a need to articulate evidence-based findings and principles of embodied cognition to the research and development communities that are looking to generate and disseminate innovative programs for promoting mathematics learning through

movement (e.g., Petrick Smith, King, & Hoyte, 2014). Generating, evaluating, and curating empirically validated and reliable methods for promoting mathematical development and effective instruction through embodied activities that are engaging and curricularly relevant is an urgent societal goal.

The EMIC Working Group: A Brief History

The first meeting of the EMIC working group took place in East Lansing, MI during PME-NA 2015. It has a somewhat longer origin, however, growing out of several earlier collaborative efforts to review the existing literature, document embodied behaviors, and design theoretically motivated interventions. One early event was the organization of the 2007 AERA symposium, "Mathematics Learning and Embodied Cognition" (Nemirovsky, 2007). This and other gatherings led to a funded NSF "catalyst" grant to explore a Science of Learning Center, which was to involve scholars from multiple institutions and countries. Though unfunded, those SLC efforts shaped a subsequent 6-year NSF-REESE grant, "Tangibility for the Teaching, Learning, and Communicating of Mathematics," starting in 2008. Interest from the International PME community in this topic grew, and led to special issues of *Educational Studies in Mathematics* (2009), *The Journal of the Learning Sciences* (2012), and an NCTM 2013 research pre-session keynote panel, "Embodied cognition: What it means to know and do mathematics," along with a series of academic presentations, book chapters, and journal articles, as well as several masters' theses and doctoral dissertations. By now, several research programs have formed to investigate the embodied nature of mathematics (e.g., Abrahamson 2014; Alibali & Nathan, 2012; Arzarello et al., 2009; De Freitas & Sinclair, 2014; Edwards, Ferrara, & Moore-Russo, 2014; Lakoff & Núñez, 2000; Radford 2009), demonstrating a "critical mass" of projects, findings, senior and junior investigators, and conceptual frameworks to support an on-going community of likeminded scholars within the mathematics education research community.

It was within this historical context that approximately 22 members of PME-NA 2015 came together for three 90-min sessions of semi-structured activities. On **Day 1,** the organizers engaged attendees in some of the body-based math activities used in their research on proportional reasoning and geometry. We discussed how embodied theories are advancing our understanding of mathematical thinking, and how these ideas are shaping a new class of educational interventions. During **Day 2**, we used hands-on activities to expand our own understanding of topology. We then built on the emerging rapport among the group to hold a facilitated discussion of the potential intellectual benefits of forming a self-sustaining Working Group on embodied cognition, along with the necessary infrastructure it would need to maintain. Several concrete proposals led to the list of Future Steps on **Day 3**. However, before we tackled those matters, participants began the session doing math games and activities in small groups, including Spirograph, Set, Rush Hour, Tangrams, and Mastermind. We reflected on how some games and activities draw people into rich mathematical thinking and actions, and how we naturally engage in math through these activities. Day 3 culminated in an organized list of Future Steps, with some working group members assigned to specific tasks.

Since our first meeting at PME-NA 2015 **our accomplishments** include:

1. Creating a contact list with names and emails of attendees ($n = 22$) and other interested scholars who could not attend PME-NA 2015 ($n = 25$);
2. Developing a group website using the Google Sites platform to support ongoing interactions throughout the year
3. Joint submission of an NSF DRK-12 by members who first met during the 2015 EMIC sessions
4. Some senior members joining a junior member's NSF ITEST grant proposal
5. Submitting a proposal for the continuation of the EMIC WG to PME-NA 2016

6. Examining the potential for an NSF Research Coordination Network (RCN)

Focal Issues in the Psychology of Mathematics Education

Emerging, yet still influential, views of thinking and learning as embodied experiences have grown from several major intellectual developments in philosophy, psychology, anthropology, education, and the learning sciences that frame human communication as multi-modal interaction, and human thinking as multi-modal simulation of sensory-motor activity (Clark, 2008; Hostetter & Alibali, 2008; Lave, 1988; Nathan, 2014; Varela et al., 1992; Wilson, 2002). These views acknowledge the centrality of both unconscious and conscious motor and perceptual processes for influencing conscious awareness, and of embodied experience as following/producing pathways through social and cultural space. As Stevens (2012, p. 346) argues in his introduction to the *JLS* special issue on embodiment of mathematical reasoning,

> it will be hard to consign the body to the sidelines of mathematical cognition ever again if our goal is to make sense of how people make sense and take action with mathematical ideas, tools, and forms.

Four major ideas exemplify the plurality of ways that embodied cognition perspectives are relevant for the study of mathematical understanding: (1) Grounding of abstraction in perceptuo-motor activity as one alternative to representing concepts as purely amodal, abstract, arbitrary, and self-referential symbol systems. This conception shifts the locus of "thinking" from a central processor to a distributed web of perceptuo-motor activity situated within a physical and social setting. (2) Cognition is for action. This tenet proposes that things, including mathematical symbols and representations, are understood by the actions and practices we can perform with them, and by mentally simulating and imagining the actions and practices that underlie or constitute them. (3) Mathematics learning is always affective: there are no purely procedural or "neutral" forms of reasoning detached from the circulation of bodily-based feelings and interpretations surrounding our encounters with them. (4) Mathematical ideas are conveyed using rich, multimodal forms of communication, including gestures and tangible objects in the world.

Alongside these theoretical developments have been technical advances in multi-modal and spatial analysis, which allow scholars to collect new sources of evidence and subject them to powerful analytic procedures, from which they may propose new theories of embodied mathematical cognition and learning. Just as the "linguistic turn" in the social sciences was largely made possible by the innovation that enabled scholars to collect audio recordings of human speech and conversation *in situ*, growth of interest in multi-modal aspects of communication have been enabled by high quality video recording of human activity (e.g., Alibali et al., 2014; Levine & Scollon, 2004), motion capture technology (Hall, Ma, & Nemirovsky, 2015; Sinclair, 2014), and developments in brain imaging (e.g., Barsalou, 2008; Gallese & Lakoff, 2005).

Plan for Active Engagement of Participants

Our formula from PME-NA 2015 proved to be effective: By inviting participants into math activities at the beginning of each session, we were rapidly drawn into those very aspects of mathematics that we find most rewarding. Facilitated discussions (and we now have many effective members who can trade off in this role!) then help us all to "pull back" to the theoretical and methodological issues that are central to advancing math education research. Within this structure of beginning with mathematical activities and facilitated discussions, on **Day 1** we plan to introduce our new website, demonstrate the online resources for building sustained community, and revisit and further develop the items listed in our Future Steps, including assigning roles to EMIC members. On **Day 2**, we will discuss concrete goals and products. One example is the NSF Research Coordination Network (RCN), as a potential compliment to the PME-NA Working Group. The RCN is not

intended to promote any one particular research program, but rather to build the networked community of international scholars from which many fruitful lines of inquiry can emerge. Commensurate with the aims of the RCN, we will explore ways to

> share information and ideas, coordinate ongoing or planned research activities, foster synthesis and new collaborations, develop community standards, and in other ways advance science and education through communication and sharing of ideas.

