After I completed the interview process I engaged in retrospective analysis by transcribing each of the teaching sessions. While watching the videos and reviewing the transcriptions I identified instances that provided insights into the students' conceptualizations of graphs, points in the Cartesian coordinate system, and variation of a quantity's value. I used these instances to generate tentative models of each student's thinking that I then tested by searching for instances that confirmed or contradicted my tentative model. When I found evidence that contradicted my tentative model, I developed a new model that accounted for the student's mathematical activity. With this new model in mind, I reviewed all of the student's mathematical activity to either modify my previously constructed hypotheses or to document shifts in the student's ways of thinking.
Figure 2. Three screenshots from animated task where values of Quantity A and B are represented along the horizontal and vertical axes with red and blue bars respectively.

Results

After reviewing videos and transcripts of each interview I found that while all three students plotted points from a table of values and interpreted the meaning of a point on a graph in a contextual situation, only one student independently constructed a point as a way to simultaneously represent two quantities' values when the values were represented on the axes.

At the beginning of each interview I asked the student to complete a set of conventional graphing tasks such as graphing a relationship described by a table of values and interpreting a point on his/her graph in terms of a contextual situation. Each student appropriately plotted points according to the conventions of the Cartesian coordinate system by going "over *x* and up *y*". For example, Carly explained that she plotted the point (4, -1) by going "over 4 on the horizontal and then down 1." When given a conceptual situation each student interpreted the meaning of the point in the plane in terms of the contextual situation. For example, Sara explained the point (1, 2) represented "at 1 second Susie was like 2 feet from her house."

The last task in the interview was the animated item I described above; I presented each student with a video where the length of the red bar along the horizontal axis represented the varying value of Quantity A and the length of the blue bar along the vertical axis represented the varying value of Quantity B. As the video played the lengths of the red and blue bars changed together so that each bar had one end fixed at the origin. While there were numerical values labeled along the axes, I anticipated that students would reason about the magnitude of each bar and not attend to the associated numerical values.

I presented each student with three versions of this task. I will focus on each student's first attempt at this type of problem in order to understand how students come to conceptualize a point in the Cartesian coordinate system as a multiplicative object. Figure 3 shows an accurate graph for the first version of this task.
Figure 3. Accurate graph for animated item presented in Figure 2.

Sara

As Sara watched the video, she appropriately described how the two quantities' magnitudes changed together. She explained, "As x was increasing at the beginning y was decreasing. But as x comes closer to 0 y also approaches 0 and they both increase for a little bit and as y keeps increasing or as x keeps increasing y starts to decrease." Although Sara described how the quantities' magnitudes changed together, she struggled to represent this graphically. In the following excerpt Sara explained her approach to constructing a graph from the video.

> *Sara*: In my head I like know like as that one is increasing you have to like. I try and like think of the shape of the line or the point or whatever to get to the line. Or yeah.
> *Int*: What do you mean you think of the shape to get to the line?
> *Sara*: So like for this like I have to see how like. Since that [value of x] is like increasing (*gestures left to right*) and that [value of y] is decreasing (*gestures up and down*) like what I am thinking in my head. Like I am like trying to figure out which way it needs to go.
> *Int*: Which way what needs to go? The graph?
> *Sara*: I don't know. That is why it takes me so long when I am just staring at the graphs.

Sara appeared to abandon her thinking about changing quantities when constructing a graph. Instead of conceptualizing the graph as a trace of how the value of x and y change together, she broke the graph up into chunks based on whether the value of y increased or decreased. Then she determined a shape that depicted the appropriate behavior of y as x increased. For example, if the value of y increased as the value of x increased then she knew the graph had to go up and to the right. While Sara appropriately described how the values of x and y changed together, her tendency to engage in static shape thinking prevented her from leveraging her reasoning about how the two quantities were changing together to construct a graph.

Carly

After Carly watched the video she sketched a graph by moving her pen up and down the vertical axis and then left to right on the horizontal axis (Figure 4). Carly was trying represent the dynamic nature of the video but in the moment of acting she did not construct a way to unite the variation of the two quantities' values. When explaining her graph Carly said, "All the x values are at zero and all the y values are at zero." It seemed Carly was attending to the red bar being on the axis and not the length of the red bar. To confirm this hypothesis, I paused the video and asked Carly to determine the value of x at that moment. She told me the value of x was 0 because the red bar was on the axis. When I asked Carly to consider the length of the red bar she determined the length of the red bar was 8 and independently concluded that meant the value of x was 8. With the video still paused, she reasoned similarly about the value of y and determined the point (8, 350) represented those two values.

Attending to the length of the red and blue bar represented a critical shift in Carly's thinking. After I supported Carly in conceptualizing the length of each bar Carly described, "plotting all the points" and sketched an appropriate graph of the behavior represented in the video.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figure 4. Carly's initial graph representing the behavior of two quantities' varying values.

Vince

After three minutes of puzzling about the task, Vince successfully represented the behavior in the video by sketching a graph in the plane. When explaining his approach, Vince described a point that he imagined as the "intersection" of the red and the blue bars and he described keeping track of this intersection as the video played. Although Vince described this approach when he first viewed the video, it took more than three minutes of reasoning for him to believe that this activity would represent how the lengths of the red and blue bars changed together.

I conjecture that Vince was able to construct the intersection point in the moment of acting because he had constructed a multiplicative object in thought that united the quantities' values. Throughout the entire interview when Vince talked about a value of x he also talked about the associated value of y. This was true whether Vince was referencing a table, graph, or contextual situation. This suggests that Vince had a way of thinking about relationships between quantities that united the values of x and y. When I presented Vince with this last task he focused on developing a way to graphically unite the values of x and y. He constructed a point as a multiplicative object in order to satisfy his need to unite the values of x and y. After conceptualizing the point as an "intersection" – a multiplicative object, he was able to represent the behavior in the video as a graph in the Cartesian coordinate system.

Discussion

All three students successfully plotted points from a table of values and gave contextual interpretations of points on their graphs. However, only Vince – with much hesitation – constructed a graph by conceptualizing a point as a way to unite two quantities' measures. These results suggest that the years of graphing practice that students endure in grade school do not necessarily prepare students for conceptualizing values in a table as measures represented along the axes nor does it prepare students for constructing a point in the Cartesian coordinate system as a multiplicative object. In the following paragraphs I hypothesize why plotting points as "over x units and up y units" does not support students in conceptualizing a point as a multiplicative object. I also provide recommendations for how educators might support students in constructing points as multiplicative objects.

When the three students in this study plotted points from a table they enacted the activity "over x and up y". The point the student plotted was the product of this activity. It is likely that as soon as the student plotted the point he/she no longer thought about the activity that produced the point he/she constructed. For a student engaged in this type of activity, it is as if there is a place called (x, y) and the student is being asked to find it. As a result, the values of x and y are tied to a single place in space, as opposed to tied to two measures on the axes. Without conceptualizing attributes to unite, the student will never necessitate constructing a multiplicative object. Thus, it is not surprising that these students had difficulty using their meaning of points – locations in the plane – to construct a

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

point in the Cartesian coordinate system as a way of uniting two quantities' values that are represented on the axes.

This suggests that educators need to support students in developing an entirely new conception of graphs that is rooted in conceptualizations of quantities' varying values being represented along the axes. Carly and Sara's work provides evidence of two difficulties students need to overcome in order to develop this conception of graphs.

When Sara first engaged with the animated task she explained how the two quantities' values changed together – she engaged in covariational reasoning. However, she abandoned this way of thinking when she went to sketch a graph and instead focused on the shapes that would represent the way the quantities' values changed together. While Sara was able to construct a correct graph, she did not construct the graph by keeping track of *how* the quantities were changing together. This suggests that conceptualizing a graph as an emergent trace of two quantities' values requires more than imagining how two quantities change together. While Sara was able to successfully complete this task, her thinking was entirely dependent upon breaking up the graph into chunks where she could appropriately determine the shape of the graph. This way of thinking is constrained to situations where Sara can imagine breaking up the behavior into graphs and limits the power of Sara's ability to represent and interpret graphs as emergent traces of covarying quantities.

Carly's difficulty stemmed from not differentiating between the length of the bar and the location of the bar on the axis. In order to construct a multiplicative object, the individual must first construct two properties to then unite. I conjecture that by focusing on the aspect of the bar that remained the same – its location on the axes – instead of attending to the aspect of the bar that varied – the length of the bar, Carly was unable to conceptualize two distinct properties. When I paused the video and asked Carly to determine the length of the bar, Carly constructed two properties - the length of the red bar and the length of the blue bar, which she could then think about uniting. While the numerical values likely helped Carly coordinate the animated task with her conception of values represented in a table, once Carly constructed the point as a way to unite two numerical values on the axes, she was able to imagine keeping track of all of the points. This suggests that Carly's thinking about points as uniting two measures on the axes was not dependent on knowing the values of the coordinates.

While Carly experienced difficulty conceptualizing two attributes to unite, Vince experienced difficulty conceptualizing the point as a way to unite two properties, namely the value of x and the value of y. This suggests that constructing a point in the Cartesian coordinate system as a multiplicative object is a nontrivial activity; conceptualizing two attributes to unite, and then conceptualizing how to unite these values graphically are both cognitively demanding activities.

By the end of the interviews, both Carly and Vince were able to construct a graph by imagining "all the points" and engaging in emergent shape thinking. Looking at the shifts in each student's thinking we see that attending to the measure of each bar's length can help students conceptualize two attributes to unite. Additionally, if a student conceptualizes relationships between quantities as a way unite values of two quantities in thought, then the student has the opportunity to construct representations of this relationship be it through tables, graphs, or formulas. Thus, educators should encourage students to unite their conception of two quantities' measures when reasoning about contextual situations, tabular representations, formulas, and graphical representations.

From a researcher's perspective, the coordinate pair (x, y) necessarily unites values of x and y in the Cartesian coordinate system. However, this study provides evidence that when plotting and interpreting points in the Cartesian coordinate system, students are not conceptualizing the coordinate pair (x, y) as a way to simultaneously represent values of two quantities. Additional research is needed to better understand how students construct coordinate pairs in the Cartesian coordinate system as multiplicative objects and how students leverage their conceptualization of coordinate

pairs as multiplicative objects when engaging in covariational reasoning and reasoning about dynamic situations.

THE BENEFITS OF FEEDBACK ON COMPUTER-BASED ALGEBRA HOMEWORK

Emily R. Fyfe
University of Wisconsin-Madison
efyfe@wisc.edu

Math homework is transforming at a rapid rate with the continuous advances in educational technology. Computer-based homework, in particular, is gaining popularity across a range of schools, with little empirical evidence on how to optimize student learning. In the current study, middle school students (N = 143) solved a set of challenging algebraic problems on a computer-based homework assignment and received (1) no feedback, (2) correct-answer feedback, (3) try-again feedback, or (4) explanation feedback after each problem. Feedback resulted in higher posttest scores than no feedback, and this was true regardless of feedback type. On transfer items, correct-answer feedback has positive effects for low-knowledge students, but neutral effects for higher-knowledge students. Results suggest the provision of basic feedback on computer-based homework can benefit novice students' mathematics problem solving.

Keywords: Problem Solving, Algebra and Algebraic Thinking, Instructional Activities and Practices, Technology

Introduction

Modern advances in educational technology and increasing access to computers gives math teachers a wide range of tools for assigning homework and assessing students' problem-solving skills. Indeed, intelligent tutor systems and computer-based homework are quickly gaining popularity and prevalence in math classrooms across the world, necessitating research that crosses the borders of math education, cognitive science, and educational technology. Many of these computer systems are designed to enhance student learning through the use of targeted problem solving and feedback. However, recent evidence suggests there may be potential consequences of providing feedback during problem solving, especially for learners with higher prior knowledge (e.g., Fyfe & Rittle-Johnson, 2016). The goal of the current research was to evaluate the effects of different types of feedback on computer-based algebra homework for middle-school students. The selection of algebra was motivated by the recognition that algebra is a gatekeeper to future educational and employment opportunities (Adelman, 2006), and by concerns about students' inadequate understanding of and preparation in algebra (NMAP, 2008).

Theoretical Framework

In general, math education research supports the use of feedback during problem solving. Meta-analyses show that, on average, feedback has positive effects on learning outcomes relative to no feedback (Hattie & Timperley, 2007). Indeed, Hattie and Timperley (2007) claim that "feedback is one of the most powerful influences on learning and achievement" (p. 81). They even identify feedback as one of the top ten influences on student achievement, along with direct instruction and reciprocal teaching. However, the effects of feedback vary widely (Kluger & DeNisi, 1996) suggesting that certain types of feedback may be more effective than others. In fact, during mathematics problem solving, students can sometimes learn just as much, if not more, when no feedback is provided (Fyfe & Rittle-Johnson, 2016; Nussbaumer et al., 2008).

A growing body of evidence suggests that some of the variability in feedback effects is due to students' prior knowledge (e.g., Fyfe, Rittle-Johnson & DeCaro, 2012; Krause et al., 2009). Specifically, feedback often has strong, positive effects for students with lower prior knowledge, but neutral or negative effects for students with higher prior knowledge.

Theoretically, there are several reasons why feedback may hinder problem solving relative to no feedback. These reasons are related to the students' perception of the feedback, including their affective and cognitive processes. For example, feedback may draw attention to the self and elicit affective reactions that interfere with learning (Kluger & DeNisi, 1996). For example, feedback on incorrect answers can produce ego-threat (i.e., a threat to one's positive self-image), which may reduce one's confidence or motivation to continue. Students with higher prior knowledge may be especially affected by ego-threat as they likely have some expectation of performing well. Another possibility is that feedback overloads cognitive resources simply by providing additional information that needs integrated with the students' existing knowledge (Sweller, van Merrienboer, & Paas, 1998). For example, feedback can disrupt a student's internal processing of the task and ultimately hinder his ability to learn from it.

One key factor to consider may be the type of feedback provided. Dempsey et al. (1993) outlined a hierarchy of feedback types based on the information provided:

1. *No feedback*: provides no information about the student's response.
2. *Verification feedback*: informs the student if the response if correct or incorrect.
3. Correct-answer feedback: informs the student what the correct answer is.
4. Elaborated feedback: provides some explanation for why a response is correct.
5. Try-again feedback: allows one or more additional attempts to try again.

One possibility is that providing feedback with more information will have positive effects for both low- and high-knowledge students because it provides helpful information for moving forward. However, providing more information may also have consequences because it is more likely to overload cognitive resources. There is some consensus that effective feedback should at least provide the correct answer (Kluger & DeNisi, 1996). But, the benefits of extra information are less clear (see Mory, 2004), particularly in the realm of computer-based homework.

Computer-based math homework has several potential advantages relative to traditional paper-and-pencil homework, including the provision of immediate feedback to students on their performance. The goal of the current study was to evaluate the effects of this feedback using a particular system, ASSISTments.org (Heffernan & Heffernan, 2014). ASSISTments is a computer tutor system that can provide scaffolds and feedback to assist student. The use of computer-based homework offers several advantages for understanding the effects of feedback.

First, computer-based homework provides an ecologically valid context in which to evaluate the role of feedback on problem solving. Many prior feedback studies have been conducted in laboratory contexts in the presence of a researcher. Here, we test the effects of feedback in an authentic learning setting on homework assignments given to students by their teachers. Second, computer-based homework represents a learning setting that may reduce the negative effects of feedback. As mentioned above, one condition under which feedback may hinder learning is when it draws attention to the self as opposed to the task (Kluger & DeNisi, 1996). Attention on the self can invoke evaluations of one's abilities that interfere with the task. Computer-generated feedback is often viewed as a less evaluative source of information than person-generated feedback (Karabenick & Knapp, 1988), and may help decrease attention on the self and increase attention on the task. Computer-based homework may also reduce overload of cognitive resources by giving students control over when and how they process the feedback.

Current Study

The current study tested the effect of different types of feedback for middle school students solving algebra problems on computer-based homework via the ASSISTments system. Teachers and students who were already using ASSISTments were recruited so that the system was familiar to the

students and part of their regular classroom experience. Students were assigned to receive no feedback, correct-answer feedback, explanation feedback, or try-again feedback. Based on previous research, feedback was predicted to interact with prior knowledge such that feedback would have stronger, positive effects on problem solving for students with lower prior knowledge than for students with higher prior knowledge.

Method

Participants

All students from two sixth-grade teachers' classrooms and two seventh-grade teachers' classrooms were invited to participate. The teachers taught at three different schools and were using ASSISTments.org as part of their regular classroom experience. Of their 160 students, 17 students were not included in the study as they did not complete all required sessions. The final sample contained 143 students (65 in sixth-grade and 78 in seventh-grade).

Materials

All materials were presented using ASSISTments.org. The *pretest* included six algebraic equations to solve (see Table 1). There were four different problems types: $ax + b = c$, $b + ax = c$, $a(x + b) = c$, and $a(x + b) + c = d$. The *homework assignment* contained two worked examples at the beginning to re-familiarize students with correct problem-solving solutions (see Figure 1 for an example). The remaining problems were equations for students to solve on their own. Students solved 12 or 16 problems (i.e., three or four of each type of problem presented on the pretest). Whether students solved 12 or 16 problems reflected natural variation in teacher preference as two teachers opted for the 16-problem assignment ($n = 65$ students) and two teachers requested a shorter 12-problem assignment ($n = 78$ students). Percent correct scores were calculated for each student based on the number of items he or she was assigned. The *posttest* included eight equations to solve (see Table 1). Four items were isomorphic to the pretest problems (i.e., learning items) and the remaining four were challenge problems with novel problem structures (i.e., transfer items). Percent correct for each subscale was calculated.

Table 1: Problems Presented on the Pretest and Posttest

	Pretest	Posttest
1.	$2x + 3 = 23$	$5x + 13 = 73$
2.	$10 + 5x = 30$	$3 + 6x = 99$
3.	$3(x + 1) = 9$	$7(x + 4) = 63$
4.	$7(x + 3) + 2 = 51$	$2(x + 3) + 4 = 16$
5.	$5(x + 3) + 14 = 64$	$x/2 + 3 = 13$
6.	$8(x + 2) = 56$	$4(x + 2) + 3(x + 2) = 35$
7.	--	$x/9 + 31 = 34$
8.	--	$6(x + 4) + 2(x +4) = 48$

Note. On the posttest, problems 1 through 4 are learning items and 5 through 8 are transfer items.

Design and Procedure

The experiment had a pretest-homework-posttest design. Students completed the pretest during class or at home. Within three school days, students completed the homework assignment on their own. For the homework assignment, students were randomly assigned to one of four conditions: no-feedback ($n = 25$), correct-answer feedback ($n = 44$), explanation feedback ($n = 41$), or try-again

feedback ($n = 33$). Finally, students completed the posttest. All teachers assigned the posttest the same day students finished the homework, but three teachers had students complete it in class and one teacher had students complete it at home.

Figure 1. Worked example. An example given at the beginning of the homework assignment.

In the *no-feedback* condition, students did not receive any feedback during the assignment. After submitting each answer, the computer provided an "answer recorded" message and students clicked a button to move on to the next problem. In the *correct-answer feedback* condition, students received immediate, correct-answer feedback after each problem. If students typed the correct answer, a green check mark appeared with the word "Correct!" If students typed an incorrect answer, a red X appeared along with the words, "The correct answer is __" (with the correct answer filled in). In the *explanation feedback* condition, the feedback message included the correct answer, an explanation of why it was correct, and a worked example. For example, for $3x + 12 = 24$, the feedback message stated:

> The correct answer is 4 because when x is 4 both sides of the equal sign have the same amount. Let's plug 4 in for x and simplify to show that both sides have the same amount.
>
> 3x + 12 = 24
>
> 3*4 + 12 = 24
>
> 12 + 12 = 24
>
> 24 = 24

In the *try-again feedback* condition, the feedback message stated, "Sorry, try again. __ is not correct" (with the student's answer filled in). Students could continue inputting responses until they entered the correct answer or they could obtain the correct answer by clicking on a button.

Data Analysis

To examine the impact of feedback and prior knowledge, regression analyses were used for each outcome measure. Condition was dummy coded with correct-answer feedback, explanation-feedback, and try-again feedback entered into the models (with no-feedback as the reference group). Thus, each regression model included three condition variables, pretest score (mean centered), and three condition by pretest score interactions.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Results

Pretest

On average, children solved 85% of the pretest problems correctly (SD = 23%). Scores did not differ significantly by condition, $F(3, 139)$ = 1.09, p = .36. Performance tended to be similar across all six items with percent correct on each item ranging from 80% to 92%.

Homework

The regression predicting homework scores from condition and prior knowledge was significant, $F(7, 135)$ = 11.64, p < .000, R^2 = .38, but the only individual predictor to reach significance was the main effect of prior knowledge, B = 0.53, SE = 0.16, p = .002. Students with higher prior knowledge on the pretest exhibited higher homework scores than students with lower prior knowledge. There were no main effects of feedback or feedback by prior knowledge interactions, ps > .10. Thus, feedback had little effect on performance during the homework.

However, qualitative evidence suggested that children were learning over the course of the assignment. For example, four problems were of the form a(x + b) = c. Only 77% of students solved the first of these problems correctly, but 88% solved the fourth of these problems correctly. Similarly, four problems were of the form a + bx = c. Only 80% of students solved the first one of these correctly, but 92% solved the final one correctly. Further, on earlier problems, errors tended to reflect common misconceptions about variables, whereas errors on later problems were more diverse, suggesting that students were at least attempting correct strategies later in the assignment. For example, the very first problem was 3x + 12 = 24. Two of the most common incorrect answers were 1.6 or 9. Students added the coefficient (3) and the isolated number (12) to get 15x on the left side. Then, they either calculated 24 divided by 15 or 24 minus 15 to get their answer. However, one of the last problems was 8 + 2x = 40, and no student showed evidence of making the mistake of adding the 8 and the 2. Thus, students appeared to improve over the course of the homework assignment, but not differentially by condition.

Posttest Learning Items

Students did well on the posttest learning items, solving nearly 90% correct. Indeed, on 3 of the 4 problems students were near mastery. The fourth problem, 2(x + 3) + 4 = 16, proved somewhat difficult with only 79% of students solving it correctly. Estimates from the regression predicting percent correct on the learning items are presented in Figure 2. The overall regression was significant, $F(7, 135)$ = 9.22, p < .000, R^2 = .32. There was a significant, positive effect of prior knowledge, B = 0.36, SE = 0.18, p = .04. However, there were also significant main effects of correct-answer feedback, B = 8.91, SE = 4.33, p = .04, and try-again feedback, B = 13.51, SE = 4.58, p = .004, as well as a marginal effect of explanation feedback, B = 7.40, SE = 4.35, p = .09. Although prior knowledge did not significantly interact with any feedback type, ps > .10, an examination of Figure 2 suggests that the effect of explanation feedback was only marginal because it was primarily effective for high-knowledge children, but not low-knowledge children. Descriptively, we also compared the percent of children at mastery by condition. Fewer children in the no-feedback condition (36%) solved all four learning items correctly compared to children who received correct-answer feedback (66%), explanation feedback (66%), and try-again feedback (72%). Thus, feedback boosted learning on the posttest relative to no feedback.

Figure 2. Posttest scores. Scores on the learning items by condition and prior knowledge. Unstandardized regression coefficients are plotted at ±1 standard deviation from the mean.

Posttest Transfer Items

Students struggled on the posttest transfer items, solving only 64% correct on average. This is expected given that these were novel problem types, which students did not practice. Although all four problems were difficult, the problems with two separate terms in parentheses, like $4(x + 2) + 3(x + 2) = 35$, were the most challenging. Estimates from the regression predicting percent correct on the transfer items are presented in Figure 3. The overall regression was significant, $F(7, 135) = 5.10$, $p < .000$, $R^2 = .21$. There was a significant positive effect of prior knowledge, $B = 1.12$, $SE = 0.33$, $p = .001$, but no main effects of feedback condition, ps $> .20$. However, there was a significant interaction between prior knowledge and the no-feedback vs. correct-answer feedback contrast, $B = -0.79$, $SE = 0.40$, $p = .05$. To examine the interaction, pretest scores were centered at one standard deviation below the mean in one model (i.e., low prior knowledge) and one standard deviation above the mean in a separate model (i.e., high prior knowledge). For low-knowledge students, there was a significant positive effect of correct-answer feedback, $B = 28.35$, $SE = 12.54$, $p = .03$. The effects of explanation feedback, $p = .14$, and try-again feedback, $p = .35$, were positive, but not statistically significant. However, for high-knowledge students, there were negative, but non-significant effect of correct-answer feedback, $p = .49$, explanation feedback, $p = .40$, and try-again feedback, $p = .40$ (see Figure 3). Thus, the effects of feedback on transfer to novel problems depended on children's prior knowledge on the pretest. Feedback (particularly correct-answer feedback) resulted in better transfer than no feedback for low-knowledge children. But, all three types of feedback resulted in slightly lower transfer scores relative to no feedback for high-knowledge children.

Discussion

The goal of this study was to test the effects of feedback and prior knowledge on computer-based algebra homework using the ASSISTments system. Middle school students were assigned to receive no feedback, correct-answer feedback, explanation feedback, or try-again feedback during problem solving. After a single assignment, feedback resulted in higher posttest learning scores than no feedback, and this was true regardless of feedback type. On transfer items, feedback interacted with prior knowledge, such that correct-answer feedback has positive effects for low-knowledge students, but neutral effects for higher-knowledge students.

The findings from the current study make at least three contributions to research in mathematics education. First, the results demonstrate the benefits of three different types of feedback on problem solving. Further, they suggest that providing additional information or attempts does not always increase the efficacy of feedback. In fact, basic correct-answer feedback resulted in the best transfer for low-knowledge students, suggesting a possible threshold account (Phye, 1979). That is, when more information or support is provided beyond what is needed, it does not provide any additional advantage. Second, the results indicate that the benefits of feedback are strong for low-knowledge students, but that high-knowledge students sometimes do just as well without feedback during problem solving. Indeed, on posttest transfer, high-knowledge students tended to exhibit higher scores in the no-feedback condition, which is consistent with recent research (Fyfe & Rittle-Johnson, 2016; Krause et al., 2009). The third contribution is to introduce an exciting new method to conduct experimental research in an ecologically valid classroom. The ASSISTments project is a system bringing researchers and teachers together to better assist and assess student learning (Heffernan & Heffernan, 2014).

Future research is needed to test different types and schedules of feedback that are more dynamic and that adjust based on the student response. Indeed, one of the benefits of computer-based homework is the possibility of adapting the provision of feedback to students' needs. Further, more work is needed to enhance the provision of feedback for high-knowledge students. The high-knowledge students in the current study did not benefit from feedback, but still had room to grow.

One potential solution is to give high-knowledge students more control over the feedback (Hays et al., 2010), allowing them to skip unnecessary feedback and spend more time on challenge problems. Future studies should explore these and other possibilities.

In general, the current research is at the border of mathematics education, cognitive science, and educational technology. The specific results highlight the power and variability of feedback effects on computer-based homework. On the one hand, researchers and educators can marvel that such basic feedback can improve problem solving for novice students. On the other hand, these results challenge the intuition that feedback is always helpful and suggest that some students, under certain circumstances, can do just as well without it.

UNDERGRADUATE STUDENTS' PERCEPTION OF TRANSFORMATION OF SINUSOIDAL FUNCTIONS

Masomeh Jamshid Nejad
Simon Fraser University
masonmehj@sfu.ca

Trigonometry is one of the fundamental topics taught in high school and university curricula, but it is considered as one of the most challenging subjects for teaching and learning. In the current study Mason's theory of attention has been used to examine undergraduate student's perception of the transformation of sinusoidal functions. Two types of tasks – (A) Recognizing sinusoidal functions and (B) Assigning coordinates – were used in this study. The results show that undergraduate students participating in this study experienced difficulties in identifying a period of a sinusoid, especially when it was a fraction of π radians.

Keywords: Post-Secondary Education, Algebra and Algebraic Thinking

Background

Trigonometry has a long history. Ancient people used trigonometry for different purposes. For example, Egyptians applied trigonometry to determine the correlation between the lengths of the shadow of a vertical stick with the time of day. Astronomers also used trigonometry to find the longitude and latitude of stars, as well as the size and distance of the moon and sun. However, trigonometry was not an essential part of mathematics textbooks until a Persian mathematician named Khwarizmi introduced trigonometric functions to the world. Since then, trigonometry has become one of the main topics in high school and university mathematics books and students are required to assign time for learning trigonometry, especially trigonometric functions. This is the case since a strong foundation in trigonometric functions will likely strengthen their learning of various mathematical topics, such as Fourier series and integration techniques (Moor, 2010). It is also shown that understanding calculus and analysis is dependent on the learning of trigonometric functions (Hirsh, Weinhold and Nicolas, 1991; Demir, 2011). However, learning and understanding trigonometric functions is a difficult and challenging task for students, compared to other mathematics functions, such as polynomial functions, and exponential and logarithmic functions. While other functions (e.g., logarithmic functions) can be computed by performing certain arithmetic calculations expressed by an algebraic formula, trigonometric functions involve geometric, algebraic and graphical concepts and procedures, simultaneously (Weber, 2005, Demir, 2011).

Despite its importance and its complexity, research on trigonometry is sparse and quite limited. In the literature, only a small number of studies concentrate on students' learning of trigonometric concepts, and in particular trigonometric functions (e.g. Gray and Tall, 1991; Brown, 2005; Weber, 2005, Moor, 2010). Challenger (2009), Moore (2010) and Weber (2005, 2008) indicated that students often have difficulty using sine and cosine functions defined over the domain of real numbers. Thompson (2008) also noted that students are unable to construct understanding of the trigonometry of right angles and the trigonometry of periodic functions. In a study of undergraduate students, Weber (2005, 2008) agreed that students could not rationalize various properties of trigonometric functions or reasonably estimate the output values of trigonometric functions for various input values. Kendal and Stacey (1997) concluded that students had difficulty interpreting trigonometric functions in the unit circle, recognizing that x and y coordinates of a point on the unit circle are cosine and sine values of corresponding angles compared with other determined trigonometric functions in terms of a right triangle.

In spite of all the research efforts in the area of teaching and learning trigonometry, especially trigonometric functions, there are still gaps in the literature. There is no research study that focuses on the concept of the transformation of sinusoidal functions; the current research attempts to fill this gap.

In order to deal with the transformation of sinusoidal functions, students need to understand the notion of the 'period of a function.' The period of a function is the distance (x value) in which function values repeat themselves. In the case of the canonical sine function $f(x) = sin\ x$, the period is 2π, the circumference of the unit circle. Considering the standard format for the sinusoidal function $f(x) = Asin(Bx \pm C) \pm D$, students are required to identify the relationship between the coefficient of x (B in the function) and the period when dealing with the transformation of sinusoidal functions. As such, the research questions are: How do undergraduate students identify period? How do they recognize the period on the graph of the sinusoidal functions?

Data Collection and Analysis

This study is part of a bigger project which examines undergraduate students' perception of the transformation of sinusoidal functions. In the larger study, seven undergraduate students from a large North American university participated They were selected from among students who had either completed a Calculus I course and were enrolled in Calculus II (3 students) or they were in a Calculus I course (4 students) in the Mathematics Department. Participants volunteered their time to contribute in the study right after I made a general request from all the classes (Calculus I and II). For the purpose of this research report, I focus only on the performance of one of the participants, Emma. She was studying Applied Science and was enrolled in a Calculus II course at the time of her interview.

A 60-minutes task-based interview was conducted and Emma was required to complete two types of interview tasks: **A)** Recognizing sinusoidal functions and **B)** Assigning coordinates. Both types of tasks were presented with the help of the Dynamic Geometry software, Sketchpad. For the 'Recognizing sinusoidal function' tasks, the sketches indicating the sinusoidal graphs were given and the student was asked to identify the sinusoidal functions represented in the given graphs (see Figure 1). For the 'Assigning coordinate' tasks, a wavy displace (see Figure 2) along with the sinusoidal functions were given and Emma was required to assign coordinates on the wavy curve such that it described the given functions. Type A tasks comprised of Task 1: $f(x) = sin(2x)$, Task 2: $f(x) = sin(\frac{2}{3}x)$ and Task 3: $f(x) = cos(\frac{2}{5}x - \frac{\pi}{5})$. Type B tasks included Task 4: $f(x) = sin(4x)$ and Task: 5 $f(x) = cos(3x - \frac{\pi}{4})$.

Theoretical Framework

The collected data in this study were analyzed and interpreted using the *theory of shifts of attention* (Mason, 2005). Mason's theory provides opportunity to study the critical role of attention and awareness in learning and understanding mathematics and in particular the concept of the transformation of sinusoidal functions. Mason (2005) distinguishes five different structures of attention: 1) Holding wholes; 2) Discerning details, 3) Recognizing relationships; 4) Perceiving properties; and 5) Reasoning on the basis of agreed properties. Mason's framework of shifts of attention is appropriate for analyzing the collected data in my research. Applying this framework supports me in gaining insights not only into '*what*' Emma attended to when completing mathematics tasks related to the transformation of sinusoidal functions, but also '*how*' she shifted her attention in identifying the period of sinusoids. Mason's terms for different structures of attention also provide a language for analyzing students' work. For example, when a student considers a particular graph and recognizes its shape as representing a sinusoidal function, s/he is *holding holes*. A student who looks for particular details from the given sinusoidal functions or the given sinusoidal

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

curve (e.g., she is seeking for the point the graph intersects the y-axis), she is, in fact, *discerning details*. The student is *recognizing relationship* when she able to find a connection between the graphical representation of the sinusoidal functions and their symbolic representations. When a student determines the particular parameters that determine the given sinusoidal curve by considering its periods, she is *reasoning based on perceived properties*. To investigate how the participant realized the transformation of sinusoidal functions, and in particular, how she identified period from the given graphs/functions, I reviewed the student's answers and the transcripts several times.

Please note that in all the five interview tasks the participant was required to connect the period of the given sinusoidal function or the given sine curve to a coefficient of x in the standard formula for sinusoidal functions (considering the sinusoidal function in the standard form: $f(x) = Asin(Bx \pm C) \pm D$)). For brevity, we refer to this connection as 'recognizing the period' (see Figure 3).
Figure 1. Graph presented in Task 1.
Figure 2. Graph presented in Task 4.
Figure 3. Recognizing the period.

Recognizing period (coefficient B of x)

At the beginning of the interview, I showed Emma Task 1 in which the graph of the function $f(x) = sin(2x)$ was given (see Figure4) and she was asked to identify the sinusoidal function

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

represented by the graph. In order to complete Task 1, Emma first focused her attention on the given graph and waited for visual feedback from the graph (her attention was on *holding wholes* according to Mason's classification). Emma stated:

> It is $f(x) = sin(\frac{1}{2}x)$. It is a sine graph because it starts at 0 and it should be $sin(\frac{1}{2}x)$. The sine graph start at 0 and then π and 2π, but in this one is 0, π,$\frac{2\pi}{3}$. This is half of sine graph, because the period here is π, while it is 2π in the original sine curve.

The above statement indicates that the participant recognized incorrectly the function for the given graph, determining it to be $f(x) = sin(\frac{1}{2}x)$. Analyzing the situation using Mason's (2008) framework it can be concluded that Emma *reasoned on the perceived properties* of the sinusoidal functions and from there she *determined (*incorrectly*) relationships* between the visual representation and the symbolic representation. Emma recalled the fact that the period of a canonical sine function is 2π, whereas the period of the curve given in Task 1 was π . She thus concluded that the given curve represented the function $f(x) = sin\left(\frac{1}{2}x\right)$. Emma then connected the period of the sine curve, which was π radians, with the coefficient of x in her suggested sinusoidal function. Her statement illustrates that Emma, in fact, divided the argument x by 2 because the period of the canonical function (2π) was divided by 2 in the given graph (the period was π).
Figure 4: Graph of function $f(x) = sin(2x)$.

Detecting Emma's mistake in recognizing the proper function for the given graph in Task 1, I showed her the graph of $f(x) = sin(\frac{1}{2}x)$. Observing the graph of the function $f(x) = sin(\frac{1}{2}x)$ made the participant realize that the graph of the suggested function did not correspond to the given curve. At this time Emma stared at both graphs #1 and #2 (see Figure 5) for a while and she *held the graphs (#1 and #2) as wholes*. She then began to *describe in detail* the given graph (#2 in Figure 5) in respect to the graph of $f(x) = sin(\frac{1}{2}x)$. Emma stated:

> ….so, if $f(x) = sin(\frac{1}{2}x)$ is like this, so it is going to finish at 4π. So this is going to be the whole graph. So it should not be $\frac{1}{2}x$, it should be 2x. Because when we have $\frac{1}{2}x$ we can see that it ends at 4π. But if I put here 2x, I compressed it and I can…have this curve finishes at π π...The period of sine graph is 2π but this one is compressed, so it is $f(x) = sin(2x)$, but $\frac{1}{2}x$ is expansion in fact.

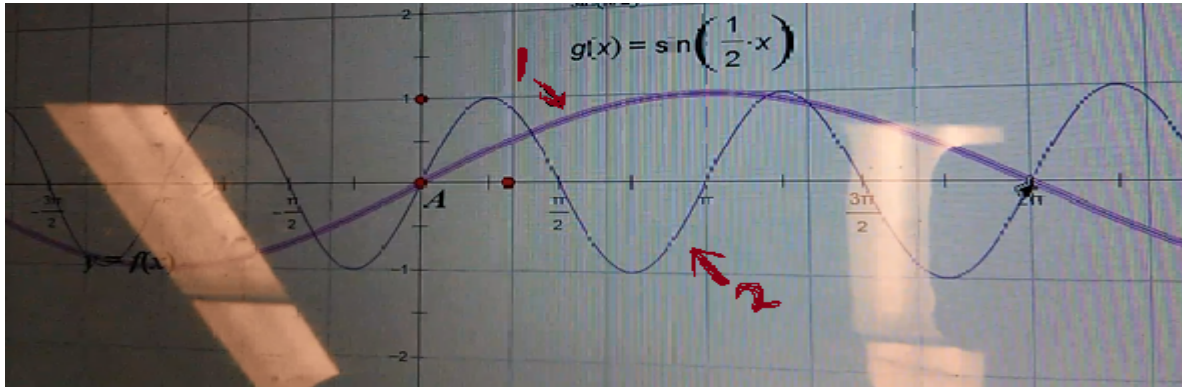
Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Tucson, AZ: The University of Arizona.


Figure 5: Graphs of $f(x) = sin(\frac{1}{2}x)$ and $f(x) = sin(2x)$.

As it is indicated from the above statement, Emma compared the end point (or the length of a full cycle) of the curve #2 with that of curve #1, considering the origin (0, 0) as a beginning of a cycle ("....$\frac{1}{2}x$ *we can see that it ends at 4π. But…I can…have this curve finishes at π…*"). In other words, by linking the end points of the full cycles (in both curves and comparing them with the graph of the canonical function), Emma was able to *find relationship* between the visual representation and the symbolic representations. She chose the number 2 (which was the reciprocal of the coefficient of $\frac{1}{2}\pi$) as a coefficient for x in the sinusoidal function. As such, she eventually recognized the correct period and thus the proper function for the given curve.

Emma's proper realization in Task 1 directed her to complete successfully similar tasks having a whole number for the coefficient of x. As an example, when approaching Task 4 in which the function was $f(x) = sin(4x)$ and a wavy curve was given, Emma was able to assign correctly the coordinates in the given wavy displace such that it represents the graph of $f(x) = sin(4x)$. After gazing at the given function in Task 4, she expressed:

> …I know that 2π is here [see Figure 6] because 1, 2, 3, and 4 periods is between 0 and 2π and here are 1 and -1…

The above excerpt shows that Emma perceived *properties of sinusoidal functions* ("*…period is between 0, 2π and here are 1 and -1*"). The feedback she received from Task 1 (the fact that there is a direct relationship between the coefficient of x in the sinusoidal functions and the number of repeated full sine cycles between 0 and 2π) allowed Emma to assign coordinates properly in Task 4. In other words, Emma was able to realize period from the given function and therefore assign axes successfully on the sinusoidal curve. Considering Emma's success in Task 1 and Task 4, one might conclude that she was able to recognize period and also sinusoidal functions, from their graphs, and vice-versa, successfully. However, Emma performed differently on the other interview tasks.
Figure 5. Emma adjusts coordinates for Task 4.

As an example, when completing Task 2, in which the graph of the function $f(x) = sin(\frac{x}{3})$ was given, after *holding the graph as whole* for a long pause, Emma did *discern some details* from the x-axis. She then stated:

> …It is sine of x over something because if it is sine of x it would end here [at 2π]…ok, it is $f(x) = sin(\frac{x}{3})$ because there are one, two and three spaces here between 0 and this point and again one, two, three here… (see Figure 6).

As it appears from the above statement, Emma counted the number of 'blocks' between 0 (the point A in Figure 6) and the point in which the curve intersected the x-axis (point B) and again from point B to another point in which the graph intersected the x-axis (point C). Since the distance between the points A and B, and B and C was 3 blocks, Emma put the fraction $\frac{1}{3}$ for the coefficient of x in the suggested sinusoidal function. It appears that she was eager to find an opposite relationship between 3π and the coefficient of x which was $\frac{1}{3}$. This evidence illustrates that Emma was unable to *recognize appropriately the relationship* between graphical representations of the sinusoidal function and its symbolic representations.
Figure 6. Emma counting the blocks between the points.

Emma's unsuccessful attempt in recognizing period and its relation with the coefficient of x in the sinusoidal function in Task 3 was typical of further errors in the other tasks having fractions for the coefficient of x. In other words, in Tasks 3 and 5, as in Task 2, Emma was unable to recognize

period successfully. As it was mentioned previously, it seems that the fractional coefficient was problematic, because Emma often attempted to reverse the point in which a full curve was finished (which was 3π in the Task 3) in order to find a coefficient for x in the sinusoidal function. Although applying this method directed Emma to determine proper functions when the coefficient of x was a whole number, it did not work for the other tasks. Emma, in fact, should find the relation between the period of a canonical function which is 2π and the point 3π in the given graph ($3\pi = \frac{2\pi}{B}$, so $B = \frac{2}{3}$) in order to identify the coefficient of x in the sinusoidal function.

Discussion

The findings of this study show that the student recognizes period and transformations in different manners when the coefficients of x in the sinusoidal function are whole numbers and when they are fractions. The data from this research demonstrates that Emma is capable in matching the algebraic representations with the graphical representations when the coefficient of x was a whole number. These results are in contrast with the findings of Leinhardt, Zaslavsky and Stein (1993), Yerushalmy and Schwartz (1993), and Knuth's (2000) studies in which a group of undergraduate students were unable to use graphical representations to complete mathematics problems in the symbolic form. The contribution of this research is in connecting together the participant's understanding of transformations, graphs and periodicity, whereas the previous research studies focused distinctly on the concepts of transformations (e.g., Yerushalmy and Schwartz, 1993), graphs (Brow, 2005) and periodicity (van Dormolen and Zaslavsky, 2003).

The findings, however, illustrate that Emma was unable to recognize period correctly, when the factor of x was not a whole number in the sinusoidal functions. That is, she was unable to connect the graphs with the sinusoidal functions when the factor of x was a fraction. As such, further research studies are required to investigate how undergraduate students interconnect the three concepts of transformations, graphs and periodicity when the coefficient of x is a fraction.

WHAT DOES IT MEAN TO "UNDERSTAND" CONCAVITY AND INFLECTION POINTS?

Steven R. Jones
Brigham Young University
sjones@mathed.byu.edu

The calculus concepts of concavity and inflection points are often given meaning through the shape or curvature of a graph. However, there appear to be deeper core ideas for these two concepts, though the research literature has yet to give explicit attention to what these core ideas might be or what it might mean to "understand" them. In this paper, I propose a framework for the concavity and inflection point concepts, using the construct of covariation, wherein I propose conceptual (as opposed to mathematical) definitions that can be used for both research and instruction. I demonstrate that the proposed conceptual definitions in this framework contain important implications for the teaching and learning of these concepts, and that they provide more powerful insight into student difficulties than more traditional graphical interpretations.

Keywords: Post-Secondary Education, Advanced Mathematical Thinking, Learning Trajectories (or Progressions)

At the level of calculus, and beyond, the twin concepts of concavity and inflection points are essential components of a complete understanding of function behavior. As such, several researchers have begun to examine how students think about these two concepts (e.g., Baker, Cooley, & Trigueros, 2000; Gómez & Carulla, 2001; Tsamir & Ovodenko, 2013). The way these concepts have been studied, as well as how they are often portrayed in textbooks, is usually deeply connected to graphical interpretations and meanings of the concepts (e.g., Baker, Cooley, & Trigueros, 2000; Stewart, 2014). Yet, on occasion, calculus education researchers seemed to have acknowledged other important interpretations or meanings of these concepts. For example, Tsamir and Ovodenko (2013) discussed how students used symbolic representations, including $f'(x)$ and $f''(x)$, to define and reason about the two concepts, and Berry and Nyman (2003) described teaching activities that develop these two concepts through physical movement. Furthermore, Carlson, Jacobs, Coe, Larsen, and Hsu (2002) explained how covariational reasoning is deeply connected to making sense of function behavior, which is closely linked to concavity and inflection points. All of this research has given us important information on how students use concavity and inflection points in activities like graphing, or on general difficulties students may have with them, or on types of reasoning that are required to make sense of them. Yet, these studies have often taken implicit stances on what the concepts concavity and inflection points actually mean. Thus, the question is raised: What are the *core ideas* we might say are contained in the concepts concavity and inflection points, and, consequently, what does it mean for a student to *understand* these ideas? While it is possible to claim that these answers can, or should, reside purely in graphical terms, such as the shape or curvature of a graph, the research literature seems to suggest that there are ideas more fundamental than simply the "shape of a graph" for these concepts. Since research has often not made explicit what these core ideas are, beyond graphical interpretations, it is important that we, as a research community, debate what might make up the core ideas of concavity and inflection points and an "understanding" of them.

Like the research literature, calculus textbooks also tend to focus on graphical interpretations of concavity and inflection points (e.g., Hughes-Hallett et al., 2012; Stewart, 2014; Thomas, Weir, & Hass, 2009). However, despite the heavy graphical treatment of the concepts, they are frequently given definitions through non-graphical language. For example, Thomas et al. (2009) define concavity based on whether "f' is increasing [or decreasing] on I" (p. 203), and in Foerster (2010),

concavity is defined by the sign of the second derivative (p. 373). Even though these books subsequently focus on graphical meanings in their treatment of the concepts, we see hints at other ideas for concavity and inflection points beyond just the shape of a graph. Again, we are left with the question as to what the core ideas are that we want to ascribe to concavity and inflection points and what an "understanding" of them might consequently look like.

In this paper I propose an argument for a particular conceptual framework that could be used as a way to *conceptually* define concavity and inflection points, which then provides one possible answer for what the core ideas are and what it might mean to "understand" them. I articulate my stance through covariational reasoning (Carlson et al., 2002), in that I see covariation as more than just "important" to an overall understanding of these concepts, but I have come to see it as the single core idea that makes up the *essence* of these two concepts. In laying out this conceptual framework, I discuss its connection to the common graphical approach to these concepts, and I discuss some pedagogical implications. I hasten to note that my stance is influenced by my examination of these concepts in real-world contexts (see Gundlach & Jones, 2015), and as such, I fully acknowledge that my view is certainly not the *only* point of departure for a conceptual discussion on concavity and inflection points. The fact that many studies and textbooks discuss concavity in other ways speaks to this. However, I propose my perspective as a way to launch a debate on what a shared idea of the *core ideas* of concavity and inflection points might be and what an *understanding* of them might look like for calculus education.

Arguments For and Against Having a Conceptual Framework

In one sense, one could argue that the various ideas about concavity and inflection points in the research literature and in the textbooks that I outlined in the introduction are all basically different ways to express the same idea, and that consequently there would be no need for a framework such as this. However, contained in this argument is exactly the issue I want to address: if they are all different ways of expressing the same idea, *what*, exactly, is that underlying idea? Similarly, one could argue that we just define an "understanding" of these concepts through the idea of making connections between representations, much as some have couched an understanding of *function* through representational connections. Yet, just as Carlson et al. (2002) have shown that there is a deeper level of function understanding in covariational reasoning, I believe concavity and inflection points also have deeper meanings beyond just connections in the ways we externally represent them to each other through graphs or symbols.

In another argument, one could dismiss the need for a framework by indicating that these different approaches in the literature and textbooks are all equivalent mathematically and that one approach or representation can be translated into another approach or representation. However, despite the *mathematical* consistency across the different approaches and representations, I argue that they are quite *conceptually* different from one another and would therefore each have separate learning implications (as opposed to mathematical implications). To develop a shared notion of what it means to *understand* concavity and inflection points, the conceptual nature, and not purely the mathematical nature, of these two concepts must be attended to. In other words, my argument is similar to—though not congruent to—Tall and Vinner's (1981) distinction between concept definition and concept image. I use the comparison to Tall and Vinner simply to illustrate the difference I see between mathematical consistency versus conceptual consistency. Despite the possible mathematical equivalence of the various definitions and uses of concavity and inflection point, it is important that we distinguish what are the core conceptual ideas that might make up the concepts.

A Proposal of a Conceptual Framework for Concavity and Inflection Points

Covariational Reasoning

Since I am using covariational reasoning as the foundation of my proposed conceptual framework, in this section I briefly describe the covariation construct as laid out in the work of Carlson and colleagues, which is rooted in research on understanding function behavior (Carlson, 1998; Carlson et al., 2002; Oehrtman, Carlson, & Thompson, 2008). Covariational reasoning is defined to be "the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (Carlson et al., 2002, p. 354). In the framework, five levels of "mental actions" are described, which correspond to increasingly sophisticated cognitive activities. These begin with simply recognizing that the two variables depend on each other, moving to coordinating the "direction" and "amount" of change, followed by a coordination of how the rate of change changes. The five mental actions of the covariational framework are summarized in Table 1.

Table 1: Mental Actions of the Covariation Framework
(Carlson et al., 2002, p. 357; Oehrtman et al., 2008, p. 163)

Mental action	Description of mental actions
1	Coordinating the *dependence* of one variable on another variable
2	Coordinating the *direction* of change of one variable with changes in the other
3	Coordinating the *amount* of change of one variable with changes in the other
4	Coordinating the *average rate-of-change* of the function with uniform increments of change in the input variable
5	Coordinating the *instantaneous rate of change* of the function with continuous changes in the independent variable for the entire domain of the function

Conceptual Objects Produced by the Mental Actions

While Carlson and colleagues obviously bring up the concepts of concavity and inflection points in their work, the framework is focused on an understanding of *function*. Yet, since mental actions 4 and 5 deal quite explicitly with concavity, I propose to define the "concavity concept" in terms of the conceptual *objects* (in the spirit of Sfard, 1991; Sfard & Linchevski, 1994) potentially produced by covariational reasoning at mental actions 4 and 5. In other words, simply put, I define concavity conceptually as "the covariation between the rate of change and the independent variable." Inherent in this definition is the claim that concavity cannot be truly understood in the absence of a mastery of mental actions 4 and 5. I acknowledge that this proposed definition extends the covariation framework beyond its original intent, in that the framework was originally meant to capture cognitive *activities* involved in coordinating change (Carlson et al., 2002, p. 354). By contrast, in this paper I am proposing a definition for a conceptual *object*. Yet, I believe the cognitive activities performed in the mental actions 4 and 5 can produce a conceptual object, which is the very covariation that exists between the rate of change itself and the independent variable. Thus, the concept of covariation dealing explicitly with the rate of change is, then, exactly the concept of concavity I propose.

To define the "inflection point concept," I note that mental actions 4 and 5 can be seen as essentially recycling through mental actions 1–3, with the "dependent variable" quantity being replaced by the "rate of change" quantity. In other words, mental actions 4 and 5 recursively trace through the first three mental actions again, but with the more sophisticated layer of one of the variables being the rate of change (see Table 2). Note that mental action 2 coordinates the *direction* of change, which I interpret to mean *increasing* or *decreasing*. Within mental action 2, one can track places where a *switch* in the *increasing/decreasing* of the rate of change takes place. Thus, within this mental action, if a switch in increase/decrease is identified, a conceptual object can be produced,

which is "change in the direction of covariation," which has much in common with the concepts of maximum or minimum. I then define this "change in covariation" as the "inflection point concept" precisely when one of the covarying quantities is the rate of change itself. Note that in this definition, an inflection point is *not* a point on a graph, but rather a "switch in increase/decrease" of the rate of change as the independent variable changes. Of course, it can be represented graphically as a point, but it is only that—a visual representation of a deeper idea centered on covariation.

Table 2: Mental Actions 4 and 5 Recycling through Mental Actions 1, 2, and 3

Mental Actions: 4. Coordinating *average rate-of-change* 5. Coordinating *instantaneous rate of change*	1. Coordinating *dependence* of rate of change on independent variable 2. Coordinating *direction* (*i.e. increase/decrease*) of change in the rate of change with respect to the independent variable 3. Coordinating *amount* of change in the rate of change with changes in independent variable
Conceptual objects produced	→ Concavity concept = *covariation* between rate of change and variable → Inflection point concept = change in *direction* of covariation

I point out that I am careful to state definitions for the concavity *concept* and the inflection point *concept*, as I am not attempting to define them mathematically. A mathematical definition is a way to take a conceptual idea and create a formal statement for it (see Tall & Vinner, 1981; Zandieh & Rasmussen, 2010). By contrast, this framework is not intended to create a standardized *formal* definition, but rather to put forward an argument for what we, as a field, should consider to be the core conceptual ideas for these two concepts, which may then be represented in various possible ways in textbooks or other mathematical writings.

Comparing the Framework to the Common Graphical Approach

In this section, I address two issues: First, if the framework is simply a repeat of the ways that concavity and inflection points are already typically approached and used, then it is of little use. This framework should offer something beyond what one could already find in other presentations on these two concepts. Second, despite the need for the conceptual framework to offer something new, it must also resonate with the way in which that concept *is* commonly used, defined, and represented in the mathematical community, including in educational research literature and textbooks. Otherwise, it may be that the framework does not even capture what the community considers to be "concavity" and "inflection point."

To address the first of these issues, I describe how concavity and inflection points are often approached and represented in the research literature and in textbooks. Many studies that deal with concavity and inflection points discuss them through the activity of graphing, or through graphical images (e.g., Asiala, Cottrill, Dubinksy, & Schwingendorf, 1997; Baker et al., 2000; Gómez & Carulla, 2001; Tsamir & Ovodenko, 2013). Similarly, many textbooks I have examined primarily define and discuss these concepts through the graphical register (e.g., Finney, Demana, Waits, & Kennedy, 2012; Hughes-Hallett et al., 2012; Smith & Minton, 2008; Stewart, 2014; Thomas et al., 2009; Zill & Wright, 2011). Many textbooks do provide a definition of concavity based on the first derivative increasing or decreasing, yet these books still seem to ascribe concavity as only a feature of a *graph*. For example, Finney, Demana, Waits, and Kennedy (2012) begin their definition with, "The *graph* of a differentiable function $y = f(x)$ is…" (p. 197, emphasis added), and Smith and Minton (2008) start their definition with, "The *graph* of f is…" (p. 238, emphasis added). The book

by Briggs, Cochran, and Gillett (2015) is the only book I have examined that indicates that the *function* itself might be considered concave up or down. Consequently, my conceptual framework offers a new perspective that takes a stance against convention, in that I do not define the concavity and inflection point concepts through graphical terms at all, but as concepts rooted in the ideas of covariation.

Moving to the second issue, given that my stance goes contrary to convention, is my conceptual framework even consistent with what the community thinks of as "concavity" and "inflection points?" In many of the studies and textbooks listed in the preceding paragraph, the discussion regarding the relationship between an increase in the derivative, f', and the shape of the graph focuses on how the slopes of the tangent lines become more steep or less steep. However, one can ask, steeper according to what? Implicit in these kinds of statements is the idea of getting steeper as one moves *left to right*. If one moves *right to left*, the steepness trend would reverse. Thus, even these strictly graphical approaches have covariation inherently embedded in them: the slopes (quantity one) change with respect to the independent variable (quantity two).

Similarly, "inflection point" is often described as a change in one kind of graphical shape to another kind of graphical shape. Inherent in this description is the need to attend to whether the slopes' steepness increases or decreases (i.e. "direction"). These increases or decreases correspond to the mental action 2 with slope or rate of change as one of the quantities. A *switch* in that increase/decrease of slopes or rates of change aligns with the definition of the "inflection point concept" in this framework. Thus, this framework does speak to the same "concepts" discussed in the typical graphical approaches.

Implications for the Teaching and Learning of Concavity and Inflection Points

So far in this paper, I have (a) outlined potential *conceptual* (not mathematical) definitions of concavity and inflection points, (b) shown that this framework differs from conventional approaches, and (c) shown that despite the difference, it still speaks to the same concepts of concavity and inflection points used by the community. However, if this framework yielded no worthwhile implications for how concavity and inflection points are to be taught and learned, then it would still be little more than an academic exercise of small value. I believe that this conceptual framework for concavity and inflection points contains significant implications for the teaching and learning of these concepts. In this section, I first outline what it might look like for a student to "understand" these concepts according to my framework. I then re-examine examples of student difficulties described in the literature regarding the concavity concept and the inflection point concept to show how this framework can further illuminate the nature of some of these difficulties and provide ways to address them.

I was recently involved in a study in which we examined how students made sense of concavity and inflection points in real-world contexts (Gundlach & Jones, 2015) . While the students in the study exhibited a range of interpretations of concavity and inflection points, one student in particular showed an ability to think about, reason about, and make sense of concavity and inflection points in a range of contexts, from intuitive contexts (temperature) to more abstract contexts (the size of the universe). He also demonstrated a facility with the type of graphing problem used in Baker et al. (2000). I believe his proficiency with these concepts stemmed from the fact that he had mastery of the covariation mental actions and seemed to have codified these into some kind of conceptual objects—or at least he had begun to. For example, in one prompt, he was asked to describe how concavity related to a person's height over their lifetime. He first discussed the early period of a person's life, which he stated reflected "concave up."

> *Student*: The way I thought about it is that, over time, it seemed like the height increases. There's a bigger increase of height as you get older, up to a certain point… So from here to here

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

[indicates two points in time] it's less increase of height, whereas from here to there, about the same [time] length, it's a greater increase of height, and this would be concave up.

Here the student's comments reflected mental action 4, wherein average rates of change over equal-sized intervals were considered. What is important to note is that he realized that one of the covarying "quantities" in this case is the "increase of height," or the growth rate. Thus, the student has demonstrated a *dependence* of the growth rate on the time variable. As he moved to discuss a concave down period, he exhibited mental action 5 by dropping finite intervals of time from his explanations, and switched instead to continuously changing rates.

> *Student*: They're starting to get close to their full height, whatever that height happens to be. It'll still be increasing, it'll be increasing at a decreasing rate, which means that—that would have to be an inflection point [in order] for that rate, at which their height is changing, to change. And at that point it would begin to be concave down.
> *Interviewer*: …If the curve [i.e. the graph of the height function] doesn't go back down, is it not concave down? What would you say about that?
> *Student*: I'd still say it's concave down… that rate at which they're growing slows down, it still is concave down.

The student used the idea of a continuously changing growth rate, and stated that an increasing growth rate is defined as concave up, while a decreasing growth rate is defined as concave down. Note that he also described the inflection point as being dependent on a "change" in the growth rate from a growth rate that is increasing to a growth rate that is decreasing. Thus, he seemed to have encapsulated the "change in direction" from mental action 2, with one "quantity" being the growth rate. These sophisticated mental actions seemed to have produced understanding of covariation and change that were associated with the terms "concavity" and "inflection point." As such, this student seemed to demonstrate an *understanding* of these concepts according to this framework.

In this illustrative example of understanding, I wish to highlight that this student's discussion of and meaning for concavity and inflection points were *not* dependent on the shape of a graph, even though a graph was drawn during the discussion. Rather, it was his coordination of a changing *rate of change* with the dependent variable that drove his thinking and seemingly produced an understanding of the conceptual objects defined in this paper.

I now switch to focus on examples from the literature regarding student difficulties. First, I discuss a student difficulty described in Baker et al. (2000), in which at least two of the students in the study (Carol on page 567 and Jack on page 568) held the idea that concave up meant the graph was increasing and concave down meant the graph was decreasing. This idea was a source of difficulty for the students when it conflicted with information about the first derivative that seemed to contradict it. The question then becomes, if these two students knew that the *first* derivative dealt with increase/decrease, why did they also apply the idea of increase/decrease to the *second* derivative? Baker et al. proposed the idea that the students were not at an "inter-property" level, meaning they could not coordinate information from two different properties simultaneously. However, it seemed like the students attempted to do so, which is what created the conflict in the first place. To provide an alternate reason, note that this difficulty is consistent with the framework's interpretation of mental actions 4 and 5 being a recycling of mental actions 1–3. That is, making sense of concavity goes through the same cognitive activities as making sense of slope or rate of change. The problem is that the activities required in making sense of concavity take on an additional layer of sophistication since the recycled mental actions 1–3 now deal with one of the quantities being the "rate of change." Since it is likely that current graph-based approaches provide little instructional support to developing these sophisticated, layered mental actions, then it is possible that the recycled layer of mental actions 1–3 collapsed to the original layer of mental actions 1–3. It may

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

be that "concavity" was reduced in some sense to the same thing as "rate of change." Thus, the two distinct conceptual objects (concavity versus rate of change) became blurred into a single conceptual object, rate of change. To separate out these two objects, instruction would have to highlight the fact that concavity essentially retraces through the same concept as rate of change, but now *using* rate of change as one of the covarying quantities. I am in no way claiming that this would be an easy feat, but a necessary one if students are to fully understand these concepts.

In a second example, Tsamir and Ovodenko (2013) describe several students identifying inflection points as places where "the graph keeps increasing, but the slope changes dramatically," like a mountain trail changing from a gentle upward slope to a steep, difficult climb (p. 421). The reasons given by Tsamir and Ovodenko for this difficulty was that students look too holistically at graphs, or base their reasoning too much in real-world contexts (p. 421). However, this explanation does not provide much by way of how to address this problem, other than to be "less holistic" or to not use "real-world contexts." By contrast, I believe my framework provides a much deeper reason for this difficulty. In general, an "inflection point" is typically presented as a *change* in something (e.g., Hughes-Hallett et al., 2012; Stewart, 2014; Thomas et al., 2009), and the issue is in *what* changes exactly. There is a significant cognitive demand in recycling through mental actions 1–3 inside of mental actions 4 and 5, replacing one "variable" with the "rate of change" quantity. Specifically, an inflection point arises by noting a change in the "increase/decrease" inside mental action 2, if one quantity is understood to represent the rate of change. The students in Tsamir and Ovodenko's study may have been looking for something that met the usual criterion of a "change in something" when seeking to identify inflection points. Indeed, the idea of the graph going from a slower increase to a sudden, dramatic increase seemed to give the students some kind of "change" happening in the rate of change. Yet, despite the students' possible recognition of the need for a change in the rate of change, they did not have a fully-formed object associated with a switch in the *direction* from mental action 2. Only a switch of *increase-to-decrease* (or vice versa) in the rate of change is appropriate for identifying an inflection point. Thus, this framework would indicate that the students in that study were, in fact, making decisions intelligently, but without a fully formed conceptual object of *what* exactly should change about the rate of change. In other words, instead of looking at students' inability to attend to relevant features of a graph, or of particular shapes, it may be that we should help students see that a change from increasing rates of change to decreasing rates of change (or vice versa) is what constitutes an inflection point.

Conclusion

In this paper, I have shown that despite the heavy graphical emphasis on concavity and inflection points, these concepts may have more important core meanings than as the "shape of a graph." What the core ideas are has important ramifications for the teaching and learning of these concepts, and how we view, understand, and address student difficulties. I have proposed a framework that *conceptually* (not mathematically) defines concavity as the concept of *covariation* in which one quantity is the rate of change, and inflection points as a *change in direction* of this covariation. Thus, this framework provides one possible answer to the question, "What does it mean for a student to understand concavity and inflection points?"

CHILDREN'S LINGUISTIC AND NUMERIC UNIT COORDINATION

Karl W. Kosko   Rashmi Singh
Kent State University   Kent State University
kkosko1@kent.edu   rsingh9@kent.edu

Detailing is a linguistic tool for mathematical argumentation in which given mathematical information is operationalized through one's warrants to support a claim. Recent literature suggests that students' detailing is related to their early algebraization. This study examined 168 elementary students' use of detailing in two mathematical argumentative tasks in relation to their enacted scheme of multiplicative unit coordination. A convergent mixed methods approach was used to analyze students' argumentative writing qualitatively, and merge these findings with quantitative indicators for students' multiplicative reasoning. Results suggest a statistically significant relationship between students' detailing and their multiplicative unit coordination.

Keywords: Elementary School Education, Number Concepts and Operations, Reasoning and Proof

The development of mathematical argument in the elementary grades is relatively undertheorized. Although various descriptions and models of how children come to engage in more sophisticated mathematical argumentation and/or proof have been proposed (Blanton & Kaput, 2011; Krummheuer, 2007; Morris, 2009; Tall et al., 2011), the vast majority of such descriptions focus only on generalized arguments. This bias towards generalization is understandable, given the necessity of generalization in the desired development of proof processes. However, it has neglected aspects of children's mathematical argumentation that may precede inference and generalization. Following Peirce, Kosko (2016) defined the purpose of mathematical argument as establishing an acceptable mathematical claim of truth. According to Peirce (1903/1998), argument necessarily involves inference for generalization. Yet, the first step of argumentation, colligation, precedes inference. *Colligation* occurs when an individual conveys the collective warrants for their argument as a singular copulative proposition. The copulative proposition can then be used to support a generalized claim. For example, in proving *the sum of two consecutive odd integers is divisible by two*, an individual may use the equation $n + (n + 2) = 2n + 2 = 2(n + 1)$ as part of their proof. The equation includes several propositions that, collectively, support the claim to be proven. Colligation in mathematical argument is facilitated by various linguistic tools (Kosko & Singh, 2016a). However, this particular study focuses specifically on the linguistic tool of detailing, in which the given information from a task is operationalized via a reference chain as a means of providing cohesion for a copulative proposition (Kosko, 2016; Kosko & Singh, 2016a).

Recent study of children's detailing in mathematical argument has identified a potential relationship with abstraction of number (Kosko, 2016; Kosko & Singh, 2016a; Kosko & Singh, 2016b). Specifically, children's abstraction in unit coordination of number has been found to relate to their abstraction of linguistic information units in argumentation. In the present study, we seek to investigate this phenomenon further by studying children's engagement in detailing in relation to their demonstrated unit coordination in multiplicative contexts. Therefore, the purpose of this study is to examine children's detailing enacted in MAW across several tasks in relation to their enacted multiplicative coordination of units.

Theoretical Framework

Detailing as Colligation in Children's Mathematical Argumentative Writing
The present study takes a Peircian semiotic view of mathematical argument as a theoretical lens, while applying Systemic Functional Linguistics (SFL) as an analytic lens. Peirce (1903/1998)

defined *argument* as a sign that synthesizes various propositions to establish a generalizable claim. Further, arguments synthesize other abstracted signs including, but not limited to, copulative signs. *Copulative signs* are the synthesized set of propositions used to foreground the inference towards a generalizable claim. As such, copulative signs are part of arguments, but do not include logical inference or a generalizable claim. The formation of a copulative sign involves the action of colligation, or the collective expression of propositions into a singular copulative proposition. Colligation is facilitated by various linguistic tools. Kosko and colleagues (Kosko, 2016; Kosko & Singh, 2016a; Kosko & Singh, 2016b; Kosko & Zimmerman, 2015) have identified at least two such linguistic tools: nominalization and detailing. Nominalization occurs when two or more mathematical linguistic objects are metaphorically conveyed as one (Halliday & Matthiessen, 2004). For example, $4n+2$ is considered as a singular expression, but includes the discrete nominal objects $4n$ and 2 as being summed. Further, $4n$ could be considered as the product of two discrete nominal objects (4 and n). Thus, nominalization facilitates colligation as a tool for abstraction of multiple nominal objects. Although nominalization is useful, and often essential, for colligation, the present study limits its focus to the linguistic tool of detailing.

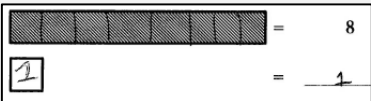
Kosko (2016) describes detailing as the operationalization of given information through the construction of a reference chain through the warranted propositions supporting a claim. According to Halliday and Matthiessen's (2004) approach to SFL, reference serves the role of establishing cohesion for a text. In this manner, reference chains can be used to establish new information and re-establish given information for conveying and establishing *information units*. Information units are grammatical units that establish new information based on given information. Detailing goes beyond more common applications of reference chains in that given information is continuously operationalized and built up over multiple warranted propositions (i.e., information units). The following third grade student's mathematical argumentative writing provides an example of detailing The child was asked to respond to the Cuisenaire-rods based task *If a red rod is 5, a yellow rod can't be 9 because…* Elements of the detailed reference chain are in bold, with grammatical clauses separated by "//":

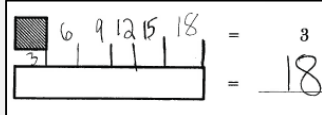
> The yellow rod can't be 9 // because **1 red one is 5** // and **that** does not take it all up // so you put **another 5** // and **it's** still not big enough // but **it [is] basically 10** // and **it's** smaller than the yellow // so the yellow can't be 9.

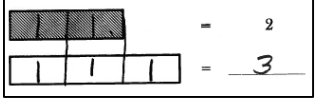
The child's writing begins and ends with their non-generalized claim that a yellow can't be 9 long. The clauses between serve the role of the copulative proposition, which is cohesively bound by a detailed reference chain. The given, **1 red one is 5**, is operationalized in the information unit **it [is] basically 10**. The operationalized referent, **10**, is exophoric in that it presents new information not in the information unit. Although technically new information, **10** is established in the information unit from the given information in a manner that represents a transformed, or operationalized, version of the given referent. Thus, **10** is part of a detailed reference chain that is used to establish the claim of yellow not being 9 long. Halliday and Matthiessen's (2004) definition identifies both referents as different information units, but detailing allows for the formation of a unique type of reference chain that establishes a copulative proposition. Specifically, **it [is] basically 10** serves as a link in the detailed reference chain connected to the given **1 red one is 5** as well as the referent in the proposition "**it's** smaller than the yellow." Although each proposition provides a different exchange of given and new information, each new information referent is a transformed version of the given information allowing for cohesion. Thus, detailing allows for all three propositions to collectively serve as a copulative proposition to support the child's claim.

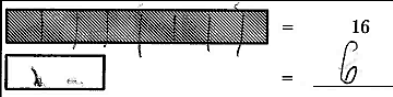
As can be gathered from the preceding description, detailing allows for the linguistic coordination and cohesion of different information units into a singular copulative proposition. The primary aim of the present study is to investigate whether children's choice of detailing (i.e.,

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

linguistic unit coordination) coincides with their demonstrated ability to coordinate mathematical units (i.e., number). Thus, we briefly discuss multiplicative unit coordination to foreground a description of a conjectured relationship between these two concepts.








Children's Multiplicative Unit Coordination

This study considers multiplicative reasoning from the perspective of scheme theory, with specific focus on Hackenberg's (2010) multiplicative concepts. According to Steffe (1994) multiplicative schemes require the coordination of at least two levels of units, and to develop multiplicative concepts students require the anticipatory use of such schemes. Specifically, students may construct schemes, or collections of actions, *in activity* (as they are engaged in a task), or they may use them in anticipation of the actions they expect to engage with the task (i.e., *anticipatory schemes*). Hackenberg (2010) suggests three stages of students' multiplicative concepts with the subsequent concept requiring more the use of anticipatory schemes where in activity schemes may have been used previously. The transition from less to more sophisticated multiplicative concepts is gradual, and intermediate levels are developed successively through internalizing in-activity schemes such that they begin to be used as anticipatory schemes (Norton et al., 2015).

Anticipatory and in-activity schemes described above are based on qualitative assessments and assume that a student transitions gradually from enacting schemes in activity, to using schemes in an anticipatory manner. However, examination of whether students enact multiplicative schemes either in activity or in an anticipatory manner incorporates a depth of analysis that requires more time than can be devoted when considering larger sample sizes. Such is the case in the present study ($n = 168$). Therefore, we adopt the approach of Kosko and Singh (in review), in which evidence of schemes *enacted* by students is identified from written work. Such evidence is, by its nature, an artifact of the activity generally observed by qualitative teaching experiments. Therefore, enacted schemes, as defined in the present study, do not distinguish between in-activity and anticipatory schemes. However, enacted schemes are further assessed with enacted reversible schemes to attempt a closer representation of anticipatory schemes than in-activity. Although enacted schemes do not allow for the critical distinction between in-activity and anticipatory schemes, their use does allow for larger scale data collection (Kosko & Singh, in review).

Following Hackenberg's (2010) three multiplicative concepts, but with the caveat of using enacted schemes in place of in-activity and anticipatory, the present study considers students' multiplicative reasoning via four tiers. The tiers align with Hackenberg's (2010) multiplicative concepts. Multiplicative Tier 0 (MT-0) involves pre-multiplicative schemes (i.e., counting by 1s with records of counting). The other three tiers (MT-1, MT-2, and MT-3) are similar to Hackenberg's three stages respectively with the primary difference that the basis of classification in our case is the enacted rather than the anticipatory scheme. In other words a student belonging to MT-1 can be considered to fall in Hackenberg's first multiplicative concept. Thus the first multiplicative tier (MT-1) involves the enacted coordination of two levels of units, and MT-2 involves the enacted coordination of three levels of units. MT-3 involves the enacted coordination of three levels of units, as does MT-2, but shows clear evidence of disembedding with non-1 units, and is considered more likely to correspond to Hackenberg's (2010) definition of the third multiplicative concept.

Table 1: Students' Unit Coordination and Enacted Schemes

Tiers	Students' ways of Unit coordination	Enacted schemes	Examples
MT-0	No unitization or unit coordination	Iterating 1 units *n* times	
MT-1	Students' may coordinate two levels of units	Partitioning into *n* parts to find 1 units.	
		Iterating non-1 units *n* times	
MT-2	Students' may coordinate three levels of units	Partitioning into *n* parts to find non-1 units.	
		Disembedding a unit to iterate *n* times.	
MT-3	Students' can coordinate with three levels of units even with rational numbers.	Decompose partitions into non-1 units (may include coordination of partitions in both length models).	

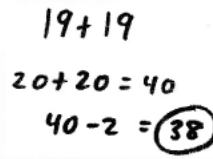
Coordination of Mathematical Quantitative and Mathematic-Linguistic Information Units

Recent examinations of elementary children's use of detailing have found relationships between whether students engage in detailing and their success on tasks requiring multiplicative reasoning (Kosko, 2016; Kosko & Singh, 2016a), as well as the emergence of nominalization in mathematical argument and the development of relational conceptions of equivalence (Kosko & Singh, 2016b). Such findings follow prior research identifying relationships between students' generalizations and their success with early algebra tasks (e.g., Blanton & Kaput, 2011; Morris, 2009), but examines the interplay between the development of mathematical argumentation and early algebra at a finer gran size of analysis. The present study posits an even more specified view of this interplay. Specifically, children's use of detailing colligates information units to create copulative signs (Kosko, 2016; Kosko & Singh, 2016a; Kosko & Zimmerman, 2015). Children's creation of copulative signs points to an ability to abstract multiple meanings as one. In a very similar fashion, children's coordination of quantitative units in ways mathematics education researchers would consider as multiplicative also points to an ability to abstract multiple meanings as one. Although these two types of coordination point to the same ability to abstract meaning, we conjecture that they are not necessarily the same, but similar enough to co-occur more often than not. However, such a potential interplay is important, given the potential of one type of coordination to influence the development of the other (Kosko, 2016).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

The interplay conjectured here provides a much needed mechanism for explaining observed co-development of early algebra and mathematical argument, with a specific focus on multiplicative reasoning and detailing. Because detailing involves the coordination of multiple information units into what Pierce (1903/1998) refers to as a copulative proposition, and multiplicative reasoning at its initial tiers involves the coordination of multiple non-1 quantities into a singular number, we conjecture that both forms of coordination involve a similar form of abstraction. Thus, they should be more likely to co-occur than not. Our rationale for this conjecture lay in the nature of both kinds of coordination. Specifically, information units are composed of multiple nominal elements such that each proposition must be considered, at least tacitly, as its own entity. Similarly, multiplicative reasoning requires that a non-1 unit be considered at least as a grouping of 1s that can be operated upon. Coordination of propositions (in the form of information units) via detailing requires a level of linguistic coordination beyond simply providing a sequence of propositions. Rather, the propositions must be cohesively joined, and this is an aspect of linguistic coordination that seems to become more prevalent beginning in the second grade (Kosko & Zimmerman, 2015). Likewise, multiplicative reasoning involves the coordination of number beyond counting by 1s; a form of unit coordination that appears to begin emerging more prevalently in second and third grade (Kosko & Singh, in review). Therefore, the level of coordination involved in detailing and multiplication is similar in that both move beyond the basic operations of their domains, but involve at least some movement to coordination units of units. Should our conjecture hold true, we would anticipate seeing a relationship between children's multiplicative reasoning and their detailing across different types of tasks. Thus, we ask the following research question: How does children's multiplicative unit coordination relate to the presence of detailing in their mathematical argumentative writing?

Methods

Sample and Measures


Data were collected in May 2015 from 168 second and third grade students in two suburban school districts in a Midwestern U.S. state. Second grade students were enrolled in four different teachers' classrooms ($n = 76$) and third grade students were enrolled in three different teachers' classrooms ($n = 92$). Participants completed two packets across two weeks. In week one, the packet included a multiplicative reasoning assessment. In week two, the packet included six mathematical argumentative writing tasks, although we limit our discussion in the present paper to only two tasks for sake of space and simplicity (Tasks 3 and 4).

The multiplicative reasoning assessment was developed by Kosko and Singh (in review) and includes 12 items designed to assess students' use of different enacted unit coordination schemes. We used a rubric involving 11 codes to assess students' demonstrated work (Kosko & Singh, in review).The students were assigned to a particular tier if they received correct scores to over half of the items in that tier. As an example we assigned students to MT-2 who got 3 out of 4 items (aligned with MT-2) correct, provided they also meet the criteria for lower tiers. Our analysis placed 67.5% students in MT-0, 18.4 % in MT-1, and 14.1 % in MT-2. None of the students were placed in MT-3. A Cronbach's alpha coefficient of .86 was calculated for the enacted schemes in all 12 items across different tiers, suggesting sufficient reliability of the assessment (for further information on the assessment, see Kosko & Singh, in review).

The mathematical argumentative writing tasks included six tasks with three incorporating length model representations of arithmetic and three incorporating the use of expressions and equations for arithmetic. The two tasks discussed in the present paper are presented in Table 2. Task 3 required students to use Cuisenaire rods (a color-coded length model) and assume that a red rod is 5 long, although it cannot be physically partitioned into 5 sub-units. Kosko (2016) found that use of this task encouraged more detailing than a similar task in which allowed for such physical partitioning.

Similarly, Task 4 requires students to consider three separate expressions/equations in relation to one another. To do so, it was assumed that detailing would be necessarily enacted to communicate the strategy cohesively (i.e., that each expression/equation serves as an information unit that can be colligated via detailing).

Table 2: Mathematical Argumentative Writing Tasks

Task 3*	Task 4
If a red rod is 5 long, a yellow rod can't be 9 because…	Omar was asked to find the answer for **19 + 19**. This is what he wrote on his paper: $19 + 19$ $20 + 20 = 40$ $40 - 2 = \boxed{38}$ Explain how Omar solved the problem and why it does (or doesn't) work.

*Students completed task 3, and other length model tasks, with Cuisenaire rods.

Analysis

The present study incorporates a data-transformation variant of convergent mixed methods design (Creswell & Plano Clark, 2011). Specifically, an SFL approach to examining functional grammar was used to qualitatively analyze second and third grade students' use of reference and detailed reference chains in their mathematical argumentative writing. Findings were organized into classifications that were quantified into variables for Chi-Square analysis. Quantitative data was collected from the multiplicative reasoning assessment and merged with the quantified SFL analysis for the mixing of data. Un-quantified qualitative findings were then used to help interpret quantitative findings from the Chi-Square analysis.

Qualitative analysis of functional grammar. We used SFL to examine the presence and patterns of reference use in children's mathematical argumentative writing. Reference is part of the textual metafunction of grammar, with its primary role to promote cohesion and coherence to an audience (Halliday & Matthiessen, 2004). A child communicating mathematically may use isolated referents, or may use reference chains that link referents in two or more propositions. In the present study, Kosko's (2016) description of detailing is used to distinguish between general reference chains and detailed reference chains. Detailed reference chains were coded for the operationalization of initial given referents in a manner that colligated two or more information units. Information units are clause-level grammatical units that connect given and new referents to convey information (Halliday & Matthiessen, 2004). Detailing, as defined in this paper, creates reference chains with endophoric and exophoric references that allow for two or more information units to be considered holistically as a colligated proposition.

The structure of mathematical writing tasks typically provides given information and an indication for a claim to be established; similar to Herbst and Chazan's (2011) described norms for providing a proof problem in high school Geometry. This structure allows for the construction of hypothetical reference chains that are more likely to be written to form a copulative proposition. For Task 3 (see Table 2), a complete and detailed reference chain should include a reference to the red rod being 5 long, operationalization of this given stating that two reds are 10 long, and an extension of this latter proposition to convey that 10 cannot be less than 9. Presence of variations of these three propositions was coded as detailing, but no other variations of detailing were observed. Both authors examined data for the initial information unit, incomplete detailing (i.e., two but not all three information units present), and complete detailing. Data were quantified, and coding was found to have strong interrater reliability (K=.67). Coding was then dichotomized to compare prevalence of detailing and not detailing in the quantitative analysis (*M*=.22, *SD*=.42).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Similar to coding of Task 3, Task 4 had one identified and coded detailed reference chain including two information units: a proposition conveying that Omar added 1 to each 19, and a proposition conveying that 2 be subtracted from the total. Incomplete detailing was observed when referents were not operationalized in a manner to colligate the two information units. As with the prior discussed task, data were quantified and coding was found to have strong interrater reliability (K=.90). Data were then dichotomized to compare prevalence of detailing and not detailing (M=.38, SD=.49).

Quantitative analysis of multiplicative reasoning and detailing. Chi-Square statistics were calculated to investigate whether the presence of detailing in students' MAW coincided with their multiplicative tiers. The relationship between detailing and multiplicative tier was found to be independent from chance both for Task 3 ($\chi^2(df=2) = 8.121$, $p = 0.017$) and Task 4 ($\chi^2(df=2) = 18.971$, $p = 0.000$). In order to better understand these findings, a post hoc analysis was used to examine the differences between specific observed and expected frequencies within individual cells of the Chi-Square contingency table. The adjusted standardized residuals for each cell in the 2x3 table (i.e., dichotomous detailing code X three observed multiplicative tiers) were calculated, and represent a statistic similar to a z-score for the difference between observed and expected counts in each cell (Haberman, 1973). Critical values for adjusted standardized residuals were ±2.0. Statistically significant and positive residuals were observed for the presence of detailing for students at MT-2 for Task 3 (2.5) and Task 4 (3.1), as well as for students at MT-1 for Task 4 (2.4). Students at MT-0 were observed to engage in detailing less than expected by chance for both Task 3 (-2.6) and Task 4 (-4.3). Therefore, the multiplicative tier a student was placed was found to coincide with the presence or absence of detailing, with the observed frequencies are outside those expected by chance. However, differences in magnitude of adjusted standardized residuals suggest that the relationship may vary by task.

Discussion and Conclusion

Findings from this paper suggest that elementary children's enactment of detailing in their mathematical argumentative writing on two tasks is not independent from their demonstrated ability to coordinate units multiplicatively. However, it is important to note that both analyzed tasks solicited detailing that directly linked endophoric with exophoric references between propositions. It is likely that some tasks may solicit less (or more) sophisticated reference chains. For example, some mathematical writing tasks may solicit reference chains that link only endophoric references together, which is less linguistically complex than detailing solicited from the tasks in this paper. It is also feasible that a task may solicit the linking of exophoric references between two information units, providing a more linguistically complex example of detailing than presented in this study. Such variations of detailing and reference use in mathematical argument are in need of further study. Although the present study did not explore such variations, there are specific and significant implications of these findings.

Earlier in this paper, we conjectured that linguistic coordination of information units via detailing and unit coordination via demonstrated multiplicative reasoning were similar enough in their observable structure to co-occur among elementary children. The findings of the present study provide additional evidence for this conjecture, as does recent work in this area (Kosko, 2016; Kosko & Singh, 2016b). Although these two types of coordination point to the same ability to abstract meaning, we conjecture that they are not necessarily the same. From a theoretical perspective, this suggests we should not expect a students' demonstrated ability with one coordination type to automatically coincide with the other. Yet from a practical perspective, findings here suggest that the similarity of each coordination type may allow for improved instruction of each via incorporation of the other.

LAS FUNCIONES SINUSOIDALES Y LOS FENÓMENOS ARMÓNICOS

THE SINUSOIDAL FUNCTIONS AND THE HARMONIC PHENOMENA

Minerva Martínez Ortega	Hugo R. Mejía Velasco	María De Los Angeles Martínez
Cinvestav IPN	Cinvestav IPN	Intituto Politécnico Nacional
cetis76@hotmail.com	hmejia@cinvestav.mx	mamigcar@hotmail.com

En esta investigación se discute el relacionar la descripción de ciertos fenómenos armónicos (física), con modelos que los representan (matemáticas), para así promover el entendimiento del período, la frecuencia y la amplitud de las funciones trigonométricas, en particular de las funciones sinusoidalesl. Esta es una investigación en curso, donde se emplea tecnología digital, como el sensor de movimiento, para generar gráficas de las funciones sinusoidales. En ellas se identifican rasgos del movimiento que siguen los fenómenos armónicos. Se hace un planteamiento que permite transitar alternativamente del análisis del fenómeno físico al del modelo matemático. Se conjetura que la forma en que se abordan las funciones sinusoidales puede permitir que se asigne significado al modelo $f(x) = A\cos(wx + \varphi)$.

Palabras clave: Educación Post-Secundaria, Modelación, Tecnología

Planteamiento del Problema

Los autores que en matemática educativa han realizado investigaciones sobre las funciones trigonométricas (Blacket y Tall, 1991; Brown, 2006; Buendía y Cordero, 2005; Hertel y Cullen, 2011; Kendal y Stacey, 1996; Moore, 2009; Weber, 2005), entre otros], concuerdan que independientemente de la estrategia que se emplee, las etapas iniciales del aprendizaje de las funciones trigonométricas están llenas de dificultades, lo cual propicia que la mayoría de los alumnos de l4 a 17 años de edad (*high school*), no interpreten adecuadamente los conceptos involucrados con este tipo de funciones, en particular, con la función sinusoidal. A pesar de ello, las investigaciones que sobre la enseñanza de las funciones trigonométricas se han realizado, son escasas (Moore, 2010).

En asignaturas de física e ingeniería es indispensable un buen entendimiento de las funciones trigonométricas*;* sin embargo, existe la problemática de que el objetivo en los cursos de matemáticas es construir significados de los parámetros de las funciones sinusoidales, mientras que, de manera particular, el objetivo en los cursos de física es construir interpretaciones de los fenómenos (armónicos) y profundizar en el entendimiento de éstos con las funciones sinusoidales; pero, el mundo físico y el mundo de los objetos matemáticos están desvinculados, de modo que la frontera entre ellos es inconexa; por ejemplo, muy pocos alumnos manejan la característica fundamental de las funciones trigonométricas: la periodicidad (matemáticas), y son menos los que pueden aplicar este tipo de funciones como modelo de fenómenos periódicos (física). Al respecto, la NCTM (1989) dentro de sus estándares (grado 9-12), para el estudio de la trigonometría (estándar 9), define que uno de los objetivos a cubrir cuando se estudia esta asignatura es que los alumnos exploren fenómenos periódicos de la vida real usando las funciones seno y coseno. Sin embargo, para entender ciertos fenómenos periódicos que ocurren de manera cotidiana o para que los alumnos de bachillerato continúen con estudios superiores de ingeniería, es esencial cruzar la frontera o tender puentes entre la física y la matemática, por lo que en este trabajo se identifican, y analizan qué significados asocian los alumnos a la función sinusoidal, a través del estudio entre la conexión de modelos físicos de fenómenos armónicos, como el péndulo y el sistema masa resorte o el caminar (regular o uniformemente) de los alumnos, con las representaciones matemáticas de éstos, como las gráficas; estas últimas representaciones serán generadas por los fenómenos a analizar, un sensor de movimiento y un programa graficador.

En este reporte de investigación, se comentarán los resultados que hasta el momento se tienen sobre el movimiento corporal de los alumnos y el péndulo. La intención de esto es llegar a definir el objeto matemático que modela a dichos fenómenos, la función sinusoidal, planteándose las siguientes preguntas de investigación: (1) ¿Qué acciones permiten describir a los fenómenos armónicos y qué representaciones surgen de dicha descripción?, (2) ¿A partir de las representaciones de los fenómenos armónicos, cómo se redescribe a estos fenómenos y qué resignificación se genera del modelo matemático que los representa?, (3) ¿El uso de herramientas digitales, de qué manera apoya en la construcción de significados de la función sinusoidal?

Como objetivo*s* se tienen: (1) Analizar, describir y sistematizar los significados que los estudiantes asocian a la relación entre el modelo de la función sinusoidal y los fenómenos armónicos, (2) Describir y analizar los argumentos utilizados por los alumnos, para justificar, explicar y/o probar conjeturas cuando se emplean herramientas digitales en la determinación de la función sinusoidal como modelo de fenómenos armónicos.

Perspectiva Teórica

En la construcción de significados, implícita o explícitamente, los estudiantes ponen en juego concepciones personales o espontáneas; en el caso de la enseñanza de la matemática en el salón de clase, comúnmente se dejan de lado dichas concepciones y se ven a los objetos matemáticos como productos acabados, desvinculados de su origen e independientes del sujeto que los estudia. Difícilmente se toma en cuenta que cualquier acercamiento a un objeto matemático transforma la relación que se tenga con él y por consiguiente la representación del mismo (Moreno, 2014).

Para darle significado a las funciones sinusoidales, en esta investigación, se considera como punto de partida a las representaciones espontáneas o implícitas y a los fenómenos que las funciones sinusoidales modelan, ya que esto puede ayudar a una reinterpretación y resignificación de las mismas, de tal suerte que éstas puedan representarse de manera explícita, **(**Pozo, 2006). De hecho, Hitt (2006, 2013) enfatiza la importancia de las representaciones espontáneas (producto de representaciones funcionales) de los estudiantes, y los procesos de objetivación que permiten realizar una evolución de esas representaciones en la construcción del signo y su significado.

Como la investigación está en curso, hasta el momento, el marco conceptual considerado para el diseño y aplicación de actividades piloto se fundamenta en que al analizar el fenómeno físico, los alumnos logran un entendimiento inicial, el cual se da de manera intuitiva y lleva a hacer una representación implícita (espontánea, primer acercamiento al objeto matemático), para que a partir de esta representación se reinterprete el fenómeno físico; es decir, se redescriba al fenómeno, lo cual implica una resignificación de los símbolos de la representación matemática (modelo matemático) para llegar una representación institucional, general y/o abstracta es decir el objeto formal: la función sinusoidal, (Figura 1).
Figura 1: Resignificación de la función sinusoidal.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Diseño de Investigación

La investigación es de tipo cualitativa. Las actividades piloto que aquí se describen se aplicaron a un grupo de 10 alumnos que se encontraban cursando el primer semestre de bachillerato (15-16 años), lo que supuso no habían tenido ningún acercamiento al tema de las funciones sinusoidales. La descripción del esquema anterior (Figura 1), como tal, determina el diseño de la investigación. El paso (i) requiere una trayectoria hipotética de aprendizaje (Simon, 1995; Simon y Tzur, 2004), un diseño de actividad para los sujetos que participan en la toma de datos. En el paso de (ii) se toman datos por escrito y en vídeo para saber qué reinterpretaciones plantean los alumnos. Finalmente, en el paso (iii), desde el fenómeno, se toman datos para saber qué resignificaciones realizan los sujetos.

Análisis de Datos

Hasta el momento, el experimento se ha realizado en tres etapas: 1) exploración, 2) interpretación-representación y 3) reinterpretación-resignificación. El desarrollo de la primera etapa se dio en 3 sesiones de 2 horas cada una; la segunda y tercera etapas se aplicaron en 2 sesiones de 2 horas. El objetivo de la primera fue identificar las concepciones previas que los alumnos tenían al describir un fenómeno armónico. En la segunda, el objetivo que se siguió fue identificar las representaciones implícitas que, con respecto al fenómeno físico y modelo matemático, lograron describir los participantes. La tercera etapa tuvo por objetivo, que a partir de la representación inicial que los alumnos tuvieron del fenómeno físico (segunda etapa), se redescribiera a éste, para así llegar a una descripción explícita (institucional) del modelo matemático $f(x) = A\cos(\omega t + \varphi),$ el cual describe al fenómeno analizado.

Primera Sesión. Descripción del Fenómeno (Concepciones Preliminares)

Se solicitó a los alumnos: Describir con el mayor detalle posible, cada uno de los fenómenos que observaron (péndulo, sistema masa resorte y movimiento circular de un objeto atado a un cordón, dicho objeto seguía una trayectoria circular vertical y circular horizontal).

Los participantes realizaron la descripción asociándola a aspectos físicos de los modelos presentados, materiales y colores. Dieron el nombre correcto de uno de los dispositivos (el péndulo). Los alumnos mencionaron ideas sobre conceptos como fuerza, movimiento, distancia, velocidad y aceleración; aunque éstas en su mayoría fueron incorrectas o ambiguas. En las respuestas se mostró la recurrencia a concepciones o ideas aprendidas previamente; o bien, a situaciones que, aparentemente, a simple vista se observaron (aun y cuando éstas eran imprecisas). Por ejemplo, el total de alumnos mencionó a la *fuerza* como la causa del movimiento de la lenteja, o que *la fuerza* en un momento determinado *se acababa*, y por consecuencia *el objeto ya no estaría en movimiento*, así como que una vez que un *cuerpo estaba en reposo ya no actuaba sobre él ninguna fuerza*, etc. Las concepciones mostradas por los alumnos en esta actividad se quedaron en la frontera de la física y eran, en gran medida, basadas en representaciones de naturaleza implícita, algunas de ellas similares a como en sus inicios la humanidad intentó conceptualizar el movimiento. Ningún alumno se apoyó en el uso de alguna representación que implicara un concepto formal, una fórmula o el uso, en particular, de algún signo aritmético, algebraico o diagramático. Las concepciones implícitas fueron el punto de partida para que, por parte de los alumnos, surgieran rasgos esenciales de las funciones sinusoidales. Se pretendió un cambio conceptual o representacional de éstas (segundo movimiento del proceso planteado en el marco teórico. Figura 1).

Segunda Sesión. Empleando Herramientas Digitales

Además de que los alumnos se ambientaran con el uso de las herramientas digitales, el objetivo de esta actividad fue que los estudiantes identificaran y asociaran la manera en que se representa el movimiento en una gráfica cartesiana; el análisis se centró en el comportamiento y representación del fenómeno físico, (1er movimiento. Significación. Figura 1); para ello, los alumnos caminaron frente

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

a un sensor de movimiento, que conectado a una computadora generaba la gráfica con rasgos particulares del andar de los jóvenes. Por ejemplo:

Alejandro: Cuando los compañeros caminaban de un punto hasta acercarse al sensor, la gráfica marcaba que en la distancia empezaba de 5 hasta disminuir a 0, porqué cada vez se acercaba más y el sensor lo reconocía muy cerca, por eso iba descendiendo y cuando empezaba cerca del sensor y terminaba alejándose, la gráfica lo reconocía desde 0 hasta que se detenía en el segundo 3.1 a 3.5, eso pasaba porque se detenía, y cuando no se detenía la gráfica seguía subiendo.

En el caso de Alejandro, la representación inicial que generó incluyó la toma de datos numéricos, a partir de los cuales regresó a la redescripción del fenómeno (2do. Movimiento. Figura 1).

Posteriormente se les pidió a los alumnos que, con lápiz y papel, bosquejaran la gráfica de la acción de asistir a la escuela si ellos partían de su casa, debiendo regresar a ella después de tomar clases.
Figura 2. Gráfica generada por Alma sobre un recorrido.

Alma: Es lo mismo, solo que el sensor es la escuela.

Lo expuesto por Alma, representó un ejemplo de que se ha construido una representación explícita del sensor al considerarlo como referente, ya que logró trasladar la situación de las gráficas generadas con el sensor a un nuevo contexto, estableciendo un nuevo punto de referencia, la escuela.

En este actividad los alumnos empezaron a rebasar la frontera de una situación física cotidiana hacia la representación matemática. A continuación se solicitó a los alumnos que bosquejaran, también en lápiz y papel, la acción anteriormente planteada, pero ahora correspondiente a una semana y sin considerar el tiempo que permanecían en la escuela.

En este punto, los alumnos identificaron características del movimiento periódico (al cual ellos se refirieron como repetitivo); de manera básica determinaron el período, en el caso de Alma, ella estableció que tarda 2 horas en ir a la escuela y 2 horas en regresar a su casa. (1er movimiento. Figura 1).
Figura 3. Gráfica generada por Alma sobre 5 recorridos.

La cuestión de la no diferenciabilidad, se trató en una sesión posterior. Los alumnos, después de un largo debate, concluyeron que *es imposible obtener* (caminando), *una gráfica con picos, ninguna persona se mueve tan rápido y logra representar el movimiento de esa manera*. (2do. Movimiento. Figura 1). Posteriormente, una gráfica sinusoidal fue presentada a los alumnos (sin que ellos supieran que se trataba de una gráfica de ese tipo), se les solicitó que caminando frente al sensor hicieran los movimientos necesarios para reproducirla. Los alumnos caminaron de diferente manera; por ejemplo, tratando de seguir la representación icónica de la gráfica, levantando las rodillas o como algunos de ellos dijeron *como si caminara un borracho* o asociaron el tipo de gráfica a la velocidad con la que se caminaba. Después de un número considerable de intentos, a Carlos se le ocurrió que el movimiento debía ser *haciendo el mismo paso, es decir ir y regresar*. El alumno parándose frente al sensor realizó un movimiento que consistió en dar dos pasos hacia el sensor y dos pasos alejándose del mismo.
Figura 4. Gráfica generada por Carlos al caminar.

Profesora: ¿Por qué se te ocurrió que el movimiento debía ser así?
Carlos: Porqué si se acercaba uno (hacia el sensor), iba bajando (la representación gráfica); si se aleja uno (hacia el sensor), iba subiendo (la misma representación).

Después de realizar esta acción, Carlos asoció que este tipo de gráficas son generadas por un movimiento periódico, ya que realiza la siguiente pregunta:

Carlos: ¿Se puede poner la mano en el sensor?

Carlos se refirió, a si el movimiento que generaría la gráfica solicitada, era posible hacerlo, en lugar de la manera anterior, acercando la mano hacia el sensor y alejando la mano del mismo, ambos movimientos repetidas veces, Carlos verificó la veracidad de su conjetura frente al sensor.

En una actividad anterior, se analizó el movimiento rectilíneo; éste, además de servir de ambientación en el uso del sensor, se tomó como referencia para identificar la características de la gráfica cuando un alumno se acercaba o se alejaba del sensor, Carlos logró integrar estos tipos de movimiento en uno solo (movimiento de carácter repetitivo a intervalos de tiempo iguales), lo cual le permitió definir las acciones a seguir para generar, con ayuda del sensor, una grafica del tipo sinusoidal. (2do. Movimiento. Figura 1).

En la segunda parte de esta sesión, se empleó un péndulo simple. Las características del movimiento pendular se representaron en el plano cartesiano, primero se hicieron manualmente (lápiz y papel), posteriormente con la mediación del sensor de movimiento. Solamente tres alumnos lograron mostrar un significado explícito al determinar la gráfica *manual* de manera correcta, justificando que recordaron lo que ocurrió cuando se solicitó reproducir la gráfica sinusoidal con movimientos corporales, los alumnos relacionaron el *caminar de manera uniforme* frente al sensor, con el *movimiento repetitivo del péndulo*, (2do. Movimiento. Figura 1). Para verificar o rectificar la gráfica bosquejada por cada alumno, se obtuvo la gráfica del movimiento pendular a través del

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

sensor, especificando que la gráfica mostrada correspondía a una función sinusoidal. Acto seguido, se discutieron las características de la gráfica, el principal rasgo a resaltar fue, como los jóvenes lo mencionaron, *la repetición o existencia de un patrón*. (2do. Movimiento. Figura 1).

Posteriormente, se eligió aleatoriamente una gráfica de las obtenidas en la actividad anterior y se solicitó a los alumnos mencionar los elementos que observaban en la gráfica (2do. Movimiento. Figura 1), primero identificaron las *oscilaciones*, los alumnos las refirieron como *montañas* o *máximos*, después de un análisis y discusión, se concluyó que hay *montañas invertidas o mínimos* a considerar, la justificación la dio Carlos argumentando que las *montañas* representaban las idas del péndulo y las *montañas invertidas* los regresos de éste. La profesora estableció que lo mencionado por Carlos se conoce como *oscilación* y que el tiempo que implica una oscilación, se identifica como *período (P)*.

La *amplitud* fue el segundo elemento mencionado, éste fue asociado con la *altura de las montañas*, la profesora retomó la idea de *máximo*, como el punto más alto de la *montaña* y *mínimo* al punto más bajo de la *montaña invertida*, al igual que el *período*, el valor de la *amplitud*, es posible determinarlo directamente con el menú del programa de cómputo empleado en la investigación. Sin embargo, la profesora mencionó un procedimiento analítico para calcular la *amplitud* |A|.

> *Profesora:* Una vez que se localizan las coordenadas del punto máximo y del punto mínimo, se suma los valores absolutos de las ordenadas y el resultado se divide entre 2, el resultado será el valor de la ordenada que junto con cualquier valor de la abscisa (tiempo), será el eje de equilibrio, ya que la amplitud puede definirse como la distancia entre el punto máximo o mínimo y el eje de equilibrio.

Al preguntar a los alumnos qué representa la *amplitud* en el fenómeno físico, fue necesario repetir el experimento del péndulo y después de un largo análisis o debate, Mariano mencionó que *la amplitud era el dibujo de las oscilaciones*, Carlos relacionó que *lo que el péndulo abre* (arco de oscilación) *era lo que en la gráfica se veía como la altura*.

El desplazamiento vertical (V), fue identificado como *la distancia de péndulo* (en la posición de equilibrio) *al sensor*, Samantha mencionó que *a mayor distancia la gráfica salía más arriba*. A los alumnos no les llamó la atención que las gráficas no empezaran en el origen cartesiano, por lo que no identificaron *el desplazamiento horizontal,* ni que el origen de la gráfica estaba determinado por el sensor, por lo que la profesora lo explicó (definiendo que forma parte del modelo matemático).

Cuando la profesora preguntó qué nombre recibían las funciones que se habían estado graficando, ningún alumno lo recordó (No se da el 2do. Movimiento. Figura 1). La profesora conjuntó lo discutido anteriormente y mencionó que la manera de representar matemáticamente este tipo de funciones es: $f(t) = A\cos(Bt + H) + V$, (3er. Movimiento. Figura 1); la representación de los parámetros, fue elegida por los alumnos) A es la *amplitud*; B la velocidad *angular*, está relacionada con el *período* (P), $B = \frac{2\pi}{P}$; H el *desfase o desplazamiento horizontal* y V el *desplazamiento* vertical. En la siguiente actividad, a los alumnus se les solicitó determiner el modelo matemático de la siguiente gráfica (Figura 5.

Figura 5. Gráfica modelada.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Los valores de los parámetros de la gráfica anterior fueron determinados por 2 de los alumnos (Samantha y Carlos); a excepción del *desfase*, Mariano calculó los valores del resto de los parámetros; los otros alumnos solo calcularon la *amplitud* y el *desplazamiento* vertical,

$$f(t) = 0.12cos(1.12t - 0.46) + 0.47$$

Posteriormente se pidió a los alumnos que comprobaran los valores determinados de la gráfica, Carlos lo hizo ayudándose del menú del programa que se empleó para generar las gráficas.

Carlos: Oscilaciones son 5.513, el 513 porque con la opción *analice* y después *examine* se obtiene el *time* en 6.2 y *position* en 513 y el 5 porque son 5 oscilaciones completas. El período 6.2 entre 5.513=1.12. El desfase, igual, con *analice* y *examine* se ve que es de 0.46 y el desplazamiento vertical de 0.47. La amplitud, en la segunda oscilación, el mínimo es de 0.354 y el máximo de 0.607, 0.354+0.607=0.961 entre 2=0.4805; 0.607-0.4805=0.1265. (3er. Movimiento. Figura 1).

Carlos determina la representación analítica de la gráfica presentada (Figura 5), aunque confundió el período con la velocidad angular; al solicitarle que aplicara la relación $B = \frac{2\pi}{P}$, él cambió el valor de la velocidad: $f(t) = 0.12cos(5.5t - 0.46) + 0.47$. Carlos obtuvo de la gráfica los desplazamientos vertical y horizontal, lo cual indicó que tuvo una representación explícita de los conceptos previamente analizados; sin embargo, *para* calcular la amplitud no la relacionó con la distancia (vertical) del punto máximo de la gráfica (o punto mínimo) con el valor del desplazamiento vertical, ya que nuevamente calculó dicho valor; por lo tanto, de la amplitud (aunque determina el valor correcto), no tiene la representación explícita completa.

Resultados Preliminares

La primera etapa permitió identificar las concepciones que los alumnos tienen al describir un fenómeno armónico. En la segunda, se lograron identificar las representaciones implícitas que lograron describir los alumnos, así como las ventajas y obstáculos de las tecnologías digitales en las que nos apoyamos. A partir de esta etapa, se pudo observar que 2 alumnos (de 10), lograron pasar de una representación implícita o espontánea a una representación explícita, el resto de los alumnos solo asignaron significado a la amplitud y el desplazamiento vertical, al lograr trasladar estos conceptos de la representación gráfica al fenómeno físico analizado y viceversa. Sin embargo, falta experimentar estas dos etapas con los modelos del sistema masa resorte y el movimiento circular y así dar respuesta a la primera pregunta de investigación. A demás falta concluir la tercera etapa de experimentación, en la cual, partiendo de la representación analítica, se reinterpretará al fenómeno físico, cerrando de esta manera un primer ciclo como el mostrado en la figura 1. Se buscará que los alumnos resignifiquen al fenómeno armónico analizado en la primera sesión, lo cual permitirá sortear la frontera que existe entre la física y la matemática, llegando así a una redescripción del fenómeno y a la resignificación del modelo algebraico institucional, enfocándose en consolidar conceptos relativos al período $P = \frac{2\pi}{B}$, la frecuencia y la amplitud.

Hasta el momento se observó que el sensor de movimiento y los modelos físicos de los fenómenos armónicos, así como el diseño y guía de la actividad fueron herramientas esenciales; a través de éstas se eliminaron algunas de las dificultades que las representaciones de las funciones sinusoidales tienen por si mismas; por ejemplo la forma de generar la representación gráfica, permitió a los alumnos identificar y asignar significado a los signos que representan los parámetros de las funciones sinusoidales; cuando fue necesario modificar dichos parámetros, se hizo de una manera relativamente sencilla, solo se tenían que caminar frente al sensor o repetir el experimento, y comprobar si las predicciones o conjeturas eran ciertas o debían replantearse.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

In this research we discuss relating the description of certain harmonic phenomena, with models that represent them, with the goal of promoting the understanding of the period, the frequency, and the amplitude of the trigonometric functions, particularly referring to sinusoidal functions; in this way the frontier between sinusoidal functions and one of its areas of application to physics is preserved. This is an ongoing research study where digital technology like a movement sensor is employed in order to generate graphics related to sinusoidal functions, in which the movement features followed by harmonic phenomena are identified. It is important to mention the use of an approach where it is possible to transit alternatively from the analysis of the phenomena to the mathematical model. It is conjectured that the way it approaches sinusoidal functions could help assign meaning to the model f(x) =Acos(ωx+ϕ).

Keywords: Post-Secondary Education, Modeling, Technology

Problem Statement

The authors who have done research in mathematics education related to trigonometric functions (e.g., Blacket & Tall, 1991; Brown, 2006; Buendía & Cordero, 2005, Hertel & Cullen, 2011; Kendal & Stacey, 1996; Moore, 2009; Weber, 2005), agree that regardless of the strategy employed, the initial stages of learning trigonometric functions are filled with difficulties, which causes most of the students between 14 to 17 years of age (High school), to incorrectly interpret the concepts related to this type of functions, in particular, referring to the sinusoidal function. Nevertheless, research studies associated to the teaching of trigonometric functions have been scarce (Moore, 2010).

In subjects related to physics and engineering a good understanding of the trigonometric functions is essential; while the goal in mathematics courses is to build meaning for the parameters of the sinusoidal functions, the aim in the physics courses is, in particular, to build interpretations of the (harmonic) phenomena and deepen in the understanding of these regarding sinusoidal functions; but, the world of physics and the world of mathematical objects are not linked, and as a result the border between them is disjointed; for example, very few students know of the fundamental feature of trigonometric functions: the periodicity (mathematics), and even fewer are the ones who can apply this type of functions as a model of periodic phenomena (physics). Regarding this situation, the NCTM (1989) within its standards (grade 9-12), for the study of trigonometry (standard 9), defines that one of the objectives to be covered when studying this subject is for students to explore real life periodic phenomena using the functions sine and cosine. However, in order to understand certain periodic phenomena that happen on a daily basis or for high school students to continue with engineering studies at the university level, it is essential to cross the border or build bridges between physics and mathematics, which is why in this paper the meanings students associate to sinusoidal functions are identified and analyzed through the study of the connections between physical models of harmonic phenomena, like the pendulum and the mass spring system or the walking (regularly or uniformly) of students, with their mathematic representations, such as graphics; these representations will be generated by the phenomena to be analyzed, a movement sensor and a graphing program.

In this research report, the current results regarding body movement of the student and the pendulum will be discussed. The intention is to be able to define the mathematical object modeling such phenomena, the sinusoidal function, posing the following research questions: (1) Which actions allow to describe harmonic phenomena and which representations arise from such descriptions?, (2) Based on the representation of harmonic phenomena, how can these phenomena be redescribed and which resignification of the mathematical model that represents them can be generated?, (3) How does the use of digital tools support the building of meanings of the sinusoidal functions?

As objectives, we have: (1) Analyze, describe and systematize the meanings students associate to the relation between the model of the sinusoidal function and harmonic phenomena, (2) Describe and analyze the arguments used by students, in order to justify, explain and/or try conjectures when employing digital tools to determine a sinusoidal function as a model of harmonic phenomena.

Theoretical Perspective

When building meaning, implicitly or explicitly, students put into play personal or spontaneous conceptions; in the case of in-class mathematics teaching, these previously mentioned conceptions are commonly left aside and mathematical objects are seen as finished products, un-linked to their origin and independent from the subject that studies them. It is hardly ever taken into account the fact that any getting close to a mathematical object transforms the relation one has with it and as a result its representation of itself (Moreno, 2014).

In order to give meaning to sinusoidal functions, in this research, spontaneous or implicit representations and phenomena modeled by sinusoidal functions are considered as a starting point, since this could help a reinterpretation and resignification of themselves, so that they can be represented in an explicit manner, (Pozo, 2006). As a matter of fact, Hitt (2006, 2013) makes emphasis on the importance of spontaneous representations (product of functional representations) from students, and the observation processes which allow to perform an evolution of these representations when building sign and meaning.

As the research is ongoing, for now the conceptual framework considered for the design and application of pilot activities is based on the fact that when analyzing a physical phenomena, students achieve an initial understanding, which is achieved intuitively and leads to an implicit representation (spontaneous, first contact with the mathematical object), so that from this representation the physical phenomena can be reinterpreted; that is, the phenomena is redescribed, which implies a resignification of the representation of mathematical symbols (mathematical model), to reach an institutional representation, general and/or abstract which means the formal object: the sinusoidal function, (Figure 1).
Figure 1. Resignification of sinusoidal function.

Research Design

It is a qualitative research. The pilot activities described in here were applied to a group of ten students during their first semester of high school (15-16 years of age), which meant that they had not had any kind of previous exposure to the subject of sinusoidal functions. The description on the previous scheme (Figure 1), as such, determines the design of the research. The step i) Physical phenomenon to representation requires a hypothetical learning trajectory (Simon, 1995; Simon & Tzur, 2004), a design of activities for the subjects who take part in the study. On step ii) Representation to physical phenomenon, written and video data are collected in order to identify the reinterpretations that students pose. Finally, on step iii), from the Physical phenomenon, data are taken in order to identify the resignifications that the subjects perform.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Data Analysis

Up until now, the experiment has been performed in three stages: 1) Exploration, 2) interpretation-representation and 3) reinterpretation-resignification. The development of the first stage took place in three two-hour sessions each; the second and third stages were applied in two two-hour sessions each.

The objective of the first stage was to identify the previous conceptions students had when describing harmonic phenomena. At the second stage, the objective was to identify the implicit representations that the participants were able to describe according to the physical phenomena and mathematical model. The main objective for the third stage was that starting from the students' initial representation of the physical phenomena (second stage), it was redescribed, in order to achieve an explicit description (institutional) of the mathematical model $f(x) = A\cos(\omega t + \varphi)$, which describes the analyzed phenomenon.

First Session. Description of the phenomena (Preliminary Conceptions)

Students were asked to: Perform a detailed description of each and every single one of the phenomena they observed (pendulum, mass spring system and circular movement of an object tied to a cord, an object which follows a vertical circular trajectory and horizontal circular trajectory).

The participants performed the description associating it to physical aspects of the presented models, materials and colors. They gave the correct name to one of the devices (pendulum). The students mentioned ideas related to concepts such as force, movement, distance, speed and acceleration; even though they were in their majority incorrect or ambiguous. Their answers showed recurrence to concepts or ideas previously learned; or, situations which, apparently, were observed at first sight (even when they were inaccurate). For example, all students mentioned *force* as the main cause for the lentils movement, or that at any given moment force would be over, and as a result the object would *no longer be moving*, as well as that once a *body was at rest no longer was any force applied*, etc. The conceptions shown by students in this activity were stuck in the physics frontier and were, in their vast majority, based on representations of implicit nature, some of them were similar to how in the beginning mankind tried to conceptualize the concept of movement. No student relied on the use of any representation that would have implied a formal concept, a formula or the use, in particular, of any arithmetic, algebraic or diagrammatic sign. The implicit conceptions were the starting point to understand essential features of sinusoidal functions. A conceptual or representative change of this (second movement of the process described in the theoretical framework. Figure 1) was intended.

Second session. Employing digital tools.

Besides getting the students acclimated to the use of digital tools, the objective of this activity was for students to identify and associate the manner in which movement is represented in a Cartesian graph; the analysis was centered around the behavior and representation of the physical phenomena, (1st movement. Signification. Figure 1); for this, students walked in front of a movement sensor, which plugged to a computer generated the graphic with the particular features of the students walk. For example:

Alejandro: When the fellow students walked from a certain point up until getting close to the sensor, the graphic pointed that the distance started from 5 decreasing up to 0, because each time they got closer and the sensor detected that they were very close, that is why it was decreasing and when they started closer to the sensor and finish further away, the graphic recognized it from 0 until they stopped at the second 3.1 to 3.5, that happened because they stopped, and when they did not stop the graphic continue to increase.

In the case of Alejandro, the initial representation he generated included the compilation of numeric data, from which he came back to the redescription of the phenomena (2nd. Movement. Figure 1).

Afterwards students were asked to use a pencil and paper, in order to sketch the graph of the action of coming to school starting at home and including their having to return home after class.
Figure 2. Alma's graph of one round trip.

Alma: It is the same thing only that the sensor is the school.

What was exposed by Alma, represented a clear example that an explicit representation of the sensor has been built by considering it a reference point, given that she was able to translate the situation from the graphics generated by the sensor to a new context, establishing a new reference point, the school.

In this activity students started to leave behind the frontier of a daily physical situation towards the mathematical representation. Next students were asked to sketch, also using a pencil and paper, the action previously posed, but now applied to a week and without considering how much time they spent in school.

At this point, students identified features of periodic movements (to which they referred as repetitive); they determined the period in a basic manner, in the case of Alma, she established that it takes her two hours to get to school and two hours to go back home. (1st movement. Figure 1).
Figura 3. Alma's graph of five round trips.

The question regarding the no differentiability, was approached in a later session. Students, after a long debate, concluded that it is impossible to obtain (walking) *a graphic with peaks, no person is able to move that fast and achieve that kind or representation.* (2nd. Movement. Figure 1).

Afterwards, students were showed a sinusoidal graph (without them knowing they were dealing with that kind of graph), they were asked to perform the necessary movements while walking in front of the sensor in order to reproduce it. Students walked in different ways; for example, trying to follow the iconic representation of the graphic, lifting their knees or as some of them stated *walking*

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

like a drunk person or associating the type of graphic to the speed with which they walked. After a considerable amount of attempts, Carlos thought the movement should *be making the same walk, meaning to go and come back*. Standing in front of the sensor the student performed a move consisting of walking two steps towards the sensor and two steps backing away from it.
Figure 4. Graphic generated by Carlos at the moment of walking.

Teacher: Why did you think the movement should be like that?
Carlos: Because if one gets closer (to the sensor), it was going down (the graphic representation); if one gets away (from the sensor), it was going up (the same representation).

After performing the action, Carlos associated that this type of graph is generated by a periodic movement, given that he stated the following question:

Carlos: Could I place my hand on the sensor?

Carlos was referring to whether it was possible to perform the movement that would generate the requested graph in a different way, by reaching his hand closer to the sensor and moving the hand away from it, repeating both movements several times; Carlos verified the veracity of his conjecture in front of the sensor.

On a previous activity, rectilinear movement was analyzed; this, aside from working as a setting for the use of the sensor, was taken as a reference to identify the features of the graph at the time when a student was getting closer or further away from the sensor; Carlos was able to integrate this kind of movement in one (movement with a repetitive nature at equal time intervals), which allowed him to define the actions to follow in order to generate, with aid from the sensor, a sinusoidal kind of graphic. (2nd. Movement. Figure 1).

On the second part of this session, a simple pendulum was employed. Pendulum motion features were represented on a Cartesian plane, first manually (pencil and paper), later on with the use of the movement sensor. Only three students were able to show an explicit meaning at the moment of determining the *manual* graph in a correct manner, justifying that they remembered what happened when they were asked to reproduce the sinusoidal graphic with body movements, students related *walking uniformly* in front of the sensor, with the *repetitive movement of the pendulum*, (2nd. Movement. Figure 1). In order to verify or rectify the graph sketched by every student, the pendulum motion graphic was obtained using the sensor, specifying that the shown graph corresponded to a sinusoidal function. Immediately afterwards, the graph features were discussed, the main feature to be pointed out was, in the manner the young people mentioned, *the repetition or existence of a pattern*. (2nd. Movement. Figure 1).

Afterwards, one of the obtained graphs on the previous activity was chosen randomly and students were asked to point out the elements observed in it (2nd. Movement. Figure 1), at first they identified the *oscillations*, students referred to them as *mountains or maximums*, after analyzing and

discussing, it was concluded that there are *inverted mountains or minimums* to be considered, the justification was given by Carlos, arguing that the *mountains* represented the going of the pendulum and the *inverted mountains* its coming back. The teacher established that what Carlos had mentioned is known as *oscillation* and that the time employed by an oscillation, is identified as *period (P)*.

The *amplitude* was the second element mentioned, this was associated with the *height* of the *mountains*, the teacher turned back to the idea of the *maximum*, as the highest point of the mountain and *minimum* to the lowest point of the *inverted mountain*, just like the *period*, it is possible to determine the value of the *amplitude* directly with the menu of the software employed in this research. Nevertheless, the teacher mentioned an analytic procedure to calculate *amplitude* $|A|$.

> *Teacher*: Once the coordinates of the highest and lowest points have been located, the absolute values of the ordinates are added up and the result is divided by two, the result will be the value of the ordinate which together with any value of the abscissa (time), will be the midline (translation). Given that, amplitude can be defined as the distance between the highest or lowest point and the balance axis.

When asking students what the amplitude represents in the physical phenomena, it was necessary to repeat the pendulum experiment and after a long analysis or debate, Mariano mentioned that the *amplitude was the drawing of oscillations*, Carlos related that *how much the pendulum opens* (arc of oscillation) *was what in the graphic is observed as height*.

The vertical displacement (V), was identified as the *pendulum distance* (on a position of equilibrium) *to the sensor*, Samantha mentioned that *at greater distance the graph was higher*. Students did not pay attention to the fact that the graphs did not start on the Cartesian origin, which is why they failed to identify the *horizontal displacement*, nor that the origin of the graph was determined by the sensor, so the teacher explained it (making it clear that it is part of the mathematical model).

When the teacher asked the name of the functions that had been graphed, no student remembered (The 2[nd.] Movement is not given. Figure 1). The teacher put together what had been previously discussed and mentioned that the mathematical way of representing this functions is: $f(t) = Acos(Bt + H) + V$ (3rd. Movement. Figure 1; the representation of the parameters, was chosen by the students), A is the *amplitude*; B is the *angular* speed, it is related to the *period (P)*; $B = \frac{2\pi}{P}$; H is the *phase shift or horizontal displacement* and V the *vertical displacement*.

On the next activity, students were asked to determine the mathematical model of the next graph (Figure 5).
Figura 5. Model of the graph.

The values of the parameters in the previous graph were determined by two of the students (Samantha and Carlos); with exception to the *phase shift or horizontal displacement*, Mariano

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

calculated the values of the rest of the parameters; the rest of the students just calculated the *amplitude and the vertical displacement,* $f(t) = 0.12cos(1.12t - 0.46) + 0.47$

Afterwards, students were asked to check specific values of the graph, Carlos did it with the help of the menu of the software used to generate the graphics.

> *Carlos:* Oscillations are 5.513, the 513 because with the option *analyze* and then *examine* the *time* is obtained at 6.2 and *position* at 513 and the 5 because there are 5 complete oscillations. The period 6.2 divided by 5.513=1.12. The phase shift, also, with *analyze and examine* shows that it is 0.46 and the vertical displacement of 0.47. The amplitude, on the second oscillation, the minimum is 0.354 and the maximum is 0.607, 0.354+0.607=0.961 divided by 2= 0.4805; 0.607- 0.4805=0.1265. (3rd. Movement. Figure 1).

Carlos determined the analytic representation of the given graph (Figure 5), even though he confused the period with the angular speed; when asked to apply the relation $B = \frac{2\pi}{P}$, he changed the speed value: $f(t) = 0.12cos(5.5t - 0.46) + 0.47$. Carlos obtained the horizontal and vertical displacements from the graphs, which indicated he had an explicit representation of the previously analyzed concepts; nevertheless, when calculating the amplitude he did not relate it to the distance (vertical) highest point of the graph (or lowest point) with the value of the vertical displacement, given that he calculated such value again, as a result; regarding the amplitude (even though he determines the correct value), he does not have a complete explicit representation.

Preliminary Results

The first stage allowed us to identify the conceptions students have when describing harmonic phenomena. In the second stage it was possible to identify the implicit representations described by the students, as well as, the advantages and obstacles of the digital technology we rely on. From this stage, it was possible to observe that 2 students (out of 10), were able to go from an implicit or spontaneous representation to an explicit representation, the rest of the students were only able to assign meaning to the amplitude and vertical displacement, by getting to translate these concepts from the graphic representation to the physical phenomena and vice versa. Nevertheless, more experimentation is needed in these two stages with the models of the mass spring system and circular movement, to then give an answer to the first research question. Besides, the third experimentation stage is yet to be concluded, in which, starting with the analytic representation, the physical phenomena will be reinterpreted, as a result closing a first cycle as it is shown on Figure 1. It will be sought for students to resignify the harmonic phenomena analyzed on the first session, which will allow to avoid the existing frontier between physics and mathematics, reaching in this way a redescription of the phenomenom and the resignification of the institutional algebraic model, focusing in consolidating concepts related to period $P = \frac{2\pi}{B}$, frequency and amplitude.

Up until now it has been observed that the movement sensor and the physical models of the harmonic phenomena, as well as the design and guidance of the activity were both essential tools; through these, some of the difficulties that the representations of sinusoidal functions representations present were eliminated; for example the way in which to generate the graphic representation, allowed students to identify and assign meaning to the signs which represent sinusoidal functions, when it was necessary to modify these parameters, it was done in a relatively simple way, it was as simple as just walking in front of the sensor or repeat the experiment, and verify if the predictions or conjectures were true or if they had to be reassessed.

RELACIONES DINÁMICAS ENTRE CONVENCIMIENTO Y COMPRENSIÓN EN LA CONSTRUCCIÓN DE SUSTENTOS

DYNAMIC RELATIONS BETWEEN CONVINCEMENT AND COMPREHENSION IN THE CONSTRUCTION OF GROUNDS

Benjamín Martínez Navarro
Cinvestav, México
benjaminmartinezn@gmail.com

Mirela Rigo Lemini
Cinvestav, México
mrigolemini@gmail.com

En trabajos anteriores los autores de este escrito identificaron relaciones puntuales entre comprensión y convencimiento. Con base en la Teoría Fundada, en la investigación actual se analizan los cambios que se dan en dichas relaciones como respuesta a condiciones cambiantes. Para su estudio se analiza una interacción, a distancia, entre un tutor y una estudiante. En un primer nivel se realiza un microanálisis -acudiendo al Modelo de Toulmin- en el cual se describen e interpretan las relaciones entre comprensión y convencimiento que ahí surgieron. Desde una perspectiva más general, en un segundo nivel se adelantan explicaciones sobre esas relaciones y sus cambios. Al final se sugieren propuestas para la práctica educativa.

Palabras clave: Razonamientos y Demostraciones, Trayectorias de Aprendizaje

Antecedentes y Objetivos

En investigaciones diversas se ha destacado el peso que durante los procesos didácticos tienen el convencimiento y la seguridad en los hechos de las matemáticas que vivencian los agentes de clase. Por ejemplo, Krummehuer (1995) resaltó el convencimiento asociado a los soportes de los argumentos, para cuyo análisis utilizó el Modelo de Toulmin; despunta en su aplicación la omisión de los calificadores modales Q, ausencia que señalaron Inglis, Mejia-Ramos, and Simpson (2007). Estos autores sostienen que uno de los objetivos de la instrucción debe ser el desarrollo de habilidades de los estudiantes para igualar "adecuadamente" tipos de garantías con calificadores modales Q (p.3). Acorde con esa perspectiva, en un análisis puntual de los estados de confianza de los estudiantes, Foster (2016) sugiere que un alumno 'bien calibrado' en un tema es aquel que confía en sus respuestas correctas y duda de las que no lo son. A diferencia de esos reportes, el presente documento –que se orienta de acuerdo a la metodología de la teoría fundada y sigue la idea de que los argumentos se desarrollan en el marco de interacciones sociales que se dan en el aula (Krummheuer, 1995)- identifica y adelanta algunas explicaciones sobre fenómenos dinámicos e integrales del salón de clases de matemáticas; específicamente, se busca conocer ¿Cuáles son los posibles cambios que durante el proceso de construcción de argumentos en el aula de matemáticas se dan en las relaciones entre el convencimiento en torno a resultados de esa disciplina, y su comprensión? así como ¿Cuáles son las posibles razones de la presencia de distintas relaciones durante ese proceso?

Marco Teórico

Para analizar las participaciones de los estudiantes se recurrió al Modelo de Toulmin (Toulmin, Rieke, & Janik, 1984). En este modelo, un argumento está compuesto por una afirmación (C), datos (D), garantías (W), un soporte (B), y calificadores (Q). Toulmin, Rieke, y Janik (1984) consideran que Q consiste en "el grado de confianza que puede ser adjudicado a las conclusiones dados los argumentos disponibles para apoyarlas" (p. 85, 1984). En esa interpretación de Q se supone implícitamente un sujeto experto que califica. A diferencia, en el presente escrito se acepta explícitamente que es el sujeto que argumenta el que califica la fuerza de los componentes del argumento, y se considera que ese sujeto (que participa en un foro virtual) vivencia un estado de

convencimiento, o bien de presunción o duda en un enunciado matemático -los que Rigo (2013) denomina "estados epistémicos de convencimiento"-, cuando cumple con alguno(s) de los criterios que aparecen en la Tabla 1 (Martínez & Rigo, 2014).

Tabla 1: Instrumento Teórico-Metodológico para Distinguir Estados Epistémicos

Elementos del habla	La persona recurre a enfatizadores del lenguaje que pueden revelar un mayor grado de compromiso con la verdad de lo que dice, por ejemplo, cuando la persona usa el modo indicativo de los verbos (e.g. "es").
Acción	El sujeto realiza acciones consecuentes con su discurso.
Determinación	La persona manifiesta de manera espontánea y determinada su adhesión a la veracidad de un enunciado matemático
Interés	Las participaciones de una persona que interviene con interés en torno a un hecho matemático específico en un foro virtual son: *sistemáticas* (es decir, el sujeto contesta todas las preguntas dirigidas a él de la manera más detallada posible), *informativas* (sus afirmaciones, procedimientos y/o resultados son suficientemente informativos), *claras y precisas*.
Consistencia	La persona muestra consistencia en sus distintas intervenciones.

El contenido matemático de los fragmentos elegidos para este estudio es el de la resolución de ecuaciones lineales. En este escrito se considera al Modelo 3UV (Ursini, Escareño, Montes & Trigueros, 2005) como el procedimiento paradigmático escolar para encarar ese tipo de tareas. De acuerdo a ese modelo, los aspectos que indican una comprensión de la variable como incógnita específica cuando se resuelven ecuaciones lineales son: interpretar la variable simbólica que aparece en una ecuación como la representación de valores específicos (aspecto I1); determinar la cantidad desconocida que aparece en ecuaciones o problemas, realizando operaciones algebraicas, aritméticas o de ambos tipos (aspecto I4) y sustituir la variable por el valor o valores que hacen de la ecuación un enunciado verdadero (aspecto I3).

Al resolver una ecuación lineal los estudiantes pueden fundar sus argumentos en distintos marcos generales, es decir, en diferentes soportes, los cuales pueden estar conformados por constituyentes diversos. Uno de los constituyentes de los soportes se relaciona con los recursos de sustentación en los que se funda el argumento. A esos recursos Rigo (2013) les llama "esquemas epistémicos" de sustentación. Según la autora, mientras algunos sustentos se vertebran en torno a razones matemáticas, como las instanciaciones de reglas generales, otros se articulan en torno a consideraciones extra-matemáticas, como los esquemas operatorios que se activan cuando se introduce una regla sin justificación, basada posiblemente en la autoridad que se le otorga a las matemáticas. Por tanto, se pueden presentar soportes matemáticos y soportes extra-matemáticos para los argumentos. Otro de los constituyentes hace referencia al carácter aritmético o algebraico del argumento. En este escrito se sugiere (cf. Martínez y Pedemonte, 2014) que la resolución de una ecuación se basa en el álgebra cuando el sistema de referencia en los datos contiene literales, y el "núcleo del argumento" (i.e., sus D y su C) presenta una estructura de tipo deductivo, la que es posible explicitar a través de las garantías, ya que éstas descubren la estructura que articula el argumento. Se dirá que una resolución se soporta en la aritmética cuando el sistema de referencia en los datos se da por ensayo y error numérico, y el núcleo del argumento presenta una estructura inductiva. Otro indicador para determinar si el soporte contiene constituyentes aritméticos o algebraicos está relacionado con los elementos conceptuales que el alumno pone en juego cuando realiza el aspecto I3. I3 presupone el desarrollo, aunque sea sólo de manera intuitiva y tácita, del siguiente argumento: a) Considerar en la ecuación $ax+b=0$ un valor específico para x, i.e., que $x=r$, $r \in \mathbb{R}$; b) Instanciar en la ecuación, i.e., $a(r)+b=0$; c) Realizar operaciones aritméticas; d) Derivar

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

(eventualmente) una tautología aritmética: m=m; e) Desprender de d) que a) es una suposición correcta (de otro modo no se derivaría de ella una tautología), y que a(r)+b=0 es una proposición verdadera, esto es, que r hace verdadera a la proposición ax+b=0 (la cual es abierta, ya que carece de un valor de verdad), y que por tanto, r es una solución para dicha ecuación. Cuando el alumno procesa I3 con la conciencia de lo que significa que un valor específico $r \in \mathbb{R}$ "satisface una ecuación y resuelve el problema" (Ursini et al., 2005, p. 27), esto es, cuando tiene algunas intuiciones relacionadas con los pasos a) al e) del argumento antes expuesto, en este documento se considera que I3 coadyuva a su comprensión de la variable y que el soporte de su argumento contiene un constituyente algebraico. Cuando I3 queda sólo como un argumento incomprensible y rutinario para el estudiante que va sólo del paso a) al d) y él lo aplica solamente con el propósito de verificar ("en la aritmética", terreno seguro para el alumno) si los valores obtenidos son correctos, en este documento se considera que ese aspecto I3 coadyuva poco a la comprensión de la variable y que el soporte de su argumento incluye constituyentes aritméticos.

Metodología y Técnicas De Recuperación de la Información

Este escrito forma parte de un trabajo más amplio, inspirado en los procedimientos de la teoría fundada (Corbin & Strauss, 2015), cuyo objetivo es describir y construir explicaciones teóricas de fenómenos relacionados con los estados epistémicos que se dan en el salón de clases de matemáticas. El estudio se llevó a cabo en un diplomado -a distancia- cuyo propósito es fortalecer la formación de asesores que enseñan álgebra a adultos. Los datos que se usaron para el estudio quedaron registrados en la plataforma Moodle para su posterior análisis y forman parte de la interacción que un tutor mantuvo con sus estudiantes (en particular, con Belarmina). El tutor, quien propuso y guió las actividades, es uno de los autores de este trabajo. En trabajos anteriores, los autores identificaron relaciones puntuales entre comprensión y convencimiento. El trabajo actual está orientado por el "principio de cambio" de la teoría fundada, según el cual, los fenómenos se conciben como continuamente cambiantes. De modo que, a diferencia de otros estudios, las relaciones entre comprensión y convencimiento se consideran como parte de un proceso dinámico en el que dichas relaciones pueden modificarse en respuesta a condiciones cambiantes. Para analizar dichos cambios en las relaciones, se eligió una pieza de una interacción entre el tutor y Belarmina. El análisis se divide en dos apartados según el nivel de profundidad. Considerando los contextos de interacción, un primer nivel está dirigido a un micro análisis de las relaciones que se dieron entre los estados epistémicos del sujeto (Q) y su nivel de comprensión, al amparo de un soporte (B) específico. Para este análisis, la interacción se separó en fragmentos (distinguidos con un numeral) y se organizó en argumentos conforme al Modelo de Toulmin. En un segundo nivel, las relaciones entre comprensión y convencimiento se concentraron en tablas de análisis con el fin de obtener una perspectiva general del cambio de dichas relaciones a lo largo de la interacción. Para ofrecer explicaciones de las complejas relaciones entre comprensión y convencimiento, se tomó en cuenta el contexto en el que éstas surgieron y el principio de la teoría fundada, según el cual, los actores son capaces de tomar decisiones precisas de acuerdo a las opciones de que disponen.

Análisis de Resultados. Primer Nivel de Análisis: Descripción e Interpretación

1a Participación de Belarmina: Expresión de una Tendencia Algebraica y Operatoria

A manera de diagnóstico, el tutor propuso resolver a los estudiantes: Rosa tiene una balanza en equilibrio, de un lado una pesa de 5 kg y del otro una pesa de 2kg y un bulto de fierro. ¿Cómo puede hacer para saber el peso del fierro? En la Figura 1 se muestra la respuesta de Belarmina.

1.1	5=2+x donde x es el bulto de fierro	**D1.** a: 5=2+x donde x es el bulto de fierro; b: x=5-2	→	**C1.** 3kg
1.2	entonces x=5-2=3kg.	**W1.** a: La solución de la ecuación esta al lado derecho del signo igual (I1); b: Trasposición de términos (I4)		
		B1. a: Esquemas operatorios y álgebra (I1); b: Esquemas operatorios y álgebra (I4)		

Figura 1. Análisis de la 1ª participación de Belarmina. Argumento 1.

En su primera intervención, Belarmina experimentó seguridad en la aplicación de I1 e I4, la cual se deja ver en el uso del enfatizador "es" en 1.1, al actuar con base en las expresiones que derivó y mostrar determinación por publicar su respuesta. La aplicación de I1 e I4 la hizo conforme a esquemas operatorios (que se revelan por el carácter implícito de las reglas que enunció) y a una perspectiva algebraica, que se refleja a través de la estructura deductiva y el sistema de referencia algebraico en los datos.

Intervención del Tutor: Cuestionamiento del Soporte

| 2.2 | Una vez planteada la ecuación acostumbramos usar "trasposición de términos", pero ¿por qué funciona? Para averiguarlo realicemos la siguiente actividad. |
| 2.3 | Da clic en el interactivo, arma la ecuación en la balanza y llega a la solución. Describe paso por paso cómo llegaste a la solución. Por ejemplo: -2x-4=4x-4; Para dejar sola a la x realizo lo siguiente: 1.-Sumo a ambos miembros 4. La ecuación nos queda: -2x=4x; 2.- Sumo a los dos miembros 2x. La ecuación nos queda: 0=6x; 3.- Divido a los dos miembros entre 6. La ecuación nos queda: 0=x. La solución es 0. |

Como respuesta a Belarmina, el tutor cuestionó (v. 2.2) el constituyente operatorio sobre el cual la estudiante apoyó I4 (v. B1b). En la Figura 2 aparece lo que la alumna respondió.

2a Participación de Belarmina: Seguridad en el Sustento Algebraico y Operatorio

3.1	Para dejar sola a la x en: -4x-4=8x-4	**D2.** a: -4x-4=8x-4; b: sumo a ambos miembros 4; c: -4x=8x; d: sumo a los dos miembros 4x; e: 0=12x; f: divido a los dos miembros entre 12; g: 0=x	→	**C2.** La solución es x!!!
3.2-3.3	Sumo a ambos miembros 4. La ecuación nos queda: -4x=8x			
3.4-3.5	Sumo a los dos miembros 4x. La ecuación nos queda: 0=12x	**W2.** b-f: Determinar el valor de la literal con las propiedades de la igualdad (I4); g: La solución de la ecuación se encuentra a la derecha del signo igual (I1)		
3.6-3.7	Divido a los dos miembros entre 12. La ecuación nos queda: 0=x	**B2.** b-f: Álgebra y razones matemáticas (I4); g: Álgebra y esquemas operatorios (I1)		
3.8	La solución es x!!!			

Figura 2. Análisis de la segunda participación de Belarmina. Argumento 2.

Belarmina desarrolló I4 con base en las reglas promovidas por el tutor (v. W2b-f), y apoyada en un soporte algebraico y matemático (v. B2b-f), extendiendo su comprensión en este aspecto. Pero nuevamente, la alumna también afianzó su argumento en esquemas operatorios (B2g) cuando en el paso de D2g a C2 dio una interpretación incorrecta del signo igual (v. W2g) que la llevó a contravenir I1. Sobre la aplicación de W2g (relacionada con I1) e I4, Belarmina experimentó seguridad que mostró con el uso de enfatizadores (!!!), al actuar siguiendo las reglas que enunció y al mostrar determinación e interés por publicarlas. Como respuesta, el tutor cuestionó el uso implícito de la garantía W2g relacionada con I1: 1. ¿Qué entiendes por la solución de una ecuación? 2. ¿La solución de una ecuación puede expresarse con literales? ¿Por qué? En la Figura 3 se analizan las respuestas dadas por Belarmina.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

3a Participación de Belarmina: Duda Asociada a la Aparición de Razones Matemáticas

4.1	1.- [La solución es] Encontrar el valor que al sustituirlo en la ecuación por la incógnita permita llegar a una igualdad	**D3.** La solución es encontrar el valor que al sustituirlo en la ecuación por la incógnita permita llegar a una igualdad (I3)	**C3.** La solución de una ecuación no se puede expresar con literales (I1)
4.2	2.- Tutor, tengo duda en esta pregunta pero checando la pregunta de arriba entonces no se puede expresar con literales porque vamos a encontrar su valor. Corríjeme.		
		W3. Si la solución de una ecuación es el valor de la literal entonces la solución no se puede expresar con literales (I1)	
		B3. Razones matemáticas y álgebra	

Figura 3. Análisis de la tercera participación de Belarmina. Argumento 3.

En su participación, Belarmina parafraseó con seguridad I3 (ver en 4.1 el uso indicativo de los verbos y el empleo de I3 para derivar otra regla) en su versión aritmética, lo cual hizo conforme a esquemas operatorios y aritméticos. De esta versión escolar de I3, la estudiante dedujo con duda (ver 4.2) una conclusión C3 acorde con I1, conforme a una garantía soportada en razones matemáticas y algebraicas, ayudando a su comprensión de I1. Con el fin de que la estudiante aplicara las proposiciones que enunció, el tutor preguntó: 1.- ¿Cuál es el valor de la incógnita?; 2.- ¿Cómo comprobamos que ese valor es solución de la ecuación? En la Figura 4 se analizan las respuestas de Belarmina.

4a Participación de Belarmina: Duda al Aplicar una Nueva Garantía en los Datos

5.1	1.- [El valor de la incógnita] sería 0	**D4.** a: D2g y C3; b: Sustituimos el valor en la ecuación; c: -4x-4=8x-4; d: -4(0)-4=8(0)-4; e: -0-4=0-4; f: -4=-4; g: Existe igualdad	**C4.** Sería 0
5.2	2.- Espero y estar bien, si no, me corrigen. [Para comprobar] lo sustituimos en la ecuación		
5.3	-4x-4=8x-4; -4(0)-4=8(0)-4; -0-4=0-4; -4=-4	**W4.** a: W3 (I1); b-g: Versión aritmética de I3 (I3)	
5.4	Existe una igualdad en ambos lados	**B4.** a: Razones matemáticas y álgebra (I1); b-g: Razones operatorias y aritmética (I3)	

Figura 4. Análisis de la cuarta participación de Belarmina. Argumento 4.

En 5.1, Belarmina aplicó C3, relacionado con I1, con cierta inseguridad (ver el uso del mitigador "sería") que en su participación anterior soportó en razones matemáticas y bajo una perspectiva algebraica. En 5.3 la estudiante aplicó D3, relacionado con I3, bajo esquemas operatorios y aritméticos y lo hizo con duda (ver 5.2). A continuación, el tutor solicitó resolver: Bety tuvo que cobrar $178 de un billete de $200. Ella le preguntó al cliente si traía cambio y él le dijo que traía $3. Ella aceptó. ¿Cuánto tiene que regresar? Esta tarea, similar a la que Belarmina enfrentó en su primera participación, la planteó el tutor para identificar cambios que se dieron en su resolución después de la interacción. En la Figura 5 se analiza la respuesta de Belarmina.

5a Participación de Belarmina: Seguridad en un Soporte Algebraico

4.1	procedemos a despejar la incógnita;	**D5.** a: 200+3=178+x; b: 203=178+x; c: 203-178=178-178+x	**C5.** x=25
4.2	200+3=178+x;		
4.3	203=178+x; 203 -178=178-178+x;	**W5.** a: Interpretar la variable como un valor específico (I1); b-c: Determinar la literal con las propiedades de la igualdad (I4)	
4.4	x=25 que es el cambio que tiene que regresar Bety	**B5.** a: Razones matemáticas y álgebra (I1); b-c: Razones matemáticas y álgebra (I4)	

Figura 5. Análisis de la quinta participación de Belarmina. Argumento 5.

Belarmina aplicó I1 (aún cuando D5c pudo activar W2g) e I4 (esta vez con las propiedades de la igualdad), aspectos que previamente re-construyó con el tutor bajo un soporte matemático. Como en los casos precedentes, ella los administró con seguridad, estado que dejó ver mediante el uso de enfatizadores ("procedemos", "es"), de acciones congruentes con lo que enunció y la determinación e interés que exhibió al publicar su respuesta. Sin embargo, la estudiante dejó de aplicar I3, la cual construyó y empleó en sus contribuciones precedentes (v. D3 y D4). Así que el tutor cuestionó su solución C5: ¿Cómo podemos comprobar que el valor que obtuviste para la incógnita es solución de la ecuación? La respuesta a esta pregunta se expone en la Figura 6.

### 6a Participación: Seguridad al Aplicar una Nueva Regla

5.1	Sustituyendo lo que vale x, que en este caso es 25, en la ecuación 200+3=178+x	**D6.** a: 200+3=178+x; 200+3=178+25; 203=203 → **C6.** x=25
5.2	200+3=178+25; 203=203	**W6.** a: Si al sustituir un valor en una ecuación existe una igualdad, entonces ese valor es solución de la ecuación
5.3	de esta manera podemos comprobar que es correcto porque en ambos lados es la misma cantidad.	**B6.** a: Esquemas operatorios y Aritmética

Figura 6. Análisis de la sexta participación de Belarmina. Argumento 6.

En esta participación, Belarmina parafraseó tácitamente la versión aritmética de I3 y la aplicó en D6 bajo esquemas operatorios y aritméticos. En esta ocasión, ella mostró seguridad en esa versión de I3, al utilizar enfatizadores (e.g. "es") cuando la enunció, actuar conforme a ella (en 5.1 y 5.2) y mostrar determinación e interés por explicitarla. Enseguida, el tutor le pidió resolver:-4x-16=9x+1. En la Figura 7 aparece lo que la alumna respondió.

7a Participación: Omisión de un Procedimiento Aritmético
6.1	Tutor, esta es mi respuesta	**D7.** a: -4x-16=9x+1; b: -4x-16+16=9x+16+1; c: -4x=9x+17; d: -4x-9x=9x-9x+17; e: 13x=17 → **C7.** X=17/13
6.2	Ecuación: -4x-16=9x+1	
6.3	-4x-16+16=9x+16+1 (propiedad usada suma); -4x=9x+17; -4x-9x=9x-9x+17 (propiedad usada resta); 13x=17 (propiedad usada división)	**W7.** a: Interpretar la variable como un valor específico (I1); b-e: Determinar la literal con las propiedades de la igualdad (I4)
6.4	X=17/13	**B7.** a: Razones matemáticas y Álgebra (I1) b-e: Razones matemáticas y Álgebra (I4)

Figura 7. Análisis de la séptima participación de Belarmina. Argumento 7.

Para resolver la ecuación, Belarmina activó los aspectos I1 e I4 siguiendo con puntualidad el procedimiento sustentado algebraicamente que construyó con el tutor. Como en las ocasiones previas, asociado a este esquema la estudiante pareció experimentar convencimiento; se ve al usar el indicativo de los verbos cuando presentó su respuesta ("esta es"), actuar conforme a las reglas que enunció y mostrar determinación e interés por publicar y explicar su respuesta. Pero nuevamente, ella dejó de aplicar I3, por las (posibles) razones que se exponen en lo que sigue.

Análisis de resultados. Segundo nivel: explicaciones plausibles

Se exponen algunas explicaciones viables sobre las complejas relaciones entre los estados epistémicos y la comprensión que pueden surgir en los procesos de desarrollo de argumentos y en los de cambios y conformación de sus respectivos soportes (v. trayectorias Tabla 2, 3, 4).

Tabla 2: Dinámica de Relaciones Entre Estados Epistémicos, Comprensión y Soporte de I4

En la Tabla 2, se observa que el estado de seguridad vivenciado por Belarmina cuando aplicó reglas relacionadas con I4 permaneció sin alteraciones, aún cuando en la segunda intervención la estudiante cambió el constituyente operatorio del soporte a uno matemático al introducir nuevas reglas matemáticas (W2b-f). Esto revela la prontitud con la que la estudiante asimiló garantías relativas a I4 y que un aumento de comprensión puede ir acompañado de seguridad. Pero como se verá en lo siguiente esta asociación no siempre es inmediata.

Con respecto a I1 (Tabla 3), en su primera participación Belarmina experimentó seguridad cuando aplicó una regla según la cual la solución está a la derecha del signo igual (W1a) apoyada en un esquema operatorio que, en conjunción con la trasposición de términos, la llevó a obtener una respuesta acorde con I1. Con las propiedades de la igualdad que ella utilizó en su segunda intervención (W2b-f), dejó de trasponer términos, pero mantuvo su seguridad en torno a la regla W1a y la aplicó, lo que la condujo a trasgredir I1; esto puede explicar cómo es que la estudiante asoció seguridad a una proposición incorrecta. Los cuestionamientos del tutor a W1a, condujeron a la estudiante en su tercera participación a explicitar reglas (W3) acordes con I1 bajo esquemas matemáticos, ayudando a su comprensión. Sin embargo, aquí Belarmina dudó. Lo anterior desvela que un incremento de la comprensión no va necesariamente aparejado de un fomento en la seguridad, porque lo primero supone reacomodos cognitivos que suelen propiciar estados de inseguridad. Dicha inseguridad continuó en su cuarta intervención; no obstante, en la quinta y séptima, Belarmina prefirió esa garantía W3 (por sobre W1a) y le asoció seguridad.

En cuanto a I3, Belarmina parafraseó la versión operatoria y aritmética en su tercera participación pero sólo la aplicó cuando se lo solicitó el tutor, primero con duda y luego con seguridad. Se esperaría que, como ocurrió con I1 e I4, ella incluyera este aspecto I3 en su séptima participación; pero nuevamente, ella lo dejó de aplicar, aún cuando antes lo había manejado con seguridad, y aún cuando le hubiese permitido detectar el error en el que ahí incurrió. La trayectoria de resoluciones de Belarmina permite suponer fundadamente que esa omisión puede obedecer a que la versión aritmética y operatoria de I3 la llevaría al terreno de la aritmética dejando relativamente a lado el del álgebra, constituyente en el que ella sustentó sus resoluciones desde el inicio. Esta consideración es consistente con la respuesta que dio Belarmina cuando el tutor preguntó por su seguridad en torno a la solución que dio a las ecuaciones: "Yo me sentí segura de mis respuestas. En este caso seguimos

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

los pasos para solucionar una ecuación donde buscamos la incógnita y utilizamos las propiedades de suma, resta, multiplicación y división." A diferencia de Belarmina, otras estudiantes como Jeymi asociaron su seguridad a la comprobación (I3, versión aritmética); ella así se expresó: "Muy segura porque en la comprobación me resulta la igualdad". Basar la seguridad en un proceso aritmético, en lugar de asociarla a procesos algebraicos, se puede explicar porque, como apuntan Martínez y Pedemonte (2014), los estudiantes utilizan la aritmética para entender el álgebra.