This sharing and coordination will continue into **Day 3**. One proposed activity is to perform a live concept mapping activity that is displayed for all participants to explore the range of EMIC topics and identify common conceptual structure. Harkening back to the four major ideas that we developed earlier, sample seed topics for organizing this activity will be explored, such as:

1. Grounding Abstractions
   a. Conceptual blending (Tunner & Fauconnier, 1995) & metaphor (Lakoff & Núñez, 2000)
   b. Perceptuo-motor grounding of abstractions (Barsalou, 2008; Glenberg, 1997)
   c. Progressive formalization (Nathan, 2012; Romberg, 2001) & concreteness fading (Fyfe, McNeil, Son, & Goldstone, 2014)
   d. Use of manipulatives (Martin & Schwartz, 2005)
2. Cognition is for Action: Designing interactive learning environments for EMIC
   a. Development of spatial reasoning (Liu, Uttal, Marulis, & Newcombe, 2008)
   b. Math cognition through action (Abrahamson, 2014; Nathan et al., 2014)
   c. Perceptual boundedness (Bieda & Nathan, 2009)
   d. Perceptuomotor integration (Nemirovsky, Kelton, & Rhodehamel, 2013)
   e. Attentional anchors and the emergence of mathematical objects (Abrahamson & Sánchez–García, in press; Abrahamson, Shayan, Bakker, & Van der Schaaf, in press)
   f. Mathematical imagination (Nemirovsky, Kelton, & Rhodehamel, 2012)
   g. Students' integer arithmetic learning depends on their actions (Nurnberger-Haag, 2015).
3. Affective Mathematics
   a. Modal engagements (Hall & Nemirovsky, 2012; Nathan et al., 2013)
   b. Sensuous cognition (Radford, 2009)
4. Gesture and Multimodality
   a. Gesture & multimodal instruction (Alibali & Nathan 2012; Cook et al., 2008; Edwards, 2009)
   b. Bodily activity of professional mathematicians (Nemirovsky & Smith, 2013)
   c. Simulation of sensory-motor activity (Hostetter & Alibali, 2008; Nemirovsky & Ferrara, 2009)

Finally, we will introduce the EMIC website (see Figure 1) and invite members to join, and to encourage their interested colleagues to email Caro at cwilliamspierce@albany.edu for access. On this website, we have a list of members with their emails and bios, information about our PME-NA presence, and short personal introduction videos. We've also created a space for members to share information about their research activities – particularly for videos of the complex gesture and action-based interactions that are difficult to express in text format. In addition, we have a common publications repository to share files or links (including to ResearchGate or Academia.edu publication profiles, so members don't have to upload their files in multiple places). At our 2015 working group, some junior members expressed particular interest in this literature support for their pending theses, while more senior members were eager to share and organize the emerging body of

work on embodied math education. We've also linked the Google Sites platform directly to a Google Group, so members can participate in online forums (or the linked listserv), and discuss cutting edge topics, share in-progress working papers for review, or advertise for conferences, special issues, or other EMIC-relevant opportunities.

Figure 1. The EMIC website landing page serves as one of the ways EMIC members can share information about themselves and their work, support a common paper repository, post relevant announcements, and coordinate emerging collaborations.

Follow-up Activities

Even prior to our first anniversary, we have already seen a great deal of progress. This is perhaps best exemplified by coming together of the EMIC website and this proposal submission, which draws across multiple institutions. We envision an emergent process for the specific follow-up activities based on participant input and our multi-day discussions. At a minimum, we will continue to develop a list of interested participants and grant them all access to our common discussion forum and literature compilation. Those that are interested in the NSF RCN plan will work to form the international set of collaborations and articulate the intellectual topics that will knit the network together. One additional set of activities we hope to explore is to introduce educational practitioners at all levels of administration and across the lifespan to the power and utility of the EMIC

perspective. We thus will strive to explore ways to reach farther outside of our young group to continually make our work relevant, while also seeking to bolster and refine the theoretical underpinnings of an embodied view of mathematical thinking and teaching.

Mathematics interventions have proliferated within the field of mathematics education as schools are under increasing pressure to raise the mathematics test scores of low-achieving students, particularly students of color and students with disabilities. These interventions target individual students and are based on a deficit model; the problem is located within the individual student rather than in the social, discursive, political, or structural context. These interventions also tend to focus primarily on rote algorithms and calculation skills rather than the solving of rigorous, high cognitive demand problems. Our working group is composed of researchers and teachers who draw upon critical theories, such as Disability Studies in Education, Critical Race Theory, and DisCrit, in order to offer an alternative vision of mathematics education based around a different type of intervention. Rather than making an intervention into the deficits of an individual student, our working group suggests that we need to make an intervention into classroom practice, utilizing models like Complex Instruction (CI) and Universal Design for Learning (UDL) to create classrooms in which all students are able to access the curriculum in meaningful and rigorous ways.

Keywords: Classroom Discourse, Equity and Diversity, Instructional Activities and Practices

Rationale: Framing the Problems/Questions of the Working Group

The title of this working group, Reframing Interventions in Mathematics Education, Emerging Critical Perspectives, is intended to evoke a double meaning. It can be read as an intention to critique the practice of intervention in the field of mathematics education; alternatively, the title can be read as inviting critical interventions into mathematics and mathematics education. By pursuing both paths simultaneously, we intend to stimulate productive discussions and lay the foundation for future projects during our work in the span of three working group sessions.

Mathematics Intervention

Intervention programs have become ubiquitous within mathematics education as teachers and schools are under pressure to raise mathematics test scores. These programs utilize service delivery models such as Resource Specialist Programs (RSP) and Response to Intervention (RTI) and techniques such as Progress Monitoring in order to identify students in need of intervention and deliver interventions. These interventions rarely focus on increasing student participation in classroom discourse; they instead focus primarily on basic fact acquisition and algorithmic fluency. Most districts use older models that measure mathematics students against normative standards of development, with instruments such as the Woodcock-Johnson, the Wechsler Individual Achievement Test (WIAT), and the KeyMath being used to diagnose areas in which students' "achievement" fails to match what IQ tests show as their "ability." Some districts use newer models

such as RTI for diagnosis, which claim to identify and classify students based on their response to "scientific", "evidence-based" interventions. Progress monitoring techniques such as AIMSweb focus less on testing of "ability" and instead focus on repeated assessment of students' mathematical skills, but the data collected still tends to focus myopically on basic calculation skills. The problem, our working group believes, is not with the instruments being used to assess, but with the very concept of intervention itself.

The Problem with Intervention

To better understand the concerns we are raising about the concept of intervention, we invoke the history of the term, finding that the very etymology of the word points to some problematic assumptions imbedded within. The English word "intervention" comes from the Latin "inter," meaning "between," and "venire," meaning "to come." Etymologically then, intervention implies "coming between." Two core assumptions are embedded in the concept of intervention. The first assumption is that there is something wrong with the situation at hand that needs to be changed. The second assumption is that it is someone or something from outside the situation that must "come into" the situation and make the change. Often, in education generally and in mathematics education in particular, the need for intervention is taken-for-granted. However, acknowledging the assumptions upon which the concept of intervention rests raises numerous questions about the idea of intervention in education, and specifically in mathematics education. The critique that we are offering asks questions such as:

1. To what extent is "intervention" necessary or desired in the situations in which it is currently used? Necessary for what and to whom? Desired by whom and for what purpose?
2. What aspects of the situations are taken as "wrong" and requiring intervention?
3. Who benefits from interventions, and in what ways?
4. What are the implications of the fact that the concept of intervention is based on the assumption that someone from the outside must "come in" to make changes?
5. What counts as "intervention"; are interventions only narrow, technical methods used to correct problems with a particular student or can we expand the concept of intervention to create meaningful change within classrooms?

In our current historical moment in the United States we believe it is important to consider the way that "interventions" are used for low-achieving students (especially students of color and students with disabilities) and to offer critical alternatives to the practice and philosophy of intervention.

Drawing upon Theory

Gathering together a group of researchers, graduate students, undergraduate students, and classroom teachers interested in developing an alternate paradigm around intervention, we have begun to explore the different theoretical frameworks that we can use to analyze and change this situation within mathematics education. Heeding Lather's (1986) call for researchers to utilize multiple theoretical schemes in their work, our working group believes that this work requires the participation of multiple paradigms of critique. Our working group draws upon critical theories such as disability studies, critical race theory, and other poststructural theories (including queer studies and trans studies) in this analysis. A commonality among these perspectives is that each problematizes normativity. We welcome the participation of those with other perspectives as well. In the following sections, we describe a sampling of these perspectives in order to frame the work of the group.

Critical Theories

Although the notion of critique dates back to antiquity, the phrase critical theory originally referred to a body of work coming out of the Frankfurt School and Institute for Social Research in the late 1920s through the early 1940s. Critical theory seeks to reshape reality, not merely explaining things. As Karl Marx (1845) wrote almost a century earlier, "The philosophers have only interpreted the world, in various ways; the point is to change it." Critical theory has come to mean not just the work of the original critical theorists, but any theory that seeks to transform rather than merely explain society. The Stanford Encyclopedia of Philosophy gives three main criteria for a critical theory, that "it must explain what is wrong with current social reality, identify the actors to change it, and provide both clear norms for criticism and achievable practical goals for social transformation." All of the theoretical perspectives that our working group draws upon are in some ways "critical theories."

Disability Studies and Disability Studies in Education

Many of the members of our working group utilize disability studies (DS) and disability studies in education (DSE) as a mode of inquiry in order to questioning the taken-for-granted assumptions and practices in mathematics education and the intervention paradigm. DS and DSE provides a framework for exploring questions such as: who is labeling, who is being labeled, and how do we advance more equitable practices for all students. Disability studies calls into question the medical/individual model of disability in which disability is seen as a deficit within an individual that requires "curing."

In contrast to the medical model, many disability studies scholars and activists have adopted a social model of dis/ability, which locates dis/ability in an inaccessible environment. Those who adopt the social model of dis/ability make a distinction between impairment, as any physical or mental limitation, and disability, as the "social exclusions based on, and social meanings attributed to, that impairment" (Kafer, 2013, p. 7). Kafer (2013), however, argues that such a sharp distinction between impairment and dis/ability is unhelpful because it "fails to recognize that *both* impairment and disability are social" (p. 7). In the book *Feminist Queer Crip*, Kafer suggests the term "political/relational model" to refer to perspectives recognizing that both impairment and dis/ability are socially constructed.

In educational settings, this construction of dis/ability manifests in the double education system that splits general education and special education. Scholars have traced the ways in which special education "serves as a vehicle for preserving general education in the midst of ever increasing diversity" (Reid & Valle, 2004, p. 468, paraphrasing Dudley-Marling, 2001; also see Skrtic, 1991, 2005). Rather than using research-validated frameworks like Universal Design for Learning (UDL) and Complex Instruction (CI) to deliver rigorous, high-cognitive demand instruction to all mathematics students, the system of special education shunts certain students (especially students of color) into an inferior, segregated mathematics education, thus providing a band-aid to a broken general education system and preventing larger, more systematic changes. One line of research pursued by working group members involves developing understanding and theorizing the research divide between special education and mathematics.

Institutional schooling practices such as writing Individual Education Plans (IEPs) construct certain students as having disabilities; however, from a disability studies perspective, "the label of students with IEPs [can be viewed] not as an inherent and static determinant of individual ability, but as a school-based designation which reflects and recreates differential ability within the classroom" (Foote & Lambert, 2011, p. 250; also see Dudley-Marling, 2004; McDermott, Goldman & Varenne, 2006; Skrtic, 2005). Certain students are chosen for this assessment and intervention, and this selection process is not objective and often singles out those students who are not from a dominant cultural background.

Returning to the assumptions inherent in the concept of intervention, a disability studies perspective problematizes the taken-for-granted assumption that what is "wrong" with the situation requiring intervention is a pathology or deficit within students. Instead, the problem is located in the inaccessibility of the environment; in other words, what needs to be changed is not the student, but rather the environment to allow access for students who differ from one another. As Reid and Valle (2004) assert, "the responsibility for 'fitting in' has more to do with changing public attitudes and the development of welcoming classroom communities and with compensatory and differentiated instructional approaches than with individual learners (Shapiro, 1999). In other words, our focus is on redesigning the context, not on 'curing' or 'remediating' *individuals'* impairments" (p. 468). A related line of research of working group members involves conceptualizing interventions into *participation* rather than content. That is, what interventions might contribute to more equitable participation and deeper engagement across students in mathematics classrooms? For example, one of the working group members has conducted empirical research focused on equitable participation in a Cognitively Guided Instruction algebra routine. Moreover, a political/relational model suggests that inaccessibility is embedded in the context of power relations. Finding ways to "intervene" to make the environment accessible, then, also requires analyzing the power relations involved in maintaining inaccessibility.

Critical Race Theory and DisCrit

Critical race theory (CRT) is another theoretical framework that informs the work of the group. According to CRT, racism is 'normal' rather than an anomaly in U.S. society (Delgado, 1995). Critical race theorists assert that the U.S. was founded on property rights, and specifically the fact that enslaved African Americans were considered property, rather than civil rights (Ladson-Billings & Tate, 1995). CRT reveals the way race and racism continue to structure U.S. society. In relation to educational interventions, critical race theorists have addressed the issue of over-representation of students of color in special education.

Often, however, these analyses leave ableist assumptions in place; similarly, DS perspectives often fail to adequately consider race. DisCrit is a perspective that acknowledges that racism and ableism are both "normalizing processes that are interconnected and collusive. In other words, racism and ableism often work in ways that are unspoken, yet, racism validates and reinforces ableism, and ableism validates and reinforces racism" (Connor, Ferri, & Annamma, 2016, ch. 1). Studies of administrators' and teachers' perceptions related to overrepresentation of students of color in special education have revealed that their perceptions tend to be rooted in "deficit thinking and infused with racial and cultural factors" (Connor, Ferri, Annamma, 2016, ch. 1; also see Abram et al., 2001 and Skiba et al, 2006). DisCrit perspectives, therefore, identify the individual problematic attitudes of teachers and administrators as one "accessible entry point for intervention" (Connor, Ferri, Annamma, 2016, ch. 1).

Summary of the Problem

This working group will investigate the problem of interventions in mathematics education. Using multiple theoretical frameworks, the working group participants will analyze current practices in mathematics interventions, including the power relations involved, and develop and elaborate on alternatives. The working group participants will also plan ways to evaluate these alternatives in various educational settings and contexts.

Plan for Active Engagement of Working Group Participants

Prior to Session 1

The organizers will choose 2-3 articles or book chapters from different perspectives related to the theme of the working group. The organizers will send out the list of readings to participants who have expressed interest in the working group.

Session 1

In the first session, the organizers will introduce the rationale for the working group and the current state of related research. Participants will share related projects in which they are involved. The group will collaboratively refine the goals of the working group. The organizers will share the list of chosen readings with any participants who did not previous have access to them.

Session 2

In the second session, participants will discuss the chosen readings in relation to the goals refined in the first session. Participants will discuss the ways in which the readings relate to ongoing projects and possible future collaborative projects.

Session 3

In the second session, participants will discuss the chosen readings in relation to the goals refined in the first session. Participants will discuss the ways in which the readings relate to ongoing projects and possible future collaborative projects.

Plan for Sustainability: Anticipated Follow-up Activities

The working group sessions during the conference are designed to enable the participants to develop concrete plans for collaborative work beyond the end of the conference timeframe. Specifically, the third session is allotted for developing specific plans for future collaborative work.

CONCEPTIONS AND CONSEQUENCES OF WHAT WE CALL ARGUMENTATION, JUSTIFICATION, AND PROOF

Megan Staples	Jill Newton	Karl W. Kosko

aconner@uga.edu	mcirillo@udel.edu	kbieda@msu.edu

Argumentation, justification, and proof are conceptualized in many ways in extant mathematics education literature. At times, the descriptions of these objects and processes are compatible or complementary; at other times, they are inconsistent and even contradictory. The inconsistencies in definitions and usages of the terms argumentation, justification, and proof highlight the need for scholarly conversations addressing these (and other related) constructs. Collaboration is needed to move toward, not one-size-fits-all definitions, but rather a framework that highlights connections among them and exploits ways in which they may be used in tandem to address overarching research questions. Working group leaders aim to facilitate discussions and collaborations among researchers and to advance our collective understanding of argumentation, justification and proof, particularly the relationships among these important mathematical constructs. The 2016 working group sessions will provide continued opportunities for participants to discuss existing definitions and descriptions as well as opportunities to consider how these definitions and descriptions are related to the positionality of researchers and the contexts of their research. Participants will examine data sources through a variety of lenses as a means to investigate the use of particular conceptualizations.

Keywords: Reasoning and Proof, Advanced Mathematical Thinking

Brief History of the Working Group

The *Conceptions and Consequences of What We Call Argumentation, Justification, and Proof* Working Group met for the first time in 2015 at Michigan State University in East Lansing, Michigan during the 37th Annual Meeting of the North American Chapter of the Psychology of Mathematics Education. The main goal of this working group is to advance the field's collective understanding of the interrelated objects and processes of argumentation, justification, and proof. Although past working groups had focused on proof or argumentation, this was the first working group at PME or PME-NA meetings focused specifically on the connections among these three constructs.