Consideraciones finales: sugerencias para la práctica didáctica

Con base en el marco teórico-interpretativo, siguiendo los principios metodológicos de la teoría fundada y mediante un estudio de caso, en los dos niveles de análisis aquí expuestos se describen e interpretan pero también se explican distintos procesos que puede desarrollar un profesor para que el alumno, durante la dinámica de ese proceso, llegue a adquirir seguridad de un conocimiento bien fundamentado (v. la idea de estado 'bien calibrado' de Foster, 2016). En esos procesos puede aparejarse, por ejemplo, un aumento de comprensión con duda, porque lo primero significa reacomodos cognitivos ante cuestionamientos o contradicciones que suelen propiciar estados de inseguridad. Asimismo, una disminución de la comprensión puede asociarse a seguridad porque las relaciones entre la seguridad y razones extra-matemáticas pueden mantenerse a falta de razones matemáticas. La diversidad de relaciones que surgen entre comprensión y convencimiento son parte de la construcción natural del conocimiento en condiciones ordinarias, y son relevantes porque pueden orientar las intervenciones del profesor: la seguridad de un estudiante coligada a incomprensión, por ejemplo, puede requerir el cuestionamiento del soporte, la construcción de nuevas garantías y su aplicación; la inseguridad aunada a la comprensión de una garantía, por otro lado, puede requerir de su aplicación en diferentes contextos. Adicionalmente, sería deseable que el profesor considerara que los procesos de conformación de un soporte y la seguridad hermanada parece ser un fenómeno local: respecto a un tema, respecto a un constituyente del soporte y también, respecto a la formulación y aplicación de una determinada garantía. Esto es significativo porque alerta sobre el hecho de que los cambios en un aspecto puntual pueden no extenderse de manera automática a otros.

In previous publications the authors of this paper identified specific relations between comprehension and convincement. On the basis of Grounded Theory, this research analyzes the changes that arise in said relations as a response to changing conditions. For their study, the authors analyze an interaction, at a distance, between a tutor and a student. At an initial level, a micro-analysis is undertaken -resorting to the Toulmin Model- which describes and interprets the relations that arise there between comprehension and convincement. From a more general standpoint, at a second level the authors contribute explanations concerning those relations and their changes. Finally, the authors suggest proposals for educational practice.

Keywords: Reasoning and Proof, Learning Trajectories (or Progressions)

Background and Objectives

Sundry research papers have underscored the importance of convincement and confidence of the mathematics facts within the didactic processes that are experienced by classroom agents. For instance, Krummehuer (1995) highlighted the convincement associated with the backings of arguments, and for his analysis he used the Toulmin Model. Of note in his application was his omission of the Q mode qualifiers, and this absence was noted by Inglis, Mejia-Ramos, and Simpson (2007). The latter authors maintain that one of the objectives of learning should be development of students' abilities to "adequately" equate types of warrants with Q mode qualifiers (pg. 3). According

to that standpoint, in an analysis of the states of student confidence, Foster (2016) suggests that a student that is "well-calibrated" in a topic is a student that has confidence in his/her correct answers and has doubts concerning incorrect answers. Unlike those reports, this paper -aligned with the Grounded Theory methodology and following the idea that arguments are developed within the framework of social interactions that arise in the classroom (Krummheuer, 1995)- identifies and puts forward several explanations concerning dynamic and integral mathematics classroom phenomena. Specifically, the paper seeks to know what the possible changes are that arise in the relations between convincement of mathematics results and understanding thereof during the process of building arguments in the mathematics classroom. It further seeks to know what the possible reasons are for the presence of different relations during said process.

Theoretical Framework

The authors used the Toulmin Model (Toulmin, Rieke, & Janik, 1984) in order to analyze student participations. In that model, arguments are made up of a claim (C), data (D), warrants (W), a backing (B) and qualifiers (Q). Toulmin, Rieke, and Janik (1984) consider that Q consists of "the degree of confidence that can be assigned to the conclusions given the arguments available to support them" (p. 85, 1984). That interpretation of Q implicitly assumes the existence of an expert subject that qualifies. Unlike the foregoing, this paper explicitly accepts that it is the subject that expresses the argument that qualifies the strength of the argument's components, and the authors contend that said subject (who participates in a virtual forum) experiences a state of convincement or of presumption or of doubt concerning a mathematics statement -which Rigo (2013) calls "epistemic states of convincement"-, when it meets some of the criteria that are included in Table 1 (Martínez & Rigo, 2014).

Table 1: Theoretico-Methodological Instrument for Differentiating Epistemic States

Elements of Speech	The person resorts to language emphasizers that can reveal a degree of commitment to the truth with what s/he states. For example, when the person uses the indicative mode of verbs (e.g. "is").
Action	The subject carries out actions that are consistent with his/her discourse.
Determination	The person spontaneously and determinedly expresses her/his adherence to the veracity of a mathematics statement.
Interest	The participations of a person who takes part with interest in a specific mathematics fact in a virtual forum are *systematic* (that is, the subject answers all of the questions posed of him in the most detailed manner possible), *informative* (his claims, procedures and/or results are sufficiently informative), *clear* and *precise*.
Consistency	The person's different interventions are consistent.

The mathematics content of the fragments chosen for this study is the solution of linear equations. Model 3UV (Ursini, Escareño, Montes & Trigueros, 2005) is used in this paper as the school paradigmatic procedure to face this type of tasks. According to said model, the following are the aspects that are indicative of an understanding of the variable as a specific unknown when linear equations are solved: interpreting the symbolic variable that appears in an equation as the representation of specific values (aspect I1); determining the unknown amount that appears in equations or problems, by performing algebraic, arithmetic or both types of operations (aspect I4); and substituting the variable for the value or values that make the equation a true statement (aspect I3).

Upon solving a linear equation, students can base their arguments on varying general frameworks. That is, they can base them on different backings that can be made up of different constituents. One of the constituents of the backings is related to the sustentation resources upon which the argument is founded. Rigo (2013) calls those resources "epistemic schemes" of sustentation. According to the author, while some grounds are supported by mathematical reasons, such as instantiations of general rules, others are articulated with respect to extra-mathematical considerations, such as the operational schemes that are activated when an unjustified rule is introduced, possibly based on the authority afforded to mathematics. Consequently, mathematical and extra-mathematical backings can be presented for arguments. Another of the constituents refers to the arithmetic or algebraic nature of the argument. In this text, the authors suggest (cf. Martínez & Pedemonte, 2014) that the resolution of an equation is algebra-based when the system of reference of the data contains literal numbers, and the "core of the argument" (i.e., its D and C) presents a deductive-type structure, which may be made explicit by way of warrants because said warrants uncover the structure that articulates the argument. A resolution will be said to be backed by arithmetics when the system of reference in the data arises by numerical trial and error, and the core of the argument presents an inductive structure. Another indicator for determining whether the backing contains arithmetic or algebraic constituents is related to the conceptual elements that the student brings into play when she performs aspect I3. I3 assumes development, even if only intuitive and tacit, of the following argument: a) In equation $ax+b=0$, considering a specific value for x, i.e. that $x=r, r \in \mathbb{R}$; b) Instantiating in the equation, i.e. $a(r)+b=0$; c) Carrying out arithmetic operations; d) (Eventually) Deriving an arithmetic tautology: $m=m$; e) Inferring from d) that a) is a correct assumption (otherwise a tautology could not be inferred from it), and that $a(r)+b=0$ is a true proposition, that is that r makes the proposition $ax+b=0$ (which is open, since it lacks a value of truth) true, and that r is consequently a solution for said equation. When the student processes I3 with the awareness of what it means for a specific value of r to $\in \mathbb{R}$ "satisfies an equation and solves the problem" (Ursini et al., 2005, p. 27), that is, when the student has a few intuitions related to steps a) to e) of the afore-mentioned argument, the authors of this paper deem that I3 aids the student's comprehension of the variable and that the backing of his/her argument contains an algebraic constituent. When I3 is left simply as an incomprehensible and routine argument for the student going from step a) to d) and the student only applies it in order to verify ("in arithmetic", safe ground for the student) whether the values obtained are correct, in this paper the authors deem that that aspect of I3 is of little help to comprehension of the variable and that the backing of the argument includes arithmetic constituents.

Methodology and Information Recovery Techniques

This paper is part of a broader work, inspired by the procedures of Grounded Theory (Corbin & Strauss, 2015), which objective is to describe and construct theoretical explanations for phenomena related to the epistemic states that arise in the mathematics classroom. The study was carried out during a distance learning, certificate program whose purpose is to strengthen the training of consultants who teach algebra to adults. The data used for the study were registered on the Moodle platform for subsequent analysis, and they are part of the interaction of one tutor with his students (in particular with Belarmina). The instructor, who proposed and guided the activities, is one of the authors of this paper. In previous works, specific relations between comprehension and convincement were identified. This paper is guided by the "principle of change" of Grounded Theory, according to which the phenomena are understood to be continuously changing. Hence, unlike other studies, the relations between comprehension and convincement are deemed to be part of a dynamic process in which said relations can shift as a response to changing conditions. A segment of one interaction between the tutor and Belarmina was chosen in order to analyze those relational changes. The analysis is divided into two sections according to the level of depth. Given the

interaction contexts, a first level aims at a microanalysis of the relations that arose among the epistemic states of the subject (Q) and her level of comprehension, under the cover of a specific backing (B). For this analysis, the interaction was separated into fragments (identified using number) and it was organized into arguments pursuant to the Toulmin Model. At a second level, the relations between comprehension and convincement were concentrated into tables of analysis so as to obtain a general perspective of the change in those relations throughout the interaction. In order to put forward explanations of the complex relations between comprehension and convincement, the authors took into account the context in which they arose and the Grounded Theory principle, according to which the actors are able to make precise decisions in line with the options available to them.

Analysis of Findings. First Level of Analysis: Description and Interpretation.

Belarmina's First Participation: Expression of an Algebraic and Operational Tendency

For purposes of diagnosis, the instructor proposed that the students resolve the following: Rosa has a balanced scale; on one side is a 5 kilo weight, and on the other there is a 2 kilo weight and a bundle of iron. What can she do to find out how much the iron weighs? Figure 1 depicts Belarmina's answer.

1.1	5=2+x where x is the bundle of iron	**D1.** a: 5=2+x where x is the bundle of iron; b: x=5-2	→	**C1.** 3kg
1.2	so x=5-2=3kg.	**W1.** a: The solution to the equation is on the right hand side of the equal sign (I1); b: Transposition of terms (I4)		
		B1. a: Operational schemes and algebra (I1); b: Operational schemes and algebra (I4)		

Figure 1. Analysis of Belarmina's first participation. Argument 1.

In her first intervention, Belarmina experienced security in her application of I1 and I4, which can be seen in her use of the emphasizer "is" in 1.1, by acting on the basis of the expressions that she derived and showing determination to announce her answer. She applied I1 and I4 according to operational schemes (revealed by the implicit nature of the rules that she enunciated) and to an algebraic perspective, reflected by way of the deductive structure and the algebraic reference system in the data.

Instructor Intervention: Questioning the Backing

2.2	Once the equation has been raised, we generally use "transposition of terms". But why does it work? To find out, let's do the following activity.
2.3	Click interactive, compose the equation on the scale and arrive at the solution. Give a step-by-step description of how you reached the solution. For example: -2x-4=4x-4; I do the following to have the x stand alone: 1. I add 4 on each side. The equation is then: -2x=4x; 2. I add 2x to both sides. The equation is then: 0=6x; 3. I divide both sides by 6. The equation is then: 0=x. The solution is 0.

To answer Belarmina, the tutor questioned (see 2.2) the operational constituent that the student used to support I4 (see B1b). Figure 2 contains the student's answers.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Belarmina's Second Participation: Confidence in the Algebraic and Operational Grounds

3.1	To have the x standing alone in -4x-4=8x-4	**D.2** a: -4x-4=8x-4; b: I add 4 to each side; c: -4x=8x; d. I add 4x to each side; e: 0=12x; f: I divide both sides by 12; g: 0=x	**C2.** The solution is x!!!
3.2-3.3	I add 4 on each side. The equation is then: -4x=8x	**W2.** b-f: Determine the value of the literal number with the properties of the equality (I4); g: The solution to the equation is on the right hand side of the equal sign (I1)	
3.4-3.5	I add 4x to both sides. The equation is then: 0=12x		
3.6-3.7	I divide both sides by 12. The equation is then: 0=x	**B2.** b-f: Mathematics reasons and algebra (I4); g: Operational schemes and algebra (I1)	
3.8	The solution is x!!!		

Figure 2. Analysis of Belarmina's second participation. Argument 2.

Belarmina developed I4 based on the rules that the tutor promoted (see W2b-f), and supported by an algebraic and mathematics backing (see B2b-f), extending her comprehension in said aspect. But yet again the student secured her argument on the basis of operational schemes (B2g), when in the step from D2g to C2 she provided an incorrect interpretation of the equal sign (see W2g) which led her to contravene I1. With respect to W2g (related to I1) and I4, Belarmina experienced security which she demonstrated by using emphasizers (!!!), by acting in adherence to the rules that she expressed and by showing determination to and interest in announcing them. In answer, the tutor questioned the implicit use of the W2g warrant related to I1, as follows: 1. What do you understand to be the solution of an equation? 2. Can the solution of an equation be expressed in literal numbers? Why? Figure 3 provides an analysis of Belarmina's answers.

Belarmina's Third Participation: Doubt Associated with the Appearance of Mathematical Reasons

4.1	1. [The solution is] To find the value that, after using it to substitute the unknown in the equation, makes it possible to arrive at an equality.	**D3.** The solution is to find the value that, after using it to substitute the unknown in the equation, makes it possible to arrive at an equality (I3).	**C3.** The solution of an equation cannot be expressed in literal numbers (I1).
4.2	2. Instructor, I am doubtful about this question, but after checking the above question then it cannot be expressed using literal numbers because we are going to find its value. Correct me.	**W3.** If the solution of an equation is the value of the literal number, then the solution cannot be expressed in literal numbers (I1).	
		B3. Mathematics reasons and algebra	

Figure 3. Analysis of Belarmina's third participation. Argument 3.

In her participation, Belarmina paraphrased I3 with security (see in 4.1 the indicative use of verbs and use of I3 to derive another rule) in her arithmetic version, which she did in keeping with operational and mathematics schemes. From this school version of I3, the student deduced with doubt (see 4.2) a C3 conclusion in line with I1, in keeping with a warrant backed by mathematics and algebraic reasons, helping her comprehension of I1. The tutor asked the following so as to have the student apply the propositions enunciated: 1.- What is the value of the unknown?; 2.- How can we prove that that value is the solution of the equation? Figure 4 provides an analysis of Belarmina's answers.

Belarmina's Fourth Participation: She Doubts when Applying a New Warrant to the Data.

5.1	1.- [The value of the unknown] would be 0
5.2	2.- I hope to be right. If not, correct me. [To prove] we substitute it in the equation.
5.3	-4x-4=8x-4; -4(0)-4=8(0)-4; -0-4=0-4; -4=-4
5.4	Both sides are equal.

D4. a: D2g and C3; b: We substitute the value in the equation; c: -4x-4=8x-4; d: -4(0)-4=8(0)-4; e: -0-4=0-4; f: -4=-4; g: Equality exists → **C4.** It would be 0

W4. a: W3 (I1); b-g: Arithmetic version of I3 (I3)

B4. a: Mathematics reasons and algebra (I1); b-g: Operational reasons and arithmetic (I3)

Figure 4. Analysis of Belarmina's fourth participation. Argument 4.

In 5.1, Belarmina applied C3 related to I1 with a certain some insecurity (see the use of mitigator "would") which in her previous participation she backed using mathematics reasons and a certain algebraic perspective. At 5.3, the student applied D3 related to I3, under operational and arithmetic schemes and she did so with doubt (see 5.2). After that, the instructor asked that the students solve the following: Bety had to charge $178 from a $200 bill. She asked the customer if he had any change, and he told that her that he had $3. She accepted the coins. How much does she have to give him back? This task, similar to the task Belarmina faced in her first participation, was raised by the instructor in order to identify changes that had arisen in her resolution subsequent to the interaction. Figure 5 contains an analysis of Belarmina's answer.

Belarmina's Fifth Participation: Security in an Algebraic Backing

4.1	Let's isolate the unknown;
4.2	200+3=178+x; b:
4.3	203=178+x; 203 -178=178-178+x;
4.4	x=25 which is the change that Bety has to give back

D5. a: 200+3=178+x; b: 203=178+x; c: 203-178=178-178+x → **C5.** x=25

W5. a: Interpret the variable as a specific value (I1); b-c: Determine the literal number with the properties of the equality (I4)

B5. a: Mathematics reasons and algebra (I1); b-c: Mathematics reasons and algebra (I4)

Figure 5. Analysis of Belarmina's fifth participation. Argument 5.

Belarmina applied I1 (even though D5c could have activated W2g) and I4 (this time with the properties of equality), aspects that she had previously re-constructed with the instructor with a mathematics backing. Like in the preceding cases, she managed them with confidence, a state that she revealed by way of her use of emphasizers "let's", "is"), of actions that were consistent with her statement and the determination and interest that she exhibited when announcing her answer. However, the student stopped applying I3, which she had built and used in her preceding contributions (see D3 and D4). So the instructor questioned her solution at C5, as follows: How can we verify that the value that you obtained for the unknown is the solution to the equation? The answer to that questions can be found in Figure 6.

Sixth Participation: Security when Applying a New Rule

5.1	By substituting the value of x, which is 25 in this case, in the equation 200+3=178+x
5.2	200+3=178+25; 203=203
5.3	so in this way we can prove that it is correct because it is the same amount on both sides.

D6. a: 200+3=178+x; 200+3=178+25; 203=203 → **C6.** x=25

W6. a: If there is equality when a value is substituted in an equation, then that value is the solution to the equation.

B6. a: Operational schemes and Arithmetic

Figure 6. Analysis of Belarmina's sixth participation. Argument 6.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

In this participation, Belarmina tacitly paraphrased the arithmetic version of I3 and she applied it in D6 under operational and arithmetic schemes. This time, she showed confidence in the version of I3, by using emphasizers (e.g. "is") when enunciating, by acting in conformity with the version (at 5.1 and 5.2) and by showing determination to and interest in explaining it. The tutor then asked her to resolve -4x-16=9x+1. Figure 7 contains the student's answer.

Seventh Participation: Omission of an Arithmetic Procedure

6.1	Tutor, this is my answer:	**D7.** a: -4x-16=9x+1; b: -4x-16+16=9x+16+1; c: -4x=9x+17; d: -4x-9x=9x-9x+17; e: 13x=17 → **C7.** X=17/13
6.2	Equation: -4x-16=9x+1	
6.3	-4x-16+16=9x+16+1 (property used: addition); -4x=9x+17; -4x-9x=9x-9x+17 (property used: subtraction); 13x=17 (property used: division)	**W7.** a: Interpret the variable as a specific value (I1); b-e: Determine the literal number with the properties of equality (I4)
6.4	X=17/13	**B7**. a: Mathematics reasons and algebra (I1) b-e: Mathematics reasons and algebra (I4)

Figure 7. Analysis of Belarmina's seventh participation. Argument 7.

To resolve the equation, Belarmina activated aspects I1 and I4, specifically following the algebraically-supported procedure that she constructed with the instructor. As on previous occasions, associated with this scheme the student appeared to experience convincement. This can be seen by her use of indicative verb forms when she presented her answer ("this is"), by acting in conformity with the rules that she enunciated and by showing determination to and interest in announcing and explaining her answer. But once again, she did not apply I3 due to the possible reasons put forth below.

Analysis of Findings. Second Level: Plausible Explanations

Some viable explanations are presented concerning the complex relations between the epistemic states and comprehension that can arise in argument development and change processes and in conformation of their respective backings (see trajectories Tables 2, 3, 4).

In Table 2 one can see that the state of confidence experienced by Belarmina when she applied rules related to I4 remained unchanged, even when in her second intervention she changed the operational constituent of the backing to a mathematics constituent by introducing new mathematics rules (W2b-f). The foregoing speaks to the promptness with which the student assimilated warrants relative to I4 and that an increase in comprehension can be accompanied by confidence. However, as shall be seen below, said association is not always immediate.

With respect to I1 (Table 3), during her first participation Belarmina experienced confidence when she applied a rule according to which the solution is on the right hand side of the equal sign (W1a), supported by an operational scheme that, together with the transposition of terms, led her to obtain an answer in conformity with I1. With the properties of equality that she used in her second intervention (W2b-f) she no longer transposed terms but maintained her confidence with respect to rule W1a and applied it, which led her to infringe upon I1; this can explain the reason the student associated confidence with an incorrect proposition. The tutor's questioning at W1a led the student in her third participation to explain rules (W3) compliant with I1 under mathematics schemes, helping her comprehension. However, this is where Belarmina had doubts. The foregoing reveals that an increase in comprehension does not necessarily go hand in hand with developing confidence, because the former assumes cognitive readjustments that usually foster states of doubt. That doubt continued through her fourth intervention, albeit in the fifth and seventh Belarmina preferred the W3 warrant (over W1a) and associated confidence with it.

As regards I3, Belarmina paraphrased the operational and arithmetic version in her third participation, and only applied it when prompted by her instructor, first with doubt and then with confidence. One would expect that, as happened with I1 and I4, she would include that I3 aspect in her seventh participation. But once again, she stopped applying it even though she had handled it with confidence before and even though it could had allowed her to identify the mistake that she had made at that point. Belarmina's trajectory of answers enables one to have grounds to assume that said omission may be due to the fact that the I3 arithmetic and operational version would lead her to the land of arithmetic, leaving the land of algebra relatively to the side, a constituent upon which she had based her resolutions from the very beginning. The foregoing consideration is consistent with the answer that Belarmina provided when the instructor asked about her confidence concerning the solution that she had given to the equations, that is: "I felt sure of my answers. In this case we followed the steps to solve an equation in which we sought the unknown and we used the properties of addition, subtraction, multiplication and division. "Unlike Belarmina, other students such as Jeymi associated their confidence with the verification (I3, arithmetic version); the latter expressed herself by saying: "Very sure because in the verification I get the equality." Basing confidence on an arithmetic process instead of associating it with algebraic processes can be explained because, as pointed out by Martínez and Pedemonte (2014), students use arithmetic to understand algebra.

Final Considerations: Suggestions for Didactic Practice

On the basis of the interpretive theoretical framework, following methodological principles of Grounded Theory and by way of a case study, in the two levels of analysis presented here the authors

describe, interpret and explain different processes that teachers can develop during the dynamics of said process so that students can acquire confidence in well-founded knowledge (see Foster's (2016) idea of the "well-calibrated" state). In those processes, for instance, an increase in comprehension can be paired with doubt, because the former means cognitive readjustments when faced with questioning or contradictions that generally foster states of doubt. Moreover a reduction of comprehension can be associated with confidence because the relations between confidence and extra-mathematical reasons may be maintained in the absence of mathematics reasons. The diversity of relations that arise between comprehension and convincement are part of the natural construction of knowledge under ordinary conditions, and they are relevant because they can guide the teacher's interventions. A student's confidence jointly tied to incomprehension, for example, may require questioning the backing, construction of new warrants and their application. Doubt tied to comprehension of a warrant, on the other hand, may require that it be applied in different contexts. Additionally, it would be desirable for teachers to consider that the processes of conforming a backing and the matched confidence seem to be a local phenomenon. That is to say they concern a topic, they concern a constituent of the backing, and they also concern formulation and application of a given warrant. This is significant because it raises a flag regarding the fact that changes relative to a specific aspect may not automatically extend to others.

THE FERRIS WHEEL AND JUSTIFICATIONS OF CURVATURE

Irma E. Stevens   Kevin C. Moore
University of Georgia   University of Georgia
istevens@uga.edu   kvcmoore@uga.edu

This report discusses the results of semi-structured clinical interviews with ten prospective secondary mathematics teachers who were provided with dynamic images of Ferris wheels. We asked the students to graph the relationship between the distance a rider traveled around the Ferris wheel and the height of the rider from the ground. We focus on the different quantitative and non-quantitative ways of thinking in which students engaged to justify the curvature of their drawn graphs. We also discuss how these ways of thinking relate to reasoning covariationally about directional change and amounts of change.

Keywords: Modeling, Cognition, Problem Solving

Introduction

Authors of the Common Core State Standards for Mathematics (CCSSM) (National Governors Association Center for Best Practices, 2010) recommended that educators provide students with repeated and sustained opportunities to model situations via constructing and comparing relationships including those involving constant and changing rates of change. Researchers have also shown that quantitative reasoning (i.e., the analysis of a situation into a quantitative structure (Thompson, 2011)) and covariational reasoning (i.e., students conceiving situations as composed of measurable attributes that vary in tandem (Carlson, M. P., Jacobs, S., Coe, E., Larsen, S., & Hsu, E., 2002)) are critical for numerous K-16 topics (Ellis, 2007; Johnson, 2015; Moore & Carlson, 2012). These researchers have argued for more research to understand how students reason when constructing and comparing relations between quantities.

Given that modeling and reasoning about rates of change are important components of mathematical reasoning, this study aims to answer researchers' calls to explore and to gain a better understanding of students' reasoning about quantities given modeling situations. Namely, we draw on the framework proposed by Carlson et al. (2002) with a particular focus on students' mental actions of directional change and amounts of change. We analyze students' reasoning against the backdrop of these covariation mental actions in the context of their justifying the curvature of graphs they constructed based on a given dynamic situation. Prior research on univariational reasoning and shape thinking also inform our analysis of students' reasoning.

Literature Review

Carlson et al. (2002, pp. 357-358) described a framework explicating students' covariational reasoning that includes five mental actions. This study focuses specifically on Mental Action 2 (MA2) and Mental Action 3 (MA3) of Carlson and colleagues' framework. MA2 is "coordinating the direction of change of one variable with changes in the other variable" (Carlson et al., 2002, p.357). Behaviors indicative of MA2 include "constructing an increasing straight line" and verbalizing "the direction of change of the output *while* [emphasis added] considering changes in the input" (Carlson et al., 2002, p. 357). MA3 involves considering (and possibly comparing) amounts of change in one quantity for amounts of change in another quantity. Some researchers (Castillo-Garsow, Johnson, & Moore, 2013; Johnson, 2012) have clarified the ways in which students reason about amounts of change. For example, Johnson (2012) provided insights into particular ways students reason about the intensity of varying quantities by "systematically varying one quantity and simultaneously attending to variation in the intensity of change in a quantity indicating a relationship between covarying quantities" (p. 327). Castillo-Garsow et al. (2013) further distinguished students imagining

the intensity of change in terms of successive chunks or in terms of a smooth, dynamic image of covariation.

Moore and Thompson (2015) clarified students' covariational reasoning in the particular context of graphs. They termed students' *emergent shape thinking* to be a student conceptualizing a graph (in ways potentially compatible with those described in the previous paragraph) as an in-progress trace of two united varying quantities. A student thinking emergently justifies the curvature of a drawn graph in terms of covarying quantities or magnitudes represented along the relevant axes. Highlighting that educators cannot take students' covariational reasoning as a given, Moore and Thompson (2015) identified other ways of thinking that we show students might use when justifying the curvature of a graph. The authors termed students' *static shape thinking* – "operating on a graph as an object in and of itself" (p. 784). Students' static shape thinking includes both iconic translations and thematic associations. Iconic translations involve associations between the visual features of the situation and graph (Monk, 1992), and thematic associations are between the graph and the event phenomena (Thompson, 2015). Lastly, one example of a quantitative justification is univariational reasoning, in which a student considers how one quantity's value changes without any systematic coordination with another quantity's value (Leinhardt, Zaslavsky, & Stein, 1990).

Theoretical Framework

We approach knowledge as actively constructed in ways idiosyncratic to the knower; an individual's knowledge is fundamentally unknowable to another (von Glasersfeld, 1995). When referring to a quantity, we do not imply that a quantity exists independent of a person conceiving it. Quantities are personally constructed measurable attributes (Steffe, 1991; Thompson, 2011). Similarly, relationships between quantities are constructed by the individual; the relationship hinges of the individual's understanding of each quantity and their image of the situation, which may not be compatible with a researcher's intentions (Moore & Carlson, 2012). Although an individual's knowledge is taken to be fundamentally unknowable to another person, it is possible for a person to make inferences about another individual's thinking. These inferences are based on the person's interpretations of the words and actions of the individual. These inferences are the basis of the person's constructed model of an individual's mathematics, referred to as *the mathematics of students* (c.f., *students' mathematics*) (Steffe & Thompson, 2000).

Methodology

This study focuses on student work from one problem during semi-structured clinical interviews (Clement, 2000; Goldin, 2000). We conducted the study with ten students (eight female, two male) who were enrolled in a secondary mathematics teacher education program at a large university in the southeast United States. The problem consisted of two tasks given during the first of three interviews with each student. At the time, the students were either enrolled in or had completed their first content course in the secondary mathematics education program, and all the students had completed a calculus sequence and at least two additional mathematics courses (e.g., linear algebra, differential equations, etc.) with at least C letter grades. Some of the students had completed additional courses in both mathematics and mathematics education, but these courses did not focus on ideas directly related to the interview tasks. Two members of the research team were present at each interview, and each interview was videotaped and digitized for analysis. We used an open (generative) and axial (convergent) approach based on grounded theory (Corbin & Strauss, 2008) and in combination with conceptual analysis (Thompson, 2008; von Glasersfeld, 1995) to analyze the results. That is, we used an iterative approach to construct viable models of the subjects' thinking and their ways of reasoning.
Task Design – The Ferris Wheel

Figure 1. Animation Snapshots of the Ferris Wheel Task I and Task II.

This study focuses on the Ferris wheel problem, which is split into two tasks. First, students view an animation of a Ferris wheel rotating clockwise (Desmos, 2014) continuously; the Ferris wheel has a green cart that begins at the bottom to represent the location of the rider (Figure 1). He or she then responds to Task I: "Graph the relationship between the total distance the rider has traveled *around* the Ferris wheel and the rider's distance from the ground." Once completed, the student views an animation of a Ferris wheel that moves at a slower speed and pauses three times at the locations seen in the latter three snapshots (Figure 1). We then provide Task II: "Watch the video, which dictates a second rider's trip around the Ferris wheel. Is the previous graph relevant? Explain." The goal of this problem is to (1) provide a student with two situations with perceivable differences, yet the same underlying relationship (ignoring explicit parameterizations) between two distances, and (2) afford MA3; for successive equal amounts of distance traveled around the Ferris wheel for the first quarter of a trip, the rider's height above the ground increases and the amount by which the height increases is also increasing.

Results

We organize students' justifications for the curvature of their graph into two categories: non-quantitative justifications and quantitative justifications. A non-quantitative justification involves reasoning in which some non-quantitative aspect of the given situation implies or necessitates a (possibly perceptual) feature of the drawn graph. A quantitative justification includes some consideration of the quantities and changes in at least one of the conceived quantities. We are not implying that a student providing non-quantitative justifications did not reason covariationally or quantitatively, only that some aspect of their justification was non-quantitative. For instance, students commonly justified their graphs via directional change (MA2), but provided non-quantitative justifications when prompted to explain the curvature of their drawn graphs further.

Non-Quantitative Justification of Curvature

The first example of a non-quantitative justification for the curvature of the graph is consistent with students' static shape thinking and iconic translation. In other words, the student relies on shapes in the situation to justify his or her drawn graph. In this task, students who exhibited static shape thinking justified the curvature of the graph based on the shape of the wheel (i.e., circular wheel implies circular graph). To illustrate, Rory created her graph (Task I) drawing a curved shape, but only described directional change (MA2) when justifying her graph:

> *R*: It starts total distance and then it gets higher about half way, so say this [marks point on the top center of her graph] is our total distance…It peaks about half way, so, however many seconds, um, and then it just goes up, I would say, uh, at a quadratic rate [plots points on the left side of her graph and connects them with a curved line, completes right side of her graph]…it goes up and down in sort of a parabola shape [Figure 2a].
Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figure 2. (a, left) Rory's First Graph and (b, right) Second Graph.

When asked to explain the "quadratic rate" further, Rory explained her "parabola shape":

R: …As we go up higher and higher, the total distance increases…but when we come down about that half-way point where the [cart] is, um, exactly 90 degrees in the opposite direction, so where it just passed [*at the top of the Ferris wheel*], um, that's where it peaks [*pointing to the top of her graph*] and that's where it's the highest, but it's only about half the total distance that it's gone. So, it could also reflect, I guess, an absolute value graph [*draws Figure 2b excluding axes and labels*], but a downward facing upside down absolute value graph…I feel like because it's more circular in nature, and not like necessarily linear, um, to where it, I guess it would be like a hexagon or something with lines connecting, I would feel more parabola shaped just because it's curved, rather than an absolute value. But I could see how it would be reflecting an absolute value graph as well, so. But, I would still go with my parabola or quadratic shape as I was saying…

I: …the parabola shape because you said it's, what's curved? Something's curved?

R: The, the Ferris wheel in and of itself is a circle.

We infer that Rory understands that both a linear (i.e., "absolute value") and a curved graph (i.e. "quadratic") capture the appropriate directional relationship (MA2). However, her explanation for why she chose to draw a curved graph is based on the shape of the Ferris wheel. Thus, she engaged in both covariational reasoning and an iconic translation, with the iconic translation implying that the graph be "parabola" and not "linear" in shape.

A second example of a non-quantitative justification is thematic shape thinking. Students' thinking of graphs thematically entail their making associates between some perceived phenomenon of a situation and features of a graph (Thompson, 2015); in such a case, relationships between quantities are *implications* of assimilating some perceived phenomenon (Moore & Thompson, 2015). In the case of Task II, a student thinking thematically could involve his or her associating pauses that occur in a trip with some perceptual feature in the graph (e.g., horizontal lines, bolded points, or breaks in the graph) that "shows" the pauses.

Moreover, students might note the constant rotational speed of the Ferris wheel and make associations with the graph on the basis of constant speed (i.e., students conclude that constant speed unquestionably implies a graph composed of linear segments, and varying speeds unquestionably imply a graph composed of non-linear curves). For example, after Rory explicitly stated "relationships don't necessarily mean anything to do with the, the actual physical being being circular" after the previous excerpt, she abandoned her graph (Figure 2a) and watched the Ferris wheel again. Then, she made the following observation about the Ferris wheel:

R: It looks more at a constant rate now that I look at it. So it would probably be more of this absolute value shape… [*completes Figure 2b*]… And I don't, again, if it speed up, sped up like at some point to where the higher it went, it would represent more of the quadratic shape [*pointing to Figure 2a graph*]. So I would go with this graph [*Figure 2b graph*].

Rory perceived the Ferris wheel rotating at a constant speed and concluded that her graph should now have an "absolute-value shape" (i.e., linear). Notice also that her language in describing her

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

graph is still based on shapes (i.e., the absolute value *shape* and the quadratic *shape*). Because Rory's justification relied on a perceived phenomenon (i.e., constant speed) implying a shift in a perceptual feature in her (distance-distance) graph (i.e., *quadratic* to a *absolute-value* shape), we infer her actions to indicate thematic shape thinking.

Quantitative Justification of Curvature

Univariational Reasoning. When a student engages in univariational reasoning, he or she alludes to and possibly compares changes in some quantity to make a claim about curvature. This comparison involves looking at different regions of the graph, although not systematically with respect to changes in another quantity, as Johnson (2012) described. For instance, in the Ferris wheel problem, students imagined that the rider's distance from the ground appears to "stay longer" at the top of the Ferris wheel than in the middle, concluding that there should be a difference in how these two regions appear on their graphs. Although their justifications considered the magnitude of the height and how this magnitude changed in some way in certain regions of the graph, the students did not explicitly or systematically hold in mind variations of the total distance traveled around the Ferris wheel; the students often made these comparisons for implicit total distance intervals of unequal sizes or interval sizes that are too large (in the sense that the relationship between the two quantities changes within the chuck under consideration).

For instance, consider Louise who initially drew her graph (Figure 3a without numerical values) considering directional changes in both quantities (i.e., "distance around [*the Ferris wheel*] is always increasing" and "distance from the ground grows and then stops and then goes back down" for one rotation around the wheel). When we asked her to justify the curvature of her graph, she considered a graph with a "peak" similar to Figure 2b. At one moment, she mentioned that a curved graph "looks better" but that maybe she is "just thinking that 'cause it's a curved circle [*referring to the shape of the Ferris wheel*]." Unsatisfied with this conclusion, she considered how the height changes in a way that we consider indicative of univariational reasoning. The following transcript includes her final justification for the curvature of her graph:

L: It's not like curved curved, but it's sorta curved. It's a small curve. Just because, it's. Because the distance around if you look at the top [*of the wheel*]…this whole area is kind of the peak [*points to range at the top of the wheel*], a little bit. Like it kind of like travels at the top, just a little bit. Um, so I think it kinda travels at the top here a little bit.

I: What about like through here [*pointing to the line segment between 0 and 5, Figure 3a*]?

L: Well, I think, 'cause it's continually growing. I mean like, coming from the ground it's not really staying anywhere. Like, it's not stopping there [*pointing at location along left side of the wheel*] and being like, "Oh, I'm gonna chill here". You know. It's constantly going, but at the top it kind of has to like go around the curve, so it's at the peak for a little longer than on here [*motioning along the right side of the Ferris wheel*]. And the same thing down here [*motioning along the bottom of the Ferris wheel*]. That's kinda why it's curved down here as well [*pointing to the bottom of Figure 3b*]. Because it, you know, stays at the bottom for just a, just like a tad bit longer than it would on the sides.

Figure 3. (a) Louise's Initial Graph and (b) Graph for Three Revolutions.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Louise split the Ferris wheel into four sections to justify the curvature of her graph: the top and bottom sections and the two sides. Within each section, she imagined the height with respect to the experience of the ride to draw conclusions about the intensity of height changes. Because the height seemed to "stay" near the top and bottom sections "longer", she concluded that these sections of her graph are curved. For the sides of the Ferris wheel, she discussed the height as "constantly" changing; she represented those sections on her graph with (nearly) linear segments. Overall, her description included the intensity of one quantity's changes in one of her four sections (of unspecified size) without referencing how the second quantity (i.e., distance traveled around the wheel) related to these changes in height. This reasoning contrasts with the covariational reasoning Johnson (2012) described, which involves reasoning about the intensity of a quantity because Louise is not systemically comparing the intensity of height changes to another quantity (e.g., intensity of changes in distance traveled around the Ferris wheel).

Conflated Amounts of Change. When a student conflates amounts of change, he or she compares the changes in one quantity with respect to another quantity by considering how equal successive changes in one quantity relate to variations in the other quantity. However, he or she may be unsure how to imagine or represent the given quantities and their changes in the situation or the graph. The former leads to considering changes of a quantity in the situation that we, as observers, consider different than requested. For the Ferris wheel problem, a student might depict equal changes of "total distance" along the horizontal diameter of the wheel instead of equal changes in "total distance" around the wheel. The latter leads to students (possibly unknowingly) conflating which axes they use to represent particular quantities.

Figure 4. Kim's Graph and Diagram.

Kim began Task I by plotting points for each quarter turn and then each remaining one-eighth turn of the Ferris wheel. She connected the points using curved lines (Figure 4). She indicated reasoning directionally (MA2) when she described "he comes back down" and "he's back at 0" while tracing along the arc of the right side of the Ferris wheel.

When asked to justify connecting her plotted points, she immediately began drawing a diagram of the situation in order to relate the situation to her graph (Figure 4). In her explanation, she made two conflations. First, turning to her diagram, Kim marked off equal changes *along the ground* (as indicated by the horizontal segments in her diagram in Figure 4) and compared changes in height. This reasoning led her to conclude that her graph needed to show "height was increasing at an increasing rate". Second, when she turned to the corresponding section in her graph, she marked equal changes along the vertical axis (i.e., equal changes in the axes labeled *height from the ground*) and appropriately concluded that she "drew it like it's increasing at a decreasing rate, though." Thus, the equal changes she was comparing in both situations did not represent the same quantity (from our perspective). However, in both her diagram and her graph, she made appropriate conclusions for the relationships between the quantities she was comparing (e.g., with respect to the drawn graph, abscissa values do increase at a decreasing rate as ordinate values increase from 0). Although Kim was able to reason with the given quantities in order to plot points on her graph and reason using

MA2, she conflated the quantities when attempting to reason about amounts of change to justify the curvature of her graph.

Amounts of Change. We argue that a student reasoning emergently about the curvature of their graph with respect to the situation they are modeling occurs when he or she is able to exhibit MA3 on the given situation (or a student's diagram of the situation) and then create/modify/justify his or her graph in terms of such a relationship. For example, April justified her graph as she drew it. She marked equal changes of "arc length or total distance around" the Ferris wheel, identified the change in height for each interval using the situation, made conclusions about rates of change for given intervals around the wheel, and finally indicated how these changes are represented on her graph (Figure 5).

Figure 5. April's Justification of Curvature Using Amounts of Change.

Discussion

This paper focuses on types of reasoning students engage in when modeling a dynamic situation. The results corroborate several of Carlson et al.'s (2002) and Saldanha and Thompson's (1998) claims. Overall, many students (8/10) reasoned directionally (MA2) from the researcher's perspective, but they often constructed graphs without considering amounts of change *prior* to their drawing a graph; several students (8/10) had difficulty (quantitatively) justifying the curvature of their drawn graphs. In our study, we identified specific ways of thinking students exhibited when attempting to justify the curvature of their graphs. Students who reasoned non-quantitatively exhibited forms of static shape thinking when asked to justify the curvature (or lack thereof) of their graphs. We also noticed students who took a quantitative approach. However, before students could reason effectively about amounts of change (MA3), they needed to construct not only the change in one quantity, but also the change in that quantity with respect to a change in another given quantity. Students who were only reasoning about the change in one quantity without systematically considering changes in another quantity reasoned univariationally. Furthermore, students who realized that they needed to compare the change in one given quantity with respect to a change in another given quantity were not always sure how to represent these quantities on either their graph or the situation, often conflating quantities from our perspective. Piaget (1974) described that the path to consciousness is a dynamic, active system, which is consistent with the idea that quantities are not intrinsic attributes of graphs and situations. Furthermore, he claimed, "knowledge does not proceed from the subject or from the object, but from interaction between the two" (p. 335). Providing students with tasks that afford opportunities to reason quantitatively and covariationally encourages students constructing situations constituted by quantities, and perhaps helps to promote the construction of quantitative MA3 reasoning.

Fifty-seven students in mathematical content and secondary mathematics methods courses from four U.S. universities participated in an instructional sequence to generate communal criteria defining mathematical proof within their respective classrooms. Participants completed a proof-related task before class, worked together in small groups to evaluate instructor-selected arguments, communally agreed upon criteria for evaluating a proof based on their evaluations, and then revised their original argument to meet the communal criteria after class. Similar criteria were constructed across the four classrooms. Moreover, the four authors coded and compared students' initial and revised arguments with respect to proof schemes to identify specific shifts in students' work after the instructional sequence. Results indicated a majority of students' proof schemes changed in their revised argument with specific trends aligning with their class-based criteria for proof.

Keywords: Reasoning and Proof, Post-Secondary Education, Classroom Discourse, Teacher Education-Preservice

Current reforms have called for a stronger emphasis on mathematical reasoning and proving in school mathematics (National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA & CCSSO], 2010; National Council of Teachers of Mathematics [NCTM], 2000). The challenge of meeting this recommendation is that students typically observe their teacher presenting a polished and completed proof (Stylianou, Blanton, & Knuth, 2009). Using this method of proof instruction suggests to students that their teacher is the primary authority to judge the validity of their proof (Harel & Sowder, 1998). Students then believe that the goal of learning proofs involves strategies that replicate similar problems (Bleiler, Ko, Yee, & Boyle, 2015). Such instructional methods complicate students' ability to judge the validity of mathematical arguments because students are not given the opportunity to "construct viable arguments and critique the reasoning of others" (NGA & CCSSO, 2010, p. 6), a necessary standard for mathematical practice. Therefore, it is not surprising that research has shown that students at all grade levels have considerable difficulty in judging the validity of a proof (Healy & Hoyles, 2000; Ko & Knuth, 2013; Segal, 1999; Weber, 2010).

Although students' difficulties with proof are well documented, to date, little research has explicitly articulated a classroom community's criteria for mathematical proof, including social dimensions necessary for proof validation. Bleiler, Thompson, and Krajčevski (2014) explain that "many researchers have called for the explicit instruction to proof validation to ameliorate common difficulties related to accepting inductive arguments or focusing on local rather than global elements of an argument" (p. 109). Concomitantly, Hanna and Jahnke (1993) remind us that "the social process of verification through which proof becomes accepted in the mathematical community should somehow be imitated in the school" (p. 433). To address this research gap, we designed an intervention where students: (1) constructed an initial argument justifying their generalization to the Sticky Gum Problem (SGP) depicted in Figure 1 before class; (2) critiqued instructor-selected

arguments in small groups and developed a list of five communal criteria necessary for writing proofs during class; and (3) revised their initial argument to the SGP to meet the classroom-based criteria for proof after class described in Table 1. In this paper, we investigated how students' written arguments differed before and after our instructional sequence. To answer this research question, we used Harel and Sowder's (2007) proof schemes to identify how the students' arguments shifted given their engagement in the instructional sequence.

The Sticky Gum Problem

Ms. Hernandez came across a gumball machine one day when she was out with her twins. Of course, the twins each wanted a gumball. What's more, they insisted on being given gumballs of the same color. The gumballs were a penny each, and there would be no way to tell which color would come out next. Ms. Hernandez decides that she will keep putting in pennies until she gets two gumballs that are the same color. She can see that there are only red and white gumballs in the machine.

1) Why is three cents the most she will have to spend to satisfy her twins?
2) The next day, Ms. Hernandez passes a gumball machine with red, white, and blue gumballs. How could Ms. Hernandez satisfy her twins with their need for the same color this time? That is, what is the most Ms. Hernandez might have to spend that day?
3) Here comes Mr. Hodges with his triplets past the gumball machine in question 2. Of course, all three of his children want to have the same color gumball. What is the most he might have to spend?
4) Generalize this problem as much as you can. Vary the number of colors. What about different size families? Prove your generalization to show that it always works for any number of children and any number of gumball colors.

Figure 1. The Sticky Gum Problem originally created by Fendel, Resek, Alper, and Fraser (1996).

Table 1: Instructional Sequence to Create Communal Criteria to Understand Proof

Before-Class Activity	• Each student solves the Sticky Gum Problem (SGP) and submits the SGP electronically prior to the before-class activity. • The instructor chooses five distinct arguments submitted by their students.
During-Class Activity	• Students break into small groups of 2-4 students. Each group (1) looks at the same five instructor-selected classmate's arguments; (2) discusses and decides which of the five selected arguments are mathematical proofs; (3) determines how they decided whether each argument is a mathematical proof; and (4) creates a list of five proof criteria through small and whole group discussions. • All small groups rejoin the entire class. The entire class has discussions, compares the small group's criteria, and determines a class-wide communal list of five criteria for proof.
After-Class Activity	• Each student revises their original argument for SGP to satisfy the communal class-based criteria and submits their revised argument.

Theoretical Framework

To investigate how developing communal criteria for proof affected students' written arguments, this study builds on the frameworks about proof in the mathematics classroom (Stylianides, 2007), the process of proving (i.e. ascertaining and persuading, Harel & Sowder, 1998, 2007), and proof schemes (Harel & Sowder, 1998, 2007).

Proof in the Mathematics Classroom

A traditional perspective of proof is "a formal and logical line of reasoning that begins with a set of axioms and moves through logical steps to a conclusion" (Griffiths, 2000, p. 2). This definition describes a formal individual process of writing a proof, but does not acknowledge the negotiation aspects of constructing and validating proofs within a mathematics community. Stylianides (2007) suggested that proof is a connected sequence of assertions because it

(1) uses statements accepted by the classroom community (set of accepted statements) that are true and available without further justification; (2) employs forms of reasoning (modes of argumentation) that are valid and known to, or within the conceptual reach of, the classroom

---

community; and (3) is communicated with forms of expression (modes of argument representation) that are appropriate and known to, or within the conceptual reach of, the classroom community. (p. 291)

Stylianides created this definition emphasizing proof that balances mathematics as a discipline and a learning tool. We use Stylianides' definition of proof as a frame of reference to interpret students' characteristics of proof and their classroom-based criteria for proof.

Ascertaining and Persuading

To understand how a mathematics community can support students' understanding of what counts as proof, it is also necessary to consider individuals' ideas of what constitutes a proof during the proving process. To incorporate both the individual and the communal aspects of proving, we use Harel and Sowder's (2007) action of proving as "the process employed by an individual (or a community) to remove doubts about the truth of an assertion" (p. 808). Furthermore, Harel and Sowder (1998, 2007) indicated proving as ascertaining (convincing oneself) and persuading (convincing one's community). Weber's (2010) research found that undergraduate mathematics majors would judge a deductive argument as proof, even if they were not convinced by its argument or the argument was logically flawed. Both Weber (2010) and Segal (1999) emphasize the need to push individual's convictions into public discussion, which was an aim of our instructional sequence. When students have to judge the validity of an argument, they are forced to negotiate between ascertaining and persuading because the judgement is based on how the argument would convince themselves and others. To this end, we designed our instructional sequence around students judging the validity of instructor-selected arguments, which allowed them to use their understanding of what counts as proof to create a discursive space and reach consensus on their judgements.

Proof Schemes

As the purpose of this study is to examine the effect that our instructional sequence would have on students' arguments, we use Harel and Sowder's (2007) proof schemes to analyze students' work because a proof scheme consists of "what constitutes ascertaining and persuading for that person (or community)" (p. 809). Harel and Sowder divided proof schemes into three main categories, which are external conviction proof schemes, empirical proof schemes, and deductive proof schemes. External conviction proof schemes mean that conviction is made by the form of an argument, such as a teacher, a textbook, or symbolic representations. In the classroom external convictions often take the form of an authoritarian proof scheme (Harel & Sowder, 2007). For empirical proof schemes, the validity of a conjecture is made by specific cases or individuals' mental images. Regarding deductive proof schemes, a conjecture's veracity is determined by logical deduction. Harel and Sowder (1998) make a strong point "that these schemes are not mutually exclusive; people can simultaneously hold more than one kind of scheme" (p. 244). For that reason, it is important for us to look for overlaps within the three proof schemes when analyzing our data.

Harel and Sowder's (1998) original proof-scheme taxonomy aligns with the focus of this study:

Our definitions of the process and proving and proof scheme are deliberatively psychological and student-centered... Thus, this classification is not of proof content or proof method…In contrast, it is the individual's scheme of doubts, truths, and convictions, in a given social context, that underlies our characterization of proof schemes. (p. 244)

In the same ilk, the focus of this research emphasizes the "social context" of the classroom. Hence, we use proof scheme categorizations as comparative tools to look for changes in students' initial and revised arguments. We are not trying to evaluate the correctness of students' arguments but rather assign a qualitative descriptor of students' justification. This allows us to gain evidence of students'

relative convictions (Weber & Mejia-Ramos, 2015) of what constitutes mathematical proof before and after the instructional sequence.

Method

Participants

This study was conducted across four separate courses across four institutions where the authors were the instructors. Two of the courses (Authors 1 and 4) were mathematical content courses, and the other two (Authors 2 and 3) were secondary mathematics methods courses. Concomitantly, three authors were within mathematics departments, and one author was in an education department. There were a total of 57 undergraduate and graduate mathematics or secondary mathematics education majors participating in the study. All of the participants either had completed calculus courses and an introductory proof course or were presently in an introductory proof course.

Design and Implementation of the Instructional Sequence

The instructional design was organized around the SGP (see Figure 1) into a before-class activity, during-class activity, after-class activity (see Table 1). The participants submitted their solutions to the SGP prior to the during-class activity. The four instructors reviewed the arguments submitted by the students and selected five arguments from each class to have the students evaluate with the during-class activity. Arguments were chosen for their diversity in mode of argumentation, mode of argument representation, and sets of accepted statements (Stylianides, 2007). Simultaneously, the four authors selected arguments that would illustrate differing modes of argumentation to promote discourse around what counts as proof.

Students individually evaluated the five selected arguments in class and then worked in small groups to negotiate and come to a consensus on which arguments they believed to be valid proofs. This negotiation provoked important conversation about what defines a proof because negotiations highlighted if the argument persuaded the students, aligned with how the students had ascertained justification, or both. The students were then instructed to articulate three to seven criteria for determining arguments to be proofs. After each small group created their list, the whole class discussed and agreed upon five appropriate criteria for proof in their classroom. Each of the four classes had some differing criteria, but their criteria all showed that a proof needs to be generalizable and have logical structure (see Boyle, Bleiler, Yee, & Ko, 2015 for a more detailed discussion of the communal criteria). An important note is that these two categories, generalizability and logical structure, are similar to what Harel and Sowder (2007) labeled as necessary characteristics of the transformational deductive proof scheme, generality and logical inference.

Data Collection and Analysis

All four authors collected their students' work and class artifacts throughout the instructional sequence. Each student's initial argument and revised argument were coded according to Harel and Sowder's (1998, 2007) proof schemes to identify their changes. As discussed in the theoretical framework section, Harel and Sowder suggested that overlaps of the categories of external conviction, empirical, and deductive proof schemes were to be expected. Thus, three more categories, "empirical/external conviction, external conviction/deductive, and empirical/deductive," were developed and included in our data analysis. We provide Gabriel's work depicted in Figure 2 as an example of the need for the overlap in coding.

Figure 2 is Gabriel's initial argument coded as Empirical/Deductive. It could be easy to classify Gabriel's argument with an empirical proof scheme because of the justification using one example with three children and three colors. However, there are elements of the deductive proof scheme within his work as well. Gabriel generalized the argument with statements, such as "worst case

scenario" and the concluding remark, "if all but one child have all the colors of gum, any color will ensure they all have the same." These statements reference the restrictive characteristics of the transformational proof scheme (Harel & Sowder, 1998), a subset of the deductive proof scheme. Gabriel presumed to understand the restrictions that transform the situation by assuming the worst case scenario and discussing what transformation would be necessary to satisfy the last child receiving the same color. Thus, Gabriel's argument was coded as Empirical/Deductive. It is important that the proof schemes are not evaluating the correctness of students' arguments but rather than describing what characteristics students communicate with their justifications.

Figure 2. Gabriel's original argument classified via empirical and deductive proof schemes.

All four authors met and agreed upon the structure and purpose of the six categorizations, and evaluated 15 randomly-selected arguments to make sure that there was strong interrater reliability. Authors then all double-coded the remaining arguments. There were a total of 54 original and 46 revised arguments, and each of them was coded by at least two authors. Any varying proof schemes were discussed amongst the authors who coded the proof scheme to find consensus. Once all arguments had been coded and consensus had been reached amongst the codes, the authors compared original and revised proof schemes amongst all students.

Results

Table 2 illustrates the coding of each student's before-class argument (rows) and after-class argument (columns). Colors have been added to illustrate blends. For example, empirical is red and external conviction is yellow, so empirical/external conviction is orange. Each cell in Table 2 illustrates the number of students that transitioned from one proof scheme to another. A row or column identified as "None" means that the students offered no argument.

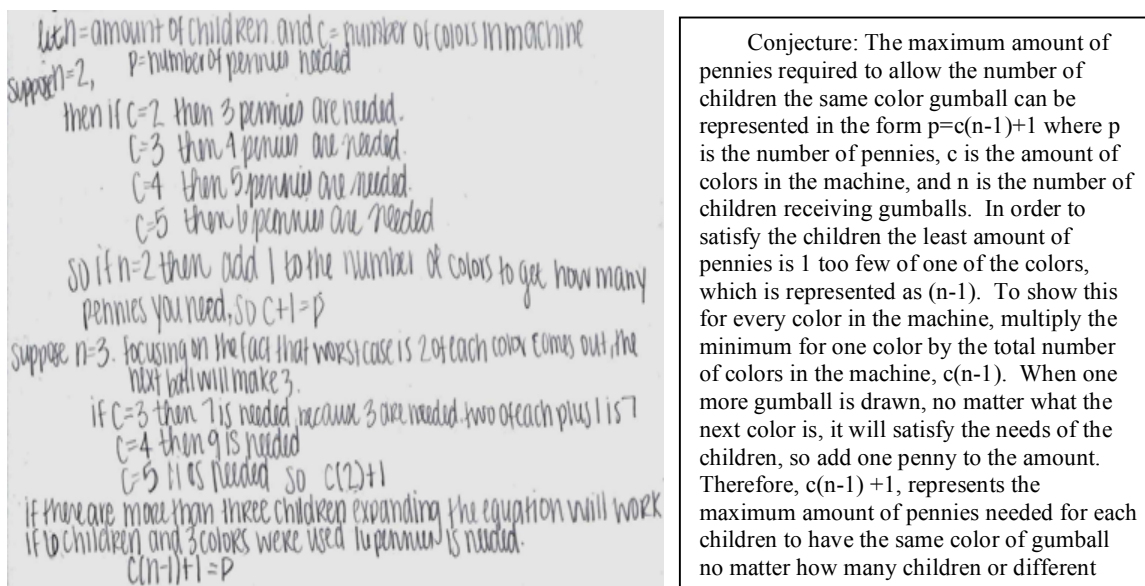
Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 2: Proof Schemes of all original and revised arguments

Brefore-Class Proof Schemes (rows) Revised Proof Schemes (columns) TOTAL	Revised None	Revised Empirical	Revised Empirical/External Conviction	Revised External Conviction	Revised External Conviction/Deductive	Revised Deductive	Revised Empirical/Deductive	Original Arguemnt Total
Original None	0	2	0	0	0	1	0	3
Original Empirical	5	5	3	6	0	6	2	27
Original Empirical/External Conviction	1	0	0	0	0	3	0	4
Original External Conviction	2	1	1	3	0	1	0	8
Original External Conviction/Deductive	0	0	0	0	0	2	0	2
Original Deductive	1	0	0	1	0	4	0	6
Original Empirical/Deductive	2	0	0	0	1	3	1	7
Revised Argument Total	**11**	**8**	**4**	**10**	**1**	**20**	**3**	**57**

The main diagonal of Table 2 shows that five empirical proof schemes remained empirical (row2, column2), three external proof schemes remained external convictions (row4, column4), four deductive proof schemes remained deductive (row6, column6), and one empirical/deductive remained empirical/deductive. Altogether, 13 of the 57 participants kept with the same proof scheme after the instructional sequence, demonstrating that the majority of students constructed arguments that provided evidence of altered proof schemes after the instructional sequence. Looking along the diagonal also reveals that no arguments that was coded initially with an overlapping code (e.g. external/deductive), kept the same proof scheme after being revised except for one student whose original argument and revised argument were coded as empirical/deductive.

Table 2 also shows that the number of strictly empirical proof schemes declined from 27 to 8 while the number of strictly deductive proof schemes grew from 6 to 20 after our instructional sequence. For instance, Kimmie's original and revised argument depicted in Figure 3 is an example of this transition. Kimmie's original argument bases its justification around the given information and justifies the general rule using examples. For her revised argument, Kimmie uses generality and logical inference, which are two aspects of Harel and Sowder's (2007) deductive proof schemes. Kimmie's work illustrates how her argument shifted from an empirical proof scheme to a deductive proof scheme after participating in the instructional sequence.

Finally, the external conviction proof schemes increased slightly from 8 to 10 after the instructional sequence. When looking closely at arguments demonstrating external conviction, the students seemed to tend to replicate a method that had been used in one of the five instructor-selected arguments (e.g., mathematical induction on both the number of children and the colors of bubble gum) to construct their revised arguments. More specifically, those students might mimic one of the instructor-selected arguments without being able to fully justify why their generalization to the SGP is always true.


Conjecture: The maximum amount of pennies required to allow the number of children the same color gumball can be represented in the form p=c(n-1)+1 where p is the number of pennies, c is the amount of colors in the machine, and n is the number of children receiving gumballs. In order to satisfy the children the least amount of pennies is 1 too few of one of the colors, which is represented as (n-1). To show this for every color in the machine, multiply the minimum for one color by the total number of colors in the machine, c(n-1). When one more gumball is drawn, no matter what the next color is, it will satisfy the needs of the children, so add one penny to the amount. Therefore, c(n-1) +1, represents the maximum amount of pennies needed for each children to have the same color of gumball no matter how many children or different

Figure 3: Kimmie's initial (hand written) and revised (typed) arguments coded as empirical and deductive, respectively.

Discussion

This study challenges the current borders surrounding students' classroom engagement with constructing and critiquing arguments. Our instructional sequence gives students opportunities to develop criteria for proof through evaluating, discussing, and negotiating what counts as proof. In addition, these results illustrate that the instructional sequence allowed students to judge the validity of arguments, empowering students to generate criteria from those judgements to influence what constitutes as ascertaining and persuading (i.e., Harel & Sowder's proof scheme, 2007) in their classroom community. Thus, this instructional sequence can aid teachers in developing what constitutes a proof through evaluating arguments, as well as discussing and negotiating their classroom-based criteria for proof.

By using Harel and Sowder's (1998) lens of proof schemes, our results show that a majority of students changed their argument after the instructional sequence. Of those changed, the number of empirical proof schemes decreased while the number of deductive proof schemes increased. Also, the number of external conviction proof schemes remained about the same. The decrease in empirical proof schemes and increase in deductive proof schemes might appear to align with the communal criteria for proof students developed, because the two of the criteria shared by all four classes—logical structure and generalizability—are the characteristics of Harel and Sowder's (2007) transformational deductive proof schemes, logical inference and generality.

When evaluating the validity of arguments, Weber and Mejia-Ramos (2015) indicate that students' convictions are often not absolute but relative, meaning that writing an argument is more than justifying one's beliefs. The research described in this paper did not measure the mathematical validity of students' initial and revised arguments. However, we identified characteristics of student justifications with respect to Harel and Sowder's (2007) proof schemes, because our study desired to determine how engaging in our instructional sequence would affect students' revised arguments. When implementing our instructional sequence, one should not see the communal criteria as an absolute final product, but they serve as a means to improve students' understanding of proof and their abilities to write proofs. Thus, we see the generation of classroom-based criteria is not limited to assessment of learning or assessment for learning, but it also serves an assessment *as* learning (Bleiler, Ko, Yee, & Boyle, 2015). A valuable future research study could include multiple iterations

of this instructional sequence with various the proof-related problems to lead to a better understanding of what students have learned about proof and proving over a full semester and across different mathematical content areas.

In sum, this study offers an alternative method of proof instruction to help students take ownership of their proof construction instead of viewing their teacher as the primary authority in the classroom. Moreover, our results show a means in which to have students develop a common understanding of what counts as proof through critiquing the reasoning of others. Thus, this instructional sequence offers a social space in which teachers and students can discuss and negotiate the meaning of what constitutes a proof.

EXPLORING STUDENTS' UNDERSTANDING OF MEDIAN

Md Amiruzzaman   Karl W. Kosko

mamiruzz@kent.edu   kkosko1@kent.edu

This paper explores middle-grade students' conceptions of median. Describes, where and why they struggle and provides learning trajectory to improve their understanding.

Keywords: Data Analysis and Statistics, Middle School Education

Background and Overview

Measures of Central Tendency (MOCT), including mean, mode and median, are important mathematical concepts typically included in middle grades standards and curriculum (National Council of Teachers of Mathematics [NCTM], 2000). However, the vast majority of research in MOCT has generally focused on the teaching and learning of arithmetic mean, with little study of median or mode (Groth & Bergner, 2006; Mokros & Russell, 1995). The few studies focusing on students' conceptions of median have found that high school and college-level students tend to have more difficulty calculating median than arithmetic mean (Barr, 1980; Zawojewski & Shaughnessy, 2000). Barr (1980) studied high school students' knowledge of median and found that less than half of participating students calculated median correctly and tended to provide incorrect explanations for their answers. Specifically, many high school students did not grasp the concept of median as the middle value in a distribution of data. Similarly, Zawojewski & Shaughnessy (2000) observed that although median is a simpler arithmetic calculation as compared to mean, most undergraduate students in their sample had more difficulty calculating median than statistical mean. Although the literature on students' understanding of median suggests that students have more difficulty with this concept than arithmetic mean, such research does not focus on the nature of such conceptions, or how and why they develop in students, indicating a significant gap in the field's models of students' learning and conceptions of median. Therefore, the purpose of the present study is to explore and model two middle grade students' conceptions of median. The study focused on a small sample of middle grades students both to allow for more in depth analysis of how conceptions are conveyed through student actions and because the middle grades are typically the initial point in K-12 curricula where these concepts are formally studied (NCTM, 2000).

Method

We used a classroom based teaching experiment to build our models of middle grade students' conceptions of median and mode. A *classroom based teaching experiment* involves the teacher-researcher (the first author) in the posing of tasks to construct models of students' conceptions, but also to provide tasks that could scaffold students' learning. As with individual teaching experiments, the approach requires the teacher-researcher to collaborate with an observer (Behr, Wachsmuth, Post, & Lesh, 1984). The approach allows the teacher-researcher to interview students individually or as a group (Behr et al., 1984), and extends the individual-based constructivist teaching experiment to the social context.

The study was conducted in an urban, middle-class school district with 6 sixth-grade students (5 males and 1 female students). Students participated in 14 teaching experiment episodes across 14 weeks in Spring 2015. All episodes were video and audio recorded, with the observer-researcher taking field notes. Each episode took place in a designated room, isolated from external distractions and noise, and all participants sat with the teacher-researcher at a round table. This environment provided the necessary proximity to establish teacher-student relationships and observe students' actions more easily. Episodes involved exchanges in which the teacher-researcher presented a task

focusing on MOCT (mean, median, and/or mode). Participants would work on the task either individually or with peers, and the teacher-researcher would ask probing questions to solicit descriptions of their mathematical thinking. However, each student was asked to explain their answers separately. After each student explained their answers, their written work was collected for further data analysis.

Each episode lasted approximately 45-50 minutes. Tasks for initial episodes focusing on a topic (i.e., median) were prepared ahead of time. However, tasks for all other episode were prepared based on the analysis of the prior episode. Specifically, the teacher-researcher and observer-researcher met and discussed current observations and developed hypotheses following each episode. Based on the hypotheses, a new protocol, including tasks, was developed for the next episode to test the hypothesis(es). For sake of space and simplicity, the present study presents data from episodes 6 and 8 to illustrate preliminary findings for learning trajectories of the participating students Alice and Bob.

Analysis and Findings

Initial conceptions

In episode 6, both Alice and Bob described the median as the middle value of a data set, and generally were able to identify the median with data sets with an odd number of elements. Figure 1 illustrates Alice's written strategy to find median from a data set with an odd number of elements. When asked to explain how she found the median, Alice replied, "Oh, it was easy…you know…you write the number small to big and cross out one number from left and one number from right until you find a number in the middle." This statement conveys a potential interpretation on Alice's part of the median as the middle value in a data set. However, when Alice was asked to find the median for data with an even number of elements, she claimed that there was no median. Figure 2 illustrates Alice's written strategy to find median from a data set with an even number of elements. Noticeably, 17 and 20 are left as is with no continuation additional work by Alice to find the median. As Alice explained, "there is no median because 2 numbers are in the middle…not one. Only one number can be in the middle, not two". Bob's work on both tasks was nearly identical to Alice's with corresponding explanations. Bob explained his position and said, "Median lives in the middle of all numbers…when there is 7 numbers then we have a middle number, but when we have 10 numbers then we do not have a middle number…no median".

Figure 1. Alice's response to data with an odd number of elements for median**.**

Figure 2. Alice's response to data with an even number of elements for median.

Although a seemingly simple 'mis'conception of the definition of the median, we conjecture that both students' conception of median is more nuanced than a simple misinterpretation. Specifically, Alice's description of how to find the median focused on marking off the discrete elements in the data set (once they were sorted). At no point did Alice or Bob data set, but instead referred to the elements within the set. We conjecture that these references, both in the students' spoken descriptions and in their written work, indicate that Alice and Bob were considering the elements as

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

discrete objects of the data set instead of seeing the elements as part of a unitized data set. Similar ways of operating mathematically have been described regarding children's counting schemes. Discussing Steffe's schemes for children's number sequences, Oliver (2000) described the difference between pre-numerical counting schemes in which the end number is not a unitized collection of 1s (i.e., a child may count 1,2,…5 but not view the 5 as five 1s), and initial number sequences where they are able to consider a number as a collection of 1s in activity. In the present study, Alice and Bob demonstrated a similar focus on operating on discrete elements in the data set to consider the median as an end result of those discrete elements, instead of as a property of the unitized data set. We refer to this initial scheme, demonstrated in episode 6 by both Alice and Bob as the middle-value scheme. *Middle-value* is the number that is in the middle of a data set with an odd number of elements.

After the learning trajectory

During the teaching experiment, we sought to promote perturbation in students' initial conceptions of median. Therefore, we asked students to begin plotting the data on a number-line. The number-line was chosen due to its potential for presenting the distribution of elements in a data set. Thus, we anticipated that the number-line might facilitate students' operating on data sets and not only data elements. So, students began using the number-lines to model their process for finding the median during episode 8. At one point in the episode, students were provided a data set with odd number of elements and asked to find the median. Alice and Bob initially wrote down each number on the number-line and tried to find which number lay in the center/middle (see Figure 3). Once they found the center/middle number they marked the number and claimed that number as median.

Figure 3. Alice's response to data with an odd number of elements for median.

After finding the median from a data set containing odd numbers of element, Alice and Bob were asked to find the median from a data set containing an even number of elements. Alice began to model the data on the number-line, as in the prior task, and used the number-line to sort the elements of the data on the number-line. Once all data were sorted, Alice identified the space between 2 and 3 (see Figure 4). Alice said, "this set has no middle value…but, we can find it…the middle number has to be in the middle of 2 and 3…we can add 2 and 3 and divide them in half…yes, then 2.5 is the median…(giggling)". Alice provided the response of 2.5 as a middle value of the given discrete elements. We interpret Alice' actions as an application of partitioning the data set when it was considered as a unitzed entity, or a *whole*. This is a distinctly different scheme than the middle-value scheme demonstrated in episode 6. We refer to this scheme as the center-value scheme because it involves operating on a unitized data set. *Center-value* is the calculated middle number from a data set with an even number of elements.

Figure 4. Alice's response to data with an even number of elements for median.

Similar to Alice, Bob said, "I see now…the middle number has to be between 2 and 3. I think, it is 2.5…it is the middle of 2 and 3…I am sure. Although it is tempting to consider the number-line as an intervention that allowed the student to clarify their definition of median, in episodes that

followed, both Alice and Bob continued to use a number-line representation when asked to find median in future tasks. Specifically, when asked to find the median, students would sketch the portion of a number line representing the middle values in a sorted data set (often excluding all other values). This suggests a particular conception of median as the middle that has yet to be fully interiorized, but suggests a new scheme for operating on data to find median. Specifically, the student continued to determine median in activity and used the number line representation to scaffold such engagement. In episodes that followed, Alice and Bob were able to find the median. We conjecture this is due to the construction of a new scheme that allowed them to consider the data set as a whole (instead of only as discrete data elements). Therefore, they were more easily able to identify the middle position of the data set (using a segment of a number line) and determine the middle of the sorted data set as the median value.

Conclusions

Findings of the present study indicate that middle grade students' conceptions of median may include middle-value and center-value schemes. Further, when presented a more visual representation of the data set, Alice and Bob both demonstrated construction of center-value schemes to consider the data set as a unitized whole, instead of as discrete data elements. Alice continued using a portion of a number line to find median, suggesting that the center-value scheme continued to be applied. These findings have several implications. A primary implication for research is that students' conception of the median is more complex than previously recognized. In regards to practice, and given the observed construction of the center-value scheme, these findings suggest that students should be afforded opportunities to manipulate data prior to being introduced to algorithms and purely symbolized definitions of these concepts.

MAKING THE IMPLICIT EXPLICIT: A CALL FOR EXPLORING IMPLICIT RACIAL ATTITUDES IN MATHEMATICS EDUCATION

Dan Battey   Luis A. Leyva
Rutgers University   Vanderbilt University
dan.battey@gse.rutgers.edu   luis.a.leyva@vanderbilt.edu

While disparities in the quality of mathematics instruction and learning opportunities are well documented in the literature for African American students, mechanisms that produce these disparities are harder to detail. We argue that work on implicit racial attitudes can contribute significant insights into the ways in which instruction and learning opportunities are differentiated. We use four literatures to support our argument: the quality of mathematics instruction for African American students, teacher-student relationships, racial comparisons of teacher expectations, and racial microaggressions in mathematics. Integrating implicit racial attitudes in our work can achieve more equitable mathematics learning for African Americans.

Keywords: Equity and Diversity, Teacher Beliefs, Instructional Activities and Practices

Disparities in the quality of instruction and mathematics achievement for African Americans are well documented (Ladson-Billings, 1997; Lubienski, 2002). However, the mechanisms that produce such disparities are less clear (Battey, 2013; Lubienski, 2002). In light of the conference theme on questioning borders, we draw on work both inside and outside mathematics education to argue that research needs to explore implicit racial attitudes to better understand dynamics that produce lower-quality instruction and learning opportunities for African American students. We use four literatures to support our argument: the quality of mathematics instruction African American students receive, relationships developed with teachers, racial comparisons of teacher expectations, and racial microaggressions in mathematics. However, before delving into this research, we briefly define and examine the literature on implicit racial attitudes.

Implicit Racial Attitudes

Researchers have found that although explicit racist attitudes have diminished, implicit racist attitudes have not (Dovidio & Gaertner, 2008). Implicit racial attitudes are characterized by unconscious feelings and beliefs, which can be orthogonal to publicly professed attitudes (Greenwald & Banaji, 1995). Implicit attitudes result from exposure to stereotypes and are characterized as evaluations and beliefs automatically activated by the presence of a particular stimulus, in this case, racial interactions (Dovidio, 2001). Contemporary research has found that whites assert that prejudice is wrong and that these values about equality inhibit the direct expression of implicit racial attitudes (Dovidio & Gaertner, 2008). Implicit attitudes are not endorsements for prejudiced views; rather, they represent exposure to broad deficit ideologies.

What keep these beliefs implicit are proxies used for discussing race. Labels that reference culture, family values, or testing categories serve as proxies for race since, socially, we have a difficult time discussing these complex issues (DiME, 2007). This is even more problematic given that whites, who would not discriminate explicitly, tend to discriminate against African Americans when bias can be attributed to a factor other than race (Dovidio & Gaertner, 2004). Racial proxies cloud instances when teachers access stereotypes, which can unconsciously affect their behavior in classrooms including limiting expectations and lowering the quality of instruction offered to African American students.

Quality of Mathematics Instruction

Research shows that mathematics teachers in urban schools are more likely to teach mathematics vocabulary out of context, disconnect taught procedures from students' thinking, use unexplained procedures, assess students based on following steps rather than student thinking or even correct/incorrect answers, and use fewer resources such as manipulatives even when available (Ladson-Billings, 1997; Lubienski, 2002). However, we still do not understand the mechanisms that deliver lower-quality mathematics instruction to African American students. For example, Hill demonstrated that lower teacher knowledge is directly related to student minority status (Hill, 2007). Shechtman and colleagues (2010) found an indirect relationship between teacher knowledge, instruction, and student learning in mathematics because while knowledge was correlated with student learning, it was not correlated with instructional quality. This signifies that these variables may be mediated by factors that the field is not considering, especially for African American students. Factors such as implicit racial attitudes or negative relationships could mediate the effects of teacher knowledge such that many African American students do not receive high-quality mathematics instruction.

Teacher-Student Relationships

Teacher-student relationships have been found to be a critical component of both psychosocial and academic development. Research has found that teachers rate relationships with African American students as more conflictual than their relationships with white students and that conflict predicted lowered standardized test performance in mathematics (Jerome, Hamre & Pianta, 2009; Pianta & Stuhlman, 2004). Teacher-student relationships relate to student learning, regardless of the quality of instruction. Our own work has shown that the quality of relationships is unrelated to the quality of instruction for African American students (Battey & Neal, under review). For example, handling of student thinking and framing student ability were not linked to the quality of problem solving and mathematical discussions. In work from the African American students' perspective, they often attribute stronger teacher-student relationships to placement in higher-tracked classes (Leyva, under review). With students' awareness of their underrepresentation in higher mathematics classes, they come to see themselves at a relational disadvantage with their mathematics teachers and can be dissuaded from seeking support. African American students had to exert extra effort in order to manage teachers' possibly implicit racially biased attitudes. When teachers bring implicit racial attitudes with them unchecked into mathematics classrooms, the burden is placed on students to navigate these spaces. Implicit attitudes hold potential for expanding our understanding of this relational phenomenon, especially in classrooms where high-quality relationships are not developed. Similarly, it can affect teachers' expectations of student behavior and engagement.

Racial Comparisons of Teacher Expectations for Behavior and Engagement

The broader literature in education has found that African American students receive more negative consequences for their behavior. Ferguson (2000) found that the behavior of black[1] boys was rated as more intentional, aggressive, and that punishments were more severe than for white boys performing the same behavior. While punishment of students can remove them from mathematics instruction, it can also impact teachers' perceptions of their cognitive abilities. For instance, Neal and colleagues (2003) found that teachers' perceived African American movement styles as lower in achievement, more aggressive, and more in need of special education services. These studies reveal that racial perceptions of behavior can impact teacher expectations of students' cognitive aptitude and possibly lower the quality of instruction.

Gershenson and colleagues (2015) examined expectations of the same black student by a black and a non-black teacher. Black teachers held significantly higher expectations for students than non-black teachers and mathematics teachers largely drove those expectations. Since the teachers in the

study rated the same students, the authors argue that this is evidence that teachers were unconsciously racially biased. Dovidio (2001) furthered this line of work in mathematics through testing white students divided into 3 groups: explicitly biased whites, implicitly biased whites, and non-prejudiced whites. After solving a logic problem together with black students, both implicitly biased and non-prejudiced whites perceived interactions as positive, while blacks only perceived interactions with non-prejudiced whites as positive. In addition, non-prejudiced whites grouped with blacks solved the problem significantly quicker and groups containing implicitly biased whites solved the problems significantly slower. The implications for mathematics education are that unconscious racial interactions can impact students' problem solving and implicit racial interactions, unconscious for whites, are perceived by black students.

Racial Microaggressions in Mathematics Classrooms

When African American students are asked about their racial and mathematics identities, they often discuss microaggressions. Microaggressions are automatic insults or slights, sometimes unconscious, directed toward oppressed groups (Sue, 2008). Mathematics education research has found a number of interactions considered microaggressions by African Americans. In McGee and Martin's (2011) research, they note instances of framing students as not smart, not belonging in mathematics classrooms, or not being capable of completing work. The interactions drove students to prove stereotypes wrong and note the hyper-visibility they felt in mathematics classrooms. Martin (2006) also noted an instance when a teacher, rather than offering support or advice, told an African American student that they had gone as far as they could mathematically. Finally, Berry (2008) studied how teachers and administrators discriminated against African American males in three ways: resisting to place African Americans in gifted programs, focusing on behavior rather than cognitive abilities, and pre-diagnosing students as having ADHD (Berry, 2008). If mathematics education researchers are noting African American students as experiencing microaggressions in classrooms, then someone must be enacting them. All of these instances are consistent with implicit racial attitudes. Understanding more about this phenomenon can only increase our understanding of transforming mathematics instruction.

Discussion

Research is clear that African American students generally receive low-quality instruction and experience microaggressions in mathematics spaces. Outside work has found that teachers perceive their relationships with African American students as conflictual and that teachers have negative perceptions of student behavior and cognitive abilities. All of these findings are consistent with the enactment of implicitly racially biased attitudes. Combining this work with research on mathematics opportunities to learn has the potential for shifting our understanding of mechanisms that impact mathematics access and opportunity for African American students.

We are not arguing that teachers are aware of ways in which racial attitudes affect their expectations and relationships. Actually, they are likely unaware of the subtle ways in which race impacts their interactions. And yet, high levels of exposure to negative interactions cause students of color to experience frustration and anxiety, leading to disengagement, dropping out, and lower grades (Feagin, Vera, & Imani, 2001; Solórzano, Allen, & Carroll, 2002). Whether teachers are aware or not, their interactions with African American students have significant repercussions. In looking for implicit bias, we might uncover the unconscious ways in which internalized racial narratives are shaping teachers' interactions in undesired ways, with the ultimate goal of supporting teachers to resist these deficit narratives.

Endnote

[1]We use the term black to remain consistent with the author's language and do this throughout the paper.

AN EXPLORATION OF COLLEGE ALGEBRA STUDENTS' UNDERSTANDING OF HIGHER ORDER POLYNOMIAL FUNCTIONS

Victor V. Cifarelli
The University of North Carolina at Charlotte
vvcifare@uncc.edu

Volkan Sevim
University of South Carolina Beaufort
vsevim@uscb.edu

This paper reports on a study of College Algebra students that examined their understanding of polynomial functions of degree three or more. The study included interviews with students as they completed mathematical problem tasks, enabling a focus on the students' on-going cognitive actions. The results summarize how the students' existing conceptual structures guide their actions to produce and make connections among polynomial function graphs.

Keywords: Algebra and Algebraic Thinking, Cognition, Problem Solving

The mathematics community agrees that the study of non-linear functions must have a prominent place in the school mathematics curriculum (National Council of Teachers of Mathematics [NCTM], 2000). This paper is the first in a series of studies we will conduct with College Algebra students, addressing their understanding of non-linear functions. The current study examines students' understanding of polynomial functions, $f(x) = a_nx^n + a_{n-1}x^{n-1} + \ldots + a_1x^1 + a_0, n \geq 3$, with particular emphasis on how students' conceptions guide their actions to produce and make connections among graphs of polynomial functions that are of degree three or more.

While studies of non-linear functions have mostly focused on quadratic functions (Ellis & Grinstead, 2008), there are few studies of higher order polynomial functions (Curran, 1995; Teachey, 2003). Our research questions were: 1) What is the nature of students' understanding of graphs of higher order polynomial functions? 2) How do students express their understandings in mathematical problem solving situations involving higher order polynomial functions?

Theoretical Framework and Related Literature

Though studies of learners' general knowledge of non-linear functions (Vinner & Dreyfus, 1989; Moschkovich, Schoenfeld & Arcavi, 1993) proved useful to our analyses, we noted some limitations. For example, the majority of studies incorporate a multiple representation view of functions, i.e., that the learners' function knowledge can be viewed as consisting of different representations such as tables, graphs and formal algebraic rules. We agree with Thompson's (1994) view that the multiple representations view may not be the best way to characterize the learners' knowledge of functions; rather, such knowledge may be more effectively characterized as a single conceptual structure that can be expressed in a variety of ways (such as tables, graphs and algebraic rules) in specific situations:

> The core concept of "function" is not *represented* by any of what are commonly called the multiple representations of function, but instead our making connections among representational activities produces a subjective sense of invariance … We should instead focus on them as representations of something that, from the students' perspective, is *representable*, such as aspects of a specific situation. (Thompson, 1994, p. 24)

In order to examine the students' conceptual structures of polynomial functions in terms of the 'subjective sense of invariance,' alluded to by Thompson, we investigated the different ways that students made connections among graphs of higher order polynomials in specific problem solving situations. We also analyzed, from the students' perspective, what the graphs represented to them. For example, we note that while quadratic functions have graphs that have a conceptual 'sameness' to them, higher order polynomial functions have a greater set of conditions for the learner to

consider. Therefore, we hypothesized that in order to produce a subjective sense of invariance for higher order polynomial functions, the learner must have a certain conceptual structure of the properties that enables him or her to see how the class of functions of a particular degree can vary in some ways yet still be similar in terms of the degree of the polynomial. Furthermore, we believed that their prior experiences with quadratics might limit their developing a sense of invariance when examining higher order polynomials. Finally, in our examination of students' understanding of what the graphs represented to them, we noted Moore and Thompson's (2015) *shape thinking* construct as a useful way to characterize and classify ways that students conceive of graphical relationships. Specifically, *static shape thinking* "entails assimilations and actions based on perceptual cues and the perceptual shape of the graph" (Moore & Thompson, 2015, p. 784). In contrast, *emergent shape thinking* involves understanding a graph *simultaneously* as what is made (a trace) and how it is made (covariation).

Methodology

A total of twenty College Algebra students participated in the current study. Observing college students solving mathematics problems has proven to be an effective way of modeling the processes of problem solving (Cifarelli & Sevim, 2014; Carlson, 1997; Schoenfeld, 1992) and thus giving insights into their conceptual understanding. Each student was interviewed twice, for forty-five to sixty minutes. All interviews were videotaped.

Table 1: Selected Tasks Used in the Study

Task 1: Without using the graphing functions of your calculator, sketch the graph of the function.	$f(x) = x^3 - 4x^2 - 7x + 10$
Task 2: Which of the following polynomial functions might have the graph shown here: (a) $y = x^4(x-a)^2(x-b)^3$ (b) $y = -x^3(x-a)^3(x-b)^3$ (c) $y = x^2(x-a)^2(x-b)^2$ (d) $y = x(x-a)(x-b)$ (e) $y = -x^2(x-a)(x-b)^4$	

We include the tasks given in Table 1 for the following reasons. Task 1 is a typical textbook problem that requires the students to sketch a graph from a given polynomial equation in expanded form. This task requires that students use their knowledge of end-behavior of the graph to determine a rough initial sketch, find and classify the zeros of the function, and plot additional points as necessary to refine the sketch. In contrast, Task 2 is non-traditional, focusing on the more difficult problem of determining a functional relationship from observation of an actual graph. Finally, we believe that these tasks, especially Task 2, would provide us with data that would both help us better understand the students' conceptual structures and also to make some specific comparisons to the work of Moore & Thompson (2015), particularly to determine if their findings extend to higher order polynomial functions of degree three and higher.

Results and Discussions

The results seem to support our hypothesis regarding how students' prior experiences with quadratics might limit their developing a sense of invariance when acting on polynomial functions of degree three or higher. Specifically, most students related the graph of the given polynomial

functions to parabolas in some way; and all demonstrated some degree of *static shape thinking* (Moore & Thompson, 2015). We will illustrate some of these findings with results from two students, with pseudonyms BD and SE.

In solving Task 1, BD used synthetic division to find a zero, x=1, found other zeros using the quadratic formula and then sketched the graph, stating that "even's touch and odd's cross." In sketching the graph, BD first made a general sketch based just on the location of the zeros, which he then modified by locating the y-intercept and one point on the graph (3, -20), and making estimates of the locations of the relative maximum and minimum points on the graph. When asked to further explain the graphs of these higher order polynomials, BD stated that: "it's all described by either a cubic function or a quadratic function, it's parabolic with an unknown middle or cubic with unknown middle." We inferred that BD could see some differences between quadratics and polynomials of degree 3 in terms of the zeros, and that he could sketch the graph by finding the zeros and some additional points, but we did not observe explicit treatment of the mathematical attributes of the graph as properties of covariation, *emergent shape thinking* (Moore & Thompson, 2015). On the other hand, BD did appear to have a coordinated understanding of the properties of cubic functions in general, particularly the classification of the zeros of the function as well as their end-behaviors.

In contrast to BD's inferred understanding of connections between the function rule and its graph, SE did not appear to make such conceptual connections. In solving Task 2, SE interpreted the given graph as a series of parabolas and recalled properties of quadratic functions in a process of elimination to make her selection.

SE: These are the ones I usually have trouble with. Where it touches the x-axis at 3 points. Usually these I'll see which one makes most logical sense to me.
Interviewer: What's hard about this problem?
SE: I think it's one of those that look very difficult but actually you can dissect it and see which one, see how it works. Yes. I'll just start from left to right and see which one. Obviously the first curve right here (*she points at choice A in Task 2*), so my choices are x^4. It's positive because it's going upwards so it can't be B or E. So it leaves me with x^4, x^2 and x.

In her analysis of the portion of the graph that includes the point (0, 0), SE ruled out the correct answer, E, reasoning that the graph "opens up" and thus the formula cannot have a term with a negative sign such as $-x^2$.

SE: B, in that problem it was a negative and it's also a parabola which means something in there had to be squared. And then there's another parabola here.
Interviewer: So you're thinking of breaking that picture up into parabolas?
SE: Yes. Looking at this parabola, B is going down making it negative. These are what go through my head. We have to pay attention to points a and b because that's what are given. I'd rule out D because this is a parabola right here. There's got to be a reason it goes down and comes up right here (*she points at the portion of the graph from x=a to x=b*). It can't be D because there's no squared. I'd rule out D so would be left with A and C.

We inferred that SE's conception of graphs is consistent with Moore and Thompson's (2015) static shape thinking in that she viewed polynomial graphs as collections of parabolas, thus focusing on graphs-as-wires with certain properties, and seeking to match the graph with the given quadratic expressions based on those properties. She had difficulty in self-initiating her solution activity and demonstrated little computational competence beyond carrying out synthetic division, a skill she could carry out only when the possible roots were provided to her. Although she could verify a particular x-value to be a zero for a given function, she was

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

not able to use the result to find other zeros nor was she able to sketch the graph without assistance from the interviewer.

Episodes from BD's interview suggest that he had a more unified view of polynomial functions and their graphs than did SE. In terms of their conceptual structures, we inferred that BD had a well-developed conceptual structure that allowed him to demonstrate flexibility, coherence and reversibility in his actions. More than SE, he could self-initiate problem solving activity and demonstrated that he could connect and coordinate the various properties of polynomial functions. In addition, he demonstrated a sense of reversibility in his actions to the extent that he could reflect on the problem and state specifically what must be true regarding the various properties (zeros, end-behavior).

Implications

We believe the experiences of students BD and SE are somewhat typical of College Algebra students in how they solve polynomial function problems. However, we were struck by the general finding that, for many students the ways that they examined higher order polynomial functions was dominated by their knowledge of quadratic functions, applying properties of quadratic function graphs when analyzing the higher degree polynomials. This finding suggests that it may be important for mathematics educators to have the instructional goal of having students first develop a sense of invariance in working with various polynomial functions before offering them graphs as objects in-themselves with various properties.

USING PHOTOGRAPHS TO AID IN CHILDREN'S DEVELOPING UNDERSTANDING OF MULTIPLICATION

Sherri Farmer
Purdue University
Farmer10@Purdue.edu

In this study, two students were provided with photographs of realistic arrays and given the opportunity to contextualize their thinking and to share their multiplication strategies over 6-7 sessions. This data was then analyzed using a nested chain of semiotics. This study challenges boundaries for what is considered 'traditional' mathematics instruction and instructional strategies that develop in tandem with a child's understanding of their mathematical world. Students were able to demonstrate a progression of understanding, and improve their structuring and enumerative qualities by referencing real-world photographs of arrays.

Keywords: Classroom Discourse, Elementary School Education, Modeling

Typical US textbooks tend to contain illustrations that do not support a student's meaningful construction of mathematical content (Sutherland, Winter & Harries, 2001). Yet, as the external world influences students' mathematical learning (Freudenthal, 1968; Sutherland et al., 2001) photographs could be an excellent resource for instruction. In this study, photographs of "naturally occurring arrays" (i.e. the arrangement of windows or floor tiles) were used to elicit students' multiplicative thinking structures. By analyzing students' abilities to mathematize these structures (Freudenthal, 1968), I explore the following question: To what extent can photographs be used to support a meaningful construction of multiplication?

Theoretical Framework

Students must be given opportunities to interact with the real world while actively engaging their developing mathematical structures through conversation (Sfard, 1998). Unfortunately, there is a tendency to teach mathematics as a set of rules and processes to be memorized, as opposed to developing conceptual skills through constructing relationships (Hiebert, 2013). This study challenges the boundaries between traditional mathematics instruction and instructional strategies that focus on students' methods for multiplicative reasoning when dealing with the structuring and enumerative qualities using photographs of arrays.

Spatial Structures and Arrays

Due to the use of arrays in classroom instruction, elements of *spatial structuring,* defined as "the mental operation of constructing an organization or form for an object or set of objects," are foundational to the explanation of students' representations (Battista, Clements, Arnoff, Battista, & Borrow, 1998, p. 503). When students view the array structures within photographs, they are identifying the shape as it exists in reality, reflecting, and then re-presenting it as their own structure, which is part of the spatial structuring and multiplicative developmental process.

Semiotics

A child's meaning for an object, such as an array, is conveyed to the world through their signs, or words (Seeger, 2005). This is the process of semiotics, and it links previous meaning with new. Using Presmeg's (2006) framework of nested semiotic chains allows for the analysis of children's constructed mathematical knowledge by revealing their process of connecting previously made relations while formulating new ones (Clark & Kamii, 2000). The previous relations are "nested" in the new; the knowledge that comes before is necessary to develop understanding at more

sophisticated levels. It is this nested function that gives the semiotic chain its power for mathematics education (Cobb, Gravemeijer, Yackel, McClain, & Whitenack, 1997; Presmeg 1997, 2006).

Methods

This study took place in an urban public charter school. One 3rd and one 4th grader will be discussed for this analysis. Over 6-7 individual sessions, photographs of multiplicative arrays were presented in a progressive sequence to students to explore their abilities to abstract, reflect, and re-present what they see using their own knowledge of mathematical structures. At the beginning of each session, they were shown a photograph of an array and told, "Describe the picture using math." Additional questions were asked in order to clarify students' comments or drawings. The images (see Figure 1) were used as models, not as instructional guides.

Analysis

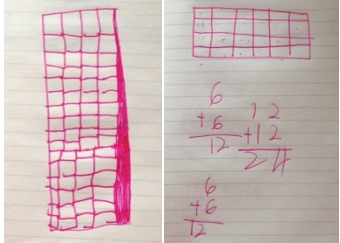
Students' responses were analyzed using Presmeg's (2006) nested semiotic chain. Any words, drawings, or other representations were recorded, collected, and later analyzed as signs, using the semiotic framework. The pictures of arrays provided the student opportunities to share their strategies. By recording strategies or algorithms, the student was afforded opportunities to contextualize thinking while negotiating meaning within the structures of the photos.

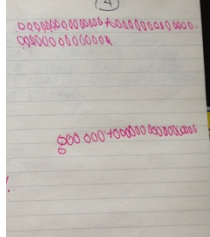
Results

I give two examples from each student in an effort to demonstrate the multiplicative progression each student undertakes: one from early in the study and one from later.

Nyla

Nyla was nine years old and in third grade. She spoke fast, counted quickly and always by one. She often "drew" a shape in the air before she explained the mathematics to me and seemed confident in both the shape and the number of "chocolates" in the photograph (Figure 1a):





| (a) Week 1, *Chocolate Bar* | (b) Week 4, *Marbles* | (c) Initial (left) and Final (right) Chocolate Bar | (d) Unitized addition |

Figure 1. Photograph models and Nyla's re-presentations for photographs of arrays by Phillips (2005). *Mathematical world exploring mathematics through photographic images.* Emeryville, CA: Key Curriculum Press.

> *Interviewer:* How many do you think are here?
> *Nyla: (referred to image, counted up rows of four counting by ones silently, her lips moving; drew 6 columns with four in each in the air)* Twenty-three…Because look, they all have four in them. See…one two three four.
> *Interviewer:* How do you know there's one there? *(pointing to the covered portion of the bar)*
> *Nyla:* Because I can see a piece of chocolate…look, there's ten, twenty, wait. 1 2 3 4 5 6 7…15… It's going to be more than 23. I'm telling you that. It's going to be fine.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Tucson, AZ: The University of Arizona.

Unlike her "drawing in the air", this shape was 4 columns, but lacked the six composite units necessary to reproduce her count (Figure 1c). She drew individual squares within the shape, four in each row, until she filled up the space. This indicates Level 2 of Battista's (2007) spatial structuring framework. She had wanted 23 or 24, but could not coordinate her model with her mathematical estimate.

Table 1: Nyla's semiotic chain for the initial *Chocolate Bar* (Figure 1c)

Object	Representamen	Interpretant
Photo of chocolate bar	Draws rectangle and fills in squares one at a time	Her drawing
Her drawing (Figure 2a)	Counts by one	=68

Her iteration of one, and knowing there were groupings of four, were not difficult for her to represent, but she became lost and could not quantify the amount she wanted. I noted that she counted and tagged by one. Nyla subitized the small arrays, though all the mathematics she performed were from signs re-presenting her count, starting with 'one' every time (Figure 2b).

She can partition space, but cannot name it in a multiplicative way. Lacking the numerical understanding necessary to iterate a composite unit, she struggled to quantify the space that she created. This was seen again when she counted the 24 squares in her *final* drawing of the chocolate bar (Figure 1c), four weeks later.

Table 2: Nyla's semiotic chain for counting the squares in the last *Chocolate Bar* (Figure 1c)

Object	Representamen	Interpretant
Chocolate Bar	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24	24
24	1,2,3,4,5,6. 1,2,3,4,5,6. 1,2,3,4,5,6. 1,2,3,4,5,6.	6 + 6 and 6 + 6
6 + 6	1,2,3,4,5,6,7,8,9,10,11,12	24 is the same as 12 + 12

Jessica

Jessica was ten years old and in fourth grade. A verbal-processor, she often repeated, not only what I said to her, but her own thinking as she worked through a problem. She did not rush, but demonstrated a thoughtful and careful process of mathematizing. In Week 1, Jessica coordinated her spatial thinking with discrete objects, not as a collection, but as individual units, in that she counted and tagged each visible element of the chocolate bar array (Figure 1a).

During Week 2, Jessica demonstrated her developing multiplicative thought process. She rationalized as she described the lower array of stars (Figure 1b): "This one…one two three going across, one two three four going down. Three times four is twelve, so there should be twelve so…1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12. Twelve, hmm, my estimate was correct."

Table 3: Jessica's semiotic chain of meaning in referencing *Cityscape*

Object	Representamen	Interpretant
Cityscape	1, 2, 3; 1, 2, 3, 4	3 across; 4 down
3 across; 4 down	3 x 4 is 12, so there should be 12	3 x 4 = 12?
3 x 4 = 12?	1,2,3,4,5,6,7,8,9,10,11,12	Yes, 3 x 4 = 12

She did not rest with the multiplication fact, which was not a fact to her since she stated it *should be twelve,* and instead relied on counting by ones to verify her thinking.

By Week 4, Jessica's ability to both conceptualize and represent number developed. Her semiotic chain indicated a deepened relationship between spatial structuring and enumeration skills (Battista et al., 1998). She no longer counted by one, but felt confident drawing a sign in the shape of a 3x3

array. She had developed in her multiplicative thinking by including multiple levels of abstraction when describing mathematical situations (Clark & Kamii, 1996). She structured her array with discrete items (three columns of three) and extended it to a continuous model using the discrete objects as individual units. The use visual imagery allows students to coordinate and structure arrays (Battista et al., 1998). Her semiotic chain for *Marbles* (Figure 1c) is as follows:

Table 4: Jessica's semiotic chain for *Marbles*

Object	Representamen	Interpretant
Marbles	3, 3, 3	They are all equal
Equal rows of three	Three rows of three	3 x 3 array

Conclusion

Nyla demonstrated spatial structuring skills using a countable unit of one with which to structure space. She recognized the repeatedness of the arrangement of the arrays that it was the same throughout. Nyla improved her spatial structures by modeling the context within the photographs, creating effective tools for her mathematization processes. With further interactions, she may have developed composite counting strategies, as research suggests (Battista et al., 1998).

Conversely, Jessica developed from representing an array additively to re-presenting multiplication *as an array*, through the process of modeling and constructive reflection. In our remaining sessions, she used the spatial representation of an array to represent her multiplicative thinking. This demonstrated an essential understanding of structure-related enumeration from Level 2, to Level 7 (Battista, 2007).

Photographs give students a realistic mental model with which to mathematize their worlds and challenge the boundaries of traditional illustrations currently used in the United States

LEARNING ABOUT MODELING IN TEACHER PREPARATION PROGRAMS

Hyunyi Jung
Calvin College

senk@msu.edu

This study explores opportunities that secondary mathematics teacher preparation programs provide to learn about modeling in algebra. Forty-eight course instructors and ten focus groups at five universities were interviewed to answer questions related to modeling. With the analysis of the interview transcripts and related course materials, we found few opportunities for PSTs to engage with the full modeling cycle. Examples of opportunities to learn about algebraic modeling and the participants' perspectives on the opportunities can contribute to the study of modeling and algebra in teacher education.

Keywords: Modeling, Teacher Education-Preservice, Algebra and Algebraic Thinking

Mathematical modeling is a critical component in school mathematics as it supports students in developing a way of thinking and interacting with the world that will be necessary later in life. Through modeling, students develop skills necessary to successfully make sense of and interact with complex mathematical systems (Lesh & Doerr, 2003). To teach mathematical modeling, teachers must learn new ways of thinking about and interacting with mathematics. Anhalt and Cortez (2015) argued, "Mathematical modeling problems present unique challenges for teachers, who are not typically required to take courses on modeling as part of their preparation" (p. 2).

In response to new guidance from *Common Core State Standards for Mathematics* (*CCSSM*) related to modeling (National Governor's Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010), there is a need for research exploring whether and how teacher preparation programs have made changes in their curricula to prepare secondary pre-service teachers (PSTs) to learn about modeling based on *CCSSM*. *CCSSM* included mathematical modeling as a mathematical practice across preK-12 grades and as a mathematical content area for High School (NGA & CCSSO, 2010). The *CCSSM* modeling cycle is described as a complex, iterative process in which assumptions are made, tested mathematically, interpreted and validated, and then potentially revised multiple times. Beginning teachers should be familiar with all steps of the mathematical modeling process as described in the *CCSSM*, should have had opportunities to develop their own expertise, and should be aware of the importance of meta-cognitive reflection throughout the modeling process. We report findings from research focused around modeling, conducted as part of a collaborative NSF research project, *Preparing to Teach Algebra*, which investigated opportunities secondary mathematics teacher preparation programs provided to learn about algebra. In this paper, we aim to answer a question, "What opportunities do secondary mathematics teacher preparation programs provide to learn about algebra related to the modeling standards described in *CCSSM*?"

Methods

To investigate PSTs' opportunities to learn algebra and modeling, we conducted interviews with secondary PSTs and instructors of required courses, and collected instructional materials (e.g., syllabi, project descriptions) used in the courses at five universities. We call these universities: Great Lakes University (GLU), Midwestern Research University (MRU), Midwestern Urban University (MUU), Southeastern Research University (SRU), and Western Urban University (WUU). Different

from other universities, WUU only admits PSTs who have already completed a Bachelor's degree in mathematics.

Among all the courses required in the secondary mathematics preparation program at the universities, we selected mathematics courses that include algebra content (e.g., Linear Algebra, Geometry, Statistics and Probability). If the teacher education program required mathematics for teachers courses (e.g., Algebra for Teachers, Geometry for Teachers), we interviewed an instructor from each course. We also interviewed an instructor from each of the mathematics education courses (e.g., Secondary Mathematics Methods) and general education courses (e.g., Teaching in a Diverse Society) that may include opportunity to learn about equity in algebra. Table 1 summarizes the course types and the number of instructors interviewed at each university.

Table 1: Number of instructor interviews by course type

Course Type	GLU	MRU	MUU	SRU	WUU	Total
Mathematics (M)	5	4	6	5	0	20
Mathematics for Teachers (MfT)	1	2	0	3	0	6
Mathematics Education (ME)	3	5	3	4	1	16
General Education (GE)	1	1	1	1	2	6

Additionally, two groups of 3-4 PSTs from each university were interviewed. We designed interview protocols in parallel for instructors and focus groups. We asked instructors and students about modeling generally first. Then we asked specifically about modeling process as described in *CCSSM*. In addition to instructor interviews, we collected corresponding instructional materials.

To analyze the interview transcripts and course materials, we developed six codes, named for each element of modeling process described in *CCSSM*: a) identifying and selecting variables, b) formulating a model, c) analyzing and performing operations, d) interpreting the results, e) validating the conclusions, and f) reporting on the conclusions. Two pairs of us independently coded each transcript based on these nodes using NVivo 10 and we then compared our coding and resolved any discrepancies.

Findings

We address our research question by describing how each group of participants responded to the interview questions related to the opportunities for PSTs to learn about modeling in algebra. The number in Table 2 represents the number of opportunities (e.g., tasks, discussions, lecture, problem) that instructors or PSTs reported related to each element of modeling process at the five institutions. Note that no General Education instructors at any university described opportunities to learn modeling, so we do not include them below.

Mathematics Instructors. Mathematics instructors reported several opportunities for PSTs to learn about "formulating a model by creating and selecting appropriate representations" and "validating the conclusions." One example of "formulating a model" is presented by Probability and Statistics instructor from GLU: "like my take-home final, they were doing a lot of this [formulating a model] because they had data, and they had to analyze it." In terms of "validating the conclusions," Linear Algebra instructor at GLU reported that he provided a unique solution to a traffic flow problem that led PSTs to validate conclusions. Other instructors described how PSTs identified variables, performed operations, and interpreted the results, but no one reported an example of "reporting on the conclusions."

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 2: Opportunities to learn about modeling in different types of courses

Elements of Modeling Process	M (20)	MfT (6)	ME (16)	GE (6)	FG (10)	TOTAL
a)Identifying and selecting variables	2	4	3	0	2	11
b)Formulating a model	4	5	6	0	5	20
c)Analyzing and performing operations	1	2	1	0	3	7
d)Interpreting the results	1	2	3	0	7	13
e)Validating the conclusions,	3	2	5	0	5	15
f)Reporting on the conclusions	0	3	3	0	2	8
TOTAL	11	18	21	0	24	74

Note. Number of instructors (or number of focus groups) interviewed in parentheses.

Mathematics for Teachers Instructors. Mathematics for Teachers instructors reported a number of opportunities even though they were few (6 of 48 instructors). One example illustrates how they asked PSTs to engage with modeling and to use the activity for teaching their own students: PSTs identified "functions to fit the data given movie money data" and considered "how to use this activity in future teaching."

These instructors also provided more opportunities related to the modeling process "identify and select variable" compared to the other participants. A following task introduced by Secondary Math Connection 1 instructor at SRU presented such modeling process:

> Ana is sitting in the bucket of a Ferris wheel. She is exactly 46.7 feet from the center and is at the 3 o'clock position as the Ferris wheel starts turning. Sketch graphs that represents Ana's different location on the Ferris wheel.

We see in this task that variables were not given in the problem statement. When PSTs sketched graphs, they decided which quantity would be labeled as independent or dependent variables.

One modeling process reported by not Mathematics instructors, but Mathematics for Teachers instructors instead, was "reporting on the conclusions." A Secondary Mathematics Connections 1 instructor at SRU said, "validating conclusions, reporting on conclusions, if the mindset's done, then this all gets wrapped up into one. You're always interpreting, validating and reporting within that process." This instructor connected several modeling process: interpreting, validating, and reporting the results.

Mathematics Education Instructors. As a group, Mathematics Education instructors provided more opportunities related to "validating the conclusions" than the other instructors. An activity provided by the Secondary Mathematics Methods instructor from WUU shows that PSTs had the opportunity to compare their answers with others during the modeling process. Mathematics Education instructors also provided several opportunities for PSTs to formulate a model. A Secondary Math Methods instructor at MUU described PSTs opportunity to discuss the meaning of variables in context and generate a model using representations when solving for the number of border tiles in a pool. The discussion led by this instructor might help PSTs make connections between the real-world situation (e.g., border tiles for a pool) and mathematics.

Focus Groups. While instructors most often reported opportunities to "formulating a model by creating and selecting appropriate representations," PSTs most often described the element, "interpreting the results." Specifically, they described a process of interpreting the results in the given context: "it's a lot of word problems to where when you're given an equation, it's not just okay x=3 it's like, in the problem we wrote this equation to model this situation. What does that variable mean?" [Focus Group from SRU]. As described, PSTs considered the meaning of each variable in

the equation that represents the problem context. PSTs also mentioned that it would be helpful to have more time validating and refining their process of solving a problem. A PST from MRU said,

> I feel like there is more of a "This is what you need, get really good at this skill" but there's not like a "Explore it and refine what you've seen."

This example shows that PSTs considered the value of exploring the problem on their own and refine the solutions, but they thought such opportunity was not provided much in their program.

Discussion and Conclusions

Findings show that both instructors and PSTs reported examples of opportunities that addressed few elements of modeling process. More opportunities to learn about modeling might be revealed from teacher education programs if our study is extended to mathematical modeling, rather than algebraic modeling. Also, if we had observed classroom practice, we may have been able to find more opportunities addressing the full modeling cycle. Nonetheless, the findings from this study show several opportunities for PSTs to learn about algebraic modeling, but also show that not all opportunities involved the full modeling cycle recommended by *CCSSM*. This result shows that PSTs need more opportunities to explore the complete modeling process (Anhalt & Cortez, 2015; Pollack & Garfunkel, 2013).

Certain modeling elements were emphasized by PSTs and instructors. PSTs reported the value of validating and refining the process of solving a modeling problem. Some PSTs remembered how a mathematics education instructor emphasized reporting and justifying answers throughout the entire modeling process. A mathematics for teachers course instructor also provided an example of reporting conclusions, saying that this process can be connected with interpreting and validating the results. Despite interviewing more mathematics instructors (20 instructors) than mathematics education instructors (16 instructors), more opportunities to learn about modeling described in *CCSSM* were reported by mathematics education instructors. Mathematics instructors, who did not provide any example related to the last element of modeling process (reporting on the conclusions), need to consider specific ways of helping PSTs report conclusions throughout modeling process.

Overall, this study incorporates the large data including interview transcripts of 48 course instructors and 10 focus groups from five universities, and corresponding course materials, which enabled us to present the overview of learning opportunities reported by instructors and future teachers. We also presented the extent and element of modeling process addressed in different courses and found that few opportunities involving the entire modeling cycle. This result supports the need for future teachers to learn about more modeling activities that address all the modeling processes.

PRODUCTIVITY AND THE DISTRIBUTION OF AUTHORITY DURING COLLABORATIVE MATHEMATICS PROBLEM-SOLVING

Jennifer M. Langer-Osuna
Stanford University
jmlo@standford.edu

Jennifer Munson
Stanford University
jmunson@stanford.edu

Emma Groetzinger

egroetzi@stanford.edu

This research brief describes an analytic approach to examining the relationship between productivity and the distribution of student authority during collaborative mathematics problem-solving among elementary learners. Our approach focuses on distributions of both intellectual and social authority – shared, concentrated, and contested – and its relations to how students engage with the collaborative task and one another. We then discuss the utility for such an approach to examine how students work together on collaborative mathematics tasks.

Keywords: Classroom Discourse, Elementary School Education, Equity and Diversity, Problem Solving

Introduction

The new Common Core State Standards in Mathematics expect students in today's schools to more centrally engage in mathematical argumentation with their peers, including constructing mathematical conjectures and critiquing the reasoning of others. These expectations shift authority to students who now have a central role in authoring and evaluating mathematical ideas and managing collaborative tasks. Dynamics around authority, inherent in peer-led mathematical argumentation, affect who gets to speak, as well as whose ideas are judged as worthwhile and ultimately influential.

Group dynamics during collaborative mathematics problem-solving have typically been analyzed in relation to shared metacognition and other regulatory processes (Barron 2003; Goos, & Galbraith,1996; Goos, Galbraith, & Renshaw, 2002; Iiskala, Vauras, Lehtinen, & Salonen, 2011). Less often considered are the relationships of authority among peers and how these relationships shape the ways in which students engage with the collaborative task and one another's ideas. In this research brief, we frame the collaborative mathematics problem-solving process to include two key dimensions: (1) the productivity of the collaboration and (2) the distribution of intellectual and social authority of the collaborating students.

We build on Engle and Conant's (2002) notion of productivity and situate our study in classrooms that embody all four of the principles to fostering productive disciplinary engagement. With respect to productive engagement, Engle and Conant (2002) state:

> …students' engagement is productive to the extent that they make intellectual progress, or, in more colloquial language, 'get somewhere'… such productivity might involve things like recognizing a confusion, making a new connection among ideas, or designing something to satisfy a goal. (p. 403)

Here we frame productivity in terms of students' engagement with one another and the task as they move the collective work forward. These forms of engagement might include: offering an idea, expressing agreement or disagreement, engaging in parallel independent work, building or connecting on peers' ideas, and so on. Of interest is how these forms of engagement might relate to the relations of authority students construct during collaborative work. We draw on Engle, Langer-Osuna, and McKinney de Royston's (2014) and Langer-Osuna's (2011, 2016) constructs of intellectual and social authority. By intellectual authority, we mean interactional moments wherein students are positioned as a credible source of mathematical information. This might include moments where a particular student's help is sought, or moments where a particular student is driving the intellectual work of the group. By social authority, we mean interactional moments

wherein students are positioned as having the right to issue directives to their peers or otherwise manage the group (Langer-Osuna, 2011, 2016; Wood & Kalinec, 2012). While both forms of authority can co-occur, we make an analytic distinction between management and the intellectual work in order to capture their interrelations.

We view this work as crossing critical intellectual borders between the problem-solving literature and research on relations of authority, which is fundamental to addressing issues of access and equity in mathematics classrooms. Our field knows relatively little about how students construct relations of authority in collaborative mathematics classrooms and its effects on the collaborative problem-solving process.

Study Context and Data Sources

This study is based on a broader teacher-initiated partnership between the research team and an elementary instructional team of five teachers (grades K, 1, 2, and 4) in an urban area of Northern California. The teachers sought support in implementing the Contexts for Learning Mathematics (CFL) instructional units (Fosnot 2007) to support student-led collaborative mathematical work. These units draw on relevant story-based contexts to engage students in inquiry-based activity and rich mathematical discussions. The research team sought to capture how students made sense of and negotiated collaborative mathematical work and to provide an ongoing external lens to partner teachers on their implementation of the unit of their choice.

Each teacher chose one CFL unit to implement in her class in collaboration with the research team. In the Kindergarten classroom the teacher taught a unit "Bunk Beds and Apple Boxes: Early Number Sense." In the first grade and two second grade classes the teachers taught the unit, "The Double Decker Bus: Early Addition and Subtraction." In the fourth grade class the teacher taught the unit, "The T-Shirt Factory: Place Value, Addition and Subtraction." Data was collected in each of the five classrooms before, during and after the teacher-chosen unit. Units lasted between three and five weeks, differing by teacher and content.

Participating teachers all worked at the same elementary school, which serves predominantly bilingual Latino and Pacific Islander students from lower-income neighborhoods. Two-thirds of students are designated as ELLs and 93% participate in the free or reduced price lunch programs. We worked with teachers over the summer to support their capacity to notice practices related to the following core ideas: (1) eliciting and responding to student mathematical thinking, (2) student group dynamics and their relation to privileged and marginalized student engagement in collaborative peer work, and (3) bilingual students' forms of mathematical communication (Moschkovich, 1999). During the academic year, participating teachers and the research team met bi-monthly to collectively watch video clips from the teachers' classrooms and engage in discussion focused on how students negotiated their collaborative work.

We collected multiple forms of data. During the academic year, we videotaped whole class discussions and student-led table work throughout the duration of the teacher-chosen unit in each of the five classrooms, capturing between one and four instructional days per week. We used one video camera to capture whole class discussions, and two additional video cameras to capture two focal tables during student-led group work. We additionally collected pre- and post-assessments of individual mathematics problem solving related to the concepts within the instructional unit and their feelings about learning mathematics. We also collected student work throughout the unit. Here, we focus exclusively on videos of student-led table work.

Analytic Process

We offer a novel analytic approach that can capture these interrelations and be usefully applied across multiple video records. We recognize the dearth of publications focused on describing the analytic process of classroom-based research and hope to contribute to greater transparency. The

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

purpose of our analytic process is two-fold: (1) to code the collaborative problem-solving process in terms of both authority; and (2) to characterize their relations.

We focus on dyadic (and, at times, group) student problem solving sessions in classrooms (grades K, 1, 2, and 4) across the course of a typically one-month long unit. Specifically, we focus on a total of 49 videos of table work gathered during these units of study: 8 videos of Kindergarten, 8 videos of 1st grade, 14 videos of 2nd grade, and 19 videos of 4th grade.

We repeatedly viewed the videos of table work in order to develop a coding scheme that captured the ways in which students engaged with one another and the task. We were initially guided by Engle and Conant (2002) to look for evidence of "moving the work forward" and student moves characterized in the literature, including "authoring ideas", "expressing agreement/disagreement", "building on the ideas of others", and so on. We added codes until multiple videos from a range of grade levels could be adequately captured with a complete, minimal set of codes. A sample of coded behaviors and moves include (a) building on or connecting to one another's ideas, (b) explaining or thinking aloud, (c) verifying the work of self or others, (d) disagreement or critique, (e) requesting help, and (f) offering ideas.

We then turned to coding interactional dynamics that capture different distributions of both social and intellectual authority: (a) shared authority, (b) concentrated authority, and (c) contested authority. We drew on Engle et al. (2014) and Langer-Osuna (2016)'s analysis of intellectual and social authority. Their work coded bids for authority and their uptake (accepted or rejected) at the interactional level. Because of the number of videos focused on here, coding each interaction in relation to authority bids and their uptake would be too onerous. We code instead interactional events we call authority distributions: shared, concentrated, or contested.

Interactional dynamics representing shared intellectual authority include events where bids for intellectual authority are made by and taken up for more than one student; shared social authority include events where bids for the management of the task or peers are likewise made by and taken up for more than one student. Examples of shared intellectual authority include events where multiple students author ideas for moving the task forward that are considered by peers; examples of shared social authority include events wherein multiple students take part in the management of the work, including the distribution of tasks and the management of off- and on-task behavior. Interactional dynamics representing concentrated authority include events where bids for intellectual/social authority are taken up for only one student; bids by other students are rejected or ignored. Examples of concentrated intellectual authority include dynamics where one student controls the intellectual work of the group. Concentrated social authority dynamics include interactions where one student controls the management of the group. Interactional dynamics representing contested authority include events where multiple bids are ignored or rejected, with no uptake for any student. Contested intellectual and social authority events include dynamics where the right to take control or contribute is explicitly contested across a series of interactions.

Using these codes, we then generate profiles of productivity based on patterns of authority distribution. Intellectual and social authority distributions were organized as a 3 (intellectual authority distributions) X3 (social authority distributions) possible combinations (e.g., instances of shared intellectual/shared social authority, shared intellectual/concentrated social authority, etc). Patterns of student engagement in the collaborative work (productivity) are then compared across the 9 authority distributions across grade levels. From these profiles, researchers are set to investigate numerous questions pertaining to how students navigate the forms of authority afforded to them in student-centered collaborative classrooms. Some of these questions might include: how do students manage collaborative work and the co-construction of mathematical ideas as they engage in complex, open-ended tasks together? What kinds of interactions tend to lead to productive collaborations, and what kinds of interactions tend to make productive collaborations fall apart? What kinds of classroom norms or teacher moves support or hinder how students negotiate their collaborative

work? These questions are central to understanding effective, inclusive collaborative mathematics classrooms.

DORI AND THE HIDDEN DOUBLE NEGATIVE

Annie Selden   John Selden
New Mexico State University   New Mexico State University
aselden@math.nmsu.edu   jselden@math.nmsu.edu

This case study elucidates the difficulty that university students' may have in unpacking an informally worded theorem statement into its formal equivalent in order to understand its logical structure and facilitate constructing a proof. This situation is illustrated with the case of Dori who encountered just such a difficulty with a hidden double negative. She was taking a transition-to-proof course that began by having students first prove formally worded "if-then" theorem statements that enabled them to construct proof frameworks, and thereby make initial progress on constructing proofs. However, later, students, such as Dori, were presented with more informally worded theorem statements to prove. We discuss what additional linguistic difficulties students might have when interpreting informally worded theorem statements and structuring their proofs.

Keywords: Post-Secondary Education, Advanced Mathematical Thinking, Reasoning and Proof

This paper sits at the border between linguistics and mathematics education. It considers linguistic obstacles that university students often have when unpacking informally worded mathematical statements into their formal equivalents. This can become especially apparent when students are attempting to prove such statements. We illustrate this with an example from Dori, who was taking a transition-to-proof course that began by having students construct proofs for formally worded "if, then" theorem statements. Early on, she was introduced to the idea of constructing proof frameworks (Selden & Selden, 1995, 2015) and was successful. Later, she encountered difficulty when attempting to interpret and prove an informally worded statement with a hidden double negative.

Theoretical Perspective

We adopt the theoretical perspective of Selden and Selden (2015) and consider a proof construction to be a sequence of mental or physical actions, some of which do not appear in the final written proof text. Each action is driven by a situation in the partly completed proof construction and its interpretation. For example, suppose that in a partly completed proof, there is an "or" in the hypothesis of a statement yet to be proved: *If A or B, then C*. Here, the situation is having to prove this statement. The interpretation is realizing that *C* can be proved by cases. The action is constructing two independent sub-proofs; one in which one supposes *A* and proves *C*, the other in which one supposes *B* and proves *C*.

A proof can also be divided into a formal-rhetorical part and a problem-centered part. The *formal-rhetorical* part is the part of a proof that depends only on unpacking and using the logical structure of the statement of the theorem, associated definitions, and earlier results. In general, this part does not depend on a deep understanding of, or intuition about, the concepts involved or on genuine problem solving in the sense of Schoenfeld (1985, p. 74). The remaining part of a proof has been called the *problem-centered* part. It is the part that *does* depend on genuine problem solving, intuition, heuristics, and a deeper understanding of the concepts involved (Selden & Selden, 2013).

Proof Frameworks

A major feature that can help a student write the formal-rhetorical part of a proof is a *proof framework*, of which there are several kinds, and in most cases, both a first-level and a second-level framework. For example, given a theorem of the form "For all real numbers x, if $P(x)$ then $Q(x)$", a first-level proof framework would be "Let x be a real number. Suppose $P(x)$. … Therefore $Q(x)$,"

with the remainder of the proof ultimately replacing the ellipsis. A second-level framework can often be obtained by "unpacking" the meaning of $Q(x)$ and putting its (second-level) framework between the lines already written for the first-level framework. Thus, the proof would "grow" from both ends toward the middle, instead of being written from the top down. In case there are subproofs, these can be handled in a similar way. A more detailed explanation with examples can be found in Selden and Selden (2015). A proof need not show evidence of a proof framework to be correct. However, we have observed that use of proof frameworks tends to help novice university mathematics students write correct, well-organized, and easy-to-read proofs.

The Formal-Informal Distinction and Linguistic Obstacles

An *informal statement* is one that departs from the most common natural language version of predicate and propositional calculus or fails to name variables. For example, the statement, "differentiable functions are continuous," is informal because a universal quantifier is understood by convention, but is not explicitly indicated; because the variables are not named; and because it departs from the familiar "if-then" expression of the conditional. Such statements are commonplace in everyday mathematical conversations, lectures, and books. They are not ambiguous or ill-formed because widely understood, but rarely articulated, conventions permit their precise interpretation by mathematicians, and less reliably, by students. In our experience, mathematicians, including those with no formal training in symbolic logic, move easily between informal statements and their equivalent more formal versions.

We suggest that an informal version of a theorem will often be more memorable, that is, be more easily brought to mind and used. However, it may also be more difficult to prove, and given a proof, be more difficult to validate, than a formal version. This suggests the question: Can undergraduates who have taken a transition-to-proof course reliably unpack an informally stated theorem into its formal version? Our earlier paper (Selden & Selden, 1995) indicates that the answer to this question is often no. Because the inability to unpack an informally written theorem statement into a formal version can often prevent a student from constructing a proof, we think that the informal way that a theorem is stated can be a *linguistic obstacle*. Such an obstacle need not be a mistake or misconception (i.e., believing something that is false). Indeed, the obstacles mentioned in the earlier paper (Selden & Selden, 1995) are related to difficulties with unpacking the logic of informally worded mathematical statements.

The Case of Dori and the Hidden Double Negative

What happens when a student is confronted with a hidden double negative in a theorem statement and wants to construct a proof? Using our field notes and photographs, we report on an beginning mathematics masters student, Dori, who in a tutoring session at the end of an inquiry-based transition-to-proof course, was confronted with the task of proving: *A group has no proper left ideals*. (This was in a semigroup setting, in which a nonempty set L is a left ideal of a semigroup S if $L \subseteq S$ and $SL \subseteq L$.) Dori had already experienced proving theorems on sets, functions, real analysis, and abstract algebra (semigroups). She had available to her the course notes, with all previous definitions and theorems. In the same tutoring session, she had just taken 40 minutes to prove, with some difficulty and backtracking, that group inverses are unique. Specifically, she had just proved: *Let G be a group with identity* 1. *If g,* g,' $g'' \in G$ *with $gg' = g'g = 1$ and $gg'' = g''g = 1$, then $g' = g''$.*

Dori, who was working at three seminar room blackboards, next began to prove the theorem about left (semigroup) ideals by writing the theorem statement on the middle board. She wrote: *A group has no proper left ideals*. Dori then looked up various definitions, such as that of left ideal and proper, in the course notes. We then talked with her about what "not proper" means, after which she wrote $GI \neq I$ and $GI \subset I$ on the right board and suggested doing a proof by contradiction. We were surprised at this suggestion, and now speculate this might have been because of the word "no" in the

theorem statement. At the time, however, realizing that this would not be a productive approach, we suggested that Dori write a proof framework as she had been accustomed to doing in the past. She continued writing, below the theorem statement on the middle board:

Suppose G is a group and I is a left ideal of G.

...
Then G=I.
Therefore, I is NOT a proper left ideal of G.

We then suggested that Dori write in her scratch work the properties of a group and of a left ideal of a semigroup. She wrote these additional observations correctly on the right board. These included noting that G has an identity and inverses, that I being a left ideal means that $GI=\{gi \mid g \in G, i \in I\}$, $GI \subseteq I$, and $I \neq \emptyset$. Dori also noted the existence of the identity element, $1 \in G$ and that there is an $i \in I$ and so $i \in G$. In addition, Dori drew an appropriate diagram of the situation.

The emphasis, in Dori's scratch work, on what it means for I to be a proper ideal may not have been helpful, as, according to her proof framework, she was trying to show that I was *not* proper, namely, the negation. It is often difficult for university students to form proper mathematical negations; instead, they often formulate the opposite, as they would in everyday life (Antonini, 2001). Somehow, Dori did *not* note, at this point, that in order to show that $G=I$ (the penultimate line of her proof framework), all she needed to show was $G \subseteq I$.

Difficulties Inherent in Converting the Theorem Statement to its Formal Version

As Dori was working diligently on her scratch work, it appeared to one of us that the informal wording of the theorem statement might be causing Dori difficulty. So, while Dori continued her scratch work, this one of us decided to try to translate the theorem into "if-then" format, judging that it might be easier to comprehend. It became clear that there were two negations involved in the phrase "no proper". The first was contained in the word "no". The second was hidden within the word "proper", which means that the ideal, I, is a proper subset of G, namely, that I$\neq$G. Thus, there is a double negation in the statement of the theorem. Having noted this, we went on to use this observation to write the theorem statement in a positive "if-then" way as, *If I is a left ideal of G, then I=G,* on the left blackboard. We went over this version of the theorem statement with Dori. The positive "if-then" formulation of the theorem has the following apparent advantages: (1) The notation has been introduced. (2) It is in the formal "if-then" form, from which a proof framework can be written in a straightforward way. (3) It does not have a hidden double negation, but rather is entirely positive and straightforward.

Dori had had no trouble introducing the notation. Perhaps this was because of the theorem on inverses that she had just proved earlier; it already contained the notation G for a group and 1 for the identity element. With encouragement from us, towards the beginning of her proof attempt, Dori had initially written a proof framework, introducing the letters G for the group and I for a left ideal of G, and scrolling to the bottom, had written $G=I$ in the penultimate line and had concluded in the final line that I is not a proper left ideal of G, as well as having produced some scratch work. After discussing with her the positively worded version of the statement, namely, *If I is a left ideal of G, then I=G*, we suggested that she "Suppose $1 \in I$" to see what happens. Dori wrote "Let $1 \in I$" and also, "Let $g \in G$, $i \in I$, so $gi \in I$. Let $i=1$, so $g \cdot 1=g \in I$." This essentially completes the argument that $G \subseteq I$, and hence, proves the theorem. From start to finish, this entire proving episode took 45 minutes. Dori, because she was proving and thinking aloud in front of us, gave us unique insight into her proving process—something not possible with written work alone or even classroom proof presentations.

The Hidden Double Negative

Did the presence of a hidden double negation in the informal version of the theorem statement cause Dori difficulty? We cannot say for sure. However, it seems quite clear that the informal version

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

of the statement, like many such informal versions, while definitely memorable, is difficult for students to unpack into its formal (positive) version. It is well-known to cognitive psychologists that negations are hard to decode and understand. Pinker (2014) reasoned as follows:

> The cognitive difference between believing that a proposition is true (which no work beyond understanding it) and believing that it is false (which requires adding and remembering a mental tag), has enormous implications for a writer [and a reader]. The most obvious is that a negative statement like The king is not dead is harder on the reader than an affirmative one like The king is alive. Every negation requires mental homework, and when a sentence contains many of them the reader can be overwhelmed. Even worse, a sentence can have more negations than you think it does. Not all negation words begin with n; many have the concept of negation tucked inside them, such as a few, little, least, seldom, though, rarely, instead, doubt, deny, refute, avoid, and ignore. The use of multiple negations in a sentence…is arduous at best and bewildering at worst... (pp. 172-173)

The word "proper" in the above informally worded theorem statement has a double negation "tucked" inside it, and according to Pinker, would be arduous and bewildering.

In future research, it would be interesting to investigate the sorts of linguistic difficulties students have when unpacking informally worded theorem statements, other than (a) introducing suitable notation; (b) structuring a proof when a theorem is not in "if-then" format; and (c) dealing with hidden double negatives.

AN EXPLORATION OF FIRST GRADE STUDENTS' ENGAGEMENT IN MATHEMATICAL PROCESSES DURING WHOLE GROUP DISCUSSIONS

Seanyelle L. Yagi
University of Hawai'i
slyagi@hawaii.edu

This paper describes the manifestation of mathematical processes within two whole group interactions in a first grade classroom. A case study research design was employed, in which an in-depth look at the whole group mathematical discourse within the classroom occurred. Preliminary results indicate students' engagement in emergent forms of the mathematical processes of making sense of problems, creating a mathematical model, and argumentation, which might serve as a basis for a framework describing young children's mathematical thinking.

Keywords: Classroom Discourse, Elementary School Education

Introduction

The role of communication in young students' learning of mathematics has been the focus of study in current and past research. Observations of young children have shown that their conceptions of the world are variable, and bound to the context with which the child associates that knowledge (Sophian, 1999). Based on this notion of variability in children's cognitive development, an implication from this research calls for opportunities in which students communicate their solution methods, through which their thinking transitions from being intuitive in nature to a more explicit state (Sophian, 1999).

Emphasis on communication and other mathematical processes in the learning of mathematics is also described in the Common Core State Standards for Mathematical Practice (SMP) (NGA & CCSSO, 2010) as behaviors, dispositions and thought processes integral to doing mathematics. These standards describe processes and habits of mind grounded in mathematics as a discipline, and do not prescribe a particular teaching method for students' development of them. However, the nature of the standards implicitly calls for an instructional approach in which students communicate their mathematical thinking and provide justification based on reasoning as a means for learning new mathematical ideas and concepts.

Although the processes exist in standards documents, there is much work to be done if the SMP are to be a part of children's formal mathematical experiences. Instructional approaches, which regularly engage students in the SMP, are challenging to implement, particularly with 6-year old children for whom actively participating in mathematics-focused discussions is a new experience. Furthermore, mathematics teachers continue to make sense of the SMP (Olson, T., Olson, M., & Capen, 2013), and more research on their enactment in the classroom is needed (Heck, Weiss, & Pasley, 2011).

The aim of this qualitative study is to describe how the mathematical processes of communicating, reasoning, and forming an argument manifest in students' whole group discourse in the classroom, through which their thinking is made explicit. Possible implications from this research include the formulation of a framework that describes the development of mathematical processes in the thinking of early elementary students.

Methods

A case study design was employed, in which classroom observations of the mathematical discourse of 20 first grade students and their teacher occurred. Observations were video- recorded one–two times a week for a period of four–six weeks, in November, February, and May. Researcher field notes were taken during observations, with semi-structured teacher interviews audio-recorded

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

once a week. Video and audio recordings were transcribed and segments of interactions that exemplified any one of the SMP's characteristics were coded and analyzed.

Selection of Subjects

The first grade mathematics classroom for this case study was purposefully selected to be one in which developing mathematical discourse was consistent with the teacher's instructional goals. The teacher had recently completed a school-based professional development project, in which developing mathematical discourse through a problem-based approach had been a focus. Furthermore, she regularly engaged her students in solving open-ended problems and tasks. The tasks primarily came from the newly state-adopted mathematics program, *Stepping Stones* (Burnett, Irons, DePaul, Stowasser, & Turton, 2013), published by Origo Education.

Findings and Implications

The findings for the study reveal the degree to which students were provided with opportunities to engage in the SMP, and whether or not those opportunities were facilitated and capitalized upon by the teacher and students. Furthermore, the findings indicate emergent versions of the SMP, as they relate to students' development in their ability to communicate mathematically and engage in whole group discourse. Students were introduced to the cultural practice of presenting and explaining their strategies and solutions using mathematical language and visuals to the whole class at the beginning of the year. The interactions presented here occurred in February, after students had been introduced to the practice of focusing on their mathematical thinking during whole group discussions.

Making Sense of and Modeling Mathematical Situations

Students were regularly provided with opportunities to collaboratively work through open-ended problems without being shown a pre-determined solution path, and they regularly engaged in making sense of problems for themselves. They were also encouraged to formulate mathematical models for problem situations. The following example was one in which these mathematical processes became salient. The class had worked on a problem in which they needed to determine the number of eggs eaten on Saturday and Sunday knowing that the total was 12. The only constraint was that more eggs had been eaten on Saturday than on Sunday. The discussion was coming to a close, when the teacher quickly put Lane's paper on display:

> *Teacher:* Ok, so look, I wanted to share, this was actually Lane and Greg. Look at their equation. Why did they have 12 and with a minus and question mark, minus a question mark?
> *Lane:* Because we don't see the numbers, we can't see the numbers that we need to make twelve.
> *Teacher:* Ah, so Lane said, it doesn't say about the other numbers. But Lane knew that you had to make....
> *Lane:* Twelve.
> *Teacher:* Twelve. They had to equal up to twelve. So that's how she was thinking about this equation, that something and something has to make.....

This interaction highlights how Lane attempted to make sense of the problem situation, and wrote an equation to model how she thought about the problem. Although Lane was not able to come to a complete solution, through the discourse and presentation, her mathematical thinking is made explicit.

Forming an Argument

As students engage in discourse focused on their solution methods, the definitions and assumptions underlying their assertions, questions, and refutations become the content of the lesson (Lampert, 1990). This view supports students' engagement in mathematical conflict, in which there is a back-and-forth discussion between at least two parties, whereby substantiation of mathematical thinking occurs. In the following excerpt, there is evidence of an emerging argument presented by Ned, who is the only student who sees that blocks might be added to both sides of a balance scale in making the position of the balance true (see Figure 1). The directions for the task were to draw more blocks to make the picture true, then to write the corresponding numbers below the balance.
Figure 1. Picture of Balance Scale Problem.

In the following interaction, Peter has just presented his solution to the class, in which he drew ten more blocks on the right pan of the balance in Figure 1, making the position of the balance true. After further questioning by the teacher, Ned argues that although Peter has added ten to the right side, one or two more blocks could still be added to left side and the picture would continue to hold true:

> *Teacher*: Ok, you said yes. You think he could have drawn it over here? (points to left pan)
> *Ned:* Because um, he could make, um, this side that I'm pointing to right now, (points to right pan) go down, he could pretend it's going down, but he could add one more to that side (points to left pan) or that side (points to right pan).
> *Teacher:* Ok, so this is what I think you're saying. You're saying he could have drawn onto this side (points to left pan).
> *Peter:* Only if it was going down (refers to left pan).
> *Teacher:* But–if it was going down (to Peter)? Or do you mean right now (to Ned)? So how many could he draw on this side? (points to left pan)
> *Ned:* He could–like one or two?
> *Teacher:* Ok, (draws in one on left side) he could put one more over there.
> *Jackie:* But the directions say you could only put it on one side.
> *Ned:* It doesn't say you have to go on this side. It doesn't say you have to.

With the teacher's facilitation in making Ned's thinking explicit, the students were able to engage in an emergent debate about the blocks on the balance. Ned was the only student in the class who saw that blocks could be added to both sides of the balance and presented his argument to the rest of the group. During the course of the year, this was the only observed interaction in which the students engaged in conversation involving differing views. For six year-olds just learning to participate in academic discussions, the act of disagreeing in a respectful way that focuses on a person's mathematical thinking, and not on the person's self can be challenging. In this first grade class, although students were beginning to question each other's mathematical thinking, the interactions did not often sustain beyond the asking of an initial question or making a statement. However, it is

evident that as students gain facility with explaining their thinking and asking each other questions, their ability to form an argument will develop.

The findings from this research show that early elementary students are capable of engaging in mathematical processes if they are provided the opportunities to do so through mathematical discourse. For first grade students, the teacher's skill in facilitating discussions in which students have opportunities to explain their thinking for themselves and consider each other's ideas, while at the same time are assisted with making their thinking explicit, is paramount. As more teachers become comfortable with teaching with these mathematical processes in mind, continued study into other classrooms in which mathematical discourse as an approach to teaching and learning mathematics might allow for the development of a framework delineating levels of development for early elementary students.

In the United States, Common Core State Standards for School Mathematics call for students to develop viable argumentation practices connected to content learning. The article reports on a research study that explores the efficacy of an intervention for improving Grade 8 students' viable argumentation practices as they learn mathematics content. Treatment students' scores on an argument and reasoning assessment and state standardized assessments are compared to comparison students' scores on these assessments. Findings demonstrate that treatment students outperformed comparison students on both measures.

Keywords: Learning Trajectories (or Progressions), Middle School Education, Reasoning and Proof

Introduction

In the United States, Common Core State Standards for School Mathematics, CCSSM, (National Governors Association Center for Best Practices & Council of Chief State School Officers [NGACBP & CCSSO], 2010) calls for developing students' mathematical practice with *constructing viable arguments and critiquing the arguments of others,* which should be connected to students' content learning. However, interventions that develop students' viable argumentation practices alongside content learning are scarce, if not absent, from the mathematics education literature. At present, the plausibility of learning viable argumentation (proving) practices alongside content has not been empirically supported. The present study explores the efficacy of an intervention for improving Grade 8 students' viable argumentation practices as they learn mathematics content.

Theoretical Framework

Viable Argumentation, Proof, and Proving

We adopt the term "viable argument" to be consistent with the terminology in the CCSSM. The term is not explicitly defined in that document, but it can be assumed the term is used instead of "proof" to note that there are proof-like, but informal, arguments that can be made in K-12 classrooms. Some of the arguments, such as *generic example arguments*, that we will label as "viable" are considered proofs by some authors (e.g., Balacheff 1988; Russell, Schifter, & Bastable 2011; Stylianides 2007). We reserve the term *proof* to describe what others might call *formal proof* or *mathematical proof*: a sequence of statements that demonstrate the truth of a mathematical statement using prior results and logic.

To us, an argument is *viable* if it has a clear, explicit, and appropriately-worded claim and support for that claim that involves acceptable data and warrants. We use broad criteria for acceptable data, including examples, diagrams, prior results and definitions, narrative descriptions, etc. We place more burdens on the warrant by noting the types of warrants that are dubbed acceptable and the types that are not. Using logical necessity, referencing prior results, and describing through narrative the meaning of a definition can be acceptable warrants.

Methods

The LAMP Intervention

The LAMP intervention is the product of the National Science Foundation (NSF) funded Learning Algebra and Methods for Proving (LAMP) project (DRL#1317034). The LAMP intervention is the practice of teaching and learning with and through viable argumentation and a learning trajectory for viable argumentation knowledge and practices. LAMP teachers are encouraged to included viable argumentation in every lesson they teach and on assessments. This includes asking students to develop explicit claims using the language of mathematics (e.g., "for all" and "there exists") and to support claims with viable referents and warrants.

The LAMP learning progression is a sequence of 24 project-developed lessons that target learning a collection of argumentation practices and conceptions as students learned content. Lessons progress in sophistication to build a coherent understanding of viable argumentation. The lessons' argumentation goals were developed from existing proof, proving, and argumentation literature; which is available from the first author upon request. The following list illustrates our assumptions about what Grade 8 students need to know and understand about viably argumentation in the context of Grade 8 content: 1) *Students need a framework to guide their argument constructions and critiques.* 2) *Claim construction is integrally linked to viable argumentation and explicit training on the language of mathematics is needed.* 3) *Students should construct and explore generalizations but should be skeptical of empirical evidence.* 4) *Students should construct referents to support their generalizations and that these referents should express a conceptual insight that structurally links the conditions of the generalization to its conclusion.* 5) *Students need explicit instruction on valid reasoning schemes to align their "every day" reasoning with valid reasoning approaches.* 6) *Students need a variety of modes of argumentation and meta-theories justifying them to construct and critique arguments viably.*

Research Questions

1. To what extent does the LAMP intervention improve students' abilities to write viable arguments and critique the arguments of others?
2. To what extent does the LAMP intervention impact student achievement?

Sample

Data were collected from 210 students (treatment N=117, comparison N=93) taught by seven teachers (4 treatment, 3 comparison) in six public or charter schools during the 2014-15 academic year. Three schools included only students in the treatment condition, two schools included only students in the comparison condition, and one school included students in both treatment and comparison classrooms (the sub-group). Treatment teachers were recruited to the project and were asked to identify a comparison teacher/classroom whose students were similar to their own. In the treatment condition, teachers employed the LAMP intervention and the LAMP teaching practice of including viable argumentation as a regular feature of instruction in Grade 8 algebra and/or traditional mathematics classes. Comparison teachers continued with their "business as usual" lessons/instruction.

All schools enrolled fewer than 600 students. Student populations were majority white, fairly evenly distributed between males and females, had small percentages of English Language Learners, had under 15% of students qualified for Special Education/IEPS, and primarily rural (except the one large school that included treatment and comparison conditions). These similarities enhance the comparability of the samples because differences in outcome scores are less likely to be due to variations in contexts.

Data

Smarter Balance Assessment Consortium (2014–2015). Adopted by 18 states including Idaho, the Smarter Balanced (SBAC, 2012) program develops accountability assessments consisting of two components: performance tasks and an end-of-year computer-adaptive assessment. The end-of-year math assessment was used in this study to measure student achievement. Scale scores were used to determine the extent to which students' overall achievement changed. Categorical mathematics levels based on scale scores were used to measure mathematics achievement categories (below basic, basic, proficient, or advanced).

The Argumentation Assessment contains two types of open-ended items: Four items assess students' ability to construct viable arguments, and one item assesses students' abilities to critique the argument of others. Items were developed by reviewing prior research on proof and proving (e.g., Healy & Hoyles, 2000), reviewing state assessments (e.g., SBAC release items), and with feedback from the external advisory board in Year 1 of the project. The scoring rubric assesses students' abilities to construct viable arguments. Each item is rated on a scale from 0 (*no elements of a viable argument)* to 3 (*elements of a viable argument)*. The rubric was developed through iterative phases involving review and rubric development by the research and evaluation team, a calibration meeting to enhance scoring accuracy among three expert raters, and a pilot sample with 25 randomly selected student assessments. Scores for all problems were summed to create a final score from 0 to 15. Pre and post Argumentation Assessment results from the treatment and the comparison students were analyzed to examine the change in students' ability to construct viable arguments and critique the arguments of others. The sample size varied for each outcome measure as follows: Argumentation Assessment (t- N=85; c- N=17; Smarter Balance Assessment Consortium (SBAC) Scale Score (t-N=117; c-N=93); SBAC Math Level (t-N=106; c-N=93); and SBAC Math Claim 3: Communicating Reasoning (t-N=115; c-N=74).

Data Analysis. Independent samples t-tests were used to assess group differences between treatment and comparison on the SBAC achievement scale scores. Chi-square tests were used to identify differences between treatment and comparison groups on mathematics levels. Paired sample t-tests for the treatment and the comparison groups were used to determine if there were statistically significant changes in overall argumentation and each of the five problems on the assessments prior to and following participation in the LAMP intervention. Effect sizes utilizing Cohen's *d* were reported for statistically significant findings for the achievement outcomes.

Results

Students in the treatment condition outscored students in the comparison condition on the SBAC (2012) state test scale scores (t = -4.98, $p < .001$), with a medium sized effect (Cohen, 1992), Cohen's d = .689. Similarly, within the subgroup, students receiving LAMP intervention scored more highly than the comparison students (t = -3.34, $p < .001$), Cohen's d = .639.

A greater proportion of treatment students were in higher mathematics levels relative to the comparison group ($\chi^2 (3) = 31.40$, $p < .001$). There were differences in the distribution of student sub-scores for the mathematics claim 3: communicating reasoning ($\chi^2 (2) = 12.26$, $p < .01$) suggesting treatment students may score significantly higher on communicating reasoning scores. In the subgroup, a greater proportion of treatment students scored proficient or advanced ($\chi^2(3) = 10.34$, $p < .05$). There were also trend differences in the distribution of sub-scores for the mathematics claim 3 ($\chi^2(2) = 5.48$, $p = .065$), indicating treatment students score higher on communicating reasoning beyond effects of school context.

Paired sample *t*-tests demonstrate that treatment students made significant pre-post gains ($t = 2.85$, $p < .01$) on the Argumentation Assessment and the comparison group did not ($t = 1.62$, $p = 1.24$). Item level analysis showed that treatment students made significant pre-post gains on Problem 1 ($t = 3.60$, $p < .01$), Problem 2 ($t = 3.64$, $p < .01$), and Problem 4 ($t = 3.55$, $p < .01$). The

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

comparison students showed significant gains only on Problem 4 ($t = 3.10$, $p < .01$). Within the subgroup, treatment students demonstrated significant gains ($t = 5.76$, $p < .01$), while the comparison students' total scores decreased significantly ($t = -5.19$, $p < .01$). These subgroup results should be interpreted with caution due to the small sample size (t- N=34, c-N=9).

Discussion

This study did not control for baseline differences between the treatment and comparison students on mathematics achievement. In 2013, Idaho adopted SBAC but did not report the 2013-2014 SBAC scores, so 2012 SBAC baseline data was unavailable. This study cannot rule out selection bias. The research team had no control over which students received LAMP intervention. Another limitation is the low completion rate of the post assessment by comparison students (N=17). At the end of the school year, comparison teachers reported feeling pressed for time. Despite these limitations, the findings support an assertion that the LAMP intervention improves students' ability to construct critique arguments viably. The findings also support that the LAMP intervention did not hinder student content learning, and perhaps enhanced it.

JUMPING THE ACHIEVEMENT STEREOTYPE THROUGH MODEL-ELICITING ACTIVITY: A COMPARISON AMONG STUDENTS AT DIFFERENT PERFORMANCE LEVELS

Jair J. Aguilar
The University of Texas at Austin
jair.aguilar@utexas.edu

Keywords: Modeling, Problem Solving

Introduction, Theoretical Framework, and Methodology

This study investigated students' thinking, understanding, and mathematical development when solving mathematical classroom open-ended, real-life context tasks in which students were required to model a solution. Specifically, Thought-Revealing activities known as Model-Eliciting Activities (MEAs) (Lesh et. al 2001) were used to compare and contrast the reasoning and solutions of 11th grade students at different levels of performance in Monterrey, Mexico. Two dimensions of contrast and comparison were considered: The quality of the students' solutions and the sophistication of the mathematical construct. MEAs are mathematical open-ended, client-driven, learning tasks that usually encourage students to mathematize by "quantifying, coordinatizing, categorizing, algebratizing, and systematizing" (Lesh and Doerr, 2003, p. 2) real-life situations to produce a model. According to Lesh and Doerr (2003), models are conceptual systems composed of elements (e.g. variables, tables, symbols, procedures, and procedures), which interact among themself, and where relations, operations, and rules dictate how these elements interact. Six principles (Lesh et al. 2001) guide the design of MEAs: 1. reality, 2. model construction, 3. self-evaluation, 4. model externalization, 5. simple prototype, and 6. model Generalization. In this research study, two MEAs were implemented during the summer and fall 2015. Sixty-five students of different level of achievement (e.g., low, average, and high performance) as measure by tests and classroom activities– participated in the study. A design-based research methodology was used to implement the two case studies of MEAs adapted to the context and reality of the target populations. For the analysis of the quality of the students' solutions, I considered all the artifacts and written material students invented and created during the solving process. For the sophistication of the solution, I considered the elements – i.e., variables, graphs, symbols, notations, tables, list, and procedures – used during the mathematical-construction process, or model development. Some of the question addressed in this research included: To what extent do the solutions to MEAs provided by students at different levels of performance differ? What are the mathematical elements that students used during the problem-solving process, and how do these differ among students labeled as low, average, and high performance? Preliminary findings include the ability of the low-performance students to propose and develop more creative solutions. Furthermore, solutions provided by the average students were not as different as the one provided by the low-performance. Finally, although the high-performance students used more sophisticated elements in their procedures, their solutions were incomplete and not well explained.

CROSSING BORDERS AND BUILDING BRIDGES WITH PROBLEMS

Hyman Bass
University of Michigan
hybass@umich.edu

"Connected Mathematical Thinking"

This is what I call thinking that seeks ways to bridge or unify a variety of different things. Its value is that the knowledge one then holds, instead of being fragmented and disconnected, becomes networked and more coherent.

But connected mathematical thinking does not happen automatically; it requires a special kind of skill and disposition, and these can be developed through experience. So if one wants students to engage in connected mathematical thinking, they should have opportunities to learn it. How can one design instruction that presents students with situations that are rich in connection making possibilities, and then gives dedicated attention to such connection making?

This study presents two approaches to this, both conceived around the relationships between mathematics problems and mathematics itself. One approach uses what I call, "cross-domain problems." The other uses what I call, "common structure problem sets." Each of these problem designs calls for significant mathematics connection making, but of very different kinds in the two cases.

Many Mathematics in the Same Problem

A *cross-domain problem* is defined to be one whose solution draws resources from two or more domains of mathematics. Such problems can present obstacles to students who tend to "type cast" a problem as belonging to a single domain, perhaps as a result of the compartmentalization of the curriculum. The student will mobilize a tool kit from that domain, but then get stuck when the solution process requires crossing a domain boundary. Here are some examples (see Table 1).

Table1: Sample Cross-Domain Problems

Cross-Domain Problem	Comments
Let N be a positive integer. Call a factor d of N isolated if d and N/d are relatively prime. Show that the number of isolated factors of N is 2^r, where r is the number of prime divisors of N.	Starts in multiplicative arithmetic, and crosses into combinatorics.
Show that any product of d consecutive integers is always divisible by d!	Multiplicative arithmetic application of combinatorics (formula for n-Choose-d).
What is the base-1,000 representation of $N = 48,574,623,791,105$?	Often unnoticed connection of our language and notation for large numbers with the concepts of place value.
Find all (real valued) functions f(x) of a real variable x that satisfy the condition: (*) $\|f(x) - f(y)\| = \|x - y\|$ for all real numbers x and y.	A geometry problem (isometries of the line) that appears to be an algebra or pre-calculus problem.

The Same Mathematics in Many Problems

A *common structure problem set* is defined to be a (diverse) set of mathematics problems that can demonstrably be shown to have a substantial mathematical structure in common. Finding, and articulating, that common structure is a kind of synthesizing mathematical action that resembles theory building practices in disciplinary mathematics. An illustrative set of thirteen problems will be presented, together with a design for its instructional use will be presented.

RELACIONES DE EQUIVALENCIA PARA LA DEMOSTRACIÓN EN ÁLGEBRA

EQUIVALENCE RELATIONS FOR PROOF IN ALGEBRA

Héber U. Corona Pérez
CINVESTAV-IPN
uzziel.corona@cinvestav.mx

Claudia M. Acuña Soto
CINVESTAV-IPN
cmacunas@cinvestav.mx

Palabras clave: Álgebra y Pensamiento Algebraico, Razonamientos y Demostraciones

Las actividades de demostración en álgebra en el nivel superior requieren, entre otras cosas, de un manejo adecuado de la operatividad, así como de contar con un buen número de expresiones equivalentes, por ello es importante desarrollar el significado del signo "=", que en la escuela básica se asocia sólo a una actividad operativa, mientras que en álgebra se ve asociado también a la equivalencia, proceso que debe ser desarrollado tanto en sus aspectos relacionales como en los operacionales, Kieran (1981).

Algunos de los recursos algebraicos que son usados con frecuencia en la demostración algebraica pasan desapercibidos, tal es el caso de procedimientos como: 1. Agrupar y desagrupar la expresión. 2. Realizar una operación descrita. 3. Sumar cero, que es la base de indicaciones como completar productos notables. 4. Multiplicar por uno de manera adecuada como en el caso de "multiplicar por el conjugado". 5. Factorizar y expandir.

A pesar de ser recursos válidos, aunque se debe considerar los dominios de definición de las expresiones, para el estudiante éstos son sólo trucos usados arbitrariamente, por lo que se debe hacer un esfuerzo para incorporarlos como algebraicamente aceptables y en particular sustentados en la idea de equivalencia. Es aquí en donde consideramos que los problemas planteados deben incorporar aspectos tanto operacionales como relacionales con el objeto de formar una base para el tratamiento de la demostración en álgebra.

Por ejemplo:

1. Para mostrar que $x \cdot 0 = 0$, primero se suma un cero $x \cdot 0 = x \cdot (0 + 0)$, después se distribuye $x \cdot 0 = x \cdot (0 + 0) = x \cdot 0 + x \cdot 0$ y sumando $-(x \cdot 0)$ a los extremos se concluye que $x \cdot 0 = 0$.
2. Para mostrar que si $a \cdot x = a$, donde $a \neq 0$, entonces $x = 1$; primero tenemos que $ax = a$ y como $a \neq 0$ existe $a^{-1} \neq 0$, multiplicando entonces a^{-1} por la izquierda obtenemos que $a^{-1}ax = a^{-1}a$, haciendo la operación nos resulta que $1x = 1$, con lo que se concluye que $x = 1$.

Los estudiantes cambian su actitud respecto a la equivalencia, luego de que se hace mención de que existen recursos disponibles para modificar las expresiones algebraicas que persiguen un objetivo específico como el de la demostración.

Keywords: Algebra and Algebraic Thinking, Reasoning and Proof

The activities of proof in algebra at the university level require, among other things, an adequate handling of operability. These activities also include equivalent expressions. Therefore it is important develop the meaning of the "=" sign, which is associated to a operability activity in elementary school, while in algebra it is also associated with equivalence; in this level both relational and operational aspects need to be developed (Kieran, 1981).

Some of the algebraic resources that are often used in the algebraic proof pass unnoticed, such is the case with the following processes: 1. Grouping and ungrouping the expression, 2. Executing a described operation. 3. Adding zero, which it is the basis of the instructions to get notable products, 4. Multiplying by an expression equivalent to one, as in the "multiply by the conjugate" case, 5. Factoring and expanding expressions.

Despite being valid resources, which should be considered domains of definition of the expressions, for the student these are just tricks that are arbitrarily used. Efforts should be made to incorporate them as algebraically acceptable and in particular based in the idea of equivalence. It is here where we consider that the teaching must incorporate both relational and operational aspects in order to form a basis for the treatment of proof in algebra. For example:

1. To show that $x \cdot 0 = 0$, first we have to add a zero $x \cdot 0 = x \cdot (0 + 0)$, later we distribute $x \cdot 0 = x \cdot (0 + 0) = x \cdot 0 + x \cdot 0$ and adding $-(x \cdot 0)$ to the extremes we conclude that $x \cdot 0 = 0$.
2. To show that if $a \cdot x = a$, where $a \neq 0$, then $x = 1$; first we have $ax = a$ and how $a \neq 0$ exists $a^{-1} \neq 0$, multiplying a^{-1} to the left we obtain that $a^{-1}ax = a^{-1}a$, by doing the operation we find that $1x = 1$, thus we conclude that $x = 1$.

The students change their attitude towards equivalence, after mentioning that there are resources available to modify the algebraic expressions that follow a specific objective like proof.

MANIPULATIVES IN MATHEMATICS LEARNING: DOES IT MATTER IF CHILDREN VIEW THEM AS TOYS OR TOOLS?

Andrea Marquardt Donovan
University of Wisconsin- Madison
Amdonovan2@wisc.edu

Martha W. Alibali
University of Wisconsin- Madison
mwalibali@wisc.edu

Keywords: Cognition, Elementary School Education, Problem Solving

Manipulatives—concrete objects that represent abstract concepts—are commonly used in mathematics instruction, but they are not always effective at promoting learning (Moyer, 2001; Sowell, 1989). One possible source of this difficulty is the need to consider an object simultaneously both as an object and as a symbol (Uttal, Scudder & DeLoache, 1997). From this perspective, one possible explanation for why students differ in their ability to learn from manipulatives is that they differ in how they view the manipulatives. Some children may attend to their function as representations of mathematical ideas, and some may attend to their function as physical objects.

Allowing children to play with mathematical manipulatives, before learning with the manipulatives, may decrease their ability to view the manipulatives as representing mathematical concepts. When allowed to play with manipulatives, children may have difficulty viewing them as symbols, rather than as toys. Further, without highlighting an object's status as a tool used for learning math, children may not make the connection from the manipulative to the concept to be learned.

We examined whether children's construal of a mathematical manipulative—either as a toy or as a tool for doing math—influences their learning from a lesson with that manipulative. Children (7-9 years old) were randomly assigned to one of four conditions for learning about mathematical equivalence. We varied the way in which children were introduced to buckets and beanbags using a 2 (toy representation) x 2 (mathematical representation) experimental design. The session included a problem-solving pretest, a lesson with the manipulative, a problem-solving posttest and transfer test, and a brief assessment of conceptual knowledge. Our preliminary findings suggest that children who were introduced to the manipulatives as tools for doing math displayed greater success at posttest and transfer test, and greater conceptual understanding of equivalence after the lesson.

Children who are encouraged to view mathematical manipulatives as tools for doing math may have greater success connecting the objects to mathematical concepts. This suggests that children may benefit from being encouraged to view manipulatives as mathematical representations, and not as objects, leading them to utilize the manipulatives more effectively, and more effectively link them to mathematical concepts. Teachers might consider providing explicit instructions that enhance the status of the manipulatives as symbols for mathematical ideas.

SUPPORTING DISCURSIVE SHIFTS TOWARD MATHEMATICAL DEFINING

Amelia M. Farid
University of California, Berkeley
millyfarid@berkeley.edu

Keywords: Instructional Activities and Practices, Reasoning and Proof

The practice of defining differs across academic and non-academic discursive genres. As a result, students often have trouble formulating, interpreting, and using definitions in mathematical proof and problem solving. This design-based research project evaluated the conjecture that under appropriate conditions students could be steered to leverage naturalistic discursive practices in generating mathematical definitions. Specifically, I examined for learning effects of a dyadic game-based activity requiring the resolution of ambiguity in reference.

Theoretical Framework

Mathematical definitions, I submit, are not inherent truisms but rather meaning-relations built to fulfill particular purposes, often via an iterative process of formulating and evaluating a definition with respect to its utility, conformity to intuition, or other criteria. A definition, I further submit, could be viewed as an *epistemic form* (a target structure guiding inquiry), the end product of an *epistemic game* (Collins & Ferguson, 1993). The Specifications Game (SG) was designed to prompt students to reinvent one such epistemic game. The outcomes of SG were interpreted through the lens of commognition as a theoretical framework (Sfard, 2007).

Methods and Data Sources

Four dyads (ages 11, 15, & 22) participated in a pilot implementation of SG. One student attempted to specify a missing shape (e.g., triangle), while the other provide counter-examples (Fig. 1). I then prompted them to examine and modify their list of requisite properties into a conjectured definition and compare and evaluate alternative definitions for the object. Specifications given (e.g., "tall," "straight sides") were analyzed for discursive shifts in the course of game play. All data was examined for participants' meta-discursive rules of defining.

Figure 1. A game board (left) and its pool of game pieces (right). Define the missing shape!

Conclusions

As they apprentice into the field of mathematics, students gradually move away from a view of mathematical definitions as arbitrary systems of constraints couched in non-normative language, towards a view of definitions as purposeful epistemic forms satisfying specific properties. By drawing on familiar cultural practices, setting up mathematical language as a potential solution to ambiguity, distributing the process over two participants, and encouraging reflection, SG supports students in enacting an epistemic game of formulating definitions. In this process, students become sensitized to properties of definitions such as specificity and minimality, resulting in a discursive shift away from mundane practices of defining.

Keywords: Cognition, Elementary School Education, Reasoning and Proof

Previous studies discussed that students in student-centered science classrooms showed higher growth in mathematics than their peers in traditional learning environments (e.g., Adey & Shayer). It is reasonable to assume that practices in science classrooms had significant roles in increasing mathematics achievement (Choi, Seo, & Hand, 2015). To understand how the growth in mathematics occur, we investigated students' *intellectual and cognitive resources* (Bailin, 2002) students used when learning. We hypothesized that reasoning used in science practices influences students' learning of mathematics. Specifically, we want to empirically investigate if reasoning developed in learning science affect fourth-grade students' mathematical reasoning.

We adopted categories of intellectual resources from the TIMSS 2011 assessment framework (Mullis, Martin, Ruddock, O'Sullivan, & Preuschoff, 2009) for the reasoning and applying domains in mathematics and science. We employed the Generalized DINA (de la Torre, 2011) to analyze 2,287 fourth-grade students' responses in subcategories of reasoning and applying domains and conducted the path analysis to elaborate the relationships between reasoning domains in mathematics (MR) and science (SR). Then we compared the direct and indirect relationships between SR and MR with and without mathematics applying (MA) as a mediator.

Without MA, the standardized direct effect of SR on MR was .977 ($p < .01$; CFI=.919, TLI=.869). However, this direct relationship was dramatically changed when MA was added. The standardized direct effects of SR on MA and MR is .587 and .065 respectively ($p < .01$ for both coefficients; CFI=.938, TLI=.913). The direct effects of SR on MR was changed from .997 to .065 by considering MA between SR and MR. The indirect effect of SR on MR was .561, which indicated that 95.57% of the total effects of SR on MR are indirect through MA.

A possible reason for this indirect relationship is that SR directly influences MA through students' solving science-context problems while indirectly affects MR focusing on unique aspects of domain-specific reasoning skills. The findings indicate that students could experience the common practices in the two subject areas disjointedly or teachers do not have good understanding of those practices either. The findings suggest that educators should consider the shared cognitive skills in the two disciplines into classroom-level and curriculum-level practices when developing and employing curricula.

MIDDLE SCHOOL STUDENTS' CONCEPTIONS ON PROPORTIONAL REASONING

Ji Yeong I   Ricardo Martinez
Iowa State University   Iowa State University
jiyeongi@iastate.edu   ricardom@iastate.edu

Keywords: Rational Numbers, Middle School Education, Problem Solving

Proportions are an important mathematics concept taught during middle school. In fact, proportional reasoning is "a milestone in student's cognitive development" (Lobato & Ellis, 2010, p. 48) and plays a critical role in developing algebraic thinking and function sense (National Council of Teachers of Mathematics, 2013; National Mathematics Advisory Panel, 2008). However, ratios and proportions are traditionally difficult concepts as Lamon (2007) stated: "the most difficult to teach, the most mathematically complex, the most cognitively challenging" (p. 629).

In this study, students (n = 59) in grades 6-8 in the Midwest of the United States solved a set of eight tasks involving ratios and proportions in an open-ended manner. Contextual tasks and non-contextual tasks were mixed in the assessment set. From initial coding, we constructed the following codes to describe what methods or misconceptions made by the students: additive reasoning (A), cross multiplication (CM), equal amount (E), equivalent ratio/fraction (Erf), and confused about "whole" (W). Then, the students' written responses were coded, using the method of content analysis. Using inter-rater reliability, we have 95% agreement on one task among two authors.

We would like to share the result of one of the tasks, which involves the context of proportional division because the students in all grades struggled the most to solve this task. Approximately 10% of them were able to find a correct answer. Other students made multiple types of errors, such as using additive reasoning instead of multiplicative reasoning (36%), incorrectly applying an algorithm of equivalent ratios (19%) or cross multiplication (5%), and confusing with the whole quantity (16%). This reveals that knowing algorithms does not guarantee students can solve a proportional task as Tjoe (2014) argued. This implies that these students have not developed proportional reasoning although they have procedural knowledge of proportions.

WORD PROBLEM SOLVING: PARSED MODELS

Victoria Kofman
Stella Academy
drkofman@gmail.com

Keywords: Modeling, Problem Solving, Elementary School Education, Middle School Education

The Common Core State Standards (CCSSI, 2010) specially emphasizes the importance of word problem solving. However, since several millions of students in the U.S. have low reading comprehension (Heller et al., 2007, Biancarosa et al., 2006), we can expect for many students, challenging word problems are unapproachable. To help students comprehend word problems, a *word problem parsed modeling* technique is developed. This technique is similar to *bottom-up parsing* and concentrates on developing a thorough understanding of a word problem's details.

It is known for a long time, two strategies—writing meaningful chunks of sentences one per line and breaking sentences into smaller, simple sentences—improve reading comprehension of low-level readers (Mason et al., 1978). This study developed *word problem parsed modeling* to combine two methods—chunking text into separated short sentences and writing these sentences, one per line. The method also involves abbreviations and pronoun decoding.

This study is based on active production—students' success with chunking, pronoun decoding, elimination of unnecessary data, and solving the problem—signaling their mathematical comprehension. Observations of students' work and informal interviews lead to designing a unit teaching word problem parsing. Next, this unit was used with multiple groups of students. The participants were 4th–8th graders, 20–30 students per grade annually, attending a Midwestern U.S. suburban learning center from 2008 to 2016.

Students' parsing models demonstrated students' misconceptions connected with decoding pronouns in complex in compound sentences and some simple sentences as well. For example, the sentences "A is greater than B and greater than C" and "A is greater than B, which is greater than C" were frequently decoded the same way. Additionally, students could not parse sentences involving clauses such as *that of*, *as much as*, and *in turn*. After remediation instruction, 8–15 classes in parsing, **all participants** were able to create effective parsed models. Such high performance was a result of an *individual pace* approach used in the learning center, where each student spends as much time as needed on a topic for understanding on the level of application.

A combination of an active production method with parsing helped create a set of short parsing exercises and challenging word problems, which significantly improve students' comprehension of word problems' text.

Besides word problem solving, the approach can be used to improve comprehension of a broad-range of informative texts. A further study could test the parsing technique with a larger variety of students.

THE INTERPLAY BETWEEN STUDENTS' CONCEPTIONS OF PROOF AND PROOF-RELATED CLASSROOM NORMS AND PRACTICES

Zekiye Ozgur
University of Wisconsin-Madison
zozgur@wisc.edu

Keywords: Reasoning and Proof, Instructional Activities and Practices, High School Education

While there is a wealth of research on students' conceptions of proof, less is known about how students' conceptions of proof relate to their experiences in classrooms. Although, through task selection, instructional emphases and practices, teachers are influential on what meanings and understandings of proof and proving students construct, very few studies (e.g., Harel & Rabin, 2010; Martin, McCrone, Bower, & Dindyal, 2005) have investigated the relationship between instructional practices and students' understanding of proof. Therefore, this study aims to investigate the relationship between students' conceptions of proof and instructional practices, by taking into account teachers' conceptions of proof and classroom norms as well.

To better understand the intricate relationships between teachers' conceptions of proof, their instructional practices, and their students' conceptions of proof, a single case study method (Yin, 2003), which allows an in-depth examination, was employed. Thus, a secondary (ages 15-16) mathematics class was observed and videotaped for 18 lessons; classroom artifacts such as lessons plans, homework, and student work were collected. Additionally, semi-structured, task-based interviews were conducted with the teacher and the students. The teacher was interviewed at the beginning and at the end of the study. 18 students (out of 31 students) were interviewed throughout the observation phase, and 7 focus students were interviewed again two months after the observations were complete. The semi-structured interviews included questions asking participants to evaluate hypothetical student proofs, to describe what proof and proving mean to them and how they view the role of proof, as well as to prove a given mathematical statement.

The data analysis process includes two foci. While the first analysis approach focuses on the teacher's and the students' conceptions of proof, the second approach focuses on the classroom norms and instructional practices related to proof. The first analysis examines the participants' discourse when they talk about their views about the nature of proof, the roles and purposes of proof, what constitutes proof, and what they understand about proof. The second analysis identifies the instructional practices and norms related to proving. Then, these analyses are incorporated by examining how the teacher's conceptions of proof are manifested in her instructional practices and, in turn, how those practices contribute to the students' developing conceptions of proof.

The poster will present in what ways the identified classroom norms and practices relate to the students' conceptions of proof. Implications of the identified links between instructional practices and students' proof conceptions will be discussed.

COLLEGE STUDENTS' PERCEPTIONS OF PROOF METHODS AND THEIR LECTURE NOTES

Hyejin Park
University of Georgia
hjpark3@uga.edu

Keywords: Reasoning and Proof, Post-Secondary Education

Research on proof at the tertiary level has largely focused on students' difficulties with understanding, constructing, and evaluating proofs and on teaching strategies. This study examined what perceptions of five proof methods—direct proof, proof by contrapositive, proof by contradiction, proof by cases, and proof by induction—college students developed during a transition-to-proof course, and what relations there exist between students' perceptions about the proof methods and their class notes; such perceptions might relate to their proof construction and proof validation. Social constructivism perspectives, along with the theoretical work of Wood, Cobb, and Yackel (1995), were used to ground the analysis of this study. Such perspectives consider knowledge as socially and culturally constructed (Ernest, 1990), thus helping in the understanding of students' learning in the context of a mathematics classroom. For this smaller study, I used open coding (Strauss & Corbin, 1990) after identifying and separating the parts in which three participants provided their thoughts about the five proof methods over the course of four interviews conducted while enrolled in a transition-to-proof course. I analyzed and summarized my participants' perceptions of the proof methods as well as their class notes, focusing on what they wrote down during the lectures on the five proof methods.

The three participants had similar perceptions about the proof methods even though their preferences for methods were somewhat different. All of the participants viewed proof by contrapositive as a kind of direct proof. Similarly, two of the participants considered proof by cases as a type of direct proof. Most participants liked direct proof, proof by contrapositive, and proof by cases, but proof by contradiction was the least liked method. Because of difficulty with algebraic manipulations in the inductive step, two of the participants disliked proof by induction compared to the other methods. An analysis of their lecture notes found that these notes could provide evidence of why they had similar views about proof methods. The lecture notes also showed that their instruction presented the five proof methods in the following order: direct proof, proof by contrapositive, proof by cases, proof by contradiction, and proof by induction. Presenting them in such an order seemed to impact the level to which the participants were familiar with each proof method; it also coincided with the order of their proof preferences. The preliminary results show that we can foresee what perceptions students might construct about proof methods based on the content of their lecture notes. Further study is needed to examine comments made when presenting proof methods in lectures and the order of presentation when considering reasons for students' preferences for proof methods.

THE ROLE OF LOGIC IN STUDENTS' UNDERSTANDING OF PARAMETERS IN ALGEBRA

Valentina Postelnicu
Texas A&M University-Corpus Christi
Valentina.Postelnicu@tamucc.edu

Florin Postelnicu
Phoenix Union High School District
postelnicu@phoenixunion.org

The purpose of this study is to analyze the role of logic in college students' understanding of parameters in algebra, as they cross the border from elementary to advanced mathematics. The research on students' understanding and difficulties with parameters in school algebra has been scarce (Postelnicu & Postelnicu, 2015). Using a theoretical framework proposed by Postelnicu & Postelnicu (2015), prior research reveals that students not yet exposed to formal logic have difficulties *identifying parameters*, and with *parameters in action*, i.e., working with mathematical objects identified with the help of parameters. We propose to address those difficulties by employing logical quantifiers. Epp (2003) argues about the benefecial role of logic in teaching advanced mathematics. Logical quantifiers may also play a beneficial role in students' understanding of parameters in algebra, and help the students *identify parameters* (discriminate between parameters and other variables), and using *parameters in action* (unpacking the mathematical object and working with its corresponding mathematical process, and reifying a mathematical object again, according to the specified restrictions of the task, if any). For example, we can define a family of lines this way - for every real number k, let L be the line with the equation $4x + ky = 5k$, where x and y are real numbers. This way the parameter k can be discriminated from the other variables x, y, the domain of k is clearly stated, and the mathematical object defined with the help of parameters, the family of lines L, may be easier to reify by students. We can ask the students to graphically represent the family L, or to prove that for every real number k, L is not parallel to x-axis.

A teaching experiment (Steffe & Thompson, 2000) was conducted by the first author with 26 college students enrolled in a transition to proofs course at a university in United States. The teaching of the logic of quantified statements was augmented by one extra class (1.5 hours) with tasks that required the students to: i) *identify the parameters* and justify their choice; and ii) use the *parameters in action* which implied finding the subdomains of the parameters such that certain conditions to be fulfilled, and graphically representing the mathematical object defined with the help of parameters, in our case families of functions and curves. At the end of the teaching experiment, the students could *identify the parameters* in statements with logical quantifiers, but still had difficulties with *parameters in action*. The difficulties increased when the mathematical objects defined with the help of parameters or the contexts were less familiar to students, or the restriction imposed by the task was formulated with a negation.

THE EXISTANCE, PERSISTANCE, AND SIGNIFANCE OF COMMON ALGEBRA ERRORS ON STUDENT SUCCESS IN UNIVERSITY MATHEMATICS

Stacy Reeder
University of Oklahoma
reeder@ou.edu

Sepideh Stewart
University of Oklahoma
sepidehstewart@ou.edu

De Morgan (1910) wrote about the difficulties students face in learning mathematics noting common errors related to arithmetic and rational number computation. Since that time, other researchers have catalogued common errors in computation and algebra. In Booth, Eyer, & Paré-Blagoev's (2014) study focused on Algebra I students, student errors were identified and classified. Although, research on students' difficulties with algebra at school has been well documented, methodical studies on the presence of these difficulties and their impact at university level are scarce. For the purpose of this paper, only a portion of the research findings from a larger study will be presented. Specifically, the existence, persistence, and significance of fraction errors found in the work on limits of Calculus I students.

This study was conducted in a mathematics department at a large research university in Southwest of the United States. Data were collected from more than 3000 students' midterm and final examinations from students enrolled in College Algebra, Pre-Calculus and Trigonometry, Pre-Calculus for Business, Life and Social Sciences, and Calculus and Analytical Geometry I. The data generated from the final exams for this course were analyzed using Booth et. al.'s (2014) categories of conceptual errors and the researchers coded the data individually before coming to a common consensus.

We found that many students struggled with the algebra and calculations needed to solve problems with limits. Research on students' understanding of limits and continuity reveal that many students find these concepts difficult to understand. Unfortunately, the results of study indicate that in addition to students' challenges with the concept of limits, their work is replete with common *fraction* errors and errors with *operations*.

The findings of this study reveal that not only the common errors and misconceptions students develop in middle school and high school mathematics exist, but they also persist into their university level mathematics coursework. Furthermore, these common errors and misconceptions cause significant challenges for students and their instructors. It is difficult for students and faculty alike to discern, based on summative test scores, what students know and understand about the new concepts they are being taught in Calculus courses. It may be possible to identify these common errors and misconceptions and work to alleviate them early in a student's university mathematics career and doing so may hold tremendous promise for students' success in their university mathematics coursework and ultimately in their ability to pursue STEM careers. It is the aspiration of this project to identify these common errors in order to create a model of intervention.

SIXTH GRADE STUDENTS' UNDERSTANDING OF PROBLEM SOLVING TASKS VIA MODEL DIAGRAMS

Kate J. Riley
California Polytechnic State University
kriley@calpoly.edu

The importance of school children learning how to problem solve has been a steadfast goal within the mathematics education community especially since the publication of Polya's (1945) four problem solving heuristics. We note that problem solving is a common theme for K – 12 students in the Common Core State Standards – Mathematics (CCSS).

There are many research studies on problem solving. However, for the purpose of this research study, we narrowed the focus to examine studies that investigated heuristics or addressed specific processes that students use in their completion of problem solving tasks. Developing students' abilities to solve problems is not only a fundamental part of mathematics learning across content areas but also an integral part of mathematics learning across grade levels. As Zhang and Manouchehri (2014) noted the issue of just how to develop problem solving skills among learners continues to be a major dilemma in research on problem solving.   In their research they noted that greater attention should be given to the processes that children use when engaged in problem solving. Their findings are supported by a research study by Pajares and Kranzler (2002) of 329 high school students. They found that students' ability and self-efficacy had strong direct effects on performance on 18 problems that ranged from algebra, arithmetic, to geometry.

The goal of this research study was to get a snapshot of students' ability to complete six word problems and also to gain insight into students' methods of solving the problems (i.e., whether students use model drawing to complete the word problems). Students were given a pre-test in mid-August and a post-test in early April. Students were prompted to use model drawing or tape diagram models to work the problems if possible.   Problems ranged from addition and subtraction word problems to multiplication, fraction, ratio, and percent word problems. The results of the 62 students' responses from the pre- and post-test show that the mean difference was 1.79 items. The p-value was less than 0.0001 showing that the results are highly significant and that the results are likely attributed to the change in the intervention.   Given that none of the students tried the model drawing in the pre-test in August and then overwhelmingly students did significantly better in the post-test by means of completing the model drawing suggests that students are capable of learning a heuristic to solve mathematical word problems.

MIDDLE GRADES STUDENTS' INTERPRETATIONS OF ADDITION OF FRACTIONS USING AN INTERACTIVE NUMBER LINE

Meetal Shah	Blain Patterson	Jere Confrey

Addition and Subtraction of Fractions

Students often have trouble with adding and subtracting fractions, especially ones with different denominators (Cramer, Post, & del Mas, 2002). Saxe et al. (2007) state that this is because students are using whole number reasoning. Further, when teachers use fraction representations such as pie charts it may not be clear to students what the fixed unit is. What does addition of fractions mean to students and how does it relate to the number line as emphasized in CCSS-M? This study investigated how middle grade students solve problems that involve the addition and subtraction of fractions using an interactive number line and coordinate the context and the features of the digital tool in doing so. Results reported here come from the study of five middle grades students. Students were given a brief demo of the features of the digital number line and then interviewed separately using a pre-designed set of tasks presented in digital form on a tablet. Each task had a blank interactive number line embedded in it, and the students were allowed to write on blank paper in addition to the digital number line to solve the problem. The interviews were conducted as clinical interviews.

Results

Analyses of interviews showed that students associated the 'equipartition' feature of the number line with finding a common unit. The 'scale' feature was primarily used to construct or extend the number line to account for larger fractions. Although the 'scale' and 'replicate' features are inherently different, students generally used them as if they were the same. This may be due to a lack of distinction between additive and multiplicative structures for the students. The 'measure' feature was used both to perform operations and justify solutions. There were multiple instances of students using the 'measure' feature to operate on two fractions. Additionally, it was common that students used the measure tool to justify a sum or difference they had already computed on paper.

CHANGE IN TEACHERS' CONCEPTIONS OF ARGUMENTATION

Megan Staples
University of Connecticut
megan.staples@uconn.edu

Argumentation, a core mathematical practice (NGA & CCSO, 2010), has received increased attention in recent years. Although research programs highlight the importance of teachers' mathematical knowledge for their teaching (e.g., Hill, Sleep, Lewis & Ball, 2007), few studies have elicited teachers' thinking about mathematical argumentation and what an argument is.

This study is situated in the context of the Bridging Practices Across Connecticut Math Educators (BPCME) Project, a math-science partnership grant project that aimed to advance participants' knowledge about mathematical argumentation and pedagogy of argumentation. Forty inservice math teachers and coaches (grades 3-12) participated. We collected a range of data on participants' initial conceptions of argumentation and how they changed over time. This analysis draws on data from 37 pre and post surveys where teachers responded to the prompt, "What is a mathematical argument?" Standard qualitative methods (Creswell, 2007) were employed. Open coding revealed two main foci of teachers' responses regarding a mathematical argument: (a) the components of an argument (what must be included) and (b) the purposes of a mathematical argument. We developed a set of codes for each focal area.

Teachers' conceptions of mathematical argumentation varied widely, and teachers changed their conceptions of a mathematical argument during the project period. A prominent trend was that teachers shifted from including non-essential components of arguments, such as multiple representations, "all steps," and "good math vocabulary," to a focus on essential components, such as evidence and reasoned chains of statements. We also found teachers honed their understanding of the purpose of a mathematical argument. Initial responses included an emphasis on explaining one's problem solving process; sharing one's ideas with others; and making conjectures. Although mathematicians engage argumentation for a variety of purposes (de Villiers, 1990), the core function a mathematical argument must accomplish is demonstrating the truth or falsehood of a well-formed claim (Staples, Bartlo, & Thanheiser, 2012) – an idea all but absent from pre survey data, but well represented in the post survey data.

With so few teachers expressing a robust and disciplinary-aligned view of mathematical argumentation at the beginning of our project, these findings urge teacher educators to be aware of teachers' detailed understandings of core constructs now emphasized by new standards.

Policy recommendations and researchers call for instruction designed to promote students' engagement with proof, argumentation, and justification. However, definitions and descriptions of these practices may vary, and even contradict one another (Cirillo, Kosko, Newton, Staples & Weber, 2015). In an effort to address this issue, a working group was established (Cirillo et al., 2015), advocating that educators clarify and refine their conceptions of these constructs.

In the working group, participants were invited to construct and analyze concept maps. In this poster, we present an analysis of the working group's concept maps, which summarized ways in which proof, argumentation, and justification are interrelated and understood by the participants. In total, we analyzed 44 maps from the perspective of researchers focusing on justification (n=11), argumentation (n=9), proof (n=19), and "other" (n=5). In analyzing the maps, we included open coding and formal techniques, such as Systemic Functional Linguistics (Halliday & Matthiessen, 2004) to identify themes.

Overall, a majority of the researchers used Venn diagrams in their maps. Some participants structured their maps to show hierarchy—most with proof at the top, which given the proportion of participants focused on proof is not surprising. The concepts were represented with both dynamic and static perspectives. The dynamic perspective illustrated how proof, argumentation, and justification are related through interactions; whereas, the static perspective defined how each concept related to the other concepts.

Many participants focused on mathematical argumentation communicated proof as a product or goal, but the role of justification was not as consistently conveyed. Furthermore, several participants who focused on justification treated the concepts of justification and proof as closely related but argumentation as separate. Even among researchers with a common focus, definitions of these constructs differed. Therefore, those conducting research in mathematical argumentation, justification or proof should be mindful of how they position these terms in their research. We recognize this analysis as a step towards developing a framework to describe how the field considers these constructs and the interrelationships among them.

Brief Research Reports

PRE-SERVICE AND FIRST-YEAR TEACHERS' VIEWS ON THE INFLUENCE OF MATHEMATICS METHODS TEXTBOOKS

Amber Brass
University of Melbourne
abrass@unimelb.edu.au

Shelly Sheats Harkness
University of Cincinnati
shelly.harkness@uc.edu

We investigated how pre-service and first-year teachers engaged with the pedagogy textbooks from their mathematics methods courses. Sixteen participants – seven pre-service teachers and nine first-year teachers – were interviewed about their interactions with mathematics methods texts and their perceptions about the texts. This paper focuses on participants' views regarding the messages sent by their mathematics methods textbooks about how to teach. Findings describe the tensions that exist between pedagogy textbooks and participants' experiences in the classroom. Implications for teacher educators are also discussed.

Keywords: Teacher Education-Preservice, Affect, Emotion, Beliefs, and Attitudes, Teacher Beliefs

How do prospective teachers interact with mathematics methods textbooks and how do these interactions shape prospective teachers' views of teaching? As Mesa and Griffiths (2012) noted, "textbooks remain a ubiquitous course component with various implications for the teaching and learning of mathematics at a tertiary level" (p. 86). We suggest that implications also exist for the use of textbooks in the teaching and learning of mathematics education in higher education settings. Yet, there is a lack of research that examines ways in which prospective teachers interact with mathematics pedagogy textbooks. Although there are numerous studies that have looked at the relationships between teachers, learners, and mathematics textbooks in K-12 education (Freeman & Porter, 1989; Haggarty & Pepin, 2002; Herbel-Eisenmann, 2007; Herbel-Eisenmann, 2009; Mesa, 2004; Remillard, 2000), few studies have examined these relationships in higher education settings. Moreover, the focus of studies conducted at the tertiary level have centered on textbook use in content courses, not pedagogy courses (Lithner, 2003; McCrory & Stylianides, 2014; Mesa & Griffiths, 2012; Weinberg & Wiesner, 2011; Weinberg, Wiesner, Benesh, & Boester, 2012). We posit that textbooks are an important component in mathematics methods courses for prospective teachers and the ways in which prospective teachers engage with these texts should be explored. In this paper, we discuss findings from interviews with pre-service and first-year teachers regarding the messages sent by their mathematics methods textbooks about how to teach.

Background and Theoretical Framework

While textbooks play a role in many mathematics methods courses, there are some issues of power that need to be addressed. Several textbook studies address the authoritative nature of textbooks and of the ways in which instructors mediate textbook use (Haggarty & Pepin, 2002; Herbel-Eisenmann, 2007; Herbel-Eisenmann, 2009; Mesa & Griffiths, 2012; Smitherman, 2006; Weinberg & Wiesner, 2011). The authoritative nature of textbooks can create tensions between the messages conveyed in texts and the ideologies of the mathematics education community. Herbel-Eisenmann (2007) investigated the "voice" of a Grade 7 textbook to see if it reflected the ideology emphasized by the *Principles and Standards of School Mathematics* (National Council of Teachers of Mathematics [NCTM], 2000). By using a discourse analytic framework to examine different linguistic features of the textbook, Herbel-Eisenmann found that the human agency in mathematics was often masked through the absence of different pronouns and the presence of modal verbs (i.e., could, might, would). Yet, many mathematics educators and the *Principles and Standards of School Mathematics* (NCTM, 2000) advocate for human agency through "doing mathematics" as one learns.

Tensions also existed with how "the text represented a strongly certain viewpoint of mathematics. This viewpoint is absolutist or Platonist in nature rather than fallible" (Herbel-Eisenmann, 2007, p. 362). This absolutist view can also be seen in pedagogy textbooks. In Smitherman's (2006) analysis of ten different mathematics education pedagogy textbooks, all but one of these textbooks "exhibit modern, rationalist, ideas in mathematics education" (p. 61). For Smitherman, this meant the pre-service teachers' expectations of what it meant to teach were shaped by notions of mathematical proof which were evident in the textbooks: replication is possible; mathematics education is comprised of a universal language; and it is based on a predictable cause-effect relationship. While aspects of these notions are indeed present with mathematics education, they also do not fully take human presence into account. For example, if predictable cause-effect relationships were possible in the classroom, then one could assume that several ideas from students "doing mathematics" would be dismissed as not fitting the prescribed relationship that is predicted and replicated.

Furthermore, Smitherman's (2006) analysis found that "the conversations in these texts [were] one-sided and unilateral" (pp. 63-64). For example, when these textbooks defined mathematics, the opinions and ideas held by the prospective teachers were never acknowledged in any of the textbooks. This emphasized the authoritative nature of the textbooks, in which "the authors of these texts [were] trying to create a particular way of conceiving math" (p. 65). We posit that this also creates an ideological tension with the mathematics learning emphasized in methods courses.

Weinberg and Wiesner (2011) also described conflict created by a textbook's authoritative nature as they applied reader-orientated theory to calculus textbooks. There are three types of readers central to reader-oriented theory: the intended reader (the image of the reader the author has), the implied reader (the qualities needed to read the text in the way the author intended), and the empirical reader (the actual reader). "The authority inherent in school textbooks adds to the tensions between the three readers" (Weinberg & Wiesner, 2011, p. 57). As explained by Weinberg and Wiesner, textbook authors typically envisage readers that employ active reading strategies (implied readers) and readers that are part of the mathematics community (intended readers). This creates a tension with the authoritative nature of textbooks that conveys a specific "truth" of mathematics to empirical readers. Weinberg and Wiesner also posited that if the intended, implied, and empirical "readers are not in alignment, the student will not be able to generate the appropriate mathematical meaning through reading the textbook" (p. 57).

Yet, the relationship between the text and the reader is often mediated through course instructors. However, if there are tensions with the authoritative nature of textbooks, then there are also tensions that exist with the authoritative nature of instructors using those textbooks. Mesa and Griffiths (2012) saw a difference in how instructors used textbooks with students depending on if instructors classified students as "undergrad students" (e.g., students in their first years of tertiary education taking courses to fulfill requirements or students taking remedial courses) or as "math students" (e.g., honors students or those students in upper division or graduate mathematics courses). Mesa and Griffiths posited that "although instructors may want students to read the textbook, or do something more with it than doing the homework or reading the examples, they seem to describe this expectation as reasonable for students in upper division courses, but not for students in lower division courses" (p. 97). This stance is confronting when combined with the role of teachers as mediators of the text as discussed by Haggarty and Pepin (2002). Textbooks have a large influence in the classroom, and teachers control the ways in which the textbooks are used. As Haggarty and Pepin suggested:

> [teachers] decide which textbook to use; when and where the textbook is to be used; which sections of the textbook to use; the sequencing of topics in the textbook; the ways in which pupils

engage with the text; the level and type of teacher intervention between pupil and text; and so on. (p. 572)

Thus, instructors can choose to use a text differently depending on how they classify students, and as Mesa and Griffiths (2012) contended, a "direct consequence of the different schemes that instructors have for using the textbook…results in different opportunities for these students to learn" (p.101).

Methodology

In order to garner multiple perspectives, we sought out participants who would be or were teaching various grade levels. Sixteen participants were chosen through a convenience sampling process (Creswell, 2012), where we invited former students to be interviewed or contacted colleagues who recommended their former students. Amber interviewed three pre-service elementary teachers and five first-year elementary teachers from a large Southwestern city in the United States. Shelly interviewed four pre-service secondary teachers and four first-year secondary teachers from a large Midwestern city in the United States.

Semi-structured, retrospective interviews were conducted in one-on-one settings. The use of retrospective interviews can generate some criticism, because interviewers try to get participants to recall and then reconstruct past experiences from memory. Although these interviews are the least likely type of interview, "… to provide accurate, reliable data for the researcher" (Fraenkel & Wallen, 2000, p. 510), the nature of our research question required us to use retrospective interviews. However, we trusted that the participants' memories were accurate based on *their* perceptions, which were their realities.

The interview protocol included demographic data questions, 11 open-ended questions about textbook use, and a final question to capture anything else the participant wished to share. Here, we focused on participants' responses to two questions within the interview protocol that related to messages sent by the pedagogy textbook: How did the texts you used in methods courses make you think about how to teach? and Considering your experience in the classroom(s) during and after your methods course(s) do you feel that texts can tell you how to teach? Why or why not?

Each interview lasted about one-half of an hour, and each interview was audio recorded. These recordings were later transcribed. After we transcribed the interviews, we also created a document that grouped participants' responses to each question. This helped us look at each participant's responses to all of the questions and to also look at all participants' responses to each of the questions. To analyze the data by utilizing a grounded theory constructivist design, no *a priori* categories for participants' responses, we focused on the meanings ascribed by the participants in the study (Creswell, 2012) and captured their experiences with texts in mathematics methods courses. During Skype™ researcher conversations we first used *in vivo codes*, labels for categories that were phrased in the exact words of the participants, and then created themes that emerged from the *in vivo codes*. As with most qualitative research, we acknowledge that our conclusions are suggestive rather than definitive.

Findings

When asked about how the texts used in mathematics methods courses made participants think about how to teach, approximately 70% of participants (n=11) mentioned the different strategies and ideas the text provided for teaching different concepts. While participants mentioned other aspects of the texts in response to this question, no other response had the same collective agreement by participants (see Table 1). There were only three other responses to this question that were given by at least three participants: an emphasis by the text on student explanations to strategies and solutions, the text leading to a realization of different ways students think about mathematics, and the text as a source of activities for the classroom.

Table 1: Responses to "How did the texts you used in methods courses make you think about 'how to teach?'"

Common Response	Number of Participants
By providing different strategies/ideas for teaching concepts	11
By emphasizing student explanations	4
By helping me see that students think in different ways/that there are different learning styles	4
By being a source for different activities	3

Mathematics methods courses often focus on pedagogical skills and knowledge, pedagogical content knowledge, and how students learn in order to help pre-service teachers develop teaching strategies aligned with these areas. Both the frameworks surrounding methods courses and the texts selected by course instructors work towards building pre-service teachers' knowledge in these areas. Yet, when we asked participants if they felt that texts could tell them "how to teach," about half of the participants (n=7) did not think the text could do this (see Table 2). Six participants gave mixed responses (yes and no), and three participants reported that pedagogy texts could tell them how to teach. Throughout these responses, four themes emerged that described participants' views related to if texts could tell them "how to teach."

Table 2: Responses to "Considering your experience in the classroom(s) during and after your methods course(s) do you feel that texts can tell you 'how to teach?'"

Response	Number of Participants
Yes	3
Yes and No	6
No	7

Textbooks as a Platform for Reflection

One theme focused on using texts as a platform for reflection on teaching. One participant said:

Texts can kind of guide you in the right direction and sort of get you to reflect on your own teaching practices. It's very just reflective…like what would it look like in my classroom? Can I get my students to the same endpoints using those methods? (participant 2, first-year teacher).

Yet, another participant viewed this question in a more personal way and stated:

I think it's beneficial to have texts to give you a solid, to give you a concrete example of what someone else thinks and I think those are beneficial because thinking about other people's thinking is as important as thinking about your own thinking…How can you teach people to teach when teaching is such a personal thing…I think that you have to find your own connections with everything. (participant 5, pre-service teacher)

Both of these quotes from participants emphasize the connections prospective teachers make between the information in the textbook and their own teaching practices. Yet, when asked in the preceding interview question about how the texts they used in their mathematics methods courses helped them think about how to teach, only one participant's response mentioned the textbook providing a reflective component.

Experience is the Best Teacher

Another theme that emerged was that texts cannot tell you how to teach, because experience is the best teacher. As one participant described:

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

> But, when you're in the thick of it, that's when you really learn, I think, you know experimenting and using the ideas that you have, bringing them into the classroom is the most effective. So, kind of a combination of both, but I don't think the book alone can tell you how to teach. (participant 9, first-year teacher)

This feeling was echoed by other participants, including one who explained:

> I feel like [the texts] can't [tell you 'how to teach']. I definitely think they help…But actually being up in a classroom and teaching and getting the feedback from your students, I think that's going to teach you the most. (participant 13, pre-service teacher)

Perhaps, being in the classroom is when it becomes "real" to prospective teachers. In fact, when asked about how the texts used in the mathematics methods courses helped him or her think about how to teach, one participant shared, "I didn't think about how to teach. That's why I think it was such a shock for me going into my 5th grade [placement] classroom" (participant 14, pre-service teacher).

All Students are Different

The next theme that developed from participants' responses was that textbooks did not tell them "how to teach," because all students are different. Interestingly, most of the participants expressing this view were first-year teachers. The response of only one pre-service teacher fell into this theme. That participant said:

> I think the text tries to tell you how to teach and it gives you strategies but a lot of teaching is based on your students and every student learns differently…I think it gives you a general overview and best practices but every teacher is gonna [sic] have to change their teaching for the students that they have in their classroom. (participant 1, pre-service teacher)

One of the first-year teachers whose response fit this theme expanded upon the notion of knowing your students to knowing the community of students:

> There are so many different parts to teaching. There's knowing your kids…So, in the most straightforward sense, no, I don't think [the text] can teach you how to teach…This textbook is for, you know, just a general population of elementary and middle school teachers but we all go off into our own types of communities. (participant 11, first-year teacher)

We also saw the realization of the different ways that students think about mathematics emerge as a common response to the preceding interview question about how the texts participants used in their mathematics methods courses helped them think about how to teach.

Textbooks do not Reflect Reality

The final theme that emerged through participants' responses to these two interview questions concerned the differences between the text and the reality of teaching. Participants often commented that texts represented a "perfect world" of teaching. As one participant explained, "I feel like textbooks can be very idealistic or optimistic and everything's going to go well and the students are going to get it" (participant 12, first-year teacher). This sentiment was echoed in several responses from participants, particularly those participants who were first-year teachers. According to one of the first-year teachers, "How did [the text] make me think about how to teach? I think the way that it made me think isn't like reality once you start doing it" (participant 16, first-year teacher). This is troubling, particularly if it impacts how teachers view their preparation. "You're not going to get a textbook situation in your teaching environment…it's a completely different world when you step into the classroom versus reading a book…I felt almost unprepared for the real world" (participant 4, first-year teacher).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Discussion and Implications

The results of our interviews emphasize the different ways pedagogy textbooks are viewed by pre-service and first-year teachers concerning ideas on how to teach. Surprisingly, approximately 81% of participants (n=13) either did not think pedagogy textbooks could tell them how to teach or were mixed in their responses. Only three participants indicated that methods texts could tell them how to teach. While the authoritative nature of texts is often considered when studying textbooks (Haggarty & Pepin, 2002; Herbel-Eisenmann, 2007; Herbel-Eisenmann, 2009; Smitherman, 2006; Weinberg & Wiesner, 2011), participants in this study did not seem to heed the assumed authority of the text on how to teach.

Based on participants' responses and the themes that emerged through them, we suggest that prospective teachers view teaching in a more personal manner than portrayed through pedagogy texts. Many viewed teaching as complex and multi-faceted, and the authority of the textbook conflicted with this view. While the textbook was influential in providing some participants with ideas about the different ways students learn and think about mathematics, several participants also felt tensions between the portrayal of classrooms within the textbooks and their own classroom experiences. We hypothesize that this tension stems from the Platonist view that textbooks present about math and mathematics education (Herbel-Eisenmann, 2007; Smitherman, 2006). If, as Smitherman posited, the notions that shape prospective teachers' expectations about what it means to teach mathematics include that replication is possible and predictable cause-effect relationships, then they may very well think that the textbook represents a "perfect world" of teaching.

The tension between the presentation of classrooms in the textbook and the participants' classroom experiences may also be the result of a misalignment between the intended reader, the implied reader, and the empirical reader (Weinberg & Wiesner, 2011). The participants being the actual readers of the texts (the empirical readers) may not match the profile of the readers the authors envision (the intended reader) and/or may not possess the qualities needed to read the text in the ways the authors intended (implied reader). What skills do prospective teachers need to read the textbook in a way that lessens this tension? Do they need additional classroom experience? Do they need more confidence in their perceptions of mathematics education? Or, do they need a stronger avenue to voice those perceptions? Perhaps, there are other factors that need further research in order for the intended, implied, and empirical readers to align when facilitating the use of pedagogy textbooks in our mathematics methods courses.

That being said, we posit that these tensions signify positive aspects in our participants as readers of the texts. The results of our interviews also suggest that participants leaned towards a critical stance when they indicated that textbooks could not tell them how to teach. This questioning of the texts is something that we would like to promote in our methods courses. Like Draper and Siebert (2004), we agree that for pre-service teachers to "acquire mathematical knowledge and participate meaningfully in mathematical activity, [they] must become adept at creating, negotiating, and consuming texts" (p. 945).

We want to position the textbook as a source of information, not *the* source for information. Helping the students in our methods courses to question and negotiate the information presented in the various texts helps create a "privileging the student" position (Herbel-Eisenmann, 2009) between the students in our methods course, us (as instructors), and the textbook. Furthermore, if we allow these tensions and the classroom experience to be exposed and discussed, we help prospective teachers create their own texts. The results of our interviews suggest that participants viewed experience as the best teacher of how to teach. Several of our participants also recognized that all students are different and responding to the needs of students in the class is important as teachers plan. We look for ways that these ideas can be recognized and built upon in our methods courses to foster the confidence of prospective teachers and position them in ways that value their contributions along with the information presented in the textbook.

Textbooks influence both prospective teachers and instructors of mathematics methods courses. We do not want to downplay their use or their importance in our courses; there is valuable information that comes from textbooks. Instead, we want to position the textbook in a way that mirrors this statement by Herbel-Eisenmann (2009), "When teachers, textbooks, and students come into contact with one another, there is the potential for each of these 'participants' in the classroom to take on responsibility for the introduction and development of mathematical knowledge" (p. 147). Indeed, we want to leverage textbook use in ways that prospective teachers will find meaningful in both their teaching preparation and in their teaching careers.

PRE-SERVICE SECONDARY MATHEMATICS TEACHERS' PERCEPTIONS OF ABILITY, ENGAGEMENT, AND MOTIVATION DURING FIELD EXPERIENCES

Toya Jones Frank
George Mason University
tfrank4@gmu.edu

Monique Apollon Williams
George Mason University
mapollon@gmu.edu

We conducted a self-study to learn more about how to support the first author's pre-service teachers (PSTs) during their field experiences in an introductory secondary mathematics methods course. The findings highlight how the PSTs' perceptions of the secondary students' mathematics ability was closely related to how they viewed the students' levels of engagement and interest. The data also indicated that PSTs often diminished the role that the cooperating teachers played in co-constructing student ability, motivation and engagement, particularly in situations where the students displayed unfavorable behaviors. The findings inform curricular development for methods courses and field experiences, both for the authors and for the mathematics educators who support PSTs in diverse school settings.

Keywords: Teacher Education-Preservice, Equity and Diversity, Teacher Beliefs

Background and Purpose of the Study

Preparing mathematics pre-service teachers (PSTs) includes supporting them as they develop dispositions toward equity (Hand, 2012), particularly in schools that are labeled as high needs. *High-needs school* is a marker used to describe schools with one or more of the following characteristics: a student population comprised primarily of students of color, a high concentration of English language learners, or a high concentration of students from families with lower socioeconomic status. At times, this label perpetuates deficit-oriented thinking about the students who attend these schools. PSTs often enter mathematics education courses well versed in popular deficit-laden discourse about high-needs schools and the challenges of working in them, deemed as "lay culture norms" by Tatto (1996). This line of thinking often leads to PSTs framing their students' experiences and ways of knowing as unfamiliar (and possibly subordinate) to their own, which negatively impacts PSTs' mathematics teaching practices. In turn, this limits students' academic trajectories and opportunities to learn. Mathematics educators must support PSTs in recognizing and challenging this deficit-oriented thinking.

I, the first author of this work, designed an introductory secondary mathematics methods course with the goal of not only promoting rigorous and standards-based mathematics teaching methods, but also in the hopes of supporting students in unpacking issues of privilege, equity, and ability in the context of diverse mathematics classrooms. One important component of this course is the field experience. Upon analyzing my program's survey data as part of a larger study of programmatic change in our Secondary Education program (Samaras, Frank, Williams, Christopher, & Rodick, in press), I learned that former students found their field experiences unbeneficial. Thus, my graduate assistant and second author, Monique, and I designed a field experience that we hoped students would find relevant and that would highlight aspects of equitable teaching in action.

This self-study (Samaras, 2011) examined the challenges the first author faced as a new mathematics teacher educator in designing a meaningful field experience opportunity for PSTs who were observing mathematics teaching and learning in a high-needs high school. The following question guided our research: What can we learn from the PSTs' field experiences to provide more meaningful fieldwork in secondary mathematics methods courses? The findings gleaned from the PSTs' reflections and observations revealed the tacit labels assigned to students in high-needs schools rooted in PSTs lay culture norms about ability, motivation, and engagement. Our findings

challenge us to find new ways to disrupt these lay culture norms and to help PSTs acknowledge the co-constructed nature of mathematics ability and participation between students and teachers in mathematics classrooms (Hand, 2010).

Theoretical Perspective

Integrated Perspective

This study is grounded in sociocultural and sociopolitical perspectives about mathematics teaching and learning, acknowledging that mathematics classrooms are cultural and political spaces. A sociocultural perspective highlights the role of participation, social interaction, and negotiation in teaching and learning, and it highlights the norms and discourse practices of educational settings and how they influence learning (Cobb & Yackel, 1996). Context is central to learning from a sociocultural perspective, meaning one cannot separate what one learns from the context in which it happens and the people with whom the learning takes place.

We also draw on Nasir and McKinney de Royston's (2013) notion of sociopolitical perspectives in mathematics education. These authors define a sociopolitical perspective as distinct from a sociocultural one in that it accounts for "how…power operate[s] in learning settings, especially as [it] may relate to privilege and marginalization" (p. 266). Sociopolitical attention to mathematics teaching and learning addresses not just how activity is organized, but also how issues of power permeate learning contexts. In this study, we see the political nature of mathematics permeating mathematics learning at three levels – at the school level as well as at the state- and national-levels where policies such as accountability mandates inform instructional choices.

We adopted an integrated theoretical lens to understand the PSTs interpretations of their field experience observations. This means that while the cultural and contextual features of the classrooms our PSTs observed were important, we also accounted for the political nature of mathematics education, which had significant influence over teachers' instructional choices.

Teacher Noticing

As a complement to our integrated perspective, we also draw on contemporary research about teacher noticing, which encompasses "not only the attention that [PSTs] give to classroom actions and interactions, but also their reflections, reasoning, and decisions based on this noticing" (McDuffie, et al., 2014). Mason (2008) noted two facets of teacher noticing which are central to our study, (a) attention, or what teachers notice as they observe practice, and (b) awareness, or how teachers make sense of or interpret what they observe. Given that PSTs' attention and awareness are culturally situated, informed by participation and negotiation in methods class and the classrooms they observed, and influenced by context, we see noticing as complementary to our theoretical perspective.

Methodology

The purpose of self-study methodology is for educators to explore issues directly relevant to the context to which it is applied (Samaras, 2011). The theoretical underpinnings of self-study acknowledge that knowledge production and development is context and cultural sensitive (LaBoskey 2004). Thus, self-study honors teacher voice, in that it allows teachers to respond "to the needs and concerns of *their* students in *their* contexts" (Kosnik, Beck, Freese, & Samaras, 2006, p. x). The five tenants of self-study research include: being self-initiated and focused, aimed at improvement, being interactive, utilizing multiple, primarily qualitative methods, and using validation procedures that are exemplar-based (Samaras, 2011). In our efforts to maintain fidelity to the characteristics of self-study, we initiated this self-study project to improve the field experiences component of the methods course. This study was highly interactive, as we served as critical friends

who provided insider (first author) and outsider (second author) perspectives during data collection and analysis.

Participants

This study examined the perceptions of four PSTs from the first author's introductory methods course who were assigned to a racially, linguistically, and socioeconomically diverse school. The group ranged in age from early 20s to late 50s. Two male and one female PST identified as White and one as an Asian immigrant woman. Three PSTs decided to teach mathematics after having careers in mathematics-related fields. One had recently earned an undergraduate mathematics degree. In their mathematics mathematics autobiographies, each of them expressed comfort and ease with mathematics throughout their K-12 schooling

It is important to note that while we are not direct participants in this study, our roles as instructor and graduate assistant are central. We entered this study aware of the power dynamics between researchers and educators when conducting research (Kvale, 2006), especially when one researcher is also the instructor of the participants. For this reason, the second author led the focus groups, though the first author probed for deeper understanding at times. Since this study, the second author has served as a teaching assistant for a subsequent introductory mathematics methods course and will be the instructor of record for future methods courses. Thus, we both have personal interests in improving this major component of the course.

Context

The context for this study was an introductory secondary mathematics methods course. The goals of the course were to introduce students to reform-minded mathematics teaching and learning via the National Council for Teachers of Mathematics (NCTM) *Principles and Standards for School Mathematics* (NCTM, 2000) and state standards, which encourage student-centered, conceptual approaches to teaching. PSTs had to complete 15 hours of observations in secondary mathematics classrooms. The first author only required PSTs to observe in this introductory course, as they are required to take an active and participatory role in a secondary mathematics classroom during their second methods course. They were encouraged to visit as many classrooms as they could to get a sense of how mathematics instruction varied both across a schools' mathematics department and within a teacher's practice as she worked with different groups of students.

The university's clinical experiences office organized the field experience placements. The PSTs completed their fieldwork at an ethnically, linguistically, and socioeconomically diverse high school in a nearby local district, which according to state-level data, is the lowest performing high school in the district. In fact, at the time of the study, the school faced sanctions for not meeting accountability standards.

Data Sources

Multiple sources of data in this study serve as a means of data triangulation to provide corroborating evidence to support our findings (Miles & Huberman, 1994). Data sources included two focus groups at the beginning and end of the field experience that ranged from 45 minutes to an hour. We also collected each PST's autobiographies where PSTs reflected on their personal experiences as mathematics learners. We also collected their final reflection papers that provided detailed accounts of their field experiences using writing prompts that encouraged PSTs to consider school and community contexts and classroom interactions among students and between students and teachers.

Given the focus on the researcher in self-study, I as the first author and instructor kept detailed personal memos. These memos were written following both focus groups. They focused on the big ideas that I heard and wonderings that I had as I listened and probed PSTs during the focus groups.

As I read my PSTs' reflection papers, I also kept memos of the themes that I noticed as I read. I shared my memos with the second author as we analyzed the data.

Data Analysis Procedures

We employed qualitative methods for this study, including document analysis and focus groups. Document analysis is a systematic procedure for evaluating printed and electronic documents that "requires that data be examined and interpreted in order to elicit meaning, gain understanding, and develop empirical knowledge" (Bowen, 2009, p. 27).

Data analysis began with pre-coding the data (Saldaña, 2009), meaning that we read the focus group transcripts and reflections and flagged, highlighted, or underlined portions that we believed would be important to this study and in need of attention during the coding process. Upon several reads and annotations of the transcripts, these themes eventually became codes and sub-codes about the nature of the PSTs observations. Once we established our initial codes via axial coding (Miles & Huberman, 1994), we used Dedoose software to code the corpus of data. With the help of the interactive data visualization tool in Dedoose, we were able to observe patterns and themes. We each coded the data sets on our own, then came together to share the patterns that emerged as well as our interpretations. We strived to validate our findings by check-coding our ongoing analysis and interpretations of the data and by meeting frequently to share our coding and to resolve discrepancies.

Approaching this work from the theoretical lens described above, we analyzed the PSTs' participation in focus groups as well as what they shared in their written reflections to explore how they drew upon artifacts, tools, fellow PSTs, and us, as faculty and graduate assistant, to make sense of their experiences and to develop new understandings (Putnam & Borko, 2000).

Findings

PSTs' Perceptions of Student Ability, Motivation and Engagement

Ability and reform-based teaching practices. An emergent theme from the data was that the PSTs' assumption that reform-minded mathematics was mainly suitable for advanced students. PSTs wondered if reform-based instructional approaches were suitable for all types of learners, or whether these practices only worked with students who were viewed as "motivated," "smart," or "high flyers" as some PSTs described them. For example, when discussing his frustration with the lack of reform-minded practices in a low-tracked Algebra class he observed, one PST shared, "I would like to see classrooms where [reform-based practices] actually work. I think that would be really interesting. What (sic) are those students? What are the demographics?" Implicit in this excerpt is the PSTs' understanding that the kind of student-centered teaching emphasized in the methods class is suited for particular learners, namely those who are considered to be advanced or "smart."

Ability related to motivation and engagement. In a similar vein, the PSTs' perceptions of student motivation and engagement were often predicated on the academic level of the class. We found numerous instances of this in the corpus of data. PSTs frequently adopted a deficit-oriented perspective when describing unfavorable student behavior or learning outcomes. Peppered throughout the focus group conversations regarding student motivation and ability were phrases such as "Some of these kids don't care," while other PSTs expressed sentiments that students who appeared unmotivated "don't want to learn."

When reflecting on observations in an advanced (International Baccalaureate [IB]) class, one PST shared, "Every single student was paying attention and doing their work. And it could be the fact that it is an IB class, which I would probably think most of the reason is." Given that this PST's reasoning for students being engaged and paying attention in class was because the class was designated for advanced students is another example of how perceptions of student ability influenced

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

the PSTs' perceptions of motivation and engagement. The PSTs often referred to the students in lower-tracked classes as unmotivated and disengaged, while the students placed in the higher-level courses were frequently posited as focused and on-task. These claims were made based on behaviors that the PSTs' observed, not on the students' work or grades in the course. Even when advanced students displayed similar behaviors as those in lower-tracked classrooms, PSTs interpreted the behavior differently. One PST recounted the following:

> Until [lower-tracked students] were called on, they were just sitting there [absorbing] whatever information made it through their skin, and the instructor said, "Look you know you guys have to care"... The [higher tracked] Probability and Statistics course, they were all very focused. So [the instructor] could lecture to the students who wanted to pay attention. There was a girl right in front of me flipping through her magazine and two students on my right on their phones. [The teacher] says, "They are good students, and they will take care of their homework after class."

This excerpt is especially salient. PSTs noticed behaviors that they believed indicated that the lower-tracked students were disinterested and not concerned with learning mathematics (i.e., "waiting for information to seep into their skin"). In the excerpt above, higher-tracked students exhibited similar behaviors, yet because of their status as higher-tracked and "good" the teacher ignored their disinterest during class.

The Impact of Accountability Mandates

PSTs who observed at this particular high school noted the disengagement of the students in lower-tracked classrooms as described above. Upon further exploration, we found that most of the classes where the PSTs noted disengagement were typically remedial or for standardized testing preparation. Cooperating teachers in these classes opted to drill subject matter, while others struggled with pacing and covering all of the necessary material for testing. Ultimately, all of these choices resulted in teacher-centered instruction and selection of materials that emphasized procedures rather conceptual understanding. When looking across all 4 PSTs' reflection papers as well as the focus group data, all of the PSTs mentioned how the pressures of standardized testing influenced their observed teachers' instructional choices; However, most missed the opportunity to connect these instructional choices to student disengagement. This finding also points to a third theme that emerged from the data, the limited acknowledgement of the cooperating teachers' role in co-constructing ability, engagement, and motivation, which we discuss in the next section.

Limited Unpacking of the Cooperating Teacher's Role

We surmise that the PSTs did not see how their cooperating teachers, through discourse, interactions with their students, and curricular choices *positioned* (Herbel-Eisenmann, 2015) students to take up or resist particular opportunities to learn in their classroom interactions. When we questioned the PSTs about how the cooperating teachers' instructional decisions contributed to their students' disengagement and perceived low mathematics ability, most PSTs admitted that they had not considered the role of each teacher in co-constructing these negative interactions that they had mostly attributed to students. This is reminiscent of the teachers in Hand's (2010) study of how secondary teachers were often unaware of how their behaviors toward their students aided in co-constructing opposition in their low-tracked mathematics classrooms.

As we noted this pattern in the data, we began to ponder why the PSTs consistently missed the opportunities to notice their cooperating teachers' roles in co-constructing behaviors they saw as unfavorable. Upon a closer look at the data, we found that PSTs expressed apprehension in framing their cooperating teachers as being ineffective. In fact, during the last focus group, several of them noted that they felt guilty about reporting what they observed. They were afraid of being "teacher bashers" as one PST explained. It is important to note that in our analysis, we found that the PSTs

gave far less attention to how they framed students in their discussions, particularly when describing unfavorable student behavior or learning outcomes. Unknowingly, the PSTs rested the responsibility for learning and engagement squarely on the students' shoulders.

When PSTs had the opportunity to consider the role of their cooperating teacher in co-constructing negative interactions, they gained deeper understanding of the teacher's role in impacting student motivation and engagement in tasks. One PST noted how even something that seemed minimally important on the surface, the way a teacher sets up her classroom, could foster unproductive participation and possibly encourage student disengagement. He shared, "All the desks were in groups of four, which meant that about half the students for the entire class period had their backs to the teacher...and those students were facing the opposite wall and were some of the ones that were the most disengaged. This no doubt encouraged the talkativeness of his class." Another PST admitted that he had not considered the role that teachers play in co-constructing student disengagement or lack of understanding of the content. When reflecting on his experiences in the two classes observed, the PST noted in his final reflection:

> "Good" teachers often create a desire in students to learn. I really enjoyed Mr. O's class. He employed the use of real world problems and all of his students were actively learning...I did not get this sense from Mrs. V's class. Hardly any of the students paid attention, which she did nothing about. I couldn't blame the students because she made Algebra I seem boring."

These quotes show that some of the PSTs had an emerging understanding of how teachers' decisions either afford or constrain opportunities for engagement and motivation.

Implications

As this is a self-study, the findings and analysis inform our practice as instructor and graduate assistant of this course. However, we believe that the implications for this work are meaningful for other mathematics teacher educators. From the findings emerged important factors to consider when designing field experiences for future methods courses. We are also grappling with how we as university-based teacher educators affect fieldwork that often takes place in our absence and under the purview of cooperating teachers.

Within our methods courses, It is essential that we provide opportunities for PSTs to make sense of the contexts of their field experience location sites, especially when placed in high-needs schools. The PSTs needed more time to work through the deficit-laden discourse that influences what they notice and attend to when observing practice. Past research has shown that PSTs who only have one-time or minimal field experiences in high-needs schools tend to deepen their deficit perspectives due to the lack of exposure to unfamiliar communities (Sleeter, 2008). Rushton (2000) argued that new teachers could begin to shift their thinking about students in these settings if they work in these communities over a sustained period of time. Further, shifts in PSTs' deficit perspectives also have implications for what they notice as they observe instruction. McDuffie et al. (2014) note, "Teachers need support in learning to attend to, or notice, students' mathematical thinking and important classroom events and interactions—in other words, noticing is a practice that needs to be developed" (p. 246).

Additionally, unpacking the accountability milieus in which teachers have to make instructional decisions must become a more explicit component of PSTs reflecting upon their field experiences. Since data collection and analysis, we co-taught another introductory methods course. We tried to make noticing with respect to issues of, ability, engagement, and motivation more explicit with respect to our reading selections and class discussions about equity, race and ethnicity, and language. Only one PST explicitly discussed race in his reflection and two directly addressed issues of language, yet most of them noted that the drastic demographics between remedial classes that were primarily Black and/or Latin@ and advanced classes that were predominately White. We also spend

time discussing how mathematics educators can shift from discussions of mathematics ability to discussions of student status (Horn, 2007). Additionally, in the subsequent advanced methods course, the first author has revised the curricular component on assessment to address the political nature of teaching mathematics in addition to more traditional mathematics assessment issues. We discuss how policies regarding mathematics assessment have very distinct outcomes for non-dominant groups of students.

Closely related to the need for PSTs to make sense of school contexts, where accountability mandates permeate mathematics instruction, we are now making space, in class and in the field, for students to think about how the political nature of teaching mathematics impacts teacher agency and instructional choices. Noting how the PSTs were reticent about sharing their observations of less desirable teaching for fear of teaching bashing pushes us to think of how we help students productively critique the cooperating teachers' practices. We ponder whether their reticence could be attributed to the PSTs' status as students who are learning to teach. Their positioning as novices could have led to them deferring to their cooperating teachers' pedagogical and relational choices. While we want our PSTs to implement more reform-minded strategies, we also want them to understand the complex nature of teaching mathematics and all of the factors that impact it. We are also pushing this work outside of the university-based methods course and working toward adopting a model of field experience where we, as instructors, visit classrooms with our PSTs and engage in conversations with cooperating teachers about their pedagogical and relational choices with respect to accountability.

With the attention to classroom context and the larger political forces that shape classroom activity, we believe that we are building a foundation for PSTs to move beyond static, one-sided characterizations of students as not caring about their mathematics courses. We hope that through our curricular changes based on this research, our PSTs come to see mathematics classrooms as dynamic spaces where teachers are co-constructing student engagement, behavior, and their students' mathematics identities. We strive to help them understand that learning mathematics cannot be viewed as a one-sided endeavor where students are framed as not interested in learning and, as a result, teachers are excused from providing effective instruction.

Conclusion

Helping secondary mathematics PSTs shift their dispositions toward teaching and learning mathematics in high-needs schools is complicated and complex work. It is essential as dispositions influence the moment-to-moment decisions mathematics teachers make in their classrooms (Hand, 2012). Supporting PSTs in this way requires attention to content, beliefs, and affect, and it requires PSTs to challenge and confront their own assumptions. Field experiences are viable spaces for doing some of this work. They give students authentic spaces to wrestle with the challenges that practicing teachers face daily. Finding new ways within methods courses to support this type of work continues to be a challenge we pursue.

The purpose of this review was to examine the 25-year period of research on elementary prospective teachers (EPTs) in mathematics content courses since publication of the Curriculum and Evaluation Standards for School Mathematics (NCTM, 1989). Analysis included an extensive electronic search and a manual search of 11 well-respected journals. Twenty-four studies met the inclusion criteria. Nineteen of the 24 studies occurred in the context of a reform pedagogy. Results showed positive changes in EPTs' affect were possible, but these shifts were sometimes difficult to come by and encountered resistance from the EPTs. Some studies showed an increase in EPTs' content knowledge, while others did not achieve the desired effects. Results show further study of EPTs' content knowledge is warranted. Implications for course learning experiences and suggestions for future research are offered.

Keywords: Mathematical Knowledge for Teaching, Teacher Education-Preservice, Teacher Beliefs, Teacher Knowledge

Introduction

Similar to many countries, in the U.S. most elementary teachers are prepared as generalists during initial teacher preparation, ultimately assuming positions in schools requiring the teaching of all subjects. Such all-purpose preparation has led to a corpus of elementary teachers needing improved knowledge for effectively teaching mathematics with understanding and proficiency at the level of rigor and depth depicted by the *Common Core State Standards for Mathematics* (CCSI, 2010). The significance of mathematical knowledge should not be underestimated, since teacher knowledge has been linked to teaching effectiveness and ultimately student learning (Hill, 2010). Wu's (2009) assertion rings true: "The fact that many elementary teachers lack the knowledge to teach mathematics with coherence, precision, and reasoning is a systemic problem with grave consequences" (p. 14). Accordingly, considerable resources and efforts have been devoted to both understanding this knowledge and determining efficacious ways of building it (e.g., Ball, Hill, & Bass, 2005). Many institutions of higher education have added specialized mathematics content courses for elementary prospective teachers (EPTs) that according to the Conference Board of the Mathematical Sciences (CBMS, 2012) should be grounded in the perspective that teachers should study the mathematics they teach in depth and from the viewpoint of the teacher.

Such mathematics courses hold challenges specific to elementary teachers, who often have negative affect toward mathematics, including dislike and avoidance (Bekdemir, 2010), and a propensity to espouse traditional, procedural views on what it means to know and do mathematics and on how it is learned (CBMS, 2012). These difficulties are compounded by the perspective of some EPTs who think they do not need to learn more mathematics, as their experiences thus far have provided them sufficient content knowledge needed for teaching in the elementary classroom. Given this increasing awareness of the need for improved mathematical knowledge of elementary teachers via specialized mathematics courses, coupled with constraints particular to this population, research on EPTs in university mathematics content course experiences is critical.

Purpose of the Review

The purpose of this review is to examine the research on EPTs in mathematics content courses since publication of the *Curriculum and Evaluation Standards for School Mathematics* (NCTM, 1989). Specifically, the review examines empirically based articles published from 1990 to 2014 (25 years) with EPTs as participants, who were completing university courses identified as mathematics content courses. We review past research in order to present the state of knowledge on the mathematical preparation of EPTs and also to highlight areas research has left unresolved. We provide summary findings and contributions of the body of work, implications for elementary teacher preparation, and suggestions for future research.

Method

The pool of articles in this review was determined through several cycles of appraisal and scrutiny using a comprehensive search strategy aimed at identifying all available studies. Criteria for initial inclusion were that the study must have: (a) been published between 1990 and 2014, (b) included EPTs in an initial certification program as participants, and (c) occurred in a university mathematics content course/university math for teachers content course/or university course that simultaneously focused on mathematics content and teaching methods as the context. A university course solely focusing on mathematics teaching methods was excluded, as were studies in yearbooks and conference proceedings.

The five-member research team engaged in several cycles of examination to arrive at the final collection of articles. The first round was an electronic search that cast a broad net for evidence of the initial inclusion criteria. The electronic databases explored were ERIC, PSYCH Info, Academic Search Complete, Professional Development Collection, and Psychology and Behavioural Sciences Collection using combinations of the following key words: elementary education, elementary teachers, mathematics, undergraduate, mathematics courses, pre-service teachers, prospective teachers, content courses, and early childhood education. Review of abstracts from this search yielded a total of 54 publications. Simultaneously, a targeted, manual review of abstracts in 11 journals considered to have high scholarly regard in the fields of mathematics education and teacher education were examined. These included *American Educational Research Journal, Cognition and Instruction, Educational Studies in Mathematics, Elementary School Journal, Journal of Mathematical Behavior, Journal of Mathematics Teacher Education, Journal of Research in Mathematics Education, Journal of Teacher Education, School Science and Mathematics, Teachers College Record,* and *Teacher and Teaching Education*, which gleaned a total of 40 articles. After eliminating duplicate articles between the electronic database and targeted journal searches the pool for the next round was 89 articles.

Because the original search cast a wide net that focused only on the content of abstracts, the second round of examination focused on the entirety of the article and involved in-depth scrutiny of each manuscript. All 89 manuscripts were carefully reviewed by at least two researchers using a rubric that applied the initial inclusion criteria. In addition to the criteria listed above, to be included the work had to: (a) be research-based, i.e., the report presented research question(s) or purpose(s); (b) provide a review of relevant research and/or theoretical frame; (c) include a description of methods, including participants, context, data collection, and data analysis; (d) present results; and (e) give some interpretation or discussion. These research-based elements were created drawing from *Standards for Reporting on Empirical Social Science Research in AERA Publications* (AERA, 2006). In addition, we noted in the review if a pedagogical approach or method was indicated. In order to establish agreement on the meaning of the components of the rubric, each member of the research team independently read and examined two pre-determined articles (one qualitative and one quantitative) before convening as a group to consider and discuss consistency of interpretation and application of the rubric across the studies. Three typical reasons for exclusion from the final pool

were studies (a) that failed to meet all the research elements criteria, (b) that appeared to have content course contexts but were in fact methods courses, and (c) that involved participants other than EPTs. Of the 89 articles in this round, 24 qualified for the final pool. Journals represented and number of studies in each included *American Educational Research Journal* (1), *Educational Research for Policy and Practice* (1), *Educational Studies in Mathematics* (4)*, International Journal of Mathematical Education in Science and Technology* (1), *Issues in Teacher Education* (1), *Journal for Research in Mathematics Education* (1), *Journal of Mathematical Behavior* (5), *Journal of Teacher Education* (1), *Mathematics Education Research Journal* (1)*, Mathematics Teacher Education and Development* (1), *School Science and Mathematics* (7).

Summary Findings

We sorted the studies using four distinctive categories from the review rubric: research method, context, purpose/focus, and pedagogical approach of the instruction. A brief overview of each follows.

When considering ***research method***, five studies involved quantitative methods only, nine studies included qualitative methods only, and ten studies involved some combination of qualitative and quantitative methods. Clustering by years is shown in Table 1.

Table 1: Clustering by year of the study and research method

	1990-1994	1995-1999	2000-2004	2005-2009	2009-2014
Quantitative				3	2
Qualitative	2	1	2		4
Mixed		2	1	2	5

With respect to ***context***, 18 of the studies data collection occurred within one mathematics content course (which may have been collected across multiple sections of the same course). In the six remaining studies, context for data collection occurred in a variety of settings including a comparison of EPTs who completed a content course and those who did not, a study of four integrated content/methods courses, and studies that looked at more than one content course.

When classified by the ***purpose/focus*** of the study, twelve studies examined affective factors of the EPTs such as beliefs, attitudes, motivation, and identity. Ten studies investigated various forms and concepts of mathematical knowledge of the EPTs. One study explored both affective factors and mathematical knowledge. The last study examined the development of classroom norms and mathematical justification. A classification by years and focus is shown in Table 2.

Table 2: Clustering by year of the study and focus

	1990-1994	1995-1999	2000-2004	2005-2009	2009-2014
Affective	1	2	2	2	5
Cognitive	1		1	3	5
Other		1		1	

Finally we clustered by ***pedagogical approach*** used in the courses. We termed the pedagogy as reform when it aligned with pedagogy described by NCTM in the *Principles and Standards for School Mathematics* (2000) and/or the *Principles to Action* (2014). Any study that generally described EPTs learning through means such as peer or small group interactions, classroom discourse, modeling and representations, and/or problem solving tasks involving reasoning and sense making, among other elements, was considered to involve reform. Nineteen of the 24 studies were

identified as reform. In the remaining five studies, the pedagogical approach was either not described or was not clear.

Extended Analysis of Courses Involving Reform Pedagogy

Within the nineteen studies identified as using reform pedagogy in the courses, we found, among others, descriptors such as: the instructor acts as a facilitator; students work in small groups; students present their ideas to the class; manipulatives are used; and problems are used to build conceptual understanding, reasoning, and sense-making. Some studies included significant details about the instruction, while others were less forthcoming. In either case, the salience of this instructional focus is evident based on the large portion of the twenty-four studies that involved reform pedagogy (79%). Within these nineteen studies, ten focused on affective factors. Five of the ten examined change that occurred over a course or courses and four were descriptive. Seven of the nineteen studies focused on content knowledge, specifically its development. One of the nineteen examined affective factors and content knowledge, one compared two groups (one having a reform course and one that did not), while the remaining study focused on constructing classrooms norms and mathematical justification within a reform approach.

Studies Not Categorized as Using Reform Pedagogy

Three of the remaining five studies addressed specific areas of mathematics content (i.e., the associative property, order of operations, and polygons), but not within a reform course. All three of these studies were descriptive, relating EPTs' understandings. The two remaining studies explored affective factors. One studied the relationship between motivation to learn mathematics and attitudes toward mathematics and the second conducted a collective case study using data from two previous studies in which the researchers contrasted the EPTs and instructors' perspectives, looking for common themes and relationships. Table 3 displays reform and other instructional approach clustered by year.

Table 3: Clustering by year of the study and pedagogical approach

	1990-1994	1995-1999	2000-2004	2005-2009	2009-2014
Reform	2	3	2	4	8
Other			1	1	3

As evidenced in Tables 1-3, research on the mathematical preparation of EPTs has increased over the last 10 years, has predominantly employed a reform approach to instruction, and as noted earlier, was primarily done within a single course or sections of a single course. Quantitative only methods were employed least.

Space limitations prevent a detailed accounting of each of the 24 studies[1] in this paper. However, some additional summary findings are worthy of mention.

- Several studies across the time frame (e.g., 1996, 2004, 2007, 2014) using both qualitative and quantitative methods and occurring within a single course employing a reform pedagogical environment revealed EPTs generally developing positive affective stances.
- While positive impact of reform pedagogies was reported, there was also evidence of mixed results where EPTs showed some reform perspectives, but continued with some traditional perspectives (e.g., 1993, 2004, 2011, 2014).
- Some studies that employed reform approaches showed little to no change in the overall content knowledge of the EPTs (e.g., 1994, 2007, 2008).

Discussion

It is noteworthy that only 24 studies across the past 25 years were identified as meeting the inclusion criteria. Eleven of these studies (46%) were published during the last five years of the period of review, showing a recent increase in attention on the mathematical preparation of EPTs. This upturn is heartening, but given the importance of elementary teachers having a deep and flexible knowledge of elementary mathematics and that courses taken during teacher preparation offer the best opportunity for development of this knowledge, more inquiry is warranted.

Affective Factors

Of the 24 identified studies, 19 were in the context of courses involving reform pedagogy and more than half (10) of the 19 looked at affective factors. Overall, this review found that a reform instructional approach had positive effects and provided opportunities for constructive shifts in affective factors such as beliefs about mathematics, confidence, motivation, and attitudes. Specifically, six studies showed EPTs developed a positive perspective toward a reform approach to instruction, while three revealed a moderate effect and one showed almost no effect. Interestingly, this last study has the oldest publication date (1993), a time when focus on beliefs and affect was in its infancy.

The significant attention on teacher affect in the studies parallels the emphasis in the field of mathematics education over the time period and also provides credence to the assertion this teacher development construct is highly relevant to EPTs. That is, elementary teachers too often have negative affect toward mathematics, including a fear, dislike, and avoidance of the subject, and this propensity needs to be considered, addressed, and examined during university courses with the goal of affecting change. When considering learning experiences prompting change in teacher affect, the studies showed the use of problem-based instruction affording EPTs opportunities to invent their own solution strategies and engage in productive struggle, in addition to an emphasis on peer interactions, were efficacious.

Though course experiences promoted the desired changes in teacher affect to a degree, some studies noted that EPTs enter courses with such deeply rooted, negative affect that change was difficult and too often persisted at some level throughout and after the courses. Letting go of traditional perspectives on mathematics pedagogy learned over many years as students in classrooms was an arduous process and fraught with resistance. Results from two of the descriptive studies on teacher affect, one from the beginning of the time period (Civil, 1993) and one at the end of it (Chamberlin, 2013) support this assertion. We found that while the more recent group showed some change, both groups of EPTs, separated by a generation, exited their mathematics course still holding *some* traditional perspectives on what it means to teach and learn mathematics.

Content Knowledge

Further consideration of the focus of the identified studies showed an increased emphasis on research on content knowledge over the time period. Of the seven studies focusing on specific content knowledge in this group, four studies revealed improved content knowledge in courses involving reform pedagogy, while the remaining three did not achieve the desired effect. A few studies (some within a reform pedagogy and some that were not) focused on examining specific areas of content knowledge (e.g., fractions, nominal categorical data, ratio, polygons, order of operations, associative property of multiplication) that revealed mixed findings of EPTs learning. Research on more areas of elementary mathematics is clearly needed. Several studies lent credence to the importance of EPTs' understanding the relevance and usefulness of the mathematics learned in the courses, including explicit connections to the elementary classroom. However, one study found instructors and EPTs had conflicting viewpoints on such an emphasis (Hart, Oesterle, & Swars, 2013).

The overall shift in attention from affective factors (e.g., teacher affect, etc.) toward content knowledge is depicted in Figure 1. Over the time period 1989-2014, the percentage of studies focusing on content knowledge increased, while studies of affective factors remained relatively constant (Three studies are not included in this total.)
Figure 1: Changes in focus related to the EPTs.

This general trend aligns with the recognition of the need for elementary teachers to have well-developed mathematical knowledge, coupled with the efforts to define the mathematical knowledge needed for teaching (MKT).

Potential Implications

As more and more institutions of higher education require specialized mathematics content courses for EPTs, this analysis revealed certain elements of reform pedagogy generated positive changes. EPTs must have time and opportunities to think about, discuss, and explain mathematical ideas, coupled with a focus on mathematics as a sense making activity. Further, it is imperative EPTs perceive the relevance of the mathematics they are learning to their future profession. Emphasizing problem solving and other mathematical processes (Lubinski & Otto, 2004) and also studying children's thinking (Philipp et al., 2007) are effective mechanisms for promoting learning and change.

Different institutions of higher education include varying mathematics topics in their content courses for EPTs. Regardless of the specific content, an emphasis on problem solving, reasoning, and justification promotes EPTs' learning and change. For example, Liljedahl (2005) suggests that through posing problems, allowing substantial time for working on problems immediately after being assigned, providing time to revisit already assigned problems, working with peers in small groups, and engaging in a reflection about problems can positively transform EPTs' mathematical affect.

Further, while the ostensible purpose of a mathematics content course for EPTs is to learn mathematics, there are strong reasons to incorporate study of children's mathematical thinking into coursework (Philipp et al., 2007). Instead of trying to interest EPTs in mathematics for the sake of mathematics itself, providing connections to something to which they are fundamentally concerned, children, prompts motivation, learning, and change. Studying children's thinking challenges EPTs' beliefs about mathematics and leads to the recognition that their own mathematical understandings are insufficient for teaching elementary mathematics. Such an emphasis also helps EPTs appreciate how important it is for them to know the content for their future roles as teachers. The relevance of the mathematics they are learning to their chosen career path is evident.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Suggestions for Future Inquiry

Considerable challenges exist for reaching the desired goals for EPTs in mathematics content courses. In general, the findings of this analysis showed positive changes in teacher affect and content knowledge are possible within a reform approach to instruction. But, these changes were sometimes difficult to come by and often encountered resistance from the EPTs. Given the paucity of studies, more inquiry is needed, particularly on the aforementioned means of prompting learning and change (e.g., a focus on problem solving, studying children's thinking, etc.). In addition, longitudinal study over several courses or an entire teacher preparation program is warranted. Further, the sustainability of changes in EPTs as they graduate and become responsible for their own classrooms, and how or if such changes translate into classroom practices, are worthy of study. We note that some longitudinal studies may exist but were not the focus of this review. Likewise, EPTs' individual characteristics or capabilities should be examined in relation to change, given the findings of one study revealing mainly high mathematical achievers in the course significantly changed their beliefs (Emenaker, 1996), in contrast with the results of Philippou and Christou (1998), who found change was not-correlated with any of the individual characteristics tested, including mathematical performance.

As a final note, one concern from this review is the significant number of the original 89 studies that failed to incorporate all the elements of quality research and therefore were not considered to meet the criteria for this project. It is imperative that future research on the mathematics education of both elementary prospective and practicing teachers attains a level of rigor that will inform the field of mathematics education in a trustworthy and legitimate way. After 25 years of research in this area, we are still limited in definitive evidence of how to make a difference with this population of learners.

FACTORS RELATING TO THE DEVELOPMENT OF MATHEMATICS FOR TEACHING

Jennifer Holm	Ann Kajander	Jimmy Avoseh
University of Alberta	Lakehead University	Lakehead University
jdholm@ualberta.ca	ann.kajander@lakeheadu.ca	javoseh@lakeheadu.ca

This study investigated the effect of different aspects of mathematics knowledge for teaching on performance in upper elementary mathematics methods courses. In the Ontario (Canada) context, prospective teachers have been, until the 2015-2016 school year, able to obtain a Bachelor of Education (BEd) degree in as little as eight months after a different undergraduate degree, with most students taking no university mathematics courses whatsoever prior to the eight month BEd. We examined the effect of performance in a new course on mathematics for teaching as well as an exam in mathematics content, on performance in the methods course. Mathematics knowledge for teaching, as measured by the final grade in the mathematics for teaching course, was found to be a significant predictor of first semester methods course performance, with general content knowledge being less important.

Keywords: Mathematical Knowledge for Teaching, Teacher Education-Preservice, Teacher Knowledge

Introduction

At the time of this study, prospective teachers at our Ontario university would enroll in a one-year Bachelor of Education (BEd) program in order to be certified to teach. This program would occur after the candidates had completed another unrelated degree, such as a BA in History or English. The majority of the prospective teachers in our program have not taken any mathematics courses at the university level prior to entering the BEd program. Within our program, prospective teachers would graduate with a BEd after taking only one thirty-six hour mathematics Methods course. Since specialised mathematical knowledge of teachers has been directly linked to student achievement (Baumert et al., 2010), developing prospective teachers' mathematical understanding, in particular the understanding needed for teaching, is an important aspect of the education program we offer. With the limited number of hours we have to build these understandings, we have been concerned with what program developments we could put in place to increase the opportunity for knowledge development. One of the changes has been a Competency Exam taken by all prospective teachers in September at the beginning of their BEd year. This exam tests only content knowledge found in the elementary curriculum (Ontario Ministry of Education, 2005). More recently, a second program change was undertaken, which supports some of the candidates and is the focus of this research.

At our institution, there is one other way that prospective teachers can achieve their degree: through the Concurrent Education program. This means that they are accepted into the BEd program and their other degree at the same time. This allows for some education courses to be taken earlier, however the majority still occur in the one-year BEd program taken after their first degree is completed. The extra time, however, has allowed for us to institute one thirty-six hour Mathematics for Teaching course prior to the Methods course in the BEd program. The effect of this addition is that these students now have double the hours in mathematics courses particularly aimed at mathematics knowledge needed for teaching. Although this alternate route is an option for our prospective teachers, the majority of prospective teachers, however, do still enter the eight month BEd program after completing their first degree and thus miss the first Mathematics for Teaching course.

We were interested in the effects of these options on performance in the Methods course, hence,

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

this study examines the effects different types of mathematics knowledge (as developed through these various components of our program) have on the prospective teachers' understandings of mathematics as needed for teaching. Specifically, we examined the influence that the performance in the Mathematics for Teaching course, and the scores on the Mathematics Competency Exam, have on performance in the Methods course.

Framework

Since mathematics knowledge for teaching is not "just" a knowledge of subject matter (Baumert et al., 2010; Kajander, 2010; Silverman & Thompson, 2008), it is important that teacher knowledge includes a knowledge of students and of teaching mathematics. Simply stating a procedure or procedural steps would not be enough to show mathematical reasoning and support a claim when teaching (Ball & Bass, 2000); indeed mathematics for teaching is often described as including 'more' than the ability to perform standard procedures (Silverman & Thompson, 2008). In many descriptions of teachers' mathematical knowledge, the content a teacher needs may be something that goes beyond, or is somehow distinct from, what any non-teacher studying mathematics would need (Baumert et al., 2010; Ma, 1999). It has been further argued that such knowledge differs from the knowledge incoming prospective teachers typically possess (Chamberlin, Farmer, & Novak, 2008; Davis & Simmt, 2006; Kajander, 2010).

In our recent work we have sought to determine, describe, and unpack specific content pieces that we feel are critical to teacher mathematical capacity. In particular, we have found the models and modelling approach described in Lesh and Doerr (2003) fundamentally helpful in this regard. It is this approach that frames the content areas and approaches chosen for inclusion in the course textbook which was written especially for our Mathematics for Teaching course (see Kajander & Boland, 2014), and which guides the course activities. Developing a deep conceptual sense of elementary mathematics content based on models, relationships, and connections, and all interconnected with reasoning which might be applicable to classroom discourse, form some of the goals of our elementary mathematics courses for teachers. In particular, we strive to focus on the development of "how to gradually decompose and unpack the mathematical rules and operations through the use of representations, and knowledge of how to use representations to develop generalizations" (Mitchell, Charalambous, & Hill, 2014, p. 55).

The Mathematics for Teaching (MKT) model proposed by Ball and her colleagues (Ball, Thames, & Phelps, 2008) makes a distinction among different kinds of mathematical understandings held by teachers, such as the descriptions of 'pedagogical' and 'specialised' knowledge. While at times we find these distinctions have been blurred in our own work, they can be helpful in providing broad ways to describe different components of teacher knowledge. For simplicity in describing our current data, we make use of the terms from three of the categories of the MKT model, specifically, common content knowledge, specialised content knowledge, and the over-arching category of pedagogical content knowledge.

Ball, Thames, and Phelps (2008) begin their discussion of the different types of mathematics knowledge with an examination of common content knowledge (CCK). Based on their research, this knowledge is described as the general mathematics knowledge that any person studying mathematics would know. The Mathematics Competency Exam in our program is designed to test basic elementary school mathematics performance to the eighth grade level. However, the exam does not include items related to the use of models, multiple methods, or connections among ideas, all of which we see as crucial to teachers' knowledge. Rather, the test draws directly from our provincial grade eight mathematics curriculum document (Ontario Ministry of Education, 2005). Hence, for the purposes of the current analysis, we use the common content knowledge acronym, CCK, to refer to the grade in the September writing of this test (the 'Competency Exam'), as we feel it represents knowledge that all school students might be expected to develop. A sample item from the

Mathematics Competency Exam is provided in Figure 1.

A small 1 m^2 garden is to be planted with herbs. One-fourth of the garden will be chives and one-fourth parsley. Of the remaining portion of the garden, one-third will be basil, one-third will be thyme, and the rest will be sage. What fraction of the total garden is sage?

Figure 1. Sample Question from Mathematics Competency Exam.

The next piece of the MKT model that is pertinent to our study is that of specialised content knowledge (SCK; Ball, Thames, & Phelps, 2008). As described in the MKT model, this knowledge is special knowledge required of teachers, and goes beyond what an individual studying mathematics would require. This knowledge, however, does not depend on knowledge of students or knowledge of teaching; it is indeed 'mathematical'. Final course grades in the Mathematics for Teaching course were used as a measure of SCK. While a thorough analysis of every examination item from this course with the MKT framework has not been conducted, the overall descriptions from the literature of important elements of SCK do align well with our course objectives and assessment items, hence a global alignment is arguable. Our course focuses, for example, on models and reasoning about problems that would be important to teachers while in the field, however does not focus on pedagogy or knowledge of students. A sample item from the final course exam is shown in Figure 2.

The following pattern is made of toothpicks:

n: 1   2   3
- State a formal or function rule using "n" as the picture number, which determines the number of toothpicks needed for each picture. Redraw the third picture in the above pattern and use it to show how your rule relates to the pattern.

- State a different formal or function rule which relies on a different geometric way of grouping and counting the same pattern of toothpicks. Again redraw the third picture in the above pattern and use it to show how the new rule relates to the pattern.

Figure 2. Sample Item for Mathematics for Teaching Course.

Lastly, we look at one final aspect of the MKT model: pedagogical content knowledge (PCK). This aspect of the model includes sub parts of knowledge of content and teaching, and knowledge of content and students (Ball, Thames, & Phelps, 2008). Based on the MKT model, PCK includes knowledge of models and reasoning in relation to student understanding, including knowledge of typical student errors and so on. To measure this attribute, we used the grade in the Methods course from the fall semester course exam. Items on this exam include extensive use of models and reasoning (as do the Mathematics for Teaching course items), but also items related to typical student errors, misconceptions, and other topics drawn from the MKT model categories of PCK. Thus we use the over-arching name of PCK to refer to the aggregate of our items of this type, as found in the fall Methods course exam. Figure 3 provides a sample item from the Methods course exam.

Consider this problem for the questions below: 1 ⅓ ÷ ¼
- Student A believes the answer is 5 ⅓.
- Student B believes the answer is 5 $\frac{1}{12}$
Is either student correct? If so, which student is correct?
Using reasoning and models, show the thinking of each student that may have resulted in their solution for the question.

Figure 3. Fall Methods Course Exam Item.

Methods

Our study sought to further enhance our understandings of what and how previous experiences in mathematics for teaching, as grounded in the MKT (Ball, Thames, & Phelps, 2008) model, might support further development at the methods course level. We used a quantitative method design to search for relationships between the different factors in our program. We were interested in whether the kinds of specialised content knowledge taught in our Mathematics for Teaching courses were helpful in supporting the development of pedagogical content knowledge in our Methods course. We also examined if there were effects from the scores on the Competency Exam on the development of pedagogical content knowledge. For ease and familiarity, we have named the three variables using the MKT descriptors, as just explained. However, agreement with our naming is not required to examine the results – the names of the variables we term CCK, SCK and PCK could simply be replaced by the course components they respectively represent, which are the Competency Exam grade, the Mathematics for Teaching course final grade, and the Methods course first term exam grade.

Participants

All participants were prospective teachers in the thirty-six hour upper elementary mathematics Methods course. All participants in the Methods courses were asked to participate in the study, and most did (N=71 each year for each of two years). In both years, data were collected from all participants who volunteered during the Methods course. In particular, we were interested in whether each participant had previously taken the new Mathematics for Teaching course (which could have been taken in any previous year since 2010-2011), and if so, how well they did in it.

Descriptive statistics were first used to examine the variables PCK and CCK by separating the groups based on whether or not participants had enrolled in the Mathematics for Teaching course (the final grade in which was recorded as the SCK score). As mentioned, the grade on the Mathematics Competency Exam was used as a measure of CCK, and grades on the Professional year Methods course fall exam were used to measure PCK. Further quantitative analysis was conducted to explore the relationships of the two independent variables SCK and CCK, to see the impact on PCK. Relationships among these three variables were explored using independent t-tests as well as regression analysis. We used independent sample t-tests to compare the PCK as well as the CCK to determine differences between the two subgroups (those with SCK and those without). A regression analysis was also conducted on those who had taken the new Mathematics for Teaching course (SCK) to determine the effect of SCK and CCK on the fall methods exam (PCK).

Since all sections of the Methods course during the three year period were taught by the same instructor (first author) in a similar manner, and all of the previously taken Mathematics for Teaching courses had also been taught by a consistent instructor (second author), we chose to combine the quantitative data sets for both years. In total then, we collected performance data from a total of 142 prospective teacher participants, drawn from two cohorts of 71 participants. Of these 142 prospective

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

teachers, only 22 of the prospective teachers had enrolled in the Concurrent Education program and therefore only these 22 had taken the Mathematics for Teaching course.

Results

We began by examining the data collected from the 142 participants in our pool of prospective teachers. As mentioned, 22 of these had taken the Mathematics for Teaching course, and 120 had not, meaning they were registered in the stand-alone eight month BEd program. Thus the subgroup with an SCK score had 22 participants. Of the 142 examined in total, 10 (only 1 from the SCK sub-group) chose not to take the September write of the Competency Exam so did not have a CCK score. Of the 132 participants who took the Competency Exam (21 with a SCK score), 66 of them did not reach the 75% required "pass" score. Of this 66, 10 were in the SCK subgroup. All of the participants had a PCK score since all were enrolled in the Methods course.

Table 1: Percentage Means by Subgroup

Subgroup	CCK Mean score (%) (Competency Exam)	PCK Mean score (%) (Methods course exam)
SCK	74.867 (N=21)	76.500 (N=22)
No-SCK	68.622 (N=111)	67.700 (N=120)

Initial observations showed that the participants with SCK, meaning they had taken the Mathematics for Teaching course, did better in both CCK and PCK (see Table 1). Since 10 of the SCK group did "fail" the CCK ("Competency Exam") portion, further analysis was performed on examining the participants in the SCK sub-group (see Figure 4) to explore this situation further. Only 21 participants are included in the graph since 1 did not have a CCK score. Prospective teachers are given the option of challenging the Competency Exam in September of their BEd year. They are encouraged to take the exam at this time in order to set goals for areas of content that they need to work on prior to taking the exam in March where a score of less than 75% would mean they do not get their BEd degree. Most prospective teachers do choose to the take exam in September for this reason.
Figure 4. Graph of SCK Participants' Percentage Scores, N=21.

Examining the graph of the performance of each of the 21 participants for whom we had all three scores, suggests that the scores for SCK and PCK were more closely clustered for more of the participants than the CCK scores. (The lines joining the points are illustrative only; the actual dataset is comprised only of the three scores for each separate person (numbered 1 to 21)).

When examining the relationship for participants with and without SCK on the fall Methods course exam (PCK), Levene's Test for Equality of Variances showed there was no significant

variance between the subgroups. Therefore, an independent t-test was run on the data as well as 95% confidence intervals (CI) for the mean difference. It was determined there was a significant difference in results of PCK between those who had taken the Pre-professional year Mathematics for Teaching course (SCK) and those who had not ($t(138) = -2.472$, $p = .015$) with a difference of -8.196 (95% CI, -14.752 to -1.64). When subsequently examining the relationship for participants who had taken the new Mathematics for Teaching course (SCK) and those who had not, on the Mathematics Competency Exam (CCK), Levene's Test for Equality of Variances determined there was significant variance ($p = .010$) between the subgroups. Therefore, an independent t-test was run on the data and equal variances were not assumed, as well as 95% confidence intervals (CI) for the mean difference was also determined. It was determined there was a significant difference in results on the Competency Exam (CCK) between those who had taken the new Mathematics for Teaching course and those who had not ($t(55.006) = -2.581$, $p = .013$) with a difference of -2.813 (95% CI, -.629 to -4.997).

Table 2: Regression Model

Predictor of Methods course exam	Beta	Sig.
Competency Exam (CCK)	.265	.099
Mathematics for Teaching course (SCK)	.662	.000

R = .797, R squared = .634, N = 21

The regression model showed a highly statistically significant ($R^2 = 0.632$, $p = .000$) prediction of the fall Methods exam (PCK) when examining the participants who had taken the new Mathematics for Teaching course (SCK). It was determined that 63% of the variance on the fall exam (PCK) could be explained by the two factors. For this model, SCK ($\beta = 0.0662$, $t(18) = 4.333$, $p=.000$) significantly predicted scores on the fall Methods exam (PCK), while CCK ($\beta = 0.265$, $t(18) = 1.737$, $p = .099$) was not significant. Scores in the new Mathematics for Teaching course (SCK) had a greater impact on the fall Methods exam (PCK) scores (see Table 2).

Discussion

The data may shed some further light on the impact and importance of different aspects of mathematics knowledge on the development of pedagogical content knowledge. While one perception might be that learning about contexts, models and reasoning in elementary mathematics might best be done in methods courses (rather than 'mathematics' courses), we continue to argue for the crucial need for such learning during *mathematics* courses for teachers, in order to better support what can be subsequently achieved during methods courses. The current data may support such an assertion. Indeed, Mitchell, Charalambous, and Hill (2014) argue that an understanding of models and reasoning is an area particularly in need of support for many teachers.

The results suggest that the Competency Exam, used in the current analysis as a measure of CCK, had a relatively weak impact on performance at the Methods course level. We argue that "knowing the curriculum", particularly the more computationally-related aspects, is far from sufficient for teaching. Certainly, our previous qualitative observations of participants during the Methods course suggest that the more specialised the background of the participants, the greater the strides they may be able to make in terms of PCK development (Holm & Kajander, 2012). Without such conceptual understanding, learning about structuring a lesson to explore mathematical concepts is impossible; teachers are left with a rule-based treatment as their only lesson option. Indeed, we have found that prospective teachers without previously-developed knowledge of how to understand and represent mathematical content (SCK) are so significantly distracted by the mathematical challenges that they are often less involved in the pedagogical conversation taking place. Hence we find that while more knowledgeable Methods course participants are having discussions regarding

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

lesson design, student responses, typical errors, and so on, the participants with weaker SCK are typically focused mainly on the mathematical concepts, missing out on the other ideas. This suggests that those with weaker SCK may well have reduced opportunities to develop PCK, and aligns with the results presented here. Hence the current results accurately reflect our anecdotal experiences while teaching the Methods course, regarding the importance of SCK in pedagogical development during elementary teacher education.

The study results suggest that the impact of a specialised course in mathematics for teachers, (SCK), does impact Methods course performance (arguably termed PCK here) in a highly significant way, and thus underscore the need for continued emphasis on *specialised* mathematical experiences for teachers. Generally, participants who did well in the Mathematics for Teaching course tended to do well in the Methods course, and additionally were also observed informally to demonstrate deeply pedagogical understandings during Methods course classes. In particular, several participants who had taken the Mathematics for Teaching course prior to beginning the Methods course and had done very well, both began and ended the Methods course in a very strong position. As course instructors, we observed generally that evolving confidence in the specialised mathematics seemed tightly aligned with pedagogical mastery. This data provides further support of the mounting evidence that it is the more conceptual and specialised mathematical knowledge that supports better teaching rather than only more general mathematics knowledge. The results also align with the Baumert et al. (2010) study, which found that the degree of teaching-specific mathematics knowledge of early secondary level classroom teachers made a measureable difference on student achievement, while general mathematics background of teachers did not.

At the institution where this study took place, there is a continued sense by non-mathematics education faculty and administration that specialised content knowledge, such as knowledge of models and reasoning, should be contained in Methods courses, rather than being thought of as 'mathematics'. Based on the MKT (Ball, Thames, & Phelps, 2008) model, and our own data, we continue to argue for the need for *mathematical* experiences specialised to teaching, in order to support richer pedagogical development. The data presented here contribute to such a stance.

The present study extends recent advances coordinating research on cognition and psychometric modeling around fractions. Recent research has demonstrated that the Diagnosing Teachers' Multiplicative Reasoning Fractions survey provides information about distinct components necessary for reasoning in terms of quantities when solving fraction arithmetic problems. The present study (a) adds a new component of validity for the survey and (b) examines the utility of the survey as a measure of growth in pre-service middle-grades teacher's facility with fraction arithmetic as they completed a 1-semester content course. Results provide an existence proof that that the survey is sensitive to shifts towards more proficient reasoning.

Keywords: Rational Numbers, Research Methods, Teacher Education-Preservice, Teacher Knowledge

One central challenge for mathematics education is fostering teachers' and students' capacities to reason about multiplicative relationships in terms of quantities. Relevant topics include whole-number multiplication and division, arithmetic with fractions, proportional relationships, and linear functions. Reasoning with quantities is emphasized in recent curriculum standards documents (e.g., Common Core State Standards Initiative, 2010; National Council of Teachers of Mathematics, 2000) and recommendations for teacher education (e.g., American Mathematical Society, 2010; Sowder et al., 1998). These standards and recommendations place high value on developing conceptual understanding by solving and reflecting on solutions to problems couched in quantities.

A second central challenge is developing ways to coordinate research on cognition with the increasing variety of available psychometric models (e.g., Izsák, Remillard, & Templin, in press). As explained below, most recent applications of psychometric models to mathematics education research, especially to research on teachers, have relied on well-established item response theory (IRT) models to measure knowledge. These models report single scores that locate examinees on uni-dimensional continuous scales. A recently developed family of psychometric models, called diagnostic classification models (DCMs), trade continuous for categorical variables in exchange for measuring multiple dimensions within practical testing conditions. Instead of reporting single scores, DCMs report profiles of strengths and weaknesses on several dimensions simultaneously. Bradshaw, Izsák, Templin, and Jacobson (2014) reported on the Diagnosing Teachers' Multiplicative Reasoning (DTMR) Fractions survey that was developed for use with DCMs and measures teachers' capacities to reason about multiplication and division of fractions in terms of quantities. That study reported on content and item-level validity of the survey and results of analyzing a national sample of 990 in-service middle grades teachers.

The present study extends research on the DTMR Fractions survey by applying it directly to mathematics teacher education. In particular, we administered the survey at the beginning and end of a 1-semester content course focused on arithmetic with rational numbers and asked two questions:

1. To what extent were the DTMR Fractions profiles consistent with pre-service teachers' reasoning across multiple survey items and related tasks?
2. Did the distribution of DTMR Fractions profiles shift after the 1-semester course on number and operations and, if so, how?

The first question addresses additional aspects of validity not taken up by Bradshaw et al., and the second question asks what growth and change might be captured by the DTMR Fractions survey that would be obscured by measures designed for uni-dimensional IRT models.

Measuring Teachers' Mathematical Knowledge for Fraction Arithmetic

In the last 2 decades, researchers have made important advances conceptualizing teacher knowledge that supports student learning. Well-known examples include Shulman's (1986) knowledge categories, especially pedagogical content knowledge, and Ball and colleagues' (e.g., Ball, Thames, & Phelps, 2008) subsequent articulation of mathematical knowledge for teaching (MKT). New conceptualizations of teacher knowledge have spurred, in turn, new approaches to measuring teachers' mathematical knowledge (e.g., Baumert et al., 2010; Hill 2007; Kersting, Givven, Sotelo, & Stigler, 2010; Saderholm, Ronau, Brown, & Collins, 2010; Shechtman, Roschelle, Haertel, & Knudsen, 2010). Most of these measures have been developed for use with traditional, uni-dimensional IRT models.

In contrast to the teacher knowledge measures mentioned above, the DTMR Fractions survey captures information about four components for reasoning about fraction multiplication and division in terms of quantities. The solution outlined to the following problem illustrates what we mean by components of reasoning:

> A batch of brittle calls for ¼ of a cup of honey. Megan has 2/3 of a cup of honey. How many batches of brittle can Megan make?

The solution we present presumes a teacher providing opportunities for students to solve fraction division problems before learning a general numeric method, such as multiplying by the reciprocal of the divisor. Thus, the teacher and students have to reason with quantities directly, which is consistent with the curriculum standards and recommendations for teacher education mentioned above.

First, to see the opportunity for discussing division, a teacher would have to recognize that the Brittle problem asks the signature how-many-groups question for measurement division. To support students' reasoning with quantities in the problem, some drawn model would be useful. The rest of the solution we present makes use of double number lines, but our larger points are not dependent on this choice of drawn model. Figure 1a shows a double number line that uses lengths to depict cups of honey. One number line represents cups subdivided into thirds, and one represents cups divided into fourths. Juxtaposing the two number lines highlights the challenge that fourths and thirds do not subdivide one another evenly. Figure 1b illustrates how partitioning thirds into 4 parts and fourths into 3 parts creates a finer unit, twelfths, which subdivide both thirds and fourths. The final challenge is to interpret the mini-pieces in terms of the given situation. There are multiple candidates, including interpreting one mini-piece as a twelfth of 1 cup, as a fourth of 1/3 cup, and as a third of ¼ cup. Because the problem asks about the number of ¼ cups in 2/3 cups, ¼ cup is the appropriate referent unit: There are 8/3 ¼-cups in 2/3 cups.

This is not the only solution to the Brittle problem, but it does illustrate that constructing a solution requires multiple, constituent components of reasoning. The given solution highlights the ability to (a) recognize the appropriateness of an arithmetic operation for modeling a given problem situation, (b) use whole-number factor-product combinations as a resource for partitioning quantities, and (c) identify appropriate referent units for each number. A measure of knowledge for this domain designed for traditional, uni-dimensional IRT models would collapse information about these different components into a single score.
Figure 1. Reasoning with a double number line.

The DTMR Fractions survey consists of 27 items that measure these three components (termed appropriateness, partitioning and iterating, and referent unit, respectively) and one more, reversibility, which is important for solving partitive division problems. Some items measure just one of the four components, referred to as attributes. Other items measure more than one attribute at the same time. Nineteen of the items are multiple choice, and eight are constructed response. Figure 2 shows a released item that measures two attributes simultaneously: Selecting the correct answer choice, b, requires identifying the correct referent unit for 1/8 and partitioning intervals appropriately. The DTMR Fractions survey systematically elicited combinations of the four target attributes and was designed for use with DCMs, which report profiles of strengths and weaknesses on the multiple attributes instead of single scores on one overall dimension.

Ms. Roland gave her students the following problem to solve:

Candice has 4/5 of a meter of cloth. She uses 1/8 of a meter for a project. How much cloth does she have left after the project?

She had students use the number line so that they could draw the lengths. Which of the following diagrams shows the solution? Assume all intervals are subdivided equally.

Methods

Data for the present report come from a larger on-going study of pre-service teachers' reasoning about multiplication and division, fractions, and proportional relationships. We administered the DTMR Fractions survey to a cohort of 22 pre-service middle-grades mathematics teachers before and

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

after a number and operations content course offered in Fall 2014. The course was part of a teacher education program in a large, public university in the Southeast United States and emphasized reasoning with quantities to develop conceptual understanding of multiplication and division with whole numbers and with fractions. A following algebra course, offered in Spring 2015, focused on proportional relationships and linear equations. Beckmann taught both courses. For the present report, we focus on data from the number and operations course.

The pre-service teachers completed the DTMR Fractions survey for the first time as the first homework assignment in the number and operations course (August 2014). They were told that the survey was a formative assessment and that they should simply do their best. Bradshaw analyzed the survey data (item responses) to estimate DTMR Fractions profiles for all 22 pre-service teachers. Given the size of the national sample ($n = 990$), the DCM analysis was limited to treating each attribute as a dichotomous variable. Bradshaw then selected six pre-service teachers with a variety of initial profiles to be focal participants for this study. She revealed the overall distribution of DTMR profiles to Izsák and Beckmann but not profiles for particular individuals. Thus, Izsák and Beckmann were blind to the profiles until the end of the study.

Izsák and Beckmann then conducted a series of six individual video-recorded interviews with each of the six focal participants. The interviews began during the number and operations course and continued into the algebra course. In addition to the interviews, we collected written artifacts (e.g., homeworks, quizzes, and tests) from all pre-service teachers in the course. The pre-service teachers completed the DTMR Fractions survey for the second time as the first homework assignment in the algebra course (January 2015). Bradshaw analyzed the item responses to estimate DTMR Fractions profiles again for all 22 pre-service teachers, but still reported only the overall distribution of profiles, not those for specific individuals.

Within 1 week after the pre-service teachers completed the DTMR Fractions survey for the second time, Izsák interviewed each of the six focal participants about their item responses. This was the third in the series of six interviews. Because the DTMR Fractions survey takes about 1.5 hours to complete, Izsák and Beckmann selected a subset of the items to address each of the four attributes, referent unit, partitioning and iterating, appropriateness, and reversibility. During the first half of the interview, Izsák went through the selected items and limited follow-up questions to ones like *How did you interpret the problem?*, *Why did you select the choice you did?*, and *For what reasons did you reject alternate choices?* He made clear that the pre-service teachers could change their answers if they wanted. Thus, the interview data were more reliable for inferring the focal participants' thinking at the time of the interview, not when they completed the survey for homework. (At the same time, the pre-service teachers did not experience instruction between completing the survey for homework and the interview that would have provided additional practice with the four attributes.) During the second half of the interview, Izsák took a second pass through the same items and asked more extensive follow-up questions. He also presented additional tasks not part of the DTMR Fractions survey to gather further information about the participants' use of the four attributes. Each interview lasted about 80 minutes.

Izsák and Beckmann then analyzed the interview data to diagnose profiles. For each participant, they analyzed the interview data item-by-item listing evidence for and against mastery of each attribute. (The term *mastery* comes from the psychometric literature, which we take as a synonym for *proficiency*.) They also included a category called "other comments." Izsák and Beckmann included evidence for and against mastery wherever they found it both in the first and the second halves of the interviews. Izsák and Beckmann first watched the interviews separately and then together to compare notes. Discrepant interpretations were discussed until resolved. Once Izsák and Beckmann had discussed the entire video, they looked at all evidence for and against mastery of each attribute. They used a 1 to indicate mastery, a 0 to indicate non-mastery, and X to indicate cases where there was too little evidence or there was a balance of contrary evidence for and against mastery of a particular

attribute. Thus, Izsák and Beckmann allowed themselves more flexibility in diagnosing profiles than was permitted in the DCM analysis. Izsák and Beckmann gave their expert diagnoses for all six focal participants to Bradshaw, who then revealed the profiles as determined by the DCM analysis.

Finally, we underscore that we take the diagnosis of attribute mastery (indicated by a 1) to mean that the person uses that particular attribute fairly consistently across situations. In contrast, we take a diagnosis of non-mastery (indicated by a 0) to simply mean that there was a lack of evidence for a particular attribute. This is not the same as saying a person does not "have" the attribute: A person might have but not demonstrate a particular piece of knowledge, even across multiple tasks, for a variety of reasons.

Results

Our first research question asked to what extent were the DTMR Fractions profiles consistent with pre-service teachers' reasoning across multiple survey items and related tasks? Answering this question extends prior research that focused on content and item-attribute validity of the DTMR Fractions survey. Content validity, that is confirming that the DTMR Fractions items did indeed address important aspects of reasoning about fraction arithmetic in terms of quantities, was established by six external reviewers (four mathematicians and two mathematics education researchers) who examined the items and a document explaining the four attributes. Item-attribute validity, that is confirming that each item addressed the intended attributes, was established through interviews with teachers as part of the item development process and confirmed by DCM analysis of item response data from the large national sample. Because teacher interviews focused only on a subset of items as part of the item development process, and before the national sample was collected, there was no way diagnose their profiles either through expert analysis of interview data or statistical analysis of item response data.

The interview data afforded comparison of profiles as diagnosed by experts (Izsák and Beckmann) reviewing performance across multiple tasks and as diagnosed by analyzing item responses using a DCM. When considering places where expert and DCM diagnoses did and did not align, it is important to remember that each was based on overlapping but not identical information. Expert diagnoses were based on a subset of item responses, item responses revised during the interview that might indicate false positives or negatives, and information from the second half of the interviews that contained additional tasks not on the DTMR Fractions survey. DCM diagnoses were based on responses to the complete set of survey items and statistical information about item characteristics.

Table 1 shows profiles for the six focal participants as diagnosed with the DCM analysis before and after the number and operations content course and as diagnosed by Izsák and Beckmann based on the interview described above. Each string indicates a diagnosis of mastery (1), non-mastery (0), or uncertain mastery status (X) for the four attributes in the following order: referent unit, partitioning and iterating, appropriateness, and reversibility. Given six participants and four attributes, Izsák and Beckmann considered 24 diagnoses. They assigned a 1 in 10 cases, a 0 in 7 cases, and an X in the remaining 7 cases. Of the 17 cases where they assigned a 1 or 0, their diagnoses and the profiles Bradshaw generated with the DCM analysis agreed in 13. The four discrepancies were concentrated in two pre-service teachers, Alex and Diana, and we explain them as follows. Based on explanations Alex provided during her interview, Izsák and Beckmann judged several of her incorrect responses to partitioning and iterating items and reversibility items to be false negatives. Thus, they attributed mastery of these attributes where the DCM analysis did not. For Diana, both the expert and the DCM diagnoses with respect to referent unit were ambivalent. The DCM diagnosis indicated a probability for mastery of about .6 (probabilities greater than .5 are assigned mastery in the DCM model) and tilted one direction; the expert diagnosis tilted the other direction. Finally, Izsák and Beckmann judged several of Diana's incorrect responses to partitioning

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

and iterating items to be false negatives, leading to an expert diagnosis (mastery) that disagreed with the DCM diagnosis (non-mastery). Of the 7 cases where Izsák and Beckmann assigned an X, indicating uncertain mastery status, the DCM analysis diagnosed mastery in 5 cases and non-mastery in 2 cases. In part, these differences reflect the fact that Izsák and Beckmann were conservative in diagnosing mastery.

These results indicate significant consistency between the expert and DCM diagnoses, especially when, as stated above, we interpret non-mastery to mean lack of evidence for a particular attribute. The consistency gives us increased confidence that DTMR Fractions profiles do, in fact, reflect relative strengths and weaknesses in reasoning about fraction arithmetic in terms of quantities. Confidence in profiles was critical for our second research question.

Table 1: Focal Profiles Before and After the Number and Operations Course

	DCM Diagnosis Pre: August 2014	DCM Diagnosis Post: January 2015	Expert Diagnosis (Post)
Alice	[0000]	[0000]	[0101]
Jack	[0000]	[0000]	[000X]
Linda	[0111]	[1111]	[11X1]
Claire	[1111]	[1111]	[X111]
Diana	[0001]	[1001]	[01X1]
Kelly	[0000]	[1011]	[X0XX]

Our second research question asked whether the distribution of DTMR Fractions profiles shifted after the 1-semester course on number and operations and, if so, how? This question is important because a primary motivation for developing the DTMR Fractions survey was to create an instrument sensitive to diversity in reasoning and shifts in that reasoning. Figure 3 shows a significant shift in the distribution of profiles before (Fall 2014) and after (Spring 2015) the number and operations course. In Fall 2014, 9 of the 22 pre-service teachers were diagnosed as masters of none of the attributes and only three were diagnosed as masters of referent unit. In Spring 2015, while 6 of the pre-service teachers still did not demonstrate mastery of any one of the four attributes, 7 more demonstrated mastery of all four attributes. Furthermore, comparing profiles before and after for each of 22 pre-service teachers revealed that 13 moved to profiles with additional mastered attributes and that all pre-service teachers who demonstrated mastery of at least two attributes at pretest demonstrated mastery of all four attributes at posttest.

Furthermore, the acquisition of additional attributes reflected what was emphasized to greater and lesser extent in the number and operations content course. In particular, Beckmann placed less emphasis on using whole-number factor-product combinations as a resource for partitioning and iterating. Of the 16 pre-service teachers who had not mastered partitioning and iterating at the inception of the course, 5 (~31%) had mastered and 11 had not mastered this attribute at posttest. Meanwhile, overall gains on the remaining three attributes, which were given more attention in the course, were higher. Of the 19 pre-service teachers who had not mastered referent unit at the inception of the course, 10 (~53%) had mastered and 9 and not mastered this attribute at posttest. Of the 16 pre-service teachers who had not mastered appropriateness at the inception of the course, 7 (~43%) had mastered and 9 had not mastered this attribute at posttest. Of the 9 pre-service teachers who had not mastered reversibility at the inception of the course, 4 (~44%) had mastered and 5 had not mastered this attribute at posttest.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 3. Distribution of DCM profiles before and after the Number and Operations content course.

We draw three main conclusions from these results. First, the shift in profiles from Fall 2014 to Spring 2015 behaved appropriately in the sense that in all but two cases when profiles shifted, pre-service teachers gained attributes. (In the two exceptions, pre-service teachers who demonstrated mastery only of reversibility on the pretest demonstrated mastery of no attributes on posttest). Second, the shift in profiles suggest that many pre-service teachers who entered the numbers and operations course demonstrating mastery of no attributes faced significant challenges developing all four components of reasoning with quantities. Teachers who had facility with at least some of these components tended to master the remaining ones during the course. Third, that shifts in profiles were consistent with what was given more and less emphasis in the course suggests that shifts in profiles reflected the pre-service teachers' opportunities to learn or develop different components of reasoning measured by the DTMR Fractions survey.

Discussion

The present study contributes to the development, validation, and application of measures that capture information about moment-to-moment mathematical reasoning, and does so in the critical mathematical domain of fraction arithmetic. We demonstrated (a) considerable agreement, or convergent evidence, between expert and DCM diagnoses of the four DTMR fractions attributes, and (b) that when pre-service teachers' profiles shifted, they added attributes in ways that reflected the mathematical emphases of their number and operations course. These results demonstrate the possibility of measurement that gets closer to moment-to-moment reasoning than can be captured by a single, summative score. In particular, we have used a survey consisting primarily of multiple-choice items to compare teachers in ways more nuanced than ordering them along a single dimension from less to more able or knowledgeable. Approaches like the one we report have the realistic potential of providing diagnostic information to teacher educators about those components of reasoning with which teachers are more and less facile. This can be useful formative and summative information. Future studies will be needed to see if our results generalize to other cohorts of pre-service teachers and other number and operations courses. Finally, although the present study is situated in teacher education, the potential benefits of multi-dimensional measurement extends to students as well.

We used the Multicultural Mathematics Dispositions (MCMD) framework to analyze preservice teachers' (PSTs) dispositions to teach diverse student populations during a cultural awareness unit in a mathematics methods course. The framework is defined as a function of three constructs: openness, self-awareness/self-reflectiveness, and commitment to culturally relevant mathematics teaching. We selected two assignments from the unit as our data sources. Using the framework, we analyzed the ways in which PSTs expressed any of the MCMD constructs in each of the assignments. Our analysis found that self-awareness/self-reflectiveness was the most common dispositional construct expressed by the PSTs, which led to their openness. However, few PSTs committed to using culturally relevant pedagogy in their future classrooms. Additional coursework may be needed to prepare PSTs to teach culturally diverse student populations.

Keywords: Teacher Education-Preservice, Equity and Diversity

Introduction

As the number of Black and Hispanic students, English Learners (ELs), and students living in poverty enrolled in U.S. public schools continues to increase (Kena et al., 2014), preservice teachers (PSTs) need to be prepared to work effectively with all students. Several mathematics teacher educators (MTEs) agree that it is important for PSTs to learn how to recognize and build on students' cultural and mathematical backgrounds to meet the needs of an increasingly diverse student population (Foote et al., 2012; Gutiérrez, 2009; Kitchen, 2005; Leonard, 2008). PSTs need to be made aware of the relationship between culture and learning and the way mathematics classroom cultures act as a context that supports or constrains different forms of knowledge (Gutiérrez, 2013; Nasir & Cobb, 2007). Being aware of culture and how it interacts with learning is especially important in the mathematics classroom because mathematics is typically thought of as a subject that is culture free (Nasir, Hand, & Taylor, 2008). MTEs can help PSTs examine their beliefs about mathematics and mathematics pedagogy, and learn that mathematics classrooms are places of enculturation where certain social norms and practices are valued, while others are considered inadequate (Diversity in Mathematics Education Center for Learning and Teaching [DiME], 2007). MTEs can also help PSTs "take into account the diverse ways in which students understand and see mathematics rather than automatically discarding them as deficient or inappropriate simply because they are different from their ways of thinking" (White, DuCloux, Carreras-Jusino, Gonzalez, & Keels, 2016, p. 164). This requires PSTs to have a disposition that is conducive to teaching mathematics to diverse populations.

Conceptual Framework

Mathematics teachers' dispositions "are critically important because they underlie distinctions teachers are likely to make in moment-to-moment classroom activity" (Hand, 2012, p. 234). These dispositions play an important role in teaching practices and effectiveness. Thornton (2006) has asserted that it is imperative for teacher educators to find ways to develop PSTs' dispositions toward

multiculturalism. She defined dispositions as "habits of mind including both cognitive and affective attributes that filter one's knowledge, skills, and beliefs and impact the action one takes in classroom or professional setting" (p. 62). White, Murray, and Brunaud-Vega (2012) argued that "teacher disposition can provide a more comprehensive perspective towards the construction of a teacher's identity in the context of a multicultural classroom" (p. 33). Thus, PSTs need to develop culturally sensitive/critical dispositions in mathematics, which White et al. (2012) call *multicultural mathematics dispositions* (MCMD). The MCMD framework is defined as a function of three dispositional factors: openness, self-awareness/self-reflectiveness (SA/SR), and commitment to culturally relevant mathematics teaching. *Openness* is receptiveness to the role of culture in teaching and learning mathematics. It includes being open to (a) others' cultures in perceptions about teaching, learning, or doing mathematics; (b) the inclusion of culture in mathematics classrooms; and (c) the use of culturally relevant strategies to teach mathematics (Ladson-Billings, 1995). *Self-awareness/self-reflectiveness* is understood as (a) identification of one's own culture and perception of the differences between it and another culture, (b) awareness of one's own beliefs about the influence of culture on teaching and learning mathematics or mathematics classroom culture, and (c) the ability to think critically about those issues. *Commitment to culturally relevant mathematics teaching* is the explicit intention of teachers to use culturally relevant strategies in the classroom.

The constructs of MCMD enable researchers to characterize and analyze PSTs' dispositions to work with diverse student populations. Thus, we examined PSTs' MCMD during a cultural awareness mathematics unit we designed for mathematics methods courses (White et al., 2016). The research question guiding the study presented here is: How does the MCMD framework unveil PSTs' dispositions to teach culturally diverse students?

Methods

Participants

Three cohorts of PSTs who participated in the unit were enrolled in three different mathematics methods courses (*Elementary Mathematics Methods II*, *Middle Grades Mathematics Methods I*, and *Secondary Mathematics Pedagogy II*). Of the 60 PSTs, 48 were White females, 2 were Black females, 1 was a Black male, and 9 were White males. The distribution of the 60 PSTs enrolled in the three methods courses is shown in Table 1.

Table 1: Distribution of Preservice Teachers by Cohort, Race, and Gender

Cohort	White Males	White Females	African American Males	African American Females	Total
Elementary	1	26	0	1	28
Middle Grades	3	12	1	0	16
Secondary	5	10	0	1	16
Total		57		3	60

Cultural Awareness Unit

The goals of the cultural awareness unit were to help PSTs become aware of (a) the roles of teachers' cultures, students' cultures, and mathematics classroom cultures in students' mathematical learning; (b) stereotypes about who can do mathematics; and (c) strategies for infusing culture in mathematics classrooms. In particular, the cultural awareness unit encouraged PSTs to reflect on their own views about culture and to challenge borders that limit diverse students' access to mathematics in classrooms. We used Dumitrescu & Iacob's (2012) definition of *cultural awareness* as "recognizing that all people do not have the same cultural background. It signifies one's ability to stand back from oneself and become aware of both one's own culture and another's culture, i.e.

cultural values, beliefs, perceptions" (p. 122). The unit included an *Article Critique* (article search and reflection), *Class Discussions*, and a *Post Reflection* (post-discussion reflection). Table 2 details how each component is related to the MCMD constructs.

Table 2: Components of the unit and corresponding tasks

Component	Tasks	Development of MCMD
Article critique	▪ Search for an article and write a reflection about teaching or learning mathematics to students who are culturally different than themselves	▪ Self-awareness by identifying their own culture and comparing to others. ▪ Openness by learning culturally relevant strategies. ▪ Openness by learning how others do mathematics.
Class discussion	▪ Share cultures and strategies discussed in article. ▪ Define culture and create cultural tool list. ▪ Discuss how culture relates to mathematics classrooms norms. ▪ Discuss differences between stereotypes and generalization.	▪ Openness as defined above. ▪ Self-awareness/self-reflectiveness by reflecting on personal culture and experiences in the mathematics classrooms.
Post Reflection	▪ Write reflection on unit	▪ Openness and self-awareness as defined above. ▪ Commitment by encouraging them to adopt culturally relevant strategies.

Data Sources and Analysis

Data were collected from the PSTs' *Article Critique* and *Post Reflection* assignments. It should be noted that all the participants submitted the Article Critique, but only 56 of the 60 PSTs submitted the final assignment. A framework analysis (Ward, Furber, Tierney, & Swallow, 2013) method was used to analyze the data. Our analysis looked for patterns across the data sources to identify qualitative instances of PSTs' MCMD. As a group, we read through the papers several times and coded sections of text according to whether they demonstrated openness, SA/SR, and/or commitment. Next, we reread the coded passages to further characterize the PSTs' MCMD. More specifically, we wanted to know in what ways PSTs were open and SA/SR and what they were committed to doing in their future classrooms. Throughout the coding process, we discussed any discrepancies or questions until we reached consensus.

Results

We were able to identify the presence of MCMD constructs in contributions from most of the PSTs. As shown in Figure 1, our analysis of the *Article Critique* unveiled openness in 26 PSTs, SA/SR in 46 PSTs, and commitment in 6 PSTs. By the end of the unit, analysis of the *Post Reflection* showed evidence of openness in 42 PSTs, SA/SR in 16 PSTs, and commitment in 8 PSTs. We were unable to characterize any of the MCMD constructs in 12 PSTs and 7 PSTs for the *Article Critique* and *Post Reflection*, respectively. What follows are examples of the PSTs' MCMD for the two assignments.

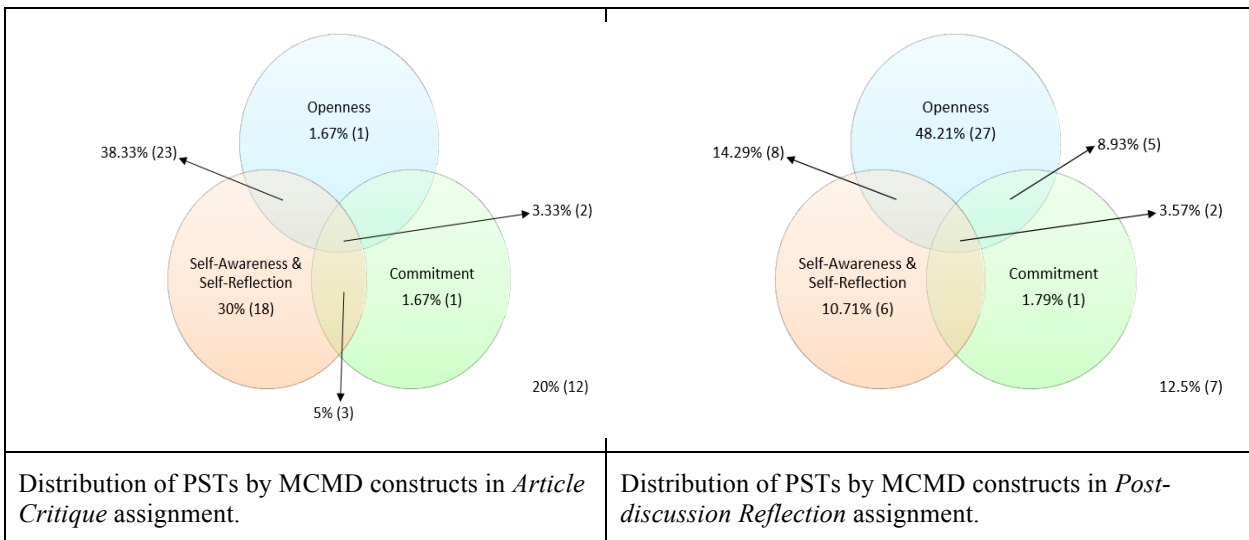
| Distribution of PSTs by MCMD constructs in *Article Critique* assignment. | Distribution of PSTs by MCMD constructs in *Post-discussion Reflection* assignment. |


Figure 1. Distribution of PSTs by MCMD constructs.

Article Critique

The article critique was completed before the class discussion in order to limit our influence on PSTs' views on culture and mathematics. By asking PSTs to read about teaching and learning mathematics to culturally diverse students and to reflect on their own cultures, we were able to unveil aspects of PSTs' MCMD.

Openness. The majority of the PSTs were open to learning and including culturally relevant strategies to teach diverse students. A comment from Eva, an elementary PST, illustrates this form of openness:

> I need to learn ways in which I can reach students who are culturally different from me. In fact, I think this strategy could be used for children of all cultural types. Having students create their own math problems that relate to their experiences not only helps them remember how to solve the problems, but lets the teacher get to know the students and what they are interested in.

Several PSTs were open to the idea that culture has a role in the way people do and learn mathematics. The article critique assignment helped them realize that there is no one way to do mathematics and that different students may think about mathematics differently. For instance, Joyce, an elementary PST wrote,

> I was under the mistaken impression that numbers are just numbers, the same everywhere. The article pointed out, however, that symbols are often different in other languages, and words that we use to describe actions in math may be confusing, unfamiliar, or misleading ... Now that this has been brought to my attention, I will give it a lot more consideration as I am learning to be a teacher.

Self-awareness/self-reflectiveness. Most PSTs expressed awareness of aspects of their own culture and how these aspects differed from the cultures described in the article. Their comparisons focused on differences across race (White vs. Black and Hispanic), class (Upper middle class vs. Poor), and geography (Suburban vs. Urban or Rural). As Bella, a secondary PST wrote, "I attended a small private school with very little cultural diversity. As a result, I was not exposed to much diversity, especially linguistic diversity."

A few PSTs were self-aware and self-reflective of their own culture and their mathematical experiences. They reflected on their experiences in the mathematics classroom and compared them to those of students with different gender, language, and race. As Sophia, an elementary PST wrote,

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

I am a White female that was brought up in an upper middle class family. I always thought my mathematical learning experience was equal to my classmates until I read this article. The article mentioned that females do not receive the same equity as males. I had never thought about this before but it is true that in my high school mathematics classes the smartest people were always boys. It seemed like they always knew so much more than me which lowered my confidence in doing, mathematical problems. … Realizing how this made me feel, I cannot imagine what this does to people that are even more different than White, upper class males. For example, someone who is an African American, lower class female must be very intimidated during math classes.

Sophia's quote shows how she positioned her mathematics experience in the classroom at the intersection of her gender and race. Sophia came to realize how our experiences in the mathematics classroom are shaped by cultural factors and how different we are from the "White, upper class males" standard.

Commitment to culturally relevant mathematics teaching. Although most PSTs saw the value of using culture in the classroom, only a few expressed their commitment to use culturally relevant strategies to teach mathematics. PSTs who expressed a commitment to using culture in their future classrooms made comments similar to the following quote by Wade, a secondary PST:

One of the strategies from this article I would implement in my future math classroom is opening clear pathways for communication between students, parents and myself. Another strategy I would use is having material that applies to their culture and that students can relate to culturally. This strategy can be achieved by learning about your students and determining what the students are interested in and what they may deem culturally relevant.

Wade's quote suggests that the article critique assignment offered concrete examples that PSTs could access if they were considering using culturally relevant strategies in their own classrooms.

Post Reflection

The post reflection was the last component of the unit. PSTs reflected on their experiences writing the article critique and participating in the class discussions where they shared their ideas and listened to the ideas of their peers and us as instructors.

Openness. More than half of the PSTs showed openness to the idea that different cultures may think about and do mathematics differently and they have a role in supporting students' mathematical learning. A quote from Hannah, an elementary PST, is an example:

Looking at cultural diversity, especially through a mathematical lens, has changed the way I look at teaching. I thought that being culturally different really only affected a person in reading and maybe social studies, but not math. However, now I know that's not true. Different cultures view and do math in different ways. Some algorithms are completely different across the world and teachers need to be prepared to teach students with all these varieties of methods. Students who speak different languages cannot grasp a strong or a conceptual understanding of math because they cannot understand what is being taught. Overall, this focus has really opened my eyes and made me more aware of cultural diversity in the classroom. I know this will impact my methods and actions as a teacher.

As Hannah's quote suggests, the post reflection challenged her assumption that mathematics is a universal and culture-free subject. Hannah realized that culture has a prominent role in shaping the way people do and learn mathematics, and hence it is important to take cultural diversity into account when teaching mathematics.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Several PSTs also mentioned how listening to their peers helped them realize the role of culture in learning and teaching mathematics. These PSTs expressed that the unit opened their minds to the importance of cultural awareness for teachers. Hope, a secondary PST, described this effect:

> I think the biggest help for me was just listening to what other students in our class thought. … It is so great to be able to see so many different views. After this unit, I feel like I see a clearer need for cultural awareness in our classroom environments. Until it is pointed out, I think people have a hard time understanding how their culture may be so much different from someone else's. It is so important that we are aware of this as teachers. Learning about and being aware of our students' cultures will have us connect with them as well as help us to [not] unintentionally offend them.

Hope explained how listening to her peers helped her pay attention to different "key points" from the article critiques and others' points of view.

Self-awareness/self-reflectiveness. We found the most common characterization of PSTs' SA/SR included awareness of their role in creating an inclusive mathematics classroom culture, the impact of stereotypes on student learning, and the importance of teachers critically thinking about the intersection of various cultures -- teachers, students, classroom, and school -- in the classroom:

> This unit has helped me see that students and teachers bring their cultures into the classroom, and that these cultures affect how mathematics is learned. Teaching students with diverse backgrounds does not involve ignoring differences, but rather involves drawing on these differences. Students should not feel as though they must set aside their cultural identity when learning mathematics. [Justin, secondary PST]

> I feel that this exercise was one that every teacher should be exposed to because we see in our classrooms how teachers that have been around lack the ability to see outside their own experiences. Stereotypes are running rampant and are reinforced by accident everyday. We as future educators need to realize that impartiality is crucial to having a fair classroom and setting up a classroom culture that mirrors reality. [Derrick, secondary PST]

As Justin suggested, the unit helped PSTs become aware of the importance of incorporating cultural differences in the classroom rather than ignoring them so that all students feel included. Some PSTs were more reflective, as illustrated by Derrick's quote. These PSTs reflected on the negative impact of stereotypes on student learning and the importance of being able to "see outside of their own experiences" to avoid stereotyping students.

Commitment to culturally relevant mathematics teaching. Similar to what we found in the article critique, few PSTs showed some form of commitment. The PSTs who showed commitment in the post reflection were motivated to include diverse methods of doing mathematics, methods that come from different cultures. Paula, a middle grades PST, wrote

> I also learned how important mathematics is in different cultures. I will take this new knowledge and apply it to my classroom. I will be sure to research again the mathematics principles of cultures other than the American culture so that I can accommodate all of the students in my classroom. Even if the students in my class are from one culture, I will still include methods of instruction that other cultures are accustomed to. I believe this will make math more interesting for both me and my students. They will view math as a universal commodity that is helpful for real life applications.

Discussion

Establishing PSTs' dispositions toward culture in mathematics helps future teachers to understand "no culture is monolithic; every culture consists of multiple subcultures" (Leonard,

Brooks, Barnes-Johnson, & Berry, 2010, p. 267) and that culturally relevant teaching is useful. This study contributes to the growing literature on ways to help PSTs reflect on issues of equity in mathematics and to prepare them to effectively teach all students. We used the MCMD's three constructs – openness, SA/SR, and commitment— as a lens to unveil PSTs' dispositions to teach diverse students. Our analysis suggests that PSTs want to learn and use strategies for teaching mathematics and they benefit from discussions with peers to reflect on their ideas about culture. An interesting finding from this study was the inverse relationship between the openness and SA/SR constructs. Initially the percentage of PSTs expressing self-awareness was greater than the percentage with openness; however, this relationship had shifted by the post reflection at the end of the unit. This finding supports Mills and Ballantyne's (2010) claim that SA/SR evolves towards openness.

We believe the multiple opportunities for PSTs to express their MCMD during the unit supported PSTs' progression towards openness. In this study, PSTs' self-awareness of their own mathematics learning experiences, especially their reflections on traditional approaches they had experienced, seemed to support them to want to provide their future students with more opportunities to learn mathematics. Learning about their students' cultures and using them in the classrooms is a strategy PSTs became more aware of and open to learn. The class discussion was an opportunity for PSTs to learn about their peers' views about culture and their experiences learning mathematics, mathematics stereotypes, and the various cultural norms that exist in mathematics classrooms. The PSTs' post reflections unveiled that PSTs broadened their views on openness as they realized that they were different from their seemingly same peers. Their post reflections showed more openness, and their SA/SR involved a more critical analysis of their own experiences. We were not surprised that only a few PSTs were willing to commit to using culturally relevant strategies. PSTs do not have their own classrooms and have limited opportunities to try strategies in the practicum classrooms. Our analysis suggests that additional experiences, reinforcement and practice are needed to adequately prepare PSTs to teach for diversity, especially PSTs' commitment to using culturally relevant strategies.

We have used the MCMD framework to unveil PSTs' dispositions toward diversity and culture during a cultural awareness unit. This framework has also been used to examine the development of equity and social justice dispositions among PSTs (Chao & Murray, 2015). Further research is needed to examine MCMD in various contexts, how to support the development of MCMD, and the ways MCMD are enacted in classrooms with diverse student populations.

Scholars posit that descriptive education research that focuses on the instructional dynamic between teachers and students is perhaps one the most salient research topics that can improve learning and teaching. This case study seeks to describe prospective teachers' mathematical affect as they engage in "rehearse teaching" in TeachLivE™, a mixed-reality simulated classroom. Utilizing Goldin et al.'s (2011) engagement structures as evidence of mathematical affect, findings reveal that simulated rehearsals improve prospective teachers' reformed-based teaching and that this improvement may be related to their improved 'in-the-moment' affective states. This study potentially connects prospective teachers' beliefs and emotions as math learners with their behaviors and instructional praxes as novice math teachers.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Teacher Education-Preservice, Equity and Diversity

Introduction

In the United States, policymakers, educational researchers and practitioners agree that one of the most important in-school predictors of mathematics student achievement is access to quality teachers (Ingersoll & Perda, 2010). It follows then that the precursor to teacher quality is quality pre-service teacher preparation (Ronfeldt, 2012). Quality pre-service teacher preparation includes rigorous foundational and methods of instruction coursework, opportunities to practice teaching, evaluation and feedback from expert mentor teachers and clinical faculty, revision of instruction and then more clinical practice to engender reflection, informed decision-making, and confidence in teaching performance (Chassels & Melville, 2009; Wilkins, 2002).

However, obtaining optimum opportunities to practice mathematics teaching in public schools remains challenging for teacher preparation programs, particularly in urban districts that serve underprivileged students (Ronfeldt, 2012). First, effective mathematics teachers who may serve as mentors must be recruited and developed; this can be difficult in urban districts where recruiting and retaining quality mathematics teachers is a challenge (Liu, Rosenstein, Swan, & Khalil, 2008; Khalil & Griffen, 2012). Second, the tenuous climate generated by the pressure of student performance on standardized testing narrows the window for innovative practice teaching (Beswick, 2006), particularly in urban districts that often face higher stakes with regards to student achievement on standardized tests (e.g. school closures and turn-around schools) (Sadovnik, O'Day, Bohrnstedt, & Borman, 2013). These conditions may then lead to a school climate that encourages more traditional ways of teaching and test preparation via scripted curriculum and less on teaching utilizing evidenced-based best practices often touted in teacher preparation programs (e.g. engaging students in reform-based teaching that is based on inquiry and conceptually challenging high cognitive demand tasks) (Ottmar, Rimm-Kaufman, Berry, & Larsen, 2013; Wilkins, 2002). Third, the advent of teacher evaluation systems has fostered concerns in potential mentor teachers who worry about the negative impact practice teaching may have on student performance on standardized tests, which in

turn may reflect poorly on their own teacher performance evaluations. Such poor evaluations may be more of a concern for elementary teachers who already struggle to teach mathematics (Ma, 1999) and whose negative affect has already been connected to their traditional instructional praxes (Wilkins, 2002).

Thus, for teacher preparation programs that seek to offer clinical experiences to prospective teachers, quality placements that provide the variety of resources and supports essential to pre-service teacher (PST) development of math teaching performance may be at a premium. Since research posits that clinical experiences are essential to teacher development, one solution to the shortage of quality placements may be simulated virtual classrooms. One key benefit of simulated clinical experiences is the feedback PSTs receive that encourages reflection and critical analysis of their teaching performance. The importance of this facet of practice teaching has been repeatedly emphasized in the literature on feedback and improved teaching performance among student teachers (e.g. see Voerman, Mejier, Korthagen, & Simons, 2012). Furthermore, Akkuzu's (2014) study illustrates that quality feedback not only improves teaching performance but that it also enhances preservice teachers' affect, specifically their self-efficacy beliefs about teaching. This research is noteworthy as other studies highlight the influence negative affect can have (e.g. low self-efficacy and anxiety) on novice elementary teachers' experience while teaching mathematics.

This paper seeks to suggest that simulated teaching experiences such *TeachLivE™* may serve as a worthy substitute for live classroom practicum teaching as a means of developing PST's instructional practices. Furthermore, simulated classrooms may ultimately be more conducive to improving overall performance of pre-service teachers prior to the student teaching experience (Dieker, Rodriguez, Lignugaris, Hynes, & Hughes, 2014). To examine the potential impact of simulated field experiences on teacher practice, the authors explored how *TeachLivE™* offers an opportunity to observe and respond to PSTs' "in-the-moment" affective behaviors patterns while the PST engaged in rehearse teaching of a math lesson. Additionally, the authors seek to further understand *how* improved teaching knowledge and practice may be related to affect among PSTs (Wilkins, 2002).

Perspectives

This paper is grounded in two bodies of theory and research: the work on prospective teachers' rehearsals as clinical practice (Lampert, Franke, Kazemi, & Crowe, 2013) and on powerful mathematical affect (Goldin, 2014; McLeod, 1992). First, this study analyzes PST reformed-based teaching while they "rehearse" teaching a math lesson in a simulated clinical environment (Dieker et. al, 2014; Lampert et al., 2013; Ronfeldt, 2012). Lampert and colleagues describe rehearsals as "a social setting for building novice' commitment to teach ambitiously" where the motivation to do so "depends on the social circumstances in which one learns and develops an identity" (p.227). This is consistent with Ronfeldt's (2012) assertion that optimal conditions for clinical work are essential as they are positively linked to improved teacher retention and student achievement. Furthermore, opportunities that permit PSTs to re-teach a lesson after receiving feedback and making revisions was found to benefit PSTs praxes in becoming more student-centered and reform-based (Chassels & Melville, 2009; Ganesh & Matteson, 2010). While, rehearsals of teaching is optimally conducted in an actual classroom where PSTs' can shape teaching identities within conditions that provide resources and support, such conditions are challenging to identify within inner cities (Ronfeldt, 2012). Therefore, this research explores the viability of a simulated classroom for rehearse teaching in an 'optimal' setting as a mean of examining simulated rehearsals' potential to improve PSTs' teaching performance.

Second, this paper utilizes Goldin, Epstein, Schorr, and Warner's (2011) "engagement structures" as evidence of PSTs' "in-the-moment" affective states experienced when interacting with mathematics. This paper posits that while "engagement structures" (ES) were first theorized to

characterize inner-city's "behavioral/affective/social constellation," this theory can *also* describe pre- and in-service "in-the-moment" teacher affect (Khalil & Johnson, 2016). Evidence of nine of Goldin and colleague's engagement structures were noted (e.g. *get the job done, look how smart I am, check this out, I'm really into this, don't disrespect me, stay out of trouble, it's not fair,* and *let me teach you*), where evidence of each structure's "in-the-moment" transaction was unpacked via seven strands (e.g. *goal or motivating desire, patterns of behavior, affective pathways, expression of affect, meanings encoded by emotions, meta-affect, self-talk or inner-speech*) (Goldin et al., 2011, p. 549). Exploring more about PSTs' "in-the-moment" affective states while teaching may lead to: a) further understanding of PSTs' affective traits, which are often negative (e.g. math anxiety and low self-efficacy) among elementary teachers teaching math, and b) improving PSTs' affective traits in an effort to encourage further reformed-based innovative teaching practices linked with positive affective traits (Wilkins, 2002).