During the first year, we made progress on considering the interrelationships among argumentation, justification and proof, and we deepened our understandings of our own perspectives and the range of perspectives held by others in the group. Our goal was not consensus or deciding a best approach, but rather making sense of the diversity among and the priorities of individuals with respect to their research agendas. We were encouraged that our efforts were well received with 46 scholars, including at least 10 graduate students participating in the working group the first year.

A focal activity during these initial working group sessions was the development of Diagrams/Concept Maps in which each participant generated a representation of the relationships among argumentation, justification and proof from his or her perspective. Each participant also identified the concept that was most central to his or her work (i.e., argumentation, justification, or proof). This activity was followed by a presentation by Keith Weber, a co-author of the proof chapter

in the forthcoming NCTM compendium for research (Stylianides, Stylianides, & Weber, in press). He offered an historical view on the use of these constructs in mathematics and educational research, highlighting for us convergence and contradictions in definitions and research results in the proof literature.

Our second day featured a panel presentation, moderated by Samuel Otten, with Kristen Bieda, AnnaMarie Conner, and Pablo Mejía -Ramos serving as our expert panelists. Each panelist identified one of the three constructs as central to his or her work (i.e., Bieda - justification; Conner - argumentation; and Mejía-Ramos – proof). The panelists shared how they conceptualized the interrelationships among argumentation, justification and proof; they explicated how they came to use the central construct they use in their research and why they felt that choice is productive for their work; and they offered their thoughts on the current state of the field and what we might need to tackle next in relation to these constructs.

The final day of our work together offered the opportunity to revisit participants' Diagrams/Concept Maps, though now potentially informed by additional perspectives and questions gained from the prior two sessions. Participants viewed the full set of Diagrams/Concept Maps through a gallery walk and had the option to annotate and revise their diagrams as desired. The set of diagrams were artifacts for extensive and lively discussion on Day 3. All participants from the working group were invited to collaborate on a white paper that would include brief analyses of the diagrams.

As a result of our three days together, three products were generated. First, a pair of podcasts are available worldwide: The first podcast is of Weber's talk, and the second podcast is the moderated panel discussion. Thanks to Sam Otten, the podcasts are available at http://mathed.podomatic.com/entry/2015-11-16T07_01_19-08_00 and http://mathed.podomatic.com/entry/2015-11-19T07_19_37-08_00, respectively. The second product is a white paper which was developed by the working group organizers, the panelists, and several other participants from the working group who volunteered to participate in the online publication (Cirillo et al., 2016). The white paper summarizes the working group activities and discussions and also includes the set of 44 Diagrams/Concept Maps that were generated as well as annotations and analyses. The final product is a poster proposal for PME-NA 2016 that is based on the analyses of the Diagrams/Concept Maps. Last, we were able to begin creating a community of mathematics education professionals who we hope will continue these discussion over several years.

Summary of Focal Issues

There is a large and growing body of research in mathematics education focused on argumentation, justification, and proof. The research on proof, for example, includes studies on: the role of proof in the discipline; proof in school mathematics and at the undergraduate level; what counts as a proof; proof schemes and categories; teachers' conceptions of proof; students' abilities to write valid proofs; and what teaching proof looks like in classrooms at various levels (e.g., Boero, 2007; Harel & Sowder, 2007; Reid & Knipping, 2010; Stylianou, Blanton, & Knuth, 2009). At the same time, researchers and policy documents have issued calls to engage K-12 students with disciplinary practices such as constructing viable arguments, justifying conclusions, critiquing the reasoning of others, and constructing proofs for mathematical assertions (National Council of Teachers of Mathematics [NCTM], 2000; National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010).

Yet, as the field moves forward to maximize students' learning opportunities for engaging in these disciplinary practices, mathematics educators need to refine their notions of these terms in scholarly activities and in policy documents (Cai & Cirillo, 2014). How, when, and why decisions related to word choices are made (e.g., 'argument' versus 'proof') in curriculum materials, policy documents, and research is an open question. In fact, some researchers have hinted that these choices

are not always purposeful. For example, Lynn Steen, a member of the 1989 NCTM Standards Committee, claimed that uncertainty about the role of proof in school mathematics caused NCTM in its 1989 *Standards* document to resort to, what he called, "euphemisms" such as "'justify,' 'validate,' 'test conjectures,' [and] 'follow logical arguments'" (Steen, 1999, p. 274). Rarely, he stated, did the document use the term 'proof.' Although Steen's comments were published more than 15 years ago, we argue that his proposition, that the role of proof (as well as argumentation and justification) in school mathematics is uncertain, continues to be true today.

One additional challenge of reading extant research or developing a research agenda related to these disciplinary practices is that the classifications offered differ according to the perspective of the researcher, the focus of the research, and the particular data being analyzed (Reid & Knipping, 2010). Only recently have we begun to see mathematics educators offering explicit definitions of these constructs in their work; this is ironic given the importance of definitions in the field of mathematics itself.

Although proof has received more attention in extant research, argumentation as a concept, seems to be garnering new prominence, as it is a process that is playing an important role in policy and curricular documents across many disciplinary fields. The notion of constructing and analyzing arguments appears in the most recent standards in four core K-12 disciplines – English, mathematics, social studies and science. For example, the *Common Core State Standards for Mathematics (CCSSM)* includes as one of its standards for mathematical practice, "Construct viable arguments and critique the reasoning of others." Similarly, *CCSS for English Language Arts* devotes a portion of an appendix to "The Special Place of Argument in the Standards," emphasizing argumentation as critical for success in college and careers (Appendix A, pp. 24-25). The National Council of the Social Studies (NCSS) highlights argumentation as an aspect of historical thinking, with a focus on causation and argumentation (NCSS, 2013). A summary table of where and how references to arguments or argumentation appear in the policy documents is included in Table 1.

On a related note, although not an explicit Standard for Mathematical Practice, we find evidence in past and current mathematics standards documents that *justification* is considered an important mathematical practice. For example, in the 1989 *Standards*, it was noted by the authors that throughout the document, "verbs such as *explore, justify,…describe, develop,* and *predict* are used to convey this active physical and mental involvement of children in learning the content of the curriculum" (NCTM, 1989, p. 17). In particular, students are asked to "justify their answers and solution processes" (p. 29) as part of the Mathematics as Reasoning Standard. In *Principles and Standards for School Mathematics (PSSM)* (NCTM, 2000), geometry is positioned as a natural site for the development of students' "reasoning and justification skills" (p. 41). Justifying is also explicitly linked to the Reasoning and Proof, Communication, and Problem Solving Process Standards in *PSSM*. Finally, the authors of *CCSSM* (NGA & CCSSO, 2010) consider "the ability to justify, in a way appropriate to the student's mathematical maturity, *why* a particular mathematical statement is true or where a mathematical rule comes from" (p. 4) to be a hallmark of mathematical understanding. Looking across time, analyses of standards adopted prior to that of *CCSSM* suggest a relatively infrequent inclusion of the terms justify/justification in content standards language (Larnell & Smith, 2011), with a significant increase in such usage in *CCSSM* (Kosko & Gao, in press). Together, these examples demonstrate that justification has been considered to be important in school mathematics for more than 35 years, with increased focus in recent years.

Table 1: Summary of References to Argument(ation) in Policy Documents

Standards	Role in Standards	Specific Reference for Practice or Recommendation
Common Core State Standards for Mathematics	One of eight Standards for Mathematical Practice that should be developed in students	3. Construct viable arguments and critique the reasoning of others. (p. 6)
Common Core State Standards for English Language Arts & Literacy	Argumentation identified as the first of the Standards' "Three Text Types"	The Special Place of Argument in the Standards in Appendix A: Research Supporting Key Elements of the Standards (p. 24)
Next Generation Science Standards	One of eight Science and Engineering Practices in the NGSS identified as essential for all students to learn	7. Engaging in argument from evidence (Appendix F, p. 13)
National Curriculum Standards for Social Studies	One of three factors related to "powerful" social studies teaching and learning	Teachers show interest in and respect for students' thinking and demand well-reasoned arguments rather than opinions voiced without adequate thought or commitment. (p. 13)

Highlights from the Year 1 Working Group Discussions

As described above, the three main activities from the Year 1 Working Group included: the Concept Map/Diagram activity, Weber's overview of where the field is now with respect to proof, and the panel discussion that featured prominent researchers of argumentation, justification and proof. Here we summarize some of the key points of discussion from these activities.