Data and Methods

Study Design

This study draws on a larger mixed-method study which sought to explore the effect of pre-service teachers engaging in a lesson study project in which they planned and rehearsed a math lesson, received feedback that informed revisions of their lesson plan, and then taught the revised lesson (Hiebert, Morris, Berk, & Jansen, 2007). The PSTs worked through multiple cycles of lesson planning prior to their rehearsals. Data collected in the larger study included pre and post measures of PSTs' *Mathematics Teaching Self-Efficacy Survey* (MTEBI scores; Enochs, Smith, & Huinker, 2000), qualitative and quantitative video analysis, PSTs' reflections, as well as other course artifacts.

The lesson study took place during the fall of 2014 in an elementary mathematics methods and practicum course at Howard University, a Historically Black University with a mission to educate underserved populations of color. The first author served as the mathematics teacher educator for the four-credit mathematics methods class. Prospective teachers were required to spend 32 hours in the classroom and 32 hours in clinical settings that offered extensive opportunity for feedback (e.g. university supervisor, cooperating teacher, teacher-educators). The teacher educator asked PSTs to design a 90-minute lesson based on one CCSSM standard, as research shows that PSTs' focus on how to teach as opposed to what to teach when a topic is chosen for them (Deiker et. al, 2014). Fractions (Lee & Boyadzhiev, 2013) were chosen as a conceptually challenging topic and PSTs were instructed to design their lesson plan using the 5-E Learning Cycle (Bybee et al., 2006). PSTs received feedback on lesson plans multiple times, as teaching fractions in a conceptually engaging way is challenging.

For this paper's focus on *TeachLivE™* rehearsals, 11 PSTs (10 females; 1 male; all African-American) participated in the portion of the study reported here. PSTs took the course twice a week for two hours. All participants were 3rd year (Junior Level) students who were completing the requirements of a Bachelor's Degree for an Elementary Education Major. PSTs were asked to choose 15 min from their lesson plan to rehearse in *TeachLivE™*, as it has been shown that 7 minutes practicing specific teaching strategies with feedback can improve teaching performance. PSTs videotaped rehearsing the 15-minute segment of instruction in TeachLivE™ then received feedback from two teacher educators. PSTs reflected upon their experience of lesson planning and teaching, revised a portion of their lesson plan to reteach in TeachLivE™, and then rehearsed the same 15-minute segment. This amounted to 30 minutes of rehearsal teaching and two rounds of feedback from two instructors).

Research Question and Data

The primary question driving this study is, "in what ways can rehearsals in a simulated clinical

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

environment like *TeachLivE™* be used as a tool to develop prospective teacher practice and powerful mathematical affect?" Qualitative data was collected and analyzed to explore the patterns and themes of PSTs' instructional practices and affective states while teaching in TeachLivE ™. Data analysis involved both a) contextual analysis of each PST's reflections, videos, and video transcripts, and b) cross-teacher analysis to compare evidence of each data point among PSTs. To establish inter-rater reliability, all coding was completed by two research assistants (Creswell, 2009). The researchers first coded videos, video transcripts, and reflections deductively by searching for instances of the 9 engagement structures, then re-coded to find evidence of each structure's "in-the-moment" transaction by searching for the aforementioned 7 strands that comprise an engagement structure (Goldin et al., 2011).

Additionally, quantitative data analysis was used to measure PSTs' reformed instructional practices. To establish inter-rater reliability, two research assistants used the Reformed Teacher Observation Protocol (RTOP; Piburn et al., 2000), observed videos of the rehearsals twice to assign scores that represent PSTs' instructional practices. RTOP provides a standardized means for detecting the degree to which classroom instruction/teaching praxes is learner-centered or engaged versus teacher-centered. RTOP includes five subscales. First, lesson design and implementation (LDI) seeks to measure what the PST intends to do. Items examine how the PST organizes the lesson to honor students' preconceptions constructed from every day experiences or previous instruction and examines how the PST creates opportunities to explore aspects of the topic prior to formal instruction. Second, the propositional pedagogic knowledge (PPK) seeks to measure what the PST knows, and how well s/he is able to organize and present material in a learner-oriented setting. Third, the procedural pedagogic knowledge (PK) seeks to measure what the student avatars did and how engaged they were in critical thinking skills advocated in the CCSSM standards of practice. Fourth, the student-student interaction (SSI) subscale measures the type of interactions among students and how the PST facilitates such interactions. Finally, the fifth subscale measures student-instructor interaction (SII), and how a PST creates learning environments where students are able to take risks asking questions. Questioning provides students the opportunity to exercise executive control over their learning process, empowers their learning, and increases their overall learning gains (Boykin & Noguera, 2011).

RTOP is one of the few validated observation tools that measure reformed-based teaching (also referred to as standards-based teaching; see Ottmar, Rimm-Kaufman, Berry, & Larsen, 2013 for further details). Reform-based teaching advocates that classes be "*taught via the kinds of constructivist, inquiry-based methods advocated by professional organizations and researchers*" (Piburn et al., 2000). Reform-based teaching is a paradigm adopted by the standards movement due to its goals of shifting traditional teacher-centered lecture-driven instruction to student-centered, activity-based learning which encourages collaboration among students (Ottmar, Rimm-Kaufman, Berry, & Larsen, 2013). The original RTOP protocol was modified to adjust for the limitations of the simulated rehearsals. Figure 1 below explains the modified interpretation of RTOP Scores (adapted for the simulated rehearsal experience).

Understanding TeachLivE RTOP Scores (Adapted for the Simulated Teaching Experience)		
Traditional Lecture	Active lecture	Active Learning
RTOP Scores 0-22	RTOP Score: 23—38	RTOP Score: 38+ (out of 77)

Figure 1. RTOP Score Meanings.

Results and Discussion

A descriptive analysis revealed that preservice teachers had an average RTOP score of 41.5 in their first teaching rehearsal in TeachLivE. This improved to an average score of 47.56 during the

second rehearsal in TeachLivE. According to figure 1, PSTs are implementing inquiry-based methods that promote active student-centered learning on average. Table 1below provides the descriptive statistics for RTOP and the respective RTOP subscales at Time 1 and Time 2.

Table 1: Descriptive Statistics

Subscale	N	Minimum	Maximum	Mean	Std. Deviation
LDI1	10	5	14	7.50	2.64
LDI2	9	4	14	8.22	3.19
PPK1	10	6	13	9.60	2.32
PPK2	9	5	14	11.11	3.14
PCK1	10	2	la11	7.90	2.81
PCK2	9	3	11	9.00	2.50
SSI1	10	5	14	7.50	2.72
SSI2	9	5	16	8.67	3.54
SII1	10	5	15	9.00	3.16
SII2	9	5	15	10.56	3.17
RTOP Time 1	10	23	67	41.50	12.47
RTOP Time 2	9	22	68	47.56	13.95

Improved Reformed Teaching: Evidence from Rehearsals

A paired-samples t-test was conducted to compare each subscale score of the RTOP at Time 1 and Time 2. There was a significant difference in Propositional Knowledge between Time 1 (M=9.60, SD=2.32) and Time 2 (M=11.11, SD=3.14); $t(8)$ = -2.600, p = .032. While scores did significantly improve, PSTs' propositional knowledge is one of the greatest challenges observed during the lesson study and required a large part of the class time. This is not unusual, as elementary PSTs need support for constructing their understanding of teaching mathematics from a procedural approach to a conceptual one. There was a significant difference in Student-Student Interaction between Time 1 (M=7.50, SD=2.72) and Time 2 (M=8.67, SD=3.54); $t(8)$ = -2.443, p = .040. PSTs were challenged during Student-Student Interaction due to the "behavioral" level of discipline we requested for the PSTs in the simulation (a level 3 typical of "urban" classrooms). Most of the PSTs did well despite this challenge. There was a significant difference in Student to Instructor Interaction between Time 1 (M=9.00, SD=3.16) and Time 2 (M=10.56, SD=3.17); $t(8)$ = -2.490, p = .038. Specifically, the results suggest that PSTs' Student-to-Instructor Interaction was a key strength of candidates. This was largely due to PSTs' affect. The affective domain includes a host of constructs, such as attitudes, values, beliefs, opinions, interests, and motivation. There was not a significant difference in LDI and PCK between Time 1 and Time 2. Table 2 presents the significant findings from the paired-samples t-test.

A paired-samples t-test was conducted to compare overall RTOP scores at Time 1 and Time 2. There was a significant difference in the RTOP scores between Time 1 (M=41.78, SD=13.19) and Time 2 (M=47.56, SD=13.95); $t(5)$=-2.550, p = .034. These results suggest that TeachLivE rehearsals, as part of an overall lesson study, may offer a venue for improving PSTs' teaching performance. Table 2 presents the results from the paired-samples t-test.

Table 2: Paired-Samples *t*-test Results

		Mean Difference	T	df	Siq. (2-tailed)
Pair2	PPK1 - PPK2	-1.44	-2.600	8	.032
Pair4	SSI1 - SSI2	-1.11	-2.443	8	.040
Pair5	SII1 - SII2	-1.44	-2.490	8	.038
Pair6	RTOP1- RTOP2	-5.76	-2.550	8	.034

Powerful Mathematical Affect: Evidence from Rehearsals

Rehearse teaching proved to be a turning point for many prospective teachers. Data collected from PSTs' journal reflections indicate that the positive affective experience of their first *TeachLivE™* rehearsal boosted their belief with regards to their ability to learn lesson planning and teaching mathematics. Some of the ES were characterized by belief systems, such as self-efficacy and self-identity while others were characterized by behaviors oriented toward fulfilling emotions. PSTs' meta-affect and affective pathways were also "strands" that helped unpack the emotions and behaviors in each ES, particularly with regards to understanding "the sequence of emotional states interact[ing] with heuristics during [lesson planning and rehearsing]" (Goldin, 2000). These emotions served as "AHA" moments signaling to the PSTs' belief that they can in fact teach a lesson on fractions (Liljedahl, 2005).

One of the most prominent engagement structures observed in PSTs' *TeachLivE™* rehearsal was *Get the Job Done*. This structure was exhibited in their focus to persevere through an explanation and in their efforts to be comprehensive in their planning. This persistence may be in deference (a meta-affect) to instructions that required a 15-minute rehearsal; instructions they felt obligated to comply. As one PST reflects, "*The only thing I got out of teach live was the fact that you can never have too much. You should plan for a lot and try your best to get through it all. Have a multitude of questions prepared for all kids who may or may not be engaged.*" Similarly, another PST reflects, "*If I over complicated them (fractions) I might not be able to accomplish them,*" while another contends she needs to "*write out some of [the] key questions to make sure that [she] asks students everything [she] want them to think about.*" Indeed, the "motivating desire for task completion [was to] evokes more procedural, time-efficient strategies" (Goldin et al, 2011; p. 552).

Unsurprising, PSTs also exhibited the ES *Let me teach you*, where they verbalized the lesson objectives by using "I" statements to demonstrate to the avatar students and their instructors their ability to teach math. For example, through a series of scaffolded questions, several PSTs exhibited their *motivating desire* (mastery-approach goal) was to help a confused student understand how to transform an improper fraction into a mixed fraction. In a similar way, PSTs exhibited the ES *Check this out,* which may be linked to PSTs' intrinsic motivation of meeting the challenge to provide clarity to difficult math problems. Thus, PSTs' *motivating desire* to obtain an *intrinsic reward* was observed when PSTs assessed CJ, an avatar who struggled the most during the lesson, or Maria, another avatar who appeared disengaged most of the time. Several PSTs demonstrated *external emotions* such as excitement and enthusiasm, which was evident in their tone of voice.

One of the most frequently observed ES in the data was *Stay out of Trouble*, where PSTs avoided interactions that may lead to distress. For example, one PST avoided feeling vulnerable in her inability to answer question (performance-avoidance goal); perhaps this was due to her initial low self-concept. A second frequently observed ES was *Don't disrespect me*, which was illustrated in the way PSTs commanded respect in a no-nonsense tone and nonverbal cues that indicated their intolerance towards distractions that detracted from meeting their lesson objectives. For example, several PSTs began calling on student avatars randomly, thereby requiring the avatars to remain focused throughout the lesson. This ES was markedly evident even within rehearsals of short

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

duration and was characterized by PSTs displaying respect for everyone's dignity and by providing a "safe" space for students to ask mathematics questions without fear about belittlement. One PST reflected in a "self-talk" tone, "*Although I was able to shut all these [student distractions] down within the first few minutes, I heard that they were worse with some of my classmates. I see how important it is to incorporate tasks that really engage the students so you can have their undivided attention for the time that you have.*" It is noteworthy that PSTs with lower self-efficacy (as it pertains to the context of modeling operations with fractions) may be linked with two additional engagement structures including *Its Not Fair* and *Pseudo Engagement.* Regarding *Its Not Fair*, PSTs expressed disappointment in their journals over rehearsing with avatars as opposed to K-12 students in the field and described their frustration with *TeachLivE's™*, which limited their proximity to students. *Pseudo Engagement* was observed among PSTs who exhibited apathetic behavior during teaching and relief when teaching sequences ended. Unsurprising, the findings revealed that PSTs often exhibited the *Let me teach you* engagement structure along with the *Look how smart I am* and *Check this out* engagement structures. These ES tended to link to PSTs' higher self-efficacy, as evidenced by language in PSTs' journal reflections and higher MTEBI scores.

Implication

Rehearse teaching in *TeachLivE™* proved to be a turning point for many prospective teachers as it allowed them an opportunity to practice teaching, which in turn improved their affect and confidence in teaching, in general, and in teaching mathematics, in particular. Further, their overall improved reformed-teaching mirrored the improved affective states as evidenced by the "in-the-moment" affective constellation in the engagement structures. Additionally, despite instances of less positive affective states, PSTs' RTOP scores did demonstrate a statistically significant increase in scores that nudged PSTs from active teaching to active learning between their two rehearsals. This paradox of instances of low affect but high teaching performance is intriguing and suggests that low affect does not always translate into poor teaching ability, just as less positive engagement structures for students does not necessarily translate into poor performance in mathematics (Goldin et al., 2011). This outcome is worthy of further research.

Rehearsals with feedback in a simulated learning environment also enabled prospective teachers to enact instruction in controlled settings and afforded university faculty opportunities to provide immediate feedback after rehearsals. These experiences helped prospective teachers transform learning into practice, which is especially important for prospective elementary teachers who experience low confidence in mathematics settings. It also provided a venue for university faculty to closely mentor students thereby overcoming some of the constraints imposed by live classroom rehearsals. This study's results suggest that simulations may prove to be viable alternatives for rehearse teaching in clinical settings where optimal conditions cannot be secured. Simulations may also provide candidates with early mentoring opportunities that build self-confidence while also reducing the burden of placements on already taxed schools. With optimal clinical settings at a premium in rural, urban and suburban school districts, alternative modes for rehearse teaching need further investigation.

MEASURING SHIFTS IN REASONING ABOUT FRACTION ARITHMETIC IN A MIDDLE GRADES NUMBER AND OPERATIONS CONTENT COURSE

deanlstevenson@uga.edu

The present study extends recent advances developing and applying measures of mathematical content knowledge for teaching. Recent research has demonstrated that the Diagnosing Teachers' Multiplicative Reasoning Fractions survey provides information about distinct but related components necessary for reasoning in terms of quantities when solving fraction arithmetic problems. The present study adds a new component of validity for the survey by examining the extent to which one pre-service teacher's growth in reasoning about fraction arithmetic, as indicated by assessments she completed for a middle grades numbers and operations course, was reflected in her performance on the survey. Results provide an existence proof that the survey is sensitive to shifts towards more proficient reasoning.

Keywords: Mathematical Knowledge for Teaching, Measurement, Teacher Education-Preservice

Recent curriculum standards documents (e.g., National Governors Association Center for Best Practices and Council of Chief State School Officers, 2010; National Council of Teachers of Mathematics, 2000) and recommendations for teacher education (e.g., American Mathematical Society, 2010; Sowder et al., 1998) have placed high value on developing conceptual understanding by solving and reflecting on solutions to problems embedded in situations. These standards and recommendations have led to two critical challenges for mathematics teacher education addressed by the present study. First, a body of past research (e.g., Ball, 1990; Izsák, 2008; Ma, 1999) has reported persistent difficulties preservice and inservice teachers have had explaining fraction arithmetic in terms of quantities and has demonstrated a need for teacher education to attend to this critical content. Second, the field has been striving to develop measures that target mathematical knowledge needed for teaching practice (e.g., Bradshaw, Izsák, Templin, & Jacobson, 2014; Hill, 2007; Izsák, Jacobson, de Araujo, & Orrill, 2012; Kersting, Givvin, Sotelo, & Stigler, 2010). For us, addressing both challenges simultaneously means developing and utilizing measures that capture information about teachers' capacities to construct chains of reasoning for explaining fraction arithmetic in terms of quantities.

The present study addresses both challenges identified above by examining the first application of the Diagnosing Teachers' Multiplicative Reasoning (DTMR) Fractions survey to study growth and change in a cohort of preservice teachers. The important feature distinguishing the DTMR Fractions survey from the Learning Mathematics for Teaching (LMT) measures of mathematical knowledge for teaching (e.g., Hill, 2007) is that it is multi-dimensional. The LMT measures are used to estimate a single score on a continuous scale that can be interpreted as an overall measure of ability with respect to the targeted mathematical content. In contrast, the DTMR survey provides information about four components of reasoning (illustrated with an example below) that are well established in the theoretical and empirical research literature on children's and teachers' reasoning about fraction arithmetic in terms of quantities. The trade-off for multidimensionality is that the DTMR components are dichotomous variables. By measuring components of reasoning, the DTMR survey has potential to capture nuanced information about teachers' reasoning and ways their reasoning can shift during content courses.

In prior work, Bradshaw et al. (2014) reported on the development of the DTMR Fractions survey and analyzed data from a national sample of 990 in-service middle grades teachers. The

results established the content validity and psychometric properties of the survey. In the present study, we administered the DTMR Fractions survey before and after a semester-long course on number and operations that gave significant attention to reasoning about fraction arithmetic in terms of quantities. The course was offered to 22 preservice mathematics teachers in a middle grades program. The goal of the study was not to evaluate the effectiveness of the course but rather to examine a form of convergent validity around growth and change in the preservice teachers' reasoning. In particular, our research question asked whether or not the reasoning that preservice teachers demonstrated on course assessments was consistent with shifts in their reasoning as indicated by their performance on the DTMR Fractions survey. Thus, this study was a test case examining the extent to which it is possible to measure shifts in multiple components of teachers' reasoning using psychometric methods.

Measuring Teachers' Reasoning About Fraction Arithmetic in Terms of Quantities

As indicated above, solving fraction arithmetic problems in terms of quantities involves multiple components of reasoning. The solution outlined to the following problem illustrates three of the four components measured by the DTMR Fractions survey.

> A batch of brittle calls for $^1/_4$ of a cup of honey. Megan has $^2/_3$ of a cup of honey. How many batches of brittle can Megan make?

The solution presented below presumes that a teacher will not employ a general numeric method, such as multiplying by the reciprocal of the divisor, but instead will reason directly with the quantities of cups and batches to solve the problem.

First, to see the opportunity for discussing division, a teacher would have to recognize that the brittle problem asks a how-many-groups question, the signature for measurement division. We use the term *appropriateness* to refer to selecting an arithmetic operation that can model a given problem situation. Next, the teacher might produce a drawn model. The double number line shown in Figure 1a, where lengths depict cups of honey, is one possibility. Our next point about partitioning is not dependent on this choice of drawn model. Juxtaposing the two number lines highlights the challenge that fourths and thirds do not subdivide one another evenly. Whole-number factor-product relationships are useful for overcoming this challenge. In this case, 12 is a common multiple of 3 and 4. Figure 1b illustrates how twelfths simultaneously subdivide thirds and fourths of cups and thus provide a finer unit with which to compare the two. Thus, teachers must be skillful at *partitioning* quantities, often using factor-product combinations as a tool. A related aspect involves *iterating* the resulting mini-piece (8 times in this example).
Figure 1. Reasoning with a double number line.

Finally, the teacher must interpret the mini-pieces in terms of the given situation. There are multiple candidates, including interpreting one mini-piece as a twelfth of 1 cup, as a fourth of $^1/_3$ cup, and as a third of $^1/_4$ cup. Because the problem asks about the number of $^1/_4$ cups in $^2/_3$ cups, $^1/_4$ cup is the appropriate referent unit: There are $^8/_3$ $^1/_4$-cups in $^2/_3$ cups. Thus, the teacher must be clear about the *referent units* for all numbers used in the solution. The DTMR Fractions survey provides information about teachers' facility with appropriateness, partitioning and iterating, referent units,

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

and a fourth component, reversibility, that is important for solving partitive division problems. Reversibility has to do with constructing the one whole given a fractional amount of the whole (e.g., $^3/_5$ or $^7/_5$).

The DTMR Fractions survey consists of 27 items that measure the four components of reasoning just discussed. We used a psychometric model called the log-linear cognitive diagnosis model (LCDM) to analyze the item responses and estimate profiles that indicate "mastery" or "non-mastery" of appropriateness, partitioning and iterating, referent units, and reversibility. (The term *mastery* comes from the psychometric literature, which we take as a synonym for *proficiency*.) The LCDM is one member of a recently developed family of psychometric models referred to as diagnostic classification models. The DTMR Fractions survey is one of the first practical applications of these new models.

Methods

Data for this report comes from an on-going study of preservice teachers' reasoning about multiplication and division, fractions, and proportional relationships. As part of the broader study, the project team administered the DTMR Fractions survey to a cohort of 22 preservice middle-grades mathematics teachers before and after a number and operations content course offered in Fall 2014. The course was offered as part of a teacher education program at a large, public university in the Southeast United States. The course emphasized reasoning with quantities to develop conceptual understanding of multiplication and division with whole numbers and with fractions. A project-team member taught the course. We administered the DTMR Fractions survey the first week of the course (August, 2014) and again at the beginning of the following semester (January, 2015). In addition to DTMR survey data, we collected all course assessments (quizzes and tests) from all preservice teachers in the course. The preservice teachers completed these assessments between mid-September and mid-December.

We selected six preservice teachers for more detailed study based on their initial fractions profiles as determined by the LCDM analysis. Of the six, the LCDM analysis indicated that Kelly's (a pseudonym) profile shifted along the most (3) dimensions. Thus, we selected her as an initial case to examine the extent to which her growth in reasoning about fraction arithmetic, as indicated by her assessments completed for the number and operations course, was consistent with her shift in profile. The first author first compiled a list of all assessment problems that provided opportunities for Kelly to use at least one of the four components of reasoning—appropriateness, partitioning and iterating, referent units, and reversibility. The compiled problems came from two quizzes, three tests, and the final exam. The first and third authors then individually analyzed Kelly's work on the selected problems, listing evidence for or against facility with each component. The first and third authors then looked at the problems together and compared their lists of evidence for or against facility with each component. Discrepant interpretations were discussed until resolved. The second author then confirmed the first and third authors' analysis, discussing discrepant interpretations with the first and third authors. We then compared Kelly's reasoning as evidenced in her course assessments with the shifts indicated by her performance the DTMR Fractions survey before and after the course.

Results

According to the LCDM analysis, Kelly was not a master of any of the four DTMR components at pretest. Her probabilities of mastery for each component at the beginning of the number and operations course were appropriateness (.01), partitioning and iterating (.01), referent units (.00), and reversibility (.15). At posttest, each of these probabilities increased: appropriateness (.98), partitioning and iterating (.30), referent units (.52), and reversibility (.86). This suggests that by the end of the course Kelly had made significant gains on appropriateness and reversibility, that there was conflicting information about her facility with referent units, and that she still struggled with

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

partitioning and iterating. Our analysis indicates that shifts in Kelly's performance from DTMR pretest to DTMR posttest was largely consistent with her performance on the assessments she completed for the numbers and operations course, and that places where her performance diverged corresponded to places where the DTMR Fractions survey was less well aligned with the course assessments.

Shifts in Kelly's Reasoning about Appropriateness

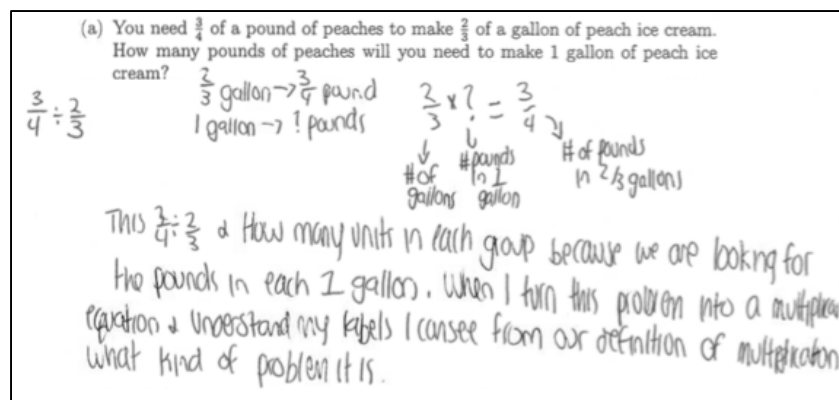
Kelly's performance on assessments for the numbers and operations course indicated that she used tools developed in the course to make appropriate determinations about when and where multiplication and division could be used to model problem situations. These tools were an explicit meaning for multiplication and a form of ratio table. Oftentimes Kelly was explicit about using these two tools. Figure 2 shows one example of her work on a test given in December, near the end of the course. The question presented four word problems and asked whether each one could be modeled by $^2/_3 \div ^3/_4$, $^3/_4 \div ^2/_3$, or neither. Kelly identified the appropriate operation in all but the second example.


Figure 2. Kelly uses tools from class to identify partitive division (December).

Figure 2 shows Kelly's work on the first word problem. The ratio table in the top left of Kelly's work and the multiplication equation in the top right illustrate the tools from class. In particular, the course instruction used multiplication with an unknown factor, represented in Kelly's work with a question mark, to represent division situations. The units Kelly attached to the $^2/_3$, the question mark, and the $^3/_4$ also followed course instruction closely. For reasons that are not clear, Kelly answered part (b) of the same question incorrectly. The only difference was the question, which asked, "How many gallons of peach ice cream can you make from 1 pound of peaches?" Although this is also partitive division, Kelly set it up as a measurement division problem and got confused. The final exam presented six word problems and asked which could be modeled by multiplication, division, or subtraction, again with the fractions $^2/_3$ and $^3/_4$. Kelly again used ratio tables and multiplication equations like those shown in Figure 2 to identify appropriately all instances of division (partitive and measurement). She also identified appropriately instances of multiplication but then changed her answers. Thus, by the end of the course, her recognition of appropriate operations was largely, but not completely, accurate.

The DTMR Fractions items that measured appropriateness asked whether situations described in word problems could be modeled by multiplication or division. (The test is secure, so we cannot provide specific items.) Kelly did not explain how she selected her choices to the DTMR items, so we cannot be sure if she used ratio tables or the meaning of multiplication illustrated in Figure 2. Nevertheless, her use of the explicit meaning for multiplication and ratio tables on course assessments as instructed in class suggested the number and operations course played a key role in her improved performance; and the contrast between her performance on the DTMR pretest and

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

posttest reflected genuine improved facility identifying which arithmetic operations can be used to model situations described in word problems.

Shifts in Kelly's Reasoning about Partitioning and Iterating

Kelly's performance on assessments for the numbers and operations course indicated frequent use of common denominators when partitioning quantities. Figure 3 shows one example of her work from a test given in September. This example occurred 2 weeks after partitioning had been introduced for the purpose of generating equivalent fractions. The question presented a number line showing the locations of 0 and $^2/_7$ and asked for the locations of $^1/_7$ and $^1/_5$. Kelly began her explanation by stating: "In order to have equally spaced tick marks we must first find a common denominator with $^1/_7$ and $^1/_5$." We did not assign much significance to the uneven spacing of her tick marks.
Figure 3. Kelly uses common denominators to partition (September).

Kelly's consistent attention to common denominators served her well in some, but not all, situations: She continued to focus on common denominators as a guide for partitioning when problems called instead for partitioning using common numerators. Partitioning by common numerators is useful for some methods for solving partitive division problems with drawings. This aspect of partitioning was not emphasized in the course. Figure 4 shows Kelly's work on a test given in December, near the end of the course. She generated an appropriate partitive division word problem as asked, again using the meaning for multiplication and the ratio table discussed above. As part of her explanation, she stated "I must find a common denominator of 4" when, in fact, partitioning $^1/_2$ into two equal parts comes from the least common multiple of the numerators for $^1/_2$ and $^2/_3$.

The DTMR Fractions items that measured partitioning and iterating presented a mix of situations calling for partitioning by common denominators and by common numerators. On the DTMR posttest, Kelly demonstrated continued use of partitioning by common denominators but missed nearly all items for which attention to common numerators would be useful. Thus, Kelly's modest increase in performance from the DTMR pretest to posttest reflected her restricted attention to common denominators when partitioning.

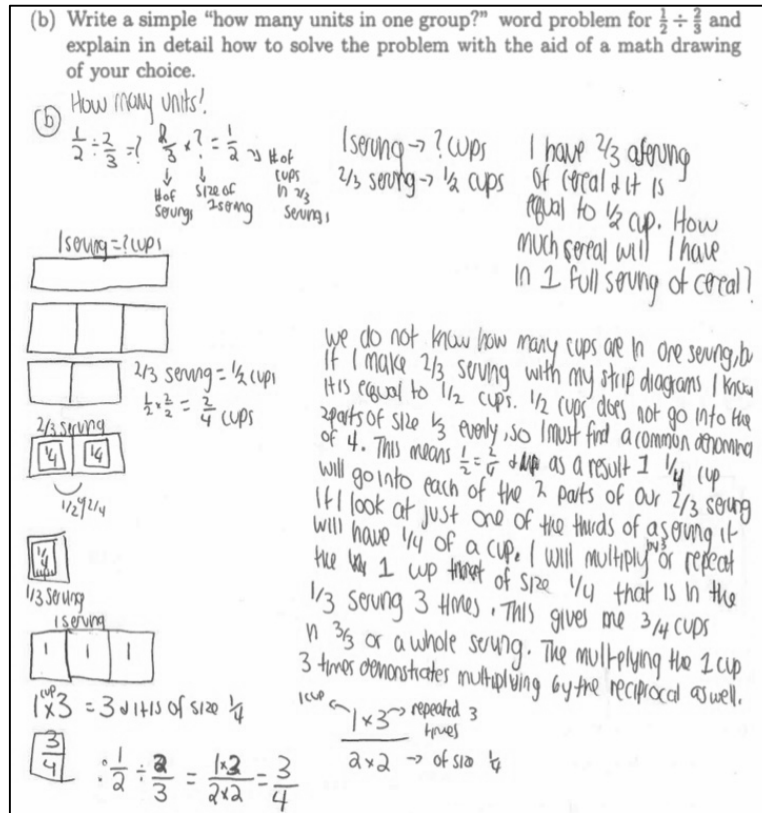

Figure 4. Kelly's reasoning about partitioning and iterating and reversibility (December).

Shifts in Kelly's Reasoning about Referent Unit

Kelly's performance on assessments for the numbers and operations course indicated inconsistent reasoning about referent units. At times she gave clear, correct explanations for the referent units in multiplication and division problems. Figure 5 shows one example where Kelly demonstrated taking part of a part correctly when explaining the meaning of $^2/_3 \times {}^4/_5$. From her written work we infer that she drew $^4/_5$ of one whole first and then took $^2/_3$ of the $^4/_5$. There were also examples where she assigned appropriate referent units to the quotient in both partitive and measurement division problems. On a test in December, Kelly wrote the following when asked for a measurement division problem that illustrated $^1/_2 \div {}^2/_3$: "One serving of cereal is $^2/_3$ cups. How many servings of cereal will I have in $^1/_2$ cups?" When solving her problem, Kelly was explicit about converting the given fractions into $^3/_6$ and $^4/_6$ and using $^4/_6$ as a new unit.
Figure 5. Kelly's reasoning about referent units for fraction multiplication (October).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

At the same time, Kelly's incorrect reasoning about units was evident in several places, including some of her work on the final exam. One problem presented a picture of a 5-part strip with three parts shaded. The problem stated that the entire 5-part strip represented $^7/_2$ acres of land and asked whether, according to the meaning for multiplication developed in the course, the 3 shaded parts represented $^7/_2 * ^3/_5$ (incorrect) or $^3/_5 * ^7/_2$ (correct). Ostensibly, this problem was about appropriateness, but a central feature of Kelly's work was incorrect referent units. In particular, she divided each of the 5 parts in half, creating 10 parts, and argued that the shaded region showed $^6/_{10}$, not the $^{21}/_{10}$, which she knew was the product. Thus she conflated $^1/_{10}$ of $^7/_2$ with $^1/_{10}$ of the whole.

The DTMR Fractions items that measured referent units for multiplication and division situations often presented a complete number sentence and several drawings indicating different choices for the referent unit for the product or the quotient. Kelly got some items correct while missing others. Thus her reasoning appeared inconsistent both on course assignments and on the DTMR survey.

Shifts in Kelly's Reasoning about Reversibility

Kelly's performance on written assignments for the numbers and operations course indicated her ability to start with a proper or improper fraction and construct the relevant whole, which is the sense of reversibility used in the DTMR Fractions survey. The examples in Figures 4 and 6 illustrate Kelly's reasoning with reversibility after the Common Core State Standards definition for fraction, which is based on iterating a unit fraction, was introduced in late August. Figure 6 shows Kelly's work on a quiz in September. Given an array of X's that was $^4/_3$ of another array, Kelly partitioned by 4 to find $^1/_3$ of the given array. She explained that "The unit whole of a fraction of $^1/_3$ would be 3 equal parts of each of size $^1/_3$." In the rest or her work (not shown) she then redrew the first three columns of circled X's shown in the figure. In Figure 4 she correctly reasoned that if $^1/_2$ cup makes $^2/_3$ of a serving, then $^1/_4$ cup makes $^1/_3$ of serving. She completed her solution by explaining that since 3 one-thirds make a serving, 3 one-fourth cups must be needed for one serving. On the final exam, she wrote a partitive division word problem for $^1/_3 \div ^4/_5$ and solved using the same method as the one used for the problem shown in Figure 4. We conjecture that the introduction of the Common Core State Standards early in the course provided Kelly a new perspective on fractions that allowed her to solve reversibility problems quickly.
Figure 6. Kelly's reasoning about reversibility (September).

Discussion

The results we present add to an accumulating body of evidence that the DTMR Fractions survey is a valid measure of teachers' reasoning about fraction arithmetic in terms of quantities. Past results

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

established the content validity and psychometric properties of the survey. The present study examines the sensitivity of the survey to growth and change in reasoning during a one-semester content course on number and operation. In particular, our results suggest that changes in Kelly's reasoning about fraction arithmetic, as evidenced by her use of tools and definition for fractions introduced during the course, were reasonably consistent with the shift in her performance on the DTMR survey before and after the course, at least in those areas where the content of the survey and course were closely aligned. Further analysis of the remaining dataset is ongoing, and we will present results of that analysis in the near future. The results we present here are a critical next step in developing measures that capture information about moment-to-moment reasoning, narrowing the gap between information about teachers that can be ascertained through large-scale surveys and detailed case studies of problem-solving performance. Narrowing this gap is critical for measuring growth in reasoning necessary for enacting current curriculum standards (e.g., National Governors Association Center for Best Practices and Council of Chief State School Officers, 2010; National Council of Teachers of Mathematics, 2000). Since the approach to measurement we used, based on diagnostic classification models, can be applied to other content areas and to students as well as teachers, the implications for psychometric models as tools for research and practical applications are broad.

EXPLORING PROSPECTIVE TEACHERS' WRITTEN FEEDBACK ON MATHEMATICS TASKS

Signe E. Kastberg	Alyson E. Lischka	Susan L. Hillman

This cross-case analysis of three distinct letter writing activities between prospective teachers (PTs) and K-12 learners provides insights into PTs' levels of feedback according to Hattie and Timperley's (2007) framework. PTs' written feedback from letter writing activities conducted in teacher preparation programs were analyzed using this framework in order to describe feedback provided to K-12 learners by PTs. Crossing the borders of programs at three different U. S. universities, elementary and secondary teacher preparation, and elementary, middle, and high school learners, evidence indicates that PTs provided feedback focused on self, task, and process but rarely on self-regulation. Further, they did not adequately address incorrect answers and redirected student thinking as often as building on student thinking. Recommendations for teacher preparation activities that address the development of feedback practices are provided.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices

Purpose for the Study

Providing feedback positively impacts student learning (Hattie & Timperley, 2007; Shute, 2008; Black & Wiliam, 1998) and mathematics performance (Fyfe, DeCaro, & Rittle-Johnson, 2015). Attention to the development of prospective teachers' (PTs') feedback practices can therefore impact student learning once PTs enter the classroom. Hattie and Timperley's (2007) review of feedback research offers a framework for describing feedback which asserts consideration of the goals, progress, and what is needed to reach the goals are required for feedback to be effective. This framework categorizes feedback as information on the self, process, task, and self-regulation and describes the effectiveness of each type. Considering evidence of the potential impact on student learning when effective feedback is incorporated, we explored the ways in which PTs give feedback. Specifically, what levels of feedback (Hattie & Timperley, 2007) do PTs provide in written comments to students about their performance or mathematics learning? To answer this question we analyzed PTs' written responses to mathematics students about their solutions to mathematics tasks. Findings from the analysis provide insight into levels of feedback given by PTs and suggest activities which develop PTs' handling of incorrect responses, attention to self-regulation, and skills in building on students' mathematical thinking are needed.

Perspective

Black and Wiliam (1998) described written feedback as a formative assessment practice used to move students toward instructional goals and significant in supporting student learning. Many factors (Hattie & Timperley, 2007; Shute, 2008; Wiliam, 2011), including the use of praise (Brophy, 1981), correlate to student learning. The use of feedback to learn is a function of how students attend to and interpret the feedback (Wiliam, 2011). Students' reflections on teachers' feedback illustrate that emotional responses to feedback mediate how the information impacts learning (e.g. Hargreaves, 2013; Havnes, Smith, Dysthe, & Ludvigsen, 2012). These factors illustrate that feedback practices are relational (Fletcher, 1998) and highlight the need to understand PTs' approaches to feedback. We view written feedback as a teaching practice that supports relational interactions between mathematics teachers and students and creates opportunities for student learning in mathematics.

While no studies have examined feedback as a relational practice, meta-analyses have highlighted the effects of feedback (Wiliam, 2011) and defined feedback in various ways: as

"information communicated to the student that is intended to modify his or her thinking or behavior for the purpose of improving learning" (Shute, 2008, p. 154); or as "information generated within a particular system, for a particular purpose" (Wiliam, 2011, p. 4). Wiliam's (2007) discussion of providing feedback in mathematics identified *comments only* feedback as having the potential to positively impact students' attitudes toward mathematics. Student characteristics were shown to mediate these effects, thereby highlighting the role of the teacher's relationship with the student in the practice of giving feedback. We draw on these definitions to create a relational view of feedback as information generated within an instructional system and communicated to the student with the intention of improving learning or performance.

A logical extension is that the feedback must be taken up by the learner in order to be effective. For this to occur the feedback must be seen as supportive of the student or the feedback likely remains a suggestion rather than a call to action. We find that PTs act relationally in letter writing, working not only to build mathematical performance, but also to show care by drawing on interests of students and their thinking to create feedback. Although efforts may begin haphazardly, Crespo's (2002) work illustrates that these efforts can be supported to encompass attention to the self as well as mathematics involved in the task.

Effective feedback answers these questions:	
Where am I going? (the goals)	Feed Up
How am I going?	
Feed Back	

↓

Each feedback question works at four levels:

↓

Task Level	**Process Level**	**Self-Regulation Level**	**Self Level**
How well tasks are understood/ performed	The main process needed to understand / perform tasks	Self-Monitoring, directing, and regulating of actions	Personal evaluations and affect (usually positive) about the learner

Figure 2. Feedback Model (Hattie & Timperley, 2007, p.87).

Hattie and Timperley's (2007) "model of feedback to support learning" (Figure 1) informs discussions about why "particular kinds of feedback promote learning" while others do not (p. 86). Focusing on PTs' feedback to students about their mathematics task work, we address the question "How am I going?" (p. 89) and use this framework to describe PT's feedback at four levels: task level (FT), process level (FP), self-regulation level (FR), and the self level (FS).

We use these levels to develop a profile of PTs' feedback approaches to answer the question: What levels of feedback do PTs provide in written comments to students about their performance or mathematics learning? Each of the authors independently designed opportunities for PTs to gain insights into students' thinking through letter writing, which we considered an approximation of practice (Grossman et al., 2009). PTs provided written feedback to students about their responses to mathematics tasks in the form of letters. Existing research on letter-writing (e.g. Crespo, 2002) has

focused on the types of tasks PTs select or create. We instead describe levels of feedback PTs provide in their responses to students' mathematics.

Modes of Inquiry

We analyzed PTs' letters from three university teacher education programs in the US. All three letter writing activities involved PTs providing feedback to students on work from mathematics tasks to support mathematics learning. The contexts are described in Table 1.

Table 1: Descriptors of the Three Letter Writing Contexts

	Context 1	Context 2	Context 3
Setting	• Rural Midwest • Elementary Education • Mathematics methods	• Suburban Southeast • Secondary Education • College Geometry	• Small Midwest City • Elementary Education • Mathematics methods
Participants	• 19 PTs • 19 Fourth grade students	• 12 PTs • 12 Ninth grade students	• 100 PTs • 76 Sixth grade students
Structure of Task	• 5 letters exchanged between PTs/students • One PT paired with one student • Different mathematics tasks were addressed	• 5 letters written by PTs with 4 student responses • One PT paired with one student • One problem situation addressed through all correspondence	• 1 letter written by PTs (draft and final letter) • 1-3 PTs paired with one student • One mathematics task was addressed
	• PTs wrote a self-report focused on difficulties and insights in corresponding with children	• PTs wrote a self-report focused on PTs abilities in eliciting student thinking and their reflections on learning about feedback	• PTs revised letters after having received written feedback provided by the instructor
Data	• Exchanged letters • PT self-reports	• Exchanged letters • PT self-reports	• PTs' letters • Students' work

Similarities cut across the borders that described the three contexts related to settings, participants, structure of the task, and data, and yet each context maintained unique features. This combination of common and unique characteristics across the contexts provided for data analysis and interpretation that considered how these characteristics might allow for similarities and differences in results and, in turn, better inform the development of PTs' feedback practices.

Hattie and Timperley's (2007) four levels of feedback (FT, FP, FR, and FS) were used to code PTs' feedback. Several coding iterations were conducted while the researchers clarified meanings of the levels of feedback in each context and appropriate uses of codes with respective data. In each context, student responses to tasks were used as a data source to clarify ambiguous

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

statements in PTs' feedback. For example, a PT reflected, "I praised her on her unique thinking strategies that helped her arrive at the correct answers." Unsure of the PTs' meanings for "praise" and a "unique thinking strategy," we searched the PT's letters for evidence of praise for a thinking strategy. The "unique thinking strategy" referred to specific approaches taken by the student such as the following: "I noticed that you knew that you could the (sic) use multiple units to measure the different items." Referring to other data sources clarified the coding of the use of praise as FS and the "unique thinking strategy" as FT. Data chunks that contained more than one level of feedback were labeled with more than one code. Categories within each level (i.e., non-specific and specific praise within FS in Context 1) were developed for each context. We then compared findings from the three groups of PTs to identify commonalities and differences in levels of feedback given, which will be presented in the cross-case discussion.

Results

Findings from Context 1

A majority of PTs in this context provided feedback in the form of FS or FT, with a few providing FP and none acknowledging FR. Twelve of 19 PTs identified praise or FS as a component of their feedback. One PT suggested she used general praise such as "good job." Two other categories of praise linked FS to FT. Five of the PTs described *non-specific praise* of the student's responses (e.g., "I liked how you answered that question"). PTs who used non-specific praise described preserving self-esteem or motivating the student as a rationale for this approach. The six remaining PTs described using *specific praise* that identified what the child had done well. One PT described this approach "My feedback to my Pen Pal was always very encouraging and included things like, 'I like that you did . . .'." These PTs valued providing task specific feedback with praise and were aware they were being specific about what was valued. For example, "I would make sure to write compliments about what they saw in the graph and then explained why that was good that they saw that." With the exception of the PT providing praise alone, the remaining PTs coupled FS (praise) with FT, such as whether the answer was correct, or FP, focusing on processes involved in mathematics. One PT wrote,

> I even broke down how I thought he was thinking about something, so that it was obvious that we were on the same page, that I liked seeing how he did it, and also to give him an example of how to be descriptive as he thinks and writes about math.

Ten PTs were aware that they were providing FT and explained their approaches. Three PTs identified providing feedback whether answers were correct or incorrect. Remaining statements about FT highlighted the PTs' need to focus on what was correct or the strengths of the student's work such as "I told him what he did well on and if he didn't get something right I would explain it so hopefully he would understand." These PTs described a desire to explain how a student might be able to think about the problem, as in the response above, or to extend the student's thinking by suggesting particular strategies. For example, when a student incorrectly interpreted a graph, the PT "recognized the method he used and then elaborated on his thinking," suggesting that the child "look at what the X and Y sides on the graph represent." Overall, the PTs were conscious of not explicitly stating students' answers were wrong, what some called "negative feedback." Instead, they provided "corrective feedback" (Hattie & Timperley, 2007, p. 91) such as solutions or suggestions, as in the graphing example.

Six PTs provided FP. One PT reflected that he always commented on the child's strategies to "help her become more aware of the different thinking methods that you can use to arrive at an answer." His feedback focused on describing the student's work as general strategies. For example, when the student gave an estimate of a measurement and a result of her measurement, the PT

described this as estimating before measuring or computing. Remaining PTs focused on "motivating" students to write more about their thinking or the numbers they choose: "I prompted her to be more specific and write about the specific numbers that she sees." PTs' focus on eliciting detail was motivated by a need to understand the child's mathematics. They shared: "I asked how he was seeing the math. The hope was that it was clear to the student that I wanted him to be detailed and descriptive so that I understood how he was seeing it." PTs' reflections suggest they provided FP to gain evidence of student thinking rather than to support the child's thinking. The PTs' need for more evidence resulted in feedback on students' processes.

Findings from Context 2

Data in the second context revealed that PTs provided feedback in the areas of FS, FT, and FP but that they did not provide FR. Thirty-seven instances of praise (FS), often addressing student's effort, were identified in the letters. Eighteen instances were non-specific statements about self (e.g., "I appreciate your hard work so far. You are making great progress."). And 19 instances included specific statements about the process (e.g., "I really like the way you used your knowledge about the angle measures of a triangle to find all three angle measures.").

PTs' FT (55 instances) attended to two particular areas: helping students draw a picture of the problem situation, and addressing a particular concept need to solve the problem. This letter writing exchange required students to draw a model to construct a solution. PTs attended to the difficulties students had drawing the model. For example, a PT wrote:

> The pirates are facing each other in the locations the problem gives. One last thing, be sure to pay attention to any geographical locations that are given. You can use the compass at the bottom of the map to help. I have highlighted these things for you!

After addressing the model, PTs made efforts to move students toward ideas that focused on concepts that would aid in solving the problem. For example, another PT wrote:

> You are correct that angles do not have the same measure. You are also correct that you know the two angle measures, but let's think about AA for a minute. You said that it was a congruence postulate, but if I had two triangles as shown below with the given angles they do not appear to be congruent triangles. Why is that? AA is a postulate, but it is not a congruence postulate. Keep working you are almost there.

In the area of FP (47 instances), PTs tended to give feedback that either used student statements as the basis for further questions (*building on*) or acknowledged the student statements and then asked a question that was not directly related (*redirecting*). For example, one PT suggested a direction the student should pursue, building on from the student's statements: "In your last letter, it looks like you created a triangle in your map. I like where you were headed with that. Perhaps that is what you should be looking for moving forward." In contrast, another PT redirected the student:

> What you did was draw two parallel lines, but why do you need them? Are we able to get rid of them and still work the problem? With getting rid of the parallel lines . . . we can now connect point A and point B, since that is where the two pirates are.

Findings from Context 3

Feedback written by PTs in Context 3 addressed FS (93 instances), FT (140 instances), FP (90 instances), and FR (7 instances). Much of the PTs' feedback included some form of praise (FS) and was more often than not connected to FT or FP. Praise related to the task addressed correct answers, such as "4/6 is a correct answer! Very good." Praise related to the process addressed strategies used by students: "Your strategy … is a smart way to approach this problem." PTs also acknowledged students' responses without specific use of praise, such as "I can see that you understood what each

fraction is." Two feedback responses included praise focused on FR such as "It was good to see that you tried a different approach at first, and when it did not work you were able to adapt your approach."

PTs provided feedback on the task (FT) that identified correct or incorrect answers (e.g., "Your answer is correct!" and "You are thinking of numbers between the 2 fractions, but 4/5 is actually bigger than 5/8 & 3/4"), and also identified when students did not provide an answer (e.g., "Unfortunately, I am unable to find your answer. What fraction falls between 10/16 and 12/16?"). Additionally, PTs encouraged students to consider more than one answer (e.g., "… could you find another answer that would fit? Or, is 11/16 the only possible answer?").

Feedback on process (FP) requested more information from students, or made suggestions to provide direction for students. A PT wrote, "… could you explain this pattern to me?" Other PTs suggested students visualize relationships among fractions by drawing shaded regions, or number lines. One student had a list of 5/8, 6/8, 7/8, 8/8, 3/4, 4/4 with no explanation, and the PT wrote:

> … start by showing the two fractions as pies so that you can see how they compare. Split the pies into parts to show 5 parts out of 8 and 3 parts out of four. To find one fraction how could you make two pies of the same size using fractions that are still equal to 5/8 and 3/4?

PTs provided FP that clarified faulty procedures in students' attempts to solve the task (e.g., "However, not all numbers between the numerators and the denominators will be between 5/8 and 3/4. For example, 7 is between 4 and 8 for the denominator, but 4/7 is not between 5/8 and 3/4."). PTs also provided suggestions to build on students' strategies. For example:

> Your number line shows us the fourths and eighths for a denominator. However, you can use this number line to show even more possible answers by including sixteenths (1/16, 2/16, 3/16 and so on) and twenty-fourths (1/24, 2/24, 3/24, and so on).

Sometimes (33 instances) PTs' feedback on process (FP) redirected students to strategies not related to the students' work:

> Although there is a pattern of numbers between numerators and denominators, . . . I would suggest to you to find what the decimals are of both fractions, and then try to make up different fractions that would give you a decimal in between both of those two numbers.

PTs were prompted to provide specific feedback to students. The findings illustrate that PTs attended to instructions with providing specific FT and FP. While FT attended to correctness and progress on completing the task, the FP requested more information from students to explain their thinking, suggested a direction that built on students' solutions, or redirected students to a different approach to the task.

Cross-Case Findings

Looking across the contexts we can answer the question: What levels of feedback do PTs provide in written comments to students about their performance or mathematics learning? Across the contexts PTs provided FS, FT, and FP, with a few instances of FR in Context 3.

Praise (FS) was present in the data from all the contexts with differences in the way it was used. The majority of the PTs in Contexts 1 and 3 provided praise either in relation to the task or to the process. In Context 1, PTs were aware of their use of praise, highlighting it as part of the design of feedback. In Context 2, praise of effort was common. We hypothesize that these differences in the use of praise are the result of the activity contexts. In Context 2, PTs were writing to high school students whose answers were generally incorrect. For those PTs, effort was the only element of the response warranting praise. Secondary PTs' attention to effort in feedback is consistent with the findings of Norton and Kastberg (2012). We hypothesize that secondary PTs might attend to effort in

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

constructing responses to problem solving situations because of their awareness of the role of effort in successful problem solving. In contrast, PTs in Contexts 1 and 3 may not have viewed problem situations as requiring sustained effort.

PTs in elementary programs may initially share general praise as shown in Crespo's (2002) findings, but for PTs in Contexts 1 and 3, praise tended to be associated with either FT or FP. Some PTs in Context 1 praised correct answers in non-specific ways. Other PTs, including those in Context 3, tended to combine praise with specific FT or FP on student responses.

While studies of teacher praise suggest that it is not useful to students, PTs may be using praise in letter writing to communicate care. Unlike oral praise that is meant to reinforce behavioral aims (Brophy, 1981), PTs identify praise as a way to demonstrate care and support effort. Particularly where PTs are unfamiliar with the students or the academic goals of the students' teachers, their feedback seeks to reach out to the students to make a connection and then to attend to feedback on the task and, in some cases, processes involved in completing the task. This finding is consistent with emerging use of reform practices across letters Crespo (2002) identified in PTs' teacherly talk.

PTs in all three contexts provided FT. Attention was paid to the student's correctness, and as in Crespo (2002), PTs were explicit when students provided correct answers, but not when answers were incorrect. Instead, PTs focused on task specific approaches or concepts that could lead to correct answers. In Study 2, PTs suggested ways in which students could create a model to support their reasoning. In all three contexts PTs provided specific examples or suggestions the students might use to solve the problem or move toward a correct answer.

PTs in all three contexts attended to FP; however, significant differences were identified. Some PTs in Contexts 1 and 3 requested further evidence from students with those in Context 1 suggesting that further evidence was needed to gain insight into student reasoning. PTs in Contexts 2 and 3 providing FP suggested processes that drew from PTs' inferences about processes students were using. This feedback was described as *building on*. Other PTs suggested processes that were not aligned with student work. This FP *redirected* students to use a new process, perhaps one preferred by the PT.

Discussion

Research shows that practicing teachers tend to give feedback that is limited to correct or incorrect responses, limiting the educative impact that productive feedback practices can afford (Crooks, 1988). Preparation of PTs in the area of effective feedback practices, based upon their current understandings, can positively impact their ability to make use of this instructional tool. Across the three contexts we see FS, FT, and FP. Some of these uses of feedback are identified as effective (Hattie & Timperley, 2007; Wiliam, 2007) and others are not. To build experience with and insight into the use of written feedback, PTs need opportunities to craft such feedback. Our analysis illuminates the PTs' attention to giving feedback as a relational practice. Attention to students as people whom the teachers did not know may have motivated them to praise the children to build relationships. PTs in Context 1 were aware they were using praise but identified it as motivating persistence and emphasizing the child as a unique person. FT focused on explicit attention to correct responses without the same explicit discussion of incorrect responses. Support for extending or repairing solutions in the form of suggestions or explanations of what to do in the context of the task were provided in FT, yet without explicit attention to incorrect responses students may be confused about the feedback and disregard it (Hattie & Timperley, 2007). FP tended to acknowledge the process used by the student, but was as likely as not to redirect the student to follow a process not related to his or her work.

With these findings in mind, mathematics teacher educators designing instructional activities for the development of feedback practices should be focused on discussions of the role of praise in the instructional system, handling of incorrect and incomplete responses, and building on to student

processes. PTs have ideas about how to give feedback on the self, task, and processes that can launch discussions of the benefits and drawbacks of various levels of feedback. After initial feedback to student work is crafted by PTs, mathematics teacher educators can discuss the affordances and limitations of various feedback responses in light of professional guidelines (e.g. Wiliam, 2007). In addition, inattention to FR in all but a few responses across the contexts suggests that instructional activities should be developed that attend to self-regulation as a factor in student performance and how to provide feedback on self-regulation. Crossing the borders of our own programs and contexts allowed us to think more deeply about the development of feedback practices of prospective teachers.

CRITICAL MATHEMATICS EDUCATION: EXTENDING THE BORDERS OF MATHEMATICS TEACHER EDUCATION

Tracy Goodson-Espy	Nirmala Naresh	Lisa Poling
Appalachian State University	Miami University	Appalachian State University
goodsonespyt@appstate.edu	nareshn2@miamioh.edu	poling11@appstate.edu

This study describes efforts at two institutions to integrate critical pedagogy within the context of two mathematics content and pedagogy courses for K-8 pre-service teachers (PSTs). The purpose of the curriculum within these courses was to focus PSTs' attention on how issues pertaining to social justice may be taught within mathematics contexts. The desired goals were for PSTs to: 1) come to appreciate individuals within their own communities as valid practitioners of mathematics; and 2) come to understand the responsibility that they, their school districts, curriculum developers, and others bear to ensure that all students have equitable opportunities to learn mathematics.

Critical Mathematics Education: Transforming Ideology

Mathematics is often taught, and learned, within the confines of a classroom where, in the classical model of mathematics education, the teacher holds the power to teach, and the student receives the information being taught. Mathematics is mostly perceived and presented as an elite body of knowledge far removed from the "lives and ways of living of the social majorities in the world" (Fasheh, 2000, p. 5). Yet, mathematics is woven within all aspects of our world and should be taught, and engaged with, through the lens of a more global perspective. There is a need to institute change in teacher education to provide a counter-narrative to traditionally-held perceptions of mathematics and its pedagogy. Mathematics education instruction needs to be constructed so that individuals may develop both cognitive and social understandings of their world (Wood, 2001). According to Bigelow and Peterson (2002):

> [we need to hold in] our minds and in our classrooms the big global picture. The world is a web of relationships. To be truly effective, every effort to make a difference needs to be grounded in that broader analysis. (p. 7)

Skovsmose (1985) states that when implementing critical education pedagogy, two criteria-subjective and objective, need to be used when selecting problems for the classroom. The subjective requires that the problem appears relevant to the students and within their conceptual understanding. The objective requires using data and detail to view an existing social issue unbiasedly to build deeper understanding. The integration of mathematics and social justice provides the potential to have meaningful conversations about issues impacting local communities, as well as the world, and prepares individuals for citizenship.

This research study inquires how we can teach mathematics that helps learners attain the content proficiencies, but beyond that, equips them with the empathy, consideration, and skills necessary to appreciate all individuals that comprise their community and to see these people as capable of learning and doing mathematics. We seek to merge the research domains of mathematics and critical mathematics education to design courses that question and extend the borders of academic mathematics to include mathematics for social justice. In this paper, we describe curricular efforts specific to two teacher education courses that address goals for PSTs to: 1) come to appreciate individuals within their own communities as valid practitioners of mathematics; and 2) come to understand the responsibility that they, their school districts, and others bear to ensure that all students have equitable opportunities to learn mathematics.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Methodology

Setting and Participants

Two mathematics teacher education courses were taught by the authors at two distinct four- year institutions, one in the midwest and the one in the southeast U.S. PSTs pursuing licensure to teach K-8 enrolled in these courses. The first class is an elective class for elementary PSTs that focuses on issues of social justice in a mathematics education context. This class focused on assignments that required PSTs to explore social justice problems involving mathematics in a global context. The second class was a required mathematics content class for elementary PSTs. The second class included components focused on projects aimed at developing PSTs' awareness of individuals within their communities doing mathematics in local contexts. The key course goals, course activities, and outlines of the course structures were designed collaboratively.

Research Methods

Quantitative. There were two aspects to the methodology of the study. First, to gain insight into PSTs' views concerning multiculturalism and diversity, we administered the scale, *Teachers Sense of Responsibility for Multiculturalism and Diversity (TSR-MD)* (Silverman, 2009) to both classes as a pre-post test to determine if the different approaches to class activities led to changes in the PSTs' scores on this instrument. The instrument requires students to respond to a set of Likert scale questions. The Wilcoxon signed-rank test was conducted on each of the questions in the scale. The significant results with their effect sizes are discussed below.

Course 1 ($n = 23$, (Spring and Fall 2015) was the elective course aimed at social justice in the context of mathematics education. The possible responses for Questions 1 – 74 were: 1 = Strongly disagree, 2 = Disagree, 3 = Moderately disagree, 4 = Moderately agree, 5 = Agree, 6 = Strong agree. Initially, some students seemed to interpret Question 1, *In general, race is unimportant to me*, as "it would be best not to see race in teaching". On the post-test, students interpreted this question differently, beginning to develop a novice understanding of why a teacher should see and accommodate racial diversity. A Wilcoxon signed-rank test determined that there was a statistically significant decline in the number of PSTs who responded positively to this statement on the post-test ($Mdn = 3.0$) compared to the pre-test ($Mdn = 5.0$), $z = -2.06$, $p = .039$, $r = .43$. For Question 8, *In general, schools are responsible for addressing the differences among races*, there was a significant increase in the number of students on the post-test ($Mdn = 4.0$, $s = 1.3$) who saw schools as being responsible for addressing difference between the races, as compared to the pre-test ($Mdn = 4.0$, $s = .96$), $z = 2.03$, $p = .042$, $r = .42$. Regarding Question 10, *My students' economic class plays a role in my teaching*, there was a significant change in how PSTs perceived how students' economic class should affect their teaching as evidence in the post-test ($Mdn = 2.0$) compared to pre-test ($Mdn = 4.0$). There appeared to be a shift toward thinking that economic class should not impact teaching and learning, which seemed somewhat paradoxical given the class focus. Test results were significant, $z = -2.09$, $p = .037$, $r = .43$. On Question 11, *It is my responsibility to ensure various economic classes are represented in my teaching*, the post-test ($Mdn = 5.0$, $s = .1$) compared to the pre-test ($Mdn = 5.0$, $s = .89$) showed more positive than negative differences indicating that PSTs were assuming more personal responsibility for ensuring that various economic classes were represented in their teaching, $z = 2.07$, $p = .039$, $r = .43$. Regarding Question 20, *Gender is relevant to learning*, post-test results ($Mdn = 5.0$, $s = 1.3$) compared to pre-test results ($Mdn = 5.0$, $s = 1.5$), yielded significance, $z = 2.41$, $p = .016$, $r = .5$, pointing to an increase in PSTs viewing gender as being important for teaching and learning. For Question 21, *Curriculum developers are responsible for ensuring various genders are represented in the content curricula*, the post-test results ($Mdn = 5.5$, $s = .87$) in relation to the pre-test ($Mdn = 5.0$, $s = 1.11$) showed significant changes in scores demonstrating that PSTs placed more responsibility on curriculum developers to represent genders in the curriculum ($z = 2.14$, $p = .032$, r

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

= .45). Question 27 asked PSTs to respond to: *It is my responsibility to ensure various faiths are represented in my teaching*. The Wilcoxon signed-rank test indicated a significant increase in PSTs assuming responsibility for representing different faiths in their teaching (post-test, *Mdn* = 6.0, *s* = 1.07; pre-test, *Mdn* = 5.0, *s* = 1.3) with *z* = 2.40, *p* = .017, *r* = .5. For Question 29, *Curriculum developer are responsible for ensuring various faiths are represented in the content curricula*, post-test (*Mdn* = 5.0, *s* = 1.3) compared to pre-test (*Mdn* = 4.0, *s* = 1.4) indicated that PSTs came to place more responsibility on curriculum developers to address diversity of faiths in the curriculum (*z* = 1.99, *p* = .047, *r* = .42).

In the second course, a required mathematics content class for elementary PSTs (n = 14, Spring 2015), we also observed some significant results on the TSR-MD (Silverman, 2009). However, all of these results should be approached with great caution, given the small sample size. For Question 7, *Various races need to be represented in teaching only if students from those races are present in the classroom*, responses on the post-test (*Mdn* = 4.0, *s* = 1.7) compared to pre-test (*Mdn* = 2.0, *s* =.1) were interesting as all of the changes (*n* = 8) were positive, with no negative changes and 6 ties in rank. PSTs seemed to register a belief that different races should be portrayed on the basis of who was in the class, which was counter to the goals of the class. Test results were significant, *z* = 2.54, *p* = .011, *r* = .68. Regarding Question 49, *In general, culture is unimportant to me*, test results were significant with *z* = 2.5, *p* = .01, *r* = .67. The post-test results (*Mdn* =2.0, *s* = 2.0) compared to the ranks of the pre-test (*Mdn* = 1.0, *s* =.61) indicated a change in how PSTs regarded culture in teaching. For Question 50, *My students' culture plays a role in my teaching*, post-test ranks (*Mdn* = 5.0, *s* =.96) compared to pre-test ranks (*Mdn* = 6.0, *s* = .5) showed a slight increase in the PSTs' understanding of their responsibility in including culture in their teaching (0 positive differences, 7 negative differences, and 6 ties) with a significant test result (*z* = -2.5, *p* = 0.14, *r* = -.67). For Question 53, *Curriculum developers are responsible for ensuring that various cultures are represented in the content curricula*, the post-test ranks (*Mdn* = 5.0, *s* = .83) compared to the pre-test (*Mdn* = 5.5, *s* = .65) indicated a slight increase in PSTs' beliefs that curriculum developers are responsible for including various cultures in the curriculum (*z* = -2.33, *p* = .02, *r* = -.63). (For Questions 75-89, the Likert responses were: 1 = Nothing, 2 = Very little, 3 = Some, 4 = Quite a bit, 5 = A great deal). On Question 75, *How much can you do to ensure diverse students learn about their own cultural heritage in your class?* the post-test ranks (*Mdn* = 4.0, *s* = .61) versus the pre-tests (*Mdn* = 4.0, *s* = .62) showed five positive differences, zero negative differences, and nine ties. The significance test was significant with *z* = 2.23, *p* = .03, and *r* = .60. Finally, for Question 76, *How much can you do to teach your students about cultural conflic*t? The post-test results (*Mdn* = 5.0, *s* = .76) compared to the pre-test results (*Mdn* = 4.0, *s* = .83) showed six positive differences, zero negative differences and eight ties, indicating a modest increase in PSTs assumption of responsibility for teaching students about cultural conflict. The test was significant, *z* = 2.33, *p* = .02, and *r* = .63.

The differences in the number and type of significant results for the two courses can be accounted for, in part, by the differences in the foci of the two courses and the emphases of the assignments within the courses, as explained below. However, we also have concerns that the wording of the TSR-MD may have sometimes confused the PSTs. In order to explore some of the results that are confounding given the goals of the courses, follow-up interviews to clarify PSTs answers would be helpful.

Qualitative. We used narrative inquiry as a research method (Creswell, 2008) to organize, present, and analyze the qualitative data, which involved a detailed examination of the field texts (e.g., course activities, projects) produced by the PSTs. In choosing this method, we "adopt a particular view of experience as phenomenon under study" (Connelly & Clandinin, 2006, p. 375). Like other qualitative research methods, well defined boundaries cease to exist in narrative inquiry. In our narratives, we consciously choose and present data that will best help us address the central goal of this paper. The two teacher education courses shape the contextual setting and the students

(PSTs) enrolled in these courses are an integral part of the study. We inquire into our practical and professional experiences grounded in this context, enact dual roles as teacher educators and researchers, and retell a story that unravels connections between theoretical ideologies and practical enactments. The story is structured around a chronology of events that include: a) course design and enactment; b) documentation of field texts; and c) our analyses and interpretation of field texts in relation to the chosen theoretical domain.

The course designs aimed to establish an equitable community of mathematics learners as they explored ways to better understand mathematics and the potential it holds to explore social justice issues. The key course goals were to help PSTs: a) begin to build a critical understanding of the world; b) enlist mathematical tools that support and promote critical understanding of social issues; and c) understand that a global perspective helps us to know ourselves, our community, and our fellow human beings. As members of a community of learners, PSTs were required to engage in class activities, listen to and learn from their colleagues, and respect the opinions of other participants. To establish specific connections to critical mathematics education, participants were asked to think more deeply about the types of tasks that are usually presented in mathematics curriculum; to attend to and explore the connections between a given mathematical task and the local and global contexts. Course content was delivered through practical and research components. As part of the practical component, each week, PSTs participated in at least one content exploration activity set in a social, cultural, and political context. As part of the research component, PSTs were required to identify and investigate a social practice and establish connections to school mathematical topics.

We highlight two course activities (field texts) collected from PSTs work from the two courses. The first activity, required participants to use the Gapminder software tool (www.gapminder.org) and thus help them probe their beliefs and perceptions of the developed and the developing nations of the world. This activity enabled participants to uncover, understand, and question their perceptions about various nations. In particular, they were asked to complete the following tasks:

1. Identify a research question.
2. Explore: a) Describe how the data was analyzed using the Gapminder software.
   b) Interpret the graphs and tell the story. c) Discuss plausible reasons that will explain the trends that were noted in the graph.
3. Reflect: In light of the presented data and its analysis, reflect on the research question.
   a) Suggest possible actions that could be initiated by various agencies to address the global issue. b) As a citizen of the world, how do the findings this concern you? What can you do about it? c) Discuss ways in which prospective teachers can engage students in a deeper analysis of global or local issues using the lens of statistics and through the use of the Gapminder software.

We provide one PST's response here.

PST Research Question: What is it that causes some countries to have such a high child mortality rate, when others don't even have to think about the possibility of their children not making it? I decided to analyze three countries from different locations all over the world: the United States of America, Colombia, and Botswana; all three are on different continents with different ways of life, and overall very diverse economic levels. I was curious to find why with the modern medicine we have is there still a reason to have any child mortality at all.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figure 1. Gapminder Graph: Children Mortality -USA, Colombia and Botswana.

Interpretation: After looking at all three graphs and countries I've learned a lot about what child mortality means in relation to the world around it. It's so interconnected with the rest of the countries issues, no matter if it's what society thinks of those around them or major issues such as the government changing power or parties, this is always being affected, like a ripple effect. It was horrifying to see the starting numbers and think about what those parents had to go through if their child played a part in that statistic, but I did find it comforting to see that even the countries I thought would still be very bad have improved so very drastically. I did catch myself losing touch with what the statistic meant though, sometimes when I would write out the numbers it was like I was almost desensitized with what that number was saying. The gravity of children dying is intense and I think sometimes when we're shown so many numbers like that it's hard to remember what they are truly portraying to us.

Reflection: I think that national agencies could initiate programs educating not only the adults of these countries but the children on health and medicine and prevention. This would help ensure that when these children grow up they know even more about how to help their own children, because if no one learns how to prevent it, these health care issues or diseases will evolve till they can't be controlled at all. I also believe that any action we do or someone does to help these people, needs to be done with these people, they aren't less than us or weaker, they are equals to those helping them.

As a citizen of the world these findings concern me that not all countries have access to the medicine, healthcare, or even knowledge about these issues, and for some to have had them for so long and not reached out to help makes my stomach hurt. ... I understand that the whole situation is more complicated than that involving the governments but I think that anyone can relate to seeing children and the thought of them not making it till they are 5, not even starting kindergarten, is horrifying.

I believe that teachers could integrate things like Gapminder into the classroom in many ways. It's a great way for children and students to start seeing what these numbers actually are and how

they compare to what we have as Americans. It could definitely show them what they take for granted everyday but I also believe in order for them to truly dive deeper into what this mean and talk about the statistics in a local, national, and global level, they need to fully understand what each means and that it isn't just a number, we can't let them desensitize themselves to what they are seeing or they will never understand the weight that these numbers hold.

Through the Gapminder exploration, Skovsmose' criteria of subjective and objective problem posing related to critical mathematics pedagogy are engaged. Students were able to define a problem, that they deemed important to society, and then utilize unbiased information provided through Gapminder to identify issues that influence the overall trends depicted in data.

An activity from the second course required participants to select a topic and complete a project emphasizing that mathematics is a human activity. PSTs identified a personally meaningful everyday activity, collaborated with individuals who were insiders to this activity, and reflected on questions such as: What counts as knowledge in school mathematics? Who are viewed as experts of knowledge? Whose mathematical expertise is valued? Project examples of some projects include firefighter's mathematics, lunchroom mathematics, mathematics of curve stitching, mathematics of a seamstress, and mathematics of a construction worker.

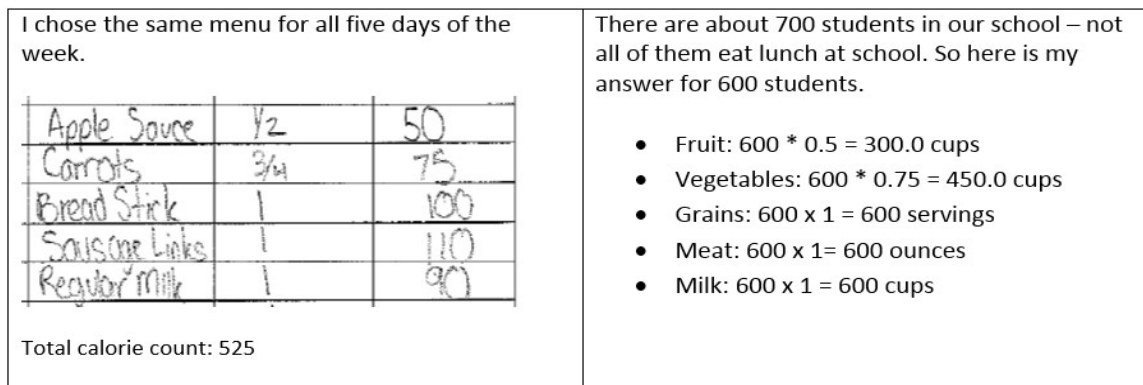
We provide a brief overview of one PST's research project titled *My mother, a lunch lady and our mathematics*. Sam, a prospective middle school teacher, chose her mother, Pam, as her inspiration and resource. Pam has worked in the school lunch industry for seven years and has progressed from an assistant cook, to head cook at a private school, and currently is the assistant cook at a public elementary school. Her role is to help develop lunches on a monthly basis, help prepare the daily lunches, and help serve the food as the students arrive. In collaboration with her mother, Sam developed a mathematical modeling task situated in the school lunchroom context.

Ms. Pam is a head cook in a school cafeteria. She must follow a set of guidelines to ensure that students receive the right amount of each food group per day. There is also a regulation that lunches must be within a certain calorie range.

4. Create a weekly lunch plan that Ms. Pam would approve.
5. On a given day, how much of each food type would Ms. Pam have to prepare?

Sam enacted this activity with a group of 5th graders. We present 5th graders' work specific to question (1) and Sam's commentary. After beginning work on the assigned task, students realized that they needed additional information regarding nutritional and serving size regulations, which Sam provided. Figure 2 captures students' initial responses to the two questions (first model).

Figure 2. Lunch Menu - Trial One.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Tucson, AZ: The University of Arizona.


Upon a review of this work, Pam noted that this simplistic plan neither fulfilled the nutritional requirements nor the recommended serving size regulations. She challenged Sam and the students to experiment with different menu options, interpret their solutions in the context of the problem, and to be explicit in communicating their thinking. Students created another model, this time using five different menu options, one for each day of the week (see Fig. 3).

Food type	Fruit			Veg			Grains			Meat			Fluid			Total Calorie count
	Name	SS	CC	Name	SS	CC	Name	SS	CC	Name	SS	CC	Name	SS	CC	
Mon	Apple sauce	1/2	50	Carrot	3/4	75	Bread	1	100	Sausage	1	110	Reg. Milk	1	90	425

Figure 3. Lunch Menu - Trial Two.

However, as they revisited the task guidelines, students realized that Ms. Pam would not approve their lunch menu. They realized that they still had not attended to the nutritional requirements and the serving size regulations. In the students' next iteration, they made three changes: a) Make changes to the grain / meat item so as to bring the serving size up; b) Make no changes to the milk/ veg. items since they conform to the serving size regulation (if possible, add fruit); and c) All changes must increase the calorie count but not exceed 700. Students realized that a revised model with these changes would certainly get Ms. Pam's approval. At this point in her project work, Sam began to notice how her mother emerged as a prominent figure in this discussion. Sam began questioning her initial beliefs about who can be considered as sources of mathematical knowledge. She began to understand the meaning of learning as, "a truthful collaboration in which all parties come both as learners and as resource" (2, 1998). Sam noted, "Through my interactions with my mother, I learned the lunchroom is full of hidden mathematical concepts. She helped me realize the potential for using them to design math activities." Sam also began to realize that while her mother did do meaningful mathematics, and appeared to be very confident about her knowledge of her practice, "she seemed to dismiss this knowledge as if there was nothing to it." Sam began to see that this dismissal was not warranted. Sam could instead see that her mother, a working class lady, was able to build on her lived experiences, to create a mathematical task that challenged the students. Sam explained, "Upon reflection, I see that I have been oblivious to my own mother's expertise because I truly did not believe that she is a source of knowledge. I have grown confident in teaching modeling to children as I no longer believe that these are abstract concepts for only a select group of students."

Implications for Mathematics Teacher Educators

Both the quantitative and qualitative analyses indicate preliminary results that suggest that through a deliberate scaffolding of course activities and projects, mathematics educators can help PSTs learn to appreciate individuals within their own local communities as practitioners of real mathematics and can leverage the expertise of these individuals in their own classrooms. This may

build confidence within diverse groups of students that they, too, can engage in meaningful mathematics and can build self-confidence within the community about what they have to offer students, mathematically speaking. The results also speak to the power of using sources of real-world data, such as Gapminder, to help PSTs learn to use mathematical tools to explore problems of a global nature and make data-driven recommendations to help solve them. The results suggest that there are concrete ways that we can help PSTs learn to use mathematics to act locally and globally and become willing to assume responsibility for doing so.

Prospective teachers (PTs) need opportunities to develop fraction number sense, yet little research has explicated how this development occurs. Our research team collaboratively designed a task targeted at helping PTs develop fraction number sense through an exploration of fraction comparison strategies. This paper focuses on developing one particular strategy, which we call Greater Number of Larger Pieces (GLP). We argue that understanding this strategy has the potential to support PTs' number sense, particularly in regards to the measure interpretation of fractions. Analysis of data from two iterations of this task (implemented by five mathematics teacher educators at five US institutions with 124 PTs) showed an improvement in the task's ability to naturally elicit the GLP strategy from PTs. We share our task, results from each iteration, and discuss modifications that we believe led to increased usage of the GLP strategy.

Keywords: Teacher Education-Preservice, Mathematical Knowledge for Teaching, Rational Numbers, Teacher Knowledge

Introduction and Background Information

Researchers have argued that number sense is an important part of the mathematical knowledge needed for teaching (Ball, Thames, & Phelps, 2008; Tsao, 2005), and thus, its development should be an integral component of the mathematical preparation of prospective teachers (PTs). Given the prevalence of fraction topics across the K-8 mathematics curriculum, we focus our work on the development of fraction number sense, which Lamon (2012) defines as "an intuition that helps [students] make appropriate connections, determine size, order, and equivalence, and judge whether answers are or are not reasonable" (p. 136). Lamon argues that this intuition is especially important for teachers to develop, as they will need it to evaluate the appropriateness of student reasoning. Yet research shows that PTs often exhibit particularly weak and procedurally-oriented thinking in terms of fractions (Tobias et al., 2014; Yang, Reys, & Reys, 2009).

In order to work proficiently with fractions, students and teachers should be familiar with a variety of fraction interpretations, rather than focusing solely on the traditionally-taught *part-whole* interpretation (Kieren, 1976; Lamon, 2012; Thompson & Saldanha, 2003). Watanabe (2007) states that "when students' understanding of fractions is limited to the part-whole meaning, it is doubtful that they understand fractions as numbers" (p. 57). Busi and colleagues (2015) note, for example, that considering 3/5 as three parts out of five can lead to a non-sensical interpretation of improper fractions, such as 7/5, as seven parts out of five.

Recommendations in the *Common Core State Standards for Mathematics* (CCSSM) in the United States (National Governors Association [NGA] & Council of Chief State School Officers [CCSSO], 2010), and throughout international curricula (Son, Lo, & Watanabe, 2015; Watanabe, 2006; 2007), suggest that viewing a fraction as a measure can help overcome some of the limitations of the *part-whole* interpretation. This view is exemplified by the following third-grade CCSSM content standard (3.NF.A.1): *Understand a fraction 1/*b *as the quantity formed by 1 part when a*

whole is partitioned into b *equal parts; understand a fraction* a/b *as the quantity formed by* a *parts of size 1/*b. The *fraction-as-a-measure* interpretation can support children's development of fraction addition and subtraction knowledge (Son, Lo, Watanabe, 2015) by helping students recognize how adding fractions with like denominators is adding additional iterations of the unit fractions that comprise the original fractions. For example, if one sees 3/7 + 2/7 as 3 pieces of 1/7 and 2 pieces of 1/7, then the combined result of 5 pieces of 1/7, or 5/7, makes sense. Such understanding could help students avoid a common error of adding across the numerators and denominators, i.e., 3/7 + 2/7 = 5/14 (Mack, 1995). These ideas can then be extended to the addition and subtraction of fractions with unlike denominators (McNamara, 2015).

A Task to Develop Fraction Number Sense

This paper reports on our efforts to help PTs develop fraction number sense, including the ability to interpret fractions as measures, through the study of comparing and ordering fractions. A group of six mathematics teacher educators developed and enacted a fraction comparison task, based on a task designed for fifth-graders, in their mathematics content courses for PTs (Tobias et al., 2014). Our goal was to help PTs shift their perspectives on fractions from a *part-whole* to a *measure* interpretation, and in doing so, begin to see fractions as numbers. Research and policy recommendations highlight the importance of providing learners with repeated opportunities to grapple with problems and generate their own solution strategies instead of applying a strategy made explicit by an instructor (Conference Board of Mathematical Sciences [CBMS], 2012; Hiebert & Wearne, 1993; Stein, Grover, & Henningsen, 1996). To this end, we created a task consisting of ten fraction comparison problems designed to help PTs develop understandings of several fraction comparison strategies beyond *common denominators*, the strategy with which they are traditionally most familiar (Olanoff, Lo, & Tobias, 2014).

Although PTs were given the freedom to construct their own fraction comparison strategies, the task was designed to support the development of several predetermined fraction comparison strategies identified in the literature, specifically: *Same Size Pieces* (SSP; also known as common denominators), *Same Number of Pieces* (SNP; also known as common numerators), and *Comparing to a Benchmark Value* (BV) (Lamon, 2012; NGA & CCSSO, 2010). Given our goal of helping teachers develop understandings of fractions as measures, we sought to introduce an additional strategy that we refer to as *Greater Number of Larger Pieces* (GLP). In this strategy, one uses the measure interpretation of fractions to consider each fraction as a certain number of equal-sized pieces. For example, when comparing 18/25 to 16/27, one can interpret 18/25 as eighteen fractional pieces each of size 1/25 and 16/27 as sixteen pieces each of size 1/27. Since pieces of size 1/25 are larger than those of size 1/27 and there is a greater number of them (18 > 16), one can conclude that 18/25 > 16/27. The use of the GLP strategy requires the simultaneous coordination of two quantities - one referring to the *number* of fractional pieces and one referring to the *size* of those pieces.

Below, we describe the implementation of two iterations of our fraction comparison task in mathematics content courses for PTs. We present data analysis focused on PTs' abilities to successfully implement the GLP strategy to solve individual fraction comparison problems and the task's ability to elicit the strategy from PTs. We will discuss GLP-related modifications that were made to the first version of the task based on our data analysis and the effects of those changes. For a more detailed explanation of the task design process, data analysis, and findings pertaining to the task as a whole, see Thanheiser et al. (2016).

Task Version 1

The first version of our task included ten fraction comparison problems designed to elicit our four targeted fraction comparison strategies noted above: SSP, SNP, BV, and GLP. Some problems also required finding equivalent fractions (EF) in conjunction with one of the four strategies. PTs

were instructed to circle the larger fraction and to provide a sense-making justification for their choice. Table 1 presents each fraction comparison problem, as well as the strategy we intended for each problem to elicit.

Table 1. Task Version 1: Ten fraction comparison problems with intended strategies (bracketed numerals following BV indicate intended benchmark values). Underlining indicates the greater fraction.

Problem	Fractions to compare	Intended strategy		Problem	Fractions to compare	Intended strategy
#1	1/2 vs. 17/31	BV [½], EF-SSP, or EF-SNP		**#6**	13/15 vs. 17/19	BV [1]
#2	2/17 vs. 2/19	SNP		**#7**	5/6 vs. 6/5	BV [1]
#3	4/7 vs. 9/14	EF-SSP		**#8**	7/10 vs. 8/9	GLP
#4	3/7 vs. 6/11	BV [½] or EF-SNP		**#9**	1/4 vs. 25/99	BV [¼] or EF-SNP
#5	8/9 vs. 12/13	BV [1]		**#10**	24/7 vs. 34/15	BV [3]

The data analysis included in this paper will focus on problem #8 (7/10 vs. 8/9) since this was the only problem intended to elicit the GLP strategy.

Task Implementation and Data Collection

We launched the task above by asking PTs to list everything they knew about 7/8. We also gave them the following two prompts to work on in small groups:

1. Keeping the denominator the same, find 3 fractions that are greater than 7/8, and 3 fractions that are less than 7/8.
2. Keeping the numerator the same, find 3 fractions that are greater than 7/8, and 3 fractions that are less than 7/8.

Following small group work, each instructor facilitated a brief whole-class discussion in which PTs articulated and justified their thinking.

One of the primary goals of the launch activity was to help PTs begin the transition towards interpreting fractions as measures. For example, many PTs' responses focused on the idea of 7/8 meaning 7 out of 8 parts, which gave instructors the opportunity to highlight additional interpretations, such as 7 pieces of size ⅛. Furthermore, some instructors asked PTs to justify their answers to the prompts above to solidify the relationship between fractions that have the same denominators and those with same numerators.

Following the launch, PTs were given handouts containing the ten comparison problems and instructed to work on the problems either individually or in small groups, without the use of calculators. PTs were encouraged to think beyond using the SSP strategy and apply their understanding of fractions as numbers to find alternative ways of determining the larger fraction in each pair. Instructors allowed the PTs to work on the task for 30-60 minutes before bringing them all together for a class discussion on their solutions and strategies. PTs' written work on the task was

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

collected and copied before the whole group discussion where individual strategies were explicated. This student work on the task prior to the whole class discussion comprises the data for this paper.

Data Analysis and Results - Round 1

Version 1 of our task was implemented in the spring of 2013 by three authors with 61 PTs in four mathematics content courses for elementary PTs across three universities. PTs' written work was analyzed for correctness of solutions, strategies applied, and quality of explanations. While this task proved successful at helping PTs elicit many of the intended fraction comparison strategies, it was not particularly successful at eliciting GLP. In fact, while 51 of the 52 (98%) PTs who answered problem #8 (7/10 vs. 8/9) were able to correctly identify the greater fraction, only three responses (6%) used the intended (GLP) strategy. An additional 10 responses (19%) included the use of valid strategies, such as finding common denominators or converting the fractions to decimals or percents. However, we found that the remaining 75% of responses offered incorrect or incomplete reasoning, e.g., claiming that 8/9 > 7/10 because 8/9 is "close to 1," while 7/10 is "3 pieces away." While this line of thinking does leverage some intuition about a fraction's magnitude, it does not provide a reasoned explanation for how one knows that 8/9 is closer to 1 than 7/10. Moreover, it does not attend to the *fraction-as-a-measure* interpretation, which is a necessary component of the GLP strategy. Additionally, data revealed that the three PTs who developed GLP were in only two of the four classes; thus the eventual presentation of the strategy in the other two classes had to come from the instructors, as opposed to the knowledge being constructed and shared by the learners.

These results led to us hypothesizing two reasons for problem #8's inability to aid in the natural emergence of the GLP strategy. First, given the rate at which algorithmic procedures were successfully applied, we believe our choice of fractions (7/10 and 8/9) did not compel PTs to reason about the number and size of pieces. It appears that PTs were familiar enough with the chosen fractions to use their intuition about their magnitude to determine the larger fraction. Many PTs applied their understanding of 7/10 = 0.7 or 70% and 8/9's "closeness to 1" to justify that 8/9 > 7/10. It seemed that the PTs did not see a need for additional reasoning or a more robust justification. Second, we believe that the GLP strategy may be more difficult to apply than other fraction comparison strategies (such as SNP) because it requires the simultaneous interpretation and coordination of both the numerators and denominators.

Task Modifications

Since the first version of our task was not as successful in eliciting the GLP strategy as we had hoped, we added three new comparison problems to the task with the goal of providing more opportunities for PTs to think about and develop GLP on their own. First, we added 2/9 vs ⅜ (problem #14), which can be solved using a variety of strategies including the GLP strategy. Eliciting multiple solution strategies is known to be an important characteristic of effective tasks (Stein, Grover, & Henningsen, 1996). Second, we added 2/7 vs ⅜ (problem #11), which is purposefully similar to 2/9 vs ⅜, but cannot be solved using GLP. We added this problem to provide an opportunity for PTs to determine when GLP is and is not applicable, as knowing when a particular strategy is and is not appropriate to use can further deepen PTs' understanding of the strategy (Borich, 2011). Third, we added 18/25 vs 16/27 (problem #15), specifically choosing fractions with larger numerators and larger, relatively prime, denominators to deter PTs from using computation-heavy strategies (e.g., common denominators or common numerators), and instead look for more efficient strategies. A total of five new items were added to the task, resulting in a second iteration containing 15 problems. Problem #8, the original GLP problem (7/10 vs. 8/9), was left unmodified.

We also revised our implementation of the launch activity to better elicit the *fraction-as-a-measure* interpretation. Instructors spent more time discussing PTs' explanations of 7/8 and pressing PTs for complete "sense-making" explanations for why certain fractions were greater than or less

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

than 7/8. As one instructor noted in her instructor memo, "I really took my time on this and pressed and probed a lot more than I did last spring" (Hillen, instructor memo). For example, explanations such as "7/9 is farther away from 1 than 7/8" were no longer deemed satisfactory; instead, instructors pushed PTs to explain how they knew this was true. When pressed to explain why 7/8 > 7/9, PTs began to recognize that both fractions have the same number of fractional pieces (7), but since eighths are larger than ninths, 7/8 must be greater than 7/9. Similarly, when explaining why 9/8 > 7/8, PTs recognized that 9/8 has a greater number of eighths. In this way, the launch provided opportunities for PTs to begin thinking about fractions as measures.

Data Analysis and Results - Round 2

The second iteration of the task was implemented during the fall of 2013 by four authors (two of whom were involved in the first implementation) in classrooms at four US institutions with a total of 63 PTs. Compared to the 3 GLP-related responses we received on the first version of the task (6% of PTs who answered #8), nearly 15% of the 61 PTs who answered problem #8 on the second version correctly applied the GLP strategy. PTs' success rates were even greater for the two newly-added GLP comparison problems #14 (2/9 vs ⅜) and #15 (18/25 vs 16/27). Of the 52 PTs who answered #14, over 21% used GLP reasoning; and, while only 46 PTs answered #15, the last item on the task, over 41% of them applied GLP.

Table 2. A comparison of success rates for PTs' application of the GLP strategy on the first and second iterations of the task. (N=61 for Iteration 1; N=63 for Iteration 2)

Iteration	Problem #	GLP Problem	# of PTs who answered the question	% of responses received with correct answers	% of responses received using GLP
1	#8	7/10 vs 8/9	55	98.0%	6.0%
2	#8	7/10 vs 8/9	61	96.7%	14.8%
2	#14	2/9 vs 3/8	52	96.2%	21.2%
2	#15	18/25 vs 16/27	46	95.7%	41.3%

It should be noted that Problems #14 and #15 were the last two comparison problems on the 15-item revised task, so low completion rates may be related to PTs not having enough time to attempt them. However, it might also be that PTs intentionally left these items blank because they were unsure about how to approach them. Regardless, we believe that the major increase in the application of GLP on #15 was at least partly due to the problem being specifically designed to discourage other comparison strategies. With the comparatively large numerator and denominator values, and the selection of relatively prime denominators, the use of the common denominator and common numerator strategies becomes quite tedious, especially without the use of the calculator. As such, it appears that PTs were more compelled to seek alternative strategies for solving #15 than #8 or #14, and ended up applying the *fraction-as-a-measure* interpretation by considering each fraction as a number of equal-sized pieces.

Discussion and Conclusions

The data provide evidence that the second iteration of the task was more successful in eliciting the GLP strategy. Out of the 63 PTs who worked on the second iteration of our task, 21 of them (33%) used GLP on at least one problem, 19% used it on two, and 8% used it on all three of the

applicable problems. These findings are in contrast to the first task iteration, during which only 5% of PTs who worked on the task attempted to use GLP. Additionally, at least two PTs in each of the four classes discovered the GLP strategy on their own, which provided an opportunity for PTs to lead discussions about the strategy with their classmates.

One task modification strategy that has potential for supporting PT learning is creating problems that lend themselves to particular solution strategies while discouraging the use of alternate strategies. Problem #15 (18/25 vs 16/27) is an example of such a problem; PTs were most successful in correctly using the GLP strategy here. Although the benefits of constructing mathematical tasks that elicit multiple strategies are well known (Stein, Grover, & Henningsen, 1996), our work suggests a nuanced approach to task design. In order to elicit particular ideas or strategies, there may be a benefit to constructing some problems that narrow the field of possible solution strategies to those under investigation. In this way, PTs are forced to abandon certain strategies that may not support reasoning and sense making.

Nevertheless, even for problem #15 the majority (58.7%) of the 46 PTs who answered the question opted to use alternative fraction comparison strategies including applying common denominators or common numerators, and comparing the distance of the fractions from ½ or 1. Five PTs (11%) correctly identified the larger fraction, but gave no explanation for their answers. It is interesting to note that seven PTs (15%) showed evidence of some GLP-related thinking, but either their thinking was incorrect or their responses were too incomplete to conclude that the GLP strategy had been successfully applied. For example, some PTs recognized that pieces of size 1/25 are larger than pieces of size 1/27, but they did not attend to the number of fractional pieces in either fraction. Others recognized that 18/25 has a greater number of fractional pieces than 16/27, but did not address the size of those pieces. This result supports the contention that the GLP strategy is challenging for PTs because it requires simultaneous coordination of both the number (numerator) and size (denominator) of the fractional pieces in each fraction being compared.

On a positive note, follow-up analysis suggests that this task can serve as a useful introduction to the GLP strategy. Data from final exams in three of the four classes showed that 78.6% (44 out of 56) of the PTs were able to correctly use a measure interpretation of fractions to justify why the GLP strategy cannot be used to compare fractions such as 27/29 and 31/33.

The evolution of PTs' fraction number sense is critical to their development of mathematical knowledge needed for teaching (Lamon, 2012). While this idea is clearly detailed in the literature, there is little research pertaining to *how* teacher educators can help PTs develop this knowledge. The results of our study provide support for the use of the GLP strategy as one way in which teacher educators can begin to facilitate PTs' fraction number sense. We also provide task design suggestions for eliciting the GLP strategy. Though we found more PTs successful on the second iteration of the task, we recognize that the GLP strategy is complex and may not be learned easily. Thus, future research will be needed to determine additional ways to increase the number of PTs that develop the GLP strategy as well as designing, implementing, and analyzing tasks that will encourage PTs to apply their fraction number sense to develop conceptual and sense-making methods for operating with fractions.

PERSPECTIVES ON TEACHING MATHEMATICS AND SCIENCE IN HISTORICAL AND CULTURAL CONTEXTS

Roland G. Pourdavood, Ph.D.
Cleveland State University (CSU)
r.pourdavood@csuohio.edu

This qualitative and descriptive study examines the evolution of secondary preservice teachers' views on teaching and learning mathematics and science in historical and cultural contexts. Data were collected throughout participants' enrollment in a semester-long course entitled, Perspectives on Science and Mathematics, which is taken in conjunction with student teaching. Data sources included university classroom observations and field notes as well as preservice teachers' verbal and written responses to class discussions, reading assignments, and course activities. Common themes and categories of response were derived from the triangulation of data to include prospective teachers' critical reflections on teaching and learning. The paper ends with a discussion of findings and concluding remarks.

Keywords: Teacher Education-Preservice

Introduction

Mathematics and science are dynamic studies of patterns and relationships that evolve as people participate in and contribute to cultural and historical activities (Wheatley & Reynolds, 1999). "It is estimated that 95% of mathematics known today has been produced since 1900" (Berlinghoff & Gouvea, 2004, p. 53). Since mathematics and science are connected to people's culture and history, many educators are convinced that the teaching and learning of these disciplines can be made more relevant and meaningful to learners if embedded in context. As a consequence, increased attention has lately been given the study of ethnomathematics and its role in helping to clarify the nature and development of mathematical knowledge (Ascher, 1994; Bishop, 1991; D'ambrosio, 2001; Frankenstein, 1995; Nunez, 1992; Orey & Rosa, 2001).

Broadly defined, ethnomathematics involves the integrated study of relationships among mathematics, culture, and history. Its classroom application is predicated on the belief that students' understanding and appreciation of mathematics and science will be enhanced when content is presented in relevant contexts. Support for this idea stems from research which indicates that brain evolution, cultural interaction, and communication all play a major role in the development of mathematical and scientific knowing and understanding (Lakoff & Nunez, 2000; Lave & Wenger,1991; Lerman, 2000).

Presumably, teachers' understanding of what comprises mathematics and science may exert a strong influence on the ways in which they think, reflect, plan, teach, and provide opportunities for their students to learn these subjects. The National Council of Teachers of Mathematics (NCTM, 2000, 1991, 1989) holds that mathematics and science are something people do. They have broad contents encompassing many fields that need to be at the command of all students in a technological society. "Mathematics [and science] are the greatest cultural and intellectual achievements of human kind, and citizens should develop an appreciation and understanding of that achievement" (NCTM, 2000, p. 4).

Methodology

This qualitative and descriptive study is guided by constructivist inquiry (Guba & Lincoln, 1989, 1994; Lincoln & Guba, 1985; McCracken, 1988). In this sense, the study is context specific (i.e., preservice secondary mathematics and science teachers' views on teaching and learning mathematic and scientific content as embedded in the historical and cultural context of a state-supported, urban,

university located in Midwestern America). Data sources include university classroom observations and field notes as well as preservice teachers' verbal and written responses to class discussions, reading assignments, and course activities. Data collection and data analysis occurred simultaneously throughout a semester-long course that aims to provide an overview of the history of science and mathematics and to enable future teachers to enact these historical perspectives and contexts throughout their pedagogy. Based on emergent patterns and themes, several factors were identified as being important considerations in promoting the integration of historical and cultural contexts when planning for and delivering mathematics and science instruction.

All participants in this study were enrolled in a course entitled *Perspectives on Science and Mathematics.* Taken concurrently with student teaching, the design and content of this course has been influenced by work of two curriculum theorists—Doll's (1993) *A Post-Modern Perspective on Curriculum* and Grundy's (1989) *Curriculum: Product or Praxis*. Briefly, Doll (1993) asserts that "curriculum is a process, not of transmitting what is absolutely known, but of exploring what is unknown; and through exploration students and teacher "clear the land" together, thereby transforming both the land and themselves" (p.155). Further, he continues by saying, "a constructive curriculum is one that emerges through the action and interaction of the participants; it is not one set in advance, except in broad and general terms (p.262). Similarly, Grundy (1989) maintains that

> Curriculum is a cultural construction. It is not an abstract concept which has some existence outside and prior to human experience. Rather, it is a way of organizing a set of human educational practices (p. 5).

From these two compatible perspectives, course assignments and activities were developed with the qualified hope that preservice teachers would make their own roads by walking them (Horton & Freire, 1990)—autonomously finding creative and meaningful ways to design, develop, and implement lesson plans based on the pedagogical premises of ethnomathematics.

Importance of Critical Reflections for Teaching and Learning

Reflection is an important tool in the repertoire of any good teacher. The power and influence of critically reflecting on reading assignments, classroom discussions, and activities cannot be underestimated. As the preservice teachers who participated in this study delved into critical reflections and expressed their thoughts and views openly and freely, they became more observant of their own practice. They made what were previously obscure connections more visible and tangible. In addition, by emancipating themselves from being evaluated by the instructor or by their peers, they were able to deconstruct their previous views and reconstruct their new ideas. For example, in a final written reflection, one preservice teacher noted,

> Without the critical reflections, I may have never noticed the issues of my teaching approach or found solutions to problems that I will most likely face in the future. In other words, these reflections have helped me plan ahead for my career and have been invaluable.

Thinking critically, not only on readings and class discussions, but also on lesson planning and presentations, played a vital role in enhancing teaching performance.

All participating preservice teachers agreed that if implemented carefully, thoughtfully, and purposefully, high school students would benefit from learning mathematics and science content from historical and cultural perspectives. One such benefit mentioned by the preservice teachers was student motivation to learn. Another benefit mentioned by interns was the opportunity such study provides for students to celebrate their respective cultures' contributions to science and mathematics. Take for instance this preservice teacher's comment:

In my Algebra I class, my kids asked "who came up with this, anyways?" and I had the chance to tell them a brief history of Algebra, and how it was an Arabic invention. One of my students who happened to be Arabic proudly claimed "no wonder I'm so good at it.

Another preservice teacher had this to say about how a mini-lesson she presented on history and culture to students who were struggling with mathematical notations and expressions increased their interest and persistence in problem solving: "By having this kind of information readily available when students show curiosity, I was able to get them engaged fairly quickly, and they surprised themselves by doing math that they thought was way beyond them." In short, preservice teachers were convinced that teaching mathematics and science in cultural and/or historic context would engage and deepen their students' understanding as they begin to perceive mathematics and science as a living, changing body of contributions and ideas. Preservice teachers felt that teaching content in context also led to an enhanced sense of self-efficacy as their students began to believe that they could overcome obstacles in solving problems just as mathematicians and scientists have done in the past.

Teachers' Realizations

There were three emerging realizations expressed by preservice teachers throughout the semester, particularly during classroom discussions and dialogues. These three realizations were 1) the marginalization of the mathematic and scientific contributions of non-western, non-white, and non-male individuals, 2) the importance of acquiring the knowledge and background needed to teach mathematics and science from cultural and historical perspectives, and 3) the need for an epistemological change in the teaching and learning science and mathematics.

The notion of how marginalized non-western, non-white, and non-male contributions to mathematics and science are in western society emerged several times during class discussions and dialogues. As one preservice teacher commented during a class discussion:

One realization I made is that young women do need particular attention when teaching math and science. I found that it makes a difference to them if they feel included in the subjects. For example, scientists such as Marie Curie and Rosalind Franklin contributed so much to our current understanding of science, and it is a disservice to young women to ignore contributions of women in a high school science classroom.

In support of this perspective, still another preservice teacher stated: "The most prominent realization is that mathematics and science did not start from Greece. If we look around carefully for evidence, we find contributions of many people from many cultures." In short, as the course progressed, the preservice teachers began to appreciate how much a historical and a cultural context can play in understanding and appreciating scientific advances.

The second realization mentioned by preservice teachers during class discussions was that they personally had no recollection of ever studying mathematics or science from a historical or cultural perspective; albeit, everyone agreed that it would have been useful to do so. Generally speaking, teachers teach the way they were taught. Hence, for lack of exposure and insufficient background knowledge, most shy away from including history and culture in their teaching of mathematics and science. This lack of knowledge limits learning opportunities for all students. Even when teachers do attempt to provide a historical context in their lesson planning and implementation, it is often pseudo- or quasi-history (Matthews, 2014). Unfortunately, this is the extent to which most teachers go when incorporating history and culture in their teaching. Hence, teachers' lack of existing knowledge was repeatedly identified as a major impediment to using the history and culture of as a means of engaging students in mathematics and science. On the other hand, as one preservice teacher

observed, "Anybody can put together a lesson plan, but it's the teachers who take the time to understand the background behind their lessons that are the most passionate about what they teach."

The third realization mentioned by several preservice teachers was a noted change in their own epistemological beliefs to include constructivism as a way of knowing and understanding mathematics and science. As one preservice teacher noted, "I believe strongly in a constructivist, problem-based, inquiry approach to teaching science. I find that adding historical and cultural components to my lessons will only serve to strengthen student comprehension and growth, as it brings command, application, and self-efficacy of student-centered learning to new heights." Constructivism asserts that understanding is an activity of the learner. It places the learner at the center of the activity and the teacher as a facilitator of learning. Thus, understanding is built by the learner from his/her experiences as they participate in and contribute to classroom activities in mathematics or science.

> When I first had the idea of teaching mathematics, I was set on teaching the basics, formulas, and everything else that math has to offer. I was very narrow-minded in that regard because that is how I was taught throughout my academic career. But after taking many educational classes, specifically this one, my mind has broadened. (Preservice Teachers Classroom Presentation)

From a constructivist perspective, many preservice teachers mentioned obstacles they faced as they tried to integrate history and culture into their lessons. Overcoming these obstacles certainly requires creativity and a change in epistemology. All preservice teachers mentioned that they needed to gain additional knowledge and experience in order to successfully integrate history and culture into their teaching of mathematics and science. They further recognized this as a virtuous goal that they have not fully achieved.

Challenges of Teaching from Cultural and Historical Perspectives

The preservice teachers who participated in this study expressed a variety of concerns, struggles, obstacles, and questions relative to teaching mathematics and science from historical and cultural perspectives. One such issue was the time it takes to prepare and implement lessons from these perspectives. As summarized by one student during a class discussion:

> I am still struggling with how to incorporate historical and cultural perspectives in a lesson plan, when I do not even have time to present the bare minimum in terms of mandated standards set before us. I feel as if I am in a constant state of 'catching up' when it comes to teaching a particular lesson.

Still another time-related matter mentioned by preservice teachers throughout the semester was the more formidable required adherence to state-mandated standards and standardized tests: "When it comes to Common Core Standards, the history of mathematics or science is not a part of those standards and can't take up too much of class time trying to explain" (Classroom Discussions). Similarly, as expressed by another preservice teacher, "As a teacher, my hands are tied by the standards that are mandated by the state, and it is frustrating that the people calling the shots typically have little to no experience in the classroom" (Classroom Discussions).

Teachers in many schools today are faced with the daily dilemma in deciding how much attention to devote to important mathematics and science content that students need to know and knowledge and skills required to pass state-mandated tests. Teachers and schools are judged on their students' performance on those tests. As a result, test content has a great influence on teachers' instructional time. Most teachers are forced to teach to the tests. However, as evident in the following comment, some of the preservice teachers were convinced that with all these limitations they can and will transform their curriculum planning and instruction by incorporating history and culture into classroom activities.

I believe if something is important to me as a teacher, then I will make time to do it. If incorporating history into my lessons and activities is truly important to me, I will find a way to integrate it in a way that supports the standards and does not cut into my limited time. I am 100% committed to making significant changes to my math curriculum in order to incorporate historical and cultural perspectives. (Classroom Discussions)

Access and equity in mathematics and science classrooms with respect to the availability of technology such as computers and smartboards for teaching and learning was another dilemma and concern expressed by several preservice teachers. This constraint limits meaningful learning opportunities for all students in this technological society. This limitation has a social justice implication. "Technology has changed the way we think and learn, so as educators we must adjust to accommodate for the young minds we are educating. Unfortunately, inner-city schools don't have adequate resources to educate youth" (Preservice Teacher's Final Written Reflection). Yet another expressed concern was finding ways to engage urban youth. As expressed by one participant, "My biggest concern and hurdle is how to take a historical or cultural issue and making it relatable or interesting to a group of students living in poor communities."

A particular challenge mentioned by preservice biology teachers was the conflict between science teaching and religious beliefs, particularly on the topic of evolution. Dialogues emerged several times in the classroom relative to using strategies for solving this type of problem. Some participants believed that they should take a non-confrontational approach to this sensitive issue:

I think at this point I will just teach what employers want to be taught at their schools. I realize that certain topics such as evolution, science and religion are still considered 'Taboo.' Therefore, they should be carefully navigated and if possible should be avoided. (Classroom Dialogues)

Another participate agreed with this non-confrontational approach by saying:

In schools, there's a separation of church and state, so do I continue to elaborate when students have questions or do I discard the questions and say that 'this is not a part of your standards, therefore, we must not discuss it?' Till this day, I have not addressed this concern. I avoid touchy subjects because I do not want my students to be uncomfortable or create a cognitive conflict between their own views and what's scientifically proven. (Classroom Dialogues)

Some participating teachers challenged this non-confrontational approach by suggesting that instead of avoiding and/or ignoring this situation, they must confront the issue and reconstruct it with their students:

I have one student in particular who despite understanding the evidence and recognizing its validity, still refuses to accept evolution as a reality. Her rationale is entirely theological. I am uncomfortable with allowing a student to miss out on such an important theory. As such, I was able to differentiate instruction to spend some time working with her so that I could learn her perspective. It is still work in progress. (Classroom Dialogues)

Another preservice teacher agreed with this approach. He mentioned that when students raise sensitive questions, teachers need to be prepared to respond thoughtfully. He said, "As a teacher I owe it to my students" (Classroom Dialogues).

Discussion

Professional transformation was one of the important realizations achieved by the preservice teachers who participated in this study. Other realizations included 1) the marginalization of non-western, non-white, and non-male contributions to science and mathematics; 2) teachers' lack of necessary knowledge and background experience for teaching mathematics and science from cultural and historical perspectives, and 3) a needed change in epistemology. Summarizing the impact of the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

course on professional development, one preservice teacher wrote, "I became aware of the fact that the idea of an effective classroom is not for all students to have the same outcomes, but more so to create an environment that is friendly, welcoming, and full of historical and cultural aspects that celebrate students' diverse backgrounds, and ultimately creates an equitable learning community." As the preservice teachers engaged in reflective processes, they became better communicators and demonstrated their growth in critical thinking. In addition, as they prepared lessons and presented them to their peers in the university classroom and shared some of their high school teaching experiences, they showed a great deal of professionalism relative to teaching and learning mathematic and scientific content embedded in historical and cultural contexts.

Primarily, the biggest issue teachers have with ethnomathematic and ethnoscientific teaching is the strict standards that are often set by school districts, states, and nationwide education agendas. As a continuing trend in education, schools continue to urge the importance of high marks on standardized tests, and with this as the primary focus, schools set their standards and develop curriculum to maximize test score results. Clearly, teaching the cultural and historical aspects of mathematics and science along with curriculum that has already been set by schools might be deemed unacceptable or a waste of time by some. Given an increasingly wide breadth of material to "cover," administrators may have issues with this approach and, in fact, find it to be too time consuming. Similarly, incorporating history and culture into a mathematics or science lesson might prove a daunting task for teachers in both the time needed for researching and planning such lessons as well as the extra time needed for instructional delivery. Despite these obstacles, participants felt the added effort was worthwhile as evidenced in this preservice teacher's final written reflection:

> With all of these issues such as high stakes assessments, pressure from administration, lack of time and resources, and varying student achievement, I have come to the conclusion, with much ease, that teaching with history and culture in mind to create a strong, student-centered environment is well worth these troubles.

A growing concern in the educational community is that students are losing the ability to create, develop, test, and ultimately think abstractly about mathematics and science content. By incorporating the incredible stories of mathematicians and scientists alike, teachers will elicit an intrinsic curiosity among students and a newfound drive to think critically. Furthermore, teaching with history and culture incorporated into the curriculum will challenge students to confront their own internal struggles with individuality and diversity. As Kragh (1992) put it:

> In an educational context, history will necessarily have to be incorporated in a pragmatic, more or less edited way. There is nothing illegitimate in a pragmatic, more or less edited way. There is nothing illegitimate in such pragmatic use of historical data so long as it does not serve ideological purposes or violates knowledge of what actually happened. (p. 360)

In using the robust history and culture of mathematics and science, teachers can create a learning environment that celebrates individual differences and ultimately promotes positive personal growth and development for all students. "Historical investigations not only promote the understanding of that which is now, but also bring new possibilities before us" (Mach, 1996, p. 316). In addition, teaching from this perspective may help establish a stronger bond between teachers and students. This caring relationship is crucial to the learning process.

Closing on a more personal note, I would simply note that while teaching *Perspectives on Science and Mathematics* for the past six years, it has been a transformative experience to observe the growth of my preservice teachers in terms of their attitudes and professed commitment for teaching and learning mathematics and science in historical and cultural contexts. Their professional transformation has, I believe, helped the interns to begin making their own roads by walking.

Refocusing teacher preparation on the practice of teaching calls for new and different knowledge and skill. We describe the types of knowledge and skill that teacher educators need in order to teach a practice-focused mathematics methods course and report on one program's exploration of possible supports to develop this knowledge in teacher educators.

Keywords: Instructional Activities and Practices, Mathematical Knowledge for Teaching, Teacher Education-Preservice

In recent years, scholars and teacher educators have called for teacher preparation to focus more directly on the practice of teaching (Ball & Forzani, 2009; Grossman, Compton, Igra, Ronfeldt, Shahan & Williamson, 2009; Lampert & Graziani, 2009). They emphasize that preservice teachers (PSTs) need to learn to do key aspects of the work of teaching, rather than just talking about teaching or analyzing someone else's teaching. This call has spurred important changes in both the design and implementation of teacher education. For example, in some teacher education programs, course content has shifted to the teaching of specific "high-leverage practices" (Ball, Sleep, Boerst & Bass, 2009; Davis & Boerst, 2014; McDonald, Kazemi, & Kavanagh, 2013). Teacher education pedagogy is also shifting, in particular, to incorporate "pedagogies of enactment" (Grossman et al., 2009), which include "approximations of practice" such as coached rehearsals (Kazemi, Ghousseini, Cunard, & Turrou, 2015).

This shift toward practice-based teacher education occurring in many programs, combined with influxes of new mathematics teacher educators (MTEs), creates a need to focus on the preparation and professional learning of MTEs. The work of teacher education is complex. MTEs must support PSTs in developing deep and usable knowledge and skill. They need to understand the content themselves and in more specialized ways to support teacher learning (Superfine & Li, 2014), be able to manage the teaching of integrated content, and be able to provide specific and detailed feedback aimed at improving teachers' practice (Van de Ridder, Stokking, McGaghie, & Cate, 2008). Our teacher education program, like many, must prepare novice MTEs to *do* the work of teacher education while simultaneously supporting the learning of PSTs. This work is different in important ways from K-12 classroom teaching. Not only must MTEs be able to enact teaching practices such as eliciting student thinking or leading mathematics discussions, in practice-based teacher education MTEs must be able to decompose teaching practice (Grossman et al., 2009) and support PSTs' learning of these practices. The work of teaching PSTs to successfully engage in these practices entails being able to identify and talk about specific skills and techniques for carrying out the practice as well as appraising PSTs' enactment of the practice. This is different than successfully engaging in the teaching practice.

Less attention has been paid to the knowledge and skills that MTEs themselves need to teach teaching practice; however, the findings we do have suggest that MTEs may be underprepared. For example, in a study of 293 practicing university-based teacher educators, Goodwin and colleagues

(2014) found that most respondents felt underprepared for the work, reporting "happenstance in becoming engaged in teacher education" and a "lack of explicit development of teaching skills or pedagogies related to teacher educating" (p. 291). It is crucial to focus on the professional learning of MTEs for a number of reasons. Practice-based teacher education places increasing demands on MTEs, both in their instruction and their appraisal of PSTs' skills. Second, in our context, our doctoral students will be among the next generation of MTEs, and we want graduates of our doctoral program to be prepared to support the learning of PSTs. Third, within our specific teacher education program, we seek ways to prepare and support MTEs to enact teacher education in ways that are aligned with the goals of the program. Across the board, MTEs' skills matter for the outcomes of teacher education and such attention is crucial to achieving the desired outcomes.

This paper is focused around two fundamental questions in the preparation of MTEs. First, what knowledge and skill is demanded of MTEs to engage in practice-based teacher education? Second, what structures are useful for supporting novice MTEs' learning of such knowledge and skill? We use the case of an elementary mathematics methods course to consider these questions.

Figure 1. Instructional triangle for teacher education (D. L. Ball, personal communication).

Theoretical Framework

Teacher education is something that people *do;* it is not merely something to *know.* MTEs must use knowledge flexibly and fluently as they interact with PSTs, with the aim of helping PSTs become proficient with teaching. This interactive view of instruction can be portrayed using the "instructional triangle" (Cohen, Raudenbush, & Ball, 2003). Conceptualizing the work of teaching PSTs as interactions among teachers (teacher educators), students (preservice teachers), content (K-12 teaching practice), and environments (see Figure 1) has important implications for the identification of skills and knowledge that MTEs need to enact practice-based teacher education. For example, MTEs' knowledge of content, particularly teaching practice, must go beyond being able to enact teaching practices to include being able to identify and decompose such practices, talk about the practices and ways of enacting them, and see different ways of enacting the practice, all of which must adhere to the articulation of the practice. Further, MTEs may need specialized knowledge of mathematics content for teaching teachers (Superfine & Li, 2014). They also need knowledge of their students including the skills that they bring to teacher education, the ways in which they are likely to interpret particular practices, and progressions of development with such practices. Further, because the environment is crucial to the work of teaching, MTEs must consider environments beyond their own classrooms such as field placement classes in which there are mentor teachers with particular orientations to teaching and supporting PSTs' learning. Thus, teaching practice-based courses requires the integrated use of knowledge and skills in particular contexts of instruction.

Context

Over the last decade our teacher education program has engaged in a collective redesign of its undergraduate elementary teacher education program, centered on an effort to focus more directly on practices of teaching (see Davis & Boerst, 2014). The mathematics methods course has been collectively developed by a rotating group of members (see Ball et al., 2009 for a description of the collective work of the planning group) to focus on preparing PSTs to teach K-6 mathematics skillfully to their students. The course works on four teaching practices with a mathematics focus: (1) explaining core content; (2) leading discussions; (3) assessing students' knowledge and skills; and (4) planning instruction. The course develops PSTs' skill with these practices while simultaneously developing mathematical knowledge for teaching. In this paper, we examine the practice of explaining core content with a particular focus on representing and connecting mathematical ideas.

Explaining core content focuses on the work a teacher does to provide all students with access to fundamental ideas and disciplinary practices. There is much for PSTs to learn about this work, including: "strategically choosing and using representations and examples to build understanding and remediate misconceptions, using language carefully, highlighting core ideas while sidelining potentially distracting ones, and making one's own thinking visible while modeling and demonstrating" (TeachingWorks, 2015). In teaching, explanations are often co-constructed with students; however, being able to co-construct an explanation requires knowing what is involved in building a mathematical explanation. Learning to do that oneself is an important part of understanding the practice of explanation well enough to help students learn to explain. We work on the practice of explaining core content across the course with a focus on explaining computational algorithms and their connections to representations in order to build PSTs' mathematical knowledge for teaching.

Mathematics Teacher Educator Knowledge and Skills for a Practice-Based Approach

The instructional triangle illuminates the complexity of the work of teaching PSTs. In this paper, we consider a subset of the knowledge and skill called for by these complex interactions – specialized knowledge of teaching, with a focus on the instructional practice of explaining core content with representations. We then turn to identifying teacher education practices and pedagogies that can be used to support PSTs' learning to teach.

Specialized Knowledge for Teaching Teachers: The Case of Explaining Core Content

To enact the type of practice-based approach to teaching "explaining core content" described earlier, MTEs need to draw on different types of specialized knowledge that could be viewed as parallel with types of mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008), that is – –common content knowledge, knowledge of content and students, and knowledge of content and teaching. However, the "content" in this case is the work of mathematics instruction, and specifically the work of explaining core content.

For MTEs, *common content knowledge* (CCK) can be viewed as the knowledge that mathematics teachers themselves hold. Consider the case of explaining subtraction with multi-digit numbers. The common content knowledge for teaching PSTs to explain multi-digit subtraction includes the mathematical knowledge for teaching (MKT) that would allow PSTs to engage in this instructional practice. This includes knowing which key mathematical ideas to highlight (e.g., importance of making equivalent trades), common student errors in a particular domain (e.g., challenges with regrouping across zero), and how different representations can be used to illustrate particular ideas (e.g., how bundling sticks can be used to show regrouping). Common content knowledge for MTEs might also include knowledge of the instructional practice itself, such as knowing characteristics of a good explanation (Leinhardt & Steele, 2005). In other words, MTEs need the knowledge that they are helping PSTs learn; however, just as teachers need more than common content knowledge of

mathematics (Ball et al., 2008), MTEs also need more specialized knowledge for teaching mathematics instruction.

MTEs would also need *knowledge of content and students* (KCS), which is characterized by knowledge of interactions between their students (in this case PSTs) and content, which in this example would be the instructional work of explaining core content. Knowledge of content and students includes knowing common errors that PSTs tend to make when engaging in the instructional practice. For example, when PSTs explain subtraction with regrouping using base 10 blocks, we have found that they often use language imprecisely when talking about "taking away" and "trading." Additionally, PSTs often attempt to explain using base 10 blocks by first solving the problem with the materials and then showing the algorithm instead of conducting them simultaneously to make clear the meaning of the steps of the process. Knowledge of content and students also includes knowing what parts of an instructional practice tend to be most difficult for PSTs such as explaining the equivalency of trades when regrouping.

Another type of specialized MTE knowledge can be described as *knowledge of content and teaching* (KCT). This includes knowing the types of tasks and representations that are useful in helping PSTs learn a particular part of mathematics instruction. In the case of explaining core content, KCT includes knowing which mathematical content domains might be productive choices for PSTs, who are just beginning to learn this practice (e.g., explaining subtraction with regrouping is more accessible than explaining long division). KCT also encompasses knowing the characteristics of video examples that might be useful in illustrating aspects of a practice.

These illustrative examples highlight that, while MTEs need the same knowledge that skilled teachers need to engage in mathematics instruction, they also need an additional layer of knowledge that can be viewed through interactions inside an instructional triangle in which PSTs are the students and the content is mathematics instruction (See Figure 1).

Teaching the Instructional Practice of Explaining Core Content

In addition to specialized knowledge, a practice-based approach also demands new skills on the part of the MTE. To illustrate some of these new pedagogical skills, we consider two different pedagogies of practice that are used in our teacher education program to support PSTs in learning to explain core content as well as a practice of teacher education which has new demands inside of practice-based teacher education[1]. These are not meant to be a comprehensive list of ways to support PSTs; rather, these serve as examples of the work that a practice-based approach demands on the part of the teacher educator and draws on the types of specialized knowledge illustrated in the previous section.

Modeling. In a practice-based approach to teacher education, "modeling by the MTE" is a key pedagogy (McDonald et al., 2013). This involves the MTE engaging in the instructional practice in front of PSTs to both demonstrate the practice and provide meta-commentary throughout to narrate and make visible the instructional work and decision-making. For example, to model the practice of explaining core content, a MTE could explain subtraction with regrouping using base 10 blocks and simultaneously comment on the instructional work (e.g., making a meta-comment about the decision of how to represent the numbers and base 10 blocks in parallel to highlight connections). This teacher educator pedagogy requires that the MTE be able engage productively in the practice of explaining core content, drawing on the common content knowledge of teachers described above; however, this pedagogy of practice also requires new and different skills not required by teachers themselves. In this case the skill of simultaneously engaging in a teaching practice while narrating and commenting on the instructional work involved. This additional layer involves skills such as deciding what to highlight (or not) about the instruction and how to describe the work in meaningful ways. These MTE skills draw on the specialized knowledge described above; for example, when modeling the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

practice of explaining core content, a MTE might decide what to highlight based on their knowledge of what common errors PSTs tend to make when explaining that core content.

Rehearsal. Another pedagogy of practice that demands new work on the part of the MTE is facilitating coached rehearsals with PSTs (Kazemi et al., 2015). Consider the case of facilitating rehearsals of explaining core content. First, this requires the MTE to establish the norms and culture for working together on practice, as PSTs actually engage in explaining core content in front of the class. This likely builds on other relational work but adds new demands as the MTE asks PSTs to share their teaching publically. Another set of skills is required for facilitating the rehearsals themselves. For example, the MTE must decide when to interrupt a rehearsing PST, what to comment on in the performance, and how to coach (e.g., asking a question, making a suggestion, commenting on what was productive). These skills of providing in the moment feedback draw on a MTEs' specialized knowledge as they simultaneously analyze instruction in the moment and determine what might be most productive to coach on.

Providing feedback on pre-service teacher enactments. A teacher education practice used in our program to support PSTs to explain core content is the work of providing formative feedback on PST enactments). Similar to the work involved in facilitating rehearsals, this practice involves determining which parts of a performance to provide feedback on and how. This rests on the MTE being able to recognize productive, problematic, or incomplete aspects of an enactment and draws significantly on the types of specialized knowledge described earlier. Additionally, MTEs need to determine how to ground their feedback in whatever rubrics or decompositions of the instructional practice are used in the course. This work on the part of the MTE is different from giving feedback on PSTs' reflections about their practice (which is also important), as it demands that the MTE interact with and directly give feedback on enactments of practice, rather than on a PST's skill with analyzing and reflecting on his or her own practice.

Given the demands of the coordination of the specialized content knowledge and pedagogies of practice required to teach a practice-based mathematics methods course, we sought to design and study supports that would enable novice MTEs to build their knowledge and skills while simultaneously supporting their PSTs in learning to teach mathematics.

Structures for Supporting MTE Knowledge and Skills for a Practice-Based Approach

To explore the ways in which support could be provided to novice MTEs, our program uses a set of structures to build the specialized knowledge and pedagogical skills demanded in the teaching of a practice-based methods course. We first describe the overarching organization of the work and then closely examine three of the structures that supported our new MTEs.

Planning group participation

To teach the mathematics methods course, novice MTEs participate in a planning group. The group consists of experienced MTEs, many of whom are not currently teaching the course but are invested in either course development or MTE development, and novice MTEs. The group meets several times prior to the start of the course and then once per week throughout the duration of the course. The group is facilitated by a lead MTE who is an experienced MTE and is also responsible for teaching the lead section of the course. All members of the group observe the lead section with an eye to identified areas of focus. Following the observation of the lead section, members debrief the class with regard to the observation focus areas.

The goal of the group is three-fold. First and foremost, we seek to ensure that the course is designed and taught to consistently provide PSTs with learning opportunities that support their development as elementary mathematics teachers. Second, we provide opportunities for new MTEs to build specialized content knowledge and pedagogical knowledge to ensure that all PSTs are receiving instruction that will allow them to engage in the mathematics teaching practices. Third, we

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

use the teaching of the lead section to adjust the plan or the materials in response to what we learn from the first teaching of the shared plan.

Detailed lesson plans. Prior to each meeting, planning group members review detailed lesson plans and decompositions of practices involved in the upcoming class. The lesson plans include scaffolds to support MTEs in the areas of specialized knowledge, pedagogies of practice, and teacher education practices. An excerpt from a lesson plan is shown in Figure 2 to illustrate the level of detail provided. This plan supports MTEs' knowledge of content and students by noting the areas in which PSTs may need support and explicitly naming what is to be worked on in the modeling. CCK is also supported through the description of the modeling and in the notes.

Activity/task	Detail	Notes
Modeling the standard algorithm for subtraction with bean sticks: Comparison • Distinguish between the take-away and comparison meanings of subtraction • Understand the meaning of the standard algorithm for subtraction and be able to explain why it works: • Begin to problematize the language that is traditionally used with the standard algorithm (e.g., borrowing, you can't take a bigger number from a smaller number) • Continue to develop skills with, and explicit knowledge of, what is involved in modeling computational procedures: e.g., physically placing materials; attending to language and using the language of the materials; coordinating use of the materials with talk and recording	Comparison interpretation: (15 minutes) Explain that we are now going to shift our focus to the comparison interpretation of subtraction. Model the standard algorithm again, with the same numbers (52 − 13), but this time using a **comparison** interpretation. Do NOT use the modeling checklist for this first performance. Elicit a few comments from the group. Ask interns to model the standard algorithm, with the same numbers (52 − 13), using a **comparison** interpretation. Suggest they start by laying out both 52 and 13. Encourage interns to use the modeling checklist. (If interns finish early, try another problem like: 60 − 27; 48 − 25 etc.) If time permits, invite an intern to come to and model for the group. Alternative, discuss questions/challenges which arose when working with a partner.	*Modeling the comparison tends to be more complicated and it is important for interns to see a complete performance.* *The comparison can be modeled by matching, either by drawing lines or by removing the matching pairs. Both have issues to consider: When doing the matching by drawing lines, the answer may not be easy to find — the answer is the amount that remains unmatched. And with taking matches off the board you lose the original numbers in the problem.* *You might comment that comparison is typically more difficult for children.*

Figure 2. Lesson plan for modeling subtraction using the standard algorithm.

Planning group structure. Each meeting is structured to first provide MTEs an opportunity to debrief both the observation of the lead section and the teaching of their own section. These debriefs are focused on questions designed by the lead to highlight the key work of MTEs in this context. For example, the lead MTE might ask group members to observe a class session in which multiple pedagogies of practice are being used to identify the pedagogies and consider the features of each and how they are supporting PSTs' learning. This type of question brings to the fore the questions that MTEs must consider when determining how to teach particular practices to PSTs as well as the key features of the pedagogies used.

Following the debriefing, MTEs engage in work to prepare for the next class. The structure of this work varies depending upon the mathematical content and required pedagogies and teacher education practices for the class. Structures include framing and walking through particular activities (e.g. setting up the goals and purpose of modeling the explanation of subtraction using a particular representation and talking about what should be highlighted for PSTs), providing space for discussion of questions that MTEs may have about the lessons, rehearsing sections of the lesson, and discussing annotated videos. Each of these structures was designed to support novice MTEs' content knowledge and development of skill with teacher education practices and pedagogies of practice. The primary (noted by P) and secondary (noted by S) uses of each of the structures in shown in the table below. Descriptions of two key structures that are specifically designed to support new MTEs' understanding of and ability to engage in pedagogies of practice and teacher education practices follow.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Question sessions	S	S	S	P
MTE rehearsal	P	P		P
Annotated videos	S	S	P	P
Observation	P	P		P
Debrief	S	S		P

MTE rehearsals. MTE rehearsals are used in two different ways. To build skill in teacher education pedagogy of modeling, we have novice MTE rehearse the modeling that will take place in front of the PSTs. One experienced MTE runs the rehearsal while other MTEs participate in the role of PSTs. The experienced MTE pauses the rehearsal at strategic moments to support the novice MTE and the group as a whole in engaging in the metacognitive work of MTEs such as considering what should be highlighted (and how) for PSTs, at which moments meta-comments should be made for PSTs, and how best to represent the connection between the mathematical notation and the representations. This collective work provides support for MTEs in understanding the pedagogy as well as the pedagogical content knowledge and knowledge of content and students required to engage in the pedagogy with particular content.

We also rehearse running a rehearsal with PSTs. It is structured slightly differently, but provides many of the same supports. In rehearsal of rehearsal, an experienced MTE serves as the PST who is engaging in the practice of explaining core content, the novice MTE serves in the role of the MTE who is running the rehearsal with the PST, and another experienced MTE runs the rehearsal, giving feedback to the new MTE on their choices for pausing the rehearsal, the feedback they give to the PST, etc. In this case, the MTE serving in the role of the PST designs their performance to highlight common ways that PSTs approach explaining the content, including challenges with coordinating between representations and common language issues. This design provides opportunities for MTEs to develop their own KCS at the same time as developing their skill with the pedagogy of rehearsal.

Annotated videos. The work of providing feedback to PSTs involves not the ability to identify key parts of the practice, but an ability to align feedback with both the decomposition of the practice that is being used with the PSTs and with the PSTs' progression of development expected at the time of the feedback. One way to support novice MTEs with this work is through the use of annotated video. Videos are annotated by experienced MTEs to provide feedback to PSTs. Initially, novice MTEs watch the videos with annotations in an attempt to notice and justify on what and how the MTE provided feedback to the PST. This initial experience supports new MTEs in developing a sense of how to align feedback with the decomposition and how to choose what to give feedback on. Later MTEs watch videos without annotation then annotate the videos themselves as if they were giving feedback to the PSTs. Their annotation is then compared with the experienced MTE's annotation. Novice MTEs are provided with opportunities to discuss decisions that experienced MTEs made when providing feedback.

Discussion

The knowledge and skills of teacher educators are crucial for the success of teacher education. Our paper focuses on one particular element of content taught in an elementary mathematics methods course and unpacks the knowledge and skill that MTE need to support the learning of PSTs. We

describe several structures that we have found useful when supporting novice MTEs' skills and knowledge development. Importantly, our analysis shows that being an experienced K-12 classroom teacher is by itself insufficient for teaching practice-based teacher education courses. As a field, we must plan deliberately for the development of novice MTEs to realize the goals of practice-based teacher education. Further, although we focus on novice MTEs in this paper, because of the context of our work, we believe that experienced MTEs who have not taught practice-focused courses need to develop additional skills to enact practice-based teacher education. As a field, we must put increased focused on the preparation of teacher educators and this paper offers an analysis of one teacher education program's attempt to do so.

Endnotes

[1]In our view, there is an important distinction between teacher education practices (such as eliciting PST thinking, assessing PSTs' work, providing feedback) and pedagogies of practice (such as rehearsal) that are activity structures in the context of teacher education. We take up this distinction in other work.

Our study investigates preservice teachers' perceptions of real-world problems; their beliefs about teaching real-world contexts, especially ones sociopolitical in nature; and their ability to pose meaningful real-world problems. In this paper we present cases of three preservice teachers who participated in interviews that probed their thinking about real-world problems, and asked them to create problems they would consider using in their future classrooms. We use the three cases to propose a potential trajectory for preservice teachers from ambivalence to certainty about teaching mathematics through real-world and controversial contexts.

Keywords: Teacher Education-Preservice, Equity and Diversity, Problem Solving

Introduction and Review of the Literature

In this paper we present work that is part of a larger study investigating different aspects of preservice teachers' (PSTs) relationship to real-world problem solving and problem posing. Here we place an emphasis on PSTs' problem posing and draw on their thinking about contexts they would (and would not) use in their teaching to inform the steps that we, as mathematics teacher educators (MTEs), need to take in order to prepare teachers to teach through real-world and controversial issues. The border-crossing metaphor applies to our work in at least two ways: we want PSTs to cross from posing superficial real-world problems to posing authentic ones; and we want them to cross from "safe" topics that do not challenge unjust systems to those that draw from sociopolitical and potentially controversial contexts.

Real-world problems have recently come into the spotlight in mathematics education due to their treatment in the Common Core State Standards for Mathematics (CCSSM) (CCSSI, 2010). The CCSSM introduced modeling not only as a content strand in high school mathematics, but also as one of the eight essential mathematical practices to be developed in all mathematics classrooms at all grade levels. According to the document, "mathematically proficient students can apply the mathematics they know to solve problems arising in everyday life, society, and the workplace" (CCSSI, 2010, p. 7). However, the types of problems recommended by the CCSSM are not the norm in school mathematics, where real-world problems are frequently understood to mean textbook story problems, with contrived contexts and neat solutions that combine the numbers given in the problem in an algorithmic manner. Verschaffel, Greer, and De Corte (2000) describe textbook problems as "routine applications without judgment or any higher level thinking skills" (p. xiii) and "artificial, puzzle-like tasks that are unrelated to the real world" (p. xv). As an alternative to scripted textbook problems, researchers suggest realistic real-world problems, as they can enhance student performance (Boaler, 1993; Verschaffel, Greer, Van Dooren, & Mukhopadhyay, 2009) and contribute to a bigger picture of mathematics (Blum, 2011).

These real-world contexts recommended by research (and the CCSSM) are rich and varied, and include examples from science, engineering, and business among others (Common Core Writing Team, 2011), but do not explicitly include applications of mathematics that emphasize (a) connecting mathematics to students' lives and backgrounds in meaningful ways and (b) using mathematics to critically analyze our world and challenge injustice. Real-world applications that exclude the aforementioned (a) and (b) can certainly improve student access to rich mathematics and their academic achievement, but do not help develop their identity or empower them as citizens

(Gutiérrez, 2007). Frankenstein (2009) argues instead for *real* real-world problems, which "use mathematics ideas in struggles to make the world better" and, along with Gutstein (2006), promotes mathematics as a tool for reading the world, explicitly focusing on issues of social justice, including, but not limited to, income inequality, education funding, homelessness, institutional racism. The use of critically oriented real-world problems is essential in mathematics teacher education, as it helps PSTs see mathematics as a window into the worlds of their future students and a mirror into their own (Gutiérrez, 2007). Through engaging with *real* real-world problems, PSTs gain an understanding of the circumstances students live in, the relevance of mathematics to their own lives, and the power of mathematics in reading the world and developing agency.

In addition to solving real-world problems, PSTs need to be able to write them as well (Gonzales, 1994). Because problem posing is typically not emphasized in mathematics education, PSTs encounter difficulties when posing real-world problems for the first time. They typically create problems that can be solved in only one way and in a single step (Crespo, 2003); limit contexts to time, food, and money (Gainsburg, 2008; Lee, 2012); and are unrealistic and can even include objects like unicorns and aliens (Lee, 2012).

Our work investigates real-world problem solving and posing in the context of PSTs' beliefs and knowledge about connecting mathematics to students' lives and about using mathematics to critically analyze the world. We have developed a survey that measures preservice teachers' beliefs about engaging in mathematics teaching based in real-world contexts (Simic-Muller, Fernandes, & Felton-Koestler, 2015); and have conducted interviews in the first author's mathematics content courses for K-8 PSTs, investigating their thinking about different types of real-world contexts. In this paper we focus on examples of real-world and controversial issues that PSTs were asked to create in the interviews. In particular, we present cases of three PSTs and propose a trajectory, based on their interview responses, towards competency in teaching mathematics through authentic problems about complex issues.

Methods and General Observations

Our 35-item survey investigates PSTs' beliefs about teaching through real-world problems (6 items) as a whole, as well as three other subscales: controversial issues (8 items), injustices (11 items), and family backgrounds and community practices (10 items). We used a 1 (Strongly Disagree) to 5 (Strongly Agree) Likert scale for each item. These categories are present in a survey we have created and conducted with 127 PSTs thus far. The survey design was informed by literature and our experience working with preservice teachers (see, in particular, Felton-Koestler, 2015). We also sought comments from seven experts in the area to ensure content validity. We highlight a few items in Table 1. The questions corresponding to the other three sub-categories closely match the ones in Table 1.

Table 1: Sample Survey Questions

1.	When I teach mathematics, I will make connections to REAL-WORLD SITUATIONS.
2.	I am interested in learning how to make connections to REAL-WORLD SITUATIONS.
3.	When I teach mathematics, I will focus on mathematical concepts (e.g., addition and subtraction, geometric shapes, etc.) and not worry about using REAL-WORLD SITUATIONS.
4.	When teaching mathematics, REAL-WORLD SITUATIONS can distract students from learning the important mathematical concepts.
5.	An advantage to teaching mathematic with REAL-WORLD SITUATIONS is that they help students learn about the world around them.
6.	Teaching mathematics with REAL-WORLD SITUATIONS helps students learn the mathematical concepts better.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

In the survey and interviews, we explained controversial issues as "topics that will likely be viewed as contentious or debatable. Not everyone agrees on what topics are controversial, but some examples might include the costs of the war on drugs, government spending, funding for schools, or climate change."

We have been recruiting preservice teachers nationwide for the survey, but have currently mostly collected data from the first author's two-part mathematics content course for K-8 PSTs. In the course, PSTs see some examples of contexts investigated in the survey prior to responding to it (e.g. they might have investigated the affordability of housing by minimum wage-earners, or the gender wage gap), and after the survey is administered (e.g. the racial make-up of the Congress or the interest rates when renting to own); but the primary focus of the course is on developing mathematical content knowledge.

Based on the 127 survey responses, 96% of the respondents agree or strongly agree with making connections to real-world contexts in their teaching. Unsurprisingly, it is much more difficult for PSTs to agree with using controversial topics, with only 24% responding with "agree" or "strongly agree." However, both the survey and interviews indicate that PSTs are generally curious about controversial issues: in the survey 64% (agree or strongly agree) said they were interested in learning how to make connections to controversial issues.

In order to better understand survey responses, the first author also interviewed nine students who were, with one exception, taking a class with her for the first time, and had had no known prior exposure to issues of social justice in the context of mathematics. The interviews took place after the end of the semester. PSTs volunteered for the interviews, and represented a wide range of interests and openness to mathematics teaching and social justice. The interviews varied in length, and followed a semi-structured format. The interview questions investigate survey topics at more length, for example:

> Some people think it is important to teach mathematics by making connections to **real-world situations**. What does that mean to you? [Can you give me some specific examples? Can you give me more specifics? How would you teach it? Which mathematics would you use? What issues are relevant to you?]

The interview protocol contains similar questions about controversial issues, injustices, and family backgrounds or community practices. For the purposes of this paper, we will consider questions related to real-world situations and controversial issues, as defined above. The first two authors coded the interviews for common themes.

While all interviews provide valuable insights, we decided to focus our attention to three PSTs: Mirinda, Briana, and Laura (pseudonyms). We began the data analysis for this paper by looking at the codes related to mathematics content present in the interviews, and extracting all relevant quotes from all nine. While rereading and organizing the quotes, we noticed that Briana's statements often emerged as significant; she was therefore the first PST chosen for a case study. We next included Laura, who we identified in prior research (Simic-Muller et al., 2015) as more advanced in her thinking about real-world and controversial issues than her peers. We realized, when comparing their responses, that there was a progression from Briana's to Laura's responses, and finally decided to include Mirinda's case to complete the progression. We identified four common themes that emerged in all three interviews: the ability to imagine relevant contexts for real-world problems, perceptions of children's ability to engage with complex real-world contexts, beliefs about the role of controversial issues in the classroom, and interest in teaching through real-world and controversial issues. We describe the range of views among the three PSTs in each of the four themes through quotes from their interviews and our interpretation of their quotes, and hypothesize that these may be a potential trajectory for PSTs engaged in course work emphasizing real-world and sociopolitical connections in mathematics.

Three Cases

Mirinda: Beginning the Journey

Mirinda is a quiet student who wants to teach third grade, and who performed well in the course, but seldom made contributions to class discussions or approached assignments in original ways. Her interview is not a departure from her typical classroom demeanor. Mirinda's interview displays characteristics we think of as emergent in the development of a positive disposition toward teaching through real-world and controversial issues. The four themes in her interview are discussed below.

Imagining relevant contexts. Mirinda thought that third-graders should encounter real-world mathematics problems, but had difficulties coming up with examples. The ones she picked were standard ones: sharing food fairly and shopping at a store. Other PSTs had similar difficulties in the interviews, and in particular also chose similar contexts: six out of nine mentioned food, and three mentioned money. The following exchange shows Mirinda proposing a promising context based in students' communities, but then turning it into a static story problem.

> *Mirinda*: For third grade, they are old enough to go to the store and buy snacks and they know how much to pay and if they are getting the right amount of change.
> *Interviewer*: How would you do that in your classroom?
> *Mirinda*: I would say word problems once more. So I would give them a scenario. They go to a store and they buy a certain item, and give them the cost, and ask them how much will the total cost and how much change with they get back.

When asked for an example of a controversial issue, Mirinda shared an example from an assignment completed earlier in the semester, and otherwise responded, "I can't really think of anything."

Perceptions of children and controversy. Mirinda seemed to believe that children cannot understand complex real-issues, stating that "it would be difficult for younger students to understand." Other PSTs in the interviews also stated that children are too young to understand issues or to care about them, even if those children live in circumstances investigated by the real-world problems.

Controversy in the classroom. Mirinda did not see a need for teachers to teach through controversial issues, saying that "it should be optional for teachers to teach it." Of course teaching controversial issues cannot and should not be mandated, but in this statement made by Mirinda we also see a relinquishment of responsibility for teaching for change to a self-selected group of teachers, instead of being distributed to all.

Interest in teaching with controversy. Mirinda also did not feel too much curiosity about teaching through controversial issues. She responded to the question of whether she was interested in learning more about the topic with, "If I find content and issues that go with it, maybe…" This was not the case with other interviewed PSTs, who all expressed interest, if accompanied with doubt, in learning more about controversial issues.

Briana: Eyeing the Line

Briana is a PST from the campus' low-income neighborhood who has lived in different parts of the city and has attended some of the highest- and lowest-performing schools in the region. She wants to teach first grade, and is an average mathematics student. Because of her background she has a greater awareness of neighborhood and community issues than most of her peers. Briana was also concerned about the effect that teaching controversial issues might have on others. In the interview she made references to borders by expressing concerns about "staying on one side of the fence" and making sure not to "cross the line." The four themes emerge in her interview as well.

Imagining relevant contexts. Briana had difficulties coming up with real-world contexts, and her mathematics examples were not particularly rich. While she said she wanted to bring children's lives into mathematics teaching, she was unable to come up with an example beyond counting, for example suggesting that "they could go outside for a homework assignment and they could count how many bikes they see and things like that. However, despite these difficulties, Briana believed that "it's not very hard to incorporate math into real world situations."

Perceptions of children and controversy. Briana believed that children should be aware of the world around them. She had some reservations about their ability to comprehend the issues, but to a lesser extent than Mirinda. For example, when discussing recycling, she noted:

> I think it is good for students and children to know what is going on around them, it may be on the broad spectrum and they may not get the whole picture but it's still important for them to know… [T]hey may not know everything about one thing that you are trying to get the point across, like recycling they don't need to know the pros and cons but they can get the point of, "Oh it's good to recycle, I recycled 10 bottles this week."

We would advocate extending this reasoning to most controversial issues: even if students do not understand it fully yet, there is usually an entry point for discussing it. We should not prevent young children from thinking critically about the world just because they will not be able to understand all its workings.

Controversy in the classroom. Briana wanted to know where to set a limit and how not to go beyond it, because "we don't know where to draw the line, or what's appropriate for what age necessarily." She also briefly mentioned that parent resistance might get in the way of teaching controversial topics to young children. Like other PSTs we interviewed, she was concerned about offending someone by teaching topics some might find inappropriate. This is understandable, and points to the need for MTEs to support PSTs in learning to navigate these complex spaces so that they and their students can learn to both play the game and change it (Gutiérrez, 2007).

Interest in teaching with controversy. Briana was open to and aware of controversial issues, but preferred safer ones. She was interested in the environment, but would pick recycling over climate change, because the latter could "start to get controversial." Similarly, if she talked about the military, it would have to be in a positive light:

> You can't go on the other side of the fence but you have to stay on one side if you talk about that with all the military families, that's where all the controversy comes in, you so you have to be very positive about it, like how many people have family in the military, so let's make them thank you cards.

While this could be viewed as backing away from controversy, it can also be seen as recognition of the local context – criticizing the military is widely unpopular in the area where Briana lives. Briana's concern about not offending people is common, and we as MTEs need to develop tools to help PSTs develop the courage to cross to the other side of this fence, i.e., be critical of and challenge the status quo, and not only help their students succeed academically, but also empower them to challenge inequity and injustice (Gutiérrez, 2007).

Laura: Over the Line, Looking Back

Laura is also White, and wants to teach upper elementary school. Her responses to the interview prompts show deeper thinking than those of her peers, and we have conjectured (Simic-Muller et al., 2015) that this is due to three factors: (a) her mathematical knowledge, as she is getting a middle-level mathematics endorsement; (b) her background, as, like Briana she grew up in the neighborhood surrounding the campus and is aware of its strengths and challenges; and (c) her position on campus as a residence assistant, in which she participated in a variety of social justice programming. We will

compare and contrast Laura's characteristics pertaining to our four stated themes to those of Mirinda and Briana, hoping to understand what sets PSTs like Laura apart from her peers.

Imagining relevant contexts. Laura had no difficulties creating real-world examples for various grade levels. For a real-world context, she gave examples of whole number and percent problems about the numbers of children who speak other languages in order to celebrate bilingual children. For a controversial issue she proposed investigating how many school lunches a favorite celebrity could buy for students with her income, with the purpose of "realizing how do we make it fun but also relate it to our own lives," and noting that "it's not just me compared to them, but our whole society compared to them [which is] easier to look at rather than me compared to you." She claimed that she is "always thinking of things in [her] daily life in math ways," and as she is "pretty confident in the content [she will be] teaching, and the standards [she will be] trying to meet," it is "easier to relate those on the spot to different things and come up with things on the spot."

Perceptions of children and controversy. Laura did not dismiss younger students' ability to deal with real-world, issues, though, like the other PSTs, thought that in-depth conversations are easier to facilitate with older students, partly because younger students do not have as many mathematical tools available to discuss complex issues. She also explicitly discussed children's backgrounds, which she believed should be celebrated, such as the number of languages a child speaks or the number of people living in his household; and she believed that even the basic data collection questions, such as recording how many pets each child has, is a "way to create a community in the classroom and have students learn about other students."

Controversy in the classroom. Laura was confident that she would teach through real-world issues. Although she too had concerns that the administration and student might disapprove of discussions about touchy subjects, she offered strategies for turning these stakeholders into allies. She built on her experience as resident assistant to describe that, when discussing a potentially touchy subject, she would explain to students who might be impacted by it that "it's great for people to be aware … of all these things going on people's lives." Similarly, she said she would "would like to be able to do what I want in my classroom with math" but would ask her supervisor, "I am interested in using these types of situations, how would you suggest, or could you suggest a different way that I bring these up in the classroom?"

Interest in teaching with controversy. Finally, although she did not explicitly say it, her entire interview indicates her openness to learning more about teaching through real-world and controversial issues.

Discussion

The three case studies show a range of beliefs and knowledge related to real-world connections. While additional research is needed to better understand how PSTs' beliefs and knowledge develop, we hypothesize that the cases may represent a possible progression that PSTs first developing familiarity with these ideas may follow.

First, mathematical content knowledge is important for problem posing (Gonzales, 1994), but it is not sufficient. Although Mirinda possessed reasonably strong mathematical knowledge, she was unable to come up with a rich context on the spot. Laura, on the other hand, talked about "always thinking of things in my daily life in math ways," and we believe that the ability to view the world through a mathematical lens, along with content knowledge, can support PSTs' problem-posing skills. A question for our consideration, then, is how to help develop a mathematical lens in all PSTs, especially those who see themselves as bad at math.

Second, if PSTs do not believe that students are capable of engaging with real-world and controversial contexts, then they will not feel compelled to think about these contexts. Doubts about children's interests or abilities repeatedly occur in the interviews, yet we know from research and our

experience that young children do possess the capacity to engage with complex contexts and mathematics (e.g. Turner, Varley Gutiérrez, Simic-Muller, & Diéz-Palomar, 2009; Murphy, 2009; Varley Gutiérrez, 2013). Many MTEs already challenge PSTs' perceptions about children's ability to develop their own strategies, and it is important to challenge their perceptions about children's ability to engage with real-world contexts as well. We need more accessible examples of young children being successful at grappling with complex real-world problems that deal with their lives or the world at large.

Third, PSTs are hesitant to introduce controversial topics into their teaching. With the current climate of excessive teacher evaluation and diminished autonomy, these concerns are far from unfounded. However, Laura's approach, which seeks to turn students and administrators into allies, is a promising one. MTEs need to provide positive examples of communities and schools working together to enact change and to support PSTs in learning to successfully navigate these complicated political spaces.

Finally, as obvious as it may seem, it is essential that MTEs provide PSTs with ample opportunities to learn about real-world mathematics problems and controversial topics. In our survey, though few PSTs readily agree to teach using controversial issues, many more are at least curious about this approach. We will also encounter PSTs like Miranda who do not yet see its point, but may begin to do so through appropriate and relevant examples. We need to better understand pathways to creating curiosity in PSTs who come to us with little prior experience with social justice in order to help them develop interest in teaching mathematics to critically analyze the world.

PRESERVICE TEACHERS' CONCEPTION OF EFFECTIVE PROBLEM-SOLVING INSTRUCTION AND THEIR PROBLEM SOLVING

Ji-Won Son
University at Buffalo – SUNY
jiwonson@buffalo.edu

Mi Yeon Lee
Arizona State University
Mlee115@asu.edu

Despite the importance of teachers' conception of effective problem-solving instruction, limited attention is given to this area in the current literature. In this study we examined 96 preservice teachers' (PSTs) views on effective problem-solving instruction and how their conceptions are related and reflected in their views on problem solving and problem solving performance. Analyses of survey responses revealed that our PSTs seem to develop narrow views on effective problem-solving instruction. In addition, we found a positive association between PSTs' conceptions of effective problem-solving instruction and problem solving. However, no such connection exists between PSTs' views problem-solving instruction and their performance.

Keywords: Teacher Beliefs, Problem Solving, Teacher Knowledge, Teacher Education-Preservice

Introduction

Preparing effective teachers of mathematics who promote students' conceptual understanding and problem-solving abilities is one of the most urgent problems facing teacher educators (Morris, Hiebert, & Spitzer, 2009). It is recognized that the quality of problem-solving instruction matters the most for improving students' mathematical abilities (e.g. Stigler & Hiebert, 1999). However, there has not been a clear agreement about what can be counted as effective problem-solving instruction (Krainer, 2005). The interpretation of a problem-solving lesson as 'good (or effective)' or 'bad (or ineffective)' is a value-loaded judgment. In addition, the notion of problem solving has been used with multiple meanings that range from "working rote exercises" to "doing mathematics as a professional" (Lesh & Zawojewski, 2007). Thus what is meant by effective problem-solving instruction is often subject to interpretation in a particular context and ill-defined in the literature, which suggests the importance of clarifying the meaning of effective problem-solving instruction in mathematics education.

Although several researchers focused on students' and teachers' perspectives of mathematics classes includes their meanings of "effective teaching", "good teaching", "good teacher", "good class", or "model class" (Kaur, 2008; Li, 2011; Seah & Wong, 2012; Cai & Wang, 2010), limited attention is given to preservice teachers' (PSTs) conception of effective problem-solving instruction in the current literature in the US context. The purpose of this study is to explore PSTs' conceptions of problem solving and effective problem-solving instruction and to investigate any relationship that might exist among PSTs' conceptions of effective problem-solving instruction, problem-solving, and their problem solving performance. In exploring the relationship between PSTs' conception of effective problem-solving instruction and their problem solving abilities, we specifically focus on fraction topics because it is often reported that not only students but also teachers have difficulties in understanding fractions and fraction operations (NRC, 2004; Son & Crespo, 2009. The research questions that guided this study are: (1) What are the characteristics of PSTs' thinking about effective problem-solving instruction and problem solving?; (2) Is there any relationship among PSTs' conceptions of effective problem-solving instruction, problem solving, and their problem solving performance?; and (3) What are the PSTs' views on what it takes to develop effective problem-solving instruction?

Theoretical perspectives

What constitutes effective problem-solving instruction?
      Problem solving is a powerful vehicle for students' mathematical learning (NCTM, 2000). Schroeder and Lester (1989) identified three types of teaching approaches to problem solving that have been emphasized at different periods of time in mathematics education: (1) teaching *for* problem solving, (2) teaching *about* problem solving, and (3) teaching *through* problem solving. Each of these perspectives offers different affordances. The first approach involves teaching skills or abstract concepts first and then students apply the learned skills or concepts to solve the given problems. The second approach indicates teaching students the process of problem solving or strategies for solving problems explicitly. In the book of *How to Solve it* (1945), George Polya generalized the four steps that can be used regardless of subject matters—(1) identifying a problem, (2) designing a strategy, (3) implementing, and (4) looking back. Teachers explicitly teach the aforementioned four-step process with strategies for problem solving (i.e., approaching methods to a problem). The third perspective includes classroom instruction where students learn mathematical concepts through real contexts and problems, which helps students build meaning for the concepts before moving to abstract concepts (Boaler, 2008; NCTM, 2000, 2014).
      Various criteria can be used in specifying the features of effective problem-solving instruction. Drawn from Stanic and Kilpatrick (1989), we believe that *problem solving as art* should be a goal of effective problem-solving instruction. According to Stanic and Kilpatrick, three different meanings were attributed to the notion of problem solving in mathematics education-- *problem solving as means to a focused end, problem solving as a skill,* and *problem solving as art.* Different from the first and second perspectives where problem solving is viewed as a means to practice skills or as one skill taught in school mathematics, problem solving should be viewed as an act of discovery through creative use of mathematical thinking. Thus, among the three types of teaching approaches by Schroeder and Lester (1989), we consider the third approach--*teaching mathematics through problem solving* as effective problem-solving instruction (NCTM, 2000, 2014).

Research on teachers' conceptions of problem solving and effective instruction
      Prior research has documented that teachers' beliefs and conceptions about the subject and its teaching interact and influence mathematics teachers' planning and delivery of instruction which may impact student achievement (Koehler & Grouws, 1992). However, research directly addressing the issue of 'good (or effective)' classroom instruction from teachers' perspectives is a relatively new endeavor in mathematics education (Cai, Kaiser, Perry, & Wong, 2009). In particular, limited attention is given to the issue of 'good (or effective)' problem-solving instruction from teachers' perspectives in the current literature in the US context.
      Kaur (2008, 2009) carried out a series of studies in Singapore where 8th grade students were asked to describe the qualities of a "good mathematics class" and the "best mathematics teachers". Kaur concluded that "good mathematics teaching in Singapore is student-focused" (2009, p. 346). However, Shimizu (2006), who investigated Japanese students' perceptions on good mathematics lessons, reported that Japanese students consider that a mathematics class is good when there is a "whole class discussion" (2009, p. 316). In general, the research presented herein shows that the views of teachers and students regarding "good teaching" or "effective teaching" vary in relation to multiple factors.
      Using the three meanings of problem-solving by Stanic and Kilpatrick (1989) and the three teaching approaches to problem solving by Schroeder and Lester (1989), we explored PSTs' conceptions of problem solving and effective problem-solving instruction.

Methods

96 PSTs from two different university sites – one from a large northeastern university and the other from a large southwestern in the US – were invited for this study. Participants majored in elementary education and they were either in their sophomore, junior or internship year. A written task was used for the study, which consists of two parts (see Fig. 1).

Part 1: Please answer the following questions in as much detail as possible.
1. When people say problem solving, what does the word "problem solving" mean to you?
2. What do you believe constitutes effective problem-solving instruction?
3. What skills are necessary to create effective problem-solving instruction?
4. How do you believe the skills necessary for teachers to create effective problem-solving instruction develop?

Part 2: Solve the following problems.
1. At both Rivers High School and Mountainview High School, ninth graders either walk or ride the bus to school. 6/7 of the 9th grade students in Rivers High School ride the bus, while 7/8 of the 9th grade students in Mountainview High School ride the bus. If there are 40 9th grade students who walk at Rivers and 25 9th grade students who walk at Mountainview, in which school do more students ride the bus? In which school do a greater fraction of the students ride the bus? Explain your strategies or solutions as much as in detail.
2. For each picture shown below, (i) write a fraction to show what part is shaded. For each picture, (ii) describe in pictures or words how you found that fraction, and why you believe it is the answer.
3. Merlyn spends $60 of her paycheck on clothes and then spends 1/3 of her remaining money on food. If she had $90 left after she buys the food, what was the amount of her paycheck? Explain your solution method as much as in detail. You may use representations (e.g., diagrams, rectangles, number line etc.).

Figure 1: Main task of this study.

For the analysis of PSTs' written response to problem solving and effective problem-solving instruction, we used an inductive content analysis approach (Grbich, 2007). We initially organized raw data into an Excel spreadsheet, read all of the responses. PSTs' responses to the notions of problem solving and effective problem-solving instruction were categorized based on themes emerging as researchers read multiple cases. Then we explored the subcategories under each analytical aspect according to the framework (e.g., Table 1). Finally, we interpreted the data quantitatively and qualitatively (Creswell, 1988).

For the problem solving task, we first created a rubric based on correctness of PSTs' responses to each item and their problem solving process and assigned a score for each item. To examine relationship among PSTs' conceptions of problem solving, effective problem-solving instruction, and

their problem solving performance, we ran SPSS statistical program (i.e., chi-squared tests and ANOVAs).

Summary of selected findings

PSTs' conceptions of effective problem-solving instruction and problem solving
To investigate PSTs' conception of effective problem-solving instruction, we reviewed their responses and classified the responses into four aspects based on common themes (see Table 1). Among the four aspects, the first one is the *purpose* aspect of problem-solving instruction (i.e., what is a good problem solving lesson aimed at?). The second aspect is *problem features* (i.e., what is considered as a good problem for problem-solving instruction?) and third one is *problem solving steps* aspect (i.e., what step(s) are/is required for problem-solving lesson?), which involves four steps to solve a problem such as identifying a problem, planning a strategy, carrying out and looking back. The last one is *teaching* aspect (i.e., what instructional strategies or teaching practice are needed for effective problem-solving instruction?).

Table 1: Four aspects of PSTs' conception of a good problem solving lesson and frequencies

Category	Sub-category	# of PSTs	Relation to 3 approaches of teaching PS
1. Purpose aspect (28)	To find a good solution	7	For
	To develop critical/ creative/ logical /reflective thinking (cognitive aspects)	16	Through
	To develop a good understanding of mathematics	5	Through
2. Problem aspect (41)	a. Word problems	2	For/Through
	b. Real-life problems	2	Through
	c. Problems that allow students to use their prior knowledge	5	Through
	d. More practice problems that allow students to apply the same technique	6	For
	a. Problems that require different strategies/multiple solutions	13	Through
	b. Problems that require explanations	0	Through
	c. Problems that require various representations	3	Through
	d. Problems that require creativity	1	Through
	h. Problems that are not overwhelming/not too difficult	9	For
3. Problem solving steps aspects (42)	a. Structuring a lesson based on all four problem solving steps	14	About

	c. Making sure if students understand the topic	7	Through
	d. Giving examples about how to solve	6	For
	e. Giving definitions	2	For
	f. Providing hands-on manipulatives	1	Through
	g. Giving enough time to work on problems	5	For/Through
	h. Providing a direct and clear direction and structure	15	For/About
	i. Engaging students in solving a problem mentally	6	Through
	j. Lessons that are interesting to students	2	Through

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Note. Majority of PSTs addressed multiple categories. These responses were coded in multiple categories as long as the categories were present in their written responses.

Out of the four aspects, the most popular category is teaching aspect, followed by problem solving steps aspect, problem aspect, and purpose aspect. Among PSTs who mentioned about the teaching aspect, 26 PSTs emphasized that different/multiple ways of solving a problem is important for effective problem-solving instruction. However, interestingly, many PSTs out of the 26 PSTs also considered that it is important to provide a direct and clear direction (15 PSTs) or give examples about how to solve a problem (6 PSTs). This finding suggests that our PSTs perceived the value of multiple solutions, but they believed that they could teach the different/multiple solutions through a *direct instruction* rather than through student-centered discussions. After identifying the four aspects, we collectively considered them to categorize PSTs' conception of effective problem-solving instruction into the three groups by referring to Schroeder and Lester's (1989) identification. Out of 96 participants, 42 participants considered effective problem-solving instruction as teaching *about* problem solving, 23 participants as teaching *through* problem solving, and 31 participants as teaching *for* problem solving. This finding indicates that despite the consistent emphasis on teaching *through* problem solving in current mathematics education, a large portion of our PSTs still did not have a clear view of teaching *through* problem solving.

In a similar way to what we analyzed for PSTs' conception of effective problem-solving instruction, to explore their conception of problem solving, we reviewed their responses and classified the responses into four aspects: problem aspect, process aspect, purpose aspect, and knowledge/skills/ability required. Out of the four aspects, the purpose aspect is the most frequent, followed by process aspect, and problem aspect and only a small number of PSTs considered the aspect of knowledge/skills/ability required for problem solving (Son, Lee, & Arabeyyat, 2015). Based on this analysis, we categorized PSTs' conception of problem solving into three groups by referring to Stanic and Kilpatrick's (1989) identification. Out of 96 PSTs, 55 PSTs considered problem solving as *means* to a focused end, 27 PSTs as a *skill*, and 14 PSTs as *art* of discovery.

Relationship between PSTs' conceptions and their mathematical performance

A chi-squared test showed that there is a positive relationship between PSTs' conception of problem solving and their conception of effective problem-solving instruction, $\chi^2 = 16.888$, $df = 4$, $p = 0.002$. That is, PSTs who perceived problem solving as *means* to a focused end seem to consider effective problem-solving instruction traditionally in that their views on effective instruction were categorized into "teaching *for* problem solving". In addition, the results for ANOVAs revealed that there is a significant difference of mean scores concerning problem solving competence among groups of PSTs who perceived different views on problem solving, $F(2, 75) = 3.292$, $p = .042$. PSTs who perceived problem solving as *art* showed highest mean scores in the problem solving tasks, followed by PSTs who with problem solving as *means* to a focused end (see Table 2).

Table 2: Results from ANOVAs test

		Sum of Squares	df	Mean Square	F	Sig.
1	Between Groups	349.936	2	174.968	3.297	0.042
	Within Groups	3980.0120	75	53.067		
	Total	4329.949	77			
2	Between Groups	25.768	2	12.884	0.216	0.807
	Within Groups	2743.049	46	59.631		
	Total	2768.816	48			

Note: 1 = PSTs' views on problem solving; 2 = PSTs' views on effective problem-solving instruction

However, there was no such connection between PSTs' conception of effective problem-solving instruction and their mathematical performance, $F(2, 46) = 0.216$, $p = .807$. Appendix A presents PSTs' mathematical competence in the problem solving task, focusing on PSTs who perceived problem solving as art.

What knowledge and skills are needed for effective problem-solving instruction?

When the PSTs were asked to indicate types of skills necessary for creating effective problem-solving instruction, our PSTs pointed out not only knowledge and disposition but also skills such as problem solving skills, teaching skills, and lesson design skills (see Table 3). Out of the three big categories, the most popular category is skills, followed by knowledge and dispositions.

Table 3: PSTs' report on knowledge and skills needed for *effective problem-solving instruction*

Knowledge and skills for good lessons	
1. Knowledge	*72*
1.1 Knowledge about content.	22
1.2 General pedagogical knowledge.	6
1.3 Knowledge about problem solving steps.	11
1.4 Knowledge on different solving strategies.	18
1.5 Thinking (critical, organized, creative, thinking)	15
2. Skills	*79*
2.1. Problem solving skills	39
2.1.1. Identifying or understanding questions/problem	18
2.1.2. Breaking problem into easier steps	2
2.1.3 Organizing or logical skill	6
2.1.4 Thinking backward/Reflect or check answers	1
2.1.5 Following the 4 steps (Work on the process behind problem solving)	4
2.1.6 General good problem solving skill (Not specified)	8
2.2. Teaching skills	30
2.2.1 Unpacking knowledge/Step by Step direction	3
2.2.2 Explaining/ Articulating	10
2.2.3 Answering students' diverse questions	3
2.2.4 Attending to students' thinking or work (Noticing skill)	6
2.2.5 Engaging/Motivating students	4
2.2.6 General teaching skill (Not specified)	4
2.3. Lesson design skills	10
2.3.1. Lesson planning	4
2.3.2 Creating a good problem	6
3. Attitude and disposition	*50*
3.1 Patient	15
3.2 Open-mind	12
3.3 Creative	18
3.4 Collaborative	2
3.5 Efforts or working hard	5

When we further explored PSTs' perception of what it takes to develop effective problem-solving instruction, ten categories emerged shown in Table 4. A large portion of the PSTs considered that necessary skills for effective problem-solving instruction are developed through teaching experience (31) or problem solving itself (44).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 4: Resources for developing skills for good problem solving lessons

Category	Total
1. By practicing problem solving or solving problems to be a good problem solver through mastering problem solving skills	44
2. Experience or trial and error (e.g., teaching and making lesson plans)	31
3. Developing dispositions (e.g., creativity, open-minded, compassionate toward kids)	12
4. Time	11
5. By learning knowledge or skills (e.g., different problem solving methods)	10
6. By understanding students' work or working with students	6
7. Teacher education program (e.g., by taking classes)	5
8. Working with other teachers	4
9. Finding resources (e.g., standard, book, videos)	3
10. By observing experienced teachers, experts, or mentor teachers	1

Discussion and Implications

This study contributes to the current literature on problem solving and the knowledge base of teacher education. In particular, this study has implication for teacher educators working to design mathematics education courses for PSTs, as well as for researchers interested in furthering understanding of teachers' knowledge, beliefs, and problem solving strategies. The findings of this study suggest that teacher educators need to find a better way to help PSTs perceive problem solving as *art* and effective problem-solving instruction as teaching mathematics *through* problem solving. One approach would be: Have PSTs experience three different perspectives of teaching mathematics and compare affordances and limitations of each approach. Then teacher educators need to give PSTs more opportunities to experience teaching *through* problem solving in their mathematics methods courses where PSTs engage in mathematical modes of thought by analyzing and interpreting the problems (Son, 2013; 2016). Future studies need to be done with different research tools and in multiple contexts, possibly using interviews or observations to provide more detailed explanations for teachers' responses. Furthermore, intervention studies that experiment with these suggestions are needed to find a better way to support PSTs' conceptions regarding problem solving, problem solving lessons, and their problem solving abilities.

IMPROVING PRE-SERVICE TEACHERS' NOTICING WHILE LEARNING TO LAUNCH

Rob Wieman   Amanda Jansen
Rowan University   University of Delaware
gomathman@yahoo.com   jansen@udel.edu

Effectively launching a task involves surfacing and addressing misconceptions so that students can make progress on the task. Launching a task is supported by teachers' noticing (interpreting and responding to students' thinking). We investigated the degree to which an intervention supported improvements in pre-service secondary teachers' (PSTs') abilities to notice when launching a rich proportional reasoning task. Through the use of representations of practice and an intervention consisting of opportunities to make sense of and discuss multiple choice options for interpreting and responding to students' thinking, we analyzed whether PSTs improved their abilities to notice. After the intervention, PSTs improved in responding to a student's misconception when PSTs concurrently exhibited expertise with interpreting students' thinking.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices

Effectively introducing or "launching" rich mathematical tasks is an important teaching skill (Jackson, Garrison, Wilson, Gibbons, & Shahan, 2013; Stein & Lane, 1996). When launching rich tasks, effective teachers support students as they make sense of the context. Effective teachers also clarify the problem to be solved and surface and address misconceptions that obscure core mathematical issues.

Jacobs, Lamb, and Philipp (2010) have identified attending, interpreting and deciding how to respond as three aspects of teacher noticing. To launch a task well, teachers need to *attend* to students' thinking, *interpret* students' thinking, and then *decide how to respond* to students' thinking in ways that support students' sense-making without reducing the cognitive load of the task. In this paper, we report on our efforts using animated representations of teaching in pedagogy courses to improve pre-service teachers' (PSTs') abilities to interpret and respond to student thinking while launching a rich mathematical task.

Perspectives on Teacher Learning

When confronted with complex phenomena, experts rely on *schema* to make sense of situations and inform decision-making (Bransford, Brown, & Cocking, 2000). Given the complexity of noticing, we hypothesize that developing sophisticated schema would enable PSTs to interpret and respond to student thinking during a launch. Their interpretations and responses would then support students' engagement with the task.

There is evidence that PSTs possess naïve schema that interfere with their efforts to engage students in productive mathematical work. When interpreting student thinking, many teachers have two categories: students that "get it" and students that do not (Otero, 2006). Additionally, PSTs often assume that students who perform procedures correctly have conceptual understanding (Bartell, Webel, Bowen, & Dyson, 2013). These schema may make it difficult for PSTs to identify and engage students' prior understandings, an essential element of effective launches in which students make sense of rich problems. Therefore, one of our goals for PSTs' learning was to expand their schema for interpreting student thinking in ways that would lead to improved launches. In particular, we hoped that PSTs would become able to: (a) identify important student misconceptions and (b) differentiate between procedural and conceptual understanding.

When responding to student thinking, PSTs also may create challenges for students based on naïve schema. Given the persistent prevalence of IRE (initiate, respond, evaluate) discourse patterns in American math classrooms (Franke, Kazemi, & Battey, 2007), PSTs might be pre-disposed to

respond to student thinking dualistically by correcting incorrect responses and praising correct ones. This precludes opportunities for reasoning and elevates correct answers over deeper understanding (Stein, Grover, & Henningsen, 1996). To promote students' opportunities to reason about mathematics, especially in working through misconceptions that could interfere with productive mathematical work, we wanted to expand PSTs' schema for responding to student thinking so that they would: (a) leverage misconceptions to engage the class in reasoning about important mathematics and (b) assert the value of understanding why a solution makes sense when confronted with a procedural response.

The Process of Teacher Learning

"Practice-based" teacher education situates teacher learning in the actual work of teaching (Ball & Cohen, 1999). However, teaching is complex (Lampert, 2001), and novices struggle to make sense of big ideas when confronted with multiple dynamics of real classroom situations. Representations of teaching that retain some of the complexity of practice, while also providing opportunities for novices to focus on specific elements of practice are a valuable tool for teacher educators as they struggle to situate learning in practice while simultaneously focusing on core ideas (Herbst, Chazan, Chen, Chieu, & Weiss, 2011). *LessonSketch* (http://www.lessonsketch.org) is a web-based platform that allows for creating cartoon storyboards of classroom interactions and embedding them in interactive assignments for PSTs. This platform can present complex situations, but focuses PSTs on specific elements of those situations, thus shaping their attention.

Research Questions

We created a *LessonSketch* experience to introduce and expand PSTs' schema for interpreting and responding to typical examples of student thinking in the context of a rich task on proportional reasoning. As a part of the experience, we presented multiple-choice options for how to interpret and respond to students' thinking. We hypothesized that by working to make sense of possibly new categories for interpreting and responding in the context of potentially realistic classroom interactions during a lesson, PSTs could expand their own schema, which could improve their abilities to effectively interpret and respond to student thinking.

Our investigation was guided by these research questions: (a) After completing a task designed to expand schema for interpreting and responding to student thinking, in what ways, if at all, do PSTs show improvement in interpreting and responding to student thinking during the launch of a complex task? (b) In what ways, if at all, do these improvements reflect the options introduced in the multiple-choice task designed to expand PST's schema?

Context and Methods

This study took place in secondary mathematics methods courses in undergraduate teacher preparation programs at two different Mid-Atlantic universities. Both of these courses were connected to field experiences, shared an emphasis on proportional reasoning, and took place near the end of the PSTs' teacher education coursework. Both courses also focused on pedagogical strategies that support students with developing conceptual understanding of important mathematics through problem-solving, including planning and enacting effective lesson launches.

To engage PSTs in thinking through the launch of a rich task, we designed a *LessonSketch* experience which featured the initial reactions of ten different students to the following task:

> At the hardware store they sell 30 pound bags of sand for 6 dollars. At the lumberyard they sell 50 pound bags of sand for 9 dollars. Where should I buy the sand? Which store has the better deal?

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

The experience also indicated that the learning goal of the lesson featuring this task was to understand the quantitative relationships in the problem and understand why scale-factor or unit rate strategies would support finding the solution.

We designed two different versions of this *LessonSketch* experience. One version was administered twice and served as a pre- and post-assessment. In this version PSTs worked individually, writing an interpretation of each student's thinking, and a description of what they (the PST) would plan to do in response.

The second version of the experience was the multiple-choice intervention, designed to expand PSTs' schema for interpreting and responding to student thinking. The task and specific examples of student thinking remained the same. For each instance of student thinking, participants were given a series of choices that represented the schema we were trying to introduce about (a) interpreting and (b) responding to students' thinking. For example, choices for interpreting, or "what can you tell about this student's thinking," included (among others):

- This student is thinking about the mathematics of the lesson in a way that will lead to a correct solution
- This student has a misconception that will get in the way of them creating a correct solution
- This student is working to remember and/or apply a procedure without any evidence of understanding the underlying mathematical relationships

Choices for responding ("What would you plan to do?") included (among others):

- Facilitate a discussion during the launch in which students respond to this student's idea; students do most of the talking
- Briefly explain or clarify to the whole class during the launch. You, the teacher, do most of the talking.
- Explain or clarify to individual student during the launch.

PSTs completed this second version in pairs. We hypothesized that the opportunity to discuss with partners would support PSTs in making sense of the multiple-choice options.

Data Analysis

This analysis focuses on PSTs' interpretations and responses to four of the ten items. Two items (1 & 6) represented univariate thinking: a student attended to only one of the quantities in the problem (i.e. only the sand or only the price) rather than a relationship between the amount of sand and the price (Harel, Behr, Lesh, & Post, 1994). The other two questions (2 & 10) represented procedural thinking: the student talked about a rule for solving the problem without evidence of deeper conceptual understanding.

We created codes for determining whether PSTs' answers were at the levels of novice, emerging expert, or expert. These codes were developed through an iterative process that involved identifying key elements of novice and expert answers, coding answers independently, and meeting to revise disagreements or address questions. For the items involving misconceptions (1 & 6), we developed the following criteria for novice, emerging expert and expert.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Codes for Student Misconception Items

	Novice (n)	Emerging Expert (em)	Expert (ex)
Interpret	• PST does not identify paying attention to one quantity as the problem	• PST uses vague language to identify that student has misconception involving attending to both quantities.	• PST clearly identifies that student has attended to only one quantity
Respond	• PST explains or tells student about relationship between quantities • PST tells student what to do • Solves the problem during the launch	• Asks questions that promote reasoning, directed to single student • Asks questions to the whole class, but does not promote reasoning or discussion	• Initiates a discussion with whole class that promotes reasoning about the relationship between the two quantities

For the items involving procedural student thinking (2 & 10), we developed the following criteria for novice, emerging and expert.

Table 2: Codes for Procedural Thinking Items

	Novice (n)	Emerging Expert (em)	Expert (ex)
Interpret	• Assumes conceptual understanding • Assumes procedure will produce correct answer • No mention of understanding • Non-specific descriptions of using prior knowledge	• Assumes that student does not understand • Aware of possible lack of understanding but assumes correct response *Or* • Qualifying language around prior knowledge	• Aware that student may, or may not understand concepts *and* • Aware that student may not get correct answer
Respond	• Amplifies procedure as method without any prompt for sense-making • No redirection to sense-making • Solves the problem during the launch	• Pushes sense-making with individual student • Discourages using formula • Changes task to forbid or discourage formula use	• Clarifies to the whole group that any solution strategy is acceptable as long as you can explain why your strategy works and makes sense

To develop a shared understanding of our refined codes, we each coded a subset of PSTs and met to resolve disagreements. We then coded the rest of the data. As we identified answers that were challenging to code, we conferred and reached agreements.

To determine whether PSTs' answers improved, we looked at whether or not individual PSTs' answers changed from pre- to post-assessment. For each of the items, we classified PSTs as same (no change), improve or decline. Types of improvements were: from novice to expert, from novice to emerging expert, and from emerging expert to expert. Finally, we tabulated the total results for each item to identify overall trends.

Results

Student Misconceptions: PSTs' Interpretations and Responses

For items 1 and 6, designed to assess PSTs' interpretations of and responses to a specific student misconception.

Item 1 depicts a student saying, "He should just buy it at the lumberyard. He gets a whole lot more sand there."

Item 6 depicts a student saying, "Hardware store; it's only six dollars, not nine."

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

We hypothesized that there would be consistency among PSTs' answers for these two items due to the similarity of the design of the items.

Table 3: Changes (Pre-Post) - Interpreting and Responding to a Misconception

Item 1: Interpretation	Item 6: Interpretation	Item 1: Response	Item 6: Response
Same (19):	**Same (22):**	**Same (13):**	**Same (13):**
17 (expert-expert)	20 (ex-ex)	2 (ex-ex)	1 (ex-ex)
2 (emerging-emerging)	0 (em-em)	8 (em-em)	7 (em-em)
0 (novice-novice)	2 (n-n)	3 (n-n)	5 (n-n)
Improve (8):	**Improve (4):**	**Improve (15):**	**Improve (16):**
5 (emerging-expert)	4 (em-ex)	5 (em-ex)	5 (em-ex)
0 (novice-emerging)	0 (n-em)	6 (n-em)	7 (n-em)
3 (novice-expert)	0 (n-ex)	4 (n-ex)	4 (n-ex)
Decline (3):	**Decline (5):**	**Decline (3):**	**Decline (2):**
1 (expert-emerging)	2 (ex-em)	1 (ex-em)	1 (ex-em)
2 (emerging-novice)	1 (em-n)	2 (em-n)	1 (em-n)
0 (expert-novice)	2 (ex-n)	0 (ex-n)	0 (ex-n)

Most PSTs were able to clearly identify the misconception. For interpretations on item 1, 83% (25 out of 30) clearly identified the misconception on the post-assessment, noticing that the student engaged in univariate reasoning. Of these, 57% (17 out of 30) did so on the pre-test as well. 27% (8 out of 30) showed improvement from pre to post. Similarly for item 6, 77% (24 out of 31) clearly identified the misconception students were displaying on the post-assessment. Of these 64% (20 of 31) had done so on the pre-assessment; 13% (4 out of 31) showed improvement from pre to post. (Note: The number of total responses differs because some PSTs did not answer every item.)

Approximately half of the PSTs showed improvement in their response to student misconceptions during the launch. PSTs improved their responses in the post-assessment by engaging the whole class in discussion and / or discussing reasoning about the misconception. 48% of PSTs (15 of 31) showed improvement in their responses on item 1. 52% of PSTs (16 of 31) showed improved responses on item 6. Out of these 31 improvements, 24 responses involved facilitating a discussion with the whole class. A typical example in the post-assessment was this PST's answer:

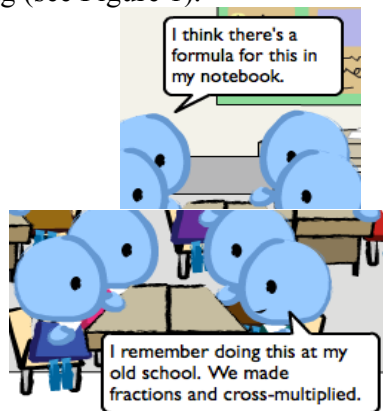
> Before asking for questions, I could pose the question that if you get more sand at the lumberyard then why not just buy it at the lumberyard? Then let the groups of students turn and talk about that before opening it up to the class.

However, only a subset of the PSTs with improved responses newly included addressing the whole class about a misconception during the launch in their post-assessment answer. Eight PSTs, representing twelve instances of improvement, did not mention addressing the whole class at all during their pre-assessment, yet they did mention discussing the misconception with the whole class during the post test. These improved responses reflected an option from the multiple choice assessment: facilitate a discussion.

The rest of the PSTs' responses improved in ways less aligned with the options in the multiple choice assessment. Six PSTs, representing 11 instances of improvement, responded with whole group discussions in both pre- and post-assessments. The nature of the discussion differed, however; in the pre-assessment, PSTs discussed correct solutions or clarified the context, and they discussed a misconception with the whole class in the post-assessment. Other PSTs (six, representing 8 instances) also improved by focusing on addressing the misconception in the post-assessment, but their post-responses still involved addressing an individual rather than the whole class.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Students' Procedural Thinking: PSTs' Interpretations and Responses

Two items (2 and 10) assessed PSTs' interpretations of and responses to students' procedural thinking (see Figure 1).


Item 2
Item 10
Figure 1. Procedural Student Thinking.

These items did not provide evidence of whether or not students had conceptual understanding. We hypothesized that PSTs would be more likely to interpret procedural thinking in item 10 incorrectly (i.e. as evidence of conceptual understanding) because that item contained more specific details about students' thinking.

Table 4: Changes (Pre-Post) - Interpreting and Responding to Procedural Thinking

Item 2: Interpretation	Item 10: Interpretation	Item 2: Response	Item 10: Response
Same (24):	**Same (23):**	**Same (19):**	**Same (23):**
0 (expert-expert)	0 (ex-ex)	1 (ex-ex)	0 (ex-ex)
16 (emerging-emerging)	5 (em-em)	10 (em-em)	7 (em-em)
8 (novice-novice)	18 (n-n)	8 (n-n)	16 (n-n)
Improve (5):	**Improve (6):**	**Improve (3):**	**Improve (4):**
2 (emerging-expert)	3 (em-ex)	0 (em-ex)	1 (Em-ex)
3 (novice-emerging)	2 (n-em)	2 (n-em)	2 (N-em)
0 (novice-expert)	1 (n-ex)	1 (n-Ex)	1 (N-Ex)
Decline (2):	**Decline (2):**	**Decline (9):**	**Decline (4):**
1 (expert-emerging)	0 (ex-em)	1 (ex-em)	0 (ex-em)
1 (emerging-novice)	0 (em-n)	8 (em-n)	4 (Em-n)
0 (expert-novice)	2 (ex-n)	0 (ex-n)	0 (Ex-N)

Most PSTs did not change their interpretations of students' procedural thinking or their responses to students' procedural thinking. For interpretations on item 2, 77% (24 out of 31) of the participants' answers did not change from pre- to post-assessment (16 were at emerging expertise and 8 were at novice). For responses on item 2, 61% (19 out of 31) of the participants' answers did not change (10 remained at emerging expertise, 8 were at novice and 1 at expert). For interpretations on item 10, 74% (23 out of 31) of the participants did not change (5 remained at emerging experts, 18 at novice and none at expert). For responses on item 10, 74% (23 out of 31) of the participants did not change (7 were at emerging expertise, 16 were at novice and none were at expert).

However, there are some important differences in the overall interpretations for items 2 and 10 that indicate that PSTs' conceptualizations of procedural thinking may be multi-dimensional and nuanced. In particular, on item 2 the majority of PSTs identified problems with procedural

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

understanding by the post-test (20 out of 30 were emerging and 2 out of 30 were expert). In contrast 20 out of 31 PSTs failed to identify any problem with the procedural approach taken by the student in Item 10. As an example, for an interpretation for item 10 on the post-assessment, a PST wrote, "The student is aware of a more advanced problem solving method that they learned previously." This would be a novice interpretation because the PST interpreted the use of cross multiplying as "advanced" without problematizing whether or not there was evidence that the student understood the quantitative relationships in the problem. Also, for a response on item 10, a PST wrote, "I would tell the student to try to solve the problem using what he remembers about cross multiplying. I would then walk away and come back minutes later." This is a novice response because the teacher does not push the individual student (or the class) to reason about why this strategy makes sense.

These results did not reflect the influence of multiple choice options on PSTs' adjustments of either their interpretations or their responses on the post-assessment. We expected that introducing PSTs to the following option for interpreting students' thinking would result in expanding their schema to move toward stronger interpretations of students' procedural thinking: "The student is working to remember and/or apply a procedure without any evidence of understanding the underlying mathematical relationships." But PSTs did not change their answers to reflect this choice. By the post-assessment, our PSTs still did not recognize that students' procedural thinking is not enough information to determine whether the student conceptually understands the quantitative relationships in the task during the launch.

Discussion

Overall, these results illustrate the following: (a) PSTs with expertise in interpreting students' misconceptions can improve their capabilities with responding to students' thinking during a launch, possibly after being introduced to and having opportunities to discuss new options for responding. (b) PSTs without expertise in interpreting students' procedural thinking may not be likely to improve interpreting or responding after being introduced to and discussing multiple choice options. Thus, the multiple choice options appeared to provide some support with expanding PSTs' schema for responding to a student misconception when PSTs had expertise in interpreting students' thinking.

Improvements in PSTs' responses to a student's misconception (items 1 and 6) are quite pronounced. One potential explanation is that PSTs' expertise in interpreting students' thinking on these items supported stronger responses to students' thinking, as their interpretations to these items were strong. It appeared that, for these PSTs, better understanding of student thinking and how it is connected to the important mathematics supported them with making instructional decisions. Recognizing that students are demonstrating a misconception may motivate PSTs to respond more actively and prompt them to look for possible responses.

A subset of the PSTs that improved responses to a student's misconception seemed to mirror one of the categories that we used in the multiple choice intervention. It may be that the motivation that PSTs had to respond to a student misconception made them more receptive to the categories introduced in the intervention, and more likely to remember and refer to them later, in the post-assessment.

The possible role of interpretation in motivating improvement in pedagogical responses can also be seen in items 2 and 10. Very few PSTs gave expert interpretations of students' procedural thinking, and none of them had expert interpretations on the pre-test. Because PSTs failed to identify the full problematic nature of procedural thinking in the context of this launch, they may have been less motivated to look for new ways of improving their responses. This may explain why there was so little improvement in PSTs' responses for these items.

Additionally, these PSTs performed worse on item 10 than item 2, likely because item 10 was more detailed and specific about students' procedural thinking. This points to important elements of procedural understanding. One element of understanding procedures consists of understanding why

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

the procedure works, what important mathematical concepts lay beneath it. The continued tendency to ascribe conceptual understanding to the student in item 10 indicates that the PSTs in this study struggled with this idea. A second element of procedural understanding entails recognizing when specific procedures are appropriate, including identifying and remembering specific problem types and larger mathematical relationships. The fact that so many PSTs identified the student in item 10 as having an understanding of the mathematics suggests that they can see this element of procedural fluency (knowing which procedure is appropriate to use in a particular situation) and that they conflate such knowledge with conceptual understanding.

The purpose of this paper is to present how mathematics teacher educators at five different U.S. institutions of higher education refined and informed their own practice through the process of lesson study. Although much used at the K-12 level to improve teaching practice, lesson study is not commonly used in higher education. The mathematics teacher educators designed and implemented a common lesson to develop noticing of children's mathematical thinking in pre-service teachers and gained insight into their own practice through lesson study methodology. Qualitative analysis of each lesson iteration including field notes, discussions and reflections on the lesson and pre-service teachers' work, transcription of lessons, and meeting notes were analyzed to identify processes and themes.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices

Introduction

This study was designed to improve the teaching and learning within a mathematics methods or content course for elementary education majors. Using data from the planning and teaching of one common lesson, mathematics teacher educators (MTEs) at five institutions investigated their own teaching and instructional practices through an iterative process of lesson study. As part of the lesson study, the MTEs researched how their instruction during the focus lesson affected what their pre-service teachers (PSTs) noticed when analyzing elementary student work samples and how PSTs made whole class instructional decisions based on those samples. In participating in this iterative cycle of lesson improvement, the MTEs sought to answer the following research question: How do MTEs from different institutions understand, inform, and improve their own teaching through a lesson study?

Theoretical Framework

Lesson study is a process of investigating instruction with the goal of instructional improvement. The iterative lesson study process is generally organized into a cycle of four steps:

- (a) study the curriculum and formulate goals,
- (b) plan,
- (c) conduct research on the lesson, and
- (d) reflect (Lewis, 2002; Lewis & Hurd, 2011).

Since arriving from Japan in the 1990s, lesson study has primarily been used to investigate instruction at the K-12 level. However, Cerbin and Kopp (2006) adapted the cycle slightly for higher education. In later years, Kamen et al. (2011), all MTEs, used lesson study to investigate how to improve their teaching in mathematics methods course so that PSTs could see the value in understanding and encouraging students' invented strategies. Through six iterations they learned better processes for engagement and encouraged more diverse thinking. In their final iteration they

concluded that PSTs were "pushed to actually study the mathematical thinking of others through a deliberate focus on analyzing their peers' mathematical thinking" (p. 173).

In their theoretical framing of how lesson study produces instructional improvement, Lewis, Perry, and Hurd (2009) built upon the traditional four lesson study components by theorizing three ways in which lesson study creates change: (a) teachers' knowledge and beliefs, (b) teachers' professional community, and (c) teaching-learning resources. This framework for understanding potential changes guided our analysis.

Connection to the PMENA 2016 Conference Theme

By conducting this lesson study in higher education and in geographically different institutions around the U.S., this study pushes the border of traditional lesson study work. The idea for this study emerged out of a common goal to understand how to support PSTs to make the leap from planning instructional next steps for one student based on each student's work to planning out instructional next steps based on a set of student work for a whole class.

Methods

Location and Context

This lesson study occurred over two semesters in five different institutions of higher education, located in diverse locations – the West Coast, Midwest, South and Northeast US, with four of the five being public. The institutions varied in size with enrollment ranging from 3,600 to 36,000 and from 6 to 30 students per class. PSTs at four institutions were enrolled in a four year Elementary Education program and at one institution were enrolled in a post-baccalaureate Multiple Subject (elementary) Credential program. The MTEs taught the first mathematics methods or content course in these programs. Similar to the nation's current enrollment in elementary teacher education programs, most students were white and female.

Research Design

Lesson study methodology began with the MTEs investigating student characteristics and long term learning goals for PSTs. A decision was made to focus on the PSTs' "noticing" of children's mathematical thinking with an emphasis on making instructional "next step" decisions (Jacobs, Lamb, & Philipp, 2010).

The researchers started the second phase of planning a lesson to support and facilitate the intended learning goals by developing a research-based lesson that was taught at one of the locations. The group reviewed the video of the lesson and reflected on various aspects of teaching using evidence from the lesson. The lesson was revised and then taught again by another member of the research team. The process of revising and teaching the lesson was done for five iterations (after each MTE conducted the lesson). The result was a final, polished lesson.

The data from various sources in the form of lesson plan iterations, explicit meeting notes, videotapes of the taught lesson, reflections, and discussions on PSTs' work was analyzed in stages. With each iteration of the lesson, the researchers met to analyze the video to determine what best supported PSTs in making thoughtful instructional "next steps." These included lesson strengths and areas for improvement: helpful questions, missed opportunities, teacher moves, etc.

Lesson Content of the Lesson Study

The designed lesson focused on multiplication solution strategies and involved an analysis of the *Mr. Harris and the Band Concert* case scenario, an NCTM publication in the *Principles to Actions* Professional Learning Toolkit (NCTM, n.d.), which also included six students' solution strategies. To understand the range of student solution strategies (direct modeling-> counting strategies->derived facts), MTEs presented videos of students solving multiplication problems in various ways. Then the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

PSTs solved the Band Concert problem individually in multiple ways and discussed their solutions with their table. Next, the PSTs looked at the six samples of student work and analyzed them using the noticing framework by: attending to the math, interpreting the solution strategies, and determining a next step for each individual student. Finally, after a whole-class discussion based on the individual students, the PSTs were asked to determine an instructional next step for the whole class.

Results – Initial Findings

When investigating lesson study, the results include both a description of the process of lesson refinement and areas for potential change identified by Lewis, Perry, and Hurd (2009): (a) teachers' knowledge and beliefs, (b) teachers' professional community, and (c) teaching-learning resources.

Lesson Study Refinement Process

Using lesson study at the university level with MTEs located in five different geographic regions required refinement of the traditional lesson study process. For example, the MTEs could not be physically present to view each other's lessons. This resulted in the need to refine the process to use video and online collaborative tools to both watch and analyze the data. For example, the MTEs used video recording to capture their lesson and uploaded the video to a secure cloud server for all to watch later. While watching, each contributed to a transcription and analysis of the video using Google documents. This allowed for the collaborative discussion and analysis required to refine the lesson for the next iteration.

Areas of Change

Under each category below, an exemplar of a change brought about by lesson study is explained in detail.

Mathematics teacher educators' knowledge and beliefs. After the first lesson iteration in which the PSTs did not study the actual noticing framework of attending, interpreting, and deciding, the MTEs realized the need for PSTs to be explicitly exposed to the components of noticing and thus decided to have the PSTs read Thomas et al. (2014), a practitioner article on noticing. After reading the article, the PSTs were better equipped to notice and interpret what students were doing in the work samples and consider the instructional next steps. As MTEs, we learned that being explicit and providing details of a framework assisted them in applying the framework.

Mathematics teacher educators' professional community. One struggle experienced by all MTEs during the lesson study was the lack of time devoted to the concluding discussion and wrap up to ensure that the goal of the lesson, to plan whole-group instructional next step decisions, was addressed. As early career MTEs, we recognized a common difficulty of concluding our lessons and spent time discussing general ideas and techniques with each other. Though the lesson analysis process, the MTEs developed a community of practice in which they not only discussed improvements to the lesson, but also discussed and refined their teaching practices in general.

Teaching-learning resources. The result of the lesson study was the creation of a refined lesson and tasks for PSTs that used the topic of multiplication and student work to support them to move from analyzing student thinking to planning the "next step" for one student and eventually for a whole class. With each iteration and planning, the MTEs developed strategies and questions that ensured PSTs engaged in whole-group instructional next step decisions. These strategies and questions served a teaching and learning resources for the lesson.

Discussion

The process of lesson study strengthened the practice and community of MTEs. It speaks to the need to create more ways for MTEs to meet and engage with each other across diverse sites in

substantive ways. There need to be additional ways for mathematics teacher educators to find common goals and answer common questions about mathematics education. Working across sites as new assistant professors of mathematics education, the researchers could identify their weaknesses and developed a safe space to not only discuss them, but to work together to try new methods/strategies to overcome them. The outcome was a refined lesson that each MTE can more confidently use with his/her students in the future.

QUESTIONING THE BOUNDARIES: KNOWLEDGE INTEGRATION IN METHODS AND CONTENT COURSES

David D. Barker

Ball (2000) noted, "subject matter and pedagogy have been peculiarly and persistently divided in the conceptualization and curriculum of teacher education" (p. 241). In this study, we investigated the opportunities secondary pre-service teachers (PSTs) had to integrate their knowledge of mathematics, learners, and pedagogy in a methods and content course taught in tandem. We describe the frequency of opportunities that PSTs had to integrate the various combinations of teacher knowledge and the instructional moves associated with this integration. Recommendations for pre-service teacher education and directions for further research will be provided.

Keywords: Teacher Knowledge, Teacher Education-Preservice

Secondary mathematics teachers must develop a deep and connected understanding of mathematics (M), pedagogy (P), and learners (L) in order to interpret student thinking, choose instructional activities, and plan effective lessons. Unfortunately, pre-service secondary mathematics teachers often perceive a chasm between their education and mathematics courses, creating a divide between their knowledge of mathematics and pedagogy. Ball (2000) succinctly summarized this challenge:

> "Subject matter and pedagogy have been peculiarly and persistently divided in the conceptualization and curriculum of teacher education and learning to teach. This fragmentation of practice leaves teachers on their own with the challenge of integrating subject matter knowledge and pedagogy in the contexts of their work. Yet, being able to do this is fundamental to engaging in the core tasks of teaching, and it is critical to being able to teach all students well" (p. 241).

In addition, "Research that has investigated the development of mathematical knowledge for teaching has shown this process to be less additive (e.g., learn content, then learn to teach it) and more iterative." (Steele & Hillen, 2012, p. 53-54). Preparing future teachers to integrate these different knowledge sets for the purpose of instruction has the potential to improve the quality of mathematics instruction.

To address this challenge, we investigated the opportunities for the integration of M, L, and P in a methods and a content course for secondary pre-service teachers (PSTs). This paper will describe some preliminary findings for the following research questions:

1. What distribution of knowledge types (M, P, and L), and opportunities for potential knowledge integration, were observed in a methods and content course for secondary PSTs?
2. What instructional moves appeared to promote knowledge integration in the methods and content course for secondary PSTs?

Theoretical Foundation

Hiebert, Gallimore, and Stigler (2002) stated that teachers do not separate knowledge types as researchers do, but weave their knowledge together around the problems of practice. With this in mind, we define *knowledge integration* as the use of multiple knowledge types in order to reflect on classroom occurrences or to make instructional decisions. Bishop and Whitefield (1972) proposed that teacher decisions are made using a framework or schema. The main operation of a schema is to

store knowledge through a network of connected pieces of knowledge called "elements" (Marshall, 1995, p. 43). The more connections that exist within a schema, the more useful the schema will be. Hence, the process of knowledge integration leads to the development of a more connected schema, resulting in more informed instructional decisions.

Our investigation of teachers' use of multiple knowledge types was inspired by Shulman's (1987) work on teacher knowledge. Our definitions are as follows:

- *Knowledge of Mathematics (M)*: knowledge regarding the mathematical concept(s) related to the content under investigation. Includes the connections and relationships among ideas, the way(s) and mean(s) of justifying and proving these ideas, and conversations focused on mathematics and reasoning about the mathematical topic.
- *Knowledge of Pedagogy (P)* – knowledge regarding the tasks, curriculum, instructional goal(s), or questions used to further the lesson. Includes comments centered on the lesson implementation or decision-making regarding the flow of the lesson.
- *Knowledge of Learners (L)* – knowledge regarding student thinking. Includes observed as well as anticipated student thinking, conversations about student characteristics, habits, or misunderstandings.

Our definitions of knowledge of mathematics, learners, and pedagogy are related to other models of teacher knowledge, such as mathematical knowledge for teaching (MKT) (Hill, Ball, & Shilling, 2008) or pedagogical content knowledge (Shulman, 1987). However, the definitions in this study are broader in scope, as we are focused more on the *interactions* among these knowledge sets (i.e. knowledge integration). Our study seeks to uncover how PSTs connect their knowledge and if instructional moves exist that promote knowledge integration among PSTs.

Methods

To answer our research questions, extensive field notes were collected for every session of a senior secondary methods and content course of an undergraduate teacher preparation program in the Midwest. A single researcher collected all field notes. The content course explored high school topics from an advanced perspective. The content and methods courses were taught in tandem, with the same set of students, in hopes of further promoting knowledge integration. This arrangement allowed the methods course instructor to use the mathematics of the content course as a foundation for pedagogical discussions. Similarly, the content instructor could highlight and model pedagogical ideas from the methods course.

Using data reduction methodology (Miles & Huberman, 1994) the field notes were initially read to identify individual episodes--sections of the transcript centered on a single idea. Following the identification of episodes, the constant comparative method (Glaser & Strauss, 1967) was used to develop definitions for statements about mathematics (M), learners (L), and pedagogy (P) (see definitions above). These definitions were then used to code all episodes. If multiple forms of knowledge were used during a single episode, we defined this to be an example of potential knowledge integration. For instance, if an episode contained both M and L statements, we identified this as an opportunity for PSTs to integrate their knowledge of M and L. We note that evidence of multiple forms of knowledge in an episode does not ensure knowledge integration, only that the prospect of knowledge integration was present. To answer the first research question we tallied the distribution of all knowledge combinations for both the methods and content course.

Our next step in analysis was to investigate the instructional moves that appeared to promote knowledge integration in the content and methods course. For the purpose of this paper, we focus on the episodes where evidence of M, L, and P were present. We applied open coding to develop categories for these different instructional moves.

Findings

From the 15 weeks of field notes, we identified 405 different episodes in the content course and 273 episodes in the methods course. Table 1 displays the number of episodes that contained evidence of the different combinations of knowledge. For instance, the 26 in the last column for the content course indicates there were 26 episodes in the content course where the knowledge of mathematics, learners, and pedagogy were exhibited.

Table 1: Combinations of Knowledge Used in Episodes from Both Courses

Course	M	L	P	M-L	M-P	L-P	M-L-P
Content	265	4	18	41	32	19	26
Methods	4	10	92	1	17	135	14

In the content course, a majority of the episodes contained only statements about mathematics. However, of the 405 total episodes, there were 118 episodes that contained multiple knowledge types, which constitutes 29% of all episodes. Although knowledge integration was not the norm in this particular class, the data reveal the potential for knowledge integration in this content course for teachers.

A majority of the episodes in the methods course, 95%, contained statements about pedagogy. However, unlike the content course, 61% of the episodes in the methods course contained evidence of multiple forms of knowledge. There were 149 episodes, 55% of the total, which contained both L and P; however, far fewer of the integrated episodes contained evidence of the knowledge of mathematics.

How can we better promote knowledge integration in our content course? How can we better integrate mathematical knowledge into our methods course? If we can answer these questions and uncover the instructional moves associated with knowledge integration, we can help our future teachers develop the robust schema required to make important instructional decisions.

To uncover the instructional moves associated with knowledge integration (Research Question 2) we first examined each episode that contained M, L, and P. Through an open coding process, we have tentatively identified four common instructional moves associated with the MLP episodes. Table 2 provides this initial categorization.

Table 2: Categorization of Episodes with M, L, and P

Category	Episodes in Content Course	Episodes in Methods Course
Reflecting on Instruction: The teacher educator reflects, or has the PSTs reflect, on the mathematical instruction in the Content Course. The conversation is focused on the pedagogical moves associated with this shared experience.	9	5
Development of a Pedagogical Product: The teacher educator asks the PSTs to develop a pedagogical product. (e.g., excerpt of lesson plan, assessment, task, lesson objective, etc.)	8	5
Focus on Student Thinking: The teacher education asks the PSTs to consider how a high school student would think about a particular mathematics topic.	8	0
Evaluation/Critique of Pedagogical Products: The teacher educator asked the PSTs to evaluate a pedagogical product. (e.g., excerpt of lesson plan, assessment, task, etc.)	0	4

To note, we only included instructional moves that occurred in at least four episodes. In addition, the instructional moves identified in this study were those used by these instructors; there could be additional instructional moves, not used by the instructors, which promote MLP integration. The data shows two instructional moves common to both courses (Reflection on Instruction & Development of Pedagogical Products) and two instructional moves used in only one of the courses (Focus on Student Thinking & Evaluation of Pedagogical Products).

Discussion and Future Direction

The initial categorization of instructional moves is based on the 40 MLP episodes. As we continue to expand our coding to the remaining 638 episodes, our categorization will continue to be refined and expanded. Once this categorization is finalized, we hope to have a better understanding of the instructional moves associated with the various knowledge combinations. It is also important to identify instructional moves that are not associated with knowledge integration. For example, the content course instructor incorporated short microteaching opportunities into his class with the hopes of encouraging knowledge integration. Unfortunately, there was only one episode of microteaching coded as an MLP episode.

This raises several important questions. Can we adjust current instructional moves to help bring out integration? Are their critical features of instructional moves that encourage knowledge integration? What other aspects of teacher preparation promote knowledge integration? How does this influence teaching practice? In the future, we hope to continue developing and revising innovative instructional methods that promote knowledge integration, with the hopes of providing mathematics teacher educators strategies that stimulate a robust schema of knowledge.

COLLABORATION FOR RICH TASKS: DEVELOPING PRE-SERVICE TEACHERS ABILITY TO CONSTRUCT LESSON PLANS WITH MASTER TEACHERS

Michael Todd Edwards	Michael Singer Meagher	S. Asli Özgün-Koca
Miami University	Brooklyn College - CUNY	Wayne State University
edwardm2@miamioh.edu	mmeagher@brooklyn.cuny.edu	aokoca@wayne.edu

Pre-service mathematics teachers collaborated with Master Teachers to experience rich problem solving, design of rich tasks, and authentic implementation of rich tasks in high school classrooms. The pre-service teachers made strides in their own problem solving abilities and made improvements in their construction of rich tasks. There were limitations in their ability and willingness to shift their thinking to design open-ended tasks that promote reasoning and problem solving.

Keywords: Teacher Education - Preservice, Teacher Knowledge, High School Education

Introduction

The *Principles to Action* (NCTM, 2014) call for teachers to "Implement tasks that promote reasoning and problem solving" and to "work collaboratively with colleagues to plan instruction." Beginning methods classes can be challenging environments in which to achieve these goals. Too often, pre-service teachers' own experiences in mathematics classes - both at the school and college level - do not include engagement with rich tasks that promote problem solving (Ball, 1990). Furthermore, teaching methodologies advocated by methods instructors in teacher preparation programs, particularly around teaching with open-ended, differentiated tasks, are often not readily observed in actual classroom settings (Zeichner, 2010). Although pre-service teachers can work collaboratively, creating rich tasks in methods courses in university settings, they often don't see the fruits of that labor because such planning is done in the abstract and not for implementation in an actual classroom. This creates a disconnect between the experience of the methods class and the reality of teaching both in field experiences and upon entering the profession (Allsopp et al. 2006; Meagher, Özgün-Koca & Edwards, 2011).

To address this disconnect, a team of three methods instructors and six practicing teachers collaborated to construct a set of experiences for Preservice Mathematics Teachers (PSMT). Specifically, the experiences required PSMTs to complete the following cycle six times:

1. Six Rich Problem Sets (RPS) constructed by six practicing classroom Master Teachers (MT), reflecting content used in authentic school classrooms.
3. In teams, adapt the Problem Sets, constructing (a) differentiated versions of tasks, (b) scoring rubrics, and (c) online video tutorials that secondary school students will use in the practicing teachers' classrooms as they solve the tasks.
4. Observe a video of the differentiated tasks being implemented in a high school classroom taught by the partnering Master Teacher who constructed the initial RPS.
5. Provide significant written feedback to students on their worksheets in an effort to strengthen and extend students' mathematical understandings; return the assessed work to the high school teacher for distribution to students.

The initial stages of the process were designed to assist teacher candidates in making the shift from being a "doer" to being a teacher of mathematics (Meagher, Edwards & Özgün-Koca, 2013). The later stages of the process gave teacher candidates authentic experiences in terms of the preparation of tasks, the enactment of tasks and assessing/giving feedback to students.

The research is guided by and designed to answer the research question:

What effect does collaboration with a cadre of master teachers (MTs) over the course of a 15-

week semester have on Preservice Mathematics Teachers' (PSMT) attitude to tasks and lesson plans that promote reasoning and problem solving (Allsopp et al. 2006; Zeichner, 2010)?

Literature review and relationship to research

Brown and Borko (1992) argue that there are three important issues in the process of "learning to teach": (a) the influence of the content knowledge, (b) novice's learning pedagogical content knowledge, and (c) difficulties in acquiring pedagogical reasoning skills. Furthermore, they assert that "one of the most difficult aspects of learning to teach is making the transition from a personal orientation to a discipline to thinking about how to organize and represent the content of that discipline to facilitate student understanding" (p. 221).

Pre-service teachers early in their program typically develop lesson plans that are never taught in a classroom - typically in isolation - creating a disconnect between planning, implementation, and assessment of student learning (Allsopp et al. 2006; Meagher, Ozgun Koca & Edwards, 2011). Developing communities of practice (Wenger, 1999) and lesson study groups (Fernandez, 2002) can help candidates and practicing teachers adopt a more research-based focus in their lesson planning and develop a shared repertoire of communal resources which transcend individual contributions. Furthermore, providing candidates with opportunities to experience their lessons taught by Master Teachers in authentic classroom settings increases motivation for lesson writing. Preservice teachers demonstrate a trajectory of learning about lesson plans in a cycle of designing a lesson to be taught by a Master Teacher and reflecting critically on the implementation of that lesson (Meagher, Özgün-Koca & Edwards, 2011).

Methods and Methodologies

The participants (n=18) in this study were candidates enrolled in the second 15-week course of a year-long methods sequence designed for prospective secondary mathematics teachers.

Completing the Rich Problem Sets

Prior to the beginning of the second methods course, the methods instructor and 6 Master Teachers worked collaboratively over a 3-week period to design a series of 6 distinct Rich Problem Set (RPS) experiences for candidates. A crucial aspect of the process was that the RPSs were designed to become progressively more open-ended as the semester proceeded. In completing the RPSs, the candidates were to experience how the content of the high-school curriculum can be framed with rich tasks - rich in content; illustrating connections among various mathematical areas and real-world application; with differentiation for different learners, requiring conceptual understanding, procedural fluency and problem solving skills.

Data Collection and Analysis

The data collected consisted of

1. PSMTs responses to the RPSs and the materials developed for the lesson plan;
2. Video of the lesson plans implemented in school classrooms by the Master Teacher;
3. high school student written work from the lesson;
4. field notes from the class meetings in the university;
5. course evaluations.

Analysis of activities, lesson plans constructed during each RPLTF, and pre- and post-survey, provides a comprehensive picture of preservice teacher development *across* the 15-week study period. Moreover, since these artifacts were constructed collaboratively using Google Docs, modifications that preservice teachers made prior to and following feedback provided by the partnering classroom teacher were tracked, giving insight into the thinking of preservice teachers'

development *within* the development of teaching artifacts for a particular RPLTF. To address the research question the qualitative data was analysed for attitudinal positions exhibited by the PSMTs with regard to tasks and lesson plans that promote reasoning and problem solving.

Results

The first 3 tasks required PSMTs to generalize numerical patterns using symbolic algebra and had one correct answer, for example, in one task PSMTs determined the total number of triangles that can be constructed on a 5 pin by 5 pin geoboard and in another they had to construct an algebraic expression describing the number of unit cubes required to construct a "Skeleton Tower" *n* units tall.

Task 4 was markedly different from the first 3 tasks. First of all, RPS 4 required candidates to write code in Matlab, a multi-paradigm numerical computing environment with none of the PSMTs enrolled in the methods course having had any previous programming experience. Secondly, and unlike previous assignments, RPS 4 required the PSMTs to have a say in the *construction of their own task*. PSMTs were asked to conduct their own research, identify an iterative approach for approximating pi, and implement the approach using the Matlab programming language. Candidates were provided with extra time to explore a variety of Matlab tutorials and supports. Given these differences, it is not surprising that problem set scores dipped from an average of 90.6% to 81.9% from RPS 3 to RPS 4. RPS 5 and RPS 6 continue in a similar vein, each with no one "correct answer" or "correct solution" method.

In RPS 5 PSMTs set up their own test to determine whether or not the shuffle feature on an iPod is random (or not). Teacher candidates were required to construct their own "randomness" criteria and apply these criteria to various playlist data. (Ziegler & Garfield, 2013). RPS 6 was similarly open-ended with no one correct approach or solution.

Although their performance on the RPSs diminished as the tasks became more open-ended, as the PSMTs became more accustomed to the openness of the tasks as the semester progressed, their scores on the RPLTF artifacts and lesson plan materials again improved. That said, there is a similar split apparent in lesson plan scores between the first 3 plans and the final 3 plans. It was clear that the PSMTs struggled to provide students with learning opportunities that included ambiguity and no clear, "correct" solution strategy. When candidates struggled to solve tasks themselves, as "students," they were also less comfortable constructing similar lessons for others. At the beginning of the semester, a sizable portion of teacher candidates noted that their enjoyment of mathematics was due to the "fact that in mathematics there is always one right answer." As one student noted in an early assignment, "1+1=2. I can count on that . . . it's comforting to have something we all can count on . . . something that is actually TRUE" [Artifact, RPLTF 1]. This fairly typical need for "right answers" and "a correct solution method" continued to be important for PSMTs throughout the experience, although we note an increasing comfort with complexity reflected in their scores on the lesson plans. That said, in some cases as tasks became more open-ended and more ambiguous, PSMTs became less comfortable and more resistant to the ideas brought forward in the methods class. In general, as work in the course became more complex - and arguably more closely aligned with CCSSM and NCTM recommendations - teacher candidates became more disconnected from the course goals.

Disconnect between "real" classrooms and RPLTF experience

Teaching methodologies advocated by methods instructors in teacher preparation programs, particularly around teaching with open-ended, differentiated tasks, are often not readily observed in actual classroom settings (Zeichner, 2010). Using qualitative codes "realistic" and "observed by me" the field notes and course evaluations were analysed. The RPLTF experiences were specifically designed to allow these PSMTs to see open-ended, rich, differentiated tasks implemented in actual high-school classes - and yet the PSMTs still struggled to make this connection. Many of the teacher candidates indicated that they were frustrated because, as one student expressed it, "this isn't the

work that high school math teachers do" [Field notes, class meeting 9]. One PSMT stated directly, "the teachers in our field placements [last semester] never did this kind of work with their students" [Field notes, class meeting 14]. The PSMTs had field placements the previous semester where they spent a considerable amount of time in high-school classrooms observing and occasionally teaching. The quotes above indicate the power of the field experiences over PSMTs approach to teaching and, in particular, their approach to tasks and lesson plans that promote reasoning and problem solving. The PSMTs observed the implementation of their lesson plans by a master teacher in an actual classroom but their field experiences did not provide enough models of mathematics classrooms where students were required to come up with their own solution techniques or grapple with the possibility that a task may have multiple correct answers or multiple solution strategies. And so many of the PSMTs thought that the work of the class was "unrealistic," despite being *initiated* by classroom teachers and enacted as part of their work in secondary school classrooms with actual students.

Conclusion

The intervention described above was designed to provide pre-service mathematics teachers with experiences in rich problem solving, experiences in designing rich tasks for implementation, and experiences in how those tasks can be authentically implemented in high school classrooms. We observed the pre-service teachers make strides in their own problem solving abilities as well as make improvements in their construction of problem-solving tasks. However, there were limitations in their ability and willingness to shift their thinking to design truly open-ended tasks that promote reasoning and problem solving with the influence of their field placements in more traditional classrooms proving to be very powerful.

DEVELOPING QUANTITATIVE REASONING IN WORD PROBLEMS

Sayonita Ghosh Hajra   Victoria Kofman
Hamline University   Stella Academy
sayonita@gmail.com   drkofman@gmail.com

Quantitative reasoning is the heart of word problem solving; it requires fluency and understanding with units and the quantities involved. We incorporated a supplementary word problem solving program in a regular arithmetic course for pre-service teachers. In the pre-test most of our pre-service teachers could not clearly identify the qualitative characteristics of the quantities. The supplementary program significantly improved students' performance in their abilities to define measurable attributes in simple word problems.

Keywords: Algebra and Algebraic Thinking, Problem Solving, Teacher Education-Preservice

One of the standards for mathematical practice in the *Common Core State Standards for Mathematics* (CCSSM) (National Governors Association for Best Practices, Council of Chief State School Officers [NGA & CCSSO], 2010) promotes abstract and quantitative reasoning. The CCSSM standards advocate for students to have the ability to *decontextualize word problems* by creating models that contain abstract symbols. Creating such models requires a conceptual understanding of the measurable attributes (*quantities*) and their units.

Researchers (Weber et al., 2014) identified the importance of quantitative reasoning in students' abilities to create mathematical models of word problems. However, students need to comprehend a problem's text before creating the models. A group of researchers (Sulentic-Dowell et al., 2007) found that the ability of teachers to meaningfully discuss word problems with their students depends on their own literacy. Particularly, non-active readers, instead of helping to analyze the text of the problems, point only to key words.

Through informal classroom observations, we found our pre-service teachers, when discussing a problem's text, do not necessarily use scientifically correct language and define measurable attributes with their corresponding units. Hence, we undertook this research to examine the level of pre-service teachers' abilities to discuss word problems' texts while clearly identifying attributes, and the possibility of increasing their abilities by providing specially-designed instruction.

Theoretical Framework

Our theoretical framework is based on Thompson's (1988) interpretation of quantitative reasoning—reasoning about quantity as a *measurable quality of something* and thinking about *a magnitude of a quantity as the quantity's measure in some units* (p. 164). For example, in the sentence, *Tom spent 3 hours doing his homework*, a qualitative attribute is *time*, and a unit of measure is *hour*. In Tom's sentence, the attribute (*time*) is not specified but can be deducted from the text. Thompson's analysis (2011) covers various types of attributes, including complex attributes that one can face in economics or high school physics classes (p. 38), but in our research, we narrowed the list of attributes we discuss with students to talking about a number of objects, amount of money, length-type characteristics (depth, width, distance, height, and length itself), volume, weight (in meaning of *mass*), temperature, and time.

As we observed in our classes, when attributes are not specified, students are not immediately aware what attributes are mentioned in a problem. Besides difficulties with assigning attributes, understanding word problems can be quite challenging, due to the use of word-problem specific vocabulary (Fuchs et al., 2015). To help pre-service teachers develop their quantitative reasoning, we applied the teaching method referred to as the 'dimension variations' (Marton & Pang, 2006) approach. This approach is based on teaching one learning dimension (one type of problem) at a time

while variations are applied. In literature connected with word problem solving, this approach is referred to as a *schemata*. A schemata subdivides one-step word problems into several groups (Jitendra, 2002; Jitendra et al., 2015). We used this schemata to teach students to use scientifically precise language when describing values in *Compare*, *Combine*, and *Change* addition and subtraction word problems. Variations were introduced by incorporating word problems with specified and non-specified attributes, varying problems' logic, etc.

Methodology

After a pretest, scientific language instruction combined with visual representations of the quantitative relations was introduced as a supplementary instruction to an arithmetic course for future elementary teachers in a southwestern research university. The lead author taught the first of two sections of the arithmetic course and implemented the supplementary program along with the standard course textbook (Beckmann, 2013) for future elementary teachers. The supplementary program used a workbook which was designed by the second author and was used successfully with children (ages 6 to 14) in a remediation/enrichment learning center in the Midwest to help students develop quantitative reasoning.

Participants

Thirty-three students enrolled in an arithmetic course for elementary pre-service teachers participated in this study. Seventeen students were in the treatment group and sixteen were in the control group. Both groups were taught the same standard course content. Additionally, the treatment group was given the supplementary workbook on word problem solving. The workbook was self-explanatory and provided a brief explanation of theory as well as some examples and exercises. Students were asked to read the text in the workbook carefully and analyze examples before starting their assignments. Instructor spent 5 minutes of each class time to discuss a concept after students read the text themselves. Students were taught how to rephrase word problems by explaining the attributes the number in the word problem is measuring, to use symbolic representations for word problems, to visualize quantitative relations using illustrations, and to identify units in the word problems.

Data Collection

Students were assigned homework from the supplementary workbook for 12 weeks of a 15-week course. Data were collected from students' written work on a pre-test questionnaire, workbook assignments, quizzes, a mid-term, and a final exam (post-test) from the treatment group. Only post-test data were collected from the control group. One example of the explanation for a post-test question on measurable attributes is shown in Figure 1.

Value-Analysis – an explanation of the meaning of each known and unknown value in a problem.

In value analysis, identify the names of the properties that the values describe.

> Examples of Givens and Unknown Value
> 5 is the number of apples Nina has.
> 6 degrees is the temperature in New York.
> ? is the number of cookies.

Figure 1. Post-test question—explanation on measurable attribute.

Data Analysis

For this preliminary study we analyzed pre- and post-test data following an open and axial coding method (Strauss & Corbin, 1998). We first coded each question in terms of the precision and clarity

on defining the involved attributes and units (Table 1). Then, we recorded students' written responses for each task against each measurable attribute and discussed each student's precision and clarity on each task.

Table 1: Code for precision and clarity in naming attributes

No defining or naming an attribute (N/A)	Low Precision (Low)	High Precision (High)
Repeating text words that do not point to attributes: *how much, size, objects, amount of* without mentioning the attribute.	Describing attribute instead of naming it: *6 is how long; 6 is how much it weighs…*	Naming attributes: Length, weight, volume, and measuring units

Results

We found that about 18% (3 out of 17) of the students in the treatment group precisely identified the measurable attribute in word problems with non-specified attribute "length" in the pre-test. Others have either repeated the keywords from the text or used *how long*, *how much*, *size*, or *amount of ribbon*. Figure 2 demonstrates an example of a student's written response.

After Teresa cut off 6 feet of a ribbon, the ribbon became 10 feet long. How long was Teresa's ribbon to start with?

6 feet is _What Teresa cut off from a ribbon that was 16ft long._

Figure 2. A student's work on the length attribute in the pre-test.

Twelve out of 17 students in the treatment group named the *weight* attribute in the pre-test. We believe it is related to the similarity between the attribute "weight" and the verb "weighs" used in the problem. On the post-test the verb "to weigh" was not used in a weight-related problem. Nevertheless, 88% (15 of 17) of the students from the treatment group named *weight* and *volume* attribute (Figure 3) correctly while none of the control group identified the *weight* attribute (see an example in Figure 4). Table 2 shows the increase in the number of students' precision in naming the attributes from the pre- and post-tests in the treatment group.

Table 2: Comparison of pre-test and post-test results on naming the attribute task

Measurable Attributes	Weight			Length			Volume		
Precision and Clarity	N/A	Low	High	N/A	Low	High	N/A	Low	High
Control Group (Post-test)	16	0	0	13	1	2	8*	-	-
Treatment Group (Pre-test)	5	0	12	13	1	3	-	-	-
Treatment Group (Post-test)	2	0	15	2	0	15	2	0	15
The data above show the number of students who fall under the three categories. *Only 8 completed the problem.									

We found knowledge of the words *length*, *weight*, *time*, and *volume* did not help students to fluently identify the attributes. Their work on supplementary materials reflected gradual progress toward defining attributes in 1–3 step word problems. Students' assignments reflected how the students started to develop a habit of specifying measuring units in all of their calculations.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figure 3. A student's work on the volume attribute in the post-test from treatment group.

Figure 4. A student's work on the weight attribute in the post-test from the control group.

Conclusion and Discussion

Pre-test results for the treatment group as well as post-test results for the control group showed most of the students do not name attributes to the quantities mentioned in word problems unless the attributes are specified in the text. It is true for the students before and after taking a standard arithmetic course. However, using supplementary materials based on the schemata, which uses scientific language to describe givens, considerably increased students' abilities to identify measuring attributes in word problems and promoted the habit of naming these attributes and measuring units when presenting solutions to the problems.

PRESERVICE MATHEMATICS TEACHERS' CONCEPTIONS OF INTENSIVE QUANTITIES COMMONLY USED TO MODEL GLOBAL WARMING

Dario A. Gonzalez
University of Georgia
darioagm@uga.edu

Here, I report preliminary findings concerning preservice mathematics teachers' (PSTs) conceptions of three intensive quantities commonly used to model global warming: concentration, energy density, and energy flux density. Three PSTs completed four mathematical tasks in two individual, task-based interviews. Analysis revealed that: (a) PSTs' conceptions of these quantities varied greatly depending on the type of quantity (Type 1 vs. Type 2), (b) confusing temperature with energy hindered PSTs' ability to conceive of energy density as ratio as measure, and (c) PSTs conceptions of energy flux density involved two types of per-one associations. The second type seemed to conduce to the development of ratio as measure conception for energy flux density. However, this was an effortful process for PSTs.

Keywords: Cognition, Modeling, Rational Numbers, Teacher Education-Preservice

Introduction

In recent years, there have been several calls to include global warming in school and college instruction (McKeown & Hopkins, 2010; UNESCO, 2012). Global warming provides a motivating context to study important scientific and mathematical concepts. For example, introductory mathematical models for global warming—for which the mathematics can be accessible to high-school students—make use of covariant physical quantities, many of which are defined through the division of other physical quantities, such as energy, area, and volume. However, research has demonstrated that students and future teachers can have persistent difficulties understanding division in terms of quantities and with comprehending and mathematically expressing co-variation between quantities (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Greer, 1992; Nunes, Desli, & Bell, 2003; Thompson, 1994). By examining how secondary preservice teachers (PSTs) learn about introductory mathematical models for global warming, my research attempts to answer two overarching questions: (a) What are PSTs' conceptions of quantities commonly used to model global warming? and (b) How do PSTs conceptualize covariant relationships between those quantities, relationships that link carbon dioxide pollution to global warming? Here, I report the preliminary findings for the first of these research questions.

Quantifying Global Warming

Earth's climate system is powered by the sun and there is a continuous flow of energy between the sun, the planet's surface, and the atmosphere. The planet's surface is warmed by the sun's energy. As the surface heats up, it radiates (infrared) energy to the atmosphere. The majority of this energy is absorbed by *greenhouse gases* (GHG) such as water vapor (H_2O), carbon dioxide (CO_2), and methane (CH_4). The atmosphere re-radiates part of the absorbed energy back to the surface. This continuous energy exchange between the surface and the atmosphere is known as the *greenhouse effect* and influences the planet's average surface temperature. Thus, quantifying changes in the flow of energy and the abundance of GHG in the atmosphere is required to accurately model climate and global warming. My research focuses on PSTs' conceptions of three quantities commonly used to model global warming: *concentration*, *energy density*, *energy flux density*. Concentration is the ratio between the volume of a gas and the total volume of the mixture in which the gas is contained, usually measured in the same units of volume like m^3/m^3 (volume concentration) or in parts per million by volume or ppmv (ppmv concentration). Abundance of GHG in the atmosphere is

measured in terms of concentration. Energy density is the ratio between the energy that an object radiates, absorbs, or reflects and the object's surface area, usually measured in Joules per square meter (J/m^2). Energy flux density is the time rate of energy density, usually measured in Joules per square meter per second ($J/m^2/s$). Flows of energy are measured in terms of either energy density or energy flux density.

Conceptual Framework

Concentration, energy density, and energy flux density are *intensive quantities* (Nunes et al., 2003). Unlike extensive quantities such as length, which are measured in the same measure space (e.g., length is measured in units of length such as foot, meter, or mile), intensive quantities are defined through division and express an invariant multiplicative relationship between two quantities that may or may not involve two measure spaces (e.g. speed is measured in units of mile/hour or meter/second). There are two types of intensive quantities (Nunes et al., 2003): Type 1 has constituent quantities that form a whole and is usually interpreted as a fraction. Type 2 has constituent quantities whose measures remain separate. Here, the intensive quantity is interpreted as a ratio and not as a fraction. Concentration is an example of Type 1, while energy density and energy flux density are examples of Type 2.

I developed a conceptual framework to characterize PSTs' conceptions of concentration, energy density, and energy flux density. The framework builds on Johnson's (2015) work and admits two levels of meaning for intensive quantities: *Ratio Level* and *Rate Level*. The levels are consistent with Thompson's (1994) distinction between *ratio*–a multiplicative comparison between particular values of two quantities–and *rate* – reflectively abstracted constant ratio. The framework describes four conceptions of ratio which, in order of increasing sophistication, include ratio as: *identical groups*, *particular per-one*, *abstract per-one*, and *measure*. Ratio Level includes the first two conceptions, while Rate Level includes the latter two conceptions.

Ratio as identical groups involves an association between particular values of two quantities (Simon, 2006). For instance, consider a diving tank containing 650 liters (L) of air of which 130 L are O_2. Here, the concentration of O_2 is conceived as an association between 130 L of O_2 and 650 L of air, or, as a simplified version, 13 L of O_2 for every 65 L of air. The framework includes two types of ratio as per-one (Simon & Placa, 2012): *particular* and *abstract*. *Ratio as particular per-one* involves associating a value of a quantity with one unit of another quantity for a <u>particular</u> situation. For instance, consider 4,200 J of energy being absorbed by a surface area of 12 m^2. Here, energy density is conceived as an association between 350 J and 1 m^2 for the <u>particular</u> case in which 4,200 J are shared equally among 12 m^2. Although *ratio as abstract per-one* also involves a per-one association, the ratio is conceived as an invariant multiplicative relationship between quantities that <u>can vary</u>. For example, an energy density of 350 J/m^2 is still conceived as an association between 350 J and 1 m^2. However, energy and surface area are conceived as varying quantities that maintain the 350 J per 1 m^2 association constant. Finally, *ratio as measure* no longer involves associating the values of two quantities. Rather, a ratio is conceived as a quantity in its own right, a quantity that measures the *strength* or *intensity* of an invariant multiplicative relationship between two quantities (Simon and Placa, 2012). For instance, a concentration of O_2 of 0.21 is conceived as a measure of the level of *oxygenation* in the air one breathes, or an energy density of 350 J/m^2 is conceived as a measure of the *intensity of the radiation* being absorbed by a surface.

Methods

Three secondary PSTs–hereafter known as Pam, Kris, and Jodi (pseudonyms)–enrolled in a mathematics education program at a large Southeastern university participated in my study. Each PST completed four mathematics tasks in the course of two individual, task-based interviews (Goldin, 2000). Task 1 required PSTs to use volume concentration to compare the level of

oxygenation in the air of two diving tanks. Task 2 required PSTs to determine ppmv concentration to compare the level of carbon dioxide (CO_2) in the air of two diving tanks. The next two tasks involved an experiment in which two devices are radiating energy in the form of heat towards two metallic sheets. Task 3 required PSTs to use energy density to determine which sheet will be hotter at the end of the experiment. In Task 4, PSTs needed to use energy flux density to determine which sheet's temperature is rising faster. These tasks were not directly related to global warming since their purpose was only to assess PSTs' conceptions of these intensive quantities commonly used to model this phenomenon. All interviews followed a *semi-structured* approach and the interview videos and transcripts were analyzed through Framework Analysis (FA) method (Ward, Furber, Tierney, & Swallow, 2013).

Preliminary Findings

PSTs did not show signs of difficulties when working on tasks involving concentration. All three PSTs conceived of volume concentration as *ratio as measure*. PSTs conceived of concentration as a measure of how "concentrated" a particular gas is in the air of a tank. Pam compared concentration to preparing lemonade to illustrate what concentration measures. Pam said that if you have more lemonade powder than water, the lemonade would taste "more lemony" because the lemonade power would be more "concentrated." Here, Pam said the drink's taste represents how concentrated oxygen (O_2) is in the tank. In addition, all three PSTs used a single value–in the form of percentage or decimal–to indicate the magnitude of a particular concentration. Kris interpreted a concentration of O_2 of 0.19 as "out of 850,000 cm^3 of air in tank B, 19% is oxygen." These PSTs also conceived of concentration as an invariant multiplicative relationship between two quantities that can vary (Rate Level). Jodi explained that a concentration of 0.21 "could be created by two different numbers as a ratio of each other … then you'll still get the 0.21 proportion of O_2 to air." Lastly, all three PSTs recognized volume concentration and ppmv concentration as two measures of the same attribute.

Unlike concentration, PSTs faced more difficulties when working on tasks involving energy density and energy flux density. All three PSTs had initial difficulties deciding on how to approach the task involving energy density. These PSTs started by calculating the ratio between energy and surface area, but they had difficulties recognizing why this ratio was important to complete the task. Initially, all three PSTs showed evidence of *ratio as particular per-one* for energy density, associating a particular energy to 1 m^2. PSTs constructed this association in the particular context of the situation described in the task. Pam interpreted energy density as "how many Joules are in 1 m^2." PSTs were able to reach Rate Level and conceived of energy density as *ratio as abstract per-one* by the end of the interview. However, before this happened, PSTs had to distinguish energy from temperature and then connect energy density to temperature. PSTs tended to confuse temperature with energy and had difficulties realizing that temperature involves a comparison between energy and size–larger objects need more energy than smaller objects to reach a certain temperature. Jodi compared a swimming pool to a cup of water being heated up by the sun, so "if you take the temperature of them at maybe midday, then the cup of water would be hotter than the swimming pool. So, size probably does have a role in how hot an object is." Once PSTs realized this, they could connect energy density to temperature since both compare energy to size.

In general, all three PSTs experienced problems conceiving of energy flux density as a single measure of how fast a sheet's temperature was increasing. All three PSTs needed help conceiving of energy flux density as a measure of this attribute. Pam, however, was not able to grasp this concept. All three PSTs conceived of energy flux density as two different types of per-one association. Pam constructed a *double per-one* between extensive quantities, associating energy with 1 m^2 and 1 second. Kris and Jodi associated an intensive quantity with one unit of an extensive quantity. Kris associated energy density with 1 second, while Jodi associated the rate at which energy is radiated

with 1 m². Unlike Pam's association, these PSTs' associations conduced to conceiving of energy flux density as the rate at which a sheet's temperature rises.

Discussion

PSTs' conceptions of intensive quantities commonly used to model global warming varied greatly depending on the type of quantity (Type 1 vs. Type 2). They faced increasing difficulties developing a ratio as measure conception as they moved from Type 1 (concentration) to Type 2 (energy density and energy flux density). Additionally, PSTs usually confused temperature with energy, which hinder their ability to conceive of energy density as ratio as measure. This is an important conceptual obstacle since connecting energy density and temperature is central for global warming. Finally, conceptions of energy flux density involved two types of per-one associations: a *double per-one* association of extensive quantities (energy per second per m²) and an association between an intensive quantity and one unit of an extensive quantity (energy density per second). The second type seemed to facilitate the development of ratio as measure conception for energy flux density. However, this was an effortful process for PSTs.

ELEMENTARY PRESERVICE TEACHERS' UNDERSTANDING OF EQUITABLE MATHEMATICS TEACHING

Monica Gonzalez
University of Houston
mladolphus@uh.edu

Imani Goffney
University of Maryland
igoffney@umd.edu

This goal of this study is to investigate how preservice elementary teachers describe equity and equitable mathematics teaching on a brief survey before and after taking an equity focused elementary mathematics methods course. At the beginning and end of this course, the preservice teachers completed a brief survey of questions that asked them to define equity and equitable teaching and give examples of how they would teach in equitable ways. Results indicate that students' pre and post responses changed in meaningful ways before and after the course. The definitions and examples were coded into three different categories: equity as academic success, equity as management of the classroom, and equity as teachers' relationships with students. Findings from this study support the hypothesis that more sophisticated or advanced ways of thinking can be developed through an equity focused methods course.

Keywords: Equity and Diversity, Teacher Education-Preservice

Elementary teachers often have direct and sustained interactions with the students in their classrooms and, as such, strongly influence how much students learn, what they learn, and how they feel about being learners of mathematics. In this way, improving teachers' knowledge through teacher preparation is therefore essential to teacher effectiveness and student achievement. Teachers need specialized training that will prepare them to provide ambitious and equitable instruction, especially in the elementary mathematics classroom. Elementary mathematics methods courses are sites to develop these specialized skills in preservice teachers. It is important to evaluate the effectiveness of the teacher preparation in order to maintain a high quality program that will produce elementary teachers that can teach mathematics in equitable ways.

Review of the Literature

Equity in Mathematics Education

Equity is a term used to describe a way in which all students can be academically successful in mathematics. NCTM (2008) published a position statement that stated equity is "high expectations, respect, understanding, and a strong support for all students" (p. 5). Additionally, Esmonde (2009) describes equity in mathematics as "a fair distribution of opportunities to learn or opportunities to participate" (p. 1010). New teachers often enter their teacher preparation programs with a professed "love of children", but are often unaware of their own bias towards the students who culturally, socially, and linguistically differ from themselves. These unexamined bias and assumptions may hinder teachers from enacting equitable teaching practices that would support all students in developing skills needed for mathematical proficiency (Downey & Cobb, 2007).

Methods as a Site for Developing Equitable Teaching Practices for Mathematics

The quality of mathematics instruction, and ultimately student learning, is directly related to teachers' knowledge and skill (Darling-Hammond, 1999). Mathematics methods courses are places for preservice teachers to develop new ways of thinking about teaching and learning (Ball, 1990), and they are places to challenge deficit views of students' abilities to learn ambitious mathematics as well as develop preservice teachers' abilities to teach ambitious mathematics content. Many mathematics teacher educators use their methods courses to shape preservice teachers' views of

students and how to teach those students. Interweaving multicultural education throughout a teacher preparation program helps elementary preservice teachers develop the necessary equitable teaching strategies in a nonthreatening environment (Chisholm, 1994). However, there is little in the literature that examines how preservice elementary teachers make sense of equity and equitable teaching when a mathematics methods class is designed to attend to equitable mathematics teaching.

Methodology

This study explores how preservice teachers conceptualize equity and equitable teaching before and after an equity focused elementary mathematics methods course by analyzing their pre and post response to a brief survey. Specifically, the research question is: In what ways do elementary preservice teachers define equity and equitable teaching before and after an elementary mathematics methods course that is focused on equitable mathematics teaching?

Sample

The participants in this study were classified as seniors in an elementary teacher preparation program at a large research-intensive university in a southern state. This university is a minority serving, Hispanic serving institution in a large urban city. Graduates from this teacher preparation program typically teach in local urban school districts. Given their anticipated first teaching assignments in urban classrooms, it is especially important that graduates of this program are prepared to work with culturally, ethnically, and linguistically diverse students. The sample for this study includes forty-three participants, only one of which was male while the rest were female. The participants were also ethnically and linguistically diverse with Spanish being the second dominate language spoken.

Mathematics Methods Course

Participants completed an elementary mathematics methods course that focused on equitable and ambitious mathematics instruction during the Fall 2014 semester. It was the first of two mathematics methods courses in the teacher preparation program, and the content focus of the course was number and operations. Equitable teaching practices were infused throughout the methods course. Some of these practices include setting up and managing group work in ways that distribute opportunities for multiple students to participate, using multiple strategies for posing questions about content, choosing and using sensitive and appropriate examples for use with diverse students, and maintaining high expectations for all students. The participants also read case studies and engaged in conversations about issues of race and language and the impact they can have on student learning. In conjunction with the methods course, the participants were also enrolled in full time student teaching. As a part of the required work for this course, pre-services teachers completed a variety of projects where they practiced the equitable teaching practices learned in the methods course and reflected on their teaching using evidence of student participation and work.

Data Collection

The instrument used in this study is a one-page equity survey asking the preservice teachers to write a definition of equity, write a definition of equitable teaching, and describe three ways in which they would teach in equitable ways during student teaching. Participants completed the equity survey twice during their methods course. Question prompts on the pre survey and post survey were identical in order to track on the difference in understanding of equity and equitable teaching by the preservice teachers' before and after the completion of the equity mathematics methods course. The pre survey was given on the first day of class as the first activity for the preservice teachers to complete, and the post survey was administered as the first activity on the last day of class.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Data Analysis

The responses to the equity survey gave the researcher a holistic understanding of how the participants conceive equity and equitable mathematics teaching. The pre and post responses for each participant were randomly coded so it could be analyzed without bias of knowing if the survey represents pre or post data. Emergent coding techniques were used to derive "understanding of equity" categories from the data. There were three rounds of coding for the analysis that consisted of descriptive coding and pattern coding. A group lens was used during the analyses to look at the percentage of responses that attended to the same "understanding of equity" categories for the pre and post surveys. This analysis gives insight into how the majority of participants understood equity and equitable mathematics teaching before and after the methods class. It will also show if there are any trends in the shift from one category to another over time.

Results

Three categories emerged from the analysis of the participants' responses and each consists of subcategories that contain specific terms or ideas expressed by the participants. The three categories are equity as academic success, equity as management of the classroom, and equity as teacher's relationships with students. Table 1 shows the percentages of each category and its subcategory from the pre survey to the post survey.

Table 1: Understanding of Equity Categories

Category	Subcategory	Percentage of Pre-Survey Responses Attending to the Subcategory	Percentage of Post-Survey Responses Attending to the Subcategory
Equity as Academic Success	Instruction	44.19%	90.70%
	Opportunity	39.53%	48.84%
Equity as Management of the Classroom	Participation	37.21%	51.16%
	Students' Environment	11.63%	51.16%
	Discipline	30.23%	6.98%
Equity as Teacher's Relationships with Students	Treatment of Students	88.37%	39.53%
	Expectations	11.63%	25.58%

Equity as Academic Success

The "equity as academic success" category contains participant responses that attended to how he or she will teach so that all students can be academically successful or how equity is related to the opportunity for all students to be academically successful. This category combined the two subcategories instruction and opportunity. The instruction subcategory contains responses related to particular teaching techniques, student learning, and ways in which the teacher will help students achieve academic goals. The opportunity subcategory consists of responses that relate equity to students' having an equal or the same opportunity to achieve academic success.

Equity as Management of the Classroom

The "equity as management of the classroom" category consists of participants' responses that attended to how students participant in the classroom, how students will feel in the classroom environment, and how discipline will be handled. Three subcategories were grouped into this one category: participation, students' environment, and discipline. The subcategory participation consists

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

of responses that relate equity to students' participating in the daily classroom routines or participating in the lesson that is taught. The students' environment subcategory describes equity as being a safe, supportive, or status-free environment for the students. The responses that received this particular code described ways in which students would interact with their whole environment and not just with the teacher. Finally, the subcategory of discipline described equity and equitable teaching as holding all students accountable to the same rules, receiving the same consequences, or looking at the cause of a behavior instead of just the student.

Equity as Teacher's Relationships with Students

The "equity as teacher's relationships with students" category contains responses that describe equity in relation to how the teacher will treat students or what the teacher expects from students. The two subcategories of treatment of students and expectations were grouped together because they only describe the relationship between the teacher and the student. The subcategory treatment of students consists of responses that relate equity to how the teacher will interact with students or treat the students. The expectations subcategory includes responses about having high expectations for students or expecting the same behavior or academic success from all students.

Discussion

The responses on the pre survey compared to the post survey showed a shift in understanding of equitable teaching. The pre survey responses revealed that pre-service teachers started the course with broad examples of equitable teaching and moved to more specific examples that they would use during a mathematics lesson. In the post surveys, the preservice teachers described equitable practices in much more specific terms revealing an increased knowledge about the complexities of equitable teaching as promoting individual academic success, managing students in ways that position them as smart and capable instead deficient, and creating relationships with students to communicate high expectations.

Conclusion

Results from this study indicate that an understanding of equity and equitable teaching can be developed through an equity focused mathematics methods course. Analysis of pre and post survey results indicate that there was a shift in the types of definitions and examples from ones focused on treating all students the same to more specific equitable teaching strategies. Additional research needs to be done to expand the sample size and scope of the study to more closely approximate causal inferences between what was learned in the course and students' pre and post survey responses. However, the implications for mathematics teacher education is that equitable teaching is a concept that needs to be embedded into a mathematics methods course so that preservice teachers can develop their understanding of equitable teaching practices in the context of mathematics.

This paper explores co-teaching as a new paradigm for secondary mathematics internships. We share an overall vision for an internship grounded in co-teaching. We describe specific co-teaching strategies from the literature and discuss our initial findings regarding the use of co-teaching during our secondary mathematics students' full-time internships. We discuss future directions for research on co-teaching and co-planning.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices, High School Education

Pre-service teachers' classroom internships are widely acknowledged as one of the most influential, and potentially problematic, components of teacher preparation programs. In addition to providing students with quality mathematics instruction, there are many other tasks that must be accomplished during the internship. Interns and mentor teachers must negotiate their roles in both the classroom and in planning. Interns, with assistance from their mentors, must make the transition from student to teacher, establish links between their theoretical understanding of pedagogy and the practical applications of that knowledge, and learn about the many non-instructional components of teaching. Mentors must assist interns with all of these tasks while maintaining quality classroom instruction and juggling time commitments to provide interns with adequate access to their expertise. Given the complexity of the internship experience, models with potential to make the experience more productive are worth exploring. In this study we investigate co-teaching as a new paradigm for how interns and clinical teachers work together.

Theoretical Framework

Our work with co-teaching during pre-service teachers' internship experiences is grounded in Lave's (1991) construct of situated learning. As interns go out into the field, their learning moves from a predominately academic experience to an apprenticeship in a community of practice. In such a setting the working relationship between intern and mentor teacher becomes a major determining factor in the intern's ability to participate productively and collaboratively in the practice of classroom teaching. In our work we consider ways to expand traditional visions of this working relationship between intern and mentor, envisioning mentor and intern as collaborators in classroom instruction.

Co-Teaching

Co-teaching involves more than just new models for how mentors and interns communicate and work together. It involves challenging the borders of what it means to be a mentor and intern. In too many internship settings, interns begin as mere observers in the classroom with no responsibility and little identity in the eyes of classroom students. Interns then begin to take on more of the classroom leadership, often abruptly, as the mentor relinquishes classes to the intern. Although excellent internship settings may provide the kind of progressive, scaffolded learning experience that helps

interns develop the skills for classroom teaching, even these settings often keep the intern mired in the identity of a student in the eyes of classroom students and, more troubling, in their own eyes (Valencia, Martin, Place, & Grossman, 2009).

In looking at other models for the intern-mentor relationship, we looked to co-teaching models found outside mathematics education literature (e.g., Bacharach, Heck, & Dahlberg, 2010; Murawski and Spencer, 2011). A synopsis of these strategies, as well as benefits and concerns for each, are shown in Table 1. These models, adapted to a mathematics education setting, envision a far more collaborative relationship, which may help interns develop their self-identity as teachers and provide some focused strategies to facilitate communication and collaboration in this relationship.

Table 1: Co-Teaching Strategies
(Adapted from Bacharach, Heck, and Dahlberg, 2010; Murawski and Spencer, 2011)

Strategy	Definition	Benefits	Concerns
One Teach, One Observe	One teacher leads instruction, while the other teacher gathers specific information.	Extra set of eyes; provides data about instruction or student learning; easy to implement.	Easy to become a habit; must agree in advance what is to be observed.
One Teach, One Assist	One teacher works with the whole class, while the other assists individual students or groups of students.	Provides assistance to individual students; easy to implement; may provide a "voice" to share student concerns.	Too easy to become a habit and for one teacher to always feel like an assistant; changing roles is essential.
Station Teaching	Students divided into three or more groups; students rotate through multiple stations; teachers facilitate individual stations or circulate among stations.	Smaller groups are better for instruction, assessment, and class management; allows for differentiation, movement, and hands-on activity.	Teachers may need to use space differently; class management and transition needs to be structured; independent stations need to be carefully planned.
Parallel Teaching	Each takes half the class. Groups may be doing the same or different content in the same or different ways. Groups do not switch during lesson.	Smaller groups better for instruction, assessment, and class management; teachers have their own groups; interns teach same lesson/mirror teacher.	Teachers need to be willing to use their space differently; both teachers need to plan for their group; class management needs to be structured.
Alternative Teaching	One teacher works with large group of students, other teacher works with smaller group (re-teaching, pre-teaching, or enrichment).	Good for smaller and more specific group work; good for addressing IEP/504 goals; teachers can plan separately.	DO NOT always pull the same kids; need place for group to meet; watch noise levels; plan how to integrate group back into class.
Team Teaching	Both teachers presenting. This may take the form of debates, modeling information, compare/contrast, or role-playing.	Demonstrates parity and collaboration between teachers; good for modeling; fun for role-playing.	Takes willingness to "share the stage"; both need to feel comfortable in front of the class.

Our Study

Educational researchers have worked to broaden the vision of co-teaching strategies beyond their roots in special education (e.g., Bacharach et al., 2010; Murawski and Spencer, 2011). Our work is focused on seeking ways that these strategies might be implemented in the unique setting of secondary mathematics classrooms. We began our work by collaborating with colleagues about math-specific examples of the strategies and used these in training sessions with our interns and mentors. These have been updated and expanded over the last three years with examples from our interns and mentor teachers. In our study we have been investigating how interns use co-teaching strategies in their placements, interns' perceptions of co-teaching as an internship paradigm, and mentor teachers' perceptions of co-teaching. We have also collected data on how interns and mentors co-plan in preparation for co-teaching. We have collected data on 33 interns and their mentor teachers over the past three years. This data includes surveys, informal observations, focus groups, and audio recordings of co-planning sessions. We are still in the process of collecting and analyzing data but initial findings are very promising.

Findings

Our ongoing analysis of data indicates that both understanding of co-teaching as a paradigm shift and the use of particular co-teaching strategies are perceived as helpful by interns and their mentor teachers. Our analysis also indicates that, over the three years of this study, engagement in co-teaching has increased and mentor teachers' resistance to trying it has decreased. For example, two years ago, interns reported using specific co-teaching strategies an average of 3-4 times per month. This semester at least half of our interns are framing all of their classroom experiences in terms of co-teaching.

We have also seen specific instances in which co-teaching served to expand all participants' vision of what secondary mathematics instruction might look like. For example, at one high school, there were two mentor/intern teams teaching the same course during different class periods. The interns were interested in trying the station teaching strategy. The interns co-planned four stations designed to help students review for an upcoming test on angle relationships and triangle congruence. When the interns began to think about implementation of these stations they realized that the lesson would likely be more effective with more than two teachers. Since the intern/mentor pairs had different planning periods, they convinced their mentor teachers to "donate" their planning period for a day so that all four teachers would be available to implement the stations in both classrooms.

Several positive outcomes should be noted from this example. First, the interns conceptualized the lesson during a co-planning session, presented the idea to their mentor teachers as part of their professional learning community, and took the lead on creating all materials for instruction. Second, both of their mentor teachers were willing to allow their interns to try a co-teaching model that neither mentor teacher had previously implemented. They were also willing to use their planning period to co-teach with a colleague and her intern, also a first for them. One of the mentor teachers shared that, despite prior non-content specific co-teaching training, before this experience she could not envision implementing stations with her high school mathematics classroom. After this lesson, she commented that this experience was one of the most interactive and engaging learning activities for not only her students, but also her colleague and their interns. Further, she could see herself continuing to use stations in the future. In this example, co-teaching not only helped to provide an excellent learning experience for the students, it expanded the mentor teachers' view of the type of teaching and collaboration possible in a high school classroom.

Discussion

As described in the case above, initial findings are promising. The two observations noted above point to the potential of co-teaching to engender confidence and leadership within interns, thus

helping them view themselves as teachers rather than students. This is a marked contrast to the challenges faced by interns as described by Valencia et al. (2009). Furthermore, in this example co-teaching allowed the interns to introduce novel instructional practices within their mentor teachers' classrooms. In this sense, co-teaching has the potential to serve as another tool for mathematics teacher educators to empower pre-service teachers and to encourage student-oriented instructional practices in high school mathematics classrooms.

While our initial results are encouraging, we need more research on the effect of co-teaching as mentors, interns, and university supervisors learn more about how to implement these strategies in high school mathematics classrooms. One critical component that also needs careful consideration and study is the role of co-planning, including strategies on how to co-plan, as a support for quality mathematics instruction, especially in a co-teaching setting. There is wide agreement in the literature (e.g., Bryant & Land, 1998; Bryant Davis, Dieker, Pearl, & Kirkpatrick, 2012; Murawski, 2012) that co-planning is essential to co-teaching but very little practical guidance exists about ways to engage in co-planning. We are currently working on developing and testing co-planning strategies to support co-teaching and intern development.

"IT'S WHAT SOCIETY THINKS": EXPLORING IDENTITY NARRATIVES IN LEARNING TO NOTICE CHILDREN'S MATHEMATICAL PRACTICES

Lynette DeAun Guzmán
Michigan State University
guzmanly@msu.edu

Attention to mathematics teacher noticing is growing in our mathematics education communities. For this study, I intended to examine prospective K-8 teacher noticing across multiple contexts outside of the classroom (e.g. science museum, nature walk); however, stories about identities were particularly salient through our conversations and reflections in learning to notice children's mathematical practices. In this paper I explore how identity narratives (e.g. gender, race, age) interact with developing teacher noticing. I present preliminary findings that suggest the importance of teachers' identity stories in their mathematics teacher noticing development.

Keywords: Teacher Education-Preservice, Equity and Diversity, Gender, Informal Education

Much of the literature on mathematics teacher noticing research primarily focuses on supporting prospective teachers' noticing through various kinds of activities, such as analyzing classroom artifacts (e.g. Goldsmith & Seago, 2011) and video recordings (e.g. Starr & Strickland, 2008), to say something about children's mathematical thinking in classroom contexts. Part of supporting mathematics teacher learning, though, involves understanding how teachers make meaning of their professional practice across multiple learning spaces and experiences. One challenge for mathematics teacher education involves understanding whether and how prospective teachers engage in interrogating dominant limiting narratives about what it means to demonstrate mathematical competencies (e.g. "I'm not a math person") through their professional learning. Identity narratives (i.e. who, in terms of multiple identity markers such as race or gender, is readily seen as a "math person") are also embedded in these discussions.

The purpose of this study is to better understand how prospective K-8 teachers make connections between identity narratives and their learning to notice children's mathematical practices. Specifically, I investigate the following research questions: (1) What identity narratives do a small group of prospective teachers and a university researcher invoke through their participation in a working group focused on learning to notice children's mathematical practices? and (2) In what ways do prospective teachers connect these narratives to mathematics teacher noticing? This research extends work of scholars investigating mathematics teacher noticing to better understand the nuances and complexities of this practice.

Related Literature

In conceptualizing ways of knowing mathematics, Nasir, Hand and Taylor (2008) argued that mathematics knowledge is fundamentally linked to cultural practices. Many scholars have also highlighted this argument through their studies of out-of-school mathematics practices (e.g. Carraher, Carraher, & Schliemann, 1985; Nasir, 2002; Taylor, 2009). Guided by scholarly work on learning as participation (Lave & Wenger, 1991), I view *mathematics* in terms of participation in the practices and discourses involved in *mathematical experiences*, which must include aspects of mathematics and mathematical practices, such as people engaging with quantities, patterns, and spatial reasoning. Mathematics, in this view, is not restricted to a formalized body of knowledge. Instead, this view validates multiple ways of meaning making and practices involving mathematical ideas. Mathematical experiences include the intersections of mathematics and any combination of disciplines and disciplinary ideas. By broadening what constitutes mathematics, I directly challenge limiting perspectives about what counts as competencies and engagement with mathematics.

Noticing Children's Mathematical Thinking

Teacher noticing, as a professional practice, involves more than just the act of observing behavior; it requires specialized knowledge and intentional decision-making that is specific to teaching. Jacobs, Lamb, and Philipp (2010) define this construct as *professional noticing of children's mathematical thinking,* which involves three interrelated skills: attending to, interpreting, and deciding how to respond to children's mathematical thinking.

Narratives as Storytelling

My explicit attention to identity narratives stems from humans making meaning of the world, shaped by experiences, values, and emotions. As Goldsmith and Seago (2011) eloquently state:

> Teachers' interpretations of classroom artifacts are influenced by the very ways they think about mathematics and mathematics teaching and learning. Teachers view video or read a student's worksheet through the lens of their own knowledge, beliefs, and experiences; this lens shapes their very perception of the artifacts themselves (Heid, Blume, Zbiek, & Edwards, 1999). (p. 170)

I consider identity narratives important in mathematics teacher education because these narratives contribute to shaping the lens through which we see the world. Drawing on Shah (2013), I view narratives as storytelling. Specifically for mathematics education, these narratives are stories that teachers tell about children, about themselves, and about mathematics.

Method

This research uses an exploratory case study design to investigate a case of prospective teachers learning to notice children's mathematical practices across multiple contexts outside the classroom. Through discourse analysis of multiple sources of generated data (i.e. written reflections, audio-recordings of meetings and site visits, individual interviews) over a period of time, this research contributes to the literature on mathematics teacher noticing by providing a collection of prospective teachers' stories about their learning.

Research Setting and Participants

The research setting takes place in meetings and site visits of a working group created by six prospective K-8 teachers and myself over a seven-month period. I pursue ethnographic traditions in this work because my active participation supports me in getting close to the teachers across the multiple contexts in which they are learning to notice children's mathematical practices. I draw on ethnographic participation that provides "access to the fluidity of others' lives and enhances sensitivity to interaction and process" (Emerson, Fretz, & Shaw, 2011, p. 3). I am fully aware of my role as both a group member and as a researcher, which is influenced by my positionality as a middle class, Latinx woman who was generally successful in traditional mathematics classroom spaces and is a visibly young beginning teacher educator. One participant (Liv) is a female Asian international student from Indonesia, and five participants (Ann, Beth, Elise, Kate, and Lilli) are female White Americans. All names are pseudonyms.

Preliminary Findings

In our group, we identified multiple narratives about being a "math person" that suggest the power and status mathematics holds within the United States and in our own lived experiences. Furthermore, these narratives point to the importance of identities in mathematics spaces and how we see ourselves as future educators. In this section, I provide examples of identity narratives we invoked and our perspectives on connecting identity narratives to teacher noticing.

Invoking Gender, Race, and Age Narratives

Each member of the working group recognized identity narratives in her written reflections and verbal group discussion contributions. Two narratives that repeatedly appeared in our discourse involved mathematics and gender (e.g. *Boys are better than girls at math; math is for boys*), and mathematics and race (e.g. *Asians are good at math and science*). For example, Elise wrote about wanting to teach math in ways that were applicable to her future female students' lives because "math is often viewed as a man's subject or profession." She also voiced her frustration that some people viewed mathematics teaching as a "waste of that math talent" and "math people" are often encouraged to pursue engineering instead of teaching.

Prospective teachers also invoked narratives about age, and in particular, being young women in mathematics spaces through our teacher noticing activities. In the following, two prospective teachers and the author debriefed an interaction between Ann, Lynette, and a White male volunteer at a science museum site visit where we engaged in our noticing.

Kate: …so much of what he says is kind of condescending. Did he know you were elementary educators at this point [in the interaction]?

Lynette: At this point he did.

Kate: Yeah, and part of it—I don't know if this is applicable, but is he older?

Lynette: Yeah.

Kate: So I don't know if age is—just treating you like, *oh, you're just these young people*. And I feel just how he talks down on everything, it definitely seems a little gendered. A little ageist, maybe. Like, something's going on here. You would think that most people would be welcoming, but he was kind of the whole time not really treating you like [what you were doing] was anything important, which isn't really good at all.

Ann: Well, I definitely felt the whole ageist thing when he realized that I was an undergrad, and at that part where I said, *No, we're observing together*…He kind of looked at me like, *well, you're just her guinea pig, you're just here for her*, and it's like, no, we're here. We're working together. I don't know. He just really rubbed me the wrong way.

Lynette: So did you feel like this interaction was gendered also for you?

Ann: Yeah. Yeah. I felt like it was very much him talking down to us. He's like, *Well, I'm a male physicist and you're just elementary ed, teaching little kids. You don't know anything*… After all that time that he kept going on about what he knows and then he kept bringing up himself how he didn't know [elementary mathematics] things, but then never started acting like—he always acted like he knew better than us, even saying, *Well, I didn't even know that*. Yeah, because you don't do elementary.

This example is one experience in which gender, age, and elementary mathematics content intersect in how these prospective teachers experienced identities in their world and through their learning to notice children's mathematical practices. This positioning speaks to marginalization as *women* in traditionally male-dominated spaces, as *young people* who are devalued as not having enough expertise, and as *elementary mathematics educators* who are devalued in favor of people who work with more 'advanced' and 'difficult' mathematics content.

Perspectives on Connecting Identity Narratives to Teacher Noticing

Overall, prospective teachers in this working group noted the value of recognizing identity narratives in their own developing professional practice, and teacher noticing in particular. Although prospective teachers identified these narratives, they also seemed to dismiss some of these narratives by drawing on their lived experiences. Some teachers also intentionally distanced themselves from these identity narratives. I asked the group why we think these narratives exist at all, and Beth referred to identity narratives as "what society thinks" without any acknowledgement of being part of

society and potentially contributing to what society thinks. Lilli also added that "it's something *they* (emphasis added) use to blame: 'Oh well, you're better than me because you're a boy!'" Later on in the conversation, though, Lilli commented that our attention to narratives is important for our teacher noticing because:

> …it's also for us to be aware that it's not—let's say if a student is struggling in math, there are so many factors. You know, you can't just assume that they don't understand the material. I mean, they could have a mental block that's like, *I'm a girl so I'm not going to be as good.*

Subsequently, Liv pointed to feelings of discomfort by saying, "I'm starting to fear that if this is how people in America, I guess, view Asian students… and the moment us Asian students come into your classroom and you think, 'Oh, you're going to need less help from me.'" Multiple of the White female prospective teachers pointed to this comment as important for their reflections.

Implications and Discussion

This work strives to highlight the complexities in developing mathematics teacher noticing—teachers may notice children's mathematics both inside *and* outside the classroom, and additionally, teachers' own stories about identities and mathematics shape what it is they attend to and interpret in their noticing. In my ongoing investigation, I seek to examine how these stories relate to our teacher noticing over time as we gain expertise. I also want to further explore the relationships between societal and individual narratives in our noticing development.

PRESERVICE ELEMENTAY TEACHERS' UNDERSTANDING OF MATHEMATICAL DEFINITION OF THE AREA OF A RECTANGLE

Jia He
Utah Valley University
Jia.He@uvu.edu

Research indicated that U.S. students had a weak understanding of spatial measurement concepts and they tended to take measurement concepts as procedures rather than meaningful knowledge. Research also found undergraduates' confusion about mathematical definitions and theorems. The formula to calculate the area of a rectangle tends to be regarded as a definition rather than as a deduced result. This study investigated preservice elementary teachers' understanding of definition of the area of a rectangle and their understanding of mathematical definitions in general. I found that most preservice elementary teachers did not know the right way to define the area of a rectangle and they tended to focus on external features when producing and evaluating mathematical definitions. Teachers also demonstrated a lack of understanding of the roles mathematical definitions play in the axiomatic system.

Keywords: Measurement, Teacher Education-Preservice

Definitions play a central role in the discipline of mathematics (e.g., Zaslavsky and Shir, 2005) and in the teaching and learning of mathematics (e.g., Tall and Vinner, 1981). In spite of the importance of mathematical definitions, the notion of definition develops through students' experience in learning specific mathematical concepts and usually is not discussed explicitly during mathematics instruction. Therefore, Wilson asserted (1990) that "Although we frequently use definitions, we rarely focus on the nature of definitions" (p. 33).

Understanding the nature of mathematical definitions is important for elementary teachers. As argued by Ball, Thames, and Phelps (2008), knowledge of mathematical definitions is an important component of Subject Matter Knowledge. *Common Core State Standards for Mathematics* (CCSSM) (National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010) says "Mathematically proficient students understand and use stated assumptions, definitions, and previously established results in constructing arguments" in the practice of "Construct viable arguments and critique the reasoning of others" (NGA & CCSSO, 2010, p. 6). Elementary teachers need to understand how to use definitions to build mathematical arguments in order to help their future students make sense of mathematics. For instance, elementary teachers need to know how the area of a rectangle equal to length times width could be explained from the meaning of area measurement.

Definitions are different from theorems because mathematical definitions are conventional knowledge and cannot be proved (Kobiela & Lehrer, 2015). Educational researchers have reported students' confusion about definitions and theorems. For instance, Dickerson and Pitman (2012) found that college students thought defining was a way to get around difficult proofs. This misconception raises a need to study if preservice elementary teachers are able to articulate key features about mathematical definitions as opposed to theorems.

In this study, I investigated preservice elementary teachers' understanding of definition of area because elementary students' deficiencies in conceptual understanding of spatial measurement was widely reported in the literature (e.g., Kamii & Kysh, 2006). Measurement tend to be taken as meaningless procedures rather than meaningful mathematical knowledge. I focused on preservice elementary teachers' thinking about definition of the area of a rectangle because the formula length times width could be easily taken as a definition rather than a deduced result. I then explored how

preservice elementary teachers think about mathematical definitions in general based on their understanding about this specific definition. Specifically, I aimed to answer the following research questions:

1. How do preservice elementary teachers understand mathematical definition of the area of a rectangle?
2. How do preservice elementary teachers think about mathematical definitions in general, as manifested through their understanding of mathematical definition of the area of a rectangle?

Methods

Participants

Twenty-four preservice elementary teachers (PETs) who were at the end of their teacher education program participated in this study at a Midwest university. At this university, PETs are required to choose one of the content areas (e.g., Mathematics, Language Arts) as their teaching major. PETs whose teaching major is not mathematics need to take two mathematics courses for elementary teachers (Number and operations & Geometry and Measurement). PETs whose teaching major is mathematics are required to take additional advanced mathematics courses. This context offered me an opportunity to investigate if the amount of mathematical training PETs received correlates to their understanding of mathematical definitions. Among the 24 participants, half are mathematics teaching majors (PETs - M) and the other half are non-mathematics teaching majors (PETs - N). I used M1 - M12 to represent PETs - M and N1 – N12 to represent PETs - N.

Data Collection

The source of data were semi-structured interviews from a larger study. This paper reports the findings to two interview questions. The first interview question (Q1) asks PETs to write a mathematical definition of the area of a rectangle. The second interview question (Q2) happened later in the interview. It asks PETs to determine if the statement "The area of a triangle with base b and height h is equal to ½ bh" is a mathematical definition. Immediately after both questions, PETs were asked to explain their thinking. I audiotaped and transcribed each interview.

Data Analysis

An analytical framework was built to categorize PETs' written definitions into four categories: (a) the amount of space inside the rectangle, (b) length times width (or its symbolic representation l x w), (c) <u>both</u> the amount of space inside the rectangle <u>and</u> length times width (or its symbolic representation), and (d) the amount of space inside the rectangle <u>or</u> length times width. The coding not only considered PETs' written responses but also their verbal explanations. I then investigated the aspects PETs attended to while constructing and evaluating definitions to explore how PETs think about mathematical definitions in general.

Results

PETs' Construction of Mathematical Definition of the Area of a Rectangle

Table 1 gives the distribution of PETs who produced one of the four statements as the definition of the area of a rectangle in Q1. Around 20% of PETs indicated that the amount of space inside the rectangle was the definition of the area of a rectangle. Two PETs - M and one PETs - N discussed the dichotomy - what it means vs. how to calculate it - as a way to distinguish a definition vs. a non-definition. One PET - M indicated that the amount of space was more like a definition because the formula can be discovered through the more basic statement "the amount of space inside the

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

rectangle". However, M9 mentioned this idea in a teaching setting instead of in a mathematics setting.

Table 1: Types of Statements PETs Wrote as Definitions of the Area of a Rectangle

Type of statement	Total	PSTs - M	PSTs - N
(a) Amount of space inside the rectangle	5	3	2
(b) Length times width	11	8	3
(c) Amount of space inside the rectangle and length times width	7	1	6
(d) Amount of space inside the rectangle or length times width	1	0	1

Almost 50% of PETs indicated that the formula was the definition of the area of a rectangle. M1 regarded the formula as the definition because "it is more specific to a rectangle." Another PET M3 indicated that the reason why she thought the formula was the definition was that the formula was more clear and straightforward. She said "I feel like that [the space contained within the perimeters] wasn't like clear enough." Another two PETs - N indicated that they thought the formula was the definition because in their mind the definitions should help calculate the concept. This is the opposite opinion to the previous two PETs - M and one PET - N who used the dichotomy - what it means vs. how to calculate it - as a way to distinguish a definition vs. a non-definitional statement.

Almost 30% of PETs indicated that both the amount of space inside the rectangle and the formula together formed the definition. Three of them expressed that definitions should include both what the concept is and how to find or use it. M7 mentioned that the formula can be discovered by the students, but this knowledge did not affect her decision to include both amount of space and formula in the mathematical definition. Another PET, N9 indicated that definitions were audience dependent. Thus in order to meet the needs of all audience, both the amount of space inside the rectangle and the formula should be included in the definition.

Overall, I found that PETs - M tended to choose formula as the definition but PETs - N tended to choose the amount of space inside the rectangle and formula as the definition. In addition, eight PETs used dichotomy, what it means vs. how to calculate it to support their claims. But they differed on how this dichotomy related to mathematical definitions. Some thought how to calculate alone cannot be counted as a definition; others thought it can be counted as a complete or part of a definition. Similarly, two PETs M9 and M7 pointed out that formula can be discovered by students in teaching contexts. But they made opposite arguments on if the formula should be included in the definition based on this observation.

PETs' Evaluation of Whether a Statement About the Area of a Triangle Is a Mathematical Definition

Only four PETs gave correct judgment to Q2, namely they rejected the statement "The area of a triangle with base b and height h is equal to ½ bh." as a mathematical definition of the area of a triangle. Because Q1 and Q2 ask for definitions of similar concepts, my hypothesis was that PETs would give similar responses. However, a comparison between PETs' responses to Q1 and Q2 suggested that only half of PETs gave consistent answers to both questions. Among them, only one PSTs - M gave consistent and correct answers to both questions. She wrote the amount of space inside the rectangles as the definition and also determined that the statement in Q2 was not a definition of the area of a triangle. Other PETs either made mistakes in Q1 or Q2.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Discussions and Conclusions

Overall, twenty percent of PETs and less than 20% of PETs gave correct responses to two interview questions respectively. Only one PET - M gave correct answers to both interview questions. This result indicated PETs' weak understanding of mathematical definition of the area of a rectangle. When PETs were making judgment about mathematical definitions, they did not consider whether a statement could be deduced from other knowledge as an essential feature. Even though two PETs pointed out that formula can be discovered by students in teaching contexts, no PET has ever mentioned this idea in pure mathematics setting. This phenomenon suggests that PETs' understanding of the difference between mathematical definitions and deduced results is weak. PETs tended to focus on external features such as if the statement is specific to a rectangle, if the statement is clear, straightforward, understandable, and can be discovered by their students. These external features are certainly good features to attend for mathematical definitions, but taking these external features as the most important features of mathematical definition is inadequate. Vinner (1991) pointed out that there is a significant difference between "technical concept" (e.g., mathematical concept) and every day concept. Obviously, the PETs in this study were not aware of the differences and many of them made incorrect judgment because they favor external features, which might be more important to a daily life definition.

Another interesting phenomenon I found is that even if PETs - M received more mathematics instruction in college, their understanding of the area of a rectangle and their understanding of mathematical definitions in general were not better than PETs - N. This implies that taking advanced mathematics courses alone does not automatically improve PETs' understanding of mathematical definitions. PETs' inconsistent responses in Q1 and Q2 further supports my claim that PETs are not clear about the nature of mathematical definitions. Therefore, explicit instructional attention should be given to clarify the nature of mathematical definitions and their roles in mathematics. Also, assessment needs to be aligned with the instruction in order to test PETs' knowledge of mathematical definitions as a meta level concept in addition to testing PETs' knowledge of specific mathematical concepts (e.g., fractions).

PRE-SERVICE TEACHERS' STRATEGIES FOR COMPARING FRACTIONS

Daniel R. Ilaria
West Chester University
dilaria@wcupa.edu

The teaching and/or learning of fractions have been a challenge for students, pre-service teachers, and teacher educators. The creation of a sequenced set of applets developed to model the approach advocated in the Common Core Standards provided the opportunity to examine their impact on pre-service teacher learning of fractions. In this study, we examined how pre-service teacher content and pedagogical knowledge compared when learning from a technology approach using the applets versus a hands-on manipulative approach. This paper reports on two groups of pre-service teachers' ability to compare fractions based on using these approaches in their pre-service teacher methodology courses.

Keywords: Teacher Education – Preservice, Technology

Fractions in the Common Core Standards

Students' struggles with fractions have been well documented in the research literature. As an example, on the 2004, National Assessment of Educational Progress (NAEP), 50% of 8th graders could not order three fractions from least to greatest, and 70% of 17-year-olds could not write 0.029 as a fraction (Siegler et al., 2010, p. 6). Because of these concerns, the *Common Core State Standards for Mathematics* (CCSSM) (National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010) promotes a more coherent learning sequence with an emphasis on unit fractions and fractions as numbers on the number line. The changes are supported by a 2010 U.S. Department of Education's Institute of Education Sciences report on effective K-8 fraction instruction and the 2008 study by the National Mathematics Advisory Panel. The authors of the IES study conclude: "A high percentage of U.S. Students lack conceptual understanding of fractions, even after studying fractions for several years" (Siegler et al., 2010, p. 6).

If future teachers are to engage their students in a coherent learning sequence about fractions, they need to have the required knowledge to help students develop a conceptual understanding. However, the limited knowledge of pre-service and in-service teachers' own understanding of fractions is a concern (Ball, 1990; Ma, 1999). Additionally, mathematics teacher educators consider this topic to be one of the most challenging in their work with pre- and in-service teachers (Tirosh, 2000; Borko et al., 1992). In this paper, we examine the effectiveness of a technology-leveraged approach compared to a non-technology approach in the development of pre-service teacher content and pedagogical knowledge with respect to fractions. The technology-leveraged approach used a carefully sequenced set of interactive documents (applets) focused on fractions and designed to adhere to the didactical approach advocated by the CCSSM, particularly an emphasis fraction as a number and using numbers lines as a central representational tool. By "interactive" we mean the document environment allows the learner to "deliberately take a mathematical action, observing the consequences, and reflecting on the mathematical implications of the consequences" (Conference Board of Mathematical Sciences [CBMS], 2012, p. 34) without requiring significant time to learn to use the technology. The design of the interactive documents has been guided by the Action-Consequence Principle (Dick & Burrill, 2009) in that the technologies should allow students to: 1) take deliberate, purposeful and mathematically meaningful actions; and 2) provide immediate, visual and mathematically meaningful consequences. The research question investigated whether or not the use of interactive documents might provide a significantly different impact on pre-service teacher

fraction content and pedagogical knowledge, both in terms of quantitative performance on measures of fraction understanding, and in the qualitative nature of the explanations and models used when teaching fraction concepts and operations.

Developing Strategies for Comparing Fractions

In this section we examine the one aspect of the results from a larger study regarding the use of a technology-leveraged approach involving the interactive documents described above to develop understandings of key fraction concepts with pre-service teachers (PSTs). In particular, we compared the results of using the interactive documents with a non-technology approach using more traditional manipulatives, such as Cuisenaire rods, fraction strips, and diagrams, e.g. area models, to develop the core fraction concepts of unit fraction, comparing fractions, and operations.

Participants and Setting

The participants in the study include 52 PSTs in an elementary methods course for pre-service teachers. The methods course was the third in a sequence for elementary teaching majors and focused on mathematical content and pedagogy appropriate for K–4 classrooms. PSTs enrolled in the course were in the second or third year of college. The PSTs were in three different classes, which are called T1, T2 and NT, of size 10, 17 and 25 respectively. The PSTs enrolled in the T1 and T2 sections were all female. The NT section consisted of 20 females and 5 males. PSTs in T1 and T2 met for 75 minutes twice a week and the NT class met for 50 minutes three times a week.

Methodology

T1 and T2 classes engaged in 9 lessons on fractions using the applets and supporting materials modified for pre-service teachers. They did not directly engage in any activities comparing fractions. The NT class engaged in 14 lessons using non-technology techniques, one explicitly addressed comparison strategies, such as benchmarking, common numerator, distance to/from and common denominator.

Data Collection & Analysis

Pre-service teachers (PSTs) were given a pre-assessment on their fraction content and pedagogical knowledge at the beginning of the course. The content questions consisted of selected NAEP questions and mathematics education faculty members developed the pedagogy questions. At the end of the course, eleven questions embedded in the final exam served as the post-assessment. The questions were aligned to the pre-assessment content and pedagogy topics.

PSTs completed the pre-assessment during the third week of the course in a regularly scheduled class meeting. The pre-assessment consisted of thirteen questions covering content and pedagogy, and PSTs were given 30 minutes to answer any questions they could. PSTs completed the post-assessment during a common final exam time, which occurred the day after the final class meeting for the NT class and five days after the final class meeting for the T1 and T2 classes.

Strategies for Comparing Fractions

In the larger study, the quantitative performance on measures of fraction understanding on aligned questions on the final exam showed a slight, but not significant positive difference for PSTs using the interactive document approach. In terms of the qualitative nature of the explanations and models, the PSTs in the technology-based classes were more likely to explain their thinking, used a larger variety of strategies, and more often used the number line as a model. As an example, we examine in detail the qualitative differences in PST explanations on one question regarding comparing fractions.

The PSTs in the technology courses were not explicitly taught strategies for comparing fractions. In several activities, PSTs in the T1 and T2 sections had to use a number line or area model to

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

describe why two fractions were either equivalent or not equivalent. In the non-technology class, PSTs engaged in one lesson where they learned strategies for comparing fractions other than common denominators. PSTs in the NT section engaged in specific problems to highlight the strategies: benchmark, distance to/from, greater number/larger size, and common numerators. These strategies were reviewed in a subsequent lesson and were part of estimation explanations prior to completing a fraction operation problem.

On both assessments PSTs were asked to determine which fraction was larger for two problems. The two problems were A) $\frac{15}{17}$, _____ , $\frac{15}{27}$ and B) $\frac{5}{12}$, _____, $\frac{7}{9}$. While very few PSTs answered these questions incorrectly, the explanations for how they determine which fraction varied. For problem A on the pre-assessment, 30% of all PSTs used a common denominator approach. On the post-assessment, no PSTs used the common denominator approach. In the non-technology class, 20 of the 25 PSTs used a common numerator approach. In the technology classes, PSTs answers varied among many different strategies, which are summarized in Table 1.

Table 1: Fraction Strategies Used by Pre-Service Teachers on Post-Assessment

Fraction Strategies	Technology courses (n = 27)		Non-technology course (n=25)	
	Problem A	Problem B	Problem A	Problem B
Common numerator	8	0	20	0
Distance to/from	1	0	2	3
Area	1	1	0	0
Number line	7	8	2	3
Benchmark on a number line	2	4	0	0
Benchmark	3	7	0	10
Number of copies	4	3	0	0
Common denominator	0	3	0	6
Greater number/larger size	0	1	1	3

The most prevalent strategies used to solve problem A in the T1 and T2 courses were common numerator and explaining the location of the two fractions on the number line. In their explanations comparing these fractions, four PSTs reasoned the number of copies of the unit fraction was the same but the size of the unit fraction was different.

For problem B, 68% of all PSTs used a common denominator approach on the pre-assessment. On the post-assessment, 3 of 27 (11%) students in the technology classes and 6 of 25 (24%) PSTs in the non-technology class used common denominators. The most used strategy in the non-technology class was the benchmark strategy that identified both fractions on either side of one-half. In the technology classes, the most frequent strategy was a number line followed by two different variations of benchmarking strategies. For the varied benchmarking strategies, seven of the PSTs stated the fractions were on either side of one-half, and four PSTs drew the fractions out on a number and indicated where one-half was located or noted that one fraction was closer to 1 while the other was closer to zero. The three PSTs who used the number of copies strategy explained their reasoning by describing that there were more copies of larger pieces in the ninths than the number of copies in smaller pieces of twelfths.

When explaining their comparison strategy, the PSTs in the non-technology class typically named a strategy, such as distance to/from, while most PSTs in the technology classes wrote out their thinking, such as two copies of seventeenths is closer to one than twelve copies twenty-sevenths.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

PSTs in the technology classes also used a larger variety of strategies for the same problems than the PSTs in the non-technology class. Based on these results, it appears using comparison ideas within activities rather than learning the strategies as tools separately benefits PST's ability to explain their approach to comparing fractions and allows them to apply the ideas flexibly.

Conclusion

If PSTs' pedagogical knowledge is influenced by their experiences in pedagogy courses, the tools used to build their understanding could have an impact on their future instructional choices as in-service teachers. Since the current standards and prior research call for an emphasis on the use of number line, the technology-based approach seems to have promise for helping future teachers understand the benefits of activities that use number lines to explain fraction concepts and operations. As the comparing fraction question from the study showed, PSTs in the technology courses developed their own strategies and explanations for comparing fractions, used a larger variety of strategies and more often used numbers lines when explaining their thinking. In contrast, PSTs that explicitly learned strategies used a prescribed strategy as their explanation for comparing fractions problems. Much of the literature cautions that teachers may use ineffective model and diagrams. However, with the mathematical practices standards call for strategic use of technology tools, the opportunity to learn through the CBMS (2012) recommendation of action, consequence, and reflection may be an approach that translates to deeper knowledge for teaching fractions and pedagogical change in the classroom.

PRESERVICE TEACHERS USE OF MATHEMATICAL EXPLANATIONS

Christa Jackson	Christopher Austin	Sarah Kasten
Iowa State Univ.	Univ. of Missouri-Columbia	Northern Kentucky Univ.
jacksonc@iastate.edu	caavz6@email.missouri.edu	kastens1@nku.edu

Research has shown that preservice teachers struggle to create and use meaningful mathematical explanations and often fall back on procedural, or step-by-step explanations. In this study, we examined how preservice teachers explained a mathematics problem by engaging them in a multi-task activity in which they recorded their own mathematical explanations using the Educreations app, listened to and watched recorded mathematical explanations, and discussed what they considered as important elements of mathematical explanations. The results indicate that the preservice teachers improved their use of language and mathematical terminology in their mathematical explanations.

Keywords: Middle School Education, Teacher Education - Preservice

The Standards for Mathematical Practice set forth by the Common Core State Standards (CCSSI, 2010) clearly call on students to explain their thinking by communicating their reasoning and using mathematically precise language and symbols. This creates a need for mathematics teacher educators to support preservice teachers in developing the practice of communicating precisely when explaining mathematics. Research has shown that preservice teachers (PSTs) struggle to create and use meaningful mathematical explanations and often fall back on procedural, or step-by-step explanations (Ball, 1990; Borko et al., 1992). These same teachers will play an important role in modeling mathematical thinking, processes and practices of mathematics for students. Therefore, it is important to support future teachers in investigating and evaluating mathematical explanations, both their own and those composed by others. The purpose of this study was to examine how PSTs explained a mathematics problem. More specifically, the research question underlying this study is: In what ways does participating in a classroom intervention focused on problematic mathematical explanations support middle level prospective mathematics teachers on providing productive mathematical explanations?

Theoretical Perspectives

While several studies in the field of mathematics have focused on developing students' vocabulary fluency and the importance of vocabulary in learning mathematics (see for example Downing, Earles-Vollrath, Lee, & Herner-Patnode, 2007), there is a dearth of research, if any, that focuses on prospective mathematics teachers use of mathematics vocabulary and mathematical language in their explanations. Furthermore, where verbal descriptions and examples fall short, visual representations can illuminate important mathematical messages. Lesh, Post, and Behr (1987) argue representations, which are essential elements of mathematical explanations, can be spoken, written, symbolic, and/or pictorial. Visual representations can help students make sense of mathematical problems and help members of the classroom mathematical community understand each other's thinking (National Council of Teachers of Mathematics [NCTM], 2014; Taylor & Dyer, 2014). We contend visual representations can be used as tools for thinking that "serve to 'unpack' the structure of the problem and lay the foundation for its solution" (Diezman & English, 2001, p. 77). In addition, we strive to help our PSTs use all forms of representations in their explanations in ways that are both precise and illustrative of the underlying mathematical meanings. We characterize representations that meet both of these goals as *productive representations*.

Methods

We designed a set of classroom activities with the dual goals of providing students with opportunities to reconceptualize mathematical explanations and modeling the types of conversations they might have in their own classrooms around mathematical explanations. We contend that students are in the best position to determine which features of an argument communicate the most meaning to them. Thus, we engaged our PSTs in activities that allowed them to construct a shared vision for mathematical explanations. A total of 26 students, 11 males and 15 females, (> 95% were Caucasian) from two different universities in the south-central region of the United States enrolled in middle level mathematics methods courses at their respective institutions participated in the study.

Data – Mathematical Explanation Task

We engaged our PSTs in a multi-task activity in which they recorded their own mathematical explanations using the Educreations app ([www.educreations.com)](www.educreations.com), listened to and watched recorded mathematical explanations, and discussed what they considered as important elements of mathematical explanations.

Task 1. Students were given a mathematical task (e.g., A circle has a radius of 5 inches. What radius will double the area of the circle?) with the following prompt:

> One of your friends is struggling with the given problem. There may be problems like this on their upcoming test. How would you explain to them so that they understand it and will do well on the test?

Students used an Educreations app, which allows users to simultaneously record voice and write on a virtual whiteboard, to record their explanations. The links to all of students' explanations were collected.

Task 2. Students watched the mathematical explanation of solving for x: $4x - -3 = 15$ that was pre-recorded on Educreations as a class. The recording deliberately focused on common problems PSTs make when giving mathematical explanations. As the class listened to the verbal mathematical explanation, they simultaneously viewed the written and symbolic representations. The following is the transcript of the mathematical explanation with the representation.

> I would begin by rewriting the problem. So, I would rewrite four x minus minus three equals fifteen. Then, I would do keep change change. Next. I will move the three over so that all of the numbers are on the same side.

$$4x + {}^+3 = 15$$
$$4x + 3 = 15 - 3$$

> From this point, I would divide both sides by four canceling out the four on the left side. Then, we have x equals twelve fourths. Finally, we will reduce down the twelve over four and get x equals three.

Students were asked to reflect on what they noticed about the explanation. Specifically, what parts of the explanation promoted understanding, what parts would hinder students' understanding, and how they would explain the problem.

Task 3. Students viewed and discussed important components of their initial mathematical explanations in their small groups. Through this iterative process and whole-group discussion of

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

important aspects of various explanations, a list of essential elements for a general mathematical explanation was developed (see Figure 1).

Students at University 1	Students at University 2
1. Clarity – clear language, correct terms, appropriate pace, clear writing 2. Completeness – show every step, don't make assumptions, full explanations, anticipate the "why" 3. Direction – states the goal	1. Correct terminology 2. Accurate and relevant visual representations 3. Provide detail to explain "why" 4. Establish a clear goal

Figure 1. Essential elements of mathematical explanations.

Task 4. After creating the final list (see Figure 1), the essential elements of mathematical explanations were used as criteria to assess students' explanations. Students were asked to record new explanations for their original mathematical task, and score their new explanations using the class-created rubric. The students then compared their first explanation with the new one in a written reflection.

Data Analysis

In order to analyze the data, we collectively watched a PST's initial mathematical explanation on Educreation and coded the representation (i.e., verbal, symbolic, and pictorial) used during the explanation. As we analyzed the explanation, we noticed the PSTs would use a representation in their explanation as an organizational tool. For example, the PST would underline different aspects of the problem or circle parts of the problem for added clarity in the explanation. So, we added a code for organization. We each coded the PSTs' initial and post explanations. During this analysis, we wrote theoretical memos (Grbich, 2007) related to the PSTs' understanding of the mathematical content, vocabulary/language use, and the visual representation used within each explanation. We then discussed the codes and theoretical memos. All discrepancies were discussed and a consensus on the codes and theoretical memos was obtained. After a consensus was reached, we identified themes that emerged across the data.

Results

We found the visual representations the PSTs used in their initial mathematical explanations were less productive (i.e., detracting from the problems conceptual meaning). For example, Dominique was asked to find the radius that would double the area of a circle with radius 5 cm. His explanation began with a sketch of a circle with radius 5.

To solve the problem, Dominique first found the area of the original circle using the area formula for a circle. He then doubled the area and solved for the radius. Although Dominique took the time to create a visual representation, he did not use or refer to it as he explained the problem. Sometimes students have become accustomed to hearing the phrase "draw a picture," they do it without thinking about how the representation will help them understand the mathematical concept (NCTM, 2014). It is possible that Dominique felt compelled to include a visual representation for the sake of having one. Dominique's less productive visual representation is not necessarily harmful, but using it to explain the problem poses a challenge because it did not help the student identify a solution path for the problem.

We also found the PSTs' improved their use of language and mathematical terminology in their mathematical explanations. For example, Kelley was asked to explain $\frac{8}{14} \div \frac{2}{7}$. In her initial

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

explanation she showed two approaches for dividing fractions: common denominator method and multiplying by the reciprocal. When she explained the division she used the phrase "those can cancel out." Kelley provided more background knowledge of defining the numerator and denominator in relation to the problem in her second explanation. Unlike the initial explanation where she divided only the numerator by two she clearly articulated that both the numerator and denominator had to be divided by two in her post explanation. Kelley did not say the denominators "cancel" out as in the first explanation, but she clearly demonstrated and explained how seven divided by seven is one. In addition, she explained the meaning of the reciprocal in the post explanation. Kelley was cognizant of her use of precise mathematical language in her post explanation.

Discussion

Our PSTs were able to consider their own ideas and assumptions, both conscious and unconscious, about what constitutes a productive mathematical explanation. We relied on Watson and Mason's (2005) characterization of non-examples as a way to "demonstrate boundaries or necessary conditions of a concept" (p. 65). In much the same way that vague or incorrect mathematical definitions can prevent a student from understanding a mathematical concept, a non-productive visual representation may lead a student to draw faulty conclusions or simply fail to help the student make any meaningful progress towards these goals. In this study, the PSTs were able to reflect on both their verbal and written explanations, which in many cases included the visual representations they used.

Activities like the ones discussed can serve as a foundation for creating mathematics classrooms focused on the kinds of meaningful mathematical discourse described in Principles to Action (NCTM, 2014). Specifically, classrooms in which "students are active members of the discourse community as they explain their reasoning and consider the mathematical explanations and strategies of their classmates" (NCTM, 2014, p. 35). Based on this, we contend PSTs should understand the purpose of mathematical explanations and why they are important.

UNDERSTANDING AND TRANSFORMING PRE-SERVICE TEACHERS' PROPORTIONAL REASONING

Dr. Kim H. Johnson
West Chester University of Pennsylvania
kjohnson2@wcupa.edu

Proportional reasoning is important to the field of mathematics education because it lies at the border between the transition from additive reasoning in the elementary school and multiplicative reasoning needed for more advanced mathematics. This research reports on findings from a qualitative study which examined pre-service teachers' (PST) proportional reasoning. In particular, this study highlights two misconceptions about proportional reasoning that were prevalent among PSTs and focuses on specific ways to transform these assumptions. Using Mezirow's transformative learning theory, tasks and targeted questioning were used to elicit disorienting dilemmas that allowed PSTs to engage in critical reflection about their proportional reasoning. Ultimately, this led the PSTs to transform their misconceptions and to understand proportional relationships in new ways as they made shifts in their understanding.

Keywords: Teacher Knowledge, Rational Numbers, Learning Theory, Teacher Education-Preservice

Proportional reasoning is important to the field of mathematics education because it lies at the border of transitioning from additive reasoning in the elementary school to multiplicative reasoning needed for more advanced mathematics. Lesh, Post, and Behr (1988) describe the importance of proportional reasoning, saying that it is "widely recognized as a capability which ushers in a significant conceptual shift from concrete operational levels of thought to formal operational levels of thought" (p. 101). This shift in understanding can lead to advanced mathematical thinking.

Pre-service teachers (PSTs) enter college with previous understandings of mathematics and mathematical concepts. Often PSTs have many deep rooted misconceptions about the multiplicative relationships involved in proportional reasoning and struggle with solving problems that involve these concepts. The question becomes: how can we help PSTs transform their understanding of proportional reasoning, so they might develop the necessary specialized content knowledge for teaching mathematics? This report focuses on how particular tasks and specific discourse moves, providing reflection on their conceptions, ultimately led to a transformation of their proportional reasoning.

Theoretical Tools: Transformative Learning Theory

According to transformative learning theory, our mission as mathematics educators is to provide opportunities for our PSTs to become aware of their prior assumptions in order to allow them to transform and deepen their knowledge. Simply presenting PSTs with information about proportional reasoning is not enough to help them alter their understanding. What is required is a transformation of their existing knowledge. Transformative learning theory attempts to first establish and clarify a learner's prior assumptions and then transform these assumptions (Mezirow, 1991). Mezirow (1991) focuses on three key components: 1) "we transform our frame of reference through critical reflection on assumptions" (p. 7), 2) that "rational discourse through communicative learning" is key (p. 78), and 3) that this reflection often takes place within the context of problem solving. Transformative learning theory suggests that in order for PSTs to make shifts in their understandings about proportional reasoning, they need to become aware of their misconceptions and then have these assumptions challenged in ways that encourage reflection about proportional reasoning. This study provides evidence that PSTs frequently made shifts in their strategies to solve proportional problems after their reasoning was perturbed through targeted discourse with the interviewer.

Methodology

Twenty-five PSTs were selected for this study at the beginning of their first mathematics methods courses at a large research university. A nine problem questionnaire was used in order to ascertain each PST's current level of understanding about proportional reasoning. (See Johnson, 2013 for more details on questionnaire). The questionnaires were coded and participants were divided into five distinct groups based on the analysis of their responses. Eleven individual interview schedules were created in order to challenge the PST misconceptions about proportional reasoning, the interviews were implemented, videotaped, transcribed and annotated. Individual interview data was coded and analyzed to create descriptions of the nature of the participants' understanding of proportional reasoning. A group of trained graduate students also coded the data and these codes were then discussed and revised to provide a higher degree of validity and reliability (Johnson, 2013). This report discusses how disorienting dilemmas and targeted questioning were used to transform these misconceptions.

Providing Opportunities for Pre-service Teachers to Overcome Challenges of Proportional Reasoning through Transformative Learning Theory

Mezirow (1991) suggests that problem solving situations often present disorienting dilemmas for learners. For this study tasks were designed to address distinct aspects of PSTs' misconceptions about proportional reasoning that surfaced from the questionnaire. Two of these previous assumptions include: (1) reasoning quantitatively (Thompson, 1994), (2) recognizing ratios as measurement (Schwartz, 1988). I will illustrate how these particular tasks and targeted questioning challenged PSTs' prior misconceptions which led them to transform their understandings of proportional reasoning.

Disorienting dilemma: quantitative reasoning versus computation. PSTs in this study struggled with proportional reasoning situations that involved the distinction between quantitative reasoning and computation. Quantitative reasoning is making sense of the relationship among measureable attributes of objects in a situation (Thompson, 1994) while computation is the result of an arithmetic operation to evaluate quantities. In general, reasoning about quantitative situations involves conceiving of circumstances in terms of quantities by constructing networks of quantitative relationships. For example, PTS often will set up proportions and not understand what the ratios represent in the context of the situation.

The Lemon/Lime task was used to challenge the PST's misconception of quantitative reasoning and computation (see figure 1). In this task participants were asked to compare two different lemon/lime mixtures (3 lemon:2 lime and 4 lemon:3 lime) **without doing ANY calculations** but by representing the mixtures with unifix cubes. The request to not use calculations posed a high degree of difficulty for most of the PST interviewed, because it forced them to reason quantitatively and conceptually not computationally.

> *Jen and Alice are making lemonade. Jen mixes 3 cups of lemon juice with 2 cups of lime juice. Alice mixes 4 cups of lemon juice with 3 cups of lime juice. Whose mixture is more lemonier? Justify your solution without using calculations. You may rearrange the cubes in such a way that they demonstrate which one's more lemony tasting or that they are the same. (Heinz [2000, p. 70])*

Figure 1. Lemon/Lime problem.

Emma is a typical example of how many of the PSTs reasoned quantitatively about the mixture (without the use of calculations). Initially, she used an additive relationship claiming that there was "one more cup of lemon in each mixture so the mixtures were the same." However, when she was allowed to utilize calculations she created a multiplicative relationship (i.e. $3/2 = 1.5$ and $4/3 = 1.333$)

---

by dividing the quantities in order to compare the decimal representations of the mixtures. This interpretation of the relationship caused her to reevaluate the mixtures and determine that the 3 lemon:2 lime mixture had more lemon taste than the 4 lemon:3 lime mixture.

Targeted questions to provide reflection. Emma was then asked to reflect on "why her answer with the calculation was different from the conclusion she made with the representation?" The fact that her initial conclusion and the calculations did not match provided a disorienting dilemma for Emma. She claimed that "because the concentration of lemon juice was stronger in the smaller volume (mixture with 5 total cups), then the larger volume (mixture with 7 total cups)" one of the mixtures would have more lemon taste. Emma exemplifies the misconceptions many of the PSTs had when only allowed to reason quantitatively about a situation. This illustrates how the lemon/lime problem posed a disorienting dilemma—multiple conflicting justifications that relate back to the original task— that provided opportunities for Emma to make sense of contradictory responses and allowed reflection on her previous assumptions and transform her reasoning. It is important that we allow PSTs to take the time to reflect and discuss these disorienting dilemmas in order to transform their understandings.

Disorienting Dilemma: Ratio as measurement (reasoning with intensive quantities). Many PSTs in this study had difficulty reasoning with ratios as measurements. Ratio as a measurement might be thought of in terms of intensive quantity. Schwartz (1988) describes quantities that can be counted or measured (e.g., distance or length) as extensive and quantities that form a composed unit between two quantities as a ratio (e.g., speed) as intensive. This distinction explains how ratios as measurements are intensive quantities. The main challenge with intensive quantities was for PSTs to overcome the "more A implies more B" comparison between the two extensive quantities involved in the relationship is a ratio not a difference. PSTs were challenged have when reasoning with intensive quantities or ratios as measures. The Housing problem (see Figure 2) was used to elicit ratio as a measurement in terms of squareness of non-square rectangular lots and intensive quantity that relates *width* and *length*. Additive relationships are often used with linear measurements in mathematics; but this problem in contrast is multiplicative, ratios of linear measurements are necessary to determine which lot is most square. This problem provides specific challenges to PSTs' initial inclination to use additive reasoning due to the presence of linear measurements given for the dimensions of the housing lots.

> *A new housing subdivision offers lots of 3 different sizes: 185 feet by 245 feet; 75 feet by 114 feet; 455 feet by 508 feet. If you were to view these lots from above, which would appear most square? Which would be least square? Explain your answer. (Adapted from Heinz [2000, p. 150])*

Figure 2. Housing problem.

For example, Eve initially claimed that "the lot that is the most square is the one with the smallest difference between length and width." She then calculated the differences between the lengths and widths of each housing lot and reported that "I would say that this one [*circles 75x114 drawing*] would be closer to a square because they are closer in distance."

Targeted questions to provide reflection. Eve was then asked to reflect on her strategy of utilizing the difference between length and width by applying it to a new scenario. In this case she was to determine whether two new lots, one that is 100' x 200' and one that is 300' x 400', is more square. The facts that her initial strategy when applied to this second task caused a disorienting dilemma for Eve since she would have to conclude that the two lots were the same squareness. After some thought, Eve claimed that,

> this [*traces 100 foot side*] length has to be half of this width, whereas this length [*traces 400 foot side*] is NOT half the width [*traces 300 foot side*] it's MORE than half, so it's going to make it appear more square.

This reasoning represents a multiplicative comparison between the length and the width as a ratio whereas Eve's previous reasoning utilized an additive comparison of differences. I then asked Eve to discuss on her response to the first prompt with the three housing lots (figure 2). After some reflection she applied this multiplicative concept of comparing the length and width as a ratio to a benchmark of half to the previously presented lots. Eve says,

> this one [*points to 75x114*] seems more like this one [*points to100x200*] because 75 is more like half of this [*points to 114*] versus 508 compared to 455 [*points to 508 then 455*] is not half so it's gonna look more square over here [*points to 300x400*], which would be like this again [*points to the 300x400*], this one [*points to 185x245*] is kind of in the middle 245 they are not really half.

In this example we see Eve transform her previous misconception of using additive reasoning to solve the problem and revise her thinking that the 455' x 508' lot would be the most square since it has the largest ratio, which involved proportional reasoning. This further illustrates how targeted questioning, discourse and reflection permitted Eve to transform her previous assumptions about ratio as measure.

Conclusion

If proportional reasoning represents an important border between elementary mathematics and higher level mathematics then PSTs need to obtain a deeper understanding of ratios and proportions in order to provide their students with richer opportunities in their future classrooms. This study illustrates how Transformative Learning Theory can be used as a guide to transform PSTs' previous assumptions regarding proportional reasoning. As such, PSTs need to first be made aware of their misconceptions about ratio and proportion and then have these assumptions challenged through questioning and discourse in their university experiences.