Weber's presentation highlighted different traditions and points of disagreement, for example, citing Reid's (2001) observation that research simultaneously suggests that secondary students struggle to construct proofs, while at the same time suggesting that primary children are capable of engaging in proof. Weber prompted the group to consider how different traditions may inform each other in order to advance the field collectively. In particular, he outlined three broad traditions in proving: *proving as problem solving, proving as convincing,* and *proving as socially embedded activity.* Each corresponds to a different focus for research and/or instruction. Weber offered two thought-provoking suggestions, both of which may help us understand the lack of convergence in results and definitions. One suggestion was that proof may not be a singular, easily defined concept, but rather a *cluster concept,* as used by Lakoff (1987). In this sense, there is no list or decision procedure to identify a proof, but rather there is a set of features associated with the concept, and many - but not all - apply in any one instance.

The second suggestion was that the features or properties associated with proof may be closely interrelated for mathematicians, but not for students. In particular, for mathematicians, a convincing argument and socially sanctioned argument are often one-in-the-same. For students, however, those are not tightly connected and may describe very different types of arguments. He suggested, "Perhaps much of the disagreement amongst mathematics educators is that they are using proof as a shorthand to denote things that are different to students but similar for mathematicians" (Cirillo et al., 2016, p. 7).

The panel discussion on our second day further raised awareness of how crucial it is to not only defines one's terms, but also the context of one's work. For example, Bieda and Conner both work closely with students and teachers in secondary settings, and in that context, they have found proof

and proving to be terms that distance or invoke conceptions of end product and formality. Consequently in their work, they have chosen different focal constructs. Both Bieda and Conner articulated an explicit link of their work to students' proof-producing capacities at the tertiary levels, but do not centralize that term in their research in school mathematics.

Our discussions and subsequent analyses of the Concept Diagrams/Maps offered additional information about the variety of ways these three important constructs are understood in relation to one another. During the gallery walk and subsequent analyses across the Concept Diagrams/Maps, we could discern little to no agreement about the relationship between justification and argumentation. It seemed that participants held these two constructs (justification and argumentation) either fully distinct from the set of things we call proof, or that proof was a very specific version of each of these. Some considered justification a subset of arguments; others positioned arguments as a subset of justifications; and still others had them as overlapping, but not concurrent, sets.

Proof (and proving) seemed to be of a different nature than argumentation and justification for our participants and proof participants either positioned it at the far end of a continuum of the constructs, a plane above, or as a separate entity. Alternately, however, others considered proof to be a specific subset of arguments and justifications. Additional details can be found in the recent White Paper (Cirillo et al., 2016). A question raised in the discussion on Day 3 was whether proof was so valorized that we position it as the "desired end product" for all arguments, even when that might not be a productive or educative goal. This lack of not only convergence, but general clarity provides an important opportunity for further exploration and raises questions about the consequences of these different concepts. It implores us to continue to work to develop a framework to connect these constructs and clarify not only our commitments and definitions, but the interrelationships among these important ideas.

Conceptual Focus for Year 2

As we move into our second year as a Working Group, we propose to focus our efforts on getting clearer about definitions of argumentation, justification, and proof with a desired goal of developing a level of shared understandings about these constructs. One idea that emerged from the panel discussion last year was how the setting, or context, of one's research informs the definitions of argumentation, justification or proof (or their corresponding actions) that a researcher uses as they carry out the work. Balacheff (2002) wrote that proof "depends upon content and context" (p. 24). Even within applied and pure fields of mathematics, what scholars accept as proof may have different characteristics.

One way to examine our conceptions of justification, argumentation and proof could be to explicitly acknowledge our positionality and commitments as researchers, particularly related to the content and/or contexts in which we study these products or processes. Consider Table 2 that shows a variety of definitions for these constructs from existing literature (summarized in Cirillo, Kosko, Newton, Staples, & Weber, 2015).

Table 2: Varying Definitions for Argumentation, Justification, and Proof

Proof/Proving	Argumentation	Justification/Justify
"the process employed by an individual to remove or create doubts about the truth of an observation" (Harel & Sowder, 1998, p. 241)	"mathematical explanation intended to convince oneself or others about the truth of a mathematical idea" (Mueller, Yankelewitz, & Maher, 2012, p. 376)	"to provide sufficient reason for" (National Research Council, 2001, p. 130)
"arguments consisting of logically rigorous deductions of conclusions from hypotheses" (NCTM, 2000, p. 55)	"discursive exchange among participants for the purpose of convincing others through the use of certain modes of thought" (Wood, 1999, p. 172)	"an argument that demonstrates (or refutes) the truth of a claim that uses accepted statements and mathematical forms of reasoning" (Staples, Bartlo, & Thanheiser, 2012, p. 448)
"a mathematical argument, a connected sequence of assertions for or against a mathematical claim, with the following characteristics: (1) It uses statements accepted by the classroom community (*set of accepted statements*) that are true and available without further justification; (2) It employs forms of reasoning (*modes of argumentation*) that are valid and known to, or within the conceptual reach of, the classroom community; and (3) It is communicated with forms of expression (*modes of argument representation*) that are appropriate and known to, or within the conceptual reach of, the classroom community." (Stylianides, 2007, p. 291)	"the process of making an argument, that is, drawing conclusions based on a chain of reasoning" (Umland & Sriraman, 2014, p. 44)	

The definitions in Table 2 take on new meaning when considered in light of the contexts and/or content in which they arose in the researchers' work, or when considering the researchers' positionality and commitments. Might it be possible that researchers could define proof differently in studying a middle school mathematics classroom than a high school geometry classroom? Consider specifically the widely cited definition of proof by Harel and Sowder (1998). For research on proving in middle school classrooms, does it make sense to view proof being done by a middle school student as something that removes or confirms doubt? How might the findings change if we are able to capture how students' define proof for their work in class? We hope for the working group to address these, and other questions, by clarifying our assumptions and positionality as researchers to get clearer about the definitions for argumentation, justification, and proof we use in our research and to advance our understanding of how contexts and content informs our conceptions.

Plan for the Working Group

As we approach Year 2, our goal for the working group is to continue to facilitate communication and collaboration among members of the mathematics education community who are involved in research and scholarship using constructs that include argumentation, proof, and justification. One of

the goals for this year is to understand the multiple definitions of these terms that inform our work. We also acknowledge that the context in which we work influences our definitions and how we use them, and we intend to examine how context relates to definitions. A second goal for this year is to focus on connecting people with similar interests in hope of facilitating lasting collaborations to further knowledge related to argumentation, proof, and justification in the field.

Session 1: Existing definitions and influence of context

In Session 1, we will begin with introductions and collecting participants' informal definitions or descriptions of argumentation, proof, and justification. An interactive panel discussion will provide additional insights and a basis for the next two sessions. Panelists will discuss the definitions or descriptions of argumentation, proof, and justification central to their work. They will also discuss how they see the relationships between the context of their research and the definitions or descriptions of argumentation, proof, and justification they employ in their analysis and findings from their work.

We have invited three panelists to participate, chosen to provide a variety of perspectives to the working group. Mara Martinez is an Assistant Professor of Mathematics Education at University of Illinois at Chicago. Her research has investigated argumentation and proof in algebra classes, and she will focus her remarks on conceptions of argumentation. Eric Knuth is a Professor of Mathematics Education at University of Wisconsin at Madison. He has published on the development of middle school students' capacities to justify and prove, as well as, more recently, the role of examples in doing proof. He will focus his remarks on conceptions of justification. Finally, Orit Zaslavsky is a Professor of Mathematics Education at New York University. Her research also focuses on the interplay among mathematical examples, definitions and proof, and her remarks will focus on conceptions of proof. The discussion will be moderated, with the following potential questions to provide focus for the discussion: *(1) Which construct (argument/argumentation, proof/proving, justification/justify) do you use most in your work? How do you define this construct? What has informed that choice? (2) What are your views on the need for researchers to establish unique definitions for these constructs? (3) In what ways are your conceptions of the phenomena central to your research still evolving*? As was done when the working group convened in 2015, Sam Otten will record the panel discussion and post the recording to the MathEd Podcast.