By helping these PSTs become aware of their misconceptions about proportional reasoning through these disorienting dilemmas (i.e., thought-provoking problem solving tasks) and providing opportunities for them to engage in rational discourse about these tasks, the PSTs were able to think about proportional problems in new ways and make shifts in their proportional reasoning. This knowledge can be used by mathematics teacher educators to develop courses for both elementary and secondary PSTs that can transform and extend their understandings of ratio and proportion and enhance their proportional reasoning so that future teachers can ultimately improve their students' learning at this important border between higher and lower mathematics.

PRESERVICE TEACHERS' FRACTIONAL KNOWLEDGE: UNDERSTANDING THE DISTINCT ROLES OF FRACTIONS

Eun Jung
University of Georgia
eunjung@uga.edu

Drawing from task-based interviews, classroom observation, and participants' homework, the present study examines ten middle grades preservice teachers' understanding of the role of fractions as operators, with an eye toward exploring how fractional reasoning is constructed. The results point to the construction of the reversible distributive partitioning scheme as a requisite for understanding fractions as operators. Further discussion will suggest that school curricula and teacher education programs may need to be adjusted to reflect more current understandings of both early childhood cognitive development and future teachers' fractional knowledge.

Keywords: Cognition, Teacher Education-Preservice, Teacher Knowledge

Writing about four decades ago, Kieran (1976) remarked that "most school curriculum materials simply treat rational numbers as objects of computation. Hence, children and adolescents miss many of the important interpretations of rational numbers" (p. 102). Since then, substantial research has further emphasized that there are multiple interpretations—or "subconstructs"—of fractions (e.g., Behr, Khoury, Harel, Post, & Lesh, 1997), and numerous books have been written reflecting this point of view in teaching rational numbers (e.g., Clarke, Fisher, Marks, & Ross, 2010). The current study concerns itself primarily with the role of fractions as "operators," referring to fractions that link two quantities of the same kind or of different kinds (see Vergnaud, 1988).

Students are normally taught fractions from third to fifth grade, before reaching the expected age range identified by Lovell (1972) for developing the proportionality schema (i.e., ages 12-14). Two subsequent studies on adolescents' comprehension of fractions as operators (Kieren, 1976) add some empirical weight to Lovell's (1972) earlier findings, showing a strong relationship between age level and scores that is consistent with this suggested age range. In that regard, Kieren (1976) suggest an important relationship between students' development of the proportionality schema and their comprehension of fractions as operators.

Post, Behr, and Lesh (1982) noted that understanding proportional reasoning is only possible once students have reached Piaget's "formal operational stage," which generally happens in the fifth grade. In that case, many students – perhaps a majority – are not ready to learn the operator role of fractions at the time when fractional foundations are being laid in school curricula. However, in the middle grades, if students cannot understand fractions both as quantities and operators, this can be a barrier to their comprehension of later topics in mathematics.

In light of these considerations, this study investigates preservice teachers' understanding of fractions as operators through task-based clinical interviews designed to reveal any areas of struggle, in order to further analyze the nature of these issues—particularly in regard to what they can reveal about how fractional reasoning is constructed—and to discuss possible solutions.

Theoretical Framework

Steffe (2003) conducted a study that can serve as an exemplar of the radical constructivist approach that forms an essential basis of my epistemological and analytical framework. Steffe (2003) adopted as part of his analytical framework the notion that both social interaction and an individual's action are crucial in learning. He regarded social interaction as a means of "generating situation" for the construction of students' cognitive schemes, and learning as a product of the "auto-regulation" of constructs within the individual's understanding. The emphasis on the individual's self-regulation

and auto-regulation is in line with von Glasersfeld basic principles of radical constructivism (1990, p. 22). What we perceive as reality is thus regarded as a construct within the mind of each individual.

Hackenberg and Lee (2015) showed that only MC3 (able to coordinate three levels of units) students could use fractions as multipliers in the context of writing equations. Unit coordination is related to the ability to construct certain schemes, such as distributive sharing and reversible distributive partitioning (Steffe & Olive, 2010). To illustrate, students who can share two identical bars among three people have constructed the "distributive sharing" scheme. To carry out this operation, they would partition each of the two bars into three parts and pull out one part from each bar, understanding that those two parts make up 2/6 of the original two bars. However, unless they had also constructed the "reversible distributive partitioning scheme," they would not understand that 1/3 of two bars is identical to the two individual thirds of each bar. Thus, students who have constructed the reversible distributive partitioning scheme understand that taking one-third of each of two objects (not necessarily identical) is equivalent to taking one-third of both objects together.

While I make use of a constructivist theoretical framework, my conceptual framework includes both the constructivist notions of fractional schemes and operations and Vergnaud's (1988) explanation of fractions as quantities and operators. For the purposes of the current study, it seems appropriate to make use of a qualitative case study design that will allow for a context-rich and focused investigation using task-based clinical interviews and participant observation.

Research Design

The present research is designed to address the following questions: How do middle grades preservice teachers reason with fractions as operators?

1. What can their reasoning with fractions as operators reveal about their construction of fractional knowledge?
2. What is the nature of their struggles in constructing fractions as operators, and what are some possible solutions to these issues in their understanding?

Building on the concept of the clinical interview developed by Piaget (1951), the "constructivist teaching experiment" (see Steffe & Thompson, 2000, p. 285; Steffe, 2003) is a method by which the researcher's ongoing analysis can interact with data in a fluid way. According to a description by Steffe & Ulrich (2014), "[a] teacher/researcher, through reviewing the records of one or more earlier teaching episodes, may formulate hypotheses to be tested in the next episode. . ." (p. 104). While this research tracks student' learning trajectories across successive teaching episodes, the pedagogical interventions themselves are supplied by the participants' course instructor, rather than directly by the interviewer. The method employed in the current research, therefore, may be regarded as a modified teaching experiment method; rather than one person acting as the "teacher- researcher" in "teaching episodes" (Steffe & Thompson, 2000), I conduct interviews as the "researcher," while the course instructor acts as the "teacher." The interviews themselves—without the expressly pedagogical element characteristic of the teaching episodes of a teaching experiment—closely resemble "task-based clinical interviews" (Goldin, 2000).

This study makes use of a multiple case study design, examining the fractional knowledge of preservice middle grades math teachers in a Math Education department at a major public university located in the Southeastern United States. The primary data source is a series of clinical interviews conducted over the course of two semesters using ten volunteer participants from a math content course. More specifically, I make use of data from task-based clinical interviews, as well as from classroom observation notes and homework submissions.

From among the initial volunteers in the math content course, I divide the participants into groups according to whether or not they have constructed the distributive sharing scheme. These

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

selections are based on analysis of an initial round of interviews, classroom observation notes and homework submissions.

Results and Significance

All clinical interviews were recorded on video, transcribed verbatim, coded and annotated for emerging themes, and analyzed. At the beginning of the interview all of participants were unable to make composite units for fractions acting as operators, which means that they had not constructed the reversible distributive partitioning scheme. In fraction multiplication and fraction equation problems, two of the participants either could not produce the drawn model of certain problems, or they could not provide a coherent interpretation of their own drawings. All participants showed signs of confusion as a result of incorrectly applying procedural knowledge. Moreover, the current progress of my data analysis indicates that the construction of the distributive sharing scheme is necessary but not sufficient to ensure a student's conceptual understanding of fractions as operators.

During each interview, variations of fraction multiplication problems were given, and students were asked to design word problems and represent the problem situations visually. For one of the problems, 4/5 times 1/3, several students drew a rectangle and partitioning it into 3 rows and 4 columns (or vice versa). They shaded 1 row and 4 columns and identified the 4 parts in the overlapping region as their answer. One of the word problems a student designed for this problem was: "You have a recipe that calls for one-third cups of flour, and you want to make four fifths of the recipe, so how much flower do you need to use?" When I asked her to show one cup and one recipe, she identified the largest box as both one cup and one recipe. This indicates that she used both fractions as extensive quantities (instead of 4/5 as the operator to show the relationship between the quantity 1/3 and the product 4/15). This shows her limitations in representing two different units in one drawing and in using one fraction as on operator.

Another identifiable limitation was in making composite units. Before classroom instruction, when asked to show 7/3 of two unit bars, two students responded that they must find one-third of one bar and then repeat it 7 times. Thus, by partitioning both unit bars into three parts and repeat-ing one of these parts seven times, in fact they showed 7/3 of just one bar. Their difficulty was in understanding the two bars together as one composite unit (treating it as the "whole" for 7/3).

After the completion of the unit on fractions in the participants' math course, students already knew that the correct answer to the problem (finding 7/3 of two unit bars) could be given as 14 parts, each being 1/3 the size of one unit bar. However, in explaining the answer with a drawing, three out of ten students showed limitations in partitioning and iterating with composite units. All students gave the answer as 14/3 of one bar, but three students still answered that they needed to understand 7/3 as equivalent to 14/6 to determine the result relative to two bars. If they could form one composite unit out of the two bars, they were able to find 1/3 of the two bars by partitioning each bar into thirds and taking 1/3 from each bar, after which they could also make a composite unit of these two parts and iterate it 7 times to make 7/3 of the two unit bars. In that case, the students do not need to consider 1/3 of one bar as 1/6 of two bars. This shows the limitations of these three students' reasoning with iterable composite units, corresponding to limitations in using fractions as operators.

Conclusion

In fraction multiplication contexts, the multiplicand represents an extensive or intensive quantity with one unit as a whole. However, the multiplier shows the relationship between the multiplicand and the product of multiplication. Thus the whole of the multiplier becomes the multiplicand, and students have to be able to use the multiplicand as one composite unit to perform the operation. This requires students' construction of the distributive sharing scheme.

These preliminary findings, although limited in scope, may direct further research that can cast additional light on the construction of fractional reasoning, both in preservice teachers and in primary

school students. Considering the foundational importance of being able to understand fractions as operators, in the very least we need to ensure that preservice teachers have a strong grasp of this fundamental fractional concept in order to teach middle grades students effectively. Moreover, if further research lends additional support to the notion that primary school is generally too early for students to understand the operator role of fractions, school curricula may need to be adjusted to reflect this.

LEARNING FOR THE TEST: GROWING UP IN THE ERA OF NCLB

Jeffrey David Pair
Middle Tennessee State University
Jeffrey.Pair@mtsu.edu

I report on an interview study conducted with a prospective teacher who began school in 2001, the year the No Child Left Behind Act was passed. Using radical constructivism, I seek to understand how the prospective teacher's experience as a learner in mathematics classrooms characterized by standardized test preparation shaped her understanding of mathematics and the possibilities for teaching mathematics in the U.S. I found the prospective teacher does not see a need to understand why in the mathematics classroom. Also she believes accountability pressures tied to standardized tests limit an elementary teacher's ability to teach comfortably in a way that is best for students.

Keywords: Teacher Beliefs, Policy Matters, Teacher Education-Preservice

In the United States, the era of No Child Left Behind (NCLB, 2001) has come to an end with the passage of the Every Student Succeeds Act (ESSA, 2015). NCLB was criticized because of the unintended effects of high-stakes testing (Lambdin & Walcott, 2007). Accountability pressures contributed to emerging school cultures characterized by mathematics instruction which emphasized preparation for end of the year standardized tests (Darling-Hammond, 2010). It is unclear if this trend will continue. Although the era of NCLB has come to an end, the impact of its implementation likely has consequences for the future of mathematics education. Many prospective teachers now enrolled in teacher education programs have spent their entire school lives as students under NCLB. How might a prospective teacher who was a learner during the NCLB era understand mathematics and her role as a teacher of mathematics?

As a doctoral student in mathematics education, I teach an undergraduate mathematics course designed for prospective elementary teachers. A nineteen year old student in the course, Jessie, began kindergarten in 2001, the year that NCLB was passed. Jessie expressed strong opinions about what she perceived to be the United States educational system and the possibility for students to learn mathematics within it. I decided to request interviews with Jessie so that I could better understand her perspective--a perspective that has been molded by her experience as a student in the era of NCLB.

Theoretical Framework
I enjoy radical constructivism and believe it provides a useful theory of learning to view the influence of NCLB on Jessie's perspective. Von Glasersfeld (1995) articulated two basic principles of this theory. The first is that "knowledge is not passively received but built up by the cognizing subject" (p. 18); and the second is that "the function of cognition is adaptive and serves the organization of the experiential world, not the discovery of ontological reality" (p. 18). Jessie's perspective has been directly influenced by her powerful experiences as a mathematics student in the NCLB era. Her constructed perspective is viable given her experience as a learner in mathematics classrooms dominated by test preparation. My goal in this study is to provide the reader with insight into Jessie's constructed reality, and to understand the ways in which her experience as a student during the NCLB era may have influenced her perspective.

Methodology
The data for this study consists of two hour-long semi-structured interviews, the second conducted one week after the first, both audio-taped and transcribed. The purpose of the first interview was to get a broad sense of Jessie's views regarding education, mathematics, and her role as a future teacher of mathematics. The purpose of the second interview was to probe Jessie to

provide greater explanation and detail illuminating and clarifying the ideas that were expressed in the first. I also desired to understand *why* she might have the perspective that she did. I sought to employ the qualitative techniques of open-ended questioning, empathic neutrality, and rich description as discussed by Patton (2015). I wrote open-ended questions and listened attentively to Jessie, probing her to say more about her ideas. I strove to be empathetic and neutral, making it known that I was interested in understanding her ideas, and that my purpose was not to judge. I engaged in data analysis with the goal of writing a rich description of Jessie's perspective and to understand how her perspective may have been influenced by her educational experiences. To this end, I developed a concept map of the ideas she expressed in the interviews. The creation of this map involved listening to interviews and reviewing transcripts, noting important quotes in the transcripts, and assigning codes to each quote. These codes were designed to summarize or capture the meaning expressed in the quote (Saldaña, 2012). I found that the map did not provide a simple translation to written results. I re-read the transcripts noting the important quotes and created a more general open code for each one so I could better organize the results section according to themes.

Results

Jessie's experience as a student of mathematics, especially in middle and high school, consisted of memorizing formulas and procedures in order to pass tests.

> I couldn't tell you even one thing I learned in high school math, at all… Instead of the teachers actually teaching the stuff, most of them honestly would just be like, "Okay here's the study guide with the exact questions and answers that's gonna be on the test. Go home and memorize it." How am I learning by you giving me the test and telling me to memorize answers?

Jessie always received good grades in math, but she "hated math" because "it just felt pointless." She noted she did not need to understand the why behind mathematics, and was angry when other students asked why during mathematics class.

> I remember in high school we would have those students who would be like "Why is this?" and I would get so mad. I would be like, "Shut up and just learn how to do it"... Because we just had to pass the test you know? It just seemed a waste of time to figure out why because, why wasn't going to be on the test. You just memorized the formula and how to do it.

Jessie did not see the value in asking why questions about mathematics. She believes the pressure for students to perform well on standardized tests precludes the possibility of teaching students to engage in proof or understanding why in the elementary mathematics classroom.

> I wasn't really saying, "No they shouldn't do proofs," and "no I don't think that they can do proofs."… My point was that as with the school system today in today's society we can't just teach however we want to teach… I have to go by what the standards, what the government says that I should teach. And that doesn't leave a lot of wiggle room… Just because a kid can explain why fractions are the way that they are doesn't mean they can solve a fraction problem… There's a big difference between what I think and what's realistic in our school system. Because it's not that kids shouldn't understand why, it's just the fact that the kids don't have to understand why, and kids knowing why isn't going to help them pass the test; and if they don't pass the stupid test then I don't keep my job.

Jessie was never required to understand why in the mathematics classroom, and so her perception is that the state standards must not require children to understand why. To meet the standards, she believes should merely ensure her students can perform procedures similar to those that would be required on a standardized examination. To devote time to understanding why would detract from

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

classroom time needed to prepare for the standardized test (and possibly cause her to lose her job as a teacher).

The education system (as Jessie perceives it) is not the way she wants it to be or how she believes it should be. She wants it "how it used to be" when teachers "were assessed based on how good of a teacher they were and not how well their kids tested." One of the influences in Jessie's life is her grandmother, a retired kindergarten teacher. Of her grandmother she said:

> That's why she retired. Cause she didn't like it anymore. She said it wasn't fun anymore. And she said it was too much stress on her and too much stress on the kids, and the kids weren't really having fun anymore. Cause she didn't have time to do any fun stuff, cause you're having to make sure they can pass the test… You basically put on paper, you try to make yourself look as good on paper as possible. But I don't know. How you look on paper doesn't make you a good teacher.

I asked Jessie how she felt about the *Common Core State Standards for Mathematics* (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010), and without hesitation she said, "I hate it." Jessie equates the standards with testing and accountability. She believes there are too many standards, and does not believe the standards are relevant to real life. Much of what she believes about the standards are based on her own experience as a student, preparing to meet previous state standards on end of the year examination. As none of what she learned in school was relevant, she has no reason to believe the new standards would be relevant.

> It tells them what they have to teach, and basically like their kids have to know that stuff. And it's a lot of stuff, and not very much time. So they have to like cram all this stuff down their kids' throats so the kid can pass the test… I feel like most of the stuff is not even important… Like I said, like in math like, all of these formulas… I guess it's not as bad at the elementary school level. It's awful in like high school and stuff. But, one, the kids are never going to remember all this information, because I couldn't tell you one thing I learned in high school honestly... I just feel like there's too much pressure on the teachers and that leads to too much pressure on the kids.

For Jessie, meeting the standards means preparing for the standardized test. The test puts pressure on the teachers and this prohibits the teacher from teaching in a comfortable way. Jessie said it would be best if "you could teach however you feel as a teacher that you are most comfortable and how you think that your students would learn best." But, because of time constraints and assessment pressures tied to tests, "comfortable" teaching must be replaced with preparing students to pass the test to meet the standards.

Concluding Discussion

Consistent with reports from states in which narrow-high stakes tests have been used for teacher accountability (Darling-Hammond, 2010), Jessie described her mathematical experience as plagued by mathematics instruction in which the goal was to memorize formulas and procedures in preparation for a test. Jessie's mathematics teachers taught *to* the test, and Jessie has consistently learned *for* the test, and this has affected her beliefs about mathematics, standards, and what is required for an elementary teacher to be successful and maintain a job.

Jessie believes that the "educational system" prohibits good teaching. Jessie, who wants to teach kindergarten, desires the freedom to teach children in a way that she is most comfortable with and that she believes is best for the students. But she notes time and accountability pressures are barriers to good teaching, and good teaching conflicts with preparing students for standardized tests. The National Council of Teachers of Mathematics (NCTM) advocates for mathematics teaching that incorporates student discussion, reasoning, and justification (NCTM, 2014). Jessie's case points to a

possible tension of advocating for instructional reforms that, while being advertised as preparing students to meet career and college readiness standards, appear (to an individual like Jessie) contrary to such a purpose.

Jessie's experience as a learner of mathematics in the NCLB era had a profound effect on her expectations for what mathematics is and how it can be taught. Will student experiences of mathematics fundamentally change with the passage of the Every Student Succeeds Act (ESSA, 2015)? Reflecting on the educational climate, Jessie reflected, "It makes me not even want to teach honestly, but, whatever. Maybe I'll change the education system." Despite a desire that the system change, Jessie does not know how such a change could take place. As educators and scholars, we should consider what can be done so that prospective teachers have a chance to develop their imagination so that they see themselves as agents, capable of improving education.

NOTICING AND WONDERING: SUPPORTING MENTORING CONVERSATIONS ABOUT MATH TEACHING

Sarah A. Roller
University of Alabama in Huntsville
sarah.roller@uah.edu

One way that mentors support prospective teachers' (PSTs') development within field placements is through conversations about classroom teaching. However, conversations based on merely descriptive teaching observations tend to be more evaluative in nature and lack educative opportunities for PSTs to reflect or inquire about the practice of teaching (Borko, Jacobs, Eiteljorg, & Pittman, 2008; Clarke, Triggs, & Nielsen, 2014; van Es, 2011). A short orientation session was implemented with three mentor-intern pairs that offered Smith's (2009) noticing and wondering language as a way to structure mentoring conversations that maintain descriptive and interpretive analytic stances. Analysis of pre- and post-conversations offer examples to illustrate how mentor-intern pairs adopt noticing and wondering language in mentoring conversations, and the ways in which this language structure supports interpretive mentoring conversations.

Keyword: Teacher Education-Preservice, Teacher Education-Inservice/Professional Development, Research Methods

Purpose of the Study

Prospective teachers (PSTs) have consistently identified clinical field experiences, such as student teaching, to be the most important experience in their teacher preparation, however the support mentors provide varies significantly based on the variety of ways that mentors engage with PSTs (Wilson, Floden, & Ferrini-Mundy, 2002). These variances have led to a greater problem of inconsistency in the quality of mentoring across schools and classrooms that PSTs experience and are attempting to learn from during field placements. Clarke, Triggs, and Nielsen's (2014) mentoring literature review reveals that PSTs varied experiences with their mentors may be because many mentors "lack specific preparation to enable high quality and developmentally appropriate support for student teachers" (p. 191). In an effort to address this need and assist mentors and PSTs in communicating across borders of teaching expertise, I created a short orientation session to offer Smith's (2009) *noticing and wondering language* for structuring mentoring conversations to mentor-intern pairs. The purpose of this initial study was to explore the ways in which mentor-intern pairs adopt noticing and wondering language and the ways in which noticing and wondering language supports mentors and PSTs to adopt an interpretive stance when discussing mathematical teaching practices.

Theoretical Framework

One way that mentors support PSTs' development within field placements is through conversations about classroom mathematics teaching, but mentoring conversations are not in and on themselves educative. Conversations that are descriptive and interpretive frame talk around investigating teaching, which is the way "[t]eachers learn to teach by treating teaching as an object of study - by trying to improve teaching by studying carefully what works and what doesn't" (Stigler & Hiebert, 2009, p. 36). These interpretive conversations are more valuable in field placements because they produce more educative opportunities for PSTs to reflect or inquire about the practice of teaching compared to only descriptive conversations or evaluative conversations which close educative opportunities (Borko, Jacobs, Eiteljorg, & Pittman, 2008; Clarke et al., 2014; van Es, 2011).

Feiman-Nemser (1998) supports that mentoring skills, particularly those focused on talking about teaching in productive ways, can be developed through professional development sessions and/or involvement in collaborative learning opportunities. I intentionally selected Smith's (2009) *noticing and wondering language* to share with mentor-intern pairs because it seemed like a structure that mentors could easily adopt and apply to mentoring conversations without a large time investment to learn this new mentoring practice. This language structure helps ground conversations in descriptive observations and then uses an interpretive stance to inquire into important teaching moments. Noticing and wondering language also supports the effort to improve a PST's mathematical teaching practice by studying teaching (Hiebert & Morris, 2012; Stigler & Hiebert, 2009).

Methods

The study took place with three mentor-intern pair volunteers from a secondary teacher preparation program at a large public university in the Midwest. Interns were PSTs in their final year of a five-year teacher preparation program. Mentors were veteran teachers that had mentored between five and fourteen PSTs. Mentor-intern pairs' content areas were mathematics and social studies, but for the purposes of this study I analyzed the mentoring conversations about a mathematics teaching episode.

Mentor-intern pairs completed a pre screener activity, participated in a short orientation session, submitted two sample conversations from the classroom, and completed a post screener activity. The pre- and post-screener activities were identical and asked each mentor-intern pair to watch two video episodes (Beginning Teacher Support & Assessment, 2012) of teaching together, and after each episode to have a conversation about the teaching they had just watched. These conversations were referred to as the mentor-intern pairs' pre- and post-conversations, because they occurred before and after the short-orientation session where mentor-intern pairs were introduced to noticing and wondering language. Mentor-intern pairs audio recorded and electronically submitted all their conversations for the study.

Out of the three mentor-intern pairs, I investigated the pre- and post-conversations about a sixth grade mathematics video from the two mentor-intern pairs (Pair 1 and Pair 2) who demonstrated no evidence of noticing and wondering language in their pre-conversations prior to the short orientation session. To illuminate how noticing and wondering language influenced the stance of mentoring conversations, each speaker turn (Johnstone, 2008) in the pre- and post-conversations was identified and coded as having a descriptive, evaluative, or interpretive analytic stance (van Es, 2011). The percentage of turns in each stance category was calculated for each conversation, and used to compare the stance of pre- and post-conversations. To explore the adoption of noticing and wondering language, the frequency of the words *notice* and *wonder* in the pre- and post-conversation transcripts were totaled. The stance of speaker turns that included *notice* and/or *wonder* were further analyzed for patterns about how mentor-intern pairs were adopting the language structure. Overall, 145 speaker turns from the four mentoring conversations served as the data analyzed for this study.

Results

In response to exploring the ways in which mentor-intern pairs adopted noticing and wondering language, the results indicate that mentor-intern pairs more frequently used the words *notice* and *wonder* within post-conversations than pre-conversations. Both pairs went from having pre-conversations that lacked any intentional form of noticing and wondering language (contained *notice* or *wonder* once), to post-conversations that contained *notice* six times and *wonder* three times for Pair 1, and *notice* four times for Pair 2. These slight increases in frequency suggest that mentor-intern pairs were attempting to use the language, and that the short orientation session provided mentors and interns with the knowledge and scaffolding to begin adopting the language structure. Mentor-intern pairs also implemented *notice* more frequently than *wonder*, possibly because it simply

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

describes an observation versus extending the thinking about an observation. This may also demonstrate part of a learning curve that mentor-intern pairs experienced as they tried to merge this new structure within their current mentoring conversations.

In response to investigating the ways in which noticing and wondering language supports mentors and PSTs to adopt an interpretive stance when discussing mathematical teaching practices, the results indicated that the mentor-intern pairs' pre-conversations contained a majority of evaluative turns (Pair 1, 67%; Pair 2, 68%), which lack educative opportunities for PSTs to reflect or inquire about the practice of teaching (Borko et al., 2008; Clarke et al., 2014; van Es, 2011). While the post-conversations also contained a high percentage of evaluative turns (Pair 1, 53%; Pair 2, 77%), Pair 2's post-conversations demonstrated an increase in the amount of interpretive turns that do encourage reflection and inquiry about teaching (8% to 33%) and Pair 1's percentage of interpretive turns remained consistent (13% to 11%). A more nuanced investigation of the 14 turns that incorporated some form of *notice* and/or *wonder* revealed that *notice* was in all three stance categories, while *wonder* was only coded as interpretive. Even with the limited number of examples, these turns illuminate the importance of *wondering* in productive mentoring conversations.

The following set of interpretive turns provides an example of the noticing and wondering language structure being utilized in a mathematics mentoring conversation. It showcases how the mentor opens with *noticing* something he finds interesting about the teaching episode, and the intern acknowledges this as a shared observation. Then, the mentor continues his inquiry about the time inconsistency by using follow-up *wondering* turns about what prompted the teacher's decision.

> *Mentor:* Now, it's interesting, the previous video we commented on, I noticed that his, 30 seconds we're gonna do this, but then he pushed it. She said in a couple minutes we'll be playing a bingo game and then at some point they say 12 minutes into the lesson, they still hadn't gotten there. Somehow that feels, his sense of time was 30 seconds well we're going to take a short period of time.
>
> *Intern:* Yeah
>
> *Mentor:* Um hers, I think, I wonder if she actually believed was gonna be a couple minutes, but then her preparation and the technology issues and whatever delayed that, and so I wonder if it was intended to take that long, to get to that point.
>
> *Intern:* Or if she found formatively they're not as ready as I thought they were.
>
> *Mentor:* Right. Was it a planning thing? Was she adjusting things on the fly?

These productive conversational moments of unpacking and making sense of observations tended to follow interpretive turns more than evaluative or descriptive turns. Overall, an interpretive stance is supported by the combination of *noticing* and *wondering* in mentoring conversations, and thus encourages improving teaching practices through inquiry, reflection, and analysis of teaching (Hiebert & Morris, 2012; Stigler & Hiebert, 2009).

Discussion

This study provides beginning support for Smith's (2009) proposed noticing and wondering language. In particular, this study demonstrates how noticing and wondering language can be used to communicate across borders of teaching expertise to support interpretive discussions about teaching episodes that have the potential to be educative for interns. It also provides research tools for studying this language structure and how it has the potential to make a difference in mentoring talk. The research tools designed for this study included: the mentoring conversation prompt of the pre/post screener activity, audio recordings of mentoring conversations, and the analytic stance framework (van Es, 2011) for coding turns. Together these tools allow researchers to examine a small enough grain size within mentoring conversations to identify initial evidence to warrant further study of how this particular language structure can make an impact on the quality of mentor talk.

Specifically, it is the few captured moments when mentor-intern pairs utilized both *notice* and *wonder* that demonstrate the potential for using this language to structure conversations that investigate and make sense of shared teaching moments that have the potential to improve PSTs' mathematics teaching practices (Hiebert & Morris, 2012; Stigler & Hiebert, 2009), and thus warrant future research.

REASONING ABOUT TELLING IN REHEARSALS OF DISCUSSIONS: CONSIDERING WHAT, WHEN, AND HOW TO "TELL"?

Sarah Kate Selling

University of Minnesota
eebaldinger@umn.edu

Telling is often set in opposition to student-centered approaches to teaching. However, current research supports a more nuanced approach that considers what, when, and how one might tell. Using a practice-based approach, we investigate the ways in which rehearsals of leading discussions offer opportunities for secondary pre-service teachers to learn about telling. Through analyzing video of 13 rehearsals with seven pre-service secondary teachers, we found that learning opportunities fell into three categories: unlearning a reliance on telling, reasoning about the role of telling, and learning strategies for telling. This study demonstrates the potential of rehearsals to support novices to connect ideas about telling to the work of leading discussions.

Keywords: Classroom Discourse, Instructional Activities and Practices, Teacher Education-Preservice

Research on mathematics instruction in the US has repeatedly documented that many US mathematics teachers use telling and lecture as predominant ways to teach (e.g., Stigler & Hiebert, 2009). Simultaneously, over the past decades, there have been many efforts to shift instruction away from the teacher as "teller" toward instruction that supports collective sense-making, a form of instruction shown to better support student learning (e.g., Boaler & Staples, 2008). As teachers work to move their practice away from a reliance on telling, they may come to think that they are not supposed to tell anything (Chazan & Ball, 1999). Scholars highlight the need to move beyond dichotomies that set telling in opposition to student-centered approaches; instead, they call for an account of telling that considers *what* might be told, *when*, and *how*. There is general agreement that socially constructed knowledge, such as particular terminology or notation, needs to be told as students are unlikely to re-invent these in ways that align with canonical notation (e.g., Hiebert et al., 1997). Lobato, Clarke, and Ellis (2005) argue for a reformulation of telling as "the set of teaching actions that serve the function of stimulating students' mathematical thoughts via the introduction of new ideas into a classroom conversation" (p. 101). They focus on the function of teachers' actions, the actions' conceptual (over procedural) content, and the relationship to other actions over time. This highlights that teachers also must decide *when* to make new contributions. Timing matters in what students are able to learn from telling, with evidence supporting telling after experience with the content (e.g., Schwartz & Bransford, 1998). Telling might also involve naming or otherwise making explicit something mathematical that students had constructed (Selling, 2016) or co-constructing an explanation with students (Leinhardt & Steele, 2005). This suggests that, in addition to unlearning a reliance on telling (Philipp, 1995), teachers need opportunities to learn about this nuanced reformulation of telling.

One place to examine dilemmas of telling is in the work of leading discussions (Chapin, O'Connor, & Anderson, 2013). A discussion is sometimes viewed as antithetical to telling, as one of its goals is to support students in collective sense-making; however, teachers may make contributions or tell in crucial moments in ways that actually deepen the discussion (Lobato et al., 2005) or help steer toward the point (Sleep, 2012). Alternatively, when challenged to respond to student thinking, teachers may fall back on telling if they are unsure how to respond or handle an error. We focus on ways to support novice teachers in learning about telling in the context of leading discussions.

Theoretical Framing

We build on a practice-based approach to teacher education. One strategy for supporting novice teacher learning of core instructional practices is through the cycle of enactment and investigation (Lampert et al., 2013). Novices work on a practice, such as leading discussion, through learning about the practice, rehearsing it in the methods class, enacting it with students, and analyzing and reflecting on their enactments. The cycle is built around instructional activities (IAs) that bound complex practice in order to support novice learning. Rehearsals represent a key set of learning opportunities as teacher educators can provide in the moment feedback around the core practice. Efforts to work on telling in teacher education, such as working with pre-service teachers around instructional explanations (Charalambous, Hill, & Ball, 2011), have highlighted that telling productively is challenging for new teachers. As novices learn to lead different types of discussions (Kazemi & Hintz, 2014), they must reason about what, when, and how to tell within these discussions in a way that stimulates student understanding. We investigate the ways in which rehearsals of leading whole class discussions offer opportunities for novices to learn about telling and its potential roles in classroom discourse.

Methods

We investigate this question in the context of a mathematics methods course for secondary teachers that we designed and co-taught. The two-semester course was organized around a set of core practices, including leading discussions. The novice teachers were concurrently in field placements in urban secondary classrooms (See Baldinger, Selling, & Virmani, 2016 for more details about context). The novices participated in two cycles of enactment and investigation around leading discussions. The first cycle (weeks 4-7, fall) focused on discussions in which students share, compare, and connect strategies for solving problems (Lampert et al., 2013). The second cycle (weeks 6-10, spring), focused on discussions in which students work to clarify and define mathematical ideas (Kazemi & Hintz, 2014). The data sources include video of all rehearsals, debriefs at the end of each rehearsal, and a final debrief after all rehearsals.

Table 1: Data Sources for the Two Cycles of Enactment and Investigation

Instructional Activity	Rehearsal Data	Debrief Data
Strategy Sharing: Number Talks - Fall Semester	6 novice teacher discussion rehearsals	6 rehearsal debriefs 1 final debrief
Defining and Clarifying Mathematical Ideas:Sorting Task (Baldinger et al., 2016) - Spring	7 novice teacher discussion rehearsals	7 rehearsal debriefs 1 final debrief

The video data were analyzed in two phrases. First, we developed detailed content logs (Derry et al., 2010) of all rehearsals and debriefs. We then identified all interactions that explicitly or implicitly addressed "telling". *Explicit opportunities* were interactions among teacher educators (TEs) and novices in which telling was brought to the collective attention of the group (e.g., a TE coached about an alternative to telling, a novice reflected on what he/she learned about telling). *Implicit opportunities* were instances when a rehearsing novice made a contribution to a discussion but it was not highlighted in the moment. This paper focuses on the explicit opportunities. Next, we coded the explicit opportunities inductively to characterize the different types of opportunities to learn about telling (e.g., unlearning a reliance on telling). Lastly, all opportunities were recoded with the final codes.

Findings

Both cycles of enactment and investigation offered explicit opportunities to learn about telling in mathematics discussions. These arose in both rehearsals and debriefs and were distributed across different rehearsals. The opportunities fell into three distinct but related categories: opportunities to unlearn a reliance on telling, opportunities to reason about telling, and opportunities to learn strategies for telling. We use vignettes to illustrate each category.

Unlearning a Reliance on Telling

Novices had opportunities to recognize and problematize a reliance on telling in discussions. One example of this occurred in Victor's (all names are pseudonyms) rehearsal of a strategy sharing discussion around a multi-digit addition problem. During Victor's rehearsal, one TE, playing a student, asked why Raul had subtracted in his strategy. Victor immediately responded with a lengthy explanation. After he finished, the TE interrupted as a coach saying, "You just did a beautiful job of explaining to us but is there any way you could have gotten one of us to do the work instead?" The TE asked him to go back and replay the episode, at which point Victor asked, "would anyone like to help [TE] out and explain why Raul decided to take 2 away from 17?" In his debrief, Victor reflected that he had learned about "when to throw it back to the class and when to lead the discussion myself". Another novice, Julia, commented on this moment in the general debrief, saying she had "learned the value of having students restate other students' answers instead of explaining it myself". This highlights how rehearsal afforded a moment for a novice to experience his tendency to tell in discussions, to problematize it as potentially taking over the work from students, and to discuss potential alternatives.

Reasoning about the Role of Telling

Both cycles offered opportunities to reason about the role of telling in discussions and when to tell. One example occurred during a sorting task rehearsal about quadrilaterals. The first two cards (a rectangle and a parallelogram) surfaced disagreement among the "students" around whether a shape had to have right angles in order to be a quadrilateral. One TE, playing a coach, suggested moving the conversation to sharing non-examples of quadrilaterals. At this point, Carl, one of the "students", paused the rehearsal to ask about how and when in the discussion one might address or resolve this disagreement. This opened up an opportunity for discussion around telling or otherwise resolving this definitional issue. One TE contributed that it would be productive to address this ambiguity, if it persisted, after the class had more opportunities to grapple with and argue about what makes a quadrilateral. The other TE suggested a strategy for how to record the disagreement to show that the issue had still not been resolved, while not directly addressing the disagreement in the moment. This illustrates how the common problem of practice of responding to errors and disagreement that surfaced in rehearsal offered opportunities to consider when one might tell socially constructed knowledge (e.g., definitions).

Strategies for Telling

There were also opportunities to discuss strategies for making mathematical contributions to a discussion. For example, in Raul's rehearsal of a strategy sharing discussion, only a few different strategies were shared. During his debrief, Raul reflected on being surprised that so few had emerged. In response, one TE suggested contributing a new strategy by framing it as a strategy used by a student from another class and asking the students to comment on or interpret the strategy. The other TE described how this technique allowed the teacher to introduce a new idea while avoiding positioning the teacher as the mathematical authority in this moment. This illustrates how a common problem of practice that arose in the rehearsal helped construct a moment to surface and reason about strategies for telling.

Discussion

These vignettes illustrate how rehearsals of whole class discussion in secondary methods classes can provide numerous opportunities to explicitly address the complex issue of telling. Novices not only had opportunities to unlearn a reliance on telling, they also had opportunities to reason about the role of telling and develop strategies for productive telling. This set of learning opportunities is not intended to be a comprehensive list of what might be learned through rehearsal; however, this study demonstrates the potential of rehearsals to offer opportunities to address telling in a nuanced way by situating work on telling inside a discussion. The novices were able to connect ideas about telling to the problems of practice they experienced while facilitating classroom discourse. This study extends prior research on rehearsals (Lampert et al., 2013) and on preparing teachers to tell (e.g., Charalambous et al., 2011) to highlight the value of addressing telling within work on other instructional practices. Future research might examine how particular discussion structures might afford different learning opportunities around telling in rehearsals. Additionally, how might explicitly addressing telling in rehearsals influence the ways in which novice teachers tell (or do not) when leading discussions in K-12 classrooms? Finally, in this study we saw that TE moves were often integral to surfacing issues of telling. Future research could TE moves that create and capitalize on problems of practice around telling.

EXAMINING PRESERVICE TEACHER TASK MODIFICATIONS FOR ENGLISH LANGUAGE LEARNERS

Matthew Sakow	Erin Smith	Zandra de Araujo
University of Missouri	University of Missouri	University of Missouri
matt.sakow@gmail.com	emsxh3@mail.missouri.edu	dearaujoz@missouri.edu

This study examined how elementary preservice teachers modified cognitively demanding (Stein et al., 2009) mathematics tasks for use with an English language learner during a four-week field experience. In the examination of the preservice teachers' lesson plans, written reflections, and video recorded interviews, we identified three categories of modifications made to accommodate their students: context, presentation, and language. The findings suggest that while the preservice teachers increasingly attended to their students' individual needs, they had limited strategies on which to draw. Implications address the need for teacher educators to address the use of tasks with English language learners.

Keywords: Teacher Education-Preservice, Equity and Diversity, Elementary School Education

Introduction and Framework

English language learners (ELLs) may possess unique experiences in mathematics; schools ask them to adapt culturally to American mathematical practices while also developing academic and everyday language in English. Despite the increase of students whose first language is not English, U.S. teacher preparation programs may not yet adequately address effective strategies for drawing on ELLs' cultural and linguistic resources in conjunction with rigorous mathematics instruction. In fact, it has been found that less than one third of teachers have received training in effective teaching strategies for ELLs (Ballantyne, Sanderman, & Levy, 2009).

This paper examines how preservice teachers (PSTs) modified mathematics tasks to work with ELLs. The modifications teachers make to tasks are important to examine because "the tasks in which students engage [in] provide the contexts in which they learn" (Henningsen & Stein, 1997, p. 525). Moreover, modification to mathematics tasks may lead to the creation of learning contexts more appropriate for ELLs. In this paper, *tasks* refer to an activity or set of activities designed to develop a particular mathematical idea (Henningsen & Stein, 1997). Today, there is growing emphasis on engaging students, including ELLs, deeply in worthwhile mathematics tasks that feature opportunities for high cognitive demand (Stein, Smith, Henningsen, & Silver, 2009).

As we examined the PSTs' task modifications, we drew on a situated-sociocultural perspective (Moschkovich, 2002) to describe how students learn mathematics. This perspective acknowledges that mathematics learning cannot be disentangled from language. Furthermore, it frames ELLs' language as a resource from which to build academic and everyday language. From this perspective we sought to identify the ways in which the PSTs supported ELLs in their language and mathematical learning as they drew on ELLs' linguistic resources. More specifically, we focused our examination on how the PSTs set up mathematics tasks (Stein, Grover, & Henningsen, 1996) as they attempted to increase mathematical and linguistic access. Thus, we sought to answer the following research question: *What modifications do elementary PSTs make to cognitively demanding mathematics tasks in order to accommodate ELLs?*

Methods

The data for this study came from a larger study that investigated four undergraduate juniors in an elementary education program (Fiona, Kimberly, Morgan, and Hannah) who worked one-on-one with an elementary ELL student in a four-week field experience. Prior to the study, each PST had assisted teachers in a classroom setting, worked one-on-one with students in classroom settings on

mathematical tasks, and received formal training on mathematics instruction, curriculum, and assessment as part of her program. That said, the PSTs had limited prior experiences working with and learning about ELLs specifically and were eager to gain additional experience. All four ELLs (Jin, Kyeong-Tae, Hwa-Young, & Ho-Min) in the study were native Korean speakers.

For the first three meetings, the research team provided the PSTs with a cognitively demanding task. These tasks featured opportunities for the ELLs to engage deeply in mathematical practices such as constructing viable arguments, critiquing the reasoning of others, and looking for and expressing regularity in repeated reasoning (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Each week, the PSTs were asked to write a lesson plan to implement their task and were permitted to modify or adapt the task to meet their student's needs. Data included video recordings of each meeting, video recordings of pre and post interviews, the PSTs' lesson plans, and the PSTs' written reflections.

In this study the research team employed an inductive approach (Thomas, 2006) to examine and analyze the modifications PSTs made to the provided tasks. This involved open coding (Strauss & Corbin, 1990) the tasks, lesson plans, and interview transcripts for each PST to identify and agree upon initial themes related to task modifications. We then used axial coding (Strauss & Corbin, 1990) to further refine these themes as we analyzed across all the data.

Findings

The PSTs modified the task context, presentation, and language. These modifications ranged from bolding a single word to significantly altering the task's purpose. The PSTs often made these modifications in response to knowledge gained in prior meetings with their ELL, with each PST waiting until after the first meeting to introduce any modifications.

Context

Mathematics tasks that draw on students' life experiences can simultaneously support language and mathematical learning (Barwell, 2003). Furthermore, such tasks can allow students to build meaning for mathematical contexts (Wager, 2012). However, the connection between culture and mathematical context is not immediately intuitive (Aguirre et al., 2012).

The PSTs in this study waited to alter task contexts until the third week. This task originally asked students to examine and critique the statements of two students, Jeff and Sara, about rounding numbers of baseball stadium seats. The task required the ELLs to discover that Jeff and Sara had rounded to different place values and their different perspectives were both valid. A portion of the task and one PST's modification is shown in Figure 1.

Given Task	Modified Task
Baseball stadiums have different numbers of seats. **Giants'** stadium **in San Francisco** has 41,915 seats and **Nationals'** stadium **in Washington** has 41,888 seats. **Padres'** stadium **in San Diego** has 42,445 seats. Compare these **statements** from two students:	**Soccer** stadiums have different numbers of seats. **U.S.A.s'** stadium has 41,915 seats and **Brazils'** stadium has 41,888 seats. **England's'** stadium has 42,445 seats. Compare these **sentences** from two students:

Figure 1. Fiona's modified task context.

After learning in the previous session that her student played soccer in P.E. class, Fiona changed the task's original context from baseball to soccer stadiums as seen in Figure 1. In her pre-interview she stated, "I changed it because I thought since he liked it, like soccer, playing it would connect more to him." Morgan also changed this task, asking her student to round the number of parts in three Transformer robots. She explained, "I was nervous because it was about the – the Giants'

stadium in San Francisco and the Nationals' stadium in Washington. I wasn't sure if he'd know what those were." Similarly, Hannah converted the numbers of stadium seats to numbers of library books; however, she did not consider her student's interests. Instead, Hannah chose this context to be more accessible, assuming that her student could envision his own school library, which contained thousands of books. Notably, the final PST, Kimberly, did not modify the context of any task and no PST changed the mathematical context (e.g., changing numbers or representations used in the tasks).

Presentation

Three of the PSTs, Fiona, Morgan, and Hannah, modified tasks' presentation in all three weeks by adding emphasis, restructuring, and appending visual aids. Visual supports such as these can aid learning by highlighting important concepts or ideas (Coleman & Goldenberg, 2010). For example, Morgan employed heavy emphasis (i.e., color-coding, bolding, underlining, etc.) in the second week's task, a section of which is shown in Figure 2. Morgan's emphases also matched accompanying, color-coded pictures of space creatures for her student's reference.

Both Morgan and Hannah restructured tasks into several parts, providing ample whitespace and blank lines for student work to make the task more manageable. Drawing on her experiences learning Spanish in high school, Morgan posited, "it's easier to see when it's broken into sentences, kind of separated from each other." Fiona anticipated her student being unfamiliar with the vocabulary of space creatures in the task in Figure 2 and countered this by providing images and cutouts of space creatures to her student. The cutouts also served as a representation her student used in reasoning mathematically. Other uses of visuals by the PSTs included showing images of stadiums on a laptop or pictures within the written task itself.

3. If you have to include **at least** <u>one</u> **2-eyed space creature,** <u>one</u> **3-eyed space creature,** <u>**AND**</u> <u>one</u> **4-eyed space creature,** how many space creatures of each kind are needed to make a group with <u>**24**</u> total eyes? If it is possible, list **all** possible pairs and explain your strategy. If it is impossible, explain why.

Figure 2. Morgan's modified task presentation.

Language

While ELLs' language learning is enhanced through an emphasis on mathematical meaning and processes (Moschkovich, 2012), the PSTs focused their linguistic modifications on single words and short phrases. For example, Kimberly attempted to challenge her high-achieving student by replacing '24' with 'twenty-four' and 'combinations' with 'explanations,' stating, "I'm wondering if this is going prove to be more of a challenge because he's not going to be able to just look at the numbers and figure out oh I have to do this." In contrast, Morgan sought to avoid such challenges, replacing the phrase "compare the statements of the two students" to "look at what the two students say" to relieve her student from speaking in week three.

Although the PSTs modified task language, they did so inattentively. For example, Kimberly and Morgan introduced changes that significantly altered the task instructions; while week two's instructions asked students to "list all possible combinations" for space creatures to have a total of 24 eyes, Morgan asked for "all possible *pairs* [emphasis added]" (Figure 2). Fiona and Hannah also included a number of typos and the inappropriate use of mathematics vocabulary, such as confusing the "tenths place" with the "tens place" in a rounding extension.

Conclusion

Throughout the field experience, all four PSTs attempted to modify the tasks in a variety of ways with differing levels of success. Thus, PSTs seem to utilize certain general strategies to improve linguistic access for ELLs. However, the PSTs struggled to modify tasks while also maintaining the

mathematical rigor, often conflating mathematical and linguistic supports. The ELLs were often relieved of requirements to express their reasoning or thinking and to critique arguments. The PSTs' difficulty maintaining cognitive demand was similar to findings in studies on inservice teachers conducted by Henningsen and Stein (1997).

The PSTs' hesitation to modify the tasks before meeting their student in conjunction with statements they made in interviews indicate their modifications were based more on anecdotal evidence gained from their ELLs rather than previous knowledge of how to implement tasks with ELLs. It was evident that the PSTs were not adequately prepared to accommodate linguistically diverse students through the modification of existing tasks or draw on their linguistic or cultural resources (Moschkovich, 2002). These findings suggest that PSTs would benefit from increased support in their programs to prepare them to effectively modify and use tasks for ELLs while drawing on these resources. Thus, further research is needed to investigate how teacher education programs can best prepare PSTs for future interactions with ELLs.

SUPPORTING PRESERVICE TEACHERS' USE OF CONNECTIONS AND TECHNOLOGY IN ALGEBRA TEACHING AND LEARNING

Eryn M. Stehr

senk@msu.edu

Secondary mathematics teacher education programs across the United States opportunities for preservice teachers to make connections and encounter technology to varying degrees, despite recommendations from the Conference Board of the Mathematical Sciences. We explore the research question: What opportunities do secondary mathematics teacher preparation programs provide for preservice teachers to learn about connections and to encounter technologies in learning algebra and learning to teach algebra? We present patterns and examples of a wide range of opportunities that instructors provided related to algebraic connections and use of technology, based on data collected from five teacher education programs across the U.S.

Keywords: Algebra and Algebraic Thinking, Teacher Education-Preservice, High School Education

Algebra is valued as a foundational subject in mathematics, and thus plays a prominent role in mathematics education reform efforts. In the United States, preparing future secondary mathematics teachers to teach algebra has gained importance as, in response to algebra-for-all initiatives, more states include algebra as a high school graduation requirement (Teuscher, Dingman, Nevels, & Reys, 2008). Not only are more secondary mathematics teachers teaching algebra in their first professional position, but these new teachers are also expected to teach algebra to a more diverse population of students than ever before (Stein, Kaufman, Sherman, & Hillen, 2011). Hence it is imperative to study the strategies and experiences that teaching programs use to prepare preservice teachers (PSTs) for teaching algebra to this diverse population and to support PSTs' development of a deep understanding of algebra. Furthermore, standards for both secondary mathematics content and teacher preparation have emphasized the importance of developing PSTs' abilities to make connections and to use appropriate educational technologies in their own mathematical learning and in their future mathematics teaching. Particularly with respect to PSTs' mathematics courses, *Mathematics Education of Teachers II (MET II)* (Conference Board of Mathematical Sciences [CBMS], 2012) recommended that instructors of mathematics courses support PSTs in "forming connections" (p. 56) and that experiences with technology "should be integrated across the entire spectrum of undergraduate mathematics" (pp. 56-57). This study explores PSTs' opportunities to expand their knowledge of algebra through connections and the use of technology, and to learn how to use both to support the teaching and learning of algebra. We explore the following research question: "What opportunities do secondary mathematics teacher preparation programs provide for PSTs to learn about connections and to encounter tools and technologies in learning algebra and learning to teach algebra?"

Perspectives

The importance of developing PSTs' abilities to see mathematics as a complex, connected system that also intertwines through other non-mathematical disciplines, as well as a way to make sense of mathematics in the real world, is recommended by standards developed by teacher preparation program accreditation agencies (e.g., Council of Chief State School Officers [CCSSO], 1995;

National Council of Teachers of Mathematics [NCTM], 2012). The National Board for Professional Teaching Standards (NBPTS) (2010) emphasized that PSTs must think about mathematics as a "whole fabric" as they make connections among mathematical topics. To support this view of mathematics, PSTs need to make connections within algebra, and between algebra and other mathematical fields, while linking algebra with real-world situations. PSTs should prepare to teach using "rich mathematical learning experiences" and provide their future students with opportunities to "make connections among mathematics, other content areas, everyday life, and the workplace" (NCTM, 2012, p. X). Further, PSTs should prepare to support their future learners in reflecting "on prior content knowledge, link[ing] new concepts to familiar concepts, and mak[ing] connections to learners' experiences" (CCSSO, 1995, p. X).

In addition, teachers must prepare to critically evaluate and strategically use technology in mathematics teaching and learning (CBMS, 2012; CCSSO, 1995; NCTM, 2012). *MET II* emphasized the importance of PSTs' preparation for using a variety of technologies, including problem-solving tools and tools for exploring mathematical concepts (CBMS, 2012). Teacher preparation standards have emphasized the importance of PSTs' own learning of mathematics using technologies as both a "practical expedient" as well as to enhance learning (CBMS, 2001).

For this paper, we focus particularly on opportunities provided by teacher education programs to support PSTs in making algebraic connections and using technology to learn and teach algebra. Making connections in the service of algebra teaching and learning includes making connections within algebra (WA), between algebra and other mathematical fields (OM), between algebra and other non-mathematical fields (NM), and between ideas in advanced algebra and school algebra (AS). Encounters with technology in the service of algebra teaching and learning include using and learning about a variety of algebra-appropriate technology, engaging in rich and technology-integrated algebra tasks and problem-solving, as well as thinking critically about the use of technology to support algebra teaching and learning.

Method

This study is part of *Preparing to Teach Algebra (PTA)*, a mixed-methods study exploring opportunities provided by secondary mathematics teacher preparation programs to PSTs to learn algebra and to learn to teach algebra. *PTA* included a national survey of secondary mathematics teacher preparation programs and case studies of five universities. The study described here is a qualitative analysis of the five case studies focusing on opportunities provided to PSTs to encounter technology and to make connections in learning algebra and learning to teach algebra.

PTA purposefully chose teacher preparation programs at five universities to represent diversity in location, demographics, and Carnegie classifications. We refer to the universities as Great Lakes University, Midwestern Research, Midwestern Urban, Southeastern Research, and West Coast Urban Universities. We conducted approximately 10 course instructor interviews, collecting relevant instructional materials, and two focus groups of 3-4 PSTs at each site. At West Coast Urban, we conducted only three instructor interviews because the program is post-baccalaureate. With the assistance of a site coordinator, we selected courses based on potential opportunities to learn about algebra or teaching algebra. We included mathematics, mathematics for teachers, mathematics education, and general education courses. Among other interview questions, we asked instructors about technology use in their course and about how they supported PSTs in making algebraic connections. Similarly, we asked PSTs about opportunities to use technology and make algebraic connections in required courses.

Prior to this more focused study, the *PTA* team coded all data for algebraic content. For this study, two researchers individually coded data sources based on the four major types of connections (i.e., WA, OM, NM, AS) and met to reconcile their coding. We developed summary documents for each university, including tables of opportunity counts with relevant quotations from courses. We

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

analyzed quotations to document types of reported opportunities (e.g., algebraic topics, specific activities, and/or experiences to help PSTs learn to teach connections). For tools and technology, two researchers similarly considered data sources for types of technology, details of how technologies were used to support algebra learning or teaching, and the rationale (if any) given by the instructor its use. We are developing summaries for each university, including types of technology used and how it was used. We are analyzing reported experiences according to whether they seem to use technology as a "practical expedient," to "advance learning," or to provide opportunities for PSTs to think critically about the choice and use of technologies by engaging with potential affordances or limitations (CBMS, 2001).

Preliminary Findings

For the purpose of this proposal, and due to space limitations, we present examples of *types* of experiences provided to PSTs by two of the five programs (Great Lakes and Midwestern Urban) in Abstract Algebra, Linear Algebra, and Secondary Mathematics Methods.

Connections

Great Lakes University. The Linear Algebra instructor reported opportunities related to all four types of connections: discussing the meaning of solving an equation through distributivity and associativity (WA), probability through Markov chains (OM), population dynamics through modeling (NM), and connections between solving systems of linear equations and college algebra (AS). The Abstract Algebra instructor provided examples of all types except NM: emphasizing common structures and themes behind different number systems, discussing connections between ring isomorphisms and graph morphisms in Discrete Mathematics course, and discussing relationships between high school level division algorithm and machinery in the division algorithm. The Secondary Mathematics Methods instructor described two types of connections (WA and NM), but focused on how PSTs made connections, specifically through creating lesson plans and participating in reading workshops.

Midwestern Urban University. Instructors of the three courses made different types of connections: the Linear Algebra and Secondary Mathematics Methods instructors reported opportunities related to three types of connections (excluding AS). The Abstract Algebra instructor described opportunities related to three types of connections, excluding NM. The Linear Algebra instructor mentioned that PSTs studied how to solve systems of equations, connected them to topics in the course, and learned how technology could best assist them. The Abstract Algebra instructor reported PSTs' opportunities to learn about abstract proofs related to college algebra and the usefulness of number theory and set theory. The Secondary Mathematics Methods instructor provided a specific activity (border problem) where PSTs discussed meanings of the variable in context and generalized the situation using both words and symbols, which provided them opportunities to connect different representations and geometry

Technology

Great Lakes University. The Abstract Algebra instructor reported using little technology in his course, but described experiences using instructional technologies to facilitate communication: students collaboratively developed class agendas using Google Docs. Use of technology was extensive in Linear Algebra, as students used Maple and Java applets in weekly computer lab activities. In speaking of computer lab activities, the instructor used phrases like "discover the concept" and "develop intuitive understanding." The Secondary Mathematics Methods instructor described activities supporting PSTs in thinking critically about technology use; for example, asking "which five problems you want to use the calculator on and why."

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Midwestern Urban University. The Abstract Algebra instructor reported little use of technology, but said he hoped he would have the time to incorporate more in the future. He described using Wolfram Demonstrations to "explore the symmetries of the equilateral triangle and the square." The Linear Algebra instructor reported heavy use of the TI84 calculator in his course, mainly to perform operations on matrices so that they can spend more time on what the matrix is used for and what conclusions can be drawn. The Secondary Mathematics Methods course instructor incorporated a technology workshop on using graphing calculators for algebra, and required PSTs to include one lesson in their unit plan that used this technology

Discussion

Preliminary results showed different types of opportunities related to making algebraic connections and encountering technology in learning and teaching algebra. Instructors reported a wide range of opportunities related to algebraic connections, including: lists of topics and ways that they made connections (e.g., Linear Algebra at Great Lakes) and specific activities that engaged PSTs to make connections (e.g., Secondary Mathematics Methods at Midwestern Urban). Instructors also described different ways of using technology in algebra teaching and learning: as a practical expedient for focusing on the meaning of mathematical objects instead of on operations (e.g., Linear Algebra at Midwestern Urban), to enhance learning to discover concepts and develop their understandings (e.g., Linear Algebra at Great Lakes), and to think critically about technology use (e.g., Secondary Mathematics at Great Lakes).

In our presentation, we will share patterns we have seen among the major types of connections and uses of technology across all five programs. We will additionally provide detailed examples of how instructors provided PSTs with opportunities to make algebraic connections and use technology as recommended by policy documents (e.g., CCSSO, 1995; NCTM, 2012), along with examples that other educators can use to enhance their own programs.

This study examines how two important aspects of classroom instruction, teacher noticing and productive struggle, can be introduced to and developed in preservice teachers (PSTs). We examined PSTs in a 2-week professional development experience associated with a summer math camp for elementary and middle school students. Findings suggest that an awareness of productive struggle can be developed through extending the borders of teacher noticing to include this construct. 13 PSTs were immersed in a setting that allowed them to observe teaching, interact with students, and reflect on both their actions and the classroom setting. The PSTs reflected on and discussed the development of their own observations of student thinking and the role productive struggle can play in both teaching and learning mathematics.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices

Introduction

Schoenfeld (2011) writes that *professional teacher noticing* matters and urges the mathematics education community to examine the development of this construct and its transferability to various settings and contexts. More recently, *Principles to Actions* (National Council of Teachers of Mathematics [NCTM], 2014) outlined eight Mathematics Teaching Practices that includes *support productive struggle in learning mathematics*. This practice encourages the use of, "effective teaching and supports to engage in productive struggle as they (students) grapple with mathematical ideas and relationships" (p.10). *Productive struggle* can support mathematical understanding and self-confidence in all students (Hiebert & Grouws, 2007).

The constructs of *teacher noticing* and *productive struggle* play important roles in the teaching and learning of mathematics (Warshauer, 2015a; Jacobs, Lamb, & Philipp, 2010). Research suggests that *teacher noticing* can be developed (Miller, 2011; Warshauer, Strickland, Namakshi, Hickman, & Bhattacharyya, 2015) and mathematics educators encourage providing opportunities for students to engage in struggle as an integral part of doing mathematics (Warshauer, 2015b; Hiebert & Grouws, 2007).

The purpose of this study is to examine how these aspects of classroom instruction can be introduced to and developed in preservice teachers (PSTs) and thereby stretching the borders of the constructs of *teacher noticing* and *productive struggle*. Our study examines PSTs in a 2-week summer math camp professional development (PD) experience. The seminar portion of the PD included written and oral reflections using the *teacher noticing* framework proposed by Jacobs, Lamb, & Philipp (2010). In addition, the seminar included discussion of content and pedagogy of the morning math camp classes.

The purpose of our focus on *teacher noticing* was to examine how to promote and support *productive struggle* as students engaged in mathematical tasks. By *productive struggle*, we mean what occurs when, "students expend effort in order to make sense of mathematics, to figure something out that is not immediately apparent" (Hiebert & Grouws, 2007, p. 387). Research suggests that engaging students in tasks that promote struggle may contribute to strengthening

students' disposition towards engaging in doing mathematics and foster persistence in students' efforts to understand and make sense of challenging mathematics (Warshauer, 2015a; Hiebert & Stigler, 2004). However, it is critical to understand how to prepare PSTs to address student struggle in a productive manner.

Studies suggest that teaching does not readily provide opportunities for students to struggle productively, and that teachers do not see the importance of *productive struggle* in learning mathematics (Hiebert & Stigler, 2004). Finding ways to expose PSTs to what *productive struggle* looks like through the lens of *teacher noticing* can introduce the PSTs to the value of these two important aspects of teaching practices through actual experiences.

In this paper, we report on the nature and development of *professional teacher noticing* among the PSTs in a professional development opportunity that promoted *productive struggle* in doing mathematics. The research questions for this study are:

1. What do PSTs attend to in the context of the morning camp observations and instructions? How do the PSTs interpret what they observe?
2. When PSTs observe students' *productive struggle* in a math camp setting, what is the nature of their *teacher noticing*?
3. How does the PSTs' *teacher noticing* of *productive struggle* develop over the course of the two-week camp experience?

This study seeks to provide insight into what PSTs notice in general and in particular what they notice about *productive struggle* in the context of students' learning of mathematics.

Methodology

We use qualitative methods (Corbin & Strauss, 2008) to open-code what the PSTs noticed in their classroom setting and describe how they appear to develop their noticing skills, particularly as they pertain to observations of *productive struggle* during the math camp professional development experience. The seminar was designed to expose the PSTs to the research base for the practices they would observe in the classrooms.

Context

Setting: The study took place in a two-week summer mathematics camp for elementary and middle school students associated with a university in the southern part of the United States. Each PST was assigned to a master teacher teaching one of five levels offered at the camp. They assisted the master teacher in the classroom for 4 hours each morning. After lunch, the PSTs attended a 2-hour seminar facilitated by two mathematics faculty members of the university who authored curriculum implemented in the camp. The seminar began with a daily written reflection followed by a discussion of the PSTs morning observations with an eye towards using the *teacher noticing* framework and observing *productive struggle* in the classroom. The seminar component of the PD fostered among the PSTs an understanding of the constructs of *teacher noticing* and *productive struggle.* PSTs also received training on using the Jacobs et al. (2010) *teacher noticing* framework to observe aspects of *productive struggle.*

Participants: The participants in the study came from a larger group of undergraduates, not all PSTs, who served as assistants in the camp. There were 13 PSTs: 3 had previously participated as assistants; 6 were just beginning their teacher preparation courses; and 4 were ready to begin their student teaching.

Data Collection: The data gathered included PSTs daily written reflections completed at the start of each seminar session; facilitators' field notes of daily reflection discussion during the seminar; pre and post surveys that included questions about PSTs understanding of *teacher noticing* and

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

productive struggle and their possible value in teaching and learning mathematics; 3 questionnaires every 3rd day targeting PSTs observation of the nature of student struggles and their resolutions; and interview transcripts of the PSTs conducted at the end of the camp.

Data Analysis: In order to answer our three research questions, we began with open-coding (Corbin & Strauss, 2008) of the reflections, surveys, and interviews for aspects of *teacher noticing* while superimposing the Jacobs, Lamb, and Philipp framework (2011). To establish inter-rater reliability of our coding, 15% of the PST reflections were examined by the researchers and reached 90% agreement on our coding. We continue our analysis and remain open to other codes that may arise in the PSTs observations of *productive struggle* and *teacher noticing*.

Findings

We report preliminary findings for each of our research questions.

Research Question 1: Based primarily on the daily reflections, PSTs noticing initially focused on attending to the routines of the classroom and the management of students by teachers. For example, PST A wrote, "We tested and started with number lines/greater then/less than". Regarding the management, PST A wrote, "One of our students threw a fit in class today because she did not get the color car she wanted. The teacher insisted that she could not switch cars or she would have to do it for everyone." However, over the two weeks, the PSTs began to notice teacher moves such as asking a series of questions instead of telling the students answers and a push for precise use of vocabulary. PSTs observed how students were encouraged to share ideas about the concepts from their experiences as in this account by PST B, "When the class was revisiting negative numbers, a student said that negative numbers don't exist. So the class talked about if they existed in real life or not." PSTs took notice of teacher's use of visual models and representations and physical objects such as blocks and number lines on the floor. One PST C reports, "Mrs. Fox really took a lot of time to work in front of the class and explain how to do the car model while subtracting w/ positives and negatives". PSTs were able to observe multiple ways students were thinking. Others noticed different levels at which students were engaging with the mathematical concepts as PST E noted, "Although some kids are much more experienced, they still get involved by teaching the other students (and they enjoy it!)".

Research Question 2: PSTs often attributed student struggles to lack of background knowledge or vocabulary as PST F wrote: "This seemed to be a vocabulary struggle or interpretation on what was being asked." The PSTs found that by having students reread the instructions or if the PST or teacher rephrased the question, many of the students were able to move forward with the task as noted by PST G: "It may have been the instructions because once I helped and restated the instructions, then they would be okay and begin (the) task." As the camp progressed, PSTs found questioning students to be an effective response to determine the source of the students' struggle. For example PST C states "… then I asked her what she needed to do next and … asked her if it was positive or negative. She then said negative and I asked her which way she had to face if it was negative … then she told me and we look at the sign in the problem and I asked her which way we would drive. And she figured that out". While PSTs observed that probing questions supported the struggle productively, they also found alternate means of addressing the task such as use of visual models or examples as PST A noted "I made him go to the number line with me so we could pretend to be cars. We walked out the problem."

Research Question 3: The PSTs noticing of productive struggle over the course of the 2-week camp experience seemed to have developed particularly in the two PSTs who were preparing for student teaching. Many PSTs had not considered *productive struggle* as a construct as noted by PST H, "I had never heard the term 'productive struggle'. However, after the afternoon classes, I searched for and noticed 'productive struggle'." Most expressed that incorporating this construct is an important part of learning mathematics as PST J noted: "Productive struggle in math for a child looks

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

like them building and discovering the pathways to connect concepts of mathematics." By the final survey, PSTs shared PST K belief that focus of their teaching should be on supporting the students to figure things out and asking why things work rather than seeking immediate answers to the questions," Instead of asking 'do you understand?', ask 'can you explain that'?". They also valued questioning students to better understand the students' thinking which integrated the *teacher noticing* along with support of *productive struggle* as noted by PST K "Instead of giving hints, I'd ask more questions".

Conclusion

This study explored PSTs' *teacher noticing* and using this to support *productive struggle.* Findings suggest that an awareness of *productive struggle* can be developed through extending the borders of *teacher noticing* to include this construct. PSTs were immersed in a setting that allows them to observe teaching, interact with students, and reflect on both their actions and the classroom setting in an intense professional development experience. The PSTs reflected and discussed the development of their own observations of student thinking and the role *productive struggle* plays in both teaching and learning mathematics. This type of professional development introduces PSTs to the practice of recognizing and responding to student struggles in a productive manner.

MATHEMATICAL VISUALIZATION SUPPORTED BY ALTERNATING PROBLEM POSING AND PROBLEM SOLVING

Jinxia Xie
Syracuse University
jxie04@syr.edu

Joanna O. Masingila
Syracuse University
jomasing@syr.edu

Research about mathematical visualization supported by problem posing is rare. This study investigated visualization during an alternating problem-posing and problem-solving process. The findings indicate that problem posing and problem solving inspired prospective elementary teachers' visualization; the visualization in turn supported their problem-posing and problem-solving performance; and visualization has specific features at different stages of that process.

Keywords: Teacher Education-Preservice, Teacher Knowledge, Problem Solving

Introduction

Researchers use the word visualization to refer to the process of constructing and using geometrical or graphical representations of mathematical concepts, principles or problems that are beneficial in doing mathematics (Presmeg, 1997b). Effective visualization helps improve teaching and learning efficiency (Duval, 1999; Guzman, 2002). Problem solving is considered a complex activity that demands cognitive thinking rather than simple recall of facts and procedures. Lesh and Zawojewski (2007) proposed an even broader definition of problem solving that emphasized problem solving as a process of interpreting a situation, during which a problem solver is usually required to refine clusters of mathematical concepts from various topics within and beyond mathematics. Problem posing is another cognitively demanding activity that asks learners to either formulate new problems based on a given situation or restructure a given problem (Kilpatrick, 1987).

Researchers have found that problem posing is closely related to problem solving (Silver & Cai, 1996). Even so, there are still many unanswered questions about the relatedness between problem posing and problem solving (Silver, 2013). Research about visualization in problem solving is limited (Presmeg, 2006), while research about visualization in problem posing is more rare. This study aimed to explore US and Chinese prospective elementary teachers' visualization performance during problem posing and problem solving. The following questions guided this study: (1) What are the patterns of visualization during US and Chinese prospective elementary teachers' alternating problem-posing and problem-solving process? (2) What are specific features of visualization during problem posing prior to problem solving, during problem solving, and during problem posing after problem solving?

Methodology

This study is part of a larger research project that was conducted among 87 first-and second-year prospective elementary teachers. Thirty-two participants were from three universities in the Northeastern part of the US and the remaining participants were from three universities in China. No participants had formal experience in problem posing before. By adapting the Active Learning Framework developed by Ellerton (2013) as well as the four cognitive problem-posing processes proposed by Christou, Mousoulides, Pittalis, Pitta-Pantazi and Sriraman (2005), this study designed a developmentally appropriate way of engaging participants in alternating problem-posing and problem-solving activities. Those four processes include: (1) Translating process for posing problems based on given graphs, diagrams or tables; (2) Comprehending process for posing problems based on given operations; (3) Editing process for posing problems according to provided information such as a real-life situation but without any other restriction; and (4) Selecting process for posing problems

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

that are appropriate to specific given answers. Figure 1 showed the two sets of tasks that we had administered.

For each set of tasks, we first asked the participants to individually pose a problem for the Translating process on a separate sheet of paper, no story was given. We then asked them to pose problems for the other three processes on another sheet of paper according to a real-life story, which corresponded to the previously provided figures. Next we asked them to solve a problem, and finally to pose two more problems on a fourth sheet of paper. All 85 participants completed the first set of tasks. We then selected 43 of them according to the criterion that the majority of their posed problems (usually more than 50%) during the first task administration were solvable mathematical problems to complete the second set of tasks.

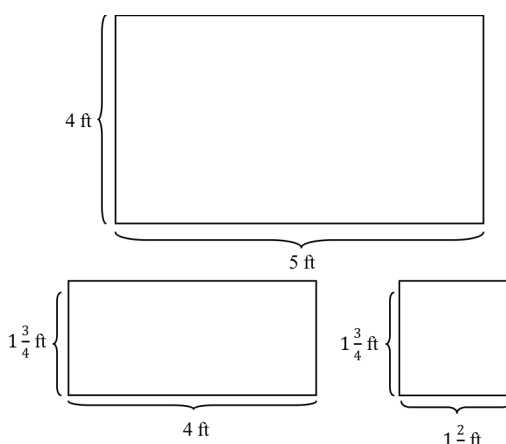
Results and Discussion

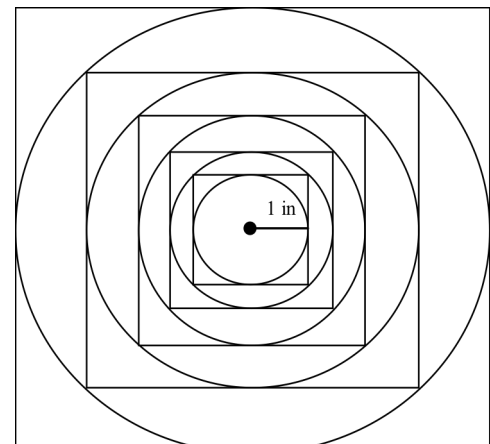
Answer Research Question 1

To answer the first research question, we examined the mathematical concepts, the associations among those concepts, and creative ideas about visualization demonstrated in participants' posed problems and their problem-solving solutions.

Concepts contained in posed problems. The participants used a large number of mathematical concepts for posing new problems during both task administrations. They commonly used the concepts of area, perimeter/circumference, ratio, percentage, proportion, inscribed circle/square, circumscribed square, as well as some concepts about three-dimensional objects. These findings demonstrate prospective elementary teachers' ability and skills in mastering mathematical concepts when visualizing geometrical objects. These findings also show that problem posing with visual images provides learners opportunities to apply mathematical concepts that they have learned.

Associations of concepts contained in posed problems and problem-solving solutions. We found that the participants made interesting associations among concepts that they used. For example, one US participant posed a problem asking about how the change in length and width of a rectangle would impact its change in area. For problem solving during the first task administration, twenty-five participants provided at least two different solutions. For the second set of tasks, more than half of the participants utilized at least one of the following associations in their posed problems or problem-solving solutions: (1) the radius of a circle was half of its circumscribing square's side length; (2) the diameter of a circle was the diagonal of its inscribed square; and (3) the Pythagorean Theorem played a significant role of connecting neighboring circles and squares. These findings show that problem posing and problem solving encouraged the participants' use of visualization; the associations discovered by participants through visualization, in turn, supported their problem-posing and problem-solving performance.

Some creative ideas. A large number of participants posed problems involving comparison ideas and these problems usually involved more than one operation. The ideas such as how many times a small rectangle fit into a big rectangle were also commonly used. Those problems involved a division with fractions as well as a division with a remainder, which were documented as challenging topics (Rizvi, 2004). Some participant even developed route problems with given speed or time, engineering problems about water injection with different rates, and so on. All these ideas indicate that prospective elementary teachers possess a huge imagination space when posing problems by visualizing geometrical figures.




First Set of Tasks	**Second Set of Tasks**

First Set of Tasks

Given the following figures:

Task I: Problem posing [40 min]

Translating: Write a mathematical story problem according to the given figures.

<u>**Here is a real life story:**</u>

Diana bought a piece of cloth 4 feet wide and 5 feet long. It cost $16. She cut off a piece that was $1\frac{3}{4}$ feet wide and 4 feet long to make a scarf. Her sister saw Diana's cloth and really liked the material. She asked for a piece that was $1\frac{3}{4}$ feet wide and $1\frac{2}{3}$ feet long to also make a scarf.

Comprehending: Write an appropriate mathematical story problem representing the following calculation: $1\frac{3}{4} \times (4 + 1\frac{2}{3})$, according to the given situation and figures.

Editing: Write a mathematical story problem according to the given story, which should be different from the problems you posed before.

Selecting: Write an appropriate mathematical story problem according to the given story so that the answer to your problem is $\frac{121}{12}$ square feet.

Task II: Problem solving [20 min]

Solve this problem: In this story, if Diana's sister wanted to pay Diana, how much should Diana charge her?

Task III: Further problem posing [20 min]

Write two more mathematical story problems that are different from all problems you posed or solved previously according to the same story.

Second Set of Tasks

Given the following figure:

Task I: Problem posing [40 min]

Translating: Write a mathematical story problem according to the given figure.

<u>**Here is a real life story:**</u>

A factory that specializes in producing dinnerware decides to produce a set of five bowls in different diameter sizes. The sizes are constrained using the following model diagram and the radius of the smallest bowl is 1 inch.

Comprehending: Write an appropriate mathematical story problem representing the following calculation: $\sqrt{1^2 + 1^2}$, according to the given situation and figure.

Editing: Write a mathematical story problem according to the given story, which should be different from the problems you posed before.

Selecting: Write an appropriate mathematical story problem according to the given story so that the answer to your problem is $2\sqrt{2}$.

Task II: Problem solving [20 min]

Solve this problem: Given that the radius of the smallest circle is 1 inch, what is the ratio of the area of the largest circle to the area of the smallest circle?

Task III: Further problem posing [20 min]

Write two more mathematical story problems that are different from all problems you posed or solved previously according to the same story.

Figure 1. Two sets of tasks administered for this study.

Answer Research Question 2

For answering the second research question, we looked into the features of visualization throughout the entire process. During the problem-posing process prior to problem solving, the majority of participants had a difficult time in posing problems. This was partially because none of

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

them had formal problem-posing experience before. Many participants posed one mathematical problem focusing on only part of the given figures (e.g., used only one rectangle during the first task administration instead of incorporating all three given rectangles). The problem-solving process after problem posing provided the participants opportunities to justify whether they accurately applied the mathematical concepts as well as the associations among those concepts in the posed problems, and whether those ideas could serve as aids for solving the given problem. During the problem-posing process after problem solving, the participants usually posed better problems, namely, problems that involved more computational steps or different creative ideas, compared to the problems they posed prior to problem solving. In this case, the participants' visualization ability was developed because many aspects, familiar or unfamiliar, were now associated with given figures.

Conclusion and Implications

This study focused on examining prospective elementary teachers' visualization during an alternating problem-posing and problem-solving process. We found that they used a large number of mathematical concepts as well as multiple associations among those concepts when trying to interpret the given figures. There were many creative ideas involved in their posed problems. We further found that visualization during different stages of problem-posing and problem-solving process had different features. Existing studies have documented that students are reluctant to engage in visual processing and reasoning (Dreyfus & Eisenberg, 1990). There have been no studies investigating visualization in the problem-posing area. Therefore, the role of problem posing in developing students' visualization remains an active question. This study serves as a first example of documenting the interplay of problem posing and visualization, specifically when problem-solving activities are alternately involved. The exploration about specific aspects and/or skills of the use of visualization during problem posing needs to continue.

The preparation of prospective secondary mathematics teachers often revolves around working to improve knowledge of mathematics for teaching and understanding the conceptual development and trajectories of mathematics. "Effective teaching of mathematics builds fluency with procedures on a foundation of conceptual understanding so that students, over time, become skillful in using procedures flexibly as they solve contextual and mathematical problems" (NCTM, 2014, p. 42). Prospective teachers need to be prepared to teach concepts along with procedures (Ball, Thames, & Phelps, 2008) particularly with the implementation of the Common Core State Standards (CCSS). In their own experience as a learner of mathematics, however, many prospective teachers come with procedural understandings of mathematics and many struggle to understand the underlying concepts and why those procedures work. Challenging prospective teachers to examine their own understandings of mathematical concepts and their preconceived ideas of good mathematics instruction becomes an important aspect of mathematics teacher preparation.

In this study, prospective secondary mathematics teachers were asked to read *Principles to Actions'* section on Conceptual Understanding and Procedural Fluency (NCTM, 2014). Having individually defined conceptual and procedural understanding in their own words, they were asked to apply those understandings to determine how a student might solve a percentage problem with a conceptual and with a procedural understanding. Prospective teachers' definitions and student solutions were examined to answer the question: In what ways do prospective secondary mathematics teachers define conceptual understanding and procedural understanding and subsequently apply those definitions to solve a percent problem?

Using the prospective teachers' own definitions of these two terms, the researchers compared the definitions with how each prospective teacher distinguished between the types of understandings when applied to the given percent problem. Data showed some disconnect between definitions and applications. Additionally, responses of prospective teachers to the percentage problem could have been either conceptual or procedural based upon varying aspects of student solutions.

COMIC STRIPS AS A TOOL FOR MAKING SENSE OF INEQUITABLE TEACHING PRACTICES IN MATHEMATICS EDUCATION

Alisa Belliston
University of Wisconsin-Madison
Belliston@wisc.edu

Introduction

This poster presentation will provide an opportunity for mathematics teacher educators to engage with ideas around teacher candidates' sense making of supporting diverse populations of mathematics learners. More specifically, it will discuss the use of student created comic strips as an alternate way (moving beyond the borders) for teacher candidates to demonstrate their understanding of inequitable teaching practices in mathematics education. Comic strips have supported students with autism in learning conversation skills (Gray, 1994), helped English language learners develop foundational literacy skills (Arif & Hashim, 2008) and brought to light myths and inaccurate conceptions about teaching (Ayers & Alexander-Tanner, 2010). Pushing even further beyond borders of alternative ways to allow teacher candidates to present their thinking in math methods courses, I will share my analysis of the text features of these comic strips to answer the question: What text features do teacher candidates use in self created comic strips to make sense of inequitable practices in mathematics education?

Methods and Analysis

As a form of culturally relevant pedagogy (Ladson-Billings, 1995), 13 special education teacher candidates were given choices about some of the learning experiences in which they would participate during their math methods course. One of the choice assignments in the "Math in the Community" component of the course was to create a comic strip dealing with a specific math issue related to equity, diversity, ability and/or social justice. Three students from this cohort chose to create comic strips. The text features of the comic strips were first coded for specific text features such as narrative captions, action words and quotations. This category also included images, which was defined as a visual that might contain words but does not use any features of explicit communication such as speech or thought bubbles. The comic strips were also coded for content. Content included state testing, student interest, individual learning abilities, and teaching for understanding. A checklist matrix (Miles, Huberman & Saldana, 2013) was used to uncover patterns and themes. Preliminary findings show that the teacher candidates' use of images supported evidence of a deeper level of understanding than their use of other text features.

Teaching is complex with teachers making whole-class decisions based on what they notice about individual students' thinking. van Es and Sherin (2008) state that teachers can improve their noticing by changing what they notice, how they reason about student work, and how they make decisions. In the case of preservice teachers (PSTs), noticing students' mathematical thinking can be particularly difficult. The poster examines elementary PSTs' professional noticing of student written work (Jacobs, Lamb, & Philipp, 2010). The focus of the study was fostering PSTs' ability to provide instructional "next steps" for a whole class based on analysis of multiple student work samples.

Elementary PSTs enrolled in a mathematics methods or content course at five different institutions in the U.S. participated in the study. The researchers planned and taught the same multiplication lesson at their respective institution that consisted of watching children's videos, analyzing a case study with written student work, and whole-class discussions on "next steps." Qualitative multiple case-study analysis was used to analyze the data, with each institution taken as a separate case.

Preliminary results indicated that providing the whole-class case study assisted PSTs in gaining insight into (a) attending and interpreting students' mathematical thinking such as identifying multiplication strategies like repeated addition and derived facts and (b) the sophistication of these strategies and how they can be used to move students to a higher level of thinking.

However, contrary to our prediction, the PSTs struggled with providing specific "next steps," such as creating specific tasks or a question to pose to move an individual student forward in their knowledge of multiplication. It was also difficult for the PSTs to use individual "next step" ideas to make whole class instructional decisions. While the process of noticing and eventually deciding the "next steps" for a whole class was difficult, there were noticeable differences seen in their responses when talking about individual student work samples and whole class needs.

This study provided a means to begin to help PSTs make evidence-based shifts from describing general strategies for individual students to deciphering key characteristics that describe important mathematical understandings for a whole class.

In this paper, we consider "unjust uses of mathematics" (p. 15) for one student at a large public university in the southeastern United States (Stinson, 2004). We focus on the oppressive and withholding functions of one particular mathematics assessment as Jamesha attempted to cross the border into teacher education.

This case study traces the story of an undergraduate middle grades preservice teacher who was provisionally accepted into an urban teacher residency program for her final practicum and student teaching year, and then subsequently denied access to the program due to low scores on a mathematics entrance exam. Though Jamesha's areas of concentration were language arts and history, she was required to pass a program admission assessment in mathematics that required knowledge of advanced mathematics in order to gain official entrance into the middle grades program and move forward in the urban residency program. After two failed attempts to pass the math exam, Jamesha studied alongside peers and professors and worked through test prep materials she and others had purchased. She took the test three more times and still did not receive scores high enough to "pass" the exam. Jamesha was removed from the residency program and denied admittance into the teacher education program. She was forced to change majors and in the following semester, she failed all of her classes outside of the education department. Jamesha remained determined to become a teacher; she decided to take the assessment a 6th time and reenter the education degree program.

In our consideration of this case, we utilize a poststructuralist lens (Foucault, 1981/2000) to think about mathematics as "gatekeeper" (Stinson, 2004) as well as mathematics and 'teacher' subject position construction, complication, and negotiation (Britzman, 2003; Davies, 2003). We pose and consider the following questions: How does mathematics assessment function as a border to teacher education for non-mathematics teachers? How is a student's subjectivity constructed through assessment? "How does school mathematics as gatekeeper function? Where is school mathematics as gatekeeper to be found?" (Stinson, 2004, p.16).

The poster will map some of the ways that the mathematics program admission assessment functions as a gatekeeper for Jamesha. We will also consider how Jamesha's subjectivity as teacher and mathematician was (re)constructed by the assessment, as well as how her subject position as a student in a large university affected her navigation and negotiation of the structures in place in the teacher education program and subsequently in her alternate degree program.

For many, crossing borders from one country to another can be quite a challenge. For at least 100 years the move from school to university is described as an equal challenge in the mathematics and mathematics education communities. In 1908, Felix Klein (1849–1925), with a special interest in secondary-level teacher training, characterized this transition from school to university as the first part of a "double discontinuity" (Klein, 1908/1932, p. 1). Recent studies show that what Klein described in 1908 is still a major problem today. Hefendehl-Hebeker and her colleagues (2010) noted that the transition problem might be connected to some kind of "abstraction shock" – meaning that pre-service teachers face a major epistemological obstacle from school to university regarding the nature of mathematics.

Our research began with the following hypothesis, which was informed by an approach based on the conception of belief systems, subjective domains of experience, and "Theory theory" (Gopnik & Meltzoff, 1997), and which we use for explaining epistemological difficulties of students struggling with new contents or situation.

The change from empirical-concrete to formal-abstract belief systems of mathematics constitutes a crucial obstacle for the transition from school to university. On epistemological grounds, similar changes regarding different natures of mathematics can be described for the history of mathematics. The explicit analysis of the historical genesis provides support for students dealing with their individual transition processes.

To test this hypothesis, we conducted research on an intensive, three-day seminar that we designed and implemented in spring 2015. We present a description of the seminar, including the readings and historical materials used with participants (see also Witzke et al., forthcoming). We then discuss the case of Inga (pseudonym), and, using excerpts from the data provide a summary to describe her experience with the transition between school and university mathematics.

EXPERIENCES AND INFLUENCES OF MATHEMATICAL AUTONOMY

Noelle Conforti Preszler
James Madison University
confornx@jmu.edu

Keywords: Teacher Education-Preservice, Affect, Emotion, Beliefs, and Attitudes

Teachers at all levels are increasingly expected to foster high quality mathematical thinking in their classes. Their students should be making sense of problems, generating solution strategies, and considering and creating representations of those strategies. This type of thinking can provide students opportunities to be more autonomous, or self-directed, in their learning, pursuing their own solution strategies and ideas to go beyond following prescribed processes given by teachers or textbooks. Many teachers were never given the opportunity to engage with mathematics in these newer ways when they were students. This poster will facilitate discussion of future K-8 teachers' experiences of autonomy in math class and how we can prepare these future teachers to foster students' confidence in their own abilities to reason mathematically.

Future teachers' experiences of mathematical autonomy will be articulated from a qualitative case study situated within in a math content course. Specifically, characterization of the course, based on observations, field notes, and video, revealed that the future teachers were expected to (a) discuss mathematics with others, including suggesting solution strategies, considering others' perspectives or answering questions, (b) construct their own solution strategies, (c) be intellectually courageous by asking questions when confused, suggesting potential ideas, and being willing to make mistakes, and (d) to let their thinking develop over time, understanding that problems sometimes require perseverance or revision of thinking. In order to carefully attend to the future teachers' affective experiences in this case study (as opposed to asking generally about feelings or emotions), I leveraged the constructs of competence (feeling capable), relatedness (social belonging), and autonomy (self-direction) from self-determination theory (Ryan & Deci, 2000). My goal was to particularly note how future teachers' affective experiences related directly to the cognitive and participatory demands of a classroom focused on promoting student engagement, and these constructs lent themselves to such connections.

As stated above, this poster will focus on the future teachers' experiences of autonomy, but it will situate these results within the larger study, expanding on the conceptual framing, data collection, and analysis briefly touched on here. The primary goal will be to highlight both the future K-8 teachers' prior experiences in their K-12 years and their experiences in the course studied, as analyzed from autobiographies and interviews, and to focus particularly on how their experiences of mathematical autonomy helped them articulate the type of classroom they hope to create for their future students. Perhaps not surprisingly, many future teachers described lacking feelings of autonomy in their prior math courses, recalling frustration with little freedom for or support of student generated ideas. However, there was a sense of autonomy in this classroom, that not only allowed, but encouraged students to see themselves as mathematical authorities. At the end of the course, when envisioning their future classrooms, each future teacher emphasized their desire to support student autonomy as it had been supported for them in this course.

HELPING PRESERVICE TEACHERS MAKE SENSE OF WHOLE NUMBER CONCEPTS AND OPERATIONS: WORKING IN BASE 8

Heidi Eisenreich	Janet Andreasen	Katie Harshman
Georgia Southern University	University of Central Florida	University of Central Florida
heisenreich@georgiasouthern.edu	Janet.Andreasen@ucf.edu	katie.harshman@knights.ucf.edu

Keywords: Mathematical Knowledge for Teaching, Teacher Beliefs, Teacher Education-Preservice

How to improve teacher education programs to allow preservice teachers (PSTs) make sense of mathematics for depth, is a topic debated among educational researchers, especially in mathematics education. PSTs and inservice teachers (ISTs) need to be prepared to teach concepts and to understand how and why students come up with different strategies and whether those strategies will work all the time. Teaching whole number concepts and operations (WNCO) in a base other than 10 can challenge PSTs and ISTs to think about mathematics in ways similar to an elementary student. Previous studies have reported PSTs and ISTs struggle when using base systems other than base 10 in an education class or a professional development workshop just like their elementary students might struggle with base 10 (Andreasen, 2006; McClain, 2003; Yackel, Underwood, & Elias, 2007; Zazkis & Zazkis, 2011).

At one university, PSTs work in base 8 for an entire 4 week unit to gain a deeper understanding of WNCO. While learning in base 8, PSTs have to make sense of mathematics strategies in a deeper level than if they were learning about them in base 10. For example, if students are asked to add 7+6 in base 10, they will say 13. When asked "how do you know?" their most likely response is that they just know. By asking the same question in base 8, PSTs make sense of regrouping in a way that is similar to how beginning learners make sense of regrouping in base 10. This can address an important barrier in supporting PSTs and ISTs to understand WNCO in ways that are important for teaching.

The purpose of this research was to use qualitative data from interviews and observations to attempt to answer the question: In what ways do PSTs perceive learning WNCO in base 8? Interviews were conducted to ascertain how PSTs may or may not have changed their views on learning in base 8. Data from interviews of four PSTs indicated they initially struggled with learning WNCO using base 8 during the four week unit. In the beginning, PSTs were frustrated with learning in base 8 and did not understand why they needed to learn this way. However, as the unit continued, researchers found that PSTs were more accepting and realized the importance of learning in base 8. Most understood that although they will not be teaching their elementary students in base 8, learning in this base system had benefits they did not initially realize, for example understanding WNCO in depth.

LEARNING TO FACILITATE GROUPWORK THROUGH COMPLEX INSTRUCTION

Jennifer A. Eli   Marcy B. Wood
The University of Arizona   The University of Arizona
jeli@math.arizona.edu   mbwood@email.arizona.edu

Keywords: Teacher Education-Preservice, Instructional Activities and Practices

Complex Instruction (CI) is a form of collaborative learning, grounded in research on students' thinking and learning that focuses on equitable groupwork collaboration (Cohen & Lotan, 2014; Featherstone, Crespo, Jilk, Oslund, Parks, & Wood, 2011). CI research posits that how a student is perceived by their peers in the group with respect to their capability to make meaningful contributions (that is, issues of status) effects whether the group will listen to that individual. If a student is seen as low status, they are seen as unable to contribute to the intellectual work of the group, regardless of how well the student understands mathematics. In contrast, a high status student will be allowed to take over a group, even if the student touts erroneous mathematical ideas. The purpose of our study was to implement three research-based pedagogical strategies grounded in CI—*establishing groupwork norms*, *designing groupworthy tasks* and *setting group goals*—that would provide access and opportunity towards equalizing status and broaden participation by all preservice teachers (PSTs) in an elementary mathematics content course.

Student reflections and post course evaluations were collected from 36 elementary PSTs across two course sections. Preliminary results indicate that CI reforms had a positive impact on PSTs' perspectives about learning mathematics through equitable collaboration with their peers. Below are some exemplar responses that support these findings.

> At the beginning of class, I was dreading working in a group. I believed, "I am smart enough to do this on my own." I have learned that using others can help because you learn the way others see a problem.

> The groupwork was the best part of the course because we got to teach one another and think about different ways to solve a problem. We were smarter together than alone. Before taking this course, I was not confident about begin able to do math. I've never really been very good at it. After this class working in groups, I see myself as capable of doing math now.

Many undergraduate elementary education majors enter their content courses with little confidence in themselves as mathematical learners. Through CI, we've seen a shift in our PTS' view that they are capable of doing mathematics and that taking risks and exploring beyond ones' comfort zone can lead to deep mathematical learning and understanding.

Acknowledgment

SUPPORTING SECONDARY MATHEMATICS TEACHER PREPARATION: A COLLABORATIVE TETRAD MODEL

Jennifer A. Eli
The University of Arizona
jeli@math.arizona.edu

During student teaching, pre-service teachers (PSTs) are expected to put into practice the integration of content and pedagogy under the mentorship of knowledgeable others in a classroom setting. This integration is traditionally accomplished through a triad model of student teaching supervision which involves daily interaction with a mentoring in-service teacher (IST) coupled with periodic visits by a university supervisor, typically a mathematics educator. Although mathematicians are responsible for significant portions of secondary teacher preparation prior to the student teaching, they are noticeably absent from the triad for mentoring and supporting PSTs during their field placement. This results in an exacerbation of the separation of PSTs' mathematical knowledge development from their pedagogical knowledge development, and from their K-12 classroom-based experiences. Importantly, this separation of mathematical and pedagogical knowledge is experienced not only by the PST, but also by university mathematics educators and mathematicians. Faculty members' vision of PSTs' needs and experiences are restricted, and cross-disciplinary knowledge development is inhibited. In general, jurisdiction over teacher preparation is divided across separate and distinct academic units, and administrative and cultural barriers impede communication and joint work. Further, mathematicians, and in some cases mathematics educators, are not directly involved in working with student teachers, or with recent graduates. Thus, they do not see the ways in which the courses they teach do, or do not, influence how their students teach mathematics.

In this paper, I propose expanding the collaborative discourse community from a triad to tetrad model through the inclusion of a mathematician. The tetrad model brings together PSTs, ISTs, mathematics educators, and mathematicians represented visually as the vertices of a tetrahedron. The tetrad model is a creation of a fourth space, visually the interior of the tetrahedron. This space is not typically reflected in current secondary teacher preparation efforts. Sociocultural learning theory helps us see PSTs' development for teaching secondary mathematics as collaborative, complex, and contextual (Fernandez & Erbilgin, 2009; Thompson, Beneteau, Kersaint, & Bleiler, 2012). From this perspective, we can examine the entire system, in this case the tetrad collaborations, as the unit of analysis. Through careful study of tetrad interactions, one can investigate (a) the knowledge and perspectives that members bring to the tetrad collaborations, (b) the interactions and negotiations of knowledge and practice, and (c) the feedback mechanisms that directly influence mathematicians' and mathematics educators' teaching practices in their university secondary mathematics teacher preparation courses.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices

To create opportunities for teacher candidates (TCs) to develop pedagogical skill that engages all students in authentic mathematics we have designed an instructional activity (Lampert & Graziani, 2009), *Going Over a Problem* (GOP) (Elliott, Aaron, & Maluangnont, 2015). GOP embeds two learning goals; opportunities for TCs to build skill with instructional practices and opportunities for secondary students to engage with mathematical practices that are critical to sense making on mathematical problems. Our research question is: How does GOP, as enacted by each TC, support or constrain *both* TC and student learning?

We used GOP in cycles of investigation and enactment (McDonald, Kazemi, & Kavanagh, 2013) with eight TCs in a secondary methods course. We coded video attending to TCs' use of discourse moves, mathematical representations, questioning strategies, eliciting and responding to students' reasoning (NCTM, 2014) and students' coordination of ratio quantities (Lobato, Ellis, & Zbiek, 2010) and argumentation (Lannin, Elliott, & Ellis, 2011). We found that TCs' use of instructional practices created opportunities for students to engage in key mathematical practices. Conversely, students' arguments created opportunities for TCs to develop skill with key instructional practices of interpreting and responding to student contributions.

The second finding, that TCs opportunities to learn are supported by interacting with students' emergent thinking may not be surprising, but it is instrumental in understanding pedagogies of investigation and enactment. TCs' enactments of GOP allowed them to confront the improvisational and responsive aspects of teaching which they may not encounter in teaching situations where they can rely on familiar instructional practices such as IRF questioning (Mehan, 1979). We claim that the ambitious practices deployed in GOP expands the types of student contributions that TCs elicit from students and to which they are required to respond in the moment.

ABRIENDO FRONTERAS: HOW PRE-SERVICE TEACHERS LEARN TO TEACH PRODUCTIVE STRUGGLE TO ALL STUDENTS, INCLUDING ELLS

James Ewing
Stephen F. Austin State University
ewingjs@sfasu.edu

Introduction and Purpose of the Study

Productive struggle is a necessary component of learning mathematics with meaning and refers to students grappling to make sense of problems (Hiebert & Grouws, 2007). Murrey (2008) advises teachers to scaffold ELLs' language if necessary, but in doing so, teachers should strive not to reduce the mathematical rigor of problems for ELLs.

Methods

The context of this descriptive multiple case study was an elementary mathematics methods course of 22 PSTs with field placements, in which I was the instructor. I analyzed the following data: open response surveys (pre-and post), homework reflections, lesson plans, university supervisors' reports, host teachers' reports, and semi-structured interviews of PSTs, university supervisors, and host teachers.

Findings and Implications

Multiple data sources suggested that all eight PSTs facilitated their students to connect with the mathematics and to provide access for students. However, only three PSTs showed signs of keeping the cognitive load high for their students in the field, which I refer to as productive struggle.
Figure 1. Trajectory for PSTs to engage students in productive struggle.

The trajectory represents a possible order for learning how to engage all students, including ELLs, in productive struggle. PSTs may need to learn how to connect and provide students' access to mathematics and acquire strong content knowledge themselves before developing a productive disposition, acquiring high expectations for students, and teaching productive struggle.

INFLUENCES AND MOTIVATIONS IN CHOOSING TO BECOME A MATHEMATICS TEACHER OR NOT

Maria Lorelei Fernandez
Florida International University
mfernan@fiu.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes, Teacher Education-Preservice, Policy Matters

Mathematics education is a field that has suffered and continues to suffer teacher shortages, particularly in relation to schools that serve low-income students (USDOE, 2012). In meeting the shortage challenge, it is valuable to research and understand the influences on and motivations of individuals, including those typically underrepresented in the field of teaching (e.g., Hispanic, Black/African American), for becoming mathematics teachers or not. Reasons for pursuing teacher education (not specifically mathematics) are inter-related to an individual's goals for the future (Schutz, Crowder, & White, 2001). According to Schutz et al. (2001), "goals are subjective representations of what one would like to happen and what one would like to avoid in the future" (p. 229). In their study, Schutz et al. (2001) found four main sources that were predominant in their participants' goal history of becoming a teacher: (a) family influences, (b) teacher influences, (c) peer-influences, and (d) teaching experience. Most studies on motivations to become a teacher (i.e., Kyriacou & Coulthard, 2000) suggest that reasons for becoming a teacher fall into three categories: intrinsic, extrinsic, and altruistic.

Survey data was collected at a minority serving institution from undergraduate students (62% Hispanic/Latino, 18% African American/Black, 9% Asian, 9% White non-Hispanic,2% Other) engaged in early experiences trialing teaching mathematics as a career option. Initial data analysis revealed that undergraduates continuing to pursue becoming a mathematics teacher reported more positive views of teaching among their parents/guardians, family, and close friends than those not becoming teachers; thus, aligned with Schutz et al. (2001). With respect to extrinsic motivations for becoming mathematics teachers, being respected by family and the community, and being seen as a good mathematics teacher by family and teachers/instructors were rated more highly by those choosing to pursue becoming a mathematics teacher than those that did not. For intrinsic motivations, seeing themselves as teachers, enjoying teaching mathematics to others, and working with people rather than objects were rated more highly by those choosing to pursue teaching in contrast to those that did not. Finally, with respect to intrinsic motivations, making a difference for people, helping people, and helping solve societal problems were rated more highly for undergraduates continuing to pursue mathematics teaching than those that did not. Findings suggest directions for recruiting or influencing students interested in mathematics related fields (at the undergraduate or secondary school levels) to pursue teaching mathematics as a career option.

TEACHING PRE-SERVICE TEACHERS TO DECONTEXTUALIZE WORD PROBLEMS

Victoria Kofman   Sayonita Ghosh Hajra
Stella Academy   Hamline University
drkofman@gmail.com   sayonita@gmail.com

Keywords: Problem Solving, Modeling, Teacher Education-Preservice, Algebra and Algebraic Thinking

One of the main goals of the *Common Core State Standards for Mathematics* (CCSSM) (National Governors Association for Best Practices, Council of Chief State School Officers [NGA & CCSSO], 2010) is to promote quantitative and algebraic reasoning (Thomson, 2011). One of the aspects of algebraic reasoning includes an ability to decontextualize word problems by presenting them in a form of equations that characterize the essence of word problems in symbolic form, while defining the meaning of each symbol. However, we observed pre-service teachers' difficulties with decontextualizing word problems when presenting them in a form of equations and defining parameters.

To meet our students' needs, we incorporated a supplementary instruction (12 weeks) in a regular 15-week arithmetic course for pre-service teachers and thoroughly monitored teachers' progress with creating equations, identifying measuring units, and defining parameters.

Seventeen pre-service teachers from a western research university participated in this study. They read self-explanatory instructions, created equations, and designed visual models as tools for decontextualizing simple arithmetic problems. When teaching the supplementary program, the instructor constantly monitored students' mistakes found in their written work (students' workbooks) and regularly spent five minutes in class discussing uncovered misconceptions. For this preliminary study, we analyzed the mid-term exam, quizzes, and final exam written data using an open and axial coding method (Strauss & Corbin, 1998).

We found students commonly misinterpret symbols used in equations and identify them as equivalent to objects, units, or words—consistent with other studies (Booth, 1988; MacGregor & Stacey, 1997). In the current study, students demonstrated difficulties with defining symbols they used when presenting 1–2-step arithmetic word problems in symbolic form. Students' work reflected (1) misconceptions in regards to the symbols' meaning and (2) misconceptions regarding the defining attributes represented by the values. Supplementary instruction in word problems solving allowed us to significantly improve pre-service teachers' precision in defining parameters. In the future, we plan to deepen the precision of our studies by redesigning the pre-test and adding a comparison with a control group—no supplementary instruction.

INTEGRATING CHILDREN'S LITERATURE IN MATH: FOSTERING PRE-SERVICE TEACHERS' UNDERSTANDINGS AND CONNECTIONS

Dittika Gupta	Melissa Whitwood	Nikki R. Bussue
Midwestern State Univ.	Midwestern State Univ.	Midwestern State Univ.
Dittika.gupta@mwsu.edu	melwhitwood@gmail.com	nikkibussue24@gmail.com

Interdisciplinary teaching is growing but despite numerous children's books available, pre-service teachers (PSTs) still are unaware of various strategies of integrating children's literature in mathematics. The knowledge about integrating children's literature needs to be built in teacher education programs (Cotti & Schiro, 2004; Ruiz, Thornton & Cuero, 2010; Ward, 2005) to help them develop conceptual models of integration for future teaching decisions. This research is a step towards providing experiences to PSTs for fostering their understanding on integrating children's literature in an elementary math classroom. This study probes, enhances, and aims to transforms PSTs perceptions about integration. The study examines attitudes and perceptions of PSTs and provides the mathematics community with a model of integration that can have significant impact in the teacher preparation program. The intervention aims to present PSTs with a model that can overcome cultural and language borders in their classroom along with borders in their own thinking about using children's literature.

Methodology

Quantitative multiple case study analysis was used to analyze 31 PSTs attitudes and perceptions about integrating children's literature over two semesters in a math methods course at a public university in north Texas. The intervention was an integration model in which PSTs rotated through several stations engaged in math activities with children's literature, designed ways to use children's literature to teach math, and participated in whole class discussions about children's literature. Data in the form of semi-structured pre- and post-interviews, class discussions, small group discussions, PSTs reflections and work, and lesson plans were analyzed through open and axial coding. Triangulation, constant comparison, and member checking were used to identify emerging themes and commonalities.

Results

Results reveal not only lack of awareness and understanding of integrating children's literature but also hesitancy and fear related to the pedagogy of integration. Results also show that the exposure to the integration model not only led to an increase in awareness, preparedness, and understanding but also translated to interdisciplinary integration in other disciplines. In addition, PSTs related using children's literature as a means to reach different learners in the classroom. The researchers propose the integration model as a useful and adaptive tool for higher education to engage PSTs in developing flexible attitude towards interdisciplinary integration.

(RE)DEFINING SMARTNESS: EXPLORING MULTIPLE ABILITIES IN ELEMENTARY AND SECONDARY MATHEMATICS TEACHER EDUCATION

Frances K. Harper
Michigan State University
harperfr@msu.edu

Barbara Swartz
McDaniel College
bswartz@mcdaniel.edu

Keywords: Equity and Diversity, Instructional Activities and Practices, Teacher Education-Preservice

Realizing equity goals in mathematics education demands effective instructional approaches that embrace student diversity and "go beyond 'good teaching,'" to ensure every student has opportunities to engage successfully with challenging mathematics content (NCTM, 2014, p. 68-69). Complex instruction (CI) offers one approach to questioning borders within classrooms around who is able to do challenging mathematics (Boaler & Staples, 2008). CI emphasizes *multiple ability tasks* that require a range of ways of 'being smart' and are *groupworthy* because they necessitate positive interdependence (Lotan et al., 1994). When students value multiple abilities as important in mathematics, they are more likely to participate eagerly and to encourage others to contribute their unique strengths.

We, two mathematics teacher educators, integrated CI into our mathematics methods courses, one elementary and one secondary, with prospective mathematics teachers (PSTs). We aimed to investigate how PSTs came to understand, enact, and recognize one slice of CI, namely, integration of multiple abilities in mathematics tasks and the recognition of different ways students can demonstrate 'smartness' in mathematics. PSTs in both courses worked in pairs or trios to design multiple ability, groupworthy tasks to learn to identify potential multiple abilities inherent in high-cognitive demand mathematics tasks and to modify these tasks to better promote collaboration and equal participation among students. The PSTs in both courses created lists of multiple abilities inherent in a high-cognitive demand task and then amended this list after revising the same high cognitive demand task to make it groupworthy. Using qualitative textual analysis, we categorized each listed ability as supporting (1) a general mathematics practice, (2) specific mathematical work of the task, or (3) productive collaboration, and compared the PSTs' initial lists with their final lists to see how they differed.

Overall, preliminary findings suggested PSTs identified vague or general abilities for the initial versions of the task, but they identified detailed abilities, grounded more firmly in the specifics of the groupworthy versions, suggesting a deepening of understanding of the different ways students can demonstrate 'smartness' in mathematics. We hope our poster will foster discussion about how changes in pre- and post-multiple abilities lists provide mathematics teacher educators, across elementary and secondary methods, insights into PSTs' understanding of groupworthy as distinct from other "good" mathematics tasks.

PRESERVICE TEACHER LEARNING TO HELP ELS UNDERSTAND MATHEMATICAL PROBLEMS

Ji Yeong I   Ricardo Martinez
Iowa State University   Iowa State University
jiyeongi@iastate.edu   ricardom@iastate.edu

There is a common belief that teachers do not need to differentiate their instruction for English Learners (ELs) and that helping ELs adjust in school culture is not a teacher's responsbility (Walker, Shafer, & Liams, 2004). This belief is due to their lack of proper training to teach ELs, as statistics show only 13% of teachers are adequately prepared to teach ELs while more than 40% of teachers have ELs in their classrooms (NCES, 2002). Responding to the great need for an adequate teacher preparation for EL in mathematics education, this study was designed to investigate preservice teacher (PSTs) learning to help ELs understand mathematics.

The problem space model (Campbell, Adams & Davis, 2007) was adapted to construct a conceptual framework for this study in order to address the following questions: (a) What strategies do middle school PSTs use to help ELs understand cognitive demanding problems? (b) In what ways do middle school PSTs change in using strategies as they worked with ELs and after they have received interventions? Three middle school mathematics PSTs volunteered to participate in this multiple-case study. Participants prepared a one-hour lesson the same week based on the same problem, each designing their own lessons. After each session, the PSTs were interviewed and provided research-based EL interventions (Chval & Chavez, 2011). The collected data (lesson plans, interviews, video, reflections, and surveys) were analyzed using *the constant comparative analysis method* (Fram, 2013). We developed a code manual after coding implemented strategies in our conceptual framework.

Data showed our intervention influenced certain strategies more than others. All of the PSTs did not consider connecting mathematics with students' life and culture before the relevant intervention. Another impact of the intervention manifested in the PSTs' use of visuals (pictures, drawings, or diagrams). They started using various visuals in more math–related ways after the related intervention. Designing a linguistically and conceptually rich lesson in order to make it accessible to ELs is an important skill for teachers of ELs. Hence, PSTs need to develop this skill in their preparation programs and consider the four components of the conceptual framework.

PRESERVICE TEACHERS' UNDERSTANDING AND USE OF COMPOSITE UNITS

Eun Jung
University of Georgia
eunjung@uga.edu

Research has shown that fractional knowledge plays a significant role in students' algebraic reasoning and whole number multiplicative structure is strongly related to fraction multiplication and division (Hackenberg, 2013). This study investigates how middle grades preservice teachers who show evidence of limitations in coordinating three composite units make sense of fraction multiplication problems involving composite units. I acknowledge a need to construct a model or hypothesis to represent their ways of their thinking (Steffe, 2010), taking into account the processes of assimilation and accommodation (von Glasersfeld, 1995). I will present one hypothesis to account for how preservice teachers who are unable to maintain composite units while partitioning and iterating may use available schemes or procedural knowledge to find correct answers in such contexts. This study draws data from a series of hour-long, one-on-one clinical interviews with ten middle grades preservice teachers attending a mathematics pedagogy course at a university in the Southeastern U.S., analyzing participants' understanding of using composite units in fraction multiplication and measurement division contexts. Interview tasks prompted students to use Java-bars 5 to visually represent their thinking as they partition bars into equal parts, pull out (disembed) parts, and repeat (iterate) them.

Analysis and Findings

Jacky was unable to maintain 3/5 as a composite unit in finding 1⁄4 of 3/5. The way she made sense of 1⁄4 of 3/5 was to create a bar as a unit, break it up into 5 columns, and pull out 3 columns. Afterward, she broke each fifth into 4 parts vertically so that she could pull out 3 parts from each fifth, without recognizing 3/5 as a composite unit (and instead treating it as a separate unit bar). Following this process, she was able to produce the correct result, but when asked to give the answer relative to the original unit bar, she had to go back to the original bar and partition all fifths into fourths to find the total number of parts in order to make a comparison between two whole numbers. Preservice teachers who are unable to maintain fractions as composite units while partitioning or iterating are able to rely instead on other existing schemes or procedural knowledge to make sense of problems involving these operations. If students conceive of partitioning and iterating along a single axis, this requires maintaining a composite unit, but students who are unable to do so may make use of two axes (partitioning both vertically and horizontally), allowing them to produce the correct result by graphically representing their mathematical calculation.

MODELING CO-TEACHING APPROACHES TO ENHANCE PRESERVICE MATHEMATICS TEACHERS' KNOWLEDGE AND SKILLS FOR TEACHING

Pier A. Junor Clarke	Alesia D. Mickle	Elijah Porter II
Georgia State University	Georgia State University	Georgia State University
pjunor@gsu.edu	amickle1@student.gsu.edu	eporter9@student.gsu.edu

In the United States, teacher educators must decide how they will respond to the increase in academically diverse populations. Likewise, the national reform for mathematics teacher education partnership (MTEP) strongly encourages secondary teacher preparation programs to rethink strategies among others in how they prepare mathematics teachers for their future classrooms. In response, co-teaching, an instructional practice that blends instructors' various teaching strengths, can be offered to provide students with differentiation and teaching support when learning mathematical concepts (Bauwens, Hourcade, & Friend, 1989).

At an urban, southeastern university, two instructors of a methods course, assigned prior to the field experience, introduced and explored with a co-teaching-for-student-teaching (CT4ST) model, which is designed to assist both cooperating teachers and preservice secondary school mathematics (PSSM) teachers as they collaborate in planning, organizing, delivering, assessing, and sharing the physical space of the classroom. The PSSM teachers then worked with their cooperating teachers using the CT4ST model to share teaching responsibilities and better meet students' needs (Bacharach & Heck, 2012).

The participants, the co-instructors and PSSM teachers, reflect on the CT4ST model integrated at both the university classroom experience and the student teaching field experience. The co-instructors as researchers examined the following research question under a constructivism framework (Ertmer & Newby, 2013): *what are the perceptions of the co-instructors and the PSSM teachers experiencing the co-teaching-for-student-teaching model (CT4ST) during the transition from course preparation to student teaching?*

With a graduate research assistant's help in interviewing and preparing the documents for analysis, the researchers coded the participants' reflections and transcribed interviews. Findings revealed that the CT4ST model integrated into both the methods course and student teaching experiences served beneficial. An instructor stated that "each member [PSSM teachers] in the small group setting took advantage of the individual attention of the instructor." Several PSSM teachers' comments confirmed that when the CT4ST model was utilized, the teacher to student ratio decreased and students received more individualized attention. Implications from this study suggest that the CT4ST model is viable to enhance the collaboration among co-instructors, PSSM teachers, and cooperating teachers. Furthermore, the researchers present an action plan to support CT4ST model work to increase teachers' knowledge and skills for teaching mathematics.

VISUALIZATION TASKS IN MATHEMATICS TEACHER PREPARATION: HOW A MATHEMATICS GAME IMPACTED PRESERVICE TEACHER LEARNING

Barbara M. Kinach
Arizona State University
barbara.kinach@asu.edu

Keywords: Teacher Education-Preservice, Technology, Instructional Activities and Practices, Learning Trajectories (or Progressions)

Innovative Visualization Tools for Learning to Teach

Digital mathematics textbooks, instructional materials integrating interactive diagrams, interactive visual examples are increasingly common in mathematics education. For what learning purposes can these innovative visualization tools be employed in mathematics teacher preparation? Exploring this question, the poster presents learning-to-teach visualization tasks based on *Spatial Temporal Mathematics,* an interactive game-based curriculum for teaching K-8 math visually without words (Petersen, 2011).

Theoretical Frame

I approach the course from a cognitive situated perspective. This means that I actively seek to elicit, develop, and assess the mathematical and pedagogical understanding of PTs through cycles of individual, small group, and whole class problem solving and interactive discussion (Simon, 2008). The visualization task is semiotically inspired (Presmeg, 2013) and builds on Bruner's (1961) theory of mathematics learning whereby mathematical abstractions and symbols evolve from carefully sequenced learning tasks whose logic progresses from visual to symbolic.

Activity, Learning Goals, Results

The ST Math Area game task consists of three levels requiring interaction between PTs and the game environment as follows: *Level 1,* given a rectangle subdivided into unit squares, PTs highlight unit squares equal in number to given rectangle's area; *Level 2,* given a rectangle subdivided into unit squares with numerical dimensions given, PTs highlight unit squares equal in number to given rectangle's area; and *Level 3,* given a rectangle and its numerical dimensions, PTs highlight unit squares equal in number to give rectangle's area. For each level PTs (1) write a learning objective*,* (2) describe how level *n+1* moves game player's mathematical thinking forward from level *n,* (3) identify math content taught, and (4) identify math standard taught.

Summary of Findings

Preliminary findings indicate ST Math visualization tasks are especially useful for learning to logically sequence learning tasks and write learning objectives.

INVESTIGATING PRESERVICE TEACHERS' CONCEPTIONS OF AND METAPHORS FOR PROBLEM-POSING AND THEIR RELATIONSHIP TO PROBLEM-POSING PERFORMANCE

Mi Yeon Lee
Arizona State University
mlee115@asu.edu

Ji-Won Son
University at Buffalo-The SUNY
jiwonson@buffalo.edu

Keywords: Teacher Education-Preservice, Teacher Knowledge

With increased interest in curricular and pedagogical innovation in mathematics education, mathematics educators have paid growing attention to problem-posing. However, the notion of problem-posing has been used with multiple meanings such as "the generation of new problems," "the re-formulation of the given problem", or "inquiry activity of persons with exceptional creativity" (Kilpatrick 1987; Silver, 1994). To understand how this critical population of future teachers perceive problem-posing and how their perceptions are reflected in their performance, this study investigates PSTs' notions of problem-posing in relation to their generation of a fraction multiplication word problem. The research questions that guided this study were: (1) How do PSTs view problem-posing?; (2) What metaphors do they use in describing problem-posing and why?; and (3) How are their notion of problem-posing reflected in their ability to pose a fraction multiplication problem?

Participants in this study were 96 PSTs in their internship year of elementary teacher preparation programs at two sites, a large northeastern university and a large southwestern university in the US. For the study, participants completed a written task consisting of two parts. In the first part, they were asked to answer three open-ended questions regarding their conception of and metaphor for problem-posing. The second part called for creating a word problem when given a fraction multiplication expression (improper fraction × whole number) and then solving their problem. For the analyses of PSTs' written responses, we used an inductive content analysis approach (Grbich, 2007). For the problem-posing task, the correctness of PSTs' responses was determined and then various strategies used and common misconceptions were explored.

Findings suggest that there was no clear connection between their views of problem posing and their problem posing abilities. However, PSTs who viewed problem-posing as a means of improving problem-solving tended to create a correct math problem in various contexts, which is consistent with prior research (Silver, 1997). The findings of this study suggest that elementary mathematics teacher education programs need to include more problem-posing activities so that PSTs can experience the benefits of problem-posing from a variety of perspectives.

Alyson. Lischka@mtsu.edu	Kristin.Hartland@mtsu.edu	Matthew.Duncan@mtsu.edu

Keywords: Instructional Activities and Practices, Teacher Education-Preservice

Letter writing activities have been implemented and studied in teacher preparation courses to research the development of teacherly-talk (Crespo, 2002), and problem-posing skills (Crespo & Sinclair, 2008; Norton & Kastberg, 2012). We consider the use of a letter writing activity in a methods class as a means to explore and develop prospective teachers' (PTs') notions for providing effective feedback when corresponding with multiple learners in individual letters. Research indicates that effective feedback, particularly feedback given without a grade (Crooks, 1988), has potential to positively influence learning (Black & Wiliam, 1998; Hattie & Timperley, 2007). Little is known concerning how PTs develop effective feedback practices to promote learning. In this study, feedback provided by PTs during a letter-writing activity between secondary PTs and high school learners, is examined to explore the question: How do the levels of feedback provided to learners by PTs vary across learners and across the letter exchange?

We define feedback as communication to a learner for the purpose of furthering their understanding and which is expected to be taken up by the learner. We adopted Hattie and Timperley's (2007) feedback framework which states effective feedback should answer the questions: "Where am I going? . . . How am I going? . . . and Where to next?" (p. 86). They further categorize feedback as focused on the task, process, self, or self-regulation and discuss the effectiveness of each type.

Data for this study were the letters exchanged between PTs and learners along with reflective papers and other methods class artifacts related to the letter exchange. Three PTs corresponded with 21 learners in an Algebra II course. PTs wrote five letters involving discussion of a problem that could be modeled with a trigonometric function. Feedback in the letters was coded according to the type of feedback provided (task, process, self, or self-regulation) and learner solutions were coded according to correctness, depth of explanation, and progress toward a solution. Corroborating and disconfirming evidence was coded throughout the additional data.

Preliminary analysis revealed that PTs provided both feedback on the task and the process but that PTs became more directive in their feedback as the exchange progressed. Insight into PTs feedback practices has potential to provide teacher educators information from which to build activities that develop feedback practices and attend to PTs existing ideas about feedback.

LANGUAGE PATTERNS OF PROSPECTIVE SECONDARY MATHEMATICS TEACHERS: A LINGUISTIC PERSPECTIVE

Janet M. Liston
The University of Arizona
jliston@math.arizona.edu

Keywords: Classroom Discourse, Teacher Education-Preservice

Mathematics education has taken up researching discourse in mathematics classrooms through linguistic approaches. This research has added to what we know about the variety of skills and language practices teachers need to create collaborative learning environments. Teachers can use interpersonal language as they interact with students to draw attention to specific mathematical content and also to build relationships with their students in the classroom. However, much remains to be understood about the ways student teachers (STs) of secondary mathematics use language to support students' engagement and interactions during shared constructions of mathematical meanings. At an interactional level of discourse analysis, I use Halliday's (1985) theory of systemic functional linguistics (SFL), drawing on a basic premise that language use is purposeful behavior, structured to make meanings through exchanges of words and grammar. For example, particular uses of pronouns can reveal personal involvements in the discourse. This study examines the ways STs *initiate* an interactive, problem-solving dialogue in secondary mathematics classrooms and the ways students *respond.*

Research Design and Findings

I video-recorded 53 conversations between three STs (all at different high schools) and small groups of algebra students working collaboratively to solve mathematical tasks. Initial passes through the data helped identify excerpts of interactional discourse patterns (IDPs) between STs and students. I have defined IDPs as two or more verbal exchanges made by students in response to initiating language moves made by the ST (statements, offers, questions, or commands). In the brief IDP example that follows, Gabe (ST) has asked a group of Algebra 2 students the question "…can *I* rewrite cosine squared in terms of sine?" (Pronouns are italicized.)

> *Barry*: So, then, *we* just replace this with cosine squared of *x* minus one. Right?
> *Ana*: … yeah, cosine squared of *x* minus one… No, *I* don't know. This is so complicated.
> *Barry*: *We* need more numbers and less letters.
> *Gabe*: *I* appreciate that.

Basic speech roles that speakers take on are either *giving* or *demanding*. Gabe initiated this IDP and demanded information by asking a question. The pronoun *I* suggested that Gabe is doing the problem solving. Barry responded with an answer but included himself in the solving process (*we*). Ana aligned her response with Barry, but then hedged by claiming '*I* don't know'. I interpreted Barry's next response to be interpersonal in nature – attempting 'lighten the mood' by implicating that students (*we*) find mathematics to have too many variables. While not agreeing with Barry, Gabe responded that *he* understood Barry's perception that the abstract nature of variables can complicate students' understandings. Examining IDPs can reveal meanings not only related to mathematical content but also to interpersonal relationships, attitudes, and roles.

UNDERSTANDING PRE-SERVICE TEACHERS' BELIEFS ABOUT MATHEMATICS

Mary Elizabeth Riley Lloyd
College of Charleston
lloydb@cofc.edu

Nenad Radakovic
College of Charleston
radakovicn@cofc.edu

Among education literature, one of the most prolific categories of research is teacher beliefs (Cochran-Smith et al., 2015). Within both the classical and contemporary belief literature, traditional cultural beliefs, also known as unproductive beliefs, are cited as a major limiting border or obstacle in reforming mathematics classrooms toward the National Council of Teachers of Mathematics (NCTM) vision of excellence and equity and toward the actualization of the federal mandate to effectively implement challenging State standards. NCTM's most recent publication Principles to Action (2014) reports, "Dominant cultural beliefs about the teaching and learning of mathematics continue to be obstacles to consistent implementation of effective teaching and learning in mathematics classrooms (Handal 2003; Philipp 2007)" (p. 10).

The purpose of this study was to thoroughly examine pre-service teachers' normative beliefs at the completion of their preparation program, investigating (a) how they compare to discursive claims, (b) how they transformed over time, (c) whose transformed, and (d) potential influencing factors such as content knowledge. Results were intended to help mathematics educators determine (a) how to best address the obstacle of unproductive beliefs, determining where to focus efforts to maximize the potential for transforming the traditional mathematics classroom culture toward the reform-based, innovative culture advocated by NCTM; (b) what traditional conceptions of teaching, learning, and the nature of mathematics are the most deeply rooted and challenging to change; and (c) what novice-teacher challenges can be discussed explicitly during pre-service preparation to assist novice teachers in negotiating the tensions between reform-based and traditional pedagogical practices and conceptions of teaching and learning mathematics. Too, results were intended to help educators better pinpoint who needs greater scaffolding in shifting their beliefs. The study's guiding questions included: What do pre-service teachers believe about teaching mathematics, the nature of mathematics, and their abilities to teach mathematics? and How are these beliefs transformed during their pre-service preparation?

To answer the guiding questions thoroughly, a mixed methods approach was employed. Statistical analysis of three iterations of a Likert-scale survey was conducted. Open-ended survey responses, lesson-plan data, reading responses, responses to reform-based mathematics classroom video clips, archival data were analyzed to identify common themes and compare to the quantitative analysis, and a typology analysis was conducted using all of these data sources, for which individual cases were identified as representative of each "ideal" type of belief transformation/transmission that emerged from the analysis (Ayres & Knafl, 2008). All pre-service teachers (n=85) entering the undergraduate, early-, elementary, and middle-level education programs as juniors in August 2011 were asked to participant in the study.

PRESERVICE TEACHERS DEVELOPMENT OF AN UNDERSTANDING OF FUNCTION USING DIFFERENT METAPHORS

Jennifer N. Lovett
Middle Tennessee State University
jennifer.lovett@mtsu.edu

Allison W. McCulloch
NC State University
allison_mcculloch@ncsu.edu

Keywords: Technology, Algebra and Algebraic Thinking

Functions are widely regarded as the unifying element of much of secondary mathematics and are a critical base for a mathematical understanding of the STEM disciplines. This is recognized in the Common Core mathematics standards where the study of functions is given its own category, separate from Algebra, in grades 9–12 (National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010). The curricular and logistical obstacles to putting function front and center are challenging enough, but conceptual obstacles have been well documented in the literature (e.g., Arnon et al., 2013) and prove particularly hard to overcome. Rather than constructing their own definition of function based on tasks, students are often presented with a highly theoretical definition, resulting in a disconnect between their concept definition and their concept image (Even, 1990). Thus it is important that teachers have a deep conceptual understanding of functions and understand how to engage students in tasks to develop their own definitions.

The goal of this study was to examine the ways in which preservice teachers (PSTs) definition and understanding of function changed as they engaged in a sequence of technological tasks that utilized different representations of functions. The sequence began by asking PSTs to each write a definition of a function and provide examples and non-examples. Then PSTs engaged in two technological tasks, "Identify Functions" (adapted from Steketee & Scher, 2011) and "Function Machine" (McCulloch, Lee, & Hollebrands, 2015) that utilized different representations and metaphors of functions. Following the task sequence PSTs were again asked to provide a definition of function and reflect on the different metaphors and representations of functions presented in the tasks. Analysis of PSTs' definitions revealed that though they had extensive mathematics backgrounds, very few had a correct concept image or definition of function at the start. The removal of quantitative characteristics (i.e., no numerical, graphical, or equation representations) in the tasks seems to have allowed the PSTs to focus on the relationships as objects, rather than just processes, which proved helpful correcting their concept image and definitions. Further analysis will be conducted on how PSTs' engaged with the "Function Machine" task and how that task impacted their understanding of function.

Introduction

Mathematics teacher educators (MTEs) are uniquely positioned to support pre-service teachers (PSTs) in pushing against mathematics education's "long history of giving access to students differentially, particularly based on the ideological construction of race" (Battey, 2013, p. 332). Martin (2013) asks "how can we more effectively partner with teachers to uncover and understand the external forces that position them in ways where their teaching and classroom practice are put in service to larger political projects and ideologies?" (p. 328). As critical mathematics educators, we are deeply concerned with the borders within mathematics that limit access to mathematics and deeply divide our students. As such, we ask what is the role of MTEs in developing awareness and agency regarding issues of equity for elementary PSTs?

Project Background

This project began as a collaborative review of the article *"A Possessive Investment in Whiteness": Access to Mathematics* (Battey, 2013). In that article, Battey highlighted the systemic marginalization of students of color in mathematics education by "analyzing national data to calculate the wage-earning differential attributable to differences in mathematics coursework by ethnic/racial groups across three time points: 1982, 1992, and 2004" (p. 332). He exposed the "differential access to mathematics" found within the data is connected with projected economic stratification based on race. We designed a social justice mathematics methods learning module that combined findings from the article and relevant mathematical content and practice standards. The learning module was used with approximately 100 PSTs at two public universities, one in Mississippi and one in New York. Quantitative and qualitative data from engagement in the module were collected and analyzed.

MTEs must understand how to breakdown the borders by developing PST awareness of the inherent power toward academic and economic opportunities that exist within the position of mathematics teacher. While many MTEs may want to teach for social justice, incorporate critical mathematics material in their courses, and encourage conversations about equity in, there may be a lack of time, resources, and support for this work (Gutstein, 2007), not to mention navigating the difficulty of doing this work well (Bartell, 2013). This poster session will provide a necessary space for critical dialogue about doing this work.

PRESERVICE TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING (MKT) AND KNOWLEDGE OF CONTENT AND STUDENTS (KCS)

Michael Singer Meagher
Brooklyn College - CUNY
MMeagher@brooklyn.cuny.edu

Michael Todd Edwards
Miami University
edwardm2@miamioh.edu

lee.1129@osu.edu

One of the principal challenges facing teacher candidates in mathematics education is making the shift from "student" to "teacher." This transition requires teacher candidates to reorient from thinking about how they solve mathematics problems to engaging with students and their work, understanding student representations, and asking questions to guide students to move their thinking forward.

In order to scaffold this transition, we developed a five-step approach that we call the Mathematics as Teacher Heuristic (MATH). In the MATH heuristic, candidates complete the following five-step process involving increasingly teacher-centric tasks.

Our identification, from an earlier study (Meagher, Edwards, Ozgun-Koca, 2013), of the engagement with student work as a key juncture in the MATH heuristic led us to use the Professional Noticing Framework of Jacobs, Lamb & Philipp (2010) as an analytic tool to examine and understand teacher candidates' developing KCS and MKT as shown in their engagement with the student work.

The twenty-one participants in this study were undergraduate students enrolled in the second course of a year-long methods sequence for prospective secondary mathematics teachers. This course was built upon candidates' initial experiences with planning and assessment activities in the previous semester. The MATH heuristic was employed early in the semester.

The Noticing Framework of Jacobs et al (2010) was a useful analytic tool for us to be able to see the development of candidates' pedagogical knowledge and also to identify the deficiencies, and some successes, in the candidates' deep engagement with the mathematical thinking of the students which is to say deficiencies in their KCS and MKT. No candidate discussed explicitly patterns of misconceptions across the more than 100 student samples and, in our analysis we saw cases where candidates were unable or unwilling to *notice* and *interpret* student thinking. The data shows that the kind of analysis that would show strong MKT does not seem to come naturally to students but their development in this area is vital if they are to become effective teachers. We plan for an adjustment in the prompts for the MATH heuristic with a requirement to describe trends in student learning as, indeed, is asked for in the edTPA.

EXAMINING POTENTIAL SUPPORTIVE FACTORS IN HELPING PRE-SERVICE TEACHERS SELECT SOLUTION STRATEGIES FOR CLASS DISCUSSIONS

Erin Meikle
University of Pittsburgh
emeikle@pitt.edu

Keywords: Teacher Education-Preservice, Teacher Knowledge, Classroom Discourse

One goal of mathematics instruction is to support students' learning of concepts (Fennema & Romberg, 1999). A set of five practices (anticipating, monitoring, selecting, sequencing, and connecting) is intended to support teachers in planning for and facilitating class discussions around solution strategies to cognitively challenging tasks in ways that will build up to a conceptual learning goal (Stein, Engle, Smith, & Hughes, 2008). The selecting practice might be especially critical because the mathematics students are exposed to depends on which solution strategies are shared during the class discussion. However, purposefully selecting solution strategies in ways that will promote a conceptual learning goal might be difficult for pre-service teachers (PSTs) because they typically lack understanding to be able to identify how solution strategies relate to mathematical concepts (Peterson & Leatham, 2009) and do not spontaneously unpack learning goals into their underlying concepts (Morris, Hiebert, & Spitzer, 2009).

The purpose of this study was to explore whether and how two factors (content knowledge and the grain size of a learning goal) might support pre-service teachers in selecting solution strategies for class discussions in ways that will promote concepts underlying a learning goal. PSTs (N=61) in an elementary mathematics methods course first completed a content knowledge instrument aimed to assess their content knowledge related to division of fractions and, in a second sitting, completed a selecting task where they were asked to select solution strategies to a division of fractions mathematical task and provide rationales for their decisions. Thirty-one PSTs were randomly assigned to a condition in which the learning goal on the selecting task was unpacked down to its underlying concepts and 30 PSTs were randomly assigned to a condition in which the learning goal was stated in its general form only on the selecting task.

The main finding from this study was that when PSTs possessed higher content knowledge or had selected solution strategies designed to be likely to promote the concepts underlying the learning goal, they were more likely to justify their selecting decisions with reasons related to these concepts. This finding suggests that which solution strategies are selected for a class discussion matters and that teacher educators need to find ways to support PSTs in identifying relationships between solution strategies and the concepts underlying the learning goal.

ASSOCIATION BETWEEN PRESERVICE TEACHERS' MINDSET AND OBJECTIVIZATION IN MATHEMATICS

Lucy Hernandez Michal
The University of Texas at El Paso
lmichal@miners.utep.edu

Keywords: Learning Theory, Teacher Education-Preservice, Teacher Knowledge

Purpose

The purpose of the study was to determine if mindset for learning mathematics could be identified in preservice teachers and if it could, what impact did mindset (Dweck, 2006) have on preservice teachers' ability to identify objectives for a lesson.

Research Question

What objectives do preservice teachers with growth or fixed mindset identify in math lessons?

Theoretical Framework

The study uses Uznadze's (1966) levels of mental activity by likening Uznadze's level of set to Dweck's fixed level of thought (2006) and likening objectivization, Uznadze's second level of thinking (1966), to Dweck's growth level of thought (2006). For Uznadze (1966), two planes of reality affect behavior: external reality (the world around us) and verbal reality (the world represented in words); this may be likened to an external domain and an internal domain where each contributes a level of thought and each develops language differently. Important to learning is that teachers recognize both levels of thought to maximize learning experiences.

Methods, Methodology, and Data

 The research was conducted as a case study of four preservice teachers in mathematics methods courses at a university in a predominantly Hispanic community. Data included content knowledge, mindset (Yeager, In Review), narratives describing lesson objectives, and individual interviews. Participants interviewed represented four profiles: high content knowledge, growth mindset, high match to expert objectives; high content knowledge, fixed mindset, high match to expert objectives; low content knowledge, growth mindset, high match to expert objectives; and low content knowledge, fixed mindset, high match to expert objectives.

Results and Significance

Mindset is measureable. Four themes emerged as knowledge needed to be effective teachers: 1) teachers' roles include more than teaching content, 2) knowledge of process standards to engage students, 3) knowledge content to recognize mathematical thinking and clarify misconceptions, and 4) using time effectively. Objectives identified included mostly process standards. Teachers as helpers emerged above teaching any kind of mathematical content or any other purpose. Participants with growth mindset identified expert lessons objectives.

PRE-SERVICE TEACHERS' DEFINITIONS OF QUADRILATERALS: CHALLENGING ASSUMPTIONS ABOUT TRANSITION FROM HIGH SCHOOL TO TEACHER PREPARATION

Susanna Molitoris Miller
Kennesaw State University
smolitor@kennesaw.edu

Keywords: Teacher Education-Preservice, Geometry and Geometrical Spatial Thinking, Learning Theory

Many studies in pre-service teacher education assume that novice pre-service teachers (NPSTs) have conceptions of mathematics similar to those held by elementary or high school students. Constructivist theory (Fosnot & Perry, 1996) suggests that teacher preparation programs might best-support NPSTs' learning by first understanding the specific kinds of mathematical ideas NPSTs hold when beginning their studies in a teacher preparation program. However, relatively little research has been done in this area (Thanheiser, Browning, Edson, Kastberg & Lo, 2013). In this study I explore how NPSTs define various types of quadrilaterals reflecting hierarchical or partitional classifications and what implications these analyses have for mathematics teacher educators (MTEs).

Forty-four NPSTs each provided a definition for rectangle, rhombus, parallelogram, trapezoid, and kite. Each definition was coded into one of three categories. (1) *Partitional* definitions described a relationship among shapes in which no quadrilateral type could be considered a sub-category of another (deVilliers, Grovender and Patterson, 2009). (2) *Hierarchical* definitions did include another class of shapes as a sub-category of the shape being defined (deVilliers, Grovender and Patterson, 2009). (3) *"Not functional"* was used to describe definitions which did not provide an accurate partitional or hierarchical description of the shape.

Analyses revealed forty-four partitional definitions (20%), forty-one hierarchical definitions (19%), and the remaining one hundred thirty-five definitions classified as "not functional" (61%). The large percentage of "not functional" definitions shows that many NPSTs need to review basic quadrilateral types. The findings also suggest that although we often assume NPSTs consider shapes only in a partitional classification (Fujita, 2012), nearly half of all functioning definitions provided were hierarchical in nature. This provides a starting point for MTEs when introducing the hierarchical classification. More detailed results for each shape type can also help MTE's when reviewing types or selecting and sequencing tasks involving hierarchy. There is a need for continued examination of what kinds of conceptual mathematical knowledge NPSTs bring as they traverse the border into teacher preparation programs.

FACILITATING CLASSROOM DISCOURSE: A PROJECT DESIGNED TO HELP PRESERVICE TEACHERS IMPLEMENT HIGH-COGNITIVE DEMAND TASKS

Michelle Morgan
University of Northern Colorado
Michelle.Morgan@unco.edu

Robert Powers
University of Northern Colorado
Robert.Powers@unco.edu

Introduction

Standard one of the *Standards for Mathematical Practice* states that students should be able to "make sense of problems and persevere in solving them" and mathematically proficient students "can understand the approaches of others to solving complex problems and identify correspondences between different approaches" (National Governors Association Center for Best Practices and Council of Chief State School Officers, 2010, p. 6). Stein and Smith (1998) argue that the ways in which tasks are actually presented and implemented to students have an important impact on what students actually learn from completing those tasks.

Methodology

In working with our preservice teachers, we have found that many of them struggle to present tasks in ways that promote the type of learning advocated by the Common Core. As a result, we created a class project focused on promoting the use of high-cognitive demand mathematics tasks to facilitate classroom discourse during the preservice teachers' field experiences. The purpose of this qualitative study was to explore the circumstances which impacted the successful implementation of this project.

The Setting and Participants

This research study took place at a four-year university in the Rocky Mountain region. The participants were enrolled in a methods for teaching secondary mathematics course. Six of the eight enrolled students in the class agreed to participate in this study. All of the participants were completing their field experience practicums in either a middle or high school setting.

Data Collection and Analysis

All project documentation was collected from participants; including their anticipated student solutions, lesson plan, video-recorded lesson, and lesson reflection. In addition, a semi-structured, simulated recall interview was conducted with participants shortly after teaching their lesson. An open coding process was used to develop themes across all participants.

Results and Discussion

Data analysis suggested that issues relating to (1) lack of supportive classroom norms, (2) lack of host teacher support and buy-in, and (3) conflicting student teacher beliefs impacted the success of the project. The research team believes that the results of this study can inform how mathematics teacher educators can better support pre-service teachers in the field.

ELEMENTARY PRESERVICE TEACHERS' PERCEPTIONS OF EXPERIENCING A REFORM-BASED NUMBER CONCEPTS COURSE

Mary A. Ochieng
Western Michigan University
maryachieng.ochieng@wmich.edu

Keywords: Teacher Education-Preservice, Number Concepts and Operations

In line with reform efforts in mathematics education, teacher educators are designing mathematics courses that allow preservice teachers to experience reform-based learning with an emphasis on sense making and conceptual understanding (e.g., Thanheiser, 2015). However, unlike the typical learner in school, elementary preservice teachers bring to their elementary education mathematics courses a sense that they already know what they are being asked to learn (e.g., Thanheiser, Philipp, Fasteen, Strand & Mills, 2013). Familiarity with the concepts being taught may create apathy and hinder preservice teachers from fully benefiting from reform-based courses. To better understand the challenge this may pose, this poster explores the research question: What are elementary preservice teachers' (PSTs) perceptions of experiencing reform-based learning for the first time in an elementary number concepts course?

To answer this question, 18 PSTs at a large Mid-western university were interviewed towards the end of their number concepts course, the first mathematics content course in the elementary teacher education program. The interview included questions about their expectations as they came into the course, their perceptions of their competence at the beginning and end of the course, and how their thinking changed about the content in the course. The interviews were transcribed and read for common themes across the interviews. Themes included discomfort with a new way of thinking, surprise at the number of different ways one can do math, and a new understanding of the meaning behind operations. Once the themes were identified, each interview was coded for evidence of those themes. Analysis of the data revealed that going through the reform-based course was an experience that perturbed their understanding of elementary school mathematics and what they thought they knew about it. In addition, despite their initial reluctance, by the end of the course the majority of the PSTs developed an appreciation for learning mathematics with meaning.

The results of this study highlight the importance of supporting PSTs, as they go through the challenging process of transitioning from the routine learning of their own school experiences to learning mathematics with understanding and provides some insight into ways teacher educators can provide that support.

INTERPRETING "STANDARD" PROPORTION EQUATIONS IN TERMS OF A QUANTITATIVE DEFINITION FOR MULTIPLICATION

Ibrahim Burak Ölmez
University of Georgia
i.burakolmez@hotmail.com

Sybilla Beckmann
University of Georgia
sybilla@math.uga.edu

Keywords: Teacher Knowledge, Teacher Education-Preservice, Algebra and Algebraic Thinking, Number Concepts and Operations

The purpose of this study was to examine how 5 future middle grades mathematics teachers interpret proportion equations in terms of quantities, especially when they were prompted to consider a definition of multiplication. In the present study, we focus on "standard" proportion equations of the form $7/4 = Y/X$ and $X/4 = Y/3$ in which there are exactly two numbers and exactly two letters. Although many studies have demonstrated that both students and teachers formulate standard proportion equations even when such an equation is not normatively correct (e.g., Jacobson & Izsák, 2014), we know of no study that has examined whether students or teachers can interpret these equations in exactly two letters when such an equation does apply.

The present study's framework is based on a quantitative definition of multiplication presented by Beckmann and Izsák (2015), so the quantities in the multiplication equation $A \cdot B = C$ can be interpreted as follows: A is the number of equal-size groups, B is the number of units in 1 or in each group, and C is the number of units in A groups. This definition of multiplication leads to two solutions to problems involving "standard" proportion equations using the variable parts perspective and strip diagrams. Data for this paper come from an ongoing project of future middle grades (grades 4-8) mathematics teachers' ecology of multiplicative reasoning. Beckmann taught a cohort of future teachers for two semesters in 2014-2015. In the first semester, the instruction developed the quantitative definition of multiplication. In the second semester, the future teachers reasoned with the variable parts and multiple batches perspectives on proportional relationships (Beckmann & Izsák, 2015) and developed algebraic equations by reasoning about relationships among quantities. Six future teachers were recruited based on their performance on a fractions survey that focused on multiplication and division with fractions. Data for the present study consist of one-on-one cognitive interviews conducted with 5 future teachers at the end of the second semester.

The main finding we report is that the explicit use of the definition of multiplication facilitated future teachers' interpretation of "standard" proportion equations in terms of quantities. Strip diagrams were found to be useful because they support those teachers' thinking about "how many of these are in that" language, which is critical for interpreting these equations.

ELEMENTARY MATH PROSPECTIVE TEACHERS AND RELATIONAL EQUITY

Byungeun Pak
Michigan State University
pakbyun1@msu.edu

Keywords: Teacher Education-Preservice, Equity and Diversity

Teacher preparation programs hold a responsibility for supporting prospective teachers (PSTs) to engage in practices that support equity in their future teaching. In particular, relational equity, which means more equitable relationships through mutual respect among students in groups (Boaler, 2008), is one dimension of equity that elementary mathematics PSTs need to make sense of as they learn to teach for mathematical understanding.

Greater attention to relational equity holds promise for supporting PSTs to cross borders of status, race, class, etc. to create more equitable classrooms in their future teaching. Strategies for teacher educators to highlight relational equity can emerge from deeper understandings of how PSTs perceive what students experience in small groups in mathematics classrooms, but researchers have not specifically paid attention to how elementary mathematics PSTs perceive students' experiences in small groups regarding relational equity. The research questions of this project are, therefore, how do elementary mathematics PSTs perceive elementary students' experiences in small groups and how do those perceptions connect to relational equity.

This project took place in a mathematics methods course for elementary PSTs in their senior year in a teacher preparation program of a large Midwestern university. Data sources included two semi-structured interviews with 3 senior PSTs and written artifacts from coursework (e.g., math stories, written lesson plans). The first interview investigated what the PSTs noticed about students' experiences in two episodes of students' inequitable participation from existing equity-related research (Bishop, 2013; Langer-Osuna, 2011). The second interview examined what the participants envisioned in lesson plans they created with respect to students' participation in small groups.

According to data analysis using thematic analysis (Glesne, 2016) to identify emerging themes across interviews and written artifacts and to identify possible implications for the PSTs' preparation to support relational equity, the participants noticed status issues to some extent in student interactions in written cases, and it is uncertain that they envisioned deeply the inner workings of small groups in terms of their lesson plans, and their life experiences in mathematics seemed to influence their perceptions of participation in small groups.

Investigating PSTs' perceptions can help teacher educators delve into ways to support PSTs' understanding of relation equity. Teacher educators in elementary methods courses can build on PSTs' perceptions to encourage, challenge, or disrupt PSTs with regard to elementary students' experiences in small groups.

PROSPECTIVE TEACHERS' NOTICING OF MATHEMATICS IN PLAY

Amy Noelle Parks
Michigan State University
parksamy@msu.edu

Kathryn Appenzellar
Michigan State University
appenze2@msu.edu

Keywords: Early Childhood Education, Teacher Education-Preservice, Teacher Knowledge

The importance of play in early childhood classrooms for learning broadly and in mathematics in particular has been recognized widely and for a long time. For example, in their joint statement the National Council of Teachers of Mathematics and the National Association for the Education of Young Children (2002, p. 3) encouraged teachers to provide "ample

time, materials and teacher support for children to engage in play, in a context in which they explore and manipulate mathematical ideas with keen interest." However, despite this and similar recommendations, prospective early childhood teachers have few opportunities to learn about supporting mathematical engagements during play (Parks & Wager, 2015). The purpose of this study is to investigate what prospective elementary teachers at the student teaching stage notice in videos of mathematical play taken in prekindergarten and kindergarten settings. To guide the study, we used the construct of professional noticing (e.g., Jacobs, Lamb, & Phillip, 2010), which provided a framework for investigating how prospective teachers made sense of play in classrooms. Jacobs, Lamb, and Phillip (2010, p. 169) defined professional noticing as an "expertise" of "interrelated skills including (a) attending to children's strategies, (b) interpreting children's understanding, and (c) deciding how to respond on the basis of children's understanding." Early childhood contexts present special challenges for teachers in noticing mathematical engagements because of the unpredictability of play contexts.

Data collection and analysis for this study are ongoing. To date, 30 elementary student teachers have completed an online, open-ended survey that was distributed through their science education methods course. All of the students had previously completed two mathematics education courses at a large public university. The goal of the study is to have a minimum of 50 completed surveys. The survey contains 12 open-ended questions that ask respondents to write about the mathematical ideas they see in videos or photos of children's play. For example, one question asks respondents to view a video of a child folding doll clothes and to name the mathematical ideas that a teacher could highlight in such play. Data analysis will seek to identify patterns through coding and data matrixes (Miles, Huberman & Saldaña, 2014) with the goal of describing what the respondents attended to in the play and their proposed strategies for responding. Informal analysis of the early results shows that respondents more frequently attended to mathematical topics common in middle and upper elementary grade levels (e.g., fractions) than topics central to early childhood (e.g., composing and decomposing.) The analysis will provide insight into the ways in which an elementary preparation program has and has not supported prospective teachers' abilities to notice mathematics in play.

UNDERSTANDING TEACHER EFFICACY FOR ELEMENTARY SCHOOL PRESERVICE TEACHERS

Jamie S. Pyper   Stephen Macgregor
Queen's University   Queen's University
pyperj@queensu.ca   11sm36@queensu.ca

In a distinctly mathematics context (e.g., teachers with a great deal of mathematics content-knowledge teaching secondary school mathematics courses) teacher efficacy often increases significantly and shows significant relationships to other meaningful constructs such as teacher concern and teacher orientation. Considering an often limited mathematics content-knowledge background for elementary school preservice teachers (EPTs), what can be said about their teacher efficacy when they consider their classroom teaching of mathematics?

Teacher efficacy is a belief teachers carry about their abilities to perform in a classroom, that is, as a teacher with students. Teacher concern is a nested construct with self-concerns at the centre, surrounded by task-concerns, and finally encompassed by impact-concerns. Teacher orientation is a conceptualization of preservice teachers' attitudes toward their teaching, in this case, the teaching of mathematics. Preservice teachers may express single or combinations of concerns and/or orientations as they reflect on their preservice learning. (See Pyper, 2014, for a more comprehensive explanation of this conceptual framework.)