Following the panel discussion, we will invite participants to meet with panelists in three breakout groups, so that attendees can interact with a panelist in a small group setting and continue the conversation about the panel discussion and their related work. These small group breakouts are intended to serve as a catalyst for networking groups that will develop throughout the sessions.

Session 2: Constructing definitions for different contexts

Session 2 will extend the discussion from Session 1 regarding the applicability and interplay of particular constructs and definitions to specific contexts for research and practice. We will begin the session with a shared, virtual representation of definitions and descriptions generated in Session 1 (i.e., using a Google Spreadsheet). We will engage participants in examining which aspects of the definitions are more useful for working in particular contexts and why those aspects seem to be important. To facilitate this discussion, participants will examine how various definitions apply when presented with artifacts of student argumentation, justification, and proof. Specifically, participants will be provided samples of data from prior studies to consider the flexibility, applicability, and limitations of posed definitions and descriptions. These data will include artifacts from published studies on argumentation, justification, and proof (used with permission) from elementary, middle, secondary, and tertiary levels such as students' writing and transcripts of verbal interactions.

Following exploration of the data artifacts, we will facilitate a group discussion of the affordances and constraints of different definitions given the nature of the data, context, and research

focus. The session will conclude with participants completing a survey identifying the definitions they wish to explore further. The survey results will be used to establish preliminary networking groups for the third session.

Session 3: Networking groups

Our goal for Session 3 is to establish networking groups among working group participants. The long-term goal for the establishment of the networking groups is for members to generate knowledge and products related to the overarching goal of the working group: to advance the field's collective understanding of argumentation, justification, and proof. We will use the surveys, definitions, and contexts from the first two sessions to create suggested networking groups at the start of Session 3. However, participants may re-assign themselves to other, or new, networking groups. Working group participants will be given one guiding question for Session 3, specifically, given the definition for argumentation/ justification/proof that they consider of interest, which potential research questions would move the field forward in understanding this topic (argumentation/justification/proof)?

We anticipate that allowing participants to spend time discussing such potential research questions will facilitate variations of networking groups to become reading groups, research discussion groups or research collaboration groups. Further, the discussion will allow for the introduction of a wiki page for members of the networking groups to share research related to specific foci and as a general resource for furthering the goals of the working group. We will conclude the session with participants identifying productive points of collaboration within their groups, as well as a survey of which network group participants wish to continue their work, and how, during the year.

Anticipated Follow-up Activities

We anticipate that the products and follow-up activities from Year 2 will build on the products from our previous year. We intend to expand the white paper to include new sections based on our working group activities. We anticipate new sections will include a collection of definitions of argumentation, justification, and proof along with rationale for their uses. We also plan to develop a wiki or website where we can share citations/papers related to these constructs, particularly articles that define one or more of them explicitly. We will conduct an analysis of the definitions/descriptions of the constructs and contexts collected during the working group to continue to develop a framework that illustrates the perceived relationships between and among them. Collaborations, should they materialize out of the networking groups, would also be an important product of the working group.

This working group will bring together researchers and practitioners to work collaboratively towards unifying goals centered around the work of elementary mathematics teacher educators (eMTEs, including mathematicians and graduate students) who teach elementary mathematics content courses. The working group will aim to conceptualize the work of eMTEs as a unique population of practitioners, their development, and the ways in which they may be supported in this work. Areas of focus will include, but are not limited to: (a) the development of prospective elementary teachers' learning in content courses; (b) the content and pedagogy enacted in elementary content courses; (c) the mathematical knowledge needed for teaching teachers; (d) the educational backgrounds and teaching experiences of eMTEs; (e) the preparation of eMTEs at the doctoral level; and (f) the institutional guidance and support from the greater community that eMTEs are currently being offered. Our vision is to create research-based practitioner resources for eMTEs, including: writing and publishing a handbook, based on research and policy recommendations, to serve as a practitioner guide for teaching elementary content courses; and building and maintaining an online repository of instructional resources that eMTEs may utilize in their work with prospective elementary teachers.

Keywords: Teacher Education-Preservice, Elementary School Education, Teacher Knowledge, Instructional Activities and Practices

Motivations for a New Working Group

History

This is a new working group that arose from interactions between the leaders of a PME-38 discussion group on the opportunities and challenges surrounding the preparation and support of mathematics teacher educators who work with elementary teachers (Welder, Jansen, & McCloskey, 2014), the presenters of a PME-39 research report on the purposes of mathematics teacher educators in their teaching of elementary content courses (Taylor & Appova, 2015), and the presenters of the Association of Mathematics Teacher Educators (AMTE) symposium on supporting mathematics teacher educators' work with elementary teachers through multiple perspectives (Taylor, Appova, Welder, & Feldman, 2016). Collective feedback received from participants (which included novice mathematics teacher educators and graduate students) highlighted a strong need for research and resources to support the development of elementary mathematics teacher educators (eMTEs), specifically in their teaching of mathematics content courses for prospective elementary teachers (ePTs).

Problem

Recent research and political initiatives have suggested that, while in teacher education programs, many ePTs receive inadequate preparation to become effective teachers of mathematics

---

and do not develop the deep, conceptual knowledge of the mathematics they will teach (e.g., Conference Board of the Mathematical Sciences (CBMS), 2012; Greenberg & Walsh, 2008). These issues stem from, among other things, a lack of clarity and consensus within in the field about what ePTs should learn and experience while in mathematics content courses (e.g., Ball, Sleep, Boerst, & Bass, 2009; Zaslavsky, 2007) and a lack of preparation and support for the eMTEs who teach mathematics content courses for ePTs (e.g., Bergsten & Grevholm, 2008).

There has been a recent increase in the efforts of mathematics teacher educators to study and share the work they are doing with ePTs, primarily regarding the content (e.g., Ball, et al., 2009) and pedagogy (e.g., Lampert et al., 2013) enacted in mathematics methods courses; however, little of this work has specifically focused on elementary content courses (e.g., Bergsten & Grevholm, 2008). Research has indicated that these content courses are often taught by eMTEs, in mathematics departments, who have little to no experience working with elementary content or children and do not receive the training or support necessary to effectively address the needs of the ePTs with whom they work (Masingila, Olanoff, & Kwaka, 2012).

Goals

In response, the leaders have developed this working group to bring together researchers, mentors of mathematics teacher educators, and experts from the larger community to work collaboratively towards unifying goals regarding the teaching of elementary mathematics content courses and the preparation and support of those who teach these courses. More specifically, the aim of this new working group is to generate an understanding of how eMTEs develop as practitioners, particularly in light of recent recommendations, including the *Mathematics Education of Teachers I and II* (CBMS, 2001; 2012), the *National Council of Teachers of Mathematics for the Council of the Accreditation of Educator Preparation Standards* (NCTM CAEP, 2003; 2012), and the forthcoming *Standards for Mathematics Teacher Preparation* (AMTE, 2016).

Specifically, we aim to better understand, document, and address eMTEs' needs by:
(a) providing opportunities for eMTEs to make sense of the content and pedagogical recommendations provided in the aforementioned documents; (b) inviting eMTEs to reflect on their current practices in light of these recommendations; (c) understanding the challenges eMTEs face in addressing these recommendations in their teacher preparation courses/programs; (d) providing a platform for eMTEs to develop a shared vision for mathematics teaching and learning in elementary content courses; and (e) constructing resources, including research-based strategies and recommendations, for strengthening the preparation and support of eMTEs. From these discussions, we aim to open new scholarly and practitioner-based avenues for research and collaborations in the field of eMTE development.