The data presented here is the quantitative data set from an ongoing multi-year mixed methods study. Data was collected four times for teacher efficacy and teacher concern, and three times for teacher orientation from two different teacher preparation program iterations in the same university. A small twelve-item scale known to accurately measure teacher efficacy, the Teachers' Sense of Efficacy Scale (TSES) (Tschannen-Moran & Woolfolk Hoy, 2001), served as the basis for the questionnaires EPTs completed at each phase of data collection. The online questionnaire also included two short answer questions, a) about the concerns they had about teaching, and b) about the contributions they felt had an important effect on their teacher efficacy (used for exploring orientation). Teacher concern and teacher orientation data were quantitized from short answer responses into ordinal variables. Descriptively, graphs of teacher efficacy, teacher concern, and teacher orientation show distinct and interesting increases and decreases over time suggesting a developmental pattern to EPT learning. Statistical analyses show significant change in the increase of teacher efficacy over time, significant change for teacher concern over time, and significant change of teacher efficacy over teacher concern.

Collectively, these statistical analyses and descriptive graphs allow for a complex interpretation of the development of EPTs' teacher efficacy, and show promising insight into changes over time in a teacher preparation program. Further replications of this study over future years will add to the data pool and potentially refine the results of the changes in teacher efficacy and its related constructs, and improve our understanding of the changes that occur.

Keywords: Problem Solving, Teacher Education-Preservice, Teacher Knowledge

While several studies have focused on students' problem solving strategies (Hmelo-Silver, 2004), pre-service teachers' conception of problem solving as a part of teaching and the curriculum has received inadequate attention. According to Dooren, Verschaffel, and Onghena (2003), although pre-service teachers can utilize various problem solving strategies, their flexibility with multiple strategies is often limited and does not improve during their traineeship. These researchers also show that pre-service teachers prefer algebraic approaches both in solving problems on their own and in evaluating student's work. This lack of variety in heuristics can hinder a teacher's ability to work with students' problem solving strategies.

This study sought to compare problem solving strategies of prospective mathematics teachers across grade bands, looking at elementary, middle, and secondary teachers focusing on similarities and differences observed while they worked on non-routine mathematics problems. Using Schoenfeld's (1985) conception of problem solving, the resources and heuristics used by teachers were investigated. Also, the impact of control on their problem solving was studied.

For the purpose of this study, task-based interviews (Goldin, 2000) were used to elicit the thinking of PTs. Three PTs from each grade band participated in the study comprised of one video-recorded task-based interview. Using Schoenfeld's (1985) model the data were analyzed at an individual problem level first, then broaden to a grade band view in order to compare across prospective teachers who intend to work with different grade bands. The outcomes of the research indicated that resources that were brought to the problems by all nine PTs were fairly consistent despite their varied mathematical backgrounds, raising questions about mathematical preparation. The use of control appears to be based on a PT's strength of resources and confidence in the problem, and the use of heuristics appeared to be subconscious for all PT''s.

While this shows their strength as problems solvers who are able to use various methods to approach a problem, it raises concern about their ability to help students become better problem solvers. As the design of the interviews did not ask the participants to be explicit about their methods of solving the problem, future studies should look to understand the awareness of PTs about their own problem solving.

ANALYSIS OF PRE-SERVICE TEACHERS' GENERALIZATION AND JUSTIFYING STRATEGIES IN SOLUTIONS TO PATTERN-GENERALIZATION TASKS

Meghan Sebranek
Marquette University
meghan.froh@marquette.edu

Marta T. Magiera
Marquette University
marta.magiera@marquette.edu

Findings from research with pre-service teachers (PSTs) document that PSTs have difficulties generalizing and justifying pattern generalizations, particularly for far generalization tasks (Hallagan, Rule, & Carlson, 2009). In order to help their future students learn about, analyze, generalize, and justify pattern generalizations, they need substantial learning to overcome their own difficulties in this area.

We analyzed 37 PSTs' written solutions to four figural pattern generalization tasks, video recordings of class discussions, and audio-recordings of problem-based interviews during which the PSTs were asked to solve one pattern generalization task, to answer the following research questions. (1) *What relationships and structural aspects of a figural pattern do PSTs build upon to formulate pattern generalization?* (2) *How do they utilize uncovered relationships and structural aspects of a figural pattern to justify their general rules?*

The results revealed that PSTs generalized by building on the structural aspects of a figural pattern or by using numerical information they collected about the task. With respect to the structural aspects of a figural pattern, PSTs focused on the changing or invariant pattern characteristics. We classified the generalizations that were developed with attention to the figural pattern structure as (a) holistic analysis of change in pattern structure, (b) decompositions of pattern structure into chunks and analysis of change in structural chunks, (c) holistic analysis of invariant and changing aspects of pattern structure, and (d) decompositions of pattern structure into chunks with a focus on their invariant and changing aspects. At the beginning of the semester, 37% of PSTs generalized patterns by drawing on their understanding of figural pattern structure compared to 67% of PSTs who generalized patterns in this manner at the end of the semester. The higher proportion of PSTs who analyzed pattern structure to develop their rules at the end of the semester was statistically significant at the 0.05 level; $z = 2.602$. Across analyses of PSTs' written solutions to all figural pattern tasks, the PSTs' ability to justify their general rules was highly correlated with their understanding of the pattern structure; $r = 0.766$, $p < 0.01$. This study contributes to the ongoing discussion about ways of supporting grades 1-8 PSTs' ability to generalize and justify.

A COMPARISON OF INSTRUCTOR AND SECONDARY PRESERVICE TEACHER NOTICINGS USING CONCEPT MAPS

Fahmil Shah
Boston University
fshah@bu.edu

Aaron Brakoniecki
Boston University
brak@bu.edu

Concept maps are a visual tool which illustrate connections between ideas around a topic (Novak & Gowin, 1984). In mathematics education, it has been shown that concept maps are an effective way to capture student understanding in ways not possible with more traditional forms of assessment (Williams, 1998). Using concept maps as a formative assessment tool in mathematics education has many opportunities for reflection, both on the part of the learner and on the part of the instructor (Kinchin, 2014). Whether students are reflecting on their own understanding and identifying opportunities for new learning, or instructors are assessing student understanding to inform future coursework, the first step is to determine what connections are being made in the content via what is represented in the concept maps. However, it's not clear that the ways in which students read and reflect on their own understanding as represented in concept maps is the same as the way instructors read and reflect on these same tools.

A concept mapping task was given to fifteen mathematics preservice teachers enrolled in a graduate level Algebra content course for teachers in a university in the northeastern United States, one during the first course meeting at the beginning of the semester, and one during the final course meeting at the end of the semester. Additionally, students were asked to reflect on the differences they noticed in their pre and post concept maps, and the course instructor examined on all students' pairs as well. The reflections of the students and the instructors were then compared for similarities and differences in content and theme. Although our previous quantitative analysis found that the concept maps produced by the preservice teachers increased in both size and complexity over the semester, we found that increases in size did not necessarily appear to correspond to an increase in the depth of student understanding. This highlights the tension between the efficiency of quantitative analysis of concept maps and the limitation of using them for summative assessment. Thus, the power of concept maps lie in their use as a formative assessment tool, focusing attention on the depth and quality of the content and connections within the map.

This poster highlights what students in the class noticed when analyzing their concept maps, what the course instructor noticed, and the differences and similarities between them. This poster adds a unique perspective, combining a metacognitive perspective of the preservice teachers with the formative assessment perspective of the course instructor.

DESCRIPTION AND INITIAL RESULTS OF THE PRESERVICE TEACHERS SEMINAR "ÜBERPRO_WAHRSCHEINLICHKEITSRECHNUNG" – UNDERSTANDING THE SECONDARY-TERTIARY TRANSITION

Gero Stoffels
University of Siegen
stoffels@mathematik.uni-siegen.de

Keywords: Affect, Emotion, Beliefs, and Attitudes, Probability, Reasoning and Proof, Teacher Education-Preservice

The secondary-tertiary transition in STEM Education is a well-known, but still unsolved problem (Holdren & et al., 2012). The proposed poster is focused on the question of how we can improve our understanding of the transition that pre-service teachers experience and support them in challenging it. Additionally, the poster presents initial results based on students' research/learning journals. A theoretical framework based on a network of theories (Bauersfeld, 1983; Schoenfeld, 1985; Gopnik & Meltzoff, 1997; Balzer, Moulines, & Sneed, 1987; Burscheid & Struve, 2010) was constructed for specifying the stated question, and which made it possible to formulate the following hypothesis describing the research perspective on the transition process. The change from an empirical-concrete to a rather formal-abstract belief system of mathematics constitutes a crucial obstacle for the transition from school to university. On epistemological grounds, similar changes regarding different natures of mathematics can be described for the history of mathematics. The explicit analysis of the historical genesis provides support for students dealing with their individual transition processes.

To test this hypothesis I developed an intervention seminar, which took place at University of Siegen in winter 2015-2016 (14 weeks/sessions) with approximately 20 participants, who were just about to finish their bachelor's degree. The main sources I used for making the students aware of different views on mathematics were the "Foundations of Probability" by A.N. Kolmogorov (Kolmogorov, 1973) and the "Lectures on Probability" by R.E. von Mises (Mises, 1945), which are prototypical examples of a formal and an empirical view on mathematics. The methodology for analyzing this seminar is the case study research approach by Stake (Stake, 1995), and is based mainly on the participants' own research/learning journals.

PRE-SERVICE TEACHERS ENGAGED IN TEAM TEACHING AND COLLECTIVE OBSERVATION USING THE MATHEMATICS QUALITY OF INSTRUCTION

Jennifer Suh
George Mason University
jsuh4@gmu.edu

Melissa Gallagher
University of Louisiana at Lafayette
mxg6401@louisiana.edu

In this study, we examine pre-service teachers' experiences in their hybrid fieldwork experiences in a Professional Development School (PDS), specifically examining the impact that using the Mathematical Quality of Instruction (MQI; Learning Mathematics for Teaching, 2014) instrument has on their collaborative planning and collective observations. In particular, the authors highlight the nature of the professional learning that takes place from the shared experiences, the reflective dialogue, and making teaching public through team teaching. We explored the following research questions:

1. How did the collaborative planning and collective observation using MQI enhance teacher candidates planning and teaching?
2. What were the affordances of a Professional Learning Team model in a Pre-service teacher education methods course?

The recurring themes included: a) Learning from one another and finding instances of Mathematics Quality of Instruction in their peer teaching. Through the co-teaching activity, our teacher candidates had the opportunities to watch their colleague respond to the teaching episode "live". By having the group lessons videotaped and on Edthena, pre-service teachers, in essence, had the ability to "rewind the lesson". In her interview, Katie commented on her colleague's questioning technique; b) Having to negotiate and being challenged during planning with diverse perspectives that improved their overall lesson; c) Supporting one another when faced with uncertainty and having pre-established trust.

The teaching profession has become more collaborative recently with the Professional Learning Community movement (DuFour, DuFour, Eaker, and Many, 2006). DuFour (2004) points out that "educators who are building a professional learning community recognize that they must work together to achieve their collective purpose of learning for all. Therefore, they create structures to promote a collaborative culture" (p. 9). We learned through this team teaching assignment that pre-service teachers also created a professional learning community that allowed for them to recognize that they needed to work together to achieve their collective purpose of teaching and impacting student learning. With many schools adopting PLC as structures for professional learning among peers, teacher education programs and educators working with pre-service teacher education courses should consider incorporating as many collaborative job-embedded activities and experiences for our pre-service teachers. In doing so, we believe our pre-service teachers will be better equipped with the skills and dispositions to work collaboratively in professional learning communities.

PRE-SERVICE TEACHERS' CULTURAL DIVERSITY KNOWLEDGE BASE AND CURRICULAR ADAPTATIONS

Tisa Trask
Illinois State University
tmtrask@ilstu.edu

Tami Martin
Illinois State University
tsmartin@ilstu.edu

Keywords: Curriculum, Teacher Education-Preservice, Equity and Diversity

Theoretical Framing and Purpose

Gay (2000; 2002) proposed a culturally responsive teaching model that included what teachers should know about students' culture—their *cultural diversity knowledge base* (CDKB)—and how teachers should use their knowledge of culture to identify or create culturally responsive curriculum that promotes academic excellence for students. We addressed these research questions:

1. What do pre-service teachers (PSTs) report about their CDKB, in general, and in relation to mathematics?
2. How do PSTs attempt to adapt mathematics instructional materials so that they are culturally responsive to African American or Latin@ students?
3. What evidence is there for a relationship between PSTs' CDKB in mathematics and ability to adapt algebraic word problems for culturally relevance?

Methods

We administered an online survey to PSTs at a large Midwestern university who were at least halfway through a mathematics teacher development program, including having completed an algebraic thinking course. PSTs reported demographic characteristics, community preference for teaching, and their number of opportunities to develop their CDKB such as classes, literature, and conversations about race with minority stakeholders. Then, PSTs were asked to adapt an algebraic word problem for cultural relevance to African American and for Latin@ students.

Results

Of the 15 PSTs who opened the survey, only 7 provided responses. All respondents were European American and six were female. There was no clear relationship between PSTs' reported CDKB and their willingness or ability to adapt the word problems for cultural relevance to African American or for Latin@ students. There were only two PSTs who attempted the word problem adaptation tasks. Both Abby, who was the only respondent who reported having at least one conversation with an African American or Latin@ student about the role of race in mathematics education, and Edward, who was the only student who expressed a desire to teach in "a school of need or urban environment," created word problems that were culturally unresponsive, according to Gay's (2002) model. Both PSTs stated or otherwise indicated a colorblind approach in which curriculum is perceived to be culture neutral.

RAZONAMIENTO DE ESTUDIANTES UNIVERSITARIOS SOBRE VARIABILIDAD E INTERVALOS DE CONFIANZA EN UN CONTEXTO INFERENCIAL INFORMAL

UNIVERSITY STUDENTS´ REASONING ON VARIABILITY AND CONFIDENCE INTERVALS IN INFERENTIAL INFORMAL CONTEXT

Santiago Inzunsa Cazares
Universidad Autónoma de Sinaloa
sinzunza@uas.edu.mx

En este artículo se presentan resultados de una investigación con una metodología de tipo cualitativo con un grupo de 15 estudiantes universitarios de ciencias sociales, sobre el razonamiento inferencial informal que desarrollaron en un ambiente computacional sobre conceptos que intervienen en los intervalos de confianza. Los resultados señalan que los estudiantes desarrollaron un razonamiento correcto sobre la variabilidad del muestreo y lograron visualizar intervalos razonables de variabilidad en un muestreo repetido, a su vez identificaron relaciones correctas entre el tamaño de muestra y la confiabilidad en la amplitud del intervalo y el margen de error, e identificaron la aleatoriedad de un intervalo de confianza. Sin embargo, tuvieron dificultades para conceptualizar la confiabilidad como el porcentaje de intervalos que capturan al parámetro en un muestreo repetido en condiciones idénticas.

Palabras clave: Análisis de Datos y Estadística, Tecnología, Modelación

Introducción

Hacer inferencias sobre poblaciones e interpretar resultados de estudios estadísticos se ha vuelto parte de la vida profesional y cotidiana de las personas. Un ejemplo concreto muy recurrente son las encuestas de opinión que aparecen casi a diario en los medios de comunicación, en las cuales se reportan estimaciones sobre parámetros de una población, margen de error y confiabilidad, entre otros conceptos. La investigación reporta que los conceptos y el razonamiento que caracteriza a la inferencia estadística son complejos para la mayoría de los estudiantes (Castro Sotos, Vanhoof, Noortgate, & Onghena, 2007), incluso para profesores e investigadores que la aplican en su profesión (Liu & Thompson, 2004).

En el caso particular de la estimación de parámetros mediante intervalos de confianza, la literatura reporta diversas dificultades de comprensión y errores en la interpretación de resultados. Por ejemplo, un error muy persistente consiste en considerar que un intervalo de 95% de confianza indica que existe un 95% de probabilidad de que el parámetro poblacional se encuentre entre los límites del intervalo. Otros errores consisten en no reconocer la aleatoriedad y naturaleza inferencial del intervalo e ignorar el efecto del tamaño de muestra y la confiabilidad en la amplitud del intervalo y el margen de error; creer que en distintas muestras se obtendrá el mismo intervalo, entre otros (Olivo & Batanero, 2007).

Entre las principales causas que se ofrecen como explicación de la complejidad de la inferencia estadística y el razonamiento a partir de muestras, destacan la multiplicidad de conceptos abstractos que se entrelazan en una inferencia (Chance, delMas & Garfield, 2004; Pfannkuch, Wild & Parsonage, 2012); el enfoque formal deductivo a través del cual se ha abordado la enseñanza de la inferencia (Lipson, 2002); y la dificultad para ver las muestras y cálculo de estadísticos como eventos estocásticos, que en un muestreo repetido presentan una distribución que revela información importante para hacer la estimación de un parámetro (Saldanha & Thompson, 2014). Un acuerdo generalizado entre investigadores, orienta a reemplazar o complementar el enfoque formal por un enfoque más conceptual y más accesible que brinde oportunidad a los estudiantes de comprender las grandes ideas que subyacen a la inferencia estadística (Cobb & Moore, 1997; Wild, Pfannkuch &

Reagan, 2011); este enfoque es conocido como *inferencia estadística informal,* y el razonamiento que lo caracteriza como *razonamiento inferencial informal.* Entre sus objetivos está generar comprensión de los conceptos de la inferencia sin depender de los métodos formales basados en la teoría estadística y la probabilidad.

El avance de las tecnologías digitales proporciona grandes posibilidades para generar este cambio de enfoque en el estudio de la inferencia estadística, dado el carácter dinámico, interactividad, múltiples representaciones y capacidad de simulación que caracterizan a algunas tecnologías educativas, lo cual les confiere un potencial cognitivo que permite visualizar e interactuar con las representaciones de los datos, el proceso de muestreo, el cálculo de estadísticos y su distribución muestral; objetos matemáticos complejos a partir de los cuales se construyen los intervalos de confianza, el margen de error y la confiabilidad. En este contexto, nos hemos propuesto analizar el razonamiento inferencial informal que desarrollan estudiantes universitarios de ciencias sociales sobre la variabilidad y los intervalos de confianza en un ambiente computacional como que el provee el software TinkerPlots (Konold & Miller, 2011). En específico, nos interesa investigar si los estudiantes identifican relaciones correctas sobre el muestreo, el efecto de tamaño de muestra y la confiabilidad en los intervalos de confianza, y si logran interpretar correctamente el margen de error y la confiabilidad en una estimación.

Marco conceptual

Una inferencia estadística es una aseveración sobre una población, la cual es generada a partir de una sola muestra y con un nivel explícito de confianza. El razonamiento inferencial informal involucra ideas y relaciones como centralidad, variabilidad, tamaño de muestra y control de sesgo (Rubin, Hammerman & Konold, 2006), y se define como la habilidad para interconectar ideas de distribución, muestreo y centralidad, dentro de un ciclo de razonamiento empírico (Pfannkuch, 2006). Zieffler, Garfield, delMas y Reading (2008) lo definen como la forma en la que los estudiantes usan su conocimiento estadístico informal para hacer argumentos para apoyar inferencias acerca de poblaciones basándose en muestras. Makar, Bakker y Ben-Zvi (2011) identifican una serie de elementos clave interrelacionados que son necesarios para apoyar el razonamiento inferencial informal, como son: el conocimiento estadístico, el conocimiento del contexto del problema, normas y hábitos desarrollados con el tiempo y ambientes de aprendizaje basados en cuestionamientos e investigación.

En el contexto de los intervalos de confianza, Pfannkuch, Wild y Parsonage (2012) proponen una ruta conceptual para desarrollar la idea intervalo de confianza desde una perspectiva informal utilizando técnicas de simulación, y definen una comprensión estocástica de los intervalos de confianza como un proceso que contempla las siguientes etapas:

- Concebir un proceso de muestreo aleatorio como la selección de una cantidad de elementos de una población y el registro de cada dato de los elementos seleccionados, para después calcular un estadístico de la muestra (por ejemplo la media o mediana) y estimar el parámetro de la población.
- Imaginar repetidamente la selección de muestras de un tamaño dado y determinar si el intervalo de confianza calculado de la muestra, "captura" el valor del parámetro.
- Comprender que este proceso producirá una colección de resultados de la forma "captura" o "no captura" el verdadero valor del parámetro.
- Comprender que en el muestreo aleatorio existe variabilidad en los resultados, pero conforme se incrementa el tamaño de la muestra, la distribución de resultados adquiere una forma más estable y centra en el verdadero valor del parámetro.
- La proporción del resultado "captura" en una larga corrida es el nivel de confianza asociado al método.

Metodología

La investigación se llevó a cabo con 15 estudiantes de ciencias sociales que tomaban un curso básico de probabilidad y estadística. Los estudiantes tenían pocos antecedentes matemáticos en la materia, por lo que decidimos enfocar el curso hacia la modelación y simulación de eventos aleatorios y muestreo de poblaciones utilizando el ambiente computacional que proporciona el software TinkerPlots, tomando como referencia contextos reales de estudios de opinión en el área de ciencias sociales publicados por empresas encuestadoras mexicanas. Por cuestiones de espacio en el presente trabajo se analizan y discuten resultados de una de las últimas actividades del curso. Como instrumentos de recolección de información se utilizaron hojas de trabajo para cada actividad, archivos del software y entrevistas con algunos estudiantes.

El software TinkerPlots permite el análisis y visualización de datos en forma dinámica e interactiva, con un gran potencial para la modelación y simulación de eventos aleatorios, como es el caso del muestreo. Para el caso específico de los intervalos de confianza, el software dispone de una herramienta de modelación conocida como "Sampler", en la cual, a través de mecanismos aleatorios (ruletas, urnas, diagramas de barras) los usuarios generan el modelo de una población y sus parámetros; posteriormente extraen una gran cantidad de muestras y visualizan el proceso de muestreo y cálculo de estadísticos conforme éste se desarrolla, para generar la distribución muestral del estadístico en cuestión, en forma gráfica o tabular. Las actividades de enseñanza se diseñaron con el propósito de desarrollar en los estudiantes una concepción estocástica de los intervalos de confianza y desarrollar un razonamiento informal adecuado sobre los conceptos como el muestreo, tamaño de muestra, distribución muestral, confiabilidad y margen de error.

Resultados y discusión

Para el diseño de la actividad y el análisis de los resultados hemos tenido en cuenta las etapas y procesos definidos por Pfannkuch, Wild & Parsonage (2012) para desarrollar una comprensión estocástica de los intervalos de confianza.

Actividad:

El tema de la legalización del consumo de mariguana en México ha generado opiniones contrarias en sectores de la sociedad. La empresa Parametría realizó una encuesta para estimar la opinión de los mexicanos (http://www.parametria.com.mx/carta_parametrica.php?cp=4816). Utilizó una muestra aleatoria de 800 personas mayores de edad y reporta una confiabilidad de 95% y una margen de error de $\pm 3.5\%$ en los resultados.

Tabla 1: Resultados de la encuesta

Opinión sobre la legalización de la marihuana	Porcentaje
A favor de	20%
En contra	**77%**
No sabe aún	3%

Considera los resultados anteriores como los parámetros de la población objetivo, en particular considera la proporción de mexicanos que están en contra de la legalización de la marihuana, esto es, P=0.77.

Población, muestreo y variabilidad muestral

El punto de partida consiste en formular el modelo de la población, para después extraer muestras aleatorias y explorar la relación entre los resultados muestrales con los parámetros de la población. Los estudiantes formularon el modelo con facilidad, como resultado de su experiencia en los temas

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

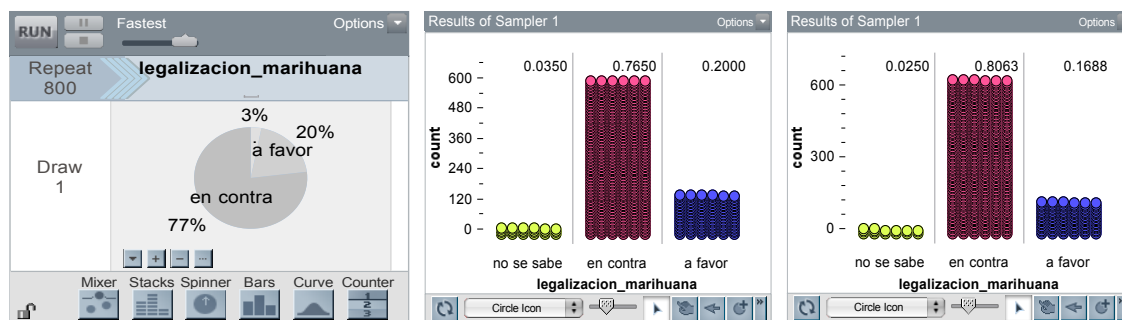
de probabilidad previamente vistos (ver figura 1).


Figura 1. Modelo poblacional y dos muestras aleatorias (n=800) extraídas de la población.

La comparación de los resultados de varias muestras con los valores poblacionales permitió a los estudiantes identificar la variabilidad como una característica intrínseca del muestreo y formular un intervalo intuitivo razonable de resultados esperados. Como evidencia se presentan las respuestas que María José (MJ) y Andrea (A) proporcionaron al investigador (R) en una entrevista:

R: Una vez que construiste el modelo de la población, en la primera muestra de 800 personas [tal como lo hizo la encuestadora] obtuviste un proporción en contra de la legalización de 0.76, ¿te pareció razonable el resultado?

MJ: Sí, me parece que no varía mucho, si tomamos en cuenta que el valor verdadero de la proporción es 0.77.

R: Si repites el muestreo, ¿esperas tener resultados iguales o diferentes?

MJ: Espero resultados diferentes, pero no muy alejados de 0.77.

R: ¿Un intervalo razonable en el cual se esperas los resultados de las muestras?

MJ: Como mínimo 0.74 y como máximo 0.80.

R: ¿Por qué lo consideras así?

MJ: Porque el margen de error que proporciona la encuestadora es del 3.5%, entonces podemos tomar el 0.77 como punto medio y sumar y restar el margen de error.

R: Si en lugar de 800 personas en la encuesta se hubieran utilizado 1500 personas, ¿crees que hubiera resultado el mismo intervalo?

MJ: Los porcentajes se elevarían, el 0.77 quizá sería más grande porque la muestra es más amplia, pero también podría bajar porque se está preguntando a más personas.

R: ¿El intervalo entre 0.74 y 0.80, sería el mismo?

MJ: El margen de error disminuiría.

R: ¿Los resultados que obtuviste en las tres muestras te parecen razonables?

A: Sí, porque el valor verdadero es 0.77, no varían mucho del parámetro.

R: ¿Podrías establecer un intervalo razonable de variación para los resultados muestrales?

A: Del 0.75 al 0.79.

R: ¿En qué te basaste para establecer el intervalo?

A: Consideré que no puede ser un margen de error tan grande, si el parámetro es 0.77.

R: Por ejemplo, sin en lugar de 800 personas se hubieran encuestado 1500, ¿que pasaría con el intervalo?

A: Sería más estrecho.

Las respuestas de Andrea (A) y María José (MJ) muestran que tienen una idea correcta de la variabilidad muestral alrededor del parámetro, y que ésta disminuye conforme se incrementa el tamaño de la muestra. Construyen un razonable intervalo intuitivo de variación de los resultados muestrales esperados. En el caso de María José relaciona el intervalo esperado con el margen de error

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

de la encuesta de manera correcta, lo cual significa que tienen un idea de intervalo formado por el estimador y la suma y resta del margen de error. Ante la pregunta sobre incrementar el tamaño de muestra, no tiene claro el efecto que tendría en la estimación, pues le atribuye mayor variabilidad, cuando en realidad muestras más grandes deben parecerse más a la población.

Distribución muestral, confiabilidad y margen de error

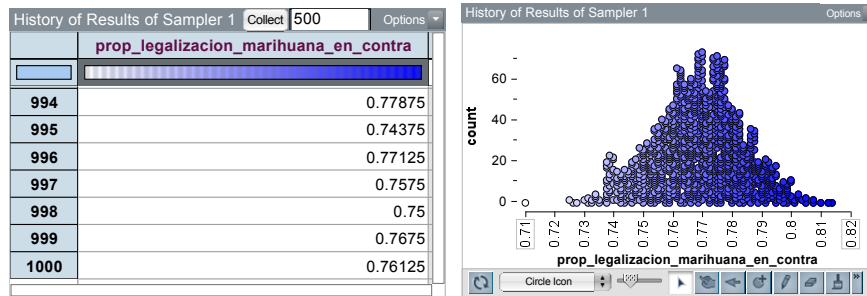
TinkerPlots permite visualizar el muestreo como un proceso repetible, calcular el estadístico en cada muestra y acumular los resultados en una tabla que posteriormente puede ser graficada; es decir, genera la distribución muestral para una cierta cantidad de muestras (ver figura 2).


Figura 2. Distribución muestral para 500 muestras de tamaño 800 (P=0.77).

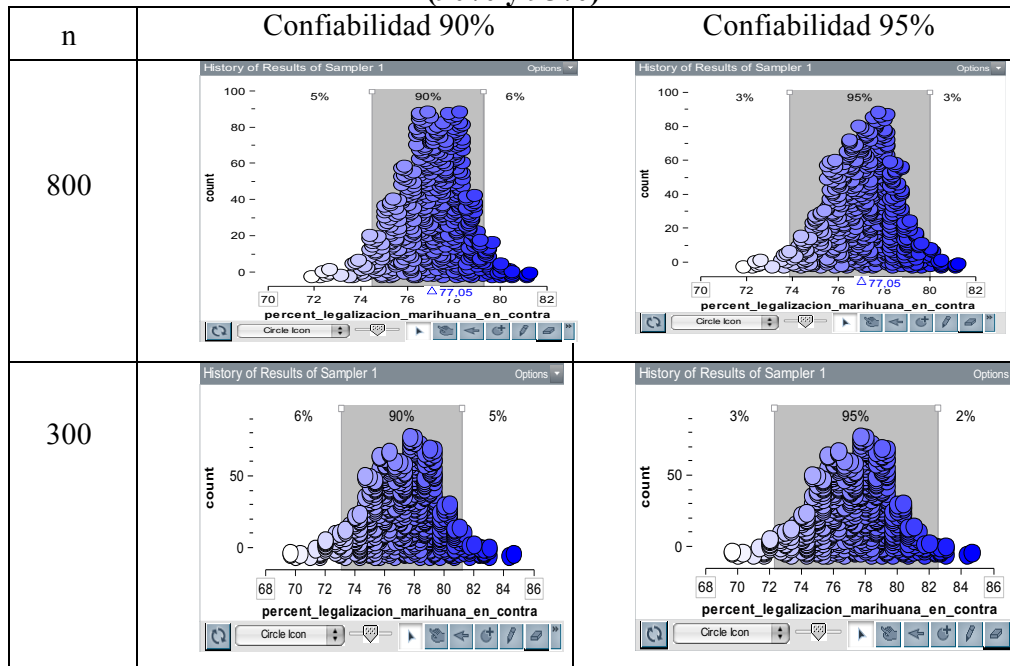
Los estudiantes seleccionaron muestras de tamaño 800 (como lo hizo la empresa encuestadora), y muestras de tamaño 300 (otra posible empresa), con el fin de comparar las distribuciones muestrales y ver el efecto del tamaño de muestra. Se agregaron bandas que sombrean una parte de la distribución muestral y que hacen el papel de intervalos gráficos capturando 90% y 95% de las muestras respectivamente (ver tabla 2).

Tabla 2: Comparación de distribuciones muestrales (n=800 y n=300) y niveles de confiabilidad (90% y 95%)

n	Confiabilidad 90%	Confiabilidad 95%
800		
300		


La comparación de distribuciones para cada confiabilidad y tamaño de muestra, permitió a los

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

estudiantes identificar algunas relaciones importantes como se muestra en las respuestas que dieron Perla y Katya en la hoja de trabajo, y Andrea (A) y Anaid (AN) en la entrevista:

"Entre más grande es la confiabilidad los intervalos serán más grandes". Perla

"El comportamiento del tamaño de la muestra en relación con la amplitud de los intervalos es a la inversa que con la confiabilidad. La distribución de las muestras de 800 es más angosta que la distribución de muestras tamaño 300". Katya

R: ¿Qué efecto tiene el incrementar la confianza en el ancho del intervalo?
A: Entre menor es la confiabilidad se hace más estrecho el intervalo.
R: ¿Qué ventajas crees que tendría un estudio con una confiabilidad alta?
A: Que cierto porcentaje de la población muy probablemente cae dentro de ese intervalo. Pero si el intervalo es muy amplio puede que no sea muy útil, ya que intervalos grandes son más confiables pero menos precisos.
R: ¿Que se puede hacer para aumentar la precisión?
A: El tamaño de muestra se debe aumentar.
R: ¿Qué nivel de confianza preferirías en un estudio: 90% o 95%?
AN: Es mejor el de 90% porque el margen de error es mas pequeño.
R: ¿Acaso no es mas confiable uno de 95%?
AN: En el de 90 tienes menos posibilidades que caiga dentro y el 95 es más grande y tiene mas posibilidades.
R: ¿Qué pasa con el aumento del tamaño de la muestra en el intervalo?
AN: El ancho del intervalo aumenta al bajar el tamaño de muestra.

Las respuestas de las estudiantes muestran que han identificado correctamente el efecto de la confiabilidad y el tamaño de muestra en el ancho de un intervalo. Sin embargo, el significado de confiabilidad para Andrea es erróneo, al considerar que representa un porcentaje de la población que caerá dentro del intervalo, una concepción muy persistente ya documentada en otros estudios (Olivo & Batanero, 2007).

Otra idea importante que nos propusimos explorar es la aleatoriedad de un intervalo, esto significa de una muestra a otra los limites y el ancho del intervalo pueden cambiar. Para esta parte de la actividad nos propusimos desarrollar en la hoja de cálculo de TinkerPlots los cálculos que se involucran en un intervalo de confianza para una confiabilidad de 90% y 95% respectivamente y repetir la simulación para 500 o 1000 muestras (ver figura 3).

	prop_legaliza...	Error_estandar	margen_de_error	limite_inferior	limite_superior	resultado
478	0.7375	0.0155561	0.0311122	0.706388	0.768612	Cae fuera
479	0.7725	0.0148216	0.0296432	0.742857	0.802143	Cae dentro
480	0.765	0.0149906	0.0299812	0.735019	0.794981	Cae dentro
481	0.77	0.0148787	0.0297574	0.740243	0.799757	Cae dentro
482	0.75375	0.015232	0.030464	0.723286	0.784214	Cae dentro

History of Results of Sampler 1 — Collect 500 — Options

Figura 3. Hoja de cálculo con los elementos de un intervalo de confianza (500 intervalos generados).

A continuación se muestran las respuestas de Andrea (A) y Anaid (AN):

R: ¿Al repetir el muestreo esperas que salga el mismo intervalo?
AN: No, porque las muestras son aleatorias.
R: ¿Varían todos los elementos de un intervalo?
AN: Si porque cada vez que lo corres da un P diferente, aunque cercano.

R: ¿Que relación crees que tiene el 97% de resultados capturados con la confiabilidad? (ver tabla 3).

AN: La confiabilidad es del 95% y ese es muy cercana a 97%, puede incluso ser igual.

R: El 96% de los intervalos que simulaste cayeron dentro y un 4% cayó fuera, ¿tiene alguna relación con la confiabilidad de 95%?

A: Si recuerdo que los resultados que caen fuera el intervalo son lo no contienen al parámetro

R: ¿Eso podría suceder en una encuesta real?

A: Si

R: ¿Lo tomarías como un error de la encuestadora?

A: No, como algo que pasa por el azar, y que sucede con poca frecuencia.

R: ¿En una distribución muestral esos valores donde los ubicarías?

A: En los extremos de la distribución.

R: Viendo estos resultados, ¿qué significa la confiabilidad?

A: Es el porcentaje que un encuestador puede decir que sus muestras contienen al parámetro, que son verdaderas.

Tabla 3: Gráficas con porcentajes de intervalos que capturan y no capturan al parámetro para los niveles de confiabilidad 90% y 95%
Las respuestas de Anaid y Andrea señalan que tienen claro la aleatoriedad de un intervalo, porque depende de los resultados variables de una muestra. No logran establecer un significado correcto sobre la confiabilidad pese a que visualizan en la gráfica los porcentajes de muestras que capturan y no capturan al parámetro, respectivamente. Sin embargo, cabe resaltar que Andrea está consciente que en una encuesta real se pueden presentar intervalos que no capturan al parámetro, los considera poco frecuentes y los ubica correctamente en las colas de una distribución muestral.

Conclusiones

Los resultados señalan que los estudiantes razonaron correctamente sobre algunos conceptos que integran una comprensión estocástica de los intervalos de confianza definidos por Pfannkuch, Wild & Parsonage (2012), tales como la relación entre el tamaño de muestra y la variabilidad muestral, el efecto del nivel de confiabilidad y el tamaño de muestra en el ancho de un intervalo de confianza. Lograron identificaron intervalos razonables de los resultados esperados en la muestra e identificaron además, el carácter aleatorio de un intervalo, conceptos que se reportan como complejos por investigaciones previas. Sin embargo la confiabilidad resultó ser un concepto muy difícil para todos los estudiantes, y no lograron conceptualizarlo correctamente, aún cuando las actividades enfatizaron en la repetición de muestras para visualizar el porcentaje de intervalos que capturan al parámetro y relacionarlo con la confiabilidad previamente establecida. El ambiente computacional como el que proporciona TinkerPlots en complemento con actividades que promueven la relación explícita entre los conceptos que intervienen en un intervalo de confianza parecen ser adecuados para el diseño de

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

trayectorias de aprendizaje que promueven un razonamiento inferencial informal correcto en los estudiantes.

This article presents the results of a qualitative research with a group of 15 university students of social sciences on informal inferential reasoning developed in a computer environment on concepts involved in the confidence intervals. The results indicate that students developed a correct reasoning about sampling variability and visualized reasonable intervals of variability in a repeated sampling, at the same time students identified correct relationships between sample size and confidence level in the width of an interval and margin of error, and identified the randomness of a confidence interval. However, they had difficulties conceptualizing the confidence level as the percentage of intervals that capture the parameter in a sampling repeated under identical conditions.

Keywords: Data Analysis and Statistics, Technology, Modeling

Introduction

Making inferences about populations and interpreting results of statistical studies has become part of people´s professional and daily lives. A concrete and very recurrent example is the opinion polls that appear almost daily in the media, in which estimates of population parameters, margin of error and confidence level, among other concepts are reported. The research reports that the concepts and reasoning that characterizes the statistical inference are complex for most students (Castro Sotos, Vanhoof, Noortgate, & Onghena, 2007), even for teachers and researchers who apply it in their profession (Liu & Thompson, 2004).

In the particular case of parameter estimation by confidence intervals, the literature reports diverse difficulties of understanding and errors in the interpretation of results. For example, a persistent error is to consider that a 95% confidence level indicates a 95% probability that the population parameter is between the limits of the interval. Other errors are not recognizing the randomness and inferential nature of the interval, and ignoring the effect of sample size and the confidence level in the width of the interval and the margin of error; believing that in different samples, the same interval will be obtained, among others (Olivo & Batanero, 2007).

Among the main causes offered as an explanation of the complexity of statistical inference and reasoning from samples, those that stand out are the multiplicity of abstract concepts that are intertwined in an inference (Chance, delMas, & Garfield, 2004; Pfannkuch, Wild, & Parsonage, 2012); deductive formal approach used to teaching inference (Lipson, 2002); and the difficulty to recognize samples and computation of statistics as stochastic events, which in a repeated sampling show a distribution that reveals important information for estimating a parameter (Saldanha & Thompson, 2014). A generalized agreement among researchers, aims to replace or supplement the formal approach with a more conceptual and more accessible approach that provides opportunity for students to understand the great ideas behind statistical inference (Cobb & Moore, 1997; Wild, Pfannkuch, & Reagan, 2011); this approach is known as an informal statistical inference, and reasoning that characterizes, informal inferential reasoning. One of its objectives it is to generate understanding of the inference concepts without relying on formal methods based on statistical theory and probability.

Advances in digital technologies provide great potential to generate this change of approach to the study of statistical inference, given the dynamic properties, interactivity, multiple representations and simulation capabilities that characterize some educational technologies. These technological advances allow for a cognitive potential to visualize and interact with representations of the data, the sampling process, the calculation of statistics measures and their sampling distribution; complex mathematical objects from which confidence intervals, the margin of error and confidence level are

---

built. In this context, we intend to analyze the informal inferential reasoning that university students of social sciences develop on the variability and confidence intervals in a computer environment such as that provided by the TinkerPlots software (Konold & Miller, 2011). Specifically, we want to investigate whether students identify correct relations on sampling, the effect of sample size and confidence level in the confidence intervals, and whether or not students correctly interpret the error and confidence level in the estimation of a parameter.

Conceptual framework

A statistical inference, is a statement about a population, which is generated from a single sample and with an explicit confidence level. The informal inferential reasoning involves ideas and relationships as center, variability, sample size, and control of bias (Rubin, Hammerman & Konold, 2006), and is defined as the ability to interconnect ideas of distribution, sampling and centrality, within a cycle of empirical reasoning (Pfannkuch, 2006). Zieffler, Garfield, delMas, and Reading (2008) define it as the way that students use their informal statistical knowledge to make arguments to support inferences about populations based on samples. Makar, Bakker, and Ben-Zvi (2011) identify a number of interrelated key elements that are needed to support the informal inferential reasoning, such as: statistical knowledge, knowledge of the context, rules and habits developed over time and learning environments based on questions and research.

In the context of the confidence intervals, Pfannkuch, Wild, and Parsonage (2012) propose a conceptual pathway to develop the idea of confidence interval from an informal approach using simulation techniques, and define a stochastic understanding of confidence intervals as a process that includes the following steps:

- Conceiving a random sampling process as selecting a number of elements of a population, and recording each data of the selected elements, then calculating a statistics measure (e.g. the mean or median) to estimate the population parameter.
- Imagining repeatedly taking samples of a given size and determinate whether or not the confidence interval calculated for each sample, "covers" the parameter value.
- Understanding that this process will produce a collection of outcomes that would either "cover" or "not cover" the true parameter value.
- Understanding that because of the random selection process there is variability in the outcomes, but as the sample size increases, the distribution of outcomes becomes stable and centered at the true parameter value.
- The long run proportion of ''covers'' is the confidence level associated with the method.

Methodology

The research was conducted with 15 social science students taking an introductory course in probability and statistics. The students had little mathematical background in the subject, therefore we decided to focus the course on the modeling and simulation of random events and population sampling using the computer environment that provides TinkerPlots software, using real contexts of opinion polls in the area of social sciences published by Mexican pollsters. Due to space limitation, in this paper we analyze and discuss results from the last course activities. The data collection instruments used were worksheets for each activity, computer activity files, and interviews with some students.

TinkerPlots software enables analysis and visualization of data in dynamic and interactive way, with great potential for modeling and simulation of random events, such as sampling. For the specific case of confidence intervals, the software has a modeling tool known as "Sampler," which, through random mechanisms (spinners, urns, bar charts), generates the model of a population and its parameters. Following, users select a large amount of samples and visualize the sampling process and

statistics measures calculation (e.g. mean, median) as they develop, to generate the sampling distribution of the statistic in question, in graphical or tabular form. The teaching activities were designed with the purpose of developing in students a stochastic conception of confidence intervals and developing an appropriate informal reasoning on concepts such as sampling, sample size, sampling distribution, confidence level, and margin of error.

Results and Discussion

For the design of the activity and the analysis of the results, we have taken into account the stages and processes defined by Pfannkuch, Wild, and Parsonage (2012) to develop a stochastic understanding of confidence intervals.

Activity

The topic of legalization of marijuana in Mexico has generated conflicting opinions in diverse sectors of society. Parametría Company conducted a survey to estimate the opinion of Mexicans (http://www.parametria.com.mx/carta_parametrica.php?cp=4816). It used a random sample of 800 people and reported a confidence level of 95% and a margin of error of ± 3.5% in the results.

Table 1: Survey results

Opinion on the legalization of marijuana	Percent
Agree	20%
Against	**77%**
Do not know yet	3%

Consider the above results as the parameters of the target population, particularly considering the proportion of Mexicans who are against the legalization of marijuana, that is, $P = 0.77$.

Population, sampling and sampling variability

The starting point consists in formulating the population model with the purpose of taking random samples and exploring the relationship between the sample results with the population parameters. Students formulated the model easily due to their experience on the issues of probability previously studied (see Figure 1).
Figure 1. Population model and two random samples (n = 800) drawn from the population.

Comparing the results of several samples with population values, allowed students to identify the variability as an intrinsic feature of the sampling and formulate an intuitive and reasonable interval of expected results. As evidence we present the answers that Maria Jose (MJ) and Andrea (A) provided to the researcher (R) in an interview:

R: Once you built the population model, in the first sample of 800 people [as the pollster did] you obtained a proportion against the legalization of 0.76. Did the result seem reasonable to you?

MJ: Yes, I think that it is does not vary much, if we consider that the true value of the proportion against is 0.77.

R: If the sampling is repeated, do you expect to have the same or different results?

MJ: I expect different results, but not far from 0.77.

R: A reasonable interval in which you expect the results of the samples?

MJ: 0.74 minimum and maximum 0.80.

R: Why do you think so?

MJ: Because the margin of error provided by the pollster is 3.5%, then we can take 0.77 as the midpoint and add and subtract the margin of error.

R: If instead of 800 people surveyed, 1500 people had been used in the survey, do you think that would have been the same interval?

MJ: The percentages would rise, perhaps 0.77 would be bigger because the sample is wider, but it could also lower because more people are been surveyed.

R: The interval between 0.74 and 0.80, would be the same?

MJ: Decrease the margin of error

R: Do the results you obtained in the three samples seem reasonable to you?

A: Yes, because the true value is 0.77, it does not vary much from the parameter.

R: Could you establish a reasonable range of variation for sample results?

A: From 0.75 to 0.79.

R: On what base did you set the interval?

A: I considered that it may not be so great a margin of error, if the parameter is 0.77.

R: For example, if instead of 800 people they had surveyed 1500, what would happen to the interval?

A: It would be narrower.

The responses of Andrea (A) and Maria Jose (MJ) show that they have a correct idea of the sampling variability around the parameter, and it decreases as the sample size increases. They built an intuitive and reasonable interval of variation of the expected sample results. In the case of Maria Jose, she relates the expected interval with the margin of error in the survey correctly, which means they have an idea of interval formed by the estimator, adding and subtracting the margin of error. When asked about increasing the sample size, she is not clear on the effect of the estimate, because she attributed a greater variability, when in fact, larger samples should be closer to the population.

Sampling distribution, reliability and margin of error

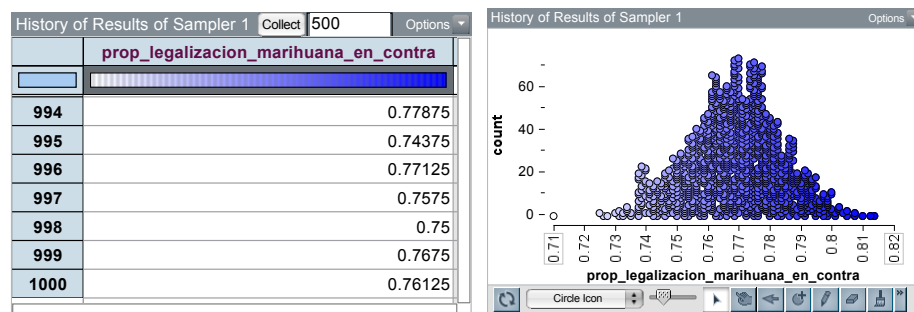
TinkerPlots displays the sampling as a repeatable process, calculate a statistics measure in each sample and accumulate the results in a table that one can then graph; that is, it generates the sampling distribution for a certain amount of samples (see Figure 2).


Figure 2. Sampling distribution for 500 samples of size 800 (P = 0.77).

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Students selected samples size of 800 (as the pollster did), and samples size of 300 (another possible company), in order to compare the sampling distributions and see the effect of sample size. Shading bands were added to a portion of the sampling distribution that make the role of graphics intervals capturing 90% and 95% of the samples respectively (see Table 2)

Table 2: Comparison of sampling distributions (n = 800 and n = 300) and confidence levels (90% and 95%)

n	Confidence level 90%	Confidence level 95%
800		
300		

The comparison of distributions for each confidence level and sample size, allowed students to identify some important relationships as shown in the answers given by Perla and Katya in the worksheet, and Andrea (A) and Anaid (AN) in the interview:

"The larger confidence level, the larger intervals will be." Perla

"The behavior of the sample size in relation to the width of the intervals is reversed with respect to the confidence level. The sampling distribution of size 800 is narrower than the sampling distribution of size 300." Katya

R: What is the effect of increasing the confidence level on the width of the interval?
A: The lower is the confidence is, the narrower the interval becomes.
R: What advantages do you think a high confidence level study would have?
A: That certain percentage of the population likely falls within that interval. But if the interval is very wide, it may not be very useful, since large intervals are more reliable but less precise.
R: What can be done to increase the accuracy?
A: We should increase the sample size.
R: What confidence level would you prefer in a study: 90% or 95%?
AN: 90% is better, because the margin of error is smaller.
R: Is it not an interval of 95% more reliable?
AN: At interval of 90% you are less likely to fall within, and 95% is larger and has more possibilities.

R: What happens to the interval when you increase the sample size?
AN: The width of the interval increases by lowering the sample size.

The responses by the students show that they have correctly identified the effect of confidence level and sample size in the width of an interval. However, the meaning of confidence level for Andrea is wrong, considering that it represents a percentage of the population that falls within the interval, a very persistent misconception documented in other studies (e.g. Olivo & Batanero, 2007).

Another important idea that we proposed to explore is the randomness of an interval, this means that the limits and width of the interval may change from one sample to another. For this part of the activity, we decided to develop, in the TinkerPlots' spreadsheet, the calculations involved in a confidence interval for a confidence level of 90% and 95% respectively, and repeat the simulation for 500 or 1000 samples (see Figure 3).

History of Results of Sampler 1						Collect 500	Options ▾
	prop_legaliza...	Error_estandar	margen_de_error	limite_inferior	limite_superior	resultado	
478	0.7375	0.0155561	0.0311122	0.706388	0.768612	Cae fuera	
479	0.7725	0.0148216	0.0296432	0.742857	0.802143	Cae dentro	
480	0.765	0.0149906	0.0299812	0.735019	0.794981	Cae dentro	
481	0.77	0.0148787	0.0297574	0.740243	0.799757	Cae dentro	
482	0.75375	0.015232	0.030464	0.723286	0.784214	Cae dentro	

Figure 3. Spreadsheet with elements of a confidence interval (500 intervals generated).

The answers of Andrea (A) and Anaid (AN) are shown below:

R: When you repeat the sample, do expect the same interval?
AN: No, because the samples are random.
R: Do all the elements of an interval vary?
AN: Yes, because every time you run it, it gives a different P, although it is close.
R: What relationship do you think 97% of captured results has with the confidence level? (See Figure 3).
AN: The confidence level is 95% and that is very close to 97%, it may even be the same.

R: In your simulation, 4% of the intervals did not capture the parameter; Does that have any relationship with the confidence level of 95%?
A: Yes, I remember that the results that fall outside the interval do not contain the parameter.
R: Could that happen in a real survey?
A: Yes
R: Would you take it as a pollster error?
A: No, I would take it as something that happens by chance, and that it happens infrequently.
R: Where would you locate those values in a sampling distribution?
A: At the ends of the distribution.
R: Seeing these results, what does reliability means?
A: It is the percentage that a pollster can say that their samples contain the parameter, which are true.

Table 3: Charts with percentages of intervals that "covers" and "not covers" the parameter for confidence levels 90% and 95%

	Confidence level 90%	Confidence level 95%
Charts of the results column		
The responses of Anaid and Andrea indicate that they are clear about the randomness of the interval, because it depends on the variable results of a sample. They are unable to establish the correct meaning of the confidence level despite the fact that the graph displays the percentage of samples that cover and do not cover the parameter, respectively. However, it should be noted that Andrea is aware that in a real survey, there may be intervals that do not cover the parameter, she considered them rare and located them correctly in the tails of a sampling distribution.

Conclusions

The results indicate that the students reasoned correctly on some concepts that integrate a stochastic understanding of confidence intervals defined by Pfannkuch, Wild, and Parsonage (2012), such as the relationship between sample size and sample variability, the effect of confidence level and sample size on the width of a confidence interval. The students identified reasonable intervals of expected results in a sample and the random nature of an interval, concepts reported as complex by previous studies. However, confidence level proved to be a very difficult concept for all students, and they failed to conceptualize it correctly, even when activities emphasized repetition of samples to display the percentage of intervals that covers the parameter, and relating it to the previously established confidence level. The computer environment such as that provided by TinkerPlots joint with activities that promote the explicit relationship between the concepts involved in a confidence interval seem to be suitable for the design of learning pathways that promote a correct informal inferential reasoning in the students.

TOWARDS A FRAMEWORK FOR A CRITICAL STATISTICAL LITERACY IN HIGH SCHOOL MATHEMATICS

Travis Weiland
University of Massachusetts Dartmouth
tweiland@umassd.edu

In the spirit of questioning, crossing, and blurring disciplinary borders with(in) mathematics education, this paper proposes a theoretical framework that merges conceptions of critical literacy and statistical literacy for high school mathematics curriculum. I begin by discussing the political nature of education and then situate this work within the goals of education for active citizenship. Next, I provide a detailed background of both critical and statistical literacy from multiple educational research perspectives. Lastly, by synthesizing notions of critical and statistical literacy, I present a theoretical framework for a critical statistical literacy in the context of high school mathematics curriculum.

Keywords: Data Analysis and Statistics, High School Education, Equity and Diversity

Introduction

In modern society, which is drenched in data (Steen, 2001), individuals need to be statistically literate (Gal, 2004). There has been an explosion of data in every facet of life including medicine, economics, education, and public opinion, just to name a few (Ben-Zvi & Garfield, 2008). As a result statistical literacy is becoming a crucial literacy for being a citizen in today's modern societies. As Franklin et al. (2007) states, "every high school graduate should be able to use sound statistical reasoning to intelligently cope with the requirements of citizenship" (p.1). However, it is important for citizenship education that this literacy goes beyond the tradition 'consumption and production' conception of statistical literacy (Ben-Zvi & Garfield, 2004; Franklin et al., 2007; Gal, 2004) to include fostering sociopolitical awareness and critique. Large scale social and environmental issues, such as racism, climate change, refugee crises, and poverty need to be addressed in school curriculum so that students are not only aware of them, but have experiences investigating them (Apple & Beane, 2007). In this way, schools can serve as sites for fostering students/citizens, who can thoughtfully engage issues in their local and global community for the purposes of creating a more just world for tomorrow.

Today in the context of secondary education in the United States, the teaching of statistics and data analysis is situated in the mathematics curriculum (National Council of Teachers of Mathematics [NCTM], 2000; National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010). As data analysis and statistical methods have gained importance in society, they have also gained emphasis in the standards for mathematics instruction in grades 6-12, for example, with the introduction of the *Common Core State Standards for Mathematics* (NGA & CCSSO, 2010). Unfortunately, situated in this context statistics concepts and practices are frequently reduced to mundane computations (Cockcroft, 1982) stripping them of the power they have in investigating issues that are meaningful to students lives as well as their historical and sociopolitical contexts. In the K-12 context there needs to be an emphasis put on teaching statistical concepts and practices consistent with the discipline of statistics, and that will be useful when investigating sociopolitical issues that are prevalent in the world today. To engage in active, critical citizenship, students need a critical statistical literacy.

Before I elaborate on what I mean by a critical statistical literacy I will situate this idea in the broad sociohistorical and political context of US education. I will also draw from multiple discourses

concerning literacy to position this form of literacy, and rationalize its importance in education, and more specifically mathematics education.

The Political Nature of Education and Citizenship

Education is inherently political in that organizations and individuals make decisions on what topics, issues, and concepts are learned, and who can learn them, therefore endorsing certain ideas, views, and individuals, while disadvantaging and excluding others. As Labaree (1997) argues, "the central problems with American education are not pedagogical or organizational or social or cultural in nature but are fundamentally political" (p.40). The problem is rooted in differing, and at times competing, goals of education. Labaree argues that one of the predominant goals of US education is democratic equality. Americans take great pride in living in a democracy, where decisions are made by the people, for the people. Education centered on citizenship benefits society by fostering a literate and educated citizenry who can make critical decisions, and in turn create a stronger democratic society for all. I firmly believe in this goal for education, viewing it as a public good, preparing youths to take up the role of citizens (Apple & Beane, 2007; Giroux, 1989; Labaree, 1997); and it is upon this goal that I situate this paper.

There are many views of what constitutes "good" citizenship, which are culturally, socially, and historically situated. These views can be roughly categorized into three main types of citizenship: personally responsible, participatory, and justice oriented, as described by Westheimer and Kahne (2004). The image of a personally responsible citizen is a hard working individual who follows the law, has good character, and is responsible in his/her community. As indicated by its name, the participatory vision of citizenship is one where citizens are active participants in the government and community. They work within the system to try to improve conditions. The third view of what makes a "good" citizen is the justice oriented citizen. "Good" citizens in this view are ones who question and critique the injustices of societal structures. This type of citizen seeks to find and address the root causes of injustices in society as well as engage in activism, and leverage social movements, to effect systemic change.

There are strengths and weaknesses to each of these views of citizenship. For example, in the personally responsible view of citizenship there is no active participation in government/community affairs, or working to change unjust laws, inequities, etc. This type of citizenship maintains the status quo. The problem with this mentality is that the status quo today includes unjust structures of racism, classism, and sexism that favor certain individuals and disadvantage others (Giroux, 1989; Knoblauch & Brannon, 1993). For example, wealth is becoming increasingly polarized with a small number of individuals holding the majority of the wealth, and an increasingly large proportion of the population sinking into poverty based on hegemonic economic structures (Brown, 2006). I see the ideal view as a blending of participatory and justice-oriented. In my opinion, a good citizen should participate actively in their community and/or government, but should also interrogate the structures at play within their community and government, which produce conditions of injustice, and actively work to change those that (re)produce injustices. Giroux (1989) describes this type of citizenship in his view of education for democracy. One of the key aspects of this view of citizenship that Giroux describes is that,

> It is important to acknowledge that the notion of democracy cannot be grounded in some ahistorical, transcendent notion of truth or authority. Democracy is a "site" of struggle, and as a social practice is informed by competing ideological conceptions of power, politics, and community. This is an important recognition because it helps to redefine the role of the citizen as an active agent in questioning, defining, and shaping one's relationship to the political sphere and the wider society. (p.28-29)

I agree with this view of democracy, as a site of struggle, and with citizens as active agents in shaping the meaning of democracy. In today's modern societies, there are a plurality of different views, values, and ideas, which citizens must be able to negotiate and navigate in daily life. Furthermore, strengthening the bonds between fellow citizens through a common goal of democracy, while appreciating the plurality inherent in our society, is also crucial to being a citizen (Giroux, 1989). I will henceforth refer to this participatory and justice oriented view of citizenship for democracy as *critical citizenship*.

Education based on critical citizenship would include learning both how institutions works, and how to critique and change them, as well as the historical, social and political discourses that shape society and the views of citizens. Students would be provided opportunities to give back to their communities, and encouraged to take action, by forming and leading their own efforts to fight injustices they see in the world around them. An example of this view of citizenship being played out in the context of mathematics education can be seen in Gutstein's (2006) descriptions of his teaching in a Chicago public middle school. Gutstein showed students how to participate in their community and government by taking them to town hall meetings, and also provided them with experiences in using mathematics to investigate injustices related to racist policing practices and gentrification present in their community. It is in this direction, I believe education needs to go, to educate students to function in society, as well as participate in shaping, and improving society for future generations. Critique is an important aspect in this type of education, but as Giroux (1989) points out, "the discourse of democracy also needs a language of possibility, one that combines a strategy of opposition with a strategy for constructing a new social order" (p. 31). It is important for students to have experiences critiquing and analyze discourses and institutional structures, however it is equally important for them to have experiences shaping and creating just practices for the wellbeing of others, in their local and global communities. It is in dialogue between these two types of experiences that schools can help students learn about democracy as a site for struggle, in constant negotiation by citizens who actively participant in creating it. One possible approach that Giroux (1989) describes for making pedagogy more political, for the purposes of educating for a critical citizenry, is to organize pedagogy around critical literacy. Literacy is already a predominant goal of education. Therefore, a critical literacy can be an entry point into school curriculum for the purposes of fostering critical citizens.

I have laid out my view of education, which I see as a public good that should promote critical citizenship for participation in democratic societies. Based on this view of education I will now describe what I mean by a critical statistical literacy, and why it is an important literacy to foster in secondary school classrooms.

Literacy

The theme of literacy has been an educational focus for some time, and has had an ever-changing history. Literacy is commonly defined around the acts of reading and writing (Gee, 2014; United Nations Educational, Scientific, & Cultural Organization [UNESCO], 2005). However the commonalities generally end there. One large difference in scholars' interpretations of literacy is whether the focus should be on the skills necessary to read and write (Scribner, 1984), or on the practices of reading and writing themselves (Perry, 2012). Another aspect of the literature on literacy that varies greatly is the *object* of reading and writing. Much literacy work has focused on the reading and writing of the written languages, in the dominant language of the community in which an individual is a member (Freire & Macedo, 2003; Scribner, 1984; UNESCO, 2005). Overtime, this has expanded to include a multitude of different types of literacy such as financial, quantitative, digital, media, and technological literacies. In this section, I will discuss two types of literacy, statistical and critical, and propose a framework for merging the two types of literacy into a critical statistical literacy. As a note, there is a large research base around quantitative and mathematical

literacies that intersects with statistical literacy. However, I am making a political choice not to draw upon this work, but to instead explicitly draw upon statistical literacy work, which is deeply situate in statistics education and the discipline of statistics, to emphasize its importance, so it is not easily subsumed in the high school mathematics curriculum.

Critical Literacy

Critical literacy draws from a sociocultural definition of literacy in that it is viewed as the practices and abilities associated with being literate. Scholars of critical literacy also foreground the connection between literacy and power (Lankshear & McLaren, 1993). Many discuss literacy as an emancipatory force (Darder, 2014; Freire, 1970; Freire & Macedo, 2003; Giroux, 1989, 1993; Gutstein, 2006), beginning with learning to read the word *and* the world, which can then lead to individuals to being able to write both the word and world—transforming their lived realities through the power of literacy. When democracy is viewed as a site for struggle, through the dialogue of a plurality of views, literacy for critical citizenship needs to include the practices of critiquing and interrogating the discourses and structures in society that reproduce oppressions and injustices. As Gutstein (2006) points out, "U.S. schools socialize students into non-questioning roles, creating and maintaining passive identities so that students do not believe in their own power to shape the world" (p.88). It is in shifting this dominant form of socialization in American schools that the work of critical literacy scholars can speak volumes. By providing students experiences to see how they are situated by social structures, and also how their own schooling is shaped by historical, political, and socially constructed institutions and discourses, can help students create and maintain active citizen identities, where they believe in their own power to influence and shape the world. Without such socialization, how can we ever expect students to become active participants in their communities, to become critical citizens working to negotiate and shape the democracies they live in? As Giroux (1989) describes,

> Critical literacy can provide the theoretical basis for presenting students with the knowledge and skills necessary for them to understand and analyze their own historically constructed voices and experiences as part of a project of self and social empowerment. Central to this view of literacy is an understanding of how knowledge and experience are constructed around particular forms of intellectual, moral, and social regulation within the various relations of power that characterize schools, families, workplaces, the state, and other major public spheres. (p. 34)

Bringing critical literacy into schools can help prepare students to be critical citizens in democratic societies actively participating in the struggle to (re)define meaning and principles of democracy in their world. An important aspect of literacy for critical citizenship includes a statistical literacy, which I will spend some time describing in the next section.

Statistical Literacy

Similar to other types of literacy, statistical literacy can be viewed in terms of reading and writing. The difference is that while literacy is typically considered as reading and writing the written symbol system of the dominant language of a community that an individual is a member of (Freire & Macedo, 2003; Scribner, 1984; UNESCO, 2005), statistical literacy is based on reading and writing a *specialized* symbol system, socially constructed by the discipline of statistics. The practice of reading and writing statistics draws on the dominant language of a social group, but also relies on a specialized symbol system that includes quantities and mathematical symbols, as well as symbols specific to the discipline of statistics. For example, the symbol $\bar{x}$ in statistics represents the arithmetic mean of a sample of data points. However, by itself, the quantity that represents the mean of a data set is relatively meaningless without using it in context, which requires using the dominant language of the individuals which the information is being presented to. For example, the mean

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

salary for public school teachers in Massachusetts was $73,908 in the 2013-2014 school year (Massachusetts Department of Elementary and Secondary Education, n.d.). The quantity 73,908 is relatively meaningless until the English language is used to describe and give context and meaning to the quantity.

In the data drenched societies of today, it is crucial for students to be educated and critical consumers of data based arguments (Ben-Zvi & Garfield, 2008; Franklin et al., 2007; Steen, 2001). Citizens today need to be able to make sense of, and critically evaluate, the validity and usefulness of the information presented in statistical arguments, and make informed decisions based on the augments presented. Reading statistical arguments is a key element of statistical literacy (Franklin et al., 2007; Gal, 2004). Gal's (2004) definition of statistical literacy describes this element well shown here:

> (a) people's ability to interpret and critically evaluate statistical information, data-related arguments, or stochastic phenomena, which they may encounter in diverse contexts, and when relevant (b) their ability to discuss or communicate their reactions to such statistical information, such as their understanding of the meaning of the information, their opinions about the implications of this information, or their concerns regarding the acceptability of given conclusions. (p.49)

Reading is only one part of literacy however; there also needs to be a writing component, as the two have a dialogical relationship with one another, just as reading the word and the world operate in dialogue. Writing in statistics involves actively investigating a phenomenon through a statistical investigation, and communicating the results of that investigation to others. The *Guidelines for Assessment and Instruction in Statistics Education* (GAISE) framework (Franklin et al., 2007), outlines four components of the statistical investigative cycle: formulate questions, collect data, analyze data, and interpret results. In drawing from this description of the statistical investigative cycle, writing statistics could be defined as,

> The ability to formulate statistical questions, collect or find data relevant to statistical questions, analyze data using appropriate graphical and numerical methods, and interpret analyzed data addressing the statistical question(s) being investigated.

Combing this description of writing statistics with the earlier description of reading statistics from Gal's (2004) definition of statistical literacy, creates a coherent description of statistical literacy, that includes both the elements of reading and writing, consistent with the broader field of literature around literacy. This also provides a view of statistical literacy that can be merged with the earlier described view of critical literacy, centered on reading and writing.

Critical Statistical Literacy

Now that I have situated the focus of this work, I think it is time I provide a description for what I am calling critical statistical literacy. I see this concept as an intersection of critical and statistical literacies. My goal here is to emphasize the importance of some powerful statistical ideas that are crucial to a critical literacy in democratic education. I have used the word critical first in order to foreground a critical literacy perspective, which is important across all curricula in education, because it is rooted in practices for participating in, critiquing, and (re)shaping structures and discourses in society that are crucial for critical citizenship in society. Next, I have used the word statistics, which is important to emphasize in the high school mathematics context, because it is a distinct discipline (Franklin et al., 2007) whose concepts and practices frequently get subsumed in the school mathematics curriculum, and stripped of their power, reduced to a litany of calculations (Cockcroft, 1982).

Table 1: Framework for a Critical Statistical Literacy

	Read	Write
Statistical Literacy	• Making sense of and critiquing statistical information and data based arguments encountered in diverse contexts. • Discussing or communicating the meaning of statistical information. • Evaluating the source, collection and reporting of statistical information.	• Formulating statistical questions. • Collecting or finding data relevant to answering posed statistical question(s). • Analyzing data using appropriate graphical and numerical methods. • Interpreting analyzed data addressing the statistical question(s) being investigated.
Critical Literacy	• Making sense of symbol systems. • Identifying and interrogating social structures in the world. • Gaining an awareness of sociopolitical issues in society. • Gaining an awareness of the dialectical tensions in society • Understanding one's social location, subjectivity, political context and having a sociohistorical and political knowledge of self and world.	• Creating and communicating one's own meaning through symbol systems. • Actively influencing and shaping structures in society. • Working to alleviate and resolve sociopolitical issues of injustice. • Actively negotiating and navigating dialectical tensions in society. • Communicating one's social location, subjectivity, and political context to others and how it influence and shapes one's meaning making of the world.
Critical Statistical Literacy	• Making sense of language and statistical symbols systems and critiquing statistical information and data based arguments encountered in diverse contexts to gain an awareness of sociopolitical issues in society. • Identifying and interrogating social structures which shape and are reinforced by the data based arguments being considered. • Understanding one's social location, subjectivity, political context and having a sociohistorical and political knowledge of self and understanding how it influences one's interpretation of information. • Evaluating the source, collection and reporting of statistical information and how they are influenced and shaped by the author's social positon and sociopolitical and historical lens.	• Using statistical investigations to communicate statistical information and arguments in an effort to destabilize and reshape structures of injustice for a more just society. • Using statistical investigations to alleviate and resolve sociopolitical issues of injustice • Negotiating societal dialectical tensions when formulating statistical questions, data collection and analysis methods and highlighting such tensions in the results of a statistical investigation. • Communicating one's social location, subjectivity, and political context to others and how it shapes one's meaning making of the world when reporting results of a statistical investigation.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Beginning with the element of reading, a critical statistical literacy would include: i) making sense of language and statistical symbols systems; ii) critiquing statistical information and data-based arguments encountered in diverse sociopolitical contexts; iii) gaining an awareness of sociopolitical issues and social structures in society; iv) interrogating discourses and social structures that are shaped and reinforced by data based arguments; v) understanding one's own social location, subjectivity, and political context to develop a sociohistorical and political knowledge of self, and how it influences one's interpretations; vi) evaluating the source, collection, and reporting of statistical information, and how they are influenced and shaped by the authors social position and broader discourses, institutions, and historical forces

Moving from reading to writing shifts the focus from being an active and critical consumer of statistical information and arguments to being a producer of statistical information and arguments. Writing within a critical statistical literacy would include: i) using statistical investigations to communicate statistical information and arguments, in order to question and reshape institutions and social structures; ii) using statistical investigations to alleviate and resolve sociopolitical issues of injustice; iii) negotiating and navigating dialectical tensions in society when formulating statistical questions, data collection, and analysis methods, and furthermore explicitly discussing these tensions related to, for example, objective versus subjective truths, or constructed categories versus continuous scales (e.g. gender, race/ethnicity, etc.), in the communication of the results of a statistical investigation; iv) communicating one's social location, subjectivity, and political context to others, and describing how it influences and shapes one's meaning making of the world, when reporting results of a statistical investigation.

A critical statistical literacy based on the elements I have described of reading and writing are summarized in Table 1. This type of literacy is crucial to critical citizenship in today's data centric societies. Statistics is now part of many of the dominant discourses of society, which critical citizens must critically make sense of and evaluate. Furthermore, because of statistics position of power in dominant discourses for providing 'evidence of truth,' it is crucial for critical citizens to be able to use that power to influence, shape, and transform the socially constructed discourses and structures around them in order to create a more just world.

Implications

If schools are to prepare students to tackle large scale social issues, they need to be addressed in school curriculum so that students are both aware of, and have experiences investigating, them (Apple & Beane, 2007). Going forward, I see two major hurdles in fostering a critical statistical literacy in secondary school mathematics curriculum. As I described earlier, critical statistical literacy draws from two main discourses, statistical literacy and critical literacy, neither of which is common in secondary mathematics curriculum. For students to develop sociopolitical awareness and the tools necessary to read and write the world with statistics as critical citizens, they need to have access to powerful statistical ideas. Furthermore, they need to have experiences using those practices and concepts to explore and interrogate structures and injustices in society, to foster sociopolitical awareness, and the practices of critique and active citizenship. I think the following statement by Giroux (1993) concerning critical literacy is quite appropriate for the critical statistical literacy I am proposing as it fits within the theme of questioning borders with(in) mathematics education,

> The pedagogical and ethical practice which I am emphasizing is one that offers opportunities for students to be border crossers; as border crossers, students not only refigure the boundaries of academic subjects in order to engage in new forms of critical inquiry, but they are also offered the opportunities to engage the multiple references that construct different cultural codes, experiences, and histories. (p. 375)

The critical statistical literacy framework proposed here is by no means complete. There are many questions that need to be considered, such as what does a curriculum that fosters such a literacy look like? How would such a curriculum be enacted in the classroom? How do we train and prepare teachers to teach such a curriculum, especially when situated in high school mathematics where many teachers have had little past experience with statistics (Shaughnessy, 2007)? These are but a few of the many questions that could be posed based on this framework.

THE DEVELOPMENT OF A PROFESSIONAL STATISTICS TEACHING IDENTITY

Douglas Whitaker
University of Wisconsin-Stout
whitakerdo@uwstout.edu

Motivated by the increased statistics expectations for students and their teachers because of the widespread adoption of the Common Core State Standards for Mathematics, this study explores exemplary, in-service statistics teachers' professional identities using a theoretical framework informed by Gee (2000) and communities of practice (Lave & Wenger, 1991; Wenger, 1998). Twelve exemplary, primarily Advanced Placement (AP) Statistics teachers participated in two semi-structured interviews. Findings indicate that these teachers developed teaching identities that cross the borders of mathematics and statistics, though these were not always recognized by administrators, other teachers, and parents. Two major contributing factors to the development of a statistics teaching identity—teachers' specialized knowledge and teacher isolation—are discussed. This work has implications for teacher preparation and professional development.

Keywords: Data Analysis and Statistics, High School Education, Teacher Beliefs, Teacher Education-Inservice/Professional Development

Background

Statistics is a mathematical science – like economics or physics – but is not a type of mathematics (Cobb & Moore, 1997; Moore, 1988; Rossman, Chance, & Medina, 2006; Usiskin, 2014). Still, statistics has been included within the mathematics curriculum at the K-12 level (National Council of Teacher of Mathematics [NCTM], 2000; National Governors Association Center for Best Practices, Council of Chief State School Officers [NGA & CCSSO], 2010) and will likely remain there for years to come (Scheaffer, 2006; Usiskin, 2014). Despite sustained calls for increasing the statistical preparation of teachers (e.g. Conference Board of Mathematical Sciences [CBMS], 2012), the current state of teacher preparation for statistics is regarded as inadequate (Franklin et al., 2015; Shaughnessy, 2007). While more mathematics teachers are being asked to teach statistics because of its inclusion in the Common Core State Standards for Mathematics (CCSSM) (NGA & CCSSO, 2010) in grades 6-12, teachers involved with the Advanced Placement (AP) Statistics program have already overcome challenges associated with an increase in statistics expectations. Therefore, AP Statistics teachers can serve as an analogue for understanding how mathematics teachers overcame challenges they encountered teaching at the border of mathematics and statistics.

Overview of the Study

A key expectation for mathematics teachers is that they develop a professional identity as such (NCTM, 1991). This professional mathematics teacher identity is fostered by teacher preparation programs, on-going professional development, and immersion in the school mathematics culture. However, the benefits of a professional mathematics teacher identity may not be directly applicable to teaching statistics, and there is little extant research on statistics teachers' identities (e.g. González & Zapata-Cardona, 2014; Peters, 2009). This study explores the professional identities of exemplary AP Statistics teachers at the high school level. The primary research question is: "What professional identities do exemplary statistics teachers develop?" Assuming that a statistics teaching identity is found, a secondary question is considered: "What are the major contributing factors to the development of a professional statistics teaching identity?"

Theoretical Framework

There are several theoretical conceptions of identity in the literature. This study draws heavily on two conceptions of identity that form the basis for its theoretical framework: Gee's (1999, 2000) contextual or socially-situated identities and Lave and Wenger's (1991; Wenger, 1998) communities of practice. Other conceptions of identity have also contributed to this theoretical framework (e.g. Juzwik, 2006; Philipp, 2007; Sfard & Prusak, 2005).

Gee's (1999, 2000) conception of identity postulates a core identity that is stable across contexts and contextual identities that are recognized by others and more prone to change over shorter time frames. There are four perspectives for contextual identities described by Gee (2000) (natural, institutional, discursive, and affinity) which are "interrelate[d] in complex and important ways" (p. 101). By employing these four perspectives, identity can be examined in several ways which has implications both for data collection and data analysis. The contribution of contextual identities to the theoretical framework of this study is important because of the multiple roles which in-service teachers have in their careers.

Identity is at the heart of the communities of practice framework. In a community of practice, learning is synonymous with the development of the practices and identity associated with the community in question (Barab & Duffy, 2000; Lave & Wenger, 1991). Identity and practice are further connected through five modes of belonging: negotiated experiences, community membership, learning trajectories, nexus of multi-membership, and the local-global relationship (Roesken, 2011; Wenger, 1998). It is through these modes of belonging that perpetually in-development identities are examined. In this study, the most salient aspects of communities of practice are teachers' learning trajectories and their nexuses of multimembership. The use of both Gee's (1999, 2000) conception of identity and communities of practice (Lave & Wenger, 1991; Wenger, 1998) ensured that the data sources addressed identity in a broad manner.

Methods

Participants

Participants were recruited using *critical case* sampling, a sampling strategy that prioritizes specific, important participants. Patton (2002) characterizes critical cases as those for which the researcher can say "if it doesn't happen there, it won't happen anywhere" (p. 236). In the present study, successful, experienced statistics teachers constitute a critical case because their professional identities (as teachers of statistics) have enabled their success; if the teachers in this study do not develop professional identities that are aligned with teaching statistics then it would not be reasonable to believe that such identities would be developed by other mathematics teachers tasked with teaching statistics.

To identify these critical cases, referrals were solicited from experts in the statistics education community with far-reaching contacts and connections. These experts were asked to identify "statistics teachers that you consider to be exemplary … primarily at the middle and high school levels" in a broad sense: no restrictions were placed on experience, gender, courses taught, etc. From these sources, a list of 24 statistics teachers – all known primarily for their work teaching statistics at the high school level – was compiled. Each of these teachers was emailed and asked if they would like to participate in the study; all 12 who responded affirmatively were included.

Among the 12 participants, there were five women and seven men. The highest level of education was a bachelor's degree for two participants, a master's degree for seven participants, and a doctoral degree for three participants. While most of the participants earned degrees in mathematics or mathematics education (i.e. they had traditional mathematics teaching backgrounds), there were several notable exceptions. One participant's highest education was a master's degree in statistics, and another participant earned a doctorate in statistics. Additionally, one participant earned a

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

doctorate in a science. The participants were primarily mid-career and late-career teachers, having an average of 30 years of teaching experience; the minimum years of teaching experience was 7, the first quartile was 19.5, the median was 32.5, the third quartile was 42, and the maximum was 50. Pseudonyms are used throughout.

Data Source

Because of the rich, multi-faceted nature of identity, semi-structured (formal) interviews were employed for data collection. As recommended by Hatch (2002), the interview protocols were viewed as 'guiding questions' rather than enforcing a rigid structure. In general, two interviews lasting about 60-90 minutes each were conducted with each participant; exceptional circumstances resulted in only one interview being conducted with two of the participants for a total of 22 interviews. Questions on the interview protocol were written by the researcher in consultation with published interview protocols from studies using similar frameworks (e.g. Burton, Boschmans, & Hoelson, 2013; Carlone, Haun-Frank, & Kimmel, 2010; Krzywacki, 2009; Settlage, Southerland, Smith, & Ceglie, 2009). The use of semi-structured interviews allows participants to describe how they recognize themselves and how they perceive themselves to be recognized by other people (Carlone & Johnson, 2007). All interviews were transcribed.

Data Analysis

The data in this study are being analyzed using inductive analysis as conceptualized in Hatch (2002). This type of inductive analysis is characterized by repeatedly re-reading the data to identify and refine domains which are then used to find larger themes (Hatch, 2002). Throughout this process, data examined both to see if it supports the working domains and themes and to see if it runs counter to them (Hatch, 2002). This flexible data analysis framework was chosen because it is consistent with the constructivist epistemology used in this study and because it allows for the use of several data sources; beyond the semi-structured interviews used in this paper, quantitative surveys and a brief biographical sketch were used as data sources.

Results

To answer the first research question, the different contextual identities that participants had with administrators, other teachers, and parents are explored. To answer the second research question, evidence of two major contributing factors to the development of a statistics teaching identity distinct from a mathematics teaching identity are presented, statistics teachers' specialized knowledge and their isolation in schools. These two factors presented are a subset of major contributing factors that have been identified in this study.

The Professional Identities of Statistics Teachers

The participants in this study typically had several professional identities, notably both a professional mathematics teaching identity and a professional statistics teaching identity. In Gee's (2000) conception of identity, one's contextual identities are predicated on being recognized by others in a certain way, i.e. in a given context, others' perceptions of a person are a core part of that person's identity for that context. Several contextual identities are evident in participants' relationships with administrators, other teachers, and parents, and these different contexts are characterized by different trends in how participants are recognized. These results report on participants' perceptions of the perceptions that others have of the participants; ideally, the others (e.g. administrators) would be directly interviewed about their perceptions, but this would substantially increase the scope of this project.

Generally, participants reported that administrators viewed them as either a solely a statistics teacher (four participants) or as both a mathematics teacher and as a statistics teacher (seven

participants); one was viewed as exclusively a mathematics teacher. Administrators tended to view participants in the role of a mathematics teacher for two primary reasons: either they continued to teach mathematics courses or they had become the chair of their school's mathematics department. One participant who was viewed as both by the administration said, "they think of statistics as being math because it lives in the math department here, but some people—who know of my background in statistics—would refer to me as the as a statistics teacher" [Samuel:385-386]. The experience of the administration not differentiating between mathematics and statistics, except in specific circumstances, was common. Some participants reported being viewed exclusively as a statistics teacher by the administration: "I think primarily they view me they saw me as a stat teacher because that was my claim to fame … that was two periods of my six-period day but yeah they would say 'she's the stats teacher'" [Laura:473-475]. Great success teaching statistics tended to be a necessary but not sufficient condition for being recognized by the administration as exclusively a statistics teacher.

Other teachers tended to view the participants as either solely a statistics teacher (four participants) or as both a mathematics teacher and a statistics teacher (eight participants); none were viewed as exclusively a mathematics teacher by other teachers. Patricia described the reason she is viewed as a statistics teacher by other teachers saying:

> a stat teacher to the other teachers, only because statistics is fortunately popping up and all the other courses—not just math but also the science courses, in psychology, economics—so [if] somebody has a statistics question they usually end up in my room [Patricia:246-248]

Similarly, Louie was viewed as a statistics teacher exclusively saying, "even within the department … I think the perception is that I'm a stats guy who happens to be chairing a math department right now" [Louie:351-352]. Other participants were viewed as both by their colleagues, reflecting a recognition by their peers that teaching statistics differs from teaching mathematics.

This recognition as a statistics teacher did not extend to parents of their students, even when restricted just to students enrolled in statistics courses. Three participants were viewed exclusively as statistics teachers by parents, two as both mathematics and statistics teachers, and five were viewed exclusively as mathematics teachers; two participants felt unable to judge parents' perceptions of them. Participants were viewed exclusively as mathematics teachers by parents even when they only taught statistics courses; Paul describes the reason as, "[students] get a math credit for it on their transcript … [parents] don't necessarily think of it as a distinction between math and stats" [Paul:449-452]. This was a common experience for participants. Participants who were viewed as solely a statistics teacher or as both attributed this recognition to widely-known successes in their schools' statistics programs or highly-educated parents. Samuel, who is viewed as both by parents, describes them saying,

> we get a lot of students whose parents are faculty members … you know really highly educated … [they'll ask] 'do you teach t-tests?' … I got a parent asking 'oh, do you do randomization tests?' … they have in their mind what a statistics class [is] [Samuel:256-260].

However, most participants did not encounter parents with well-formed conceptions of a statistic class, and so were viewed more often as mathematics teachers by parents than by administrators or other teachers.

Depending on the context of an interaction (Gee, 2000) with administrators, other teachers, or parents, participants reported having to navigate professional identities at the borders of mathematics and statistics. Every participant was viewed by other teachers—the colleagues who would know them best—as a statistics teacher, and sometimes additionally as a mathematics teacher depending on the specifics of their school. On the other end of the spectrum, parents—who would be expected to be less familiar with participants than teachers or administrators—largely viewed them as

mathematics teachers, reflecting a limited understanding of the differences between mathematics and statistics. Administrators had mixed perceptions of participants, often recognizing them as both mathematics and statistics teachers. A primary reason for this recognition as statistics teachers is that participants had specialized knowledge that was useful for helping others with both teaching and research.

Major Contributing Factors

To explain why participants had different mathematics and statistics teaching identities, major contributing factors were explored. Two such factors are described here, teachers' specialized knowledge and their isolation as statistics teachers within a school.

Specialized Knowledge. Within their schools, participants were able to use their specialized statistical knowledge to support their colleagues' teaching. This support was often in the form of extended collaborations between courses or more focused teaching support to help individual teachers. Environmental science provided opportunities for robust collaboration with colleagues for two participants in this study. Early in his statistics teaching career, Louie co-taught AP Statistics along with AP Environmental Science; this collaboration served both courses by incorporating the collection of real data with a meaningful context which could be analyzed and interpreted appropriately using statistical tools. Similarly, Samuel is in the early-phases of a collaboration with an English teacher at his school to link AP Statistics with an environmental literature course that is being taught. This connection between statistics and environmental science is not isolated to individual schools. While not a local collaboration with an individual teacher as in the cases of Samuel and Louie, Patricia has presented workshops nationally about integrating AP Statistics and AP Environmental Science. Such collaborations with statistics are long-term and are a benefit to both halves of the partnership.

Other collaborations address more immediate statistical teaching needs of teachers. After conversations with the AP Biology teacher at his school about how best to teach statistical topics such as the chi-squared test in response to changes in the curriculum, Bob was invited into the science classroom for several years to teach that material. Additionally, because of the new emphasis on statistics in the AP Biology curriculum, Bob worked closely with that teacher to ensure that he was comfortable teaching statistics. Bob recounts, "I spent almost 4 years working with him to get his stat up to the point where he's comfortable doing that now so I don't have to go in [to his class] anymore" [Bob:325-327]. While Bob's work with the biology teacher spanned several years, its focus was more limited in scope than a partnership between two courses as above. Still, Bob was being consulted for statistical expertise that many mathematics teachers would not have.

Addressing immediate needs of teachers is not limited to helping science teachers. Rebecca has helped algebra teachers with statistics material that is included in the CCSSM such as regression analysis and residuals. This type of assistance can range from offering out-of-class descriptions and help with specific problems to co-teaching lessons and offering question-and-answer sessions in-class for students. Rebecca recounts:

> We co-teach [because] with the students you know they feel they can ask questions that she may or may not be able to answer as in depth, and then I have another teacher that asked me about residuals. We co-taught residuals together for a day. [Rebecca:506-508].

Part of the reason that Rebecca welcomes questions from her colleagues about statistics is that the asking of such questions reveals that they are trying to teach the material rather than skipping it. She says, "Several of them come to me with stats questions, it's in the Common Core units that they have, which is [why] I welcome that because that means that they are teaching the units" [Rebecca:287-288]. In response to curricular changes such as the CCSSM or updates to AP Biology, additional statistics content beyond what these colleagues of the participants have been prepared to

teach are required; statistics teachers are being consulted specifically–rather than mathematics teachers–because of their specialized knowledge and the different roles they serve within a school.

Isolation in Schools. Perhaps unsurprisingly, many of the teachers in this study reported being the only statistics teacher at their school, and also reported that this was also the case for many colleagues they knew. To address this situation, the exemplary statistics teachers sought out a different community from the school mathematics community. For Rebecca, her isolation was unlikely to change in the immediate future:

> I'm the only person at my school that's been to the training for AP Statistics, and I'm probably one of the only ones that really wants to teach it. There's not too many people that really like statistics [Rebecca:13-15]

Patricia began teaching statistics because "when [AP Statistics] first came out nobody else wanted it, so I just kind of fell into it" [Patricia:28]. When colleagues are not prepared and express no desire to teach a course, an isolated teacher can have difficulty even finding another teacher to discuss ideas with. As described by Amber, teachers of mathematics courses generally do not have this problem:

> One of the first challenges was not having anyone to be a soundboard for you. You know, 'What do you think about this? You think this might work?' … like where you have in algebra or precalculus there's going to be multiple teachers–you can work together. Having to work in isolation was really difficult in terms of teaching statistics. [Amber:231-234]

Participants cited not having "that regular opportunity for collaboration" [Paul:407] within their schools and the ensuing challenges as a reason for engaging with the broader statistics education community. Engaging with a professional community was a major contributing factor to the development of the participants' professional statistics teaching identities.

Discussion and Conclusions

The exemplary statistics teachers in this study developed professional identities as both mathematics teachers and statistics teachers. Depending on the specific context of an interaction, one professional identity may be brought to forefront. The effect of this is that the exemplary statistics teachers are continually working at and across the border between mathematics and statistics, even for teachers who only teach statistics classes.

The participants in this study had many years of teaching experience and had grown comfortable operating with these contextual professional identities and were able to use their specialized knowledge to serve their colleagues as a resource. Mathematics teachers who are less experienced with statistics, however, may not be so comfortable. The participants in this study each took several years developing their professional statistics teaching identities.

Improvements should be made to the statistical preparation provided mathematics teachers. Such recommendations are not new (CBMS, 2012; Franklin et al., 2015), but the experience of these exemplary statistics teachers provides further support for these calls. Participants in this study generally reported not feeling prepared to teach statistics when they were early in their careers. None was specifically trained to be a statistics teacher, and developing a statistics teaching identity required engaging with colleagues beyond their local school.

Participants found it critical to be connected with a broader community because they were often so often isolated, being either the only or one of only a few statistics teachers. Many of the participants reported that participation in the AP Statistics Reading or the AP Statistics Teacher Community (formerly the AP Statistics Listserv) provided initial and on-going experiences that helped them become exemplary teachers. Unfortunately, no direct analogues for either the AP Statistics Reading or AP Statistics Teacher Community exist for non-AP Statistics teachers at the 6-

12 level. Addressing teacher isolation within schools by connecting statistics teachers (particularly those new to the subject) with broader communities—either virtual or in-person—may be a viable approach for supporting teachers' transitions and growth. Teachers could be directed to such resources while they are still in their preparation programs.

Mathematics teachers who are being asked to teach more statistics now in grades 6-12 under the CCSSM (NGA & CCSSO, 2010) are likely to require different preparation and professional development than is required for mathematics. However, administrators, other teachers, and parents—groups who could conceivably support new statistics teachers—may not know enough about the disciplinary and instructional differences to recognize that additional, different supports are needed.

Asking mathematics teachers to teach statistics is more than simply asking them to teach new or additional mathematics material. Rather, because of widely-acknowledged disciplinary differences between mathematics and statistics (e.g. Cobb & Moore, 1997; Moore, 1988; Rossman et al., 2006), mathematics teachers are being asked to cross the border between mathematics and statistics. There are many potential benefits for teachers and students that may arise from this arrangement, e.g. new avenues for teaching quantitative literacy (Scheaffer, 2003; Steen, 2001) and changes in mathematics teaching practice. However, the complexities of the identities of these exemplary statistics teachers suggest that purposeful reforms to teacher preparation and professional development must be made and cannot be done in ways that recognize only the professional mathematics teaching identity.

EXPLORATION OF THE VARIABILITY OF INFORMAL INFERENCES DRAWN FROM SIMULATED EMPIRICAL SAMPLING DISTRIBUTIONS

Jeffrey A. McLean
St. Lawrence University
jamcle01@syr.edu

Two groups of introductory statistics students (at the secondary and tertiary level) participated in a model exploration activity that explored the dotplot representations of simulated empirical sampling distributions. Students compared and discussed informal inferential claims drawn from the sampling distributions as the amount of simulated data in the sampling distributions increased. The students began to develop a global view of sampling (Pratt & Noss, 2002) by exhibiting an understanding of the long-term randomness of sampling by describing the trend of the growing collection of simulated data and the informal inferences that could be drawn.

Keywords: Data Analysis and Statistics, Modeling

Introduction

Influential documents such as the *Guidelines for Assessment and Instruction in Statistics Education Report* (Franklin et al., 2007) and *The Common Core State Standards for Mathematics* (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) have emphasized the use of simulations in statistics coursework. Technology now allows simulations to be performed nearly instantaneously, thus making accessible new approaches to teaching statistical inference through simulations. Researchers have claimed that technology can allow the teaching of statistics to be visual, dynamic, and interactive with students engaging in experimentation with data rather than computations and can support student learning through the automation of calculations, emphasis on data exploration, visualization of abstract concepts, and use of simulations as a pedagogical tool (Garfield & Ben-Zvi, 2008). In this study, introductory statistics students used *TinkerPlots* (Konold & Miller, 2014) to simulate data, make informal inferential claims from simulated empirical sampling distributions, and explore the effects that increasing amounts of simulated data had on their informal inferences.

Review of Literature

For this study I drew from two bodies of research literature: modeling and informal inferential reasoning. Models are "conceptual systems … that are expressed using external notation systems, and that are used to construct, describe, or explain the behaviors of other system(s)" (Lesh & Doerr, 2003, p. 10). In this study, students participated in a model exploration activity (MXA), which often use computer graphics, diagrams, or animations in order to develop a powerful representation system for the students to make sense out of the situation (Lesh, Cramer, Doerr, Post, & Zawojewski, 2003). The goal of MXAs is to introduce students to conventions that have taken mathematicians and statisticians many years to develop and provide more in-depth understanding of their model.

Central to the MXA in this study was students' informal inferential reasoning, which is the drawing of conclusions from data that extend beyond the data, from the viewing, comparing, and reasoning with distributions of data (Makar & Rubin, 2009). Researchers have claimed that the use of simulation to teach informal inferential reasoning can help students to build a deep understanding of the abstract statistical concepts and suggested that informal inferential reasoning may support the development of students' understanding of formal inferential reasoning (Bakker & Gravemeijer, 2004; Saldanha & Thompson, 2002). Some research has shown that the use simulations can develop students' understanding of the value making data-based inferences from larger collections of samples (Stohl & Tarr, 2002), yet earlier research indicated that while students were proficient at describing

short term randomness, identified as a local view, through observations such as the variations between subsequent samples, they had trouble expressing their understanding of the long term randomness, identified as a global view, such as the overall trend of a growing collection of samples (Pratt & Ross, 2002).

Design and Methodology

This study is a qualitative case study and part of a larger study where four introductory statistics classes at the secondary and tertiary levels participated in a month long instructional unit. I will report the findings from two groups of students (Groups X and Y) while participating in the second activity in the instructional unit, a model exploration activity, during one 75-minute class period. The groups consisted of three to four students with each student at their own computer station with *TinkerPlots* (Konold & Miller, 2014). During the class period I videotaped each group and collected written classwork in order document the students' developing models of sampling and inference. In the results section I will provide a narrative of developments in the students' models.

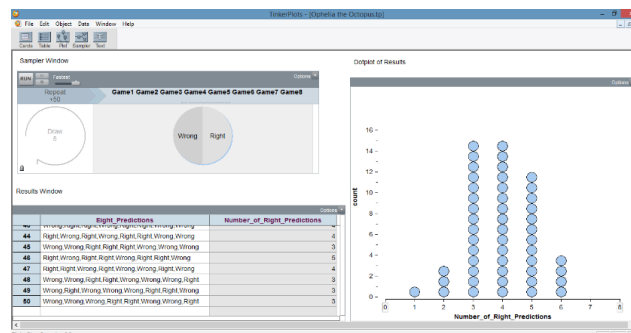
Prior to this activity, the students participated in a modeling eliciting activity (MEA) that told a brief story of an octopus that predicted eight of eight soccer matches correctly during the 2010 World Cup. Local zookeepers planned to have their octopus predict the winners of eight upcoming basketball games. Groups of students were asked to determine the range of outcomes that they thought were likely for the octopus to correctly predict. Students then participated in a model exploration activity (MXA) that investigated the same context with Ophelia as the MEA, but students now used *TinkerPlots* (Konold & Miller, 2014) to simulate outcomes. I created an environment in *TinkerPlots* that contained a sampler, results, and dotplot window (Figure 1).


Figure 1. *TinkerPlots* environment for the MXA.

The sampler window in *TinkerPlots* (shown in the upper left) used a spinner with half of the area marked right, the other half wrong. This corresponded to the flipping of one coin to predict the octopus' predictions. The results window (shown in the lower left) showed the outcomes simulated by the spinner in sets of eight predictions. The dotplot window (shown on the right) displayed the number of right predictions in each set of eight. Each student ran the simulation on an individual computer. The activity asked the students to compare their individual dotplots and inferences with their group members' and guided the students to explore how the simulation of an increasing number of samples affected the inferences that they drew from the data. With the dotplot representation of the data, students had the opportunity to visually explore the shapes of the distributions of data simulated by fellow group members, and the changing shape of their own distribution of data as an increasing amount of samples were simulated.

Results

Both groups of students began by simulating 10 samples of Ophelia's predictions and examined their dotplots. A student from group X stated that most of his outcomes were as he expected them to

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

be, in the range of four to six correct predictions, but he also generated outcomes of one and two correct predictions. His fellow group member stated that these outcomes "seemed very strange because they are so far off from what the outcomes should have been (4/8, 50%)". This second group member had similar results, with most of his values between three and five correct predictions with additional outcomes of one and seven that he also thought seemed "very unusual because it is so far from 50%". These students did not anticipate that the simulation of a small number of samples would produce what they considered as unlikely results.

When students from group Y each simulated 10 samples and compared their dotplots, one student stated that two of their dotplots:

> … had some form of a bell curve, while one was skewed to the left …They all thought it was going to be a bell curve, but the results didn't comply. They [the dotplots] should be the same because all trials are similar and they are independent and there is a 50/50 chance of it being correct or not.

I interpreted the statement that "results didn't comply" to demonstrate that this student, like those from group X, did not anticipate the variability in sampling. Students in Group Y anticipated the shape of the distribution to be bell curved and both groups of students anticipated aspects of the distribution of data and expected most, or all, data to be in the center of the dotplot.

When focus group X simulated 50 samples, the students noted that each other's dotplots were "very similar and all/most of the dots were around 50% or 4/8", and that each of their dotplots had a "pyramid shape". They concluded that the likely ranges were three to six correct predictions and three to five correct predictions. These inferences were similar, but still not the same.
Figure 2. Group X's 50 simulated samples.

After students in group X each simulated 1000 samples, one student noted that they had "identical graphs" and "that all dots / number of dots per # of games correct were very similar" I interpreted this to mean that he was referring to the number of times that each outcome occurred was similar between him and his partner's dotplots. Both students concluded from these dotplots that Ophelia is likely to predict three to six of the eight basketball games correctly.

When group Y simulated 50 and then 1000 samples, the students claimed that each dotplot looked like a bell curve and did not change their predictions for the likely ranges of correct predictions. One student asserted that, "the more trials conducted will help conclude a more accurate prediction". I interpreted that by more accurate, this student meant that as more samples were simulated, the dotplot would look more like the bell curve that the group members had anticipated. Another student from group Y continued to simulate samples and came to the conclusion that at some point, simulating more samples did not change the look of the dotplot. She concluded that the plot was "saturated with data".

Discussion and Conclusions

This study demonstrated the use of *TinkerPlots* (Konold & Miller, 2014) to view dynamic dotplot representations of empirical sampling distributions. As more samples were simulated, the students compared their sampling distributions with those simulated by other students, and observed

that as more samples were simulated, the variability between each sampling distribution decreased. This variability in sampling distributions led students to draw differing informal inferences from the data when simulating a small number of samples, but to draw identical inferences when simulating many samples. Consistent with Stohl and Tarr (2002), these results suggest that students can recognize the importance of simulating large numbers of samples to draw their inferences. I assert that the students began to develop a global view of sampling (Pratt & Ross, 2002) by exhibiting an understanding of the long-term randomness of sampling when describing the trend of the growing collection of simulated samples. The results also indicated that the use of model exploration activities can be used to promote informal inferential reasoning. Future statistics curricula may benefit from the use of modeling and model exploration activities.

CROSSING THE BOUNDARY: RESULTS FROM THE TEACHER ATTITUDES AND BELIEFS TOWARD STATISTICS SURVEY (TABSS)

Christina M. Zumbrun
Trine University
zumbrunc@trine.edu

Due to the increased attention given to statistics in the school curriculum over the last several decades, there is a need to study the attitudes and beliefs of secondary mathematics teachers (SMTs) with respect to statistics since research has linked teachers' affect to student learning (Estrada & Batanero, 2008). Because the attitudes, beliefs, and emotions (affect system) of practicing SMTs toward statistics are not exactly known, an inventory of these constructs was conducted via a survey instrument. Most of the survey items were developed in light of the GAISE framework and the CCSSM; hence SMTs' affect toward statistics was described in terms of these documents. Based on responses to the survey items, SMTs indicated confidence in their own ability to master statistical content, belief that students can learn statistical concepts, and some agreement with the goals established by the GAISE framework.

Keywords: Teacher Beliefs, Data Analysis and Statistics, Affect, Emotion, Beliefs, and Attitudes

Over the last several decades, mathematics education researchers have given increased attention to students' and teachers' attitudes and beliefs toward mathematics and statistics, but no work has been done that examines practicing secondary mathematics teachers' (SMTs') attitudes and beliefs towards statistics in light of the *GAISE* framework and the *Common Core State Standards for Mathematics* (*CCSSM*). This study begins to address this gap in the research by analyzing the results from the Teacher Attitude and Beliefs toward Statistics Survey (TABSS), a synthesis of items taken from the Survey of Attitudes Toward Statistics (Schau, 2013), the Statistics Course Attitude Scale (SCAS), and newly developed items reflecting current trends in thinking about K-12 statistics education.

Purpose of the Study

The focus of the study was to investigate and characterize the affect system of SMTs toward statistics via the Teacher Attitudes and Beliefs toward Statistics Survey (TABSS) as the method of data collection. The items on the survey were designed to explore SMTs' affect systems toward statistics relative to their experiences as teachers and students of mathematics and statistics. The purpose of this paper is to filter the data related to attitudes and beliefs in order to describe and clarify the affect system that SMTs, as a group, hold toward statistics. General analysis of the data from the study is highlighted and conclusions are suggested that help to characterize this population of teachers.

The primary goal of the study was to characterize the attitudes and beliefs of practicing SMTs toward statistics based on their responses to the TABSS. Specifically, the *affect system* of practicing SMTs toward statistics was determined by the responses to the items on this survey instrument. Therefore, each of the 10 survey items was analyzed individually for mean responses from the total group of teachers ($n = 141$). The measures of center, together with the variation observed in the data set, were used to characterize the attitudes and beliefs of the population of SMTs based on the responses of this sample of teachers. Hence, the research question was initially explored via the summaries of responses to each of the ten survey items.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Methods

The SATS-36 served as a basic yet thorough inventory for SMTs' attitudes and beliefs towards statistics, and thus it was a valuable tool for an introductory study. Furthermore, the SATS-36 was the most comprehensive survey available that situated attitudes and beliefs towards statistics in an educational context. While it had not been used with this population of SMTs, it had been validated as a stand-alone instrument for use in similar populations (university students) (Schau, C., Stevens, J., Dauphine, T., & del Vecchio, A., 1995; Schau, 2013) and provided a basic accounting of SMTs' attitudes and beliefs towards statistics. Because the attitudes, beliefs, and emotions of SMTs was expected to be similar to this population (Pierce & Chick, 2008), the existing instrument provided the best basis on which to begin studying this new population. Researchers agree that existing survey instruments designed to measure attitudes and beliefs regarding statistics could be strengthened if they included more items related directly to statistics teaching (Pierce & Chick, 2008). Hence, the TABSS was developed by adding items to the SATS-36 and SCAS in order to address specific concerns related to the *CCSSM* and teaching statistics in light of the *GAISE* document's emphasis on recent statistics education reform efforts.

The teacher response data was collected by using an online survey system which emailed the TABSS to a random sample of SMTs from a Midwestern state. The survey was initially emailed to 502 teachers. Of the 502 who were emailed the survey, 92 filled out the survey giving a response rate of 18.3%. Based on this response rate, the survey was emailed to an additional random sample of 276. Of the 276 who were emailed the survey, 49 filled out the survey giving a response rate of 17.8% for the second mailing. Thus, the overall response rate was 18.1%. The results for the ten survey items are found in Table 1.

Table 1: Summary Statistics for All SMTs (*n* = 141), Arranged in Ascending Order

Survey Item	Mean	Std. Dev.
[a] There are only a few methods that are useful for teaching statistical concepts to students.	3.79	2.12
Understanding probability and statistics is becoming increasingly important in our society, and may become as essential as being able to add and subtract.	3.84	2.33
A student's statistical reasoning should be assessed based on experience with concepts, not age or grade.	3.85	2.19
[a] I found it difficult to understand statistical concepts.	4.24	2.14
[a] I had no idea of what was going on when I learned topics from statistics.	4.46	2.18
[a] I had trouble understanding statistics because of how I think.	4.48	2.22
I understood statistics equations.	4.52	2.11
[a] Typical students cannot expect to understand statistics; they should just memorize and apply what they have learned mechanically and without understanding.	4.60	2.45
Hands-on, active learning is an important part of learning and understanding statistics.	4.60	2.48
Students should be allowed to use appropriate technology when learning statistics.	4.97	2.55

[a] Items are rescaled positively.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Discussion of Results

Items with Negative Responses

The SMTs responded to the survey items based on a scale of 1 (strongly disagree) to 4 (neither disagree nor agree) to 7 (strongly agree); hence a higher score on a particular item indicated a more positive response to the item. The *lowest* mean response out of the 10 final items was given for "There are only a few methods that are useful for teaching statistical concepts to students." Thus, the low mean score of 3.79 (low in comparison to the neutral survey response of 4) indicated teachers' slight agreement with the statement. Overall, teachers ($n = 141$) agreed that there are indeed only a few methods that are useful for teaching statistical concepts to students. This item was original to the TABSS and was constructed in response to the *CCSSM*, indicating some agreement among the teachers with the aims of that document.

The next two items, "Understanding probability and statistics is becoming increasingly important in our society, and may become as essential as being able to add and subtract" and "A student's statistical reasoning should be assessed based on experience with concepts, not age or grade" were constructed in response to the *GAISE* document. The results related to these items can be further compared since wording of the items is positive and the teachers' mean responses to these items were close (3.84 and 3.85, respectively). These mean scores were below the neutral response of 4, indicating overall slight disagreement with the items. Thus, the teachers' responses to these items revealed that they did not seem to agree that statistical skills are growing more important within modern society and they generally disagreed with the guideline suggested by the *GAISE* document that statistical skills should be taught based on experience with concepts. Based on the results for the first three survey items in Table 1, the SMTs seemed more in agreement with the principles supported by the *CCSSM* rather than the *GAISE* document.

Items with Positive Responses

For the last seven items in Table 1, the responses were more positive than the first three. The determination of "positive" responses is based on comparisons with the neutral survey response of four, which indicates no agreement or disagreement with each item. This discussion focuses on the three items with the most intensely positive reactions.

Teacher responses to the items were moderately positive, and they are each related to teachers' attitudes toward statistical learning. Two of these three items directly follow from the *GAISE* document, which supports hands-on active learning and technology use in the statistics classroom. Additionally, teachers tend to moderately disagree with the item stating that typical students could not expect to understand statistics. This item was constructed in response to the *CCSSM* document, and stands in contrast to those items related to the *GAISE* document.

Thus, the SMTs as a group are in disagreement with some of the ideas reflected in the *GAISE* document. They *disagree* that "Understanding probability and statistics is becoming increasingly important in our society, and may become as essential as being able to add and subtract" and "A student's statistical reasoning should be assessed based on experience with concepts, not age or grade." They *agree* with "There are only a few methods that are useful for teaching statistical concepts to students," which was written for the TABSS to reflect the *CCSSM* document. Despite these findings, SMTs have a high level of confidence regarding their own learning of statistical topics, indicating general agreement with "I understood statistics equations." These findings seem contradictory. While SMTs feel confident in their own abilities to learn and solve statistical problems, they also indicate general disagreement that understanding probability and statistics is important.

Summary of Findings

Teachers' responses to the survey items provide valuable information about SMTs' general affect systems toward statistics, and the study provides an important first step towards studying teacher affect in light of teacher practice (Zumbrun, 2015). Based on the responses to the survey, the SMTs agree that typical students *can* expect to understand statistics, hands-on active learning is an important part of learning and understanding statistics, and students should be allowed to use technology when learning statistics. They are also in common agreement that as students they *did not* find it difficult to understand statistics concepts, they *did* have an idea of what was going on when they learned statistics, they *did not* have trouble understanding statistics, and they *did* understand statistics equations, in general. These findings signify that SMTs, as a group, are largely confident in their own ability to master statistical topics and believe that their students can also learn statistics. Hands-on, active learning and appropriate technology are also important parts of the learning process. These commonalities provide a strong basis for beginning to form a profile of SMTs' affect toward statistics, which was the fundamental goal of this study.

CHARACTERISTICS OF SECONDARY STATISTICS TEACHERS

Christopher Engledowl
University of Missouri
ce8c7@mail.missouri.edu

The importance of developing students' statistical literacy prior to entering post-secondary education has gained increased attention over the past decade (Franklin et al., 2007). However, secondary mathematics teachers have limited statistical background knowledge and feel inadequately prepared to teach such content (Banilower et al., 2013). Further, many schools offer Advanced Placement (AP) Statistics and other college preparatory statistics courses, implying teachers of such courses should have stronger statistics backgrounds. Since students who pass the AP Statistics exam typically receive college credit, non-AP statistics courses provide the largest opportunity to prepare students for introductory college level statistics, where students make minimal gains (delMas et al., 2007). Furthermore, non-AP statistics teachers may experience a wider range of student achievement levels. This implies a need for both deep content and teaching knowledge that benefits a variety of students in developing statistical literacy.

Data from Banilower and colleagues' (2013) national survey provides an opportunity to examine non-AP statistics teacher characteristics. Specifically, the research aim is to capture teacher characteristics regarding their (a) background knowledge, (b) pedagogical practices, and (c) ability to apply this knowledge across various student achievement levels. A secondary analysis on the teachers indicating they taught a non-AP statistics course resulted in some important findings. In particular, a large proportion of teachers reported a wide range of student achievement levels in their courses and not feeling well prepared to teach statistics. Moreover, a notable proportion reported not frequently engaging students in building arguments for solutions and about half reported not frequently engaging students in considering multiple representations.

The findings of this study provide some direction for building professional development for non-AP statistics teachers that focuses on specific types of pedagogical practices that can be used across achievement levels. The border between secondary statistics and collegiate study currently appears to limit success and opportunities for developing statistical literacy. Such borders could be reduced with targeted professional development for teachers of non-AP statistics courses.

INVESTIGATING SECONDARY STUDENTS' INTEGRATION OF EVERYDAY AND SCIENTIFIC IDEAS OF PROBABILITY (INDEPENDENCE AND DEPENDENCE)

Robert A. Mixell
University of Delaware
mixellr@udel.edu

Keywords: Probability, Learning Theory, High School Education, Instructional Activities and Practices

Rationale and Theory

Lev Vygotsky (1987) asserted that learning occurs via the convergence of *everyday* understandings (real-world/concrete) and *scientific* understandings (school-based/abstract). However, students tend to experience a natural *border* between their everyday ideas and what they learn in school. Using Vygotsky's perspective, I conducted a study to determine ways in which instruction could be purposefully designed to foster the convergence of students' *everyday* and *scientific ideas,* as expressed through their language. I chose the topic of probability because of its importance in K-Post-Secondary education (Common Core State Standards Initiative [CCSSI], 2010; National Council of Teachers of Mathematics [NCTM], 2000) and because students must "recognize and explain" probability in "everyday language and everyday situations" (CCSSI, 2010). More specifically, I chose the concepts of *independence* (events not affecting each of their likelihood of occurrence) and *dependence* (one event affecting the likelihood of another's occurrence).

Methods and Analysis

Four high-school students participated in a four-lesson intervention. To elicit their *everyday ideas*, students were first asked to identify pairs of everyday events so that events in one pair were associated and events in the other pair were not associated. Then they were to explain if the events for each pair were independent or dependent. While receiving initially abstract and gradually contextualized instruction designed to develop their *scientific ideas* of probability, students routinely revisited their original contexts. Participant data were coded using a-priori and grounded categories to determine if the integration of *everyday* and *scientific ideas* transpired throughout the lessons.

Results and Discussion

Analysis revealed that most students' *everyday* and *scientific ideas* of *dependence* achieved integration, yet with some logical errors and misunderstandings of probability. For *independence* however, such integration occurred later in the lesson or not at all. One hypothesis for the greater *removal of borders* for *dependence* is that the term is often used in common language to indicate that one event affects the likelihood of the other (e.g., "that depends"). However, *independence* is often used in a way that indicates a relationship involving authority (e.g., "gaining independence from your parents"). This study contributes to the field's understanding about using instruction to intentionally foster the integration of *everyday* and *scientific ideas*. More research is needed to test this hypothesis and to determine whether scientific underpinnings exist for everyday ideas of other concepts.

THINKING INSIDE THE BOX: STUDENTS' DIFFICULTIES WITH BOXPLOTS

S. Asli Özgün-Koca	Thomas G. Edwards	John Barr
Wayne State University	Wayne State University	Wayne State University
aokoca@wayne.edu	t.g.edwards@wayne.edu	johnbarrmi@yahoo.com

Common Core State Standards and other reform documents ask teachers to foster statistical reasoning at all grades (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). To do that, students need to have a profound understanding of statistical representations (Ben-Zvi & Garfield, 2005). Understanding and interpreting statistical representations are crucial as students build and improve their statistical reasoning and conceptual understanding in statistics. Boxplots are statistical representations that are fairly easy to create but complicated to understand and interpret. In this study, our research questions were: What are the strengths and difficulties of middle school students in constructing boxplots? How do middle school students read and interpret information presented in a boxplot?

Based on our interpretation of the literature on boxplots (Bakker, Biehler, & Konold, 2004; Pfannkuch, 2007; and others), we created a conceptual framework having five constructs: a major focus on the five-number summary, boxplots presenting data in an aggregated format, the density display of boxplots, the median as a measure of center, and students' previous knowledge of concepts. We studied 259 students in two middle schools in a large metropolitan area in the Midwestern United States. The teachers in both schools assured us that their students had previously studied boxplots. In order to investigate our research questions, we administered a pre-test and post-test the day before and the day after students completed a boxplot activity that used TI-Nspire calculators. In this paper, we report only what we found in the pre-test results.

As a result of cross-tab analysis on multiple items of the pretest, we found that a correctly constructed boxplot was not a strong predictor of providing correct responses to questions asking for an interpretation of information presented in a boxplot. Using previous knowledge and skills to construct a boxplot or make sense of a boxplot often interferes with this new way of representing and interpreting data. For instance, students learn about the frequency bar and the longer the box, the more data there are. When current previous knowledge and experiences do not provide a strong enough foundation for students to learn, think about, and interpret a new concept, it acts as a barrier preventing students from moving forward. When this happens, we need to think about new ways to introduce the new concept. With boxplots, we can get help from technology, which offers novel ways of visualizing and experiencing statistical representations with an access to dynamically linked multiple representations. Using these novel capabilities of cutting edge technologies, we can create representations that students can both act on and interact with as they learn.

INVESTIGATING MIDDLE SCHOOL STUDENTS' UNDERSTANDING OF RISK AND SOCIAL JUSTICE IN THE MATHEMATICS CLASSROOM

Nenad Radakovic
College of Charleston
radakovicn@cofc.edu

Mary Elizabeth Riley Lloyd
College of Charleston
lloydb@cofc.edu

Keywords: Data Analysis and Statistics, Middle School Education

Educators and researchers are advocating for the teaching of risk and its exploration within an educational setting. For example, studies focus on teachers' understanding of risk (Levinson, Kent, Pratt, Kapadia, & Yogui, 2012; Pratt et al., 2011), as well as high school students' understanding of risk (Radakovic, 2015). These studies address risk in a personal context (e.g. risk of surgery) and a socio-scientific context (e.g. the safety of nuclear power plants). However, there is a gap in the literature when it comes to teaching risk in a social justice context (i.e. on the exploration of how risk affects various groups and how societal structures play a role in an unequal distribution of risk). The closing of this gap should be top priority, as it is well documented that underrepresented groups are more likely to be exposed to certain risks. The research questions for the study were: 1) How do the middle school students reason about risk? 2) What is the relationship between math and students' understanding of an authentic issue? and 3) What is the role of context in their understanding of risk?

Methods

We conducted semi-structured interviews with 14 seventh graders. The interviews focused on the students' understanding of the concept of the average life expectancy at birth and the factors that may influence it. The interviewer (one of the authors) presented students with average life expectancy data across countries, the US states, and socioeconomic groups. The interviews were one-on-one and were audio recorded, video recorded, and screen-recorded. The interview transcripts and video files were imported into NVivo 10 and coded using open codes. Using the constant comparative method, different themes were then identified. The themes include: student understanding of gender, socioeconomic status, and nationality in relation to the average life expectancy.

Findings and Discussion

This study is an initiating work in the critical pedagogy of risk as it merges two research programs: one in the pedagogy of risk and another in critical mathematics education. The findings show a complex relationship between students' understanding of risk (i.e. risks that may influence the average life expectancy) and their mathematical knowledge. Consistent with Levinson et al. (2012) and Radakovic (2015), understanding of the notion of average life expectancy depended on representations (graphs) as well on student values, experiences, and personal and social commitments (e.g. stance on gun control). The study serves as a blueprint for the further exploration of the critical pedagogy of risk in the classroom.

In this work, we are interested in observing how high school students reason with or ignore variability when faced with a situation of prediction/uncertainty in which the underlying distribution is the binomial distribution $b(x, 2, \frac{1}{2})$.

The Conceptual Framework for this work is formed by concepts related to probabilistic reasoning and informal reasoning. The first one is the reasoning in which one of the 'big ideas' of probability occurs. These big ideas are randomness, variation, independence and the pair of complementary ideas, predictability and uncertainty, Gal (2005). The informal reasoning is a process in which the student builds a model of the situation, articulating several of its elements and obtaining consequences with the help of common sense and previous knowledge. Informal probabilistic reasoning is informal reasoning that involves some of the big ideas of probability.

The method consisted of four-step study with 37 high school students (15-16-year-old) who had not previously taken a course in statistics and probability. The task of predicting the results of drawing 1000 times the random variable $b(x, 2, \frac{1}{2})$ and giving its distribution, was administered in four steps: 1) Students were asked to respond according their actual knowledge. 2) Students simulated the situation with manipulatives. 3) Students simulated the situation using the software Fathom. 4) Students were asked to respond again the same questions.

As a result, we found that there are two main patterns of responses. 1) Responses that consider the theoretical distribution but without integrating variability of the results, for example: "probability distribution: ¼, ½, ¼. Prediction: 250, 500, 250 [expected frequencies]". 2) Responses that consider empirical distribution where variability is reflected but without consider the theoretical distribution, for example: "probability distribution: 0.23, 0.52, 0.25; prediction 234, 521, 245". Only in one case, in the final step, a student identified the distribution ¼, ½, ¼, and predicted frequencies different of expected frequencies. In closing, some students choose the frequency approach to probability but without considering the underlying distribution. Other students calculate classic probabilities and propose determined expected frequencies without considering variability. Articulating classic and frequency approaches, including the role of variability, requires larger processes of conceptualization.

The Modules for Teaching Statistics with Pedagogies using Active Learning (MTStatPAL) project creates and studies modules used to implement active learning lessons in collegiate introductory statistics courses. Modules include online pre/post-class activities for students, instructor materials, and in-class activities focused on active learning. While much is known about the benefits of active learning at the university level (Prince, 2004), less is known about university instructors' implementation of active learning in statistics classrooms. It is no simple matter for instructors to transition from lecture to active learning. Understanding how instructors develop new forms of practice while participating in mathematics education reform efforts requires an understanding of how instructors orient themselves to mathematics, to learning in general, and to mathematical learning in particular (Simon, Tzur, Heinz, Kinzel, & Smith, 2000). This ongoing project uses design experiment methodology (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) to understand how the learning ecology of statistics classrooms is impacted while teachers transition to implement the MTStatPAL modules.

This poster focuses on the question: how do faculty who have taught primarily using classroom lectures adapt their teaching practices to implement the MTStatPAL modules' active learning approach, and what issues arise during the implementation? Instructor interviews and observations of classroom instruction provide data for this investigation. Through a qualitative analysis of the data (open coding, memoing, and axial coding), connections have been observed between the instructors' orienting perspectives (Simon et al., 2000), conceptions of teaching (categorized along a continuum that describes the extent to which instructors have a relational view or a treatment view of teaching (Noddings, 2003)), and the ways instructors implement the modules. In the poster, we display ways in which instructors' conceptions of teaching and orienting perspectives are associated with the instructors' implementation of the MTStatPAL modules. This research addresses an important topic in mathematics education. Specifically, it reveals important issues to which university instructors must attend while crossing the border from lecture to active-learning pedagogies in introductory statistics classes.

PRELIMINARY GENETIC DECOMPOSITION OF INDEPENDENCE OF EVENTS

Karen Zwanch
Virginia Tech
kzwanch@vt.edu

Shaughnessy (2003) indicates that "students have difficulty just sorting out the mathematics of whether events are statistically … independent" (p. 221). Ollerton (2015) attributes this difficulty to a disconnect between an intuitive sense of the term and its mathematically correct definition. This is supported by the fact that the mathematical definition is reliant upon conditional probability, however, independence is often introduced intuitively prior to instruction on conditional probability. As a means of determining the conceptual structures students must construct to eventually link their intuitive understands to formally conceptualized independence, I constructed a preliminary genetic decomposition of independence of events, using APOS theory, based on self-reflection and research on student thinking (Arnon et al., 2014).

Necessary mental constructions to conceptualize independence begin with simple probability. The basis for constructing an action conception of simple probability involves randomness, quantification, and logical disjunction (Piaget & Inhelder, 1951/1975). Within this frame of understanding, students require manipulatives to complete probabilistic tasks and are unlikely to be perturbed by a mismatch of frequentist and classical results, as students are unlikely to understand these two types of problems as equivalent. The process of calculating probability is external and cannot be anticipated mentally. To advance to a process conception, students must interiorize their actions, thereby generalizing the frequentist and classical probability to represent equivalent situations. This allows for probabilistic reasoning without manipulatives, the comparison of probabilities, and the reversibility of the mental structure. With a process conception, students have yet to formalize the law of large numbers, and are likely to be perturbed when frequentist and classical results are unequal. Not until simple probability is encapsulated into an object can students reason about multiple (compound) and nested (conditional) probabilities, as an object conception can support the coordination of combinatorial reasoning schemas with probability. Through this encapsulation, students resolve their perturbations regarding classical and frequentist probabilities and the law of large numbers. Ultimately, constructing independence involves the coordination of two objectified probabilities, and therefore, the construction of a schema conception of probability.

IS THIS MATH? COMMUNITY APPROACHES TO PROBLEM SOLVING IN YUCATEC MAYA MATH CLASSROOMS

Felicia Darling
Stanford University
fdarling@alumni.stanford.edu

In Yucatec Maya middle schools in the Yucatán, math scores are low and drop out rates are high. Although addressing larger social and economic causes may ameliorate these issues, improving math instruction may be a more immediate, feasible approach. This ethnographic, mixed-methods study explores community approaches to problem-solving relevant to middle school math classrooms. Findings indicate: (1) community members possess specialized, practical mathematical expertise that is overlooked in the research around rural, impoverished students, and (2) formal math instruction misses opportunities to capitalize upon cultural approaches involving autonomy and improvisational expertise. Results are relevant for curriculum reform in the US, México, and beyond.

Keywords: Equity and Diversity, Advanced Mathematical Thinking, Middle School Education, Problem Solving

A Yucatec Maya carpenter remodels a kitchen using no tape measure, yet armed with specialized knowledge of the 3-4-5 right triangle, a length of string, and a makeshift level crafted from plastic pipe and water. Despite this engineering expertise, he does not consider his mathematical knowledge to be legitimate, because it is not a product of formal schooling.

Introduction
This carpenter lives in a typical village in the Yucatán with low national math scores and high drop out and poverty rates. His story illustrates the tension between formal and informal schooling in rural, high-poverty communities in many countries. Today, in México and the U.S., academic achievement of socioeconomically disadvantaged students is a pressing issue, because the majority of students enrolled in public schools in México (INEGI, 2005), and the U.S., are low-income (Suitts, 2015). My study departs from the typical deficit framework as it documents, often unrecognized, expertise of socioeconomically disadvantaged students. Results inform mathematics instruction, because they illuminate undocumented cultural assets that can be capitalized upon in math instruction to teach 21st century skills like innovation and creativity.

Bourdieu states that students arrive to school with a "habitus," a well-established set of dispositions and knowledge imparted by families and communities that may be incongruent with school culture (1986). Several studies build upon Bourdieu's theory to illustrate that redressing tensions between home and school cultures of ethnic/racial minority students improves academic outcomes (Au and Mason, 1981; Lee, 1995; Lipka, 2005). Given that recent research in the U.S. demonstrates that the socioeconomic achievement gap is as salient as the ethnic/racial achievement gap (Carnoy & Rothstein, 2014; Reardon, 2011; Suitts, 2015), my study focuses on impoverished students. While the majority of studies emphasize deficits of low-income students such as high absenteeism and low rates of word recognition, one researcher, Laureau, takes an asset-based approach. She finds that working-class students in the U.S., because of their upbringing, are afforded certain qualities like autonomy that are not readily available to their more affluent peers (2003). Because schools, ultimately determine what constitutes legitimate knowledge and learning (McDermott, 2006; Saxe, 1985), these "assets" are not valued when navigating the U.S. school culture, which is constructed to advantage more affluent students. Like Lareau, I am pioneering asset-based research of economically disadvantaged students. I explore a specific case where two community assets in one Yucatec Maya Village are relevant to math instruction. Several landmark

ethnographic studies demonstrate antagonism between formal schooling and problem-solving approaches of impoverished or indigenous youth (Chavahay & Rogoff, 2002, Nunes, Schliemann, Carraher, 1993; Saxe, 1988). However, my study explores tensions that are especially pertinent to current educational initiatives in both México and the US to teach 21st century skills like innovation and creativity.

Results are relevant to math curriculum in México, because stronger Yucatec Maya ethnic identity and sense of school belonging are linked to positive academic outcomes for indigenous students (Casanova, 2011; Reyes, 2009). If formal schooling could reinforce cultural identities and foster a sense of belonging, then students might simultaneously maintain ties to their cultural heritage while excelling academically. Perhaps, capitalizing upon cultural approaches to problem solving like student autonomy and improvisational expertise could ultimately improve outcomes in the math classroom. Results are also relevant to math instruction in the US and elsewhere because 21st century skills require students to learn innovative and creative problem solving. In math classrooms, this means emphasizes solving open-ended, inquiry-based, and real-life math problems that have multiple entry points, requiring skills of adaptive expertise. This learning approach is linked to improved academic achievement and engagement for minorities (Boaler, 2002), and requires that students exercise autonomy and improvisational expertise rather than simply relying on pre-determined algorithms to solve single-solution problems.

My study is an ethnographic, mixed-methods study documenting how one rural, indigenous community in the Yucatán employs autonomy and an improvisational expertise to solve problems in everyday life. Furthermore, it explores the degree to which local middle school teachers capitalize upon these assets in the math classroom. Through grounded research, my study seeks to contribute to the discussion about: (1) math education of socioeconomically disadvantaged students using an asset-based framework; and (2) how to conceptualize autonomy and improvisational expertise in a manner relevant to implementing the national math curriculum promoting 21st century skills in both the US and México.

Methods

This village is a specific case of a rural, indigenous community that possesses a wealth of community problem-solving expertise, but low math scores. The three middle-school teachers are from the local community, but possess different experience and training. Research questions are:

1. How do community members use math in everyday life?
2. What is considered "legitimate" math knowledge and what traits make someone "good" at math according to community members, students, and teachers?
3. To what extent does math instruction capitalize upon community approaches to problem-solving?

Math In The Community And The Classroom

I define "community approaches to problem solving" as a constellation of culturally imparted mindsets, reasoning, skillsets, or strategies used to solve everyday problems that involve logic, spatial reasoning, navigation, or practical engineering. To explore how community members approach problem solving in everyday life, I conducted over 500 hours of participant observations in the village over a five-month period. In addition, I conducted 14 interviews with community members--including a focal family. I focused on businesses, transportation, community events, and central activities like farming. In addition, I conducted 15 interviews with six insiders to verify findings and adapt methodology. See Table 1 for the complete list of data sources and analyses. To explore the extent to which math instruction incorporated two community approaches to problem solving, I spent over five months at the local middle school. I conducted: 15 classroom observations;

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

5-10 informal interviews and one video stimulated recall interview with each of two teachers; six student interviews; observations of two student tasks with 62 students with follow-up interviews with 3 focal students; and 280 student math mindset surveys.

Table 1: Matrix of Research Questions, Data Sources, and Analyses Methods

Question	Data Source	Data Analysis
1.) *How do community members use math in everyday life?*	Field notes from observing 500 hours of community activities over 5 months.	Open code. Write initial memos, then focused coding and integrative memos.
	14 interviews from a range of community members. Snowball sampling used.	Audiotape & transcribe. Open-code, a priori code, or statistically consider items.
	15 hours of Community Advisory interviews with 6 people to verify findings with school and community members.	Audiotape. Transcribe. Open code. Write initial memos, then focused coding and integrative memos.
2.) *What is considered "legitimate" math knowledge and what traits make someone "good" at math according to community members, students, and teachers?*	14 interviews with community members, 5-10 formal and informal interviews with each of 3 teachers, 6 student interviews, 15 classroom observations.	Audiotape and Transcribe (some). Open code. Write initial memos, then focused coding and integrative memos. Some items statistically analyzed (IRA & IRR)
	Audiotape and Transcribe. Open code. Write initial memos, then focused coding and integrative memos.	15 hours of Community Advisory interviews with 6 people to verify findings with school and community members. Some items statistically analyzed (IRA & IRR)
	280 Student surveys (questions 10 and 11)	Descriptive statistics, correlation analysis, subgroup analysis.
3.) *To what extent does math instruction capitalize upon student approaches to problem-solving?*	Series of 5-10, informal interviews with each of 3 teachers.	Open code. Write initial memos, then focused coding and integrative memos.
	One, 1-hour, VSR interview with two of 3 teachers on selected clips from one lesson.	Audiotape, transcribe, open-code for beliefs & reported practices.
	Field notes from observations of 5 lessons from each of 3 teachers.	Open code. Write initial memos, then focused coding and integrative memos.
	1 Videotaped lesson of two teachers.	Transcribe, open-code for observed teacher practices.
	280 student surveys with math mindset questions.	Qualitative and quantitative analysis (IRA & IRR).
	Observations of 2, one-hour student tasks with 62, 9th grade students that draw upon student approaches involving autonomy and improvisational expertise—with follow up interviews with 3 students.	Videotape. Transcribe. Open code. Write initial memos, then focused coding and integrative memos. Attitudinal question on tasks are a priori coded. Descriptive statistics on some items. (IRA & IRR)

Results

The Disconnect

There is a disconnect between school and community math (Darling, 2016a). In this study, I defined math as any activity done outside of school that involves reasoning, justification, logic, arithmetic, or spatial orientating to solve problems. However, community members considered math as arithmetic one learns in school: counting, adding, dividing, paying. I asked a motorcycle-taxi driver, José, how he used math in everyday life. He responded, "I do not use math in everyday life, because I stopped going to school in the fourth grade." Interviews, student surveys and classroom observations indicated that community members thought someone who was "good" at math was someone who was "rapido" (fast) at doing arithmetic or solving school math problems.

Two Approaches: Autonomy And Improvisational Expertise

I documented two approaches to problem-solving in everyday life in the community; autonomy and improvisational expertise (Darling, 2016a). In essence, they are part of a student's habitus that specifically relates to problem solving. Similar to Rogoff, Paradise, Arauz, Correa-Chávez, & Angelillo (2003), I define autonomy as an independence, a self-directedness that is likely fostered by repeated opportunities to engage in independent play and problem solving without adult supervision. Like Yackel and Cobb, I reject "the conception of autonomy as a context free characteristic of the individual" (1996, p. 473). Instead I define autonomy with respect to students' participation in practices in specific contexts within the community. Lareau describes autonomy as independence among working class U.S. students that is at odds with navigating the school culture (2011). I define autonomy as an independence in terms of problem solving and how it may be at odds with math instruction. Also, I describe how it fuels improvisational expertise. I define improvisational expertise as a culturally imparted skillset or mindset used for solving real-life problems in innovative ways. For example, the mototaxista, José, tells me how he does not use math. However, when I ask him how he improvises in everyday life, without hesitation, he says, "yo calculo la kilometraje" (I calculate my mileage). Using no gas gauges or odometers, he calculates his mileage using an elaborate system based on collected fares, estimated distances between landmarks, and gas tank capacity. I documented six distinct methods used by mototaxistas. This is consistent with Saxe's finding that there is wider diversity of problem-solving methods in communities where there is limited access to schooling, as people tend to derive math meaning from solving real-life problems (1988). Findings indicate that autonomy fuels the improvisational expertise much in the same way that Rogoff, et all found that autonomy informs collaboration among indigenous heritage Mexican children (2003). In my study two children aged 5 and 9, with no money to purchase a kite, engineered one from garbage bags, salvaged sticks and string remnants. Unaccompanied by adults, they flight-tested their kites for an hour at the ocean's edge. They launched it with the wind, against the wind, and from the edge of a rock wall. They scavenged beach materials to add weight to the tail, lengthen the string, or adjust the kite's cross spar. They approached problem solving with autonomy and improvisational expertise, but will math teachers capitalize upon this practical, problem solving expertise when they go to middle school?

Opportunities Untapped In The Classroom?

School math instruction incorporated student autonomy and improvisational expertise in terms of completing tasks, but not in terms of solving math problems (Darling, 2016b). Many students chatted while the teacher was speaking. At 10-minute intervals during class at least 1/3 of the students were "off task". Students completed classroom tasks at the pace and order in the order they chose. Were they disrespectful? No. When an adult entered the room, students rose in unison and chimed, "Buenas tardes Maestro Olegario. " Teachers in this pueblo school accommodated students'

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

autonomy and improvisational expertise in the math classroom in one non-math domain. This was similar to Boaler's 2002 study that demonstrated that minority students' math achievement improved in inquiry-based math classes where students were afforded the opportunity to complete tasks at their own pace and in their own ways. Olegario, the oldest teacher in my study said: Teachers provide "libertad" (freedom to act); students improvise while learning and completing tasks; consequently, students learn to act responsibly. In essence, teachers granted student autonomy, and students chose how and when to be "on task." Their autonomy informed their improvisational expertise, and students learned how to act responsibly. Although students were encouraged to be autonomous and improvise in terms of how they completed their tasks, teachers' strict adherence to the national math curriculum limited student opportunities to improvise while solving math problems. This is not surprising, because almost all opportunities to learn math involved single-solution, single-method problem solving.

I observed 62 students doing two math tasks based on real-life problems that invited improvisation. I gave attitudinal questions and did follow-up interviews. These triangulated to indicate that students welcomed opportunities to improvise, but did not like the "math part." The first task was presented in an ethics class to mask the math aspect. It required students to identify social problems in the community and then to address them by designing a community center according to explicit geometric specifications leading to the discovery of the Pythagorean theorem. Interviews indicated that students liked the improvisation, but not the math. The second task was completed in math class and yielded similar results. Students were asked to develop a plan to insure that a motorcycle taxi driver does not run out of gas. They were provided with real-life data in the form of a table. Three students interviewed said that at first they thought the problem was hard because they had to use math, then they said, It was easy when they realized they only had to use "sentido común"(common sense). In conclusion, teachers capitalized upon the cultural approaches of autonomy and improvisational expertise in terms of the completion of classroom tasks, but did not capitalize upon either in terms of solving math problems. Students enjoyed solving open-ended, multiple solution problems that were radically different than the typical math problems completed in class (Darling, 2016b).

Implications

Study results are relevant for alleviating academic achievement gaps in math in México. Incorporating previously overlooked cultural assets of student autonomy and improvisational expertise into the curriculum may improve math outcomes for Yucatec Maya youth, because ethnic identity and school belonging may be nurtured. Also, it is likely that these assets are not unique to this one Yucatec Maya community in México. Findings may be relevant to other impoverished, rural, or indigenous heritage immigrant communities in the U.S. Finally, the constructs of autonomy and improvisational expertise are relevant to math instruction that focuses on 21st century skills like innovation and creativity. Adaptive expertise is emphasized in reform mathematics classrooms, because it shifts the learning focus from algorithmic, procedural knowledge to deep conceptual understanding (Torbeyns, Verschaffel, & Ghesquière, 2006). Rather than teach students adaptive expertise from scratch, perhaps scholars could study how to capitalize upon already existing cultural assets to teach reform mathematics to historically marginalized students. Finally, perhaps we can learn from this Yucatec Maya community to teach other students to approach problem solving with autonomy and improvisational expertise to promote 21st century skills.

USING LINGUISTICS TO EXAMINE A TUTORING SESSION ABOUT LINEAR FUNCTIONS

Anna F. DeJarnette	Casey Hord	Samantha Marita
University of Cincinnati	University of Cincinnati	University of Cincinnati
dejarnaa@ucmail.uc.edu	hordcy@ucmail.uc.edu	maritasj@mail.uc.edu

We applied techniques from systemic functional linguistics to examine how a student and a tutor construed meaning related to linear functions during a 1-1 tutoring session. The student and tutor varied in how they discussed rates of change. This difference highlights that there are multiple correct ways to use this term in algebra, although small differences in speakers' use may create the potential for confusion. Additionally, the different ways that the student and tutor spoke about rates of change illuminate how any scenario may be represented by multiple different linear functions. This study has implications for providing teachers in a variety of settings information about how students construct meaning through their discussions.

Keywords: Algebra and Algebraic Thinking, Classroom Discourse, Instructional Activities and Practices

In most school districts in the U.S., Algebra 1 is a required course for students to graduate from high school and go on to post-secondary opportunities. In this way, Algebra 1 can be viewed as a "gatekeeper course"; in other words this course is a border between the work students are required to complete and the opportunities that come beyond it. Many students struggle to learn the foundational concepts of a typical Algebra 1 course, and disparities in student performance are greater along racial and socioeconomic lines (Chazan et al., 2007; Lubienski, 2002). There are efforts in place to provide one-on-one or small group tutoring services outside of students' typical mathematics classes, so that students can receive individualized attention and instruction (Hord, DeJarnette, & Marita, 2015; Hord, Marita, Walsh, Tomaro, & Gordon, in press). We conducted a project in which a group of university pre-service teachers provided tutoring for struggling eighth-grade students in Algebra 1 at an urban, high-needs public school. We sought to understand the features of students' and tutors' interactions that supported students' achievement in the course and conceptual understanding of algebra.

In this study, we focus specifically on one tutoring session between a tutor, whom we call Emily[1], and an eighth-grade student named Tanisha. We pose the question, *what are potential sources of ambiguity in a conversation between a student and a tutor about linear functions?* We use Systemic Functional Linguistics (SFL) (Halliday & Matthiessen, 2014) as an analytical tool to identify potential ambiguity in the pair's discourse. By looking for ambiguities in conversation, we bring up some of the barriers in communication that may surface when experts and novices talk about mathematics. Through a better understanding of how teachers and students construct meaning through discourse, we see opportunity to overcome these barriers and support all students to be successful in and beyond Algebra 1.

Theoretical Framework

We draw on a social semiotic framework to inform this study. This perspective emphasizes the importance of our choices in representation for constructing meaning through social activity (Kress & van Leeuwen, 2006; O'Halloran, 2014). Interactions in mathematics classrooms are multi-semiotic, in that communication between teachers, students, and textbooks requires a variety of representation systems including visual representations, symbolic notation, and gesturing (Alshwaikh, 2011; Arzarello & Edwards, 2005; Chapman, 1993; Dimmel & Herbst, 2015; O'Halloran, 2003, 2005; Radford, 2009). The use of spoken language can be considered one of the

primary means through which academic subjects such as mathematics are taught and learned (Lemke, 1988). In particular, spoken interactions can provide a primary means of support for struggling students in mathematics (Hord et al., in press; Ketterlin-Geller, Yovanoff, & Tindal, 2007; Scheuermann, Deshler, & Schumaker, 2009). For these reasons, we attend to the interactions between a student and her tutor through the lens of how the pair co-constructed meaning related to linear functions through their conversations about a task.

Thematic analysis is a method within the theory of SFL, which focuses on the ways that ideas are connected to one another (Lemke, 1990; see also Chapman, 1993; Herbel-Eisenmann & Otten, 2011; O'Halloran, 2005). The primary assumption guiding thematic analysis is that meaning is not made through individual words alone. Instead, meaning is given to words and phrases through the ways in which they are connected to other words and phrases. In an example provided by Herbel-Eisenmann and Otten (2011), the base of a triangle refers to two different constructs depending on how the term is used. In one context, the *base* of a triangle refers to a tangible part of the triangle, specifically the edge of the triangle that serves as the base. In another context, the *base* of a triangle refers to a measurement of that edge. Neither use of the term is more correct, but the term "base" is given meaning based on how it is used in relation to other words. Although communication is achieved through choices in representation—in this case, choices about the ways in which words and phrases are connected to one another—those choices are not always made explicit at the moment of an interaction (Lemke, 1990). Thematic analysis provides an analytical framework to examine the implicit connections between ideas.

Data and Methods

Setting of the Study

We conducted this study in a large, urban public school serving grades 7–12. All students at this school take Algebra 1 during their eighth-grade year, and students who do not pass the course are required to re-take the course during the summer. In collaboration with the eighth-grade mathematics teacher and the special education teacher, the second author established a tutoring program with the school. Beginning in December 2014, and running through the end of the school year, pre-service teachers went to the school on a weekly basis to work individually or in small groups with struggling students on their current classwork and homework. Students were selected for the tutoring program by the mathematics and special education teachers, who identified students that they expected to benefit from individualized attention.

In this study, we focus on one particular student, Tanisha, and her work with a tutor named Emily. Emily had developed rapport with Tanisha prior to the implementation of the present study. Specifically, Emily was an undergraduate pre-service special education teacher at a local university, and she had worked with Tanisha during a prior semester as part of a field placement focusing on literacy interventions. Tanisha was struggling in Algebra 1 and requested to participate in tutoring. Tanisha and Emily had a positive relationship, and Tanisha often requested to work with Emily. Tanisha was especially talkative around Emily, and she seemed highly motivated to use her tutoring time to make progress on her classwork.

Data Collection

We audio recorded all of the tutoring sessions, in addition to making copies of student work and taking field notes during the sessions. In total, we have records of 7 different tutoring sessions with Tanisha, ranging from March-May of 2015. For this analysis, we focus on one particular session, which took place between Emily and Tanisha in early May, when students were preparing for final exams. The task, included below, presented a scenario in which an individual named Katie was saving money from her part-time summer job.

Task: Each week in the summer Katie earned $95 as a lifeguard. Katie deposited 10% of her earnings into her account. At the start of the summer, Katie had $60 in her account. Write an equation to represent the amount of money Katie had in her bank account after a certain number of weeks.

At this time of the year, students had studied linear functions, and they were accustomed to setting up linear equations of the form *y=mx+b*. Students had previously learned about using linear functions to represent real-world scenarios. The above task served as a practice problem for students to prepare for their final exam. The conversation about the task lasted approximately 2 minutes and 30 seconds. We produced transcripts of the pair's conversation based upon the audio records, field notes, and work samples.

Methods

After transcribing the interaction between Tanisha and Emily, we identified the semantic relations between terms and phrases related to the rate of change. *Semantic relations* (Halliday & Matthiessen, 2014; Lemke, 1990) refer to relationships between words or phrases in a text. For example, when the *base* of a *triangle* refers to a specific part of the given triangle, the semantic relationship between the terms *base* and *triangle* would be that of part/whole (Herbel-Eisenmann & Otten, 2011). The part/whole relationship is used when a particular term refers to an object or item that is part of some larger object (Lemke, 1990).[2] Alternatively, when the *base* of a *triangle* refers to the length of that specific part of the triangle, the term *base* would be related as a measure of the *triangle* (Herbel-Eisenmann & Otten, 2011). By identifying the semantic relations among terms, it is possible to describe how words and phrases are connected to one another through speech and, thus, how meaning is construed in these interactions.

We focus our analysis for this presentation on Tanisha and Emily's use of ideas specifically related to the rate of change of a linear function. To do so, we first identified the key terms and phrases that Tanisha and Emily used in their comments about rates of change. For example, the pair used phrases such as "the amount that Katie earns per week," and "she gets that much money," in addition to phrases such as "rate of change." After noting these key phrases, we described the semantic relations between those words and phrases. Prior work using SFL has identified many of the relations that may exist between mathematical terms (Table 1) (Chapman, 1993; Herbel-Eisenmann & Otten, 2011; Lemke, 1990; O'Halloran, 2005). These relations build upon the identification of semantic relations among participants within and between clauses (e.g., Halliday & Matthiessen, 2014). We include in Table 1 only the semantic relations that are most relevant to this study.

Table 1: A Partial List of Semantic Relations Connecting Mathematical Terms

Relation	Description	Example
Part/Whole	An object or figure is part of a larger figure.	Katie deposits 10% of the $95 she earns.
Identified/Identifier	An object or figure is identified in a specific way.	$95 is the amount that Katie earns per week.
Synonyms	Two terms or phrases are equivalent.	The amount Katie earns is the amount of money Katie gets per week.
Subcategory/Category	A category fits inside a broader category.	Katie's total earnings are one example of varying quantities.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Analysis and Findings

We present our analysis and findings together, focusing on the conversation Tanisha and Emily had about the task presented above. We include specific excerpts of the interaction where Emily and Tanisha discussed the rate of change of the function. We share parts of the transcript with our analysis, to exemplify our findings related to potential sources of ambiguity in the conversation. Numbers in parentheses indicate turn numbers. We identify speakers by their first initials. We bold parts of the transcript to highlight specific points in the analysis. To begin, Emily posed a question about Katie's earnings.

> *Emily*: So how much does **Katie earn per week?** (17)
> *Tanisha*: **95 dollars.** (18)
> *Emily*: Cool. So she **earns** a certain amount of money per week. So each week she **gets that much money**, right? (19)
> *Tanisha*: So **that's** the **rate of change.** (20)
> *Emily*: Yes, awesome. (21)
> *Tanisha*: So **that's m.** (22)
> *Emily*: Yes, wonderful. (23)

With this section of the transcript we can begin to identify the semantic relations among ideas in Emily and Tanisha's talk. We see that $95 identifies the amount that Katie earns per week, and Katie's earnings are synonymous with how much money Katie gets (lines 17-19). After establishing that, Tanisha made a statement that *that* (i.e., $95, or the amount of money Katie earns) was synonymous with the rate of change, which is denoted by *m* in a typical linear equation (lines 20-22). At this stage in the conversation, *Rate of change* seemed to be synonymous with *Katie's earnings per week*, at least as described by Tanisha in line 20.

After determining the starting value of the linear function to be 60, Emily returned to the issue that Katie would only be depositing 10% of her weekly earnings into her bank account.

> *Emily*: So what are we gonna do with the **10%**? The tricky part… (35)
> *Tanisha*: Probably **put it in for x.** Won't we put, $y=mx+b$, for *m* we're gonna put 95, b we're gonna put 60, and then that *x* **we're gonna put 10.** (36)
> *Emily*: You're right there. You're so close, and it's crazy. Cuz you're so – Okay, so **how much money does she put in her account per week? That's what *m* is gonna equal, each week how much money she puts into her account.** (37)

Following the question about what to do with the 10%, Tanisha suggested that they might substitute 10% for *x* in the equation $y=mx+b$ (lines 35-36). From an outside observer's perspective, Tanisha's response might indicate a complete misunderstanding of linear functions. However, consider the scenario from Tanisha's perspective. She had already determined that Katie's earnings were synonymous with the rate of change of the function, which would be represented by *m*. Following that, the pair had quickly determined the starting value to be $60, which would be represented by *b*. With those assumptions, Tanisha was limited in how she might use the value of 10% in an equation of the form $y=mx+b$. At this point, from Tanisha's perspective, *x* was the only variable that had not yet been assigned a value.

The source of ambiguity in the conversation between Katie and Emily starts to become clear in line 37, when Emily noted, "*m* is gonna equal, each week how much money she puts into her account." This statement seems to be in direct contradiction to the earlier exchange in lines 17-22, when Emily and Tanisha established that *m* would be equal to the amount of money Katie earns per week. To make sense of this contradiction, we consider the possible differences between the semantic relations used by Emily and Tanisha in making sense of the rate of change. For Tanisha, the semantic relation between *Katie's earnings* and *Rate of change* seemed to be a synonym relationship

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

(Figure 1). In other words, the rate of change was equivalent to Katie's earnings, which had been identified as the specific value of $95 per week.
Figure 1. Tanisha's semantic relations between earnings and rate of change.

Once Emily clarified that the value of *m* would be determined by how much money Katie deposited per week, Tanisha needed to redefine the rate of change of the function. They agreed that Katie deposited 10% of her earnings, so Tanisha suggested that perhaps 10% would be the rate of change of the function.

> *Tanisha*: I mean, I meant, put **10%**, right? (42)
> *Emily*: Mm hmm. (43)
> *Tanisha*: So it'll be $y=\textbf{10}x+\textbf{60}$? (44)
> *Emily*: Close. Close. (45)

Here, Tanisha replaced *Katies's earnings* with *Katie's deposits* as synonymous with the rate of change of the function (Figure 2). Tanisha substituted 10 for *m* in the equation $y=mx+b$, as 10% identified specifically what Katie deposited on a weekly basis.
Figure 2. Tanisha's semantic relations when replacing earnings with deposits.

The semantic relation in Figure 2 seemed to replace Tanisha's earlier construction. Because Katie's earnings and deposits were not the same thing, it would be impossible for them to both be synonymous with the rate of change of the function. In order to account for the 10% deposit, Tanisha needed to disregard the previous information about Katie's $95 weekly earnings.