Focal Issues

Jaworski (2008) defines mathematics teacher educators as "professionals who work with practicing teachers and/or prospective teachers to develop and improve the teaching of mathematics" (p. 1). Studying the work and practices of teacher educators is a fairly new area of research in the field of mathematics education. In the past two decades, the related research has mostly fallen into six overall categories: (1) knowledge needed by teacher educators to teach prospective teachers (e.g., Chick & Beswick, 2013; Rowland, Turner, & Thwaites, 2014; Superfine & Li, 2014); (2) general pedagogical practices of mathematics teacher educators (e.g., Dixon, Andreasen, & Stephan, 2009; Steele, 2008); (3) efforts of mathematics teacher educators to improve their own practices (e.g., Berk & Hiebert, 2009; Cady, Hopkins, & Hodges, 2008; Hiebert et al., 2003; 2007; Marin, 2014; Monroe, 2013; Nolan, 2015; Tzur, 2001); (4) actions, goals, purposes, and intentions enacted by experienced mathematics teacher educators in their content/methods courses (e.g., Appova & Taylor, 2014; Taylor, 2013; Taylor & Appova, 2015); (5) effects of particular activities, or series of activities, on

prospective teachers' learning (e.g., Castro 2006; Goodell, 2006); and (6) the design of tasks specifically for use in mathematics content courses for ePTs (e.g., Chval, Lannin, & Bowzer, 2008; Liljedahl, Chernoff, & Zazkis, 2007; Thanheiser, et al., 2016; Van Zoest & Stockero, 2008).

The working group leaders have been directly and indirectly involved in this research community, collecting, analyzing, and reporting data related to various aspects of the work of eMTEs. A major impetus for our work is our overlapping interests in strengthening the development of ePTs' mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008) through the preparation and support of the eMTEs who work with them. The leaders of the working group have critically considered several factors influencing the work and development of eMTEs, including: (a) educational backgrounds, research, and teaching experiences of eMTEs (especially those related to elementary mathematics); (b) specialized knowledge needed by eMTEs for teaching mathematics content to ePTs; (c) actions taken by eMTEs in elementary mathematics content courses and the purposes/intentions behind those actions; and (d) preparation and support of eMTEs for their work with ePTs. Below, we summarize the current research foci of the working group leaders and how we envision our work connecting to the larger goals of the working group, both during and after the conference. For the purpose of the working group, we will use the term "elementary" to broadly encompass PreK-8 grade-levels to be inclusive of varying state-certification requirements and institutional course offerings.

Educational Backgrounds and Teaching Experiences of eMTEs

Many, if not most, instructors of elementary mathematics content courses have not worked as elementary teachers themselves (Masingila, Olanoff, & Kwaka, 2012). Welder and McCloskey (under review) have been working to investigate this phenomenon through three lenses: (a) analyzing job opportunities for mathematics teacher educators, (b) surveying early-career mathematics teacher educators, and (c) conducting focus group interviews with educators who lack elementary experience yet work primarily with elementary teachers. Preliminary findings suggest that most mathematics teacher educators will work with elementary teachers in some capacity at some point in their careers and highlight that most will do this work without being able to claim the title or draw upon the expertise that only comes with having worked as a practicing elementary teacher (Welder, McCloskey, & Searle, 2013). By better understanding the nature of the challenges faced by eMTEs, especially those without elementary-specific educational backgrounds or teaching experience, the goal of this research is to find ways in which eMTEs may be better supported for their work with elementary teachers.

Connection to working group. In addition to better understanding the multitude of factors that may affect the quality of eMTEs' interactions with teachers, there is much work to be done to identify *where* and *how* eMTEs develop (or *could* or *should* develop) such knowledge, experience, and dispositions toward elementary mathematics teaching. Reys and Reys (2012) note, "[P]rofessionals continue to grow and adapt throughout their careers. It is unreasonable to expect that a Ph.D. program will adequately prepare mathematics educators for the wide range of challenges and expectations they will confront" (p. 290). How might responsibility for eMTE development be shared among doctoral programs, hiring institutions, and individual eMTEs themselves? The field of mathematics education could benefit from collectively identifying learning goals for the preparation of eMTEs and developing practices to support eMTEs in reaching these goals.

Specialized Knowledge of eMTEs Needed for Teaching Mathematics to ePTs

Much research has been done on the nature of mathematical knowledge for teaching (MKT) children (e.g., Ball, et al., 2008). However, much less research has looked at the knowledge required by mathematics teacher educators to facilitate the development of ePTs' MKT. It is generally assumed that teachers need to know *more* than their students, but in looking at the mathematical

knowledge for teaching teachers (MKTT), researchers are still investigating what this "more" entails. Deborah Zopf (2010) identifies three areas where the work of teaching mathematics to teachers differs from teaching the subject to students. First, the content is different; students are learning mathematics, whereas ePTs are learning MKT. Second, the audience is different; eMTEs are teaching adults who are already somewhat familiar with the mathematics content that they are learning, though mostly in procedural ways (Thanheiser et al., 2014). Third, the goals for instruction are different; students generally learn mathematics for academic purposes, whereas ePTs learn mathematics for the purpose of teaching it to children.

Connection to working group. Research is needed to look more deeply at how the differences between teaching students and ePTs influence the knowledge required by eMTEs. What challenges are involved in teaching mathematics to ePTs who already have some (albeit mostly procedural) knowledge of the content, but lack the deep, conceptual understandings needed to teach the subject to children? How should eMTEs determine the scope and sequence of mathematics content courses? Is less content, studied at a deeper level, more effective than covering more topics in less depth? How can eMTEs design formative and summative course assessments to capture the development of ePTs' conceptual understandings (Hill, Schilling, & Ball, 2004)? These are merely a few of the field's unanswered questions regarding MKTT.

Classroom Actions and Purposes of eMTEs in Mathematics Content Courses

Taylor and Appova (in preparation) closely examined the classroom actions, and purposes and intentions behind those actions, of experienced eMTEs. The authors define *classroom actions* as teaching practices eMTE employ during instruction (i.e., what eMTEs say and do while instructing ePTs, including the content that is visually presented) and *purposes/intentions* as what eMTEs want ePTs to learn from content and methods courses, which may or may not be listed in the course syllabi and/or curriculum. Preliminary results from this study indicate that experienced eMTEs situate their actions and purposes around specific learning opportunities that provide ePTs with essential foundations for developing two specific domains of MKT: *specialized content knowledge* (SCK), mathematical knowledge separate from pedagogy and knowledge of students, that is not needed in other professional settings (Ball et al., 2008), and *pedagogical content knowledge* (PCK), a special type of knowledge that blends "content and pedagogy into an understanding of how particular topics, problems, or issues are organized, represented, and adapted to the diverse interest and abilities of learners" (Shulman, 1987, p. 8).

More specifically, in their content courses, experienced MTEs provided opportunities for ePTs to re-learn elementary mathematics in a way that helped them to make pedagogical connections to children's learning, teaching, and curriculum. They also focused on providing ePTs with opportunities to experience mathematics beyond the surface-level procedural learning, developing a deeper conceptual knowledge and problem-solving nature of mathematics through connections, representations, and modeling (echoed in the *Standards*-based documents, put forth by NCTM, 2000). These visions are described by Magnusson, Krajcik, and Borko (1999) as *orientations towards teaching*, encompassing "teachers' knowledge and beliefs about the purposes and goals for teaching [mathematics] at a particular grade level" (p. 97).

Connection to working group. The authors hope to open a window of collaborative research opportunities to extend their current work and provide the mathematics education research community with additional and new insights into the knowledge, practices, and purposes that eMTEs draw upon in their content and methods courses. Without a shared knowledge base, eMTEs will continue to teach and design courses with limited resources and support, contributing to even greater variability variability across teacher preparation programs (Floden & Philipp, 2003). Specifically, the authors are interested in exploring ways in which university faculty (especially non-mathematics educators, such as, graduate students, adjuncts, and mathematics faculty) can be supported in

developing ePTs' PCK and SCK through content and methods courses. Such work will help the mathematics education community develop a shared vision, curriculum, and knowledge base for the work of eMTEs, specifically in regards to their classroom actions, practices, and intentions/purposes when teaching courses for ePTs.

The Preparation and Support of eMTEs

With the recent policy documents and recommendations regarding elementary teacher preparation, there comes a greater need to prepare and support eMTEs in their work with ePTs. However, Masingila, Olanoff, and Kwaka (2012) found that, in their survey about who teaches mathematics content courses for ePTs, over half of the respondents indicated that there is no training or support for the eMTEs who teach content courses at their institutions. Of those who indicated that there is support, most described it as informal and infrequent (only occurring once or twice a year). Furthermore, findings from a study of novice mathematics teacher educators highlighted their collective need for gaining additional teaching experience during doctoral preparation programs and receiving mentorship during their initial years as university faculty (Yow, Eli, Beisiegel, McCloskey, & Welder, 2016). Kimani, Olanoff, and Masingila (2012) were able to successfully support the development of novice eMTEs by creating mentoring programs and relationships between novice and experienced eMTEs. In their research, the authors formed a community of practice to reflect on the processes of learning to teach mathematics content courses for ePTs. Through this community of practice, novice and experienced eMTEs were able to work together to establish learning goals for their ePTs and reflect on their abilities to help ePTs achieve these goals.

Connection to working group. This avenue of research is strongly aligned with all of the aforementioned areas of our working group; yet, little research has been conducted in this area suggesting that the field of mathematics education needs to identify best practices in preparing and supporting eMTEs and implement these practices throughout various stages of eMTEs' development. The leaders of this working group believe that this work is particularly important for novice mathematics teacher educators who are often assigned to teach content and/or methods courses for ePTs, within their first few years as faculty, regardless of their backgrounds or experiences (Welder & McCloskey, under review). Forming communities of practice to address the mathematical preparation of elementary teachers and conduct action research around the teaching of mathematics content courses for ePTs will help the field better recognize, understand, and address the needs of eMTEs. By helping the field better define the goals, purposes, and classroom practices that may best support the development of ePTs' learning, eMTEs will be able to confront their own knowledge, backgrounds, and experiences that may aid (or impede) their ability to facilitate ePTs' development. This knowledge may help us begin to develop a shared vision for effective mentorship practices and professional development structures specific to the needs of eMTEs (including mathematicians and graduate students).

Projected Working Group Outcome

Our primary goal is publishing a handbook containing research-based practitioner resources, based on theories of eMTE development, that will guide eMTEs (including mathematicians, graduate students, and those who prepare and mentor eMTEs), in their work with elementary teachers. Although the focus of our materials will be specifically on the teaching of content courses for ePTs, they will also be relevant to eMTEs who provide inservice teacher professional development. Our plan is to contact several publishers to find an appropriate outlet for our work, mainly focusing on opportunities for publishing research-based recommendations and guidelines (rather than individual research reports) such as those provided by special issues of Theory into Practice (published by Taylor & Francis).

We foresee the printed handbook being comprised of several interrelated chapters for eMTEs to draw upon when teaching elementary content courses. Potential chapters and/or topics may include, but are not limited to:

- An overview of elementary mathematics curriculum development in the United States (e.g., state-level standards and assessments; commonly used elementary curricula, state-specific teacher certification requirements);
- The mathematical content and practices recommended for supporting the development of ePTs' MKT through content coursework, as explicated in local and U.S. national standards and policies related to elementary teacher preparation (e.g., CBMS, NCTM CAEP, AMTE);
- Unique aspects of the ePT population (including an overview of the research on ePTs' knowledge, misconceptions, attitudes, beliefs, dispositions, etc.);
- The ways in which teaching mathematics content courses for ePTs differs from the teaching of other mathematics courses, including discussions of unique challenges faced by eMTEs when teaching teachers mathematical content they will eventually teach and asking ePTs to develop conceptual knowledge of content for which they are most likely procedurally fluent;
- Task design for content courses for ePTs (including samples of problem-based exploratory tasks, research-based recommendations for engaging teachers in cognitively challenging tasks [Stein, Grover, & Henningsen, 1996; Stein, & Smith, 1998], and resources for finding research-based tasks designed for elementary content courses);
- Benefits of having ePTs work directly with elementary children (through lab schools or fieldwork experiences) and/or exposing them to the mathematical thinking of children during content courses (e.g., children's math ingenuities, problem-solving strategies, and misconceptions, Cognitively Guided Instruction [CGI; Carpenter, Fennema, Franke, Levi, & Empson, 2015], van Hiele levels of thinking [Fuys, Geddes, & Tischler, 1988]);
- Sample course syllabi and suggestions for the scope and sequencing of content based on various university course offerings (e.g., how content goals and pacing may differ at institutions offering one, two, or three semester- or quarter-long courses);
- Valid and reliable assessments that eMTEs can use to measure various aspects of ePT development throughout content courses and teacher preparation programs, including MKT (e.g., Hill, Schilling, & Ball, 2004; Welder & Simonsen, 2011), attitudes, beliefs, and dispositions towards the teaching and learning of mathematics (e.g. Jong, Hodges, Royal, & Welder, 2015), self-efficacy (e.g., Bandura, 2006; Tschannen-Moran, Hoy, & Hoy, 1998), and math anxiety (e.g., Bursal & Paznokas, 2006; Vinson, 2001);
- A printed collection of resources relevant to the development of ePTs, including books, activity guides, articles, student artifacts, information regarding projects, conferences, and professional development opportunities for eMTEs, and online resources for tasks, lessons, and video collections (e.g., the IMAP Integrating Mathematics and Pedagogy: Searchable Collection of Children's-Mathematical-Thinking Video Clips, [Philipp, Cabral, & Schappelle, 2012]; Videos of How Children Learn [Children's Mathematical Learning, Feikes, 2016]; GDK Math Lessons [GDKMath, 2016]; CGI Online Video Clips [Carpenter, Fennema, Franke, Levi, & Empson, 2015]).

Plan for Working Group Sessions

The *first* session will begin with an overview of the literature on mathematics teacher educators to build rationale and purpose for this working group. The working group leaders will highlight gaps

in the extant literature surrounding eMTE development and use these as starting points for guiding the direction of the group's work. Key activities will include:

- Providing a platform for eMTEs to begin developing a shared vision for elementary content courses and the learning of ePTs;
- Identifying challenges faced by eMTEs and how they may differ from those of classroom mathematics teachers and other teacher educators;
- Sharing the leaders' goals for developing research-based resources for eMTEs teaching content courses;
- Providing the opportunity for participants to articulate their specific interests regarding the development of eMTEs and how they might fit into the overall goals of the working group.

The *second* session will provide opportunities for participants to break into smaller subgroups based on their areas of interest. Each subgroup will discuss the current research related to their area with the goal of making research-based recommendations and suggestions related to their topic. This may include identifying possible avenues for future research and resource development. Each group will have an opportunity to brainstorm and develop an outline for how their topic may contribute to the development of a practitioner handbook for eMTEs.

During the *third* session, each group will finalize their discussions, prepare a report to present to the larger group, and map-out a plan for "next steps" in moving forward with the work, goals, and outcomes of the working group. In particular, participants will identify specific opportunities for organizing future work and collaborations, including co-authoring the chapters of the upcoming publication and contributing to anticipated follow-up activities.

Anticipated Follow-up Activities

In addition to writing and publishing the practitioner handbook described above, the leaders of the working group intend to build, develop, and maintain an online repository of resources and instructional materials specifically designed for eMTEs. The goal of providing the repository is to support eMTEs in providing effective learning opportunities for ePTs and align their instruction with national standards and recommendations for mathematics teacher preparation (AMTE, 2016; CBMS, 2001; 2012). The online repository will offer explicit and concrete information about the instructional resources provided, such as mathematical tasks and activities, sample lesson plans, ideas for course scope and sequencing, videos of children's mathematical thinking and experienced eMTEs leading ePT instruction, and links to relevant online resources, such as virtual classrooms and manipulatives. The leaders plan on pursuing grant opportunities to secure funding sources to support the continued development and maintenance of this online repository. Together, the handbook and repository will provide an effective platform for building a community of practice of eMTEs and supporting the development of their work with ePTs.