Emily seemed to be using a slightly different semantic construction to describe the relationships between earnings, deposits, rate of change, and the value of *m*. After determining with Tanisha that 10% of $95 is $9.50, Emily made the following comment:

> *Emily*: So **that is our new *m***. Because since she doesn't, since she doesn't deposit all 95 dollars, then that's not our rate of change. Our **rate of change is how much she deposits per week.** (55)

Importantly, in turn 55, Emily noted that the value of 9.5 represented a new *m*. To suggest that Katie's deposits represented a new value of the rate of change indicates that, for Emily, rate of change did not refer to a unique item. Instead, *Katie's earnings* and *Katie's deposits* could both be considered sub-categories of a broader category of *Rate of change* (Figure 3). Ninety–five dollars identified the specific value of Katie's weekly earnings, which provided one example of a rate of change. Additionally, 10% represented the part of that $95 that Katie deposited in her bank account, another example of rate of change.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.
Figure 3. Semantic relations according to Emily.

In summary, there was one key difference in the semantic relations used by Tanisha and Emily, which seemed to be a source of ambiguity in their conversation. After establishing Katie's earnings as the rate of change of the function in turns 19-20, Tanisha used *Katie's earnings* synonymously with *Rate of change*. This became apparent, and also problematic, when Tanisha needed to account for the 10% deposited each week. Having already accounted for all of the parameters in the equation *y=mx+b*, Tanisha's only remaining option was to replace *Katie's earnings* with *Katie's deposits* as the rate of change. To make sense of Emily's comments, on the other hand, one can recognize Emily employed a sub-category/category relationship between *Katie's earnings*, *Katie's deposits*, and *Rate of change*, rather than a synonymous relationship. This difference helps explain Tanisha's apparent confusion about how to account for the value of 10% in the linear function.

Discussion and Conclusion

A primary point that we emphasize in our observations of Emily and Tanisha's conversation is that there is no single correct way to use specific terms in algebra. In a discussion about semantic differences in a science classroom, Lemke (1990) made an even stronger argument, noting, "words do not necessarily 'have' meanings in themselves. A word in isolation has only a 'meaning potential,' a range of possible uses to mean various things" (pp. 34–35). In this study, we saw that phrases such as "Katie's earnings" or "amount deposited" had potential for different meanings related to the rate of change of a linear function, depending on how the interactants used those phrases. Because Tanisha and Emily did not recognize the difference between their semantic constructions, when Emily proposed a new value for the rate of change, Tanisha attempted to accommodate this information into her existing semantic construction.

A natural question to pose is whether Tanisha or Emily was more or less correct in her semantic constructions. Emily, in fact, agreed with Tanisha when Tanisha suggested, "that [Katie's weekly earnings] is the rate of change." Only later did Emily propose that the $9.50 that Katie deposited per week would represent the rate of change. However, we keep in mind that the use of the term *is* can be ambiguous in how it relates terms or ideas (Schleppegrell, 2007). For Tanisha, to state that $95 *is* the rate of change seemed equivalent to stating that a dog *is* a canine; in each case the two phrases are synonyms for the same thing. For Emily, to agree that $95 *is* the rate of change seemed equivalent to suggesting that a dog *is* a mammal. In this case, the two terms are not synonymous. Instead, a dog is one subcategory of the category of mammals, which also includes many other things. Examples of this subcategory/category relationship can be identified in other areas of mathematics as well. For example, a square *is* a rectangle in the sense that squares constitute one subcategory of rectangles. From this study, we see that a construct such as "rate of change" can be viewed as a category of things, with multiple different subcategories. Because small differences like this in semantic relations are often left implicit in interaction (Lemke, 1990), research making these distinctions explicit is necessary to support teachers and students to recognize the nuances in their use of spoken language.

Beyond individuals' use of spoken language, this study highlights the way in which any given scenario can be represented by multiple different functions. The task as it was given required

students to write a function representing how much money Katie had in her bank account each week. Given the same information, one could represent how much money Katie had earned as a function of the number of weeks, using Tanisha's initial equation $y=95x+60$. Alternatively, one could represent the amount of money Katie had deposited as a function of how much she had earned using the equation $y=.10x+60$, similarly to Tanisha's third attempt at constructing the linear equation. Students in a variety of settings struggle to translate problem contexts into linear equations (Capraro & Joffrion, 2006). Moreover, students' errors in setting up linear equations stem partly from their attempts to make sense of the meaning of a problem (MacGregor & Stacey, 1993). We see it as a strength that students like Tanisha make connections between algebraic symbols and the scenarios they represent. To be able to correctly express a problem context symbolically, students must be able to interpret the relationship between the various quantities and components of that context. Students need opportunities to develop understanding of a context using informal language in order to be successful representing that context with symbols (Kieran & Chalouh, 1993). The specific function requested in the task could have been somewhat arbitrary, and an alternative question could have been posed for which one of Tanisha's linear equations would have been appropriate. The more that students can develop the skills to understand the semantic relationships between components of a problem context, the more equipped students will be to select an appropriate symbolic representation of that context.

Finally, because low-achieving students often opt out of whole-class discussions in mathematics classrooms (Baxter, Woodward, & Olsen, 2001), individualized or small group settings can be ideal for struggling students and students with learning disabilities to engage in conversations about mathematics (Woodward, 2006). In order to make the most of these opportunities, it is essential to understand how students and instructors work together to construct mathematical meaning through their talk. The analytic tools of SFL, and specifically analysis of the semantic relations among ideas in a text, provide a resource for ensuring that students and instructors are able to understand one another's meanings.

Endnotes

[1] We use pseudonyms for all names and institutions.

[2] Lemke (1990) and Herbel-Eisenmann and Otten (2011) use the more formal linguistic terms meronym/holonym to describe the part/whole relationship. We use the more colloquial terms here for brevity and clarity.

AN EXAMINATION OF RACIAL COMPOSITION IN CULTURALLY RELEVANT MATH STUDY GROUPS ON MATH LEARNING OUTCOMES

This paper proposes to use communalism, an asset-driven strategy effective with Black learners, with racially mixed study groups. This study found that students who studied in racially mixed groups performed better when told that individuals would receive a reward for scoring the highest in their group. Also, the White students' perceptions of how much they mattered differed based on the racial composition of the study groups where those studying with only White students felt they mattered more than those who studied with White and Black participants. Implications of the importance to have culturally relevant and responsive resources for racially diverse classrooms are discussed.

Keywords: Elementary School Education; Equity and Diversity; Instructional Activities and Practices; Affect, Emotion, Beliefs and Attitudes

Purpose

Currently, there have been no longstanding viable solutions to the problem of the achievement gap between Black students and their White counterparts. As revealed by the Nation's Report card (NAEP, 2015), though both group's scores have increased in the past 30 years, the White-Black learning gap has persisted with no significant gains made by Black students to close it. Black students' learning gap is a more severe problem when compared at the global level, where students in the United States are falling behind the scores of students from other developed nations (Boykin & Noguera, 2011). Students in countries such as Singapore, South Korea, Japan, Belgium, The Netherlands, Hungary, and Russia are all out-performing students in the United States in both fourth and eighth grade mathematics. To close this international achievement gap, culturally relevant and responsive resources targeting the performance of Black (and Brown) students both nationally and internationally must be implemented (Blanco-Álvarez & Luisa Oliveras 2016), as the number of K-12 students of color are projected to increase consistently in the coming years (NCES, 2011). Mathematics achievement, in particular, is imperative--as it has been noted as the "new" civil rights movement (Paige & Witty, 2009)--where students' achievement is linked to opportunities in the global political economy (Blanco-Álvarez & Luisa Oliveras 2016).

This study hypothesizes to increase scores in students of colors' mathematics performance by utilizing cultural assets that students possess stemming from norms and values in their home and surrounding communities (Hurley, Allen, & Boykin, 2009). Based on work that flows from "communalism" (Boykin & Noguera, 2011), the authors sought to explore the effects of an afro-cultural learning context in a racially mixed classroom setting. Specifically, the goals in this study were to examine A) the effects of racial composition of study groups and B) learning context/communalism on A)math performance, B)group processes/behaviors, and C)students' perceptions of how much they matter in their study groups. Implications from findings are to add more depth to the literature on the importance of group learning contexts, such as communalism, as a culturally responsive paradigm geared to empower nondominant youth's learning ecologies.

Theoretical Framework and Relevant Literature

In order to increase the performance of Black students, Boykin and Noguera (2011) posited that it was important to utilize students' assets in educational reform strategies. Asset-focused factors deal with the contextual conditions in which teaching, learning, and engagement are manifested (Boykin & Noguera, 2011). They are called assets because they involve learning exchanges that

build on what students bring to the classroom. Within the asset-focused factors are strategies that strive to align the values, interests, and learning priorities of both teachers and students (Boykin& Noguera, 2011). The authors describe meaningful learning and cultural resources as two major strategies that can create this alignment. However, for the purposes of this study, the researchers paid specific attention to cultural resources. The use of cultural resources, like culturally relevant pedagogy, understands that schooling does not take place in a vacuum, and students' cultural orientations can be valuable resources in the classroom. Out of these resources, one of the most successfully implemented cultural resources has been communalism (Boykin, 1986).

Boykin (1986) defines communalism as "a commitment to social connectedness which includes an awareness that social bonds and responsibilities transcend individual privileges" (p. 61). Similarly to collectivism (Triandis, 1995), communalism is an ethnographic paradigm that stands in contrast to that of individualism or—for this study—interpersonal competition. Where interpersonal competition focuses on individuals placing an emphasis on their own performance and accountability, communalism places individual performance as a responsibility of the group where all members are held accountable for the group's success (Boykin, 1986; Johnson et al., 1981). A number of empirical studies have found that Black students' performance has increased when they were placed into communal group learning contexts across a number of learning tasks. This was shown in with performance measures such as: text recall, multiplication performance, math-estimation, vocabulary, geography, and learning transfer (Dill & Boykin, 2000; Hurley, Allen, & Boykin, 2009; Hurley, Boykin, & Allen, 2005).

When students perform better academically after studying in a group, whether communally or cooperatively, there must be some underlying group processes at work that cause students to work well together where they would not have done as well working alone. To understand these processes, Hurley, Allen, and Boykin (2009) examined group processes as a means to see the differences between communalism and other group-based learning contexts. Indeed, the researchers found that there were significant differences in students' ratings for learning context. Students in the communal condition were rated higher in group behaviors (e.g. accountability for actions, {a lack of} task hindering behaviors) than did those in a competitive group condition. Moreover, a marginally significant difference was found for the interaction between condition and ethnicity. In this case, Black and White students achieved their highest ratings for positive group behaviors when they were in different learning contexts, Black students in the communal condition and White students in a more individual oriented learning context condition (Hurley, Allen, and Boykin, 2009). Furthermore, both groups of students performed best in the conditions that yielded their highest group ratings. Though not significant, the findings cannot go unnoticed.

In addition to understanding the link between communalism and group processing, the present authors sought to examine students' perceptions of whether they matter during their group work. The mattering literature had its start in the mental health field first examined by Rosenberg and McCullough (1981), who defined mattering as the "direct reciprocal of significance" (1981). The scholars further described mattering as a "motive: the feeling that others depend on us, are interested in us, are concerned with our fate, or experience us as an ego-extension exercises a powerful influence on our actions." Wicker (2004) further describes mattering as how one perceives himself as being important to another person, or group of people. Simply put, mattering asks the question: How important do I feel I am to you (Wicker, 2004)? Mattering has been divided into three components: attention, importance/appreciation, and dependence (Elliot, Kao, & Grant, 2004).

In its 30 years of research, perceived sense of mattering has been tied to important psychological outcomes such as self-esteem, relatedness to others, sense of purpose, meaningfulness in life, and job satisfaction in higher education (Gibson and Myers, 2006; Rosenberg and McCullough, 1981). For example, in a study on students attending The Citadel, a military college in the southeastern United States, researchers found that perceived mattering was positively related to a measure of Total

Wellness, particularly as it relates to the Social Self subfactor where the underlying constructs were 'love' and 'friendship' (Gibson and Myers, 2006). In a particularly disturbing study, Elliot, Colangelo and Gelles (2005) found that mattering was a significant predictor of adolescent suicide ideation; where the further participant responses for mattering went below the mean, the further the instances of suicide ideation increased. As the researchers looked more deeply into the data, they found mediating properties of other variables such as depression, self-esteem, and religiosity. Researchers found a model where depression and self-esteem mediated the effects of mattering on suicide ideation being that the addition of depression and self-esteem completely erased the established relationship between mattering and suicide ideation (Elliot, Colangelo, and Gelles, 2005). To confirm the literature that says mattering is an issue across one's life span, Dixon (2007) explored the relationship of mattering and important wellness variables for older adults; here the author found that mattering to others was a significant predictor in participants' overall wellness (positively related to purpose in life and overall wellness and negatively related to depression).

To understand why students perform differently in different learning contexts, the purpose of this study was to examine how afro-centric learning contexts, specifically utilizing communalistic cooperative learning settings, relates to group processes/behaviors and student mattering. Moreover, although numerous studies have empirically proven communalism's utility in improving African American students' achievement in performance tasks, further research is needed to examine its utility with racially mixed student demographics where African American learners are present. Thus, this study sought to answer: what are the effects of racial composition of study groups (All Black students or all White students in the same group) and mixed racial groups (Black and White students in the same group), and communalism as a learning context on the math performance, group processes, and perceptions of mattering for 5th grade Black and White students? The study also sought to understand what, if any, were the relationships between academic performance, group processes, and perceptions of mattering.

Methodology

The research reported here stems from a math intervention project that sought to investigate the math performance, perceived group processes, and perceived mattering for students as a function of learning context and the racial composition of their study groups. Data from this study was collected from a math performance task and survey measures in the southeastern United States. The sample consisted of 110 Black and White 5th grade students. These students were sampled from three racially integrated elementary schools. Each school was a part of a large school district in a large metropolitan area.

For this design, all procedures were conducted in a simulated classroom setting excluding any students who were not Black or White. Prior to the manipulation of the independent variables, participants took a pretest to assess their skill level in mathematics-estimation. Their scores were used as a covariate to control for individual/condition variation and prior knowledge before the learning phase of this study. To orient them to mathematics estimation, the researcher took the students through an example problem on the first two pages of the math estimation study packet. The students were required to follow along and answer any questions that the example problem asked. The orientation portion of the study took approximately 5 minutes. After the orientation, the researcher read the instructions for the math estimation study packet to the participants and then read the prompt for the group's respective learning context.

Prior to the administration of this study, students were randomly assigned to group learning contexts that were either the communal condition or the interpersonal competition condition. For both the communal and interpersonal competition learning contexts, students were placed in groups of four, sat together in a cluster of desks, and given one math estimation study packet. Students in the communal condition were encouraged to work together, share, and do well for the good of the

group. Students in the interpersonal condition were told that the student who performs the best on the quiz would win a prize, and that they should each worry only about themselves as they studied. The students then began the 20-minute mathematics estimation study session. Students were also randomly assigned to either participate in a racially homogeneous group or a racially mixed/heterogeneous group.   The homogeneous racial groups had students of all one race working together in the two learning context conditions. Students' study groups were either all Black or all White. In the heterogeneous racial groups, there were two Black students and two White students participating in the study session together. Students then completed the opposite form of the math estimation performance measure individually to ensure individual performance was being measured.

Students completed two surveys, the Process Loss Questionnaire (PLQ; 20 items on a 1-4 4-point likert scale; alpha reliability coefficient was .75, 13 items were used for analysis) to assess group processes, and the Perceived Mattering Questionnaire (PMQ; modified version included 15 items on a 1-5 likert scale; the three components of the mattering index reached the proper level of internal consistency with reliabilities of .78, .82, and .72 for attention, importance, and dependence, respectively). The PLQ (Hurley, Allen, & Boykin, 2009) is a measure that is built to understand children's specific group-work related behaviors. The scale pays attention to behaviors that are "presumed to be manifestations of the participants' perception of their accountability, and of the level of task hindering group dynamics that occurred in their study groups." The PMQ is a modified version of Elliot, Kao, and Grant's (2004) Mattering Index. It contains three components of the mattering construct (attention, importance, and dependence), and where the original mattering index only asks questions about students mattering as a general state, the items in the PMQ were modified to reflect the participants' sense of mattering in the group context during their study session. To ensure the students understood the questions in the surveys, the first author read each question, and explained each questionnaire's answer choices.

Results

The study sought to examine the effects of three variables (learning context as a cultural resource, racial composition of the study group, and race) on the math performance, group processes, and mattering of 110 fifth grade children. The data were analyzed by conducting a 2 (Learning Context) X 2 (Racial Composition of the Study Group) X 2 (Race) Analysis of Covariance on the dependent variable, math performance, using pretest performance as a covariate. Secondly, the group processes and mattering variables were entered into a 2 (Learning Context) X 2 (Racial Composition of the Study Group) X 2 (Race) Multivariate Analysis of Variance. Lastly, the dependent variables were entered into a correlation analysis to test the relationships between them.

For the first set of analyses, there was a two-way interaction between learning context and racial composition on performance ($F (1, 101) = 5.285$, $p < .05$). Based on pair-wise comparisons as a post hoc analysis, students who studied in the interpersonal competition performed significantly better than their communal studying counterparts (11.69 and 8.75, respectively). No other combinations of the variables' effects on math performance were statistically significant. Figure 1 below displays the means for performance in highlighting the aforementioned two-way interaction.

Figure 1: Math performance by learning context and racial composition.

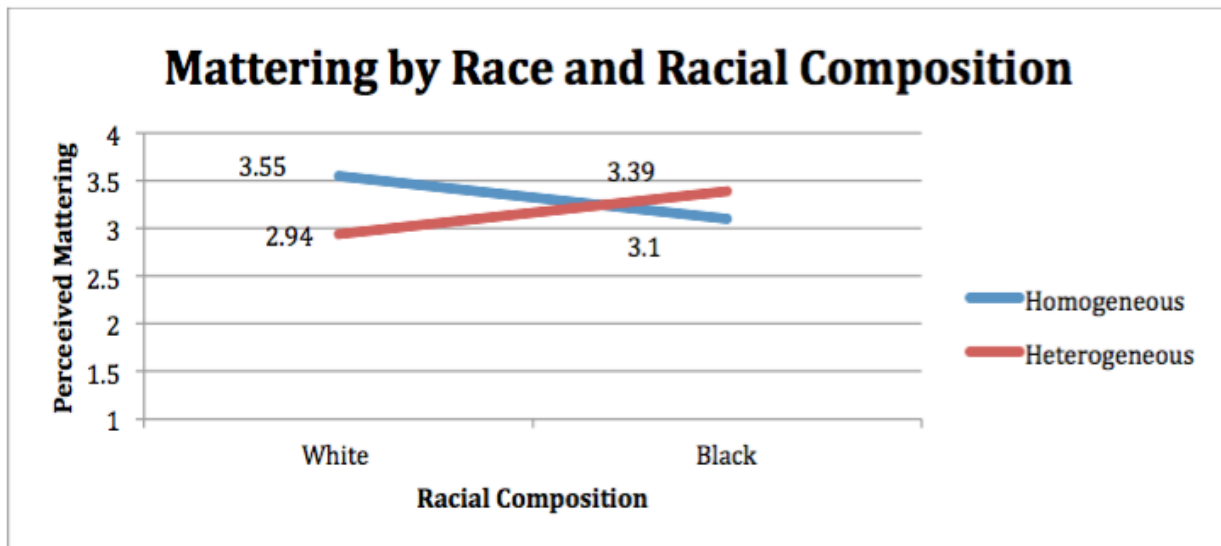
For the next set of analyses, there was a significant two-way interaction between race and racial composition on participants' perceived mattering ($F (1, 101) = 6.529$, $p < .05$). In this interaction, post hoc analyses indicated that participants who studied in the homogeneous groups felt they mattered more (3.55) than those who studied in the heterogeneous groups (2.94). However, no other differences between the combinations of race and racial composition were statistically significant. Figure 2 displays the means for the two-way interaction.


Figure 2: Mattering by race and racial composition.

Lastly, the researcher ran a correlation analysis for the dependent variables including the three subscales for the mattering survey. This analysis found that there was a negative relationship between the attention component of mattering and group process ($r = -.248$, $p < .01$) suggesting that as students perceived themselves to hold other's attention more and be noticed more by their group members, they exhibited less process loss behaviors. The table below highlights the correlation coefficients for all of the variables of interest.

Discussion and Implications

To date there has been no work exclusively examining the studying of Black and White students *together* in a communal learning context. The added layer of racially heterogeneous study groups to the communalism research led to this experiment having an exploratory nature. Finding that students studying in the heterogeneous groups with an incentive for their individual performance performed better than those who studied communally was a very interesting outcome to add to the communalism research. The pattern of findings is not an indictment of the previous communalism literature (Boykin, 1986). The findings could be attributed to the possibility that working communally in a heterogeneous group presented African American students with difficulty in code-switching, or a sense of culture shock that disrupted their abilities to work well together (Baugh and Graen, 1997; Stahl et al., 2010). On the other hand, this was only apparent for the communal groups and not the interpersonal competition groups. The students-theoretically—had to work together in this condition. However, they did not have the same impetus for cooperating with one another. The students only were required to focus on their own wellbeing when it came to the performance on the math estimation task. This competitive reward structure could also be more typical of their traditional group work, and could have led the interpersonal competition condition to be more comfortable for them.

This study also found that students' perceived sense of mattering was lower when they studied in racially heterogeneous study groups than those who studied in the homogeneous study groups. From this set of analyses, it seems that White students experienced some pro White bias regarding when they felt they mattered most based on whether they studied with students of their same race or with Black students. Contrarily, Black students experienced no differences based on racial group composition. One explanation from previous literature could potentially shed light on this pattern of findings. First, some of the mattering research examines people's feelings of marginalization and how they relate to perceptions of mattering. In this sense, experiences of marginalization have led students to feel that they matter less. Interestingly enough, in the mattering research, the marginalization-mattering connection has been made for participants of color including Black, Latino, and Middle-Eastern students attending school in the United States (Huerta & Fishman, 2014). However, in this study, perhaps the students felt some sense of marginalization as they worked in the heterogeneous groups that led to a lower perception of their own mattering. The possibility exists that students have been more comfortable working exclusively with their own race whereas Black

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

students are not affected by a change in racial composition as feelings of marginalization occur both in and outside of the classroom setting in racially mixed contexts. Also, even though the groups had the same number of Black and White students, White students possibly felt some feelings of exclusion, what some students of color feel on a daily basis.

Lastly, there was a relationship between group processes and the attention component of the mattering construct. This relationship indicated that as one felt that they were noticed more by their group members they exhibited less process loss behaviors characterized by a lack of accountability of one's own actions but a proliferation of task hindering dynamics. This result may be due to a link in how one perceives his or herself and how he or she then interacts with the group as they study. One possibility is that as students perceive themselves to be "invisible" in a setting, they may seek out behaviors that led to lack of positive group processes. Attempts to be noticed may work, but they may ultimately sacrifice the wellbeing of the group's interactions as they work together on the given task. Accounting for this outcome requires further research.

Conclusion

This research has opened the door to the complexities of communal research when one attempts to use a sample perhaps more closely aligned to the average make up of the classroom across the nation. Placing both Black students and White students together in a communal learning context when studying mathematics estimation did not benefit both races significantly. However, with the current trends of the student population for this country, it is important to change the focus from what has historically worked for and in favor of White students and utilize what has been effective for African American and other students of color. Doing so can solidify achievement solutions for generations to come. There is promise in how the students behaved while they were in their study groups regardless of the condition. Researchers expected some arguing and scrambling for materials displayed by the students, especially in the interpersonal competition condition. However, this occurred minimally, and most participants either shared the materials completely of used some form of taking turns during the study phase of this experiment. Therefore, with more time, performance could follow the example of how the participants acted towards one another, especially in a communal setting. Lastly, the examination of mattering as a variable in the classroom setting shed light on how students in diverse classrooms' perceptions can change based on different learning contexts. Future research should plan to understand how students' sense of mattering operates to potentially help or hinder their wellbeing and/or academic performance in the school environment.

A QUEER TURN IN MATHEMATICS EDUCATION RESEARCH: CENTERING THE EXPERIENCE OF MARGINALIZED QUEER STUDENTS

Christopher Dubbs
Michigan State University
dubbschr@msu.edu

Evidenced by the lack of research considering queer students, mathematics education researchers are continuing to marginalize the experiences of queer youth and the only resolution is to center the queer student experience in the mathematics context. To accomplish this, I choose to dwell in the borderlands between queer theory and mathematics not only to challenge the border between them, but also to push on the borders of mathematics education research. In order to do so, I offer ways in which mathematics education researchers can take a queer turn in mathematics education research by generating queer curriculum, engaging in queer pedagogy, and queering mathematics content.

Keywords: Equity and Diversity

> The knower and the known are intertwined, for realizing that a science without humanity - without values, purposes, beliefs - is a false science, the false science of the spectator who always stays outside the arena of action, removed from the existential happenings of life - the 'pure' scientist as the phrase goes. This spectator view of science, of knowledge and of teaching is a thing of the past. (Doll, 1989, p. 248)

Introduction

William Doll foreshadowed the sociopolitical turn in education, that would not take root in mathematics education until more than a decade later (Gutiérrez, 2013). Another turn, a queer turn, began in education more than a decade ago (e.g., geography (Elder, 1999); biology (Snyder & Broadway, 2004); English (Greene, 1996)) and is invigorated with attention today (e.g., Gowlett & Rasmussen, 2014). This call to include queer theory in mathematics education research is not independent of the call for the inclusion of gender and sexuality topics in pre-service and in-service teacher education (Hansen, 2015; Martin, 2014; Robinson & Ferfolja, 2008; Vavrus, 2009). Nevertheless, the mathematics education research community has yet to engage with queer theory in earnest. In this theoretical exploration, I argue that mathematics education researchers continue to marginalize the experiences of queer youth by not focusing on queer students in their research, and the only resolution is to center the queer student experience in the mathematics context. At the expense of oversimplifying, queer as an identity will be used as a non-exclusive umbrella term for lesbian, gay, bisexual, and transgender (*à la* LGBT). *Queer* is discussed at length in the following section. Research centering queer students is necessary if we hope for equitable opportunities to learn mathematics for all students (Esmonde, 2007).

Mathematics education has a *significant* role in students' development of learner identities (Gates & Jorgensen, 2009) and student positioning has a lasting effect on children's perceptions of their available social roles (Cannela, 2008). In light of this research, hegemonic discourses within mathematics, such as *mathematics as masculine* (Mendick, 2006) and the *white male math myth* (Stinson, 2013), are particularly damaging. Despite this concern, the mathematics education research community cannot begin to identify equivalent discourses which oppress queer students if it continues to marginalize the queer student experience. This tension is evidence of the borderlands created between sexuality and mathematics, queer theory and mathematics education. The mathematics classroom is held to be culture-free or unbiased, despite literature indicating the oppressive nature of content and pedagogy (e.g., Kumashiro, 2004; Ladson-Billings, 1997). The ability to consider sexuality irrelevant in the mathematics context is a heteronormatively privileged

position; for queer students, their queerness, indeed *other*ness, is intersectional across social contexts. As Anzaldúa (1987/2012) does, I choose to dwell in these borderlands, for me the borderlands between queer and mathematics, to leverage my "outsider within" status as a queer individual in the mathematics education context not only to challenge the border between mathematics and queer, but also to push on the borders of mathematics education research. In order to do so, I offer ways in which mathematics education researchers can take a queer turn in mathematics education research by generating queer curriculum, engaging in queer pedagogy, and queering mathematics content.

Queer(ing) Identity

Queer does not have a fixed definition; it is "relational, in reference to the normative" (Letts, 2002, p. 123). Historically, queer was linked with insult and shame. Today, queer has become the "rallying point" not only for young gays and lesbians concerned with the homonormative images of gay men and lesbian women, but also for those whom wish to identify themselves with the anti-homophobic movement (Butler, 1993). By combining the works of Butler and Anzaldúa (1991), queer is understood as a false unifying umbrella, useful for solidarity with the necessary error of homogenizing and erasing differences to yield a temporarily totalized identity, which then necessarily fails to represent the person. Queer as an identity, henceforth, will be used as an umbrella term for lesbian, gay, bisexual, transgender, and other gender and sexual minorities.

Queer students can and do have academic and emotional success; Robinson and Espelage (2011), however, highlighted the higher incidence of suicidal thoughts, suicide attempts, victimization by peers, and unexcused absences for queer students compared with their non-queer peers. Additionally, Toynton (2007) documented the alienation of queer science students while Yoder and Mattheis (2015) followed this phenomenon of marginalization into STEM workplaces. I contend that mathematics education researchers are in a key position to work against the alienation of queer students and their underrepresentation in STEM careers by challenging discourses and structures which position queer students as *other*.

Beyond the classical components of identity (e.g., gender, sexuality, racialized group, etc.), Bishop (2012) offered mathematics identity as the collection of ideas one has about who they are, and the way they should act, in the mathematics context. Bishop offers identities as multiple, flexible, and fluid, and "ways of acting" (p. 39) suggests compatibility with identity as performative (Butler, 1993), but Bishop does not offer an operationalization of performative identity. To that end, Darragh (2015) operationalized the notion of a performative mathematics identity as the repeated performances that shape student recognition of themselves as certain types of learners of mathematics and, in particular, focused her research on whether students could see themselves in the descriptions of performances of good at mathematics that they identified. The notion of intersectional identities, introduced next, yields that studying mathematics students' identities, in particular their mathematics identity, without consideration of queerness, will be necessarily incomplete.

Intersectional Identities

Envez de dejar cada parte en su región y mantener entre ellos la distancia de un silencio, mejor mantener la tensión entre nuestras quatro [sic] o seis partes/personas [Instead of keeping each part [of our identities] separate and maintaining a "distance of silence" between them, it would be better to hold in constant tension our four or six identities/*personas*]… There is no way that I can put myselves through this sieve, and say okay, I'm only going to let the "lesbian" part out, and everything else will stay in the sieve. All the multiple aspects of identities (as well as the sieve) are part of the "lesbian." (Anzaldúa, 1991, p. 252-3)

In the first half of this quotation, Anzaldúa not only highlights the multiplicity of our identities by mentioning a rhetorical four or six parts of identity but also advocates against maintaining a

"distance of silence" between them. Furthermore, Anzaldúa's assertion that each part of her identity is also a part of her lesbian identity, highlights the intersectionality of identity and, in turn, the necessity to consider student queerness in mathematics education research. I connect the second half of Anzaldúa's quotation, the analogy of the sieve, to the notion of researcher positionality (e.g., Foote & Bartell, 2013). Just as Anzaldúa highlights the impossibility of realizing some idealized form of a lesbian writer by leaving her Chicana identity unacknowledged, so too it is impossible for the mathematics education research community to leave all aspects of our identity when we perform mathematics education research. In particular, Milner (2007) provided seen, unseen, and unforeseen dangers that might emerge if researchers *detach* themselves from their research. In a sense then, through this article I "come-out" as a queer theorist with queer intentions as a mathematics education researcher. I offer my abbreviated positionality as a white, queer, assigned-male-at-birth individual that is able to *leer y escribir en español* and instead of maintaining a distance between these facets of identity, I keep them in tension, bringing my queer identity to bear on my mathematics education research.

A Queer Turn in Mathematics Education Research

Thus far, I have motivated the necessity to consider the needs of queer students in the mathematics education context. In this section, I introduce queer theory and investigate the intersection of queer theory and mathematics education research. Like Letts (2002), who held queer theory "still long enough to get a good look at it," I do not claim to present queer theory as a defined package. Instead, I first provide a theoretical overview of queer theory followed by *instantiations* of queer theory. These instantiations are like a photograph that freezes-in-time one instance of queer theory in practice and necessarily reports it back in an incomplete way. I introduce queer theory here for three key reasons. First, existing research fails to address the experience of the queer student in the mathematics context, which queer theory enables. Second, the notion of intersectional identities yields that each facet of identity is part of each other facet and, as a result, studying mathematics students' identities (e.g., racialized or gendered) without consideration of queerness will be necessarily incomplete. Finally, I introduce queer theory to offer an illustration of the types of work that queer theory can enable in mathematics education.

Queer Theory

Queer theory: is an epistemological stance (Letts, 2002); appropriates the forms of curriculum and pedagogy to investigate how sexuality is organized, how sexuality is identified, how knowledge is unfixed, unstable, and how knowledge "unfolds…subject to individual insights and cultural contingencies" (Davis & Sumara, 2000, p. 832; Sumara & Davis, 1999); is deviant and critiques normativity (Jourian, 2015); signifies action and is unstable and multiplicitous (Britzman, 1995); and is about making normal queer, revealing the socially constructed nature of truths and selves, and ultimately asks "what can be, rather than what is" (Gunckel, 2009, p. 63; Snyder & Broadway, 2004). The eight authors cited in this list present eight different descriptions of what queer theory does; queer theory *appropriates, investigates, critiques, identifies, deviates, signifies, reveals*, and ultimately, *queers*.

In *A Critical Introduction to Queer Theory* (2003), Sullivan provided a detailed history of socially constructed sexuality and gay and lesbian rights activism. Two key movements, the assimilation and liberation movements, contextualize the strands within the queer theory movement in education. The assimilationist groups did (and continue to) fight for social acceptance; often their methods involve minimizing differences and emphasizing sameness through essentialization. Dissatisfied with hiding, gay and lesbian liberationists such as Wittman offered a different perspective: "Liberation for gay people is to define for ourselves how and with whom we live, instead of measuring our relationships by straight values… we must govern ourselves, set up our own

institutions, defend ourselves, and use our own energies to improve our lives" (Wittman, 1970, as cited in Adam, 1995). These two camps, the assimilationists and the liberationists, continue to exist in tension today.

Although queer theory has its history in gay rights activism, there are "homophobic and marginalizing implications of leaving much queer studies work to queers themselves" (Marshall, 2014). That being said, if one cannot understand the implications of being queer as a result of one's own non-queerness, "the only way to act with integrity is to follow the leadership of those who are oppressed in that way, [to] support their projects and goals" (Indigenous Action Media, 2015). Having presented several understandings of queer theory, I now present queer curriculum and queer pedagogy. Queer curriculum and queer pedagogy represent only two instantiations of queer theory– examples of how queer theoretical concepts have been applied in the past, but not in an exhaustive nor definitive way. These examples do not wholly constitute queer theory but instead serve as starting points for mathematics education researchers to take a queer turn.

Queer Curriculum

The *queer curriculum movement* is my term for the collective efforts of researchers across the disciplines interested in developing queer-inclusive curriculum and queer curriculum theory. I contend that activity within the queer curriculum movement is the modern, educationally-relevant, reincarnation of the assimilationist's work in that queer curriculum is often of the "add-queers-and-stir" (Rands, 2009) variety. In other words, queer curriculum often features homonormatively-inclusive examples. As researchers work towards a queer curriculum, that curriculum must obtain additional demands; curriculum must now meet both the demands of content standards while including socially aware queer content. Scholars have argued that curriculum is obligated to interrupt the heteronormative, that sexuality is an analytic category appropriate to curriculum studies, and that curriculum might be better suited to unpack the "heterosexual closet" than to elaborate on queer identities (Davis & Sumara, 2000). By considering queer students and children with queer families or family members, culturally relevant mathematics that seeks to legitimize students' experiences in the "official" curriculum converges interest with queer curriculum (Ladson-Billings, 1994; Rands, 2009).

Such moves for queer-inclusive curriculum is not without theoretical basis. Sumara and Davis (1999, 2000) have contributed substantially to the development of a queer curriculum theory. They argued for curriculum theory to seek to understand desire, pleasure, and sexuality (1999), in part through creating *heterotopic* events, events which comprise the juxtaposition of not-often-associated objects (e.g., positive queer role models would be heterotopic to a dominant discourse of queers as perverse; the positive-queer association being heterotopic). In particular, these researchers investigated examples from queer literature curriculum and highlighted ways in which heterotopic events from the readings were juxtaposed with students' lived experiences. In a similar way, mathematics education should provide heterotopic events for students, not only for queer students by juxtaposing *visible inclusion* with their *lived hiding* (e.g., being "closeted") but particularly for non-queer students by juxtaposing queer voices with the dominant discourse of queer silence. Luecke (2011, p. 117) eloquently summarized Style's "Curriculum as Window and Mirror" (1996) as a call that "All children need curricular mirrors to see themselves reflected and thus feel safe in being themselves, and they also need curricular windows to feel safe with the differences of others."

There is a paucity of research in mathematics education using queer theory; in fact, searching ERIC for "Queer Theory" and "Mathematics" returned zero relevant articles (and five irrelevant ones; Google Scholar corroborated such findings). Broadening the search to "Queer" and "Mathematics" increased the total results to six and yielded Rands' seminal piece in queer theory and mathematics education. This article was published in *Sex Education* yet focuses exclusively on the mathematics classroom and exclusively offers mathematical examples. As Rands was, and remains to

be, one of the few authors addressing the intersection of mathematics and queer theory, I present in detail two of her pieces here to center this previously marginalized work.

Add-queers-and-stir mathematics. In "Mathematical Inqu[ee]ry: Beyond 'Add-Queers-and-Stir' Elementary Mathematics Education," Rands (2009) began by recounting a story from personal experience as an elementary teacher and the choice to queer literacy, through heterotopic readings, prior to queering mathematics. Rands' literature review referenced several anthologies of queer theory in education, but none of these included mathematics. Addressing this gap, Rands provided six examples across 1st and 3rd-5th grades of how one might queer mathematics curriculum. These examples fall into one of two categories: "Add-Queers-and-Stir" or "Mathematical Inqu[ee]ry" (Rands, 2009). The former aligns well with the assimilationists while the latter begins to advance the liberationist's goals. To elucidate, Add-Queers-and-Stir examples would generally have a goal of inclusion in homonormative ways. One such example by Rands involves finding the area of queer symbols (such as the rainbow flag, pink triangle, etc.). This approach fails to consider sexuality as a dimension of "teacher practice, student learning, and the production of knowledge" (Letts, 2002, p. 119). We can contrast the superficial inclusion of this area example with the latter category of Mathematical Inqueery.

Mathematical inqueery. In Mathematical Inqueery, students appropriate the role of liberationists and there are often tones of teaching mathematics for social justice (viz., Rands, 2013). For example, consider Rands' (2009) fifth-grade mathematical investigation on income of married couples. In this investigation, students used mathematics to challenge the hegemonic structure of marriage by considering the intersectionality of sexuality, gender, and class. Men and women in same-sex married couples, due to the income inequality between men and women, would be structurally positioned financially ahead of/behind each other. This example clearly moved beyond the superficial inclusion of the area example and began to address systemic inequalities which oppress queer lives. By following this task about income inequality with an action component, one could see this progress towards action research (Cammarota & Fine, 2006) and, in particular, I see a clear connection to teaching mathematics for social justice.

In fact, in 2013, Rands published "Supporting Transgender and Gender-Nonconforming Youth Through Teaching Mathematics for Social Justice" in the *Journal of LGBT Youth*. In this piece, Rands "synthesize[d] perspectives on gender-complex education, teaching mathematics for social justice, and research on students' development of proportional reasoning and statistical concepts, and then propose[d] a mathematics project for middle schoolers to facilitate their agency in challenging transphobia and gender oppression in their schools" (p. 106). The benefit of such activities is two-fold: the benefit of inclusion and the benefit of the social justice/action component. There is a clear need for research on additional teaching mathematics for social justice projects which consider the queer student experience. We turn our attention to a novel concept in queering the content of mathematics, and specifically queering geometry with fractal geometry.

Queering mathematical content. Both Add-Queers-and-Stir and Mathematical Inqueery work within the prescribed mathematical context whereas queering mathematical content rejects existing borders and offers an alternative reality. The following example goes beyond the understanding of queer as an identity, and queer theory's minor goal of queer-inclusive curriculum, to queer as opposition-to-the-normative and queer theory's major goal of challenging the normative. Instead of providing queer-inclusive curriculum and working within the given mathematical structure, Davis and Sumara (2000) challenge the dominant position that Euclidean geometry holds in school mathematics. By reframing geometry as a "systematic reduction of all phenomena to fundamental particles, root causes, and original principles" (p. 823), the authors challenge the necessity of Euclidean rigidity particularly in light of fractal geometry which evades it. Furthermore, by making a connection between knowledge and fractals, the authors continue the analogy between fractals and grain size: regardless of individual, social, or cultural foci, each are nested within or wholly contain

others. It is important to note that Davis and Sumara align themselves with post-modern curriculum theory in their piece, not explicitly queer theory. This, however, does not change the interpretation presented. Characterizing additional work *ex post facto* as having converging interest with queer theory would only further emphasize the lack of explicit attempts to queer mathematical content.

Queer Pedagogy

Moving beyond the queer curriculum movement, into what most closely aligns with the liberationist's work, is the queer pedagogy movement. In fact, at its center, queer pedagogy disrupts the normative and its reproduction of oppressive structures (Luhmann, 1998), by adding goals of social justice to the educational system. Such an approach of working within structures, however, echoes assimilationist motives. Nonetheless, as mentioned above, I am particularly optimistic toward projects which consider a queer turn in teaching mathematics for social justice. Furthermore, little work has considered a uniquely queer pedagogy and none has considered a queer mathematics pedagogy. One such queer pedagogy which might be suitable for the mathematics context is presented next.

Beyond aligning existing movements such as teaching mathematics for social justice with queer pedagogical goals, scholars such as Britzman have described features of a uniquely queer pedagogy. For Britzman (1995, p. 165), a queer pedagogy is a pedagogy that "refuses normal practices and practices of normalcy,… begins with an ethical concern for one's own reading practices,… is interested in exploring what one cannot bear to know,… [and is] interested in the imagining of a sociality unhinged from the dominant conceptual order." Britzman provided us with four key features of a queer reading pedagogy, which I offer as transferrable to the mathematics education context: a queer mathematics pedagogy is one that: rejects the normative, has an ethical concern at its center, explores "what one cannot bear to know" (p. 165), and decenters normative structures and discourses. In other words, I propose that a queer mathematics pedagogy is one that, from a center of ethical concern for queer students, rejects the heteronormative systems, structures, and discourses by bringing to light queer experiences excluded by the heterosexual understanding. There is a tangible need for research on what might further constitute a queer mathematics pedagogy and what that pedagogy might offer in practice.

Concluding Remarks

Looking ahead, I see several key directions in which mathematics education researchers must move. First, mathematics education researchers should strive to operationalize performative and intersectional notions of identity (e.g., Darragh, 2015); such a distinction challenges the normative (separable) notion of identity. Incremental changes to existing research trajectories, such as simply drawing on updated notions of gender identity within the current context of gendered research in mathematics education, will still fail to include queer students. Second, I challenge the mathematics education research community to push against the borders of mathematics education research by centering the experience of queer students in their current research while simultaneously advocating that more mathematics education researchers must adopt a queer theoretical stance to accomplish this centering, not only in the mathematics context, but within the overall education system. Finally, I urge mathematics education researchers to develop and engage with queer curriculum and queer pedagogy, despite a theoretical basis outside of mathematics education and the relative lack of adoption in mathematics education research thus far. In addition to simply including queer examples, however, mathematics education researchers should continue to question the nature and boundaries of mathematics itself to challenge the notion of mathematics as fixed, neutral, and culture free. By embracing the tension between queer and the self-imposed, artificial borders of mathematics education research, the mathematics education research community can only continue to grow as more mathematics education researchers draw on the queering notions of queer theory. Taking a

queer turn in mathematics education research is the most direct path toward the safe and equitable education of queer students.

SPATIAL ACTIVITIES AT HOME AND THE CRITICAL TRANSITION TO KINDERGARTEN

In this research we explored the relationship between spatial activities in the home and spatial ability at the start of formal schooling at age four. In total, 30 children participated in this research. Data sources included a demographic questionnaire, a survey of at home spatial activities, and standardized testing in verbal and non-verbal spatial ability. Our results showed that the spatial activities in the home did not predict spatial ability at age four. Gender differences were observed with boys scoring higher in verbal- and non-verbal visual-spatial ability. Given the highly malleable nature of spatial ability and the importance of spatial ability to future STEM-based learning, intentionality in spatial learning by teachers is important.

Key words: Cognition, Early Childhood Education

Introduction

Studies have found that experiences in early childhood have important academic implications for children at the start of schooling and beyond (Alexander & Ignjatovic, 2012). Yet, for both children in early learning settings and those in a home care setting, there may be great variability in the kinds of opportunities for learning (Marope & Kaga, 2015). Expectations for social, emotional, and intellectual engagement may differ significantly. For some children, particularly those in early learning settings, the expectations and routines may not be that vastly different. The differences may be substantial and may even be partially cultural (Brooker, 2010). Consequently, the start of formal schooling is a critical transition for many young children.

Readiness for mathematical learning may be a particularly type of critical transition. Studies report that often relatively little emphasis is placed on mathematics in the home (Blevins-Knabe & Musun-Miller, 1996) or in early learning centers (Early et al., 2005). However, early mathematical ability is related to future success in mathematical learning (Geary, 2011; Sasanguie, De Smedt, Defever, & Reynvoet, 2012). The kinds of activities young children engage prior to formal schooling and in their homes in are linked to future academic outcomes in mathematics (Anders et al., 2012). For example, studies have shown that higher levels of mathematical and spatial talk (Gunderson & Levine, 2011), block play (Hanline, Milton, & Phelps, 2010), and puzzle play (Levine, Ratliff, Huttenlocher, & Cannon, 2012) are related to mathematical ability or spatial ability.

A recent study by Aunio and colleagues (2015) showed that schooling does *not* mediate for lack of prior experience or knowledge, particularly for those children who begin schooling with less basic mathematic understanding than what might be anticipated. Children's (age in months, M = 74.55; SD = 3.50) number knowledge was tested at three time points during kindergarten. While lower achieving children showed the most gains, children who started school with high mathematical abilities remained high – and higher than those children who tested at medium or low mathematical ability. In short, schooling did not help the lower achieving children catch up to the higher achieving children. This study illustrates the importance of a strong mathematical start and highlights that starting school *is* a critical transition in terms of mathematical learning – albeit perhaps unrecognized by teachers or parents. This research suggests that schools may need to rethink assumptions about a

young child's mathematical-readiness for schooling and how different levels of readiness need to be supported by teachers.

The early mathematics advantage is not exclusively about basic number knowledge. Studies show that spatial ability also has lasting implications for future success in mathematics and even in participation in STEM-based disciplines (Lubinski, 2010; Wai, Lubinski, & Benbow, 2009). Gunderson and colleagues (2012) found that spatial ability at age five contributed to level of number knowledge at age eight. Moreover, spatial skills in kindergarten have been found to be a more powerful predictor of mathematics ability in grades one and two than even mathematics skills in kindergarten (Frick, Möhring, & Newcombe, 2015). Childhood spatial activities are linked to spatial skills and mathematics grades in adulthood (Doyle, Voyer, & Cherney, 2012).

Spatial ability is defined broadly as the understanding of relations about (i.e., properties and attributes) and between objects and spaces including transformations in either two or multiple dimensions (i.e., mental rotations) (Clements, 2004; Linn & Peterson, 1985). Often spatial ability is associated synonymously with "visual-spatial ability." That is the case with our use of the term and that is clear in our choice of standardized tests described shortly.

In this research we look specifically at the spatial activities of four-year-old children and how the types of activities/toys children engage with intersects with spatial ability at the start of kindergarten. Our research questions were as follows: (1) *What are the sorts of spatial activities four year olds children engage in, as reported by their parents?* (2) *Do these activities contribute to children's spatial ability at the start of formal schooling in kindergarten?*

Given that approximately 60% of young children are cared for at home (Barnett, Carolan, Fitzgerald, & Squires, 2012), we analyze our results further by considering whether early childhood education and care is connected to the experiences reported by parents and spatial ability at the start of formal schooling. We also analyze our results by gender because of the numerous studies that report a gender advantage to boys in spatial ability (Frick et al., 2015; Linn & Peterson, 1985).

In our jurisdiction age four represents the start of formal schooling with a full-day kindergarten program and thus this age is the critical transition point between home and school or early learning/childcare setting and school for these young children. Given the highly malleable nature of spatial ability (Uttal et al., 2013), an understanding of how home environments contribute to the development of spatial ability is important to subsequent spatial ability but also to future mathematics learning.

Recent research exploring spatial ability in girls (approximate age 6) by Dearing and colleagues (2012) found that home spatial activities were related to the girls' spatial skills but not proximal predictors of spatial skills. Other recent research using longitudinal data found that spatial activities in the home of children age four to seven, were predictive of spatial ability when tested on the Block Design subtest from the WPPSI-IV (Frick et al., 2015). This research also found a gender difference with boys engaging more in spatial activities than boys. In our research, we consider whether the same trends observed in these other studies are evident at age four and whether these trends hold true for boys and girls. Moreover, we consider both non-verbal and verbal measures of spatial ability (cf. Block Design used by Frick et al., 2015) and a wider range of proposed spatial activities.

The theoretical framework for this research is *critical praxis*. Drawn from Tilleczek (2012), critical praxis "denotes critique and interrogation of the theory and practice surrounding childhood transitions" (p. 13). The objective of the critical praxis is to enhance the experiences of young children by inspiring "schools and people to function as communities which build bridges between students, parents, teachers, and communities" (Tilleczek, 2012, p. 17). In the present research, theory intersects practice through an analysis of the juxtaposition of home practices against young children's spatial ability as a possible precursor for future spatial learning in a school setting.

Methods

Participants

Thirty junior kindergarten children (*M* ₐgₑ = 49.9 months; *SD* = 3.2; *Range* = 45 to 56 months; 19 males) were recruited from six classrooms within one elementary school. While mandatory schooling begins in grade one, or age six, full day schooling is available for all children starting at age four. Out of the 30 children, 27 parents (23 mothers, 4 fathers) participated in the parental portion of the study. The other three parents chose to not complete any of the questionnaires and thus these children were removed from the study. The available demographic data for the 27 participants indicated that English was the most frequent language spoken at home for all children. The socioeconomic status (SES) of the participants was determined by using mother's highest education level (Catts, Fey, Zhang, & Tomblin, 2001). The highest education level attained by mothers was as follows: 4% completed some high school, 19% high school, 30% college/trade, 41% university, and 7% completed graduate/professional education.

Procedure

Children's visual-spatial ability was assessed by the Stanford Binet Intelligence Scales for Early Childhood, Fifth Edition (SB5; Roid, 2003). The children were administrated the SB5 in the school library. Each child was assessed one-on-one by either the second author or a trained research assistant. The study also consisted of a parental portion, in which parents were asked to complete a demographics questionnaire, and an at-home spatial activities questionnaire (Dearing et al., 2012).

Stanford Binet Intelligence Scales for Early Childhood, Fifth Edition (SB5; Roid, 2003). The children were administrated both the Nonverbal and Verbal Visual-Spatial Processing subtests from the SB5. Age normed scaled scores (*M* = 10, *SD* = 3) were calculated for each subtest. The Nonverbal subtest includes 16 items and requires the child to fit shapes and combine shapes into a plastic board that has forms of shapes cut out in it. These items measure the child's visualization ability of visual-spatial processing. For the last eight questions on the Nonverbal subtest, the children are presented with a two-dimensional image and are required to recreate that image with three-dimensional geometric figures. The Verbal Visual-Spatial Processing (Position and Direction) subtest is comprised of 12 items. The Verbal subtest evaluates children's understanding of position and direction by following verbal instructions and moving objects into the certain positions. The child is presented with an image and is asked to place a block on a certain direction or position with relation to the image.

Demographic Questionnaire. The participating parent completed a demographic questionnaire indicating their child's gender, date of birth, the language most frequently spoken at home, their relationship to the child, mother's highest education level, and how many hours the child spent in child care from ages one to three. Children were grouped into low (college and under) or high (university and above) SES groups.

Child Spatial Activities Questionnaire. The spatial activities questionnaire was adopted from Dearing and colleagues (2012) and it measures the frequency of children's engagement in spatial activities and toys at home. The spatial activities questionnaire (Cronbach's Alpha = .85) has good reliability (Dearing et al., 2012). Parents were asked how often their child engages in 20 spatial activities (e.g., builds with construction toys such as building blocks, LEGO®, and magnet sets). The parents indicated the frequency of each activity on a five-point scale (1 = *never*, 2 = *seldom*, 3 = *occasionally /a couple times per month,* 4 = *often/weekly,* 5 = *many times per week*). An average was computed in order to obtain an average frequency score for the spatial activities. Children were also grouped into either a high and low spatial activity group based on the average median cut-off.

Results and Discussion

We examined the types of spatial activities parents engage in with their child. The most frequently occurring spatial activities were as follows: playing in parks, playing with action figures or cars, colouring, painting, or drawing free hand, and building with construction toys. Parents also indicated that play with blocks and puzzles also occurred often or weekly (See Table 1 for mean frequencies of each activity).

Table 1: Spatial Activities Engaged in at Home

Spatial Activity	Mean (*SD*)	Min – Max
1. Play in parks or green spaces when the weather permits	4.7 (.52)	3 – 5
2. Play with toy soldiers, action figures, cars/trucks, planes or trains	4.4 (.89)	2 – 5
3. Colour, paint, or draw free hand (not filling-in outlines)	4.3 (.86)	2 – 5
4. Build with construction toys (such as building blocks, Legos, magnet sets)	4.2 (.65)	3 – 5
5. Set up play environments with toy furniture, toy buildings, train tracks or building blocks	4.1 (.81)	2 – 5
6. Play with puzzles (such as picture puzzles, tangrams, slide puzzles, 3-D puzzles)	4.1 (.84)	2 – 5
7. Race toy animals or cars on the ground or around obstacles	4.1 (.84)	3 – 5
8. Do arts and crafts projects	4.0 (.78)	2 – 5
9. Explore woods, streams, ponds, or beaches or search for plants, bugs, or animals outdoors when the weather permits	3.7 (.76)	2 – 5
10. Use a computer/video games to do drawing, painting or matching and playing with shapes	3.7 (.90)	2 – 5
11. Play paper and pencil games (such as mazes, connect-the-dots)	3.3 (1.1)	1 – 5
12. Set up obstacle courses, tunnels, or runways for kids or pets	2.8 (1.0)	1 – 5
13. Build dams, forts, tree houses, snow tunnels, or other structures outdoors when the weather permits	2.8 (1.1)	1 – 5
14. Use tools (such as hammers or screwdrivers) to make things or take things apart to see how they work	2.7 (1.3)	1 – 5
15. Play with flying toys (such as kites, paper airplanes)	2.5 (.8)	1 – 4
16. Fold or cut paper to make 3-d objects (such as origami, paper airplanes)	2.5 (1.1)	1 – 4
17. Climb trees when weather permits	2.1 (1.2)	1 – 5
18. Draw maps (such as treasure hunt maps)	2.0 (1.1)	1 – 5
19. Draw plans for houses, forts, castles or other buildings or layouts	1.8 (1.2)	1 – 5
20. Use kits to build models (such as airplanes, animals, dinosaurs, doll houses)	1.7 (.65)	1 – 3

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Note. Mean frequency and minimum and maximum for each spatial activity. Parents indicated the frequency of each activity on a five-point scale (1 = never, 2 = seldom, 3 = occasionally /a couple times per month, 4 = often/weekly, 5 = many times per week).

Children were grouped into high- and low-frequency of spatial activity groups. There were 14 children in the low spatial activity group and 13 were in the high spatial activity group (*Range* = 2.05 to 4.15, *Median* = 3.40). Children in the high spatial activity group had higher scores on their nonverbal visual-spatial ability; however, children in the low and high spatial activity group had similar scores for their verbal visual-spatial ability (See Table 2 for means). This research did not explore actual levels of spatial talk in the home which have been found to be related to spatial thinking (Gunderson & Levine, 2011). This may have explained the lack of differences between the groups.

Table 2: High- and Low-frequency Spatial Activity Groups

Spatial Task	Spatial Activity Group		Years in Child Care			
	Low	High	0	1	2	3
Nonverbal Mean *(SD)*	11 *(3.1)*	12.2(3.8)	9.5(6.3)	10.7(2.8)	11.5(4.3)	12.5(3.1)
Verbal Mean *(SD)*	12.3 *(2.6)*	12.2 *(2.6)*	12.5(0.7)	11.7(2.4)	11.6(3.4)	12.9(2.5)

Note. Mean scaled scores and standard deviations for nonverbal and verbal visual-spatial ability examining high and low spatial activity groups and years in child care.

We also examined whether attending child care prior to entering formal schooling influenced children's spatial abilities. There were two children that never attended child care, seven children attended for one year, six children for two years, and 12 children attended child care for three years. During the first three years of life every additional year spent in child care showed an increase in their average nonverbal visual-spatial ability (See Table 2 for means). In terms of verbal spatial ability there was not an evident pattern of increase based on years spent in child care, however children who attended child care for all three years had the highest scores (See Table 2). This would be expected given the many studies that report that early childhood education, particularly that of a higher quality, can have important implications for future academic outcomes (Alexander & Ignjatovic, 2012).

We found that boys (*M* = 11.79, *SD* = 3.6) had higher nonverbal visual-spatial scores compared to girls (*M* = 10.45, *SD* = 3.5). Girls (*M* = 12.36, *SD* = 3.1) had slightly higher verbal visual-spatial scores compared to boys (*M* = 12.16, *SD* = 2.6). Boys and girls frequency of spatial activities were also compared. Boys (*M* = 3.4, *SD* = 0.4) and girls (*M* = 3.16, *SD* = 0.4) had similar mean frequencies, with boys showing a slightly higher frequency. A Mann-Whitney test showed this to be a non-significant difference (*U* = 46.7, *p* = .08). Parental reports of higher frequency of spatial activity in boys is consistent with reported results (Frick et al., 2015).

Correlations were conducted for nonverbal and verbal visual-spatial ability between the following factors: gender, SES, child care attendance, and at home spatial activity average. There were no significant correlations (*p* > .05). There was also no correlation between nonverbal and verbal visual-spatial ability, therefore indicating that doing better one subtest did not mean children were more likely to do better on the other subtest.

To examine if there were any significant effects or interactions between spatial activities, child care attendance, SES and gender a 4 (child care: 0 years vs. 1. vs. 2 vs. 3) x 2 (spatial group: low vs. high) x 2 (SES: low vs. high) x 2 (gender: boys vs. girls) Analysis of Variance (ANOVA) with nonverbal visual-spatial ability as the dependent variable was conducted and revealed no significant main effects or interactions ($p > .05$).

The same ANOVA was conducted with verbal visual-spatial ability as the dependent variable. There were also no significant effects or interactions for verbal visual-spatial ability ($p > .05$). Similar to Dearing and colleague's research (2012), spatial activities were not predictors of spatial ability girls but also boys. Dearing et al.'s research considered six year olds. Our research provides further evidence. Different than Dearing et al. is that we did not find any correlations between the spatial activities and spatial ability.

The lack of significant findings could be explained by the low sample of children across groups. This is recognizably a limitation of this research. However, there are other possible explanations. Frick and colleagues (2015) recently reported that spatial activities in the home at age five were related to spatial ability at age eight. According to Uttal and colleagues (2013), spatial ability is highly malleable and thus children in Frick et al.'s study likely benefited from formal school instruction or a malleability effect. Additionally, the higher levels of spatial play that were reported by parents may not have been sufficiently complex for the child to move the child along in their continuum of learning (Gregory, Kim, & Whiren, 2003; Hanline et al., 2010; Lee, Kotsopoulos, & Zambrzycka, 2013). Finally, parents' perception of a "high" level may vary – despite the Likert scale qualifiers. Some naturalistic observational data would be helpful to offset self-reports on such frequencies, as well as larger sample sizes.

Conclusions and Educational Implications

Research has shown that spatial skills are important for future success in both mathematics and in STEM-based disciplines (Lubinski, 2010; Newcombe, 2010; Tolar, Lederberg, & Fletcher, 2009; Wai et al., 2009). Understanding the degree to children's spatial ability is developed at the start of formal schooling and the kinds of activities in the home environment that contribute to the development are important. The results from the present research suggest that home activities are not necessarily mapping directly onto spatial ability at the start of formal schooling. These results have important implications for teachers – and perhaps lasting implications for children. Schooling itself does not contribute to mathematical resilience in the absence of intentionality (Aunio et al., 2015). A lack of intentionality may be even more problematic for spatial ability. Recent research reports that relatively little time is spent overall on spatial ability (or geometry) in schools compared to other curricular strands such as numbers, data management, and measurement (Mullis, Martin, Foy, & Arora, 2012; Organisation for Economic Co-operation and Development, 2012). Consequently, intentionality in nurturing spatial ability is important.

Such intentionality would involve having a clear understanding of the beginning points of the child's spatial understanding and then building pedagogical moments to advance the child's understanding based on their unique starting point. Teachers may be challenged in determining the starting point because early mathematical development, including the development of spatial ability, may be underemphasized in their professional training. Future research should explore the ways in which professional programing prepares future teachers and early childhood educators to understand early spatial and mathematical development.

From a critical praxis perspective, the importance of occasioning spatial learning and in fostering a deeper understanding of spatial learning amongst teachers should be evident. By linking the home-school connections, the potential for enhancing opportunities for learning are increased. In the case of spatial ability and even mathematical ability, the need to occasion such bridges is paramount given the clear research that shows an academic advantage to those young children that come to school

knowing more mathematical concepts (Aunio et al., 2015; Geary, Hoard, Nugent, & Bailey, 2013; Romano, Babchishin, Pagani, & Kohen, 2010).

DIS/ABILITY AND MATHEMATICS: THEORIZING THE RESEARCH DIVIDE BETWEEN SPECIAL EDUCATION AND MATHEMATICS

Rachel Lambert
Chapman University
lambertr@chapman.edu

Paulo Tan
University of Tulsa
paulo-tan@utulsa.edu

Based on an analysis of 408 mathematics research articles published in 2013, this presentation theorizes the current divide between research in mathematics education and special education using Disability Studies in Mathematics Education. For those without disabilities, mathematical learning was understood primarily through constructivist, sociocultural, and sociopolitical perspectives, the research was both quantitative and qualitative, and almost 50% of the research was focused on the role of the teacher in learning. For those with disabilities, mathematical learning was understood primarily from medical and behavioral perspectives. This research was predominantly quantitative, and rarely focused on the teacher. We contend that this divide constructs and reifies the notion that there are two categories of mathematics learners who need different kinds of mathematics.

Keywords: Equity and Diversity, Learning Theory, Research Methods

Introduction

Students with disabilities are offered fewer opportunities to engage in meaningful mathematics, as special education classrooms and curriculum are focused on procedural rather than conceptual instruction (Jackson & Neel, 2006). Based on a content analysis of current research in both mathematics education and special education mathematics, we contend that disparities in access are influenced by a research divide between these two fields, which differ in the epistemologies, methodologies, and pedagogies used to understand learners. The research divide constructs and reifies what many consider to be a "common sense" assumption: children with and without disabilities are different, and should be educated differently in mathematics.

While this paper/presentation will describe that research divide using data from a research content analysis, our focus is to theorize that divide. Theory matters, because for some, including perhaps many at this conference, this divide may seem unremarkable. After all, disability is a medical condition, and mathematics education researchers are not experts in disability. Even in the rhetoric of equity in mathematics education research for marginalized student groups, students with disabilities are often not part of such conversations (Tan, 2014). We believe that Disability Studies can illuminate the historical reasons for this divide and challenge such borders moving forward. The conference theme of Questioning Borders is a generative location for our analysis, as we seek to deepen our understanding not only of the borders between these two academic fields, but the areas of intersection as well.

Conceptual Framework

Disability Studies in Education

Activists with disabilities pioneered the academic field of Disability Studies, advocating replacement of the medical model of disability with the social model (Union of Physically Impaired Against Segregation [UPIAS], 1975). While individuals may have cognitive or physical differences, disability is created through society's response to these differences. As Siebers (2008) writes, "the medical model defines disability as an individual defect lodged in the person, a defect that must be cured or eliminated if the person is to achieve full capacity as a human being" (p. 3). In contrast, Disability Studies "defines disability not as an individual defect but as the product of social injustice, one that requires not the cure or elimination of the defective person but significant changes in the

social and built environment" (p. 4). The response to difference is not to seek to cure it in the affected individual, but to understand how unjust social systems create or exacerbate differences. Applied to schools, Disability Studies in Education (DSE) examines disability in schools as a social construction that results in social exclusion and oppression (Gabel, 2002).

Disability Studies in Mathematics Education (DSME) (Tan, 2014) reimagines the structures and processes of teaching and learning mathematics. Students with disabilities (and all students) are representative of the diversity of human experiences for which all educational environments should be designed. DSME also draws from critical mathematics education (CME) perspectives. CME is concerned with the social and political aspects of the learning of mathematics and how students and teachers operate in a social system rife with hegemonic power (Gutiérrez, 2002). CME aims to broadly (1) develop within individuals a political awareness of individual's position in a system (e.g., classroom, school, or community), and (2) motivate individuals to enact change toward advancing social justice (Powell & Brantlinger, 2008). DSME troubles conventional mathematics research by involving students with disabilities and by surfacing and questioning power differentials. This process includes challenging "hegemonic narratives about who can do mathematics and to reconstruct the role of mathematics in the struggle to empower learners whose mathematical powers have been underdeveloped" (Powell & Brantlinger, 2008, p. 425). In utilizing DSME, action towards more just practices is led first and foremost by students with disabilities where their lived experiences and voices are privileged in the conversation. Additionally, we situate our analysis within Dis/Crit, which highlights how race and disability intersect (Annamma, Connor, & Ferri, 2013).

Historical Roots of Mathematics Education

Mathematics education has been influenced by (and has influenced) larger epistemological stances about learning and learners such as behaviorism, information processing, constructivism, and sociocultural theory (Woodward, 2004). Gutiérrez (2013) has called for mathematics education to address learning from a sociopolitical perspective as well, to better understand how larger social forces, power and positioning affect not only learning, but access to learning. We found that constructivist and sociocultural approaches to learning currently dominated research in mathematics education. In general, constructivist theories of learning understand individual learners as active participants in constructing knowledge through experience and reflection (Draper, 2002); sociocultural theory expands analysis of learning to the product of interactions between two or more people (Lerman, 2000). Learning is situated in contexts, and mediated by tools that include mathematical discourse.

Historical Roots of Special Education

Special education philosophy and research have historical roots in psychology and medicine guided by behaviorism and positivism orientations to develop and test interventions for students with disabilities (Paul, French, & Cranston-Gingras, 2002). Paul and colleagues noted that despite advancements and evolution in social science perspectives, special education researchers have maintained a strong commitment to a positivist epistemology. Mathematics research in special education continues to be heavily influenced by behaviorist theories of learning such as direct instruction (Woodward, 2004).

In the field of special education, evidence-based practices must include experimental control (Cook, Tankersley, Cook, & Landrum, 2015), significantly reducing the kinds of possible research that could influence teaching practice. Subscribing to such standards of what constitutes research evidence-based practices means only quantitative methods are valid. Research designs involving students with disabilities tend to focus on evaluating instructional practices on children's learning with limited focus on teachers' pedagogical understanding and curriculum design (e.g. Griffin, League, Griffin, & Bae, 2013) and limited focus on how students construct mathematical learning.

Direct instruction in mathematics is widely endorsed and qualify as being evidence-based (Gersten et. al, 2009). Hence, researchers grounded in conventional special education epistemologies who desire to advance knowledge in their field are strongly pulled in the direction of the "evidence." Teacher directed and explicit instruction represents mathematical knowledge that must be transmitted from "knowers" and reifies acquiescence to societal power structures (Charlton, 1998). Thus, the prevalent and long-standing stance of who benefits and who does not benefit from certain mathematics pedagogies establishes and is established by omnipresent borders across societal structures that influence research and practice restricting what is possible for students with disabilities.

Methods

In order to understand the present state of this research divide, we conducted a content analysis of research articles published in 2013 that focused on mathematics and PK-12 education (Lambert 2015a; Lambert & Tan, 2016). Our research question asked how research on mathematical learning of children with and without disabilities differed in terms of academic fields, methodologies, mathematics content, and participants. Additional information on methodologies and findings can be found in previous publications.

We limited the sample to mathematics education research articles published in peer-reviewed journals in English in 2013. We excluded research that focused exclusively on mathematics at the undergraduate level, unless the participants were pre-service teachers. We found articles through searches of educational databases (ERIC, JSTOR, & PsychINFO) looking for descriptors and keywords of mathematics, math, and numeracy. We did a hand search through all journals mentioned in an analysis of equity in research published by Lubienski and Bowen (2000). The resulting data set was 408 articles. In the first stage of research, we coded based on the title, abstract and keywords for each article. We coded for academic field of the journal, methodology of article, participant focus, equity groups mentioned (such as race or disability), mathematical content focus, and pedagogy. Some articles did not present enough information in the title, abstract or keywords for us to code, particularly in methodology and pedagogy. In some categories, it was possible to combine more than one content area or pedagogy. Inter-rater reliability of coding was 97.3%. In the second stage of research, we looked more closely at two subsets of the data: (a) the articles that included disability (n=42) and (b) the articles that focused on problem solving (n=45). We read these articles in their entirety, coding again if necessary. Our study has several limitations. We only included research published in English. While this iteration only included one year, we are beginning a second round of coding that will include 2013-2015. We were not always able to determine coding from the title, abstract or keywords.

Findings

Of the entire set of articles (408), 42 included disability, or 10.3% of the sample. Much of the following data compares the set of articles that included disability (42) to the set of articles that did not include disability (366). We do not report on all aspects of our findings, focusing here on academic field, methodology, participant focus and pedagogy.

Academic Field. We found that mathematics research on students with disabilities was overwhelmingly published in special education or psychology journals, with very little included in mathematics education journals. Articles that did not include disability were primarily published in mathematics education journals (68.3%). Only 8.5% of those articles were published in special education or psychology journals. 90.5% of articles that included disability were published in special education or psychology journals. Mathematics education journals only published 2 articles that included disability in 2013.

Methodology and Participants. Research on the mathematical learning of students with disabilities was predominantly quantitative (83.3%), with only 9.5% qualitative. In contrast, research on the mathematical learning of students without disabilities was more evenly distributed: 32.8% was quantitative and 40.2% was qualitative.

For each article, we determined whether the unit of analysis was learners in preschool, elementary school, middle school, high school or teachers. Research on the learning of students with disabilities was focused on younger learners, with over half of the research on elementary-aged students, while research on learning of students without disabilities was more evenly spaced across ages. For articles that did not focus on disability, the most frequently researched participant category was teachers (48.6%). In contrast, only 11.9% of articles that focused on learners with disabilities focused on teachers.

Disability is a highly diverse category, not only racially and culturally, but in wide variety of differences that fall under the umbrella of disability. Research on mathematics learning did not reflect that diversity, as most articles about disability and mathematics focused on one category: students with mathematical learning disabilities (71.3%). Of those articles, 40% focused not on learning, but on diagnosis. A very limited sample of people with disabilities was included in mathematical research at all.

Pedagogy. Coding the articles for pedagogy was a critical part of our investigation since we were interested in whether or not students with disabilities were understood differently in the research literature. However, coding for pedagogy was complex. Following Woodward (2004), we first identified Behaviorist, Information Processing, Constructivist and Sociocultural as theories of pedagogy that have influenced mathematics and special education, using his description of the differences between these categories as coding indicators. We added two additional categories: (a) Sociopolitical/Critical (Gutiérrez, 2013) to capture an emerging focus in mathematics education on analysis of wider contexts and processes that affect classrooms and learning, and (b) Medical. We added the category of medical because we found a significant number of research articles that understood learning as mediated or controlled by psychometrics alone. Articles could be coded for more than one pedagogical perspective. Additional information on how we coded for these categories will be available at the session.
Figure 1. Percentage of Articles by Pedagogical Focus.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Figure 1 suggests that learners with disabilities and those without are conceptualized differently in mathematical research. We recognize the limitations of this particular analysis, particularly that we determined pedagogy through the title, abstract, and keywords alone, which meant that we did not assign a code to all articles. However, we found similar percentages in this analysis of all articles, and a follow up analysis of the full-texts of all articles that focused on problem-solving for both learners with and without disabilities.

Discussion

Based on this analysis of research published in 2013, there was significant differences between mathematics educational research focused on learners with disabilities, and that which was focused on those without disabilities. For those with disabilities, mathematical learning was understood primarily from medical, behavioral and information processing perspectives, the research was predominantly quantitative, and rarely focused on the teacher. For those without disabilities, mathematical learning was understood primarily through constructivist, sociocultural, and sociopolitical perspectives, the research was both quantitative and qualitative, and almost 50% of the research was focused on the role of the teacher in learning.

How might this matter? One way to understand the impact was to look closer at one content focus. In the articles focused on problem solving, most research articles including students with disabilities focused on "word problems," while for those without disabilities, "problem solving" was more common. Much of the research in word problem solving for students with disabilities used a schema-based approach, which builds at least partially on constructivist research on how children approach different problem types (Carpenter et al., 1999). Articles in our sample, however, reformulated that research to better fit a behaviorist model of both learning and research. Children in these studies were given "explicit instruction" on the problem types in a scripted intervention. Jitendra et al. (2013) made a clear distinction between the two pedagogies, "Standards-based instruction is characterized by an inquiry-based, student-directed approach, whereas SBI [Schema Based Instruction] incorporates an explicit, teacher-mediated approach" (p. 257). We do not intend to devalue particular research methodologies or pedagogies, rather we seek to question why certain methodologies are used for certain groups almost exclusively.

Analyzing the research published on problem solving for learners without disabilities, we found eight studies of problem posing, which was defined as a process in which students used their experiences to "construct personal interpretations of concrete situations and from these situations formulate meaningful (i.e., non-trivial) mathematical problems" (Harpen, & Presmeg, 2013, p. 119). This article, along with two others in a special issue on problem posing in our sample, made explicit claims about the connection between problem posing, creativity, and mathematical giftedness. Do articles that seek to understand the relationship between problem posing and mathematical ability further deny access to those who are not currently seen as mathematically able to make sense of their worlds using mathematics.

We argue that this research divide in methodologies and pedagogy continually reinscribes an assumption that students with disabilities are a completely different kind of learner. Learners with disabilities are understood through a medical model that seeks to identify psychometric deficits that can inform remediation. These remediations are typically designed through a behaviorist lens, focusing on simplifying mathematics by breaking mathematics into tasks, teaching students procedures to solve word problems. Policy initiatives such as Response to Intervention (RTI) ask that interventions be evidence-based, yet the definition of evidence privileges particular quantitative methodologies.

In these 2013 articles, however, we have two examples of research that challenge these borders. One article from a constructivist perspective focused on using artifacts such as grocery store flyers to develop students' problem posing (Bonnoto, 2013). This article did not create a distinction between

ability and mathematical creativity, and found that children with histories as underachievers were able to engage deeply in problem posing when artifacts were relevant to their lives. All children were expected to make mathematical meaning as long as they could connect their own lived experience. Bonnoto (2013) rejects understanding mathematical creativity as incommensurate with disability. In another article from the sample, Heyd-Metzuyanim (2013) analyzed the co-construction of learning disabilities in mathematics through interaction between a mathematics teacher and a student. As in Lambert (2015b), disability was contextual, produced through interaction. These studies suggest connections between sociocultural analysis and disability studies that should be further explored.

Implications

As mathematics education researchers, we must honor our long-standing commitment to equity for marginalized groups of students. Both activists and academics who identify with the disability rights movement increasingly demand that diversity include disability (e.g. Siebers, 2008). DSME and Dis/Crit provide mathematics education researchers theoretical frameworks that shift perception of disability as a deficit toward viewing disability as a difference. We seek a deeper analysis of disability in mathematics through these lenses, including analysis of how disability intersects with race and genders (Annamma, Connor, & Ferri, 2013).

We call for including disability, not only to improve the lives of those with disability, but to improve mathematics education. As de Freitas and Sinclair (2014) suggest, mathematics education could benefit from more deeply considering the perspective of learners with disabilities, as exploring the mathematical world through these diverse learners can help us better understanding the relationship between embodiment and knowing in mathematics.

We believe that shifting mathematics research towards learners with disabilities will allow our field to rethink assumptions that privilege the mythical "normal" mathematical learner. The borders between these academic fields police a distinction between students without disabilities and those with disabilities, who are not recognized as competent and able mathematics learners. These learners are separated from inquiry and problem-solving pedagogy and curriculum, which can affect not only learning, but identity development, or who students with disabilities are learning to become in mathematics (Lambert, 2015b). Non-disabled peers also stand to academically and socially benefit as classrooms shift to recognize and develop a wider range of mathematical competencies.

COMPENSATION: REWRITING OUR UNDERSTANDING OF MATH LEARNING DISABILITIES

Katherine E. Lewis
University of Washington
kelewis2@uw.edu

Dylan M. Lynn
University of Washington
dylanml@uw.edu

Research has yet to make measurable progress toward understanding how to help students with math learning disabilities (MLDs) overcome their persistent difficulties. Prior research has traditionally framed MLDs as cognitive deficits and studied these deficits by analyzing failing students' errors. In this paper, we provide an alternative. We explore a student with an MLD who has compensated so effectively that she was able to major in statistics. Eight videotaped interview session were conducted. We identify how symbolic notation was inaccessible for her and how she developed ways of compensating. This research pushes boundaries not only by breaking away from the traditional deficit model, but also by removing the delineation between researcher and participant. The case study participant (second author) was an active member of the research team collaborating in the design, analysis, and dissemination of this work.

Keywords: Equity and Diversity

How do you solve the problem: 8x3=? Most adults simply retrieve the answer from memory, requiring only a fraction of a second. This problem took "Dylan," a statistics major with a mathematical learning disability (MLD), over 10 seconds to solve. She later explained her calculation process, "two eights is sixteen, and then I'm adding [another] eight. Sixteen plus what equals 20? Sixteen plus four. Now the eight, minus the four, and there is four left over. Twenty plus four, twenty-four." Rather than retrieving this solution from memory[1], she was solving four independent calculation problems each with an intermediate sum. Although it is well documented that students with MLDs have difficulties solving basic number fact problems (Geary, 2004; Swanson & Jerman, 2006), research has rarely, if ever, examined the ways in which students, like Dylan, might be solving problems differently.

In this study we take an in depth look at Dylan's mathematical understanding and problem solving approaches. She is particularly worthy of study because despite having an MLD, she was incredibly successful in navigating upper division mathematics classes as a statistics major. By examining the ways in which she compensates, we can begin to understand the unique difficulties students with MLDs may experience and explore avenues to consider when designing instruction for students with MLDs. This paper provides a novel vantage point on MLDs by drawing upon a Vygotskian notion of disability and emancipatory research approaches used in disability studies. Through videotaped interviews, we explored the nature of Dylan's difficulties and the ways in which she compensated. In this paper we focus on one predominant category of compensatory strategies that emerged from the data that we termed "rewriting." Although there were various kinds of "rewriting," each involved representing numbers or symbols in an altered form, which enabled Dylan to remember, understand, or solve problems more effectively.

Prior Research on MLDs

Math learning disabilities are neurologically based differences in how an individual processes numerical information, which lead to significant difficulties learning and doing mathematics (Butterworth, 2010). Although it is estimated that 5-8% of students have MLDs (Shalev, 2007), the field lacks methodological approaches to accurately identify students with MLDs (Mazzocco, 2007). Currently, researchers classify students as having MLDs if they fall below a researcher-established achievement threshold and conduct statistical analyses to establish the ways that the students

classified as having MLDs are deficient as compared to their typically achieving peers (Lewis & Fisher, in press). Because of the focus on documenting deficits and the reliance upon low achievement as a proxy for disability, the field has made little progress towards understanding the characteristics of MLDs or identifying potential strategies to help students overcome their difficulties.

Context of This Study

This research endeavor pushes on traditional borders between "researcher" and "participant". This work is aligned with the principles of "emancipatory research" – in which the individual with disabilities is an active member determining the goals, design, analysis, and dissemination of the research (e.g., Walmsley, 2004). Emancipatory research is an important step forward to address issues with the traditional researcher-participant dichotomy, which is oppressive to individuals with disabilities (Walmsley, 2004). Collaborating with individuals with disabilities is a major step forward because it shifts research "on" individuals with disabilities to research "with" individuals with disabilities (Charlton, 2000; Ginsburg & Rapp, 2001). This collaborative research project was initially undertaken 5 years ago by Dylan – an undergraduate statistics major with an MLD – and Katie – a math education graduate student. Although not the focus of the present analysis, it should be noted that Katie has a diagnosed language-based learning disability (i.e., dyslexia) and therefore, in some ways, also has an "insiders" perspective on disability.

Dylan (second author) initially contacted Katie (first author) in an attempt to learn more about research on adults with math learning disabilities so she could understand what strategies were available to help overcome her difficulties. Katie informed her that unfortunately there was almost no research on MLDs beyond elementary aged students engaged in basic arithmetic (Lewis & Fisher, in press). Furthermore, the field had no documented cases of an individual with a math learning disability who had majored in the field of mathematics. Dylan, therefore, had unique insight into the nature of difficulties she experienced across a range of mathematical topics (including upper division math classes) and had a wealth of compensatory strategies she employed to adjust for the atypical ways her brain processed numbers. Together, we decided to embark upon a research project to document both the nature of Dylan's difficulties and the ways in which she learned to compensate. Our shared goal for this research was to identify the particular compensatory strategies in order to inform the design of instruction for students with MLDs. Because the typical terms of "researcher" and "participant" are insufficient for this kind of collaborative and co-constructed work, Dylan is referred to as the "expert" and Katie is referred to as the "inquirer" (see Knox, Mok, & Parmenter, 2000 for similar terminology).

Theoretical Framework

In this study, we draw upon a Vygotksian theoretical framing of disability, which stands in stark contrast to the deficit model predominantly used in research on MLDs (e.g., Geary, 2010). Vygotsky (1929/1993) argued that a child with a disability is not *less* developed than his/her peers, but has developed *differently*. Vygotsky's understanding of disability was aligned with his general theory of human development. He argued that human development progressed along two lines: biological and the sociocultural. In children without disabilities these two lines of development intertwine and are mutually constituted. In children with disabilities, mediational tools (e.g., language, symbols), which have developed over the course of human history, often do not serve the same function. For example, printed text may be inaccessible to a blind child, and therefore this standard mediational form does not serve the same function in the blind child's development of literacy as it would for a child who could see.

Central to Vygotksy's theory is that the disability creates the impetus for the development of *compensatory* processes. For example, a blind individual who cannot rely upon visual stimuli to

navigate may naturally begin to echolocate (i.e., use clicking sounds to navigate; e.g., Thaler, Arnott, & Goodale, 2011). The biological difference (e.g., blindness), therefore has led to the recruitment of alternative resources and the same task is accomplished with compensatory processes. To understand a disability researcher must not only document the student's difficulties, but also the student's strengths and the ways in which a student compensates. In this study we use this Vygotkisan framing to explore MLDs. We specifically focus on identifying how standard mediational forms (i.e., numerals, symbols, representations) may be inaccessible to Dylan and the ways in which she compensates.

Methods

Classification of MLD

Given the difficulty involved in accurately identifying students with MLDs recent research that attempts to differentiate low achievement from MLDs have suggested tests of numerical processing (e.g., Dyscalculia Screener, Butterworth, 2003) or timed calculation tests (Mazzocco, 2009) be used to help identify students with cognitively-based numerical processing problems. Both of these measures were used to establish that the student, Dylan, met the qualifications for having a mathematical learning disability. On the Dyscalculia Screener (Butterworth, 2003), she received a classification of "dyscalculiac tendencies with compensatory aspects", and measures of her timed arithmetic performance indicated that she processed single-digit addition and multiplication problems slowly, (averaging 2.355 and 5.235 seconds/problem respectively). Given her performance on the Dyscalculia Screener and on the timed calculation test, Dylan is considered to have a MLD.

Data Collection

Fourteen hours of videotaped interview data was collected during eight separate sessions. During these sessions we explored various mathematical domains, including: basic arithmetic, fraction operations, algebra, and statistics. We began each session by clarifying any outstanding questions from the previous session and making any needed modifications to the agenda we had planned in the previous session. As we worked through our agenda for the day, Dylan's role in the sessions was as an expert informant, someone who was able to reflect upon and demonstrate the kinds of difficulties she experienced and explain the ways in which she was able to compensate. Katie's role in the sessions was to listen attentively and ask questions to better understand the scope of the difficulties or compensatory strategies Dylan reported. We concluded each session by collaboratively deciding our agenda for the following session. After each session Katie wrote up notes from the session, which included scanned copies of all written artifacts and a general description of what was discussed. In many instances the production of these notes resulted in Katie posing several clarifying questions, which were discussed at the start of the next session. Dylan reviewed these notes to ensure the accuracy of Katie's descriptions.

Analytic Approach

All videos were transcribed and all artifacts were scanned. The research team, comprised of the authors and one graduate research assistant, conducted an open coding on the transcripts then met to discuss preliminary coding categories. This analysis identified several predominant themes in the data. Several of these themes can be loosely classified as instances in which Dylan used the compensatory strategy of "rewriting." We explore the various ways in which Dylan employed this strategy and how it enabled her to compensate for the particular difficulties she experienced when using numeric or symbolic notation.

Results

The results focus on several different ways in which Dylan used the compensatory strategy of "rewriting". Through different kinds of rewriting Dylan accomplished several different goals, which directly addressed her difficulty processing, manipulating, and remembering symbolic representations of numbers. The first kind of rewriting enabled Dylan to kinesthetically encode numerical information that she found difficult to remember. The second kind of rewriting enabled Dylan to connect the symbols to their underlying meaning by translating the symbols into words. The third kind of rewriting involved addressing notational ambiguity by rewriting the problem in a consistent form. In each case she reflected on why the particular compensation was needed. These episodes, therefore, illuminate both the ways in which standard mediational forms were inaccessible and also how Dylan learned to compensate through various kinds of rewriting.

Rewriting For Memory

The first form of rewriting allowed Dylan to compensate for difficulties remembering numerical information. Dylan had significant difficulties using and remembering numbers throughout her life. She reported that she had difficulty remembering her pin number, the number and zip code of her street address, and historical dates. She recalled that when she was young, "I could remember what street name I lived on, but for the life of me I could not remember the house number." Dylan developed ways of compensating for her difficulties memorizing numbers. For example, to remember her address she described, "I would write it out a ton of times. And even if I couldn't actually remember it, I would remember the sensation of that movement, so that I could replicate that movement on a page," "so even if I couldn't recall it, if I had a piece of paper, and I wrote it out and then I could read it to you." She clarified that she was remembering the kinesthetic experience of writing the numerals, rather than the numerals themselves, "So you're not actually inherently remembering the thing, you are just remembering the feeling of creating it. And then once I see it again, then I remember, but it isn't until it's written."

This kind of rewriting involved kinesthetically encoding information represented with numerical digits. It is worth noting that this kind of compensatory strategy appeared to be used primarily in cases where the digits themselves did not have any quantitative property. For example, the house number for "1610 Main Street" does not represent one-thousand six hundred ten of anything. Similarly, dates and pin numbers use numerical digits but similarly do not represent quantities.

Rewriting to Connect to Meaning

The second form of rewriting involved Dylan rewriting mathematical symbols in words in order to help her connect the mathematical symbols to their underlying meaning. Dylan reported that she had difficulty being able to "read" mathematical notation particularly when she was learning new mathematical content. When she was very young and learning arithmetic, she explained, "I'd write it out as a sentence, I guess, is like the best way to think about it. And in sentences you don't use symbols, you use words." For example, when learning to solve a problem like 3+2= she would translate the symbols into words and write underneath it "three plus two equals." She explained, "Because the word, like: T - H - R - E - E , has much more meaning to me than these two little backwards Cs laying on top of each other." She clarified that it was not the auditory word "three," but actually the written English word "T H R E E," that gave the symbol meaning. She described it as a sequence of steps she needs to go through to decode the numerical symbol, "If I can go from the symbol to the actual written word, then I can go to relating it to something in real life." "*Three* - I have that word and now I can think of three objects."

Although she no longer needed to translate arithmetic problems into words, she explained that, "in my higher division math courses I will actually still write these things out." She gave an example from her probability class, "this (writes "P(A|B)") is so incredibly short but it actually translates to

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

the probability of event hap – event A happening, given event B has happened. I actually have to physically write that down every time I do one of these." These examples suggest that this kind of rewriting was necessary not only for the numerical symbols zero through nine, but for other symbols that had a mathematical or quantitative meaning.

Rewriting to Remove Ambiguity

The third form or rewriting involved rewriting problems in a standardized form to remove notational ambiguity. Dylan identified symbolic notation as being particularly problematic for her. Although many students experience difficulties as symbols take on new meaning, these notational issues caused persistent issues for Dylan and her ability to engage with the problem. For example, when solving a problem presented as: $\frac{1}{2} \times \frac{1}{5} =$ (see Figure 1), she immediately rewrote the problem using parentheses and said, "Because I have taken algebra, and I know that x can in fact be a variable and not necessarily multiplication… I always use parentheses now for multiplication." Because of the ambiguity around the meaning of the "x" she found it necessary to rewrite the problem before solving it.

Figure 1. Scanned artifact of the presented problem "1/2x1/5=" and Dylan's rewritten problem form.

Dylan also found that she frequently needed to rewrite parts of the problem while in the process of solving it. For example, as she was solving the problem 123-47=, she rewrote the problem in multiple parts to be able to clearly "see" the borrowed values (see Figure 2 and Figure 3). She noted that the standard superscript notation was ineffective and problematic for her, which resulted in her rewriting parts of this problem three times in the process of solving it.

Figure 2. Step-by-step illustration of Dylan's solution process for the problem "123-47=".

Figure 3. Scanned artifact showing Dylan's work for the problem "123-47=".

Commonalities of Rewriting

Dylan used the compensatory strategy of rewriting in several different contexts with different goals (memory, meaning, and resolving ambiguity). In each case her compensatory strategy of rewriting required more time and more effort. It is precisely because rewriting is *not* efficient that it indicates that this is truly a way in which Dylan is compensating for particular characteristics of her disability. Attending to instances in which Dylan uses rewriting, highlights both how she is compensating and suggests potential areas of difficulty.

Endnotes

[1]We are not arguing that deriving arithmetic facts is not desirable or productive for many students, however when students use derived facts to solve a problem, the answer is often achieved in a couple seconds. Our point here is that the time and process that Dylan used to solve the problem "8x3=" is unusual for a statistics major.

Conclusion

Dylan reported difficulties in remembering numbers, connecting symbols to their underlying meaning, and dealing with symbolic ambiguity. Mathematical symbols can be thought of as being at least somewhat inaccessible to Dylan. She reported several different ways in which she used the compensatory strategy of "rewriting" to accomplish the same goals. Although the three forms of rewriting presented here involved different features to accomplish different goals, in each case she rewrote something in a more accessible form. Similar to her strategy for solving "8x3=", Dylan's strategy produces the correct answer, but time consuming and more cognitively demanding.

In this paper we have attempted to push the boundaries of how MLDs have traditionally been conceptualized in two specific ways. First, we rejected the deficit-model of the learner and adopted a Vygotskian notion of disability focusing explicitly on a student who has developed sophisticated ways of compensating. Second, our collaborative effort represents break down the traditional researcher-participant hierarchy. Dylan was positioned as the expert and was a meaningful collaborator in the conception, design, analysis, and dissemination of this research. We believe that pushing on these boundaries enables possibilities for innovative research where new questions are posed and new avenues pursued because the participant has a voice and power over determining the direction of the research.

"A BANK ON EVERY CORNER":
STUDENTS' SENSE OF PLACE IN ANALYZING SPATIAL DATA

Vivian Lim	Maren Hall-Wieckert	Laurie Rubel
Brooklyn College	CUNY Research Foundation	Brooklyn College
viv.lim@gmail.com	maren.hall.wieckert@gmail.com	lrubel@brooklyn.cuny.edu

This paper describes the role of sense of place in students' analysis of spatial data toward understanding the distribution of financial services in their city. High school students participated in a 10-session module about their city's two-tiered financial system of banks and alternative financial institutions. The paper analyzes two class sessions organized around the use of ratios, or intensive variables, to understand the distribution: an embodied distribution activity atop a large floor map and individual exploration of scalable, data-rich digital maps. Analysis investigates the role of students' sense of place as they grappled with these ratios. Students drew on their senses of place to interpret data and generate their own sets to associate in ratios. Abstract measures and data visualizations contained in the digital maps were less accessible to students in this iteration of the module.

Keywords: Equity and Diversity

The concept of ratio cross cuts school mathematics at all levels and is an important tool for making sense of the world, in relating pairs of quantities and as building blocks of rates. Reasoning with ratios "plays such a critical role in a student's mathematical development that it has been called a watershed concept, a cornerstone of higher mathematics, and the capstone of elementary concepts" (Lesh, Post, & Behr, 1988 as cited by Lamon, 1993, p. 41). Ratios are integral to investigations of issues of social (and spatial) justice, as they are useful for analyzing equitable or fair-share distributions of resources.

This paper examines student work with associated sets ratios in the context of a spatial justice investigation around the theme of local access to financial institutions. Banks and alternative financial institutions (AFIs, such as pawnshops, wire transfer, and check-cashing stores) form a two-tiered financial system. Banks offer credit-building opportunities as well as lower rates for services than their AFI counterparts, but they tend to cater their services to people with better financial credentials and more flexible income (Servon, 2013). As part of a larger project, a curricular module was designed for high school students to use mathematics to contrast the interest rates of banks and AFIs and to build on that contrast in analyzing the local spatial distribution of these institutions. This paper focuses on the latter component and pursues the following research question: How did students' sense of place support and complicate their use of ratios in evaluating the spatial distribution of financial institutions in their city?

Guiding Frameworks

Place, Space, and Social Justice

Teaching mathematics for social justice entails reading and writing the world with mathematics; "reading" with a critical perspective on the social and political circumstances that structure the world, and "writing" with agency to respond to or change inequities or injustices (Gutstein, 2006). This paper presents findings from a mathematics module oriented around an extension of teaching mathematics for social justice: teaching mathematics for spatial justice (Rubel, Lim, Hall-Wieckert, & Sullivan, 2016).

Traditional notions of "space" in mathematics refer to geometric abstractions in which the concept of "justice" would seem to lack pertinence. This paper draws on social rather than geometric

definitions of "space" (Soja, 1996; Tuan, 1977). With such an understanding, space encompasses social, historical, and geographical dimensions, each contributing to the world's ongoing state of affairs. Abstract "space" comes to be bounded by human experience and imbued with historical meaning, taking on character as a particular, locatable "place" (Tuan, 1977). The associations that people have with a particular place, or "sense of place," can color their perceptions of the world around them (Lim & Barton, 2006; Tuan, 1979). Maps and GIS-enabled digital presentations of data can present authoritative, bird's-eye-view perspectives about place (Wood, Fels, & Krygier 2010) but can misrepresent the reality of being on foot in a particular location, and can conflict with people's sense of place (Monmonier, 1991; Pickles, 2004).

The extent to which the multi-dimensional relations that structure space and place are fair or unfair constitutes spatial justice (Soja, 2010). Spatial justice provides a context for mathematical questions and tools focused on uncovering and examining hidden biases and agendas which structure the spatial relations people inhabit. An example of this can be seen in a critical mathematical examination of a state's lottery, which can analyze lottery ticket sales by location to investigate relationships between lottery spending and income level (Rubel et al., 2016).

Intensive and Extensive Variables

Variable quantities of space can be categorized as extensive (i.e., 'quantity of space,' such as area) or intensive (i.e., ratios of extensive variables, such as population density) (Lawvere, 1992, p.18). For example, banks per square mile is an intensive variable that relates two extensive variables (number of banks and area in square miles) and coordinates a single measurement to formulate a property description of a place. Extensive and intensive variables can be used to frame data for mapping (Goodchild & Lam, 1980), as in choropleth maps, which correspond color shades to ranges in numerical data (Buckley, 2013). Since geographic areas vary in shape and size (and other properties), comparing spatial data typically necessitates normalization of data using intensive variables. In the case of this project's digital maps, extensive variables that quantify numbers of banks and AFIs by neighborhood demand normalization, in relation to other properties like area (e.g., pawnshops per square mile) or number of households (e.g., households per bank), or by comparing them against each other (e.g., banks per AFI).

As associated sets, intensive variables like these are known to be accessible to students in the way that the relationship between the two extensive measures can be imagined more concretely than in other categories of ratios (Lamon, 1993). Students' sense of place could serve as a resource for concretization of the intensive variables necessary to analyze the spatial justice of a distribution.

Methods

This paper presents findings from the first iteration of a 10-session mathematics curricular module. The module was piloted in a 10th-grade advisory class taught by a mathematics teacher at a high school located in Harwood, a low-income, predominantly Latin@ neighborhood.

Researchers audio recorded and collected detailed field notes for each class session, and recordings were used to clarify and enrich fieldnotes. The focus here is on sessions five and seven because of their emphasis on using intensive variables to normalize data. The fifth session ("Big Map Day") featured an embodied distribution activity to highlight the conceptual underpinnings about normalizing data, atop a big floor map of the city (Edelson, 2011). The seventh session ("Ratio Map Day") engaged students with custom-made digital maps that were produced as part of a suite of digital tools for the larger project.

Whole group discussions from these two sessions were transcribed from audio. Focal students' work (3 groups) with digital maps was captured using Camtasia (Techsmith, 2010), which video-records students' screens, including the actions of their cursor, in sync with audio/video of students at work though the computer's built-in camera. The Camtasia recordings were used to produce

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

narrative descriptions of students' actions with the digital maps with corresponding transcription of spoken utterances. Two main sets of codes were used to analyze the data: 1) the various ways to read and compare ratios (i.e. comparing numerators additively), and 2) the variables students identified to explain distribution as well as how students used the idea of proportionality to make an argument about fairness. A collaborative process was used to generate and apply the codes to the data.

Results

Big Map Day (Session 5)

Students began with a free-form exploration of a walking-scale, 140-square-foot map of the city temporarily installed on the classroom floor. Next, standing in and representing respective counties, students received various scaled props to demonstrate relative numbers of pawnshops and banks in these spaces and were prompted to discuss their reactions to these various distributions (Figure 1). As we have noted elsewhere (Hall-Wieckert, Rubel, & Lim, 2016), the activity engaged students' sense of place (Lim & Barton, 2006) about the city. This place-based knowledge served to support students in understanding the need to normalize data and to begin to coordinate such measures with demographic characteristics.
Figure 1. Students participate in embodied distribution on large map.

The activity started with a hypothetical equal distribution of pawnshops by county. A student, Sheeda, almost immediately refuted this as not making sense, saying that "some places are bigger than others, and some places are poorer than others," which suggested that the normalization should compensate for these distinctions. The teacher highlighted the former part of Sheeda's observation and led an activity distributing the institutions by area, then progressed to a distribution normalized according to households by county. Finally, the teacher revealed the actual distribution, which corresponded to none of these hypothetical and seemingly fair arrangements. When the actual distribution was shown, students confirmed the distribution using their sense of place. Sheeda explained the large number of banks in one particular county by pointing out, "...he got a bank on every corner though." This idea of normalizing by "corner" seems to suggest that she recruited her sense of the density of banks there to confirm the skewed distribution and add further nuance to the distribution of banks at a finer level of spatial scale.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Students also drew on their sense of place to generate their own variables associated with the distribution of banks and pawnshops. Some students conjectured that some areas have more banks because they have a higher concentration of stores or more expensive stores. Several students associated variables related to their sense of place in terms of income inequalities across their city. For example, Rebecca stated, "I think that the ones that have the most pawnshops is where people have less money." Rebecca later reacted to the idea that pawnshops and banks might not be distributed fairly, and pointedly asked the teacher, "Why they never fix that, Miss?" In this case, "fixing" or redistributing institutions for equitable access and services would involve a transformative "rewriting" of the world, a line of thought that is encouraged by teaching mathematics for social (or spatial) justice, but beyond Rebecca's query is not further picked up by the teacher or other students in this discussion.

Ratio Map Day (Session 7): Whole-class Discussion

A suite of digital maps enabled students to explore the distribution of financial services in the context of various socioeconomic variables. The suite included three types of map layers: 1) points representing the locations of banks, AFIs (pawnshops, wire transfer, and check-cashing stores), and McDonald's, which was included as a service likely more familiar to youth than financial institutions; 2) demographic variables (e.g., median household income); and 3) ratio maps, which used intensive variables to normalize distribution of institutions by relating the quantity of institutions to area, number of households, or to another category of financial institution (e.g., banks per AFI). The demographic and ratio maps were choropleth layers that could be displayed concurrently with the location points. In other words, the intensive variables were displayed using a color scale by intensity and could be layered underneath the view of the extensive variables, showing the count and location of each category of institution (see Figure 2). Session 7 was the second day that students engaged with the digital maps and the first day that the ratio maps were introduced.

At the start of this session, the teacher conducted a whole-group discussion orienting students to the McDonald's maps as a way of priming them to conduct similar explorations about financial institutions later in the session. Of course, the notion of a fair distribution of McDonald's is not equivalent in significance to a fair distribution of financial services, and some might consider the presence of McDonald's as a disservice, but the example was intended to serve as a tangible, familiar variable for students to situate their reasoning about distribution in relation to area and households.

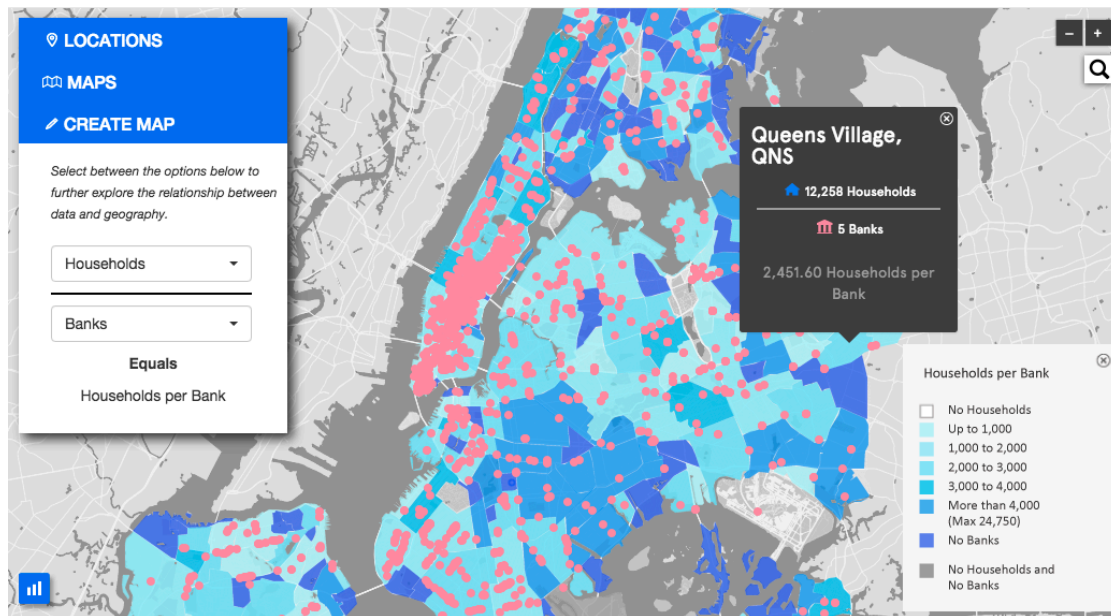
The teacher-led exploration began with a choropleth visualization of the number of McDonald's per square mile. Where on the huge map, students' sense of place about locations in the city served to prompt their association of variables toward normalizing the distribution, in this session, they recruited their sense of place as a way of interrogating the accuracy of the digital maps being presented as authoritative and official (Monmonier, 1991; Pickles, 2004). Immediately, Lina questioned this normalization and wanted to know how many blocks were equivalent to a square mile. Lina's understanding of units of measurement in city distance understandably did not conform to the traditional measure of square miles used in the maps. In this instance, Lina recruited her sense of place about the city's spatial arrangement to interrogate the decision to normalize density with square miles. Lina's skepticism was a shift from her participation on the Big Map Day when she generated associated variables with other students, like the density of stores or malls, to interrogating the variables presented on the digital maps.


Figure 2. Location and distribution of banks in relation to number of households.

Lina's skepticism of the digital maps carried over to a questioning of the basic counts data embedded in the intensive variables like households per McDonald's. When presented with data showing that Harwood had 35,000 households for only one McDonald's, Lina exclaimed, "And one McDonald's? They lyin'!" She then proceeded to enumerate additional McDonald's located in what she considered to be Harwood; however, her sense of place in terms of the neighborhood's boundaries did not correspond with the boundaries encoded in the map.

Students' sense of place drew them to focus primarily on the map's extensive data, comparing the absolute number of McDonald's by neighborhood rather than intensive relationships. Which neighborhoods had "more" or "less," in an absolute sense, was more tangible and important. An exception to this was when Rebecca noted the crux of the relationship between the school neighborhood's McDonald's and another's: "So we only have one we share with more, and then they have way more and they share with less." This observation enabled Lina to reduce the fraction 23,000/23 to its unit ratio and follow up with, "So a thousand people go to one McDonald's?" These combined observations fed into Rebecca's expression that the distribution was unfair, and she pointedly asked the teacher again, "So why doesn't anyone fix that?" Rebecca's realization suggests that by understanding the intensive variables at work in the maps, she was able to question fairness using spatial data.

Ratio Map Day (Session 7): Map Exploration

After an introduction to the ratio maps included in the mapping tool, students explored digital ratio maps of their choice. Students, in pairs, were prompted by a worksheet to choose one map layer (i.e., one intensive variable), interpret the map's data for Harwood, notice and examine patterns across the map, and compare the data for any two neighborhoods. The different ways in which students engaged their sense of place contributed to differences in their sense making about the predetermined intensive variables to evaluate the distribution of financial institutions across the city.

Green pair. Miguel spent most of the session silently clicking through and across all of the different ratio maps as Rafaela watched, and engagement with their senses of place was not apparent. His clicks focused on each map's dark-shaded neighborhoods; that is, the neighborhoods with the highest ratios for each intensive variable. This does not necessarily mean he was looking at the most-serviced neighborhoods. For example, darker shading in the households per bank map layer would

mean a lower rate of services. In his explanation for choosing the banks per square mile variable, he stated, "Because we wanted to see how many banks were in each square mile"; and he reported that in Harwood, "for each 1.81 square miles, there's only 3 banks." The use of the word "each" in both of these statements indicates an understanding of the multiplicative relationship between the extensive quantities. Miguel's interpretation of the map shading did not coordinate between a neighborhood's number of banks and number of square miles and referred only to the extensive variable of the counts of banks. He wrote, "The darker the color becomes, the more banks you will find in that location. And the more lighter the color becomes, the less banks you will find."

Orange pair. Sheeda and Miriam engaged their sense of place by focusing on comparing Harwood with Montgomery, another familiar and adjacent neighborhood. These students ignored the worksheet, and instead spent most of their time exploring the absolute numbers of financial institutions by neighborhood. As a typical instance, upon examining the pawnshops per square miles map, Sheeda clicked on Montgomery and noted, "There's 3 pawnshops," by reading only the numerator from the fraction shown in the pop-up box. She ignored the square miles in the denominator and the resulting ratio of pawnshops per square mile. Again, examining the ratio of AFIs per bank for Harwood, Miriam compared the quantities in the numerator and the denominator additively: "We got more pawnshops than banks." At no point did Sheeda or Miriam demonstrate thinking about the intensive quantities, and they persisted in engaging only with the extensive components, even with adult intervention. A researcher guided the students to observe that Harwood was smaller in area but had more AFIs than Montgomery. When the researcher asked the students to explain what this means, Sheeda focused only on the extensive variables and responded, "That means Montgomery is bigger than Harwood."

Purple pair. Rebecca worked alongside an assistant teacher and focused on the households per bank map. Rebecca wrote an analysis of Harwood's data that went beyond Miguel's by not only interpreting the ratio terms but also how it related to the unit ratio: "The data says that there are 35,521 households for each 3 banks. So 11,840 people share each bank. It says that Harwood shares each bank with a lot of people." After reading the number of households and institutions in her chosen neighborhoods, she stated, "So this one [Portmore] has less households and it has more banks. And this one [Easington] has more people and just one bank." She concluded, "They [Easington] should have put … had more [banks]."

Rebecca did not generalize her interpretation beyond making sense of specific data points. When prompted to explain what a higher ratio meant for her chosen variable, Rebecca said, "When it says the ratios are higher, I think it means where the banks are more at." She did not recognize that in the case of households per bank, a higher unit ratio would indicate a lower proportion of banks per household. Rebecca's sense of place confounded her analysis in that her hypothesis that the number of banks was related to a neighborhood's income level was a distraction from interpreting the given legend. Rebecca stated that she "just wanted to know where was the more banks for houses with less money," and she expected to be able to answer this question through a single map layer. This expectation led her to try to inject income into her analysis of the households per bank map and read the categories in the legend as referring to ranges in household income rather than ranges in number of households.

Discussion

Sense of place contributed to students' understanding of the rationale for launching a mathematical exploration of the distribution of financial institutions. The idea of dividing up the number of institutions equally by county evoked a voicing of ideas about variables, related to their sense of place, that they considered important in analyzing this distribution. Students' consideration of these variables provided a launching point for the teacher to introduce data normalization.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

In contrast, students' senses of place challenged the representations in the digital maps. Some student-generated associated variables, like relative size of different parts of the city, connected well to ratio measures of distribution like density per square mile, which were included on the digital maps. However, many of the suggested variables by students, like the density of stores in different parts of the city, were unanticipated and not available as intensive ratio maps. The map tool did not allow for students to follow through with their own ideas about what variables might be salient and thereby engage in more authentic data explorations.

In addition to a fixed set of variables to examine, the way that the maps were designed did not allow for flexibility in approach. The mathematization of the selected variables in these maps were imposed; for instance, the choice of square miles made sense to the designers as a unit of areal measure, but blocks or "corners" could have been a more accessible unit. Similarly, neighborhood delineations on the map did not always correspond with students' senses of boundaries. For Rebecca, her desire to examine a direct relationship between income and number of banks on the map was constrained by the designers' decision to include demographic maps as separate static maps to be compared, but not combined, with the chosen ratio maps.

Sense of place served as an anchor for students to grasp the tangible aspects of the given variables; at the same time, it distracted them from engaging with more abstract, intensive variables. During the whole-class discussion and in their investigations with digital maps, students tended to compare extensive variables–in this case, the discrete number of institutions. Scaffolding concrete representations of abstract intensive measures, such as households per institution as the number of people sharing one institution, aided in students' interpretation of these variables and supported their mathematical arguments about fairness. Miguel and Rebecca, for example, were successful at interpreting intensive variables with respect to specific neighborhoods but struggled to interpret the more abstract choropleth layers.

Conclusion

Students' sense of place engaged them in considering and analyzing spatial data. The open-endedness of the huge floor map enabled students to understand the conceptual basis of and suggest strategies for normalization. Students drew on their sense of place to imagine concrete representations of intensive variables, which allowed them to interpret data points, make comparisons, and even formulate arguments about fairness. These concrete representations could serve as building blocks toward making sense of the data represented more abstractly in the map's choropleth layers, which were more elusive for students to interpret.

The closed nature of the larger project's digital maps did not enable students to use the maps to fully explore variables that connected to or built on their sense of place. Rather, students' sense of place became a tool to critique the point of view presented by the seemingly authoritative digital maps. More support towards activities that combine the open-endedness of the big map activity with the abstraction and mathematization of the digital maps is needed. A future goal is the design and implementation of digital mapping tools that enable students to generate their own intensive variables or ratios, based on their sense of place, which can then be visualized in authoritative map layers. The authors are currently investigating new designs for activities to engage students in map-making of this kind.

Mathematics has long been understood to be a "gatekeeper," which functions to restrict access to educational opportunities due to (a) its central role in formal educational sequences, and (b) the high failure rates often observed in mathematics courses. Failing is an encounter with a type of border: a border that divides a continuous scale into two categories, passing and failing. Typically, this border is understood as restrictive. We present a more nuanced view of the role of borders in mathematics education. In particular, we argue for a view of borders as fundamentally productive objects, and suggest that analytical attention should be focused on who or what gets produced, rather than on who or what gets restricted.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Learning Theory, Post-Secondary Education

Mathematics occupies an interesting position in engineering education. On the one hand, the calculus sequence occupies a central role in the curriculum. On the other hand, the calculus sequence is widely recognized by students, faculty, and researchers as a "gatekeeper," which often functions to push students out of engineering. The gatekeeping role has been ascribed to the calculus sequence due to (a) its centrality in engineering curricula, and (b) the astonishingly high rates at which students fail calculus courses (Seymour & Hewitt, 2000). In this paper, we examine the centrality of mathematics in the engineering curriculum, and we analyze what happens when students fail. This is, by now, well-worn territory. However, our analysis offers new insight into this process.

Failing is an encounter with a type of border: a border that divides a continuous scale into two categories, passing and failing. Typically, this border is understood as restrictive, in that it is used to restrict access to future course work. From this perspective, the work summarized above can be understood as attempts to document the restrictive nature of the border, and to help more students land on the passing side of it. We do not disagree with these efforts. Our goal with this paper, however, is to present a more nuanced view of the role of borders in mathematics education. In particular, we argue for a view of borders as fundamentally *productive* objects, and suggest that analytical attention should be focused on *who or what gets produced*, rather than on who or what gets restricted.

Theoretical framework

We take a critical, situated perspective on learning, in which learning is understood as an ontogenetic process of *becoming* a member of a community of practice. Traditionally, such analyses focus on how both people and communities of practice are produced and re-produced through collective, often asymmetric, participation in cultural practices. In this perspective, *trajectories of membership* are often invoked to describe a person's "changing participation in changing practices" (Lave, 1996, p. 150), and such trajectories are analyzed to document the ways in which participants are produced as new kinds of people (e.g., Nasir & Cooks, 2009). We adopt a similar focus, but augment it by considering also the role of *objects*— that is, "stuff and things, tools, artifacts and techniques, and ideas, stories, and memories […] that are treated as consequential by community

members" (Bowker & Star, 1999, p. 298)—in the production of persons and communities of practice.

We draw on two key theoretical constructs to examine the relationship between objects and participation in the production of people and communities of practice. *Trajectories of membership* (Bowker & Star, 1999; Lave & Wenger, 1991) describe the adoption of and conferral of practice-based identities upon newcomers. *Trajectories of naturalization* (Bowker & Star, 1999) describe the ways in which objects—including categories and categorization systems and their attendant borders—enter into and become naturalized within a community of practice.

Such a dual focus is crucial in understanding membership because the naturalization of objects is the process through which norms and values become embodied in practices of everyday life. In this perspective, interactions among people are always mediated by objects, because it is through objects of various kinds that people become seen as a certain type of people:

> The relationship of the newcomer to the community largely revolves around the nature of the relationship with the objects and not, counterintuitively, directly with the people. This sort of directness only exists hypothetically—there is always mediation by some sort of object. Acceptance or legitimacy derives from the familiarity of action mediated by member objects (Bowker & Star, 1999, p. 299).

Research method and context

Our research focuses on the experiences of students in a diversity program in the engineering school at State U, a flagship state university in the Western United States. To capture student experiences and the ways in which those experiences were organized within this community of practice, we conducted field-based ethnographic work centered on students, faculty, and staff in the program. We used a variety of fieldwork methods including ethnographic observations of routine activities, ethnographic interviews, and focus groups. Our data include fieldnotes, meeting minutes, and video and audio recordings. Our analysis involved concurrent engagement in data collection and data analysis, using Constant Comparative Analysis (Glaser & Strauss, 1967). We analyzed data from initial fieldwork early in the research process, leading to a preliminary "grounded theory," which led in turn to further fieldwork to refine the theory, and so on through multiple iterative cycles.

The engineering school at State U is predominantly composed of white, male, middle- and upper-class students. *Access* is a program that seeks to broaden access to the college by admitting a cohort of approximately 30 "next-tier" students to the college each year. Students in the Access cohorts were initially denied admission to the engineering school, but were accepted via the Access program after a second round of admission screening. The Access program has explicit diversity goals, and is composed almost entirely of women, students of color, and first-generation college students. Although these students are admitted directly to the engineering school, they are enrolled in a "performance-enhancing year," in which they take remedial courses to prepare for courses in the engineering school.

Our initial field work pointed to the centrality of Calculus in the organization of the experience of Access students. Calculus is a naturalized, taken-for-granted object within the community of practice. How did this come to be, and how does calculus organize the trajectories of membership for students? In the sections below, we document the trajectory through which calculus came to be a naturalized part of engineering education, and we describe how one Access student's trajectory of membership into engineering school became torqued by this trajectory of naturalization.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Trajectory of naturalization: Mathematics as a naturalized object in the engineering curriculum

In the late 19th century, an American engineer beginning his career (in reality, it was almost always "his" career) likely would have started on the shop floor and learned his craft through a practice-based apprenticeship. In those days, engineering was a craft, practiced by masters who relied on "design experience and rules of thumb" (Seely, 1999, p. 289). By 1965, aspiring engineers would experience something very different. Instead of a shop floor, they were likely to find themselves sitting at a desk in a classroom at a four-year university. Gone was the practice-based apprenticeship, replaced by a curriculum based in theory (viz. math and science). Gone too was the image of an engineer as a craftsman, replaced by an image of the engineer as a rational technicist. As Seely (1999) traces, over the course of 80 years, mathematics became naturalized in engineering education.

Three broad trends propelled mathematics along its trajectory of naturalization in engineering education. First was the emergence in the U.S. of new technologies such as electricity that appeared to defy the commonsense rules of thumb that had previously guided engineering design. Second, the expansion of land grant colleges, along with an emerging belief in the power of math and science to make the world better, began a general trend to push professional preparation out of apprenticeships and into universities. Even so, university engineering programs at the start of the 20th century were dominated by practical concerns. While these programs involved some math and science, the curriculum remained grounded in practice, and students spent a good deal of time in machine shops and at drafting tables (Reynolds, 1992; Seely, 2005). Finally, an influx of European engineers—who were trained in physics and mathematics, and who approached engineering problems as applied exercises in these disciplines—into the U.S. occurred during the early part of the 20th century.

Concerned by what they perceived as American engineers' poor technical training, European engineers turned their sights to education. Here the trajectories of European engineers became coordinated with those of U.S. students. Students were entering universities to learn engineering, and European engineers were entering universities to teach it. Guided by a belief that engineering was a technical discipline resting on a foundation of basic mathematics and science, European approaches to engineering began to transform engineering education at the same time as the rise of the rational thinker in the American imagination (Seely, 1999).

The transformation of engineering education was not a smooth one, however, and debates over the nature of engineering and engineering education were "loud and prolonged" (Seely, 2005, p. 116). While this debate took place largely on university campuses, it can be read as a struggle over the nature of engineering itself, as a practice-based trade or as a theory-based profession. Geopolitics entered this debate in the form of the Second World War. Pre-war, engineering faculty were primarily occupied with teaching. Research was rare, and what research was conducted was small-scale, practical research driven by the needs of local industry. During and post-war, the Department of Defense, which was determined to maintain an arsenal of cutting-edge vehicles and weaponry, demanded basic research into explosives, propulsion systems, and materials. Engineering faculty were determined that they, rather than researchers in the basic sciences, should get this funding and its associated prestige. Soon basic research was woven into the fabric of engineering schools, and curricula were twisted to match the demands of the research. Machine shops were replaced with classrooms, drafting tables with desks, and practical experience with math and science. By 1965, mathematics and science were fully naturalized objects of the engineering curriculum (Seely, 1999, 2005).

Today, mathematics is a naturalized, taken for granted part of the infrastructure of the engineering school at State U, encoded into such objects as curriculum flowcharts, shown in Figure 1. One way to see this naturalization is to examine the role of math courses on the one hand, and projects courses on the other. First, notice the centrality of math courses. This can be seen by examining the dependency trees for courses with pre-requisites. All of these dependency trees

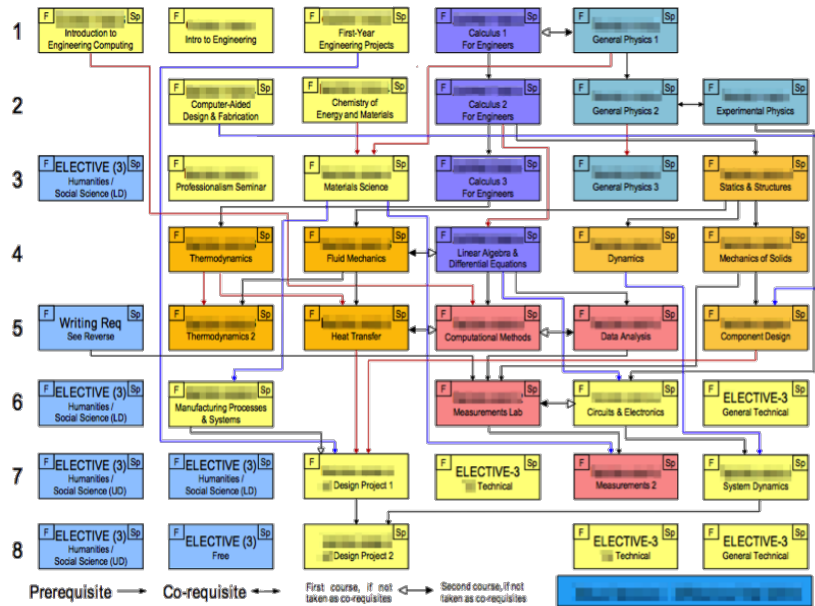
include math. Now, compare this with the two "projects courses" that are part of the first and fourth year. As shown, these courses are widely separated and generally disconnected from the rest of the curriculum. Within math and science courses, the course called "Calculus 1 for Engineers" stands out. This is arguably the most important course in the flowchart, as it is part of every dependency tree, and it is the only course for which this is true. Furthermore, it is the first course in each of these dependency trees. In other words, the first step to accessing any course with a pre-requisite is passing Calculus 1.


Figure 1. Engineering curriculum flowchart at State U. Course numbers are blurred to preserve anonymity. Numbered rows indicate academic semesters.

Notice the logic inscribed in this object, and the role of borders in producing and maintaining this logic. The rows of the flowchart segment time into semesters. The rectangles segment content into courses, with borders that bound both time and content. The borders between courses can only be breached in a particular sequence, signified on the flowchart with arrows. Taken together the flowchart inscribes a logic of learning as a linear process that occurs within bordered units of content and time.

Moreover, the flowchart necessitates a set of institutional practices for producing and policing borders. Chief among these "*border-policing practices*" are *testing* and *grading*, as these are the practices through which students are classified into courses, that move students from course to course. In overview: tests are composed of problems; students provide solutions to these problems by making inscriptions—a process through which students translate some piece of themselves into marks on paper; and these inscriptions are mobilized into a separate room where instructors translate them into scores—a different set of marks on paper. These scores are then aggregated and translated into a grade, yet another mark on paper. Final grades, then, are produced via a cascade of inscriptions. Students produce inscriptions in response to test problems, these inscriptions are assembled and translated into a numerical score, and these numerical scores are assembled and translated into a final grade.

These grades serve as the mechanism by which the institution polices the borders inscribed in the flowchart. Depending on the grade a student receives, she is either granted or denied passage through the flowchart. Passage from one course to the next is binary—the border either opens or it doesn't—

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

and this gives certain categories heightened importance. For Access students, the category that determines passage into the next math class is a B-.

In addition to doing institutional work, the flow chart also serves as a resources for students to locate and construct themselves in relation to the institution (Nespor, 2007). The flowchart translates time (measured in semesters) to space, and produces a standardized "path" onto which students reckon themselves in spatial terms. For example, students talk about being "ahead" or "behind." These reckonings are value-laden; it is much better to be "ahead" than "behind," and being "behind" brings with it costs in terms of money, time, and status. Thus the borders of the flowchart don't just serve to segment content and time, they also serve to produce students' institutional identities. As such, the borders do both institutional and identity work, as we highlight in the case below.

Trajectory of membership: Mary

Mary is a white female student whose experience in the Access program has been shaped by mathematics and its associated boundary-policing practices. She came into the program having taken calculus in high school, and expected that she would take calculus during her first semester. She never had the option. In order to understand why, we have to examine the history of the Access program, and its relationship to calculus.

The Access program has enrolled six cohorts of students. From the beginning, the program has faced opposition from some faculty in the school of engineering, who see the program as a sign that the school is "lowering standards." This opposition became especially salient for Professor Turner, the director of the Access program, in the program's third year when it became clear that students in the Access program were not passing Calculus at a rate commiserate with the rest of the school of engineering. In a focus group she explained, "when we saw our kids failing [Calculus], were like, 'oh crap, we're about to lose this program.'" Professor Turner recognized that at State U, calculus doesn't just legitimize students, it legitimizes *programs*.

Calculus I for Engineers at State U has a 30% failure rate, and, because it's so central in the flowchart, this leads to attrition in the engineering school. Still, it's largely untouchable. From Professor Turner's perspective, "changing calculus is like moving an elephant—a mountain." So rather than change calculus, the Access program changed their remedial sequence. They worked with the math department to create a new Pre-calculus course with the explicit goal of making Access students "calculus ready." Because passing calculus is so important for engineering students (and the programs they populate), Professor Turner decided to enroll all of the students in Mary's Access cohort in Pre-calculus, regardless of each student's history with mathematics.

While Professor Turner made the decision to enroll Mary and the rest of her cohort in Pre-calculus in order to enhance the legitimacy of Access students and the Access program, the decision initially had the opposite effect for Mary. This is because the nuance of such a decision cannot be captured on the flowchart, which enforces a standardized pathway through the curriculum. Professor Turner's decision pushed students like Mary outside of the borders of this pathway, into into the margins of the flowchart. Mary explained:

> Almost all of the classes here for engineering are based off of calc, so if you're not caught up in calc you're gonna be behind in all of your other classes as well. And there's like no getting around it. So that means I'm definitely way behind other people in the engineering school.

One the one hand, such a position is expected for Access students. It's a natural outcome of the "performance enhancing year" that is at the heart of the program, and of Professor Turner's decision to enroll all Access students in Pre-calculus. From this perspective, Mary, who took Calculus I in the fall semester of her second year at State U, isn't behind at all. She's exactly where the Access Program expects her to be. However, such a perspective fails to account for the lived experience of

students like Mary, who took what she calls "freshman classes" during her sophomore year. During an interview, her voice cracked as she described what this is like:

> [It's] kind of embarrassing almost, cause you feel like you can be smarter than this, and like moving on, but you're not. Yeah. I don't know. I, it's just, I don't know... I don't know (softly). I can't- I don't know how else to describe it.

The margin of the flowchart is not a neutral space. In the margin, Mary questioned her legitimacy as an engineering student.

This is not the only way that mathematics and its associated border-policing practices affected Mary's sense of self. She describes herself as someone who tries to "think things through," and "show all the steps." For her, this is how to make learning "stick." However, at State U, Mary experienced mathematics as an exercise in answer-getting under time pressure. In the segment below, she talks about doing slow, careful work in mathematics.

> Well, it's not good if you want to actually get stuff done. [Last semester] I would just run out of time to do stuff, because I spent so much time like, going through… And it's not a good thing for exams because that's kind of like, you've got to know it, you've got to write it out really fast. And you've got to know all the stuff, you can't just like stop to think for too long, otherwise you run out of time.

As Mary describes, borders are important in testing. Tests are temporally and spatially bounded. Inscriptions that are produced outside of these borders are not allowed in. Hence, "you've got to write it out really fast," because inscriptions made outside the temporal border aren't mobilized into the grading room. If you "run out of time," you bump up against the impermeable temporal border of the test.

Mary "ran out of time" on her tests in Pre-calculus, and this turned out to be consequential. At the end of her first semester, her grade was below the binary cut-off and she therefore had to repeat the course the following semester. For Mary, mathematics was refusing to be naturalized, and this pushed her further into the margins of the flowchart. In large part, this was due to the way that mathematics was construed at in the engineering school at State U. Because the border-policing practices privileged answer-getting and speed over reasoning and thoughtfulness, her pensive style went unrecognized by the institution.

Mary "passed" Pre-calculus after her second semester. Looking back, she describes Pre-calculus as "very important" for calculus. In large part, this is because exam problems *made* it important:

> [Pre-calculus] was very important. The first test was like over all things pre-calc basically. With a couple of calc things. […] They had a question on absolute value. And you learned like a lot about absolute value and translations and stuff [in pre-calc]. And you needed that information to solve a certain problem on the calc exam.

Under these circumstances, Pre-calculus helped Mary to perform on the consequential knowledge displays (Stevens, O'Connor, Garrison, Jocuns, & Amos, 2008) that police the borders of the flowchart. As such, it helped propel Mary out of the margins of the flowchart and onto the standard pathway.

But it is in the margins, after Mary failed her first semester of Pre-calculus, that something even more extraordinary happened. Because of her non-standard position as a student repeating Pre-calculus, Mary was in a small class of students. In this environment, her instructor came to know Mary and her thoughtful style. This led the instructor to ask Mary to be a Learning Assistant (LA) for the Pre-calculus course in the following year. LAs are undergraduates who help to facilitate small-group interaction in large-enrollment courses. As an LA, Mary was positioned as an expert in mathematics. Students looked to her for help, this helped to affirm Mary's legitimacy:

You feel like, kinda, proud of yourself and like, um, really happy that you got to help someone and like, make their life a little easier. Um, it's just, yeah, a really good feeling.

In addition to helping students, she worked with and socialized with Pre-calculus instructors, she helped to grade exams, and she conducted an independent education research project that she presented at a poster session on campus.

In some ways, mathematics—and the boundary-policing practices that allow it to be institutionalized—pushed Mary into the margins of the engineering curriculum, causing Mary to question her identity as a member of the engineering community. This began with the Access program's decision to enroll Mary in Pre-calculus—a decision that ensured that Mary would always be behind on the flowchart, but which, in retrospect, helped Mary gain legitimacy in calculus. It continues with the ongoing violence that timed tests inflict on Mary's sense of self. At the same time, the margin became a space of possibility for Mary (hooks, 1989). In the margin of the flowchart, mathematics pulled Mary into a position of some power and authority within the engineering school, allowing her to build relationships and participate in practices that affirm her legitimacy in the community.

Conclusion: The role of borders in the production of persons

Foucault (1978) presented a radical new vision of power. While the received view was (and continues to be) that power was coercive, Foucault argued that, on the contrary, power was fundamentally *productive*. This was not an argument that power was benign, just that power produced people and society in particular ways.

In this paper, we advanced a similar argument for the role of borders in mathematics education. We first documented how, in its trajectory of naturalization within engineering education, mathematics became intertwined with institutional borders. Next we illustrated how these borders (and their associated border-policing practices), are fundamentally productive objects that constantly work to produce students in particular and complex ways. To be sure, borders do violence to Mary. They create margins and produce suffering, as Mary questioned her legitimacy as an engineering student. But at the same time, the very same margin became a place of possibility for Mary, and helped to produce her as a privileged member of the community. There is little doubt that Mary has been produced in complex ways by the borders associated with mathematics.

Mary's story is just one of the many we could have told about the complex ways that borders become productive in mathematics education. For many of the students that we have worked with, borders have produced both injury and possibility. For example, another student in the Access program, driven by fears that his marginality (due to mathematics) will lead to him getting "kicked out of the engineering school," designed and patented a "high-end upgrade for 3-D printers," which he is currently selling online. Another collection of Access students formed a student-led group to argue for more individuation in the Access program, largely in response to Professor Turner's decision to enroll entire cohorts in Pre-calculus.

We stress that when we argue that borders are productive, we are not arguing that borders are benign. Borders produce students in complex ways that cannot be encapsulated *a priori* using simplistic categorizes like "good" or "bad." Instead, our argument is, to paraphrase Jean Lave (1993, p. 8): *that borders are productive is not problematic. What gets produced is always complexly problematic*. We argue, then, that more analytical attention should be focused on what gets produced by the borders in mathematics education.

CROSSING THE LITERACY/QUANTITATIVE LITERACY BORDER

Jeffrey Craig
Michigan State University
craigjef@msu.edu

Samuel Luke Tunstall
Michigan State University
tunstal1@msu.edu

Researchers have described the relationship between quantitative literacy (QL) and literacy in various ways: from distinctly separate, with quantitative literacy as the mirror image of literacy (e.g. Cockcroft, 1982) to quantitative literacy as one subset within a broad literacy conceptualization (e.g. Suda, 2000). However QL scholars conceptualize their work with reference to literacy, they invoke historical narratives about literacy and its scholarship. We wanted to embrace literacy scholarship as having the potential to productively inform QL scholarship. In this paper, we share some of what we have learned so far from acknowledging and investigating that potential by crossing the literacy/QL border. We conclude by crafting a working definition of QL that we think helps illuminate challenges in effecting it pedagogically.

Keywords: Equity and Diversity, Curriculum, Technology

Steen (1997) claimed that quantitative literacy (QL) had emerged as a partner to literacy and that supporting people's development of QL has similarly emerged as a crucial educational endeavor. For instance, Steen (1997) claimed that "an innumerate citizen is as vulnerable as the illiterate peasant of Gutenberg's time" (p. xv). Bass (2003) argued that most scholars engaged in QL research are interested in effecting QL rather than etymology, so it is neither productive nor urgent to develop a precise definition. We believe, in contrast, that attending to literacy scholarship has helped us begin to construct a more precise definition that helps illuminate complexities of and challenges to effecting QL.

How Literacy Informs Quantitative Literacy

We want to share three findings from our exploration of literacy research that have helped us inform our conceptualization of quantitative literacy. First, literacy is *deictic*, or continuously changing, due to technological changes and emergent social practices (e.g. Gee, 1989; Leu, Kinzer, Coiro, Castek & Henry, 2013). Second, *critical* literacy is an ideology that empowers people to both read the word and read the world; that is, people become critically literate by reading and writing language as a means to interpret, reflect on, and change their world (Freire & Macedo, 1987). Finally, being *willing* to read and write the world requires a focus on people's dispositions that needs to be attended to pedagogically (e.g. Giroux, 1988).

Changing Quantitative Information

Leu and colleagues (2013) described the transformative power that technology generally, and the internet specifically, have had on literacy. The authors claimed the internet drives the emergence of new social practices of literacy both by creating new literacies and systematically transforming existing literacy practices. Steen and colleagues (2001) made their *Case for Quantitative Literacy* on the premise that the 21st-century is, and will continue to become, a significantly more quantitative environment than any previous time in history. Steen (1997) claimed "as the printing press gave the power of letters to the masses, so the computer gives the power of number to ordinary citizens" (p. xv). Computers and the internet have also transformed QL by changing what quantitative information people see in several ways. Many researchers in statistics education have acknowledged the prevalence and pervasiveness of statistics, data, and representations in the digital information age (e.g. Gal, 2002). The nature of those statistics, data, and representations has not been static over time, however; for example, *infographics* that combine graphics, text, mathematics and statistics. Bertini,

Perer, Plaisant, & Santucci (2008) have worked to unpack how people understand infographics and data visualizations and have found that different evaluation strategies are used for these new representations.

Bezemer and Kress (2008) used social semiotics to investigate the evolution of creating multimodal representations of information with potential for learning. By arranging the information as an infographic, words with particular mathematical or statistical meanings (a percent, relative sizes, etc.) are often translated into and shared in graphical form, further connecting QL and literacy. The move of multimodal representations from static to dynamic recontextualizes the social meaning of the representation. Specifically, the social structures in which knowledge is generated, presented, shared and validated, affect and are affected by the mode of representation (Bernstein, 1996). Infographics online, therefore, are qualitatively different than their previous static, paper counterparts due to the social structure of the internet; infographics online can be shared with comment, and traditional consumers of information have become creators who reconstitute and validate the information as knowledge.

Infographics are one example of how technology can change the ways people encounter quantitative information. Integrating quantitative information into politics, businesses, and other social decisions also changes those decisions. This integration raises dilemmas: ethically, politically, socially and legally (e.g., Kitchin, 2014). For example, an overreliance and overvaluation on big data sets can give less space for and attention to dissent and counter-narratives that come from thick data (Dove & Özdemir, 2015). How do we acknowledge the hope that people not only understand the quantitative information, but also these dilemmas?

A Critical Quantitative Lens

Critical literacy differs from literacy because critical literacy refers "only [to] where concerted efforts are being made to understand and practice reading and writing in ways that enhance the quest for democratic emancipation" (Lankshear & McLaren, 1993, p. xix). Mathematics and related disciplinary lenses can powerfully function to "understand, identify, and tak[e] action on social justice issues" (Esmonde, 2013, p. 349). Scholars have done an impressive amount of work unpacking and examining critical theory in domains related to QL. These works include: teaching for social justice (e.g., Gutstein, 2003), criticalmathematical literacy (e.g., Frankenstein, 2001), mathematical literacy (e.g., Jablonka, 2003), critical mathematics education (e.g., Skovsmose & Niss, 2008), and work in equity which is informed by a Freirean critical stance toward mathematics education (e.g., Gutierrez, 2012).

Just knowing how to do the mathematics and statistics that you face during your life does not capture what we consider a critical quantitative lens. A critical lens more clearly includes what Gutstein (2003) calls writing the world with mathematics. Understanding the mathematics and statistics in how the unemployment rate is calculated, budgeting for their property tax, or the logic backing a legal decision is important. But, a critical lens toward these quantitative arguments involves acknowledging dilemmas; why is a person who has stopped looking for work excluded from the labor force during the calculation? Should education funding be tied to property tax? Are the premises of a legal decision true? These questions represent some of what Frankenstein (2001) meant when she delineated understanding mathematical knowledge from understanding the mathematics of political knowledge and understanding the politics of mathematical knowledge, and we think they clarify what we mean by a critical lens.

Jablonka (2003) stated "mathematical literacy focusing on citizenship should refer to the aim of critically evaluating aspects of the surrounding culture – a culture that is more or less colonised by practices that involve mathematics" (p. 76). Expressions of QL should similarly extend beyond understanding the ways mathematics and statistics have embedded into contemporary life. Critical

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

expressions of quantitative literacy embrace the power of mathematics and statistics as lenses to read and write the world.

Willingness to Engage

What effects do changing quantitative information and attending to a critical stance have pedagogically? Leu et al. (2013) argued that new literacies further complicate professional teaching by requiring a shift in role and by placing new demands on teacher knowledge. Specifically, Leu et al. (2013) claimed that a pedagogy reactive to the speed at which literacy changes creates an untenable demand on teachers to stay technologically current. The authors proposed that teachers move from dispensers of literacy knowledge to facilitators of productive literacy strategies and practices. Supporting critical literacy development also requires particular forms of pedagogy. Giroux (1988) pointed out that participating in direct forms of instruction is contradictory to a goal of helping students become critically literate. Likewise, careful attention to pedagogical strategies which support a person's disposition to engage in reading and writing the world with mathematics is necessary.

Wagner and Herbel-Eisenmann (2009) described the socio-psychological implications of choosing dispositions as a learning goal. Dispositions are more stable aspects of a person's identity than ways students might position themselves while in the classroom. In particular, the authors argued that dispositions are those socially constructed positions that people reify and transfer between contexts. Steen et al. (2001) claimed that students would develop a quantitative literacy habit of mind "only by encountering the elements and expressions of numeracy in real contexts that are meaningful to them" (p. 18).

Changes to pedagogy in a classroom devoted to critical QL involve more than developing contextual mathematical problems; students need opportunities to decide the problems they want to pursue in order to develop an active sociopolitical consciousness and a willingness to read and write the world with mathematics (Gutstein, 2003). Gutstein's (2003) students developed a sense of agency as actors who could change their world with mathematics by developing mathematical power. The challenge of creating a high quality curriculum is not met by developing artificial problems meant to meet mathematical goals (Romberg, 1992). To develop mathematical power and agency, a curriculum should reflect students' sociopolitical realities wherein mathematical and statistical understanding can be leveraged. Gutstein (2003) relinquished sole authority of problem posing; instead, he shared the decisions about which problems to pursue with his students.

A Working Definition and Implications

As a working definition, we take a person's *quantitative literacy* to be their willingness to engage a critical quantitative lens towards their changing world. We think this definition helps to illustrate particular challenges to effecting QL: (1) the world about which we want people to be quantitatively literate is transformed by and itself transforms quantitative information, (2) our goals for effecting QL extend beyond understanding the quantitative information they encounter to critically reading and writing their world, including its quantitative information, and (3) critically reading and writing the world with QL is not just an ability, but also an action: a person expresses QL not just by being able to read and write their world, but by actually doing it.

In this paper we crossed the QL/literacy border with the goal of using literacy scholarship to inform QL scholarship. We think that important differences between QL and literacy exist, however, and suggest that scholars continue illustrating those differences. We also think that QL scholarship can help inform some literacy scholarship, for instance bringing a QL lens to infographics can contribute to investigating multimodality in literacy scholarship.

BLACK GIRLS IN HIGH SCHOOL MATHEMATICS: CROSSING THE BORDERS OF DEFICIT DISCOURSES

Teresa K. Dunleavy	Nicole M. Joseph	Maria del Rosario Zavala
Vanderbilt University	Vanderbilt University	San Francisco State University
teresa.dunleavy@vanderbilt.edu	nicole.m.joseph@vanderbilt.edu	mza@sfsu.edu

This paper explores the discourses of three Black girls in one high school Algebra 1 mathematics classroom. We investigate how these students navigate a border crossing from deficit discourses about student success and toward success in mathematics. We further argue that the teacher's classroom practices, which facilitated this border crossing, were striving toward equity. The classroom practices we found included: (a) assigning competence, (b) valuing multiple solution paths, (c) helping group members, and (d) explaining mathematical thinking.

Keywords: Classroom Discourse, Equity and Diversity, Gender, Instructional Activities and Practices

Significance and 2016 PMNEA Theme Connections

One of the most pressing issues in American education is the underperformance of Black girls and women in mathematics across the P-20+ pipeline (Herzig, 2004; National Science Foundation [NSF], 2013). Deficit-based discourse about this population's performance has exacerbated poor performance (Solorzano & Yosso, 2001). Deficit-based discourse is a "border" that has significantly limited marginalized students' access to rigorous mathematical content and pedagogy. This discourse segregates Black girls to mathematics classrooms that under or devalue their ways of knowing, thinking, and engaging with mathematics, decreasing their opportunities to learn. Deficit discourses can also include how standardized tests are talked about and are made the center of knowledge production when it comes to identifying who succeeds and who fails. Deficit discourses also include conscious and unconscious low teacher expectations and negative beliefs about Black girls, which can be shaped by broader narratives in media and the literature (Russell, Viesca, & Bianco, in press). All of these deficit discourses can contribute to a socially-constructed border that teachers and students must confront, cross, and/or tear down to achieve success for all in mathematics. We argue that certain mathematics teaching practices can be enacted to help Black girls navigate crossing such borders. We explore the discourses of Black girls in an Algebra class who began our study achieving at lower levels, when compared with most ninth graders at their school and district, but who, over time, shifted their self-perceptions of competence because of their teacher's attention to equitable teaching practices. We seek to begin a conversation of this "border crossing" for Black girls in U.S. mathematics classrooms (Anzaldúa, 1987; Newman, 2003). We investigate how three Black girls navigated border crossing into self-identified success in mathematics through equitable mathematics teaching practices that sought to disrupt normalized expectations for competence. We adopt Esmonde's (2009) definition of equitable teaching and learning as "a fair distribution of opportunities to learn" for all students (p. 1008). We raise tensions, challenges, and we put forth generative possibilities for successful border crossings.

Research Questions

This study asked and answered the following questions:

1. What teaching practices do Black girls report as influencing their mathematics learning?
2. How do the reported practices reflect equitable mathematics learning?

Theoretical Framing

In order to navigate the perspective of our Black girls, we draw on a framework that combines status and positioning theories. This framework attends to how and whether students are positioned as competent (Campbell & Dunleavy, 2016) and cross the border from deficit-based discourses toward successful self-identification in mathematics (Newman, 2003). Status theory offers an explanation for how generalized expectations for competence develop from the academic power held in a given community (Webster & Foschi, 1988). Positioning theory offers the opportunity to understand the moment-to-moment discursive acts that create storylines over time (Harré & van Langenhove, 1999). We describe a successful border crossing as students and teachers moving away from deficit-discourses about who can be successful and toward equitable learning outcomes. We use this framing to understand who has academic power in a given classroom, how the power is distributed, and which discourses and practices affect change.

Participant Selection, Data Collection, & Analysis

We situated this study in a racially, ethnically, linguistically, and socioeconomically diverse school. The teacher, whom we call Ms. Martin, was invited to participate because she described making pedagogical choices that fostered student-to-student discourse (Cazden, 2001), interdependence (Lotan, 2003), and countered status issues (Cohen, 1997). This study represents the voices of 3 of the 14 Black girls from the class, each of whom completed all interviews. The girls featured are Jaelyn, a 10th grader, and Neesha and Irene, 9th graders.

Each participant completed 2 individual interviews between November 2011 and January 2012 and 1 group interview in February 2012. Other data sources included (a) field notes taken during classroom observations, (b) daily qualitative records, (c) video recordings of focal classroom sessions, (d) classroom work, and (e) video recordings of each interview.

We sought to understand which classroom practices these Black girls found influential in their mathematical learning in their Algebra 1 class. Initial analyses of classroom and interview data took place by coding field notes and interview transcripts, looking for how the participants identified competence for themselves and for their classmates. In a second round of analysis, the teacher's classroom practices were identified, including (a) assigning competence, (b) valuing multiple solution methods, (c) helping other group members, and (d) explaining mathematics thinking. Once initial findings emerged, we analyzed the students' border crossing away from deficit discourses by examining students' self-perceptions over time.

Findings

We investigated the classroom practices that emerged to look for evidence of equitable teaching and learning. Overall, our findings indicate that each Black girl described mathematics classrooms practices that positively shaped her self-perception of mathematics learning. We argue that these practices translated to positive experiences for these girls, which afforded each girl to disrupt previous negative conceptualizations of her mathematics learning. We further found these disruptions facilitated a space for grand narratives about their border crossing toward self-described success in mathematics.

We found that Jaelyn, Neesha, and Irene's interpretations of their experiences with mathematics drastically improved during first semester in Algebra 1. We coded interviews for how students described their mathematics experience. In the January and February interviews, each student shared a positive outlook of mathematics and of her interpretation of her abilities. Each student's change in self-perceptions of competence is shared in Table 1.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 1: Students' Changed Self-Perceptions of Mathematics Competence

Student	Initial Self-Perceptions	End-of-Study Self-Perceptions
Jaelyn	"Last year I didn't like to go to class."	"I was curious to get to class and see what everybody else's answer was."
Neesha	"I used to shut down." "I'm not very good at math."	"Math is one of my favorite classes." "I am. I am good at Algebra."
Irene	"Since 7th grade math has not been my strongest subject. It is either confusing or I just don't understand it."	"Now that I'm in this class, it's actually kind of easier. I don't get as much stuff wrong with math now. This year, I get it."

After coding interviews for students' interpretations of their mathematics abilities, we looked to the classroom practices that Ms. Martin implemented. We were curious about whether there would be a link between classroom practices and what students' reported influenced their learning. Four classroom practices emerged from our analyses, including: assigning competence, valuing multiple solution methods, helping group members, and explaining mathematical thinking. See Table 2 for an illustration of these classroom practices.

Table 2: Classroom Practices that Influenced Learning

Structure	Student	Evidence
Assigning competence	Jaelyn	Ms. Martin told students to "bug Jaelyn" about how to use Lab Gear to explain simplifying an algebraic expression.
	Neesha	"Ms. Martin won't give you the answer, she'll listen and eventually say, 'I knew you'd [get it]!' "
	Irene	"Ms. Martin might have come over and asked us to start sharing about that equations. She came over and she saw [mine]. I was supposed to put mine in the middle to share with the table. And after she left, I continued with that."
Valuing multiple solution paths	Jaelyn	Jaelyn described students regularly putting their papers in the middle to compare solution methods.
	Neesha	"[You have to] learn your own way and your group members' way[s] to solve a problem."
	Irene	"After Ms. Martin leaves, it seems like more people start to talk. And then, you get more like, you get different kinds of ways people do it, and you get different answers and you figure out how to get the same answer."
Helping group members	Jaelyn	"As a learner, if you don't understand it, this is where a group comes in…Ms. Martin will make everybody in your group help you out."
	Neesha	"[We] wanna make sure everyone gets it."
	Irene	"It helps more when we're on the same problem, because they'll just stop and like, 'wait, what'd you get for this problem?' 'how'd you get that?' "
Explaining mathematical thinking	Jaelyn	"When you get everybody going 'Oh!' that just makes you move through the process easier. Like, when I was in that group, we all had it down. We'd stop, one of us would be confused for a minute and then [by explaining], you flowed through it easier."
	Neesha	"When somebody else doesn't understand it, you have to find a different way to explain it to them."
	Irene	"We had to go back and help her, and explain how we did it. And then sometimes, when I would explain and people would catch that I said the wrong thing or I got the wrong thing, they would explain how they did it."

Linking Equitable Teaching, Learning, and Border Crossing

Many classroom episodes highlighted connections between Ms. Martin's classroom practices and equitable learning opportunities for Jaelyn, Neesha, and Irene. Each classroom practice from our analysis supported our Black girls' border crossing from deficit-discourses toward self-identifying as competent mathematicians. In one instance, Ms. Martin assigned competence to Jaelyn by

positioning her as the group-member who was competent to explain Lab Gear to her group members. In another, Irene described Ms. Martin's encouragement that she physically moved her work to the center, and she admitted that once Ms. Martin left, she continued explaining the mathematics to her group. Neesha reported that Ms. Martin regularly listened to groups come to a mathematical understanding themselves, after which time she would reaffirm their competence, telling them, "I knew you would!" Each of these instances is representative of the many times these girls described Ms. Martin assigning them and their classmates competence. By regularly assigning competence to these students, Ms. Martin influenced these students' perceptions of competence (Cohen & Lotan, 1997). Changing self-perceptions of competence gave our Black girls the tools to counter deficit notions of self, aiding them in dismantling false borders of incompetence. Moving toward improved self-perceptions of competence also highlights evidence that these students, by the end of the study, saw themselves as mathematics authorities in their classroom, which moves her classroom toward equity (Dunleavy, 2015).

Crossing the Borders of Deficit Discourses

Our findings provide existence proof of how these Black girls spoke to countering deficit narratives and crossed the border toward seeing themselves as competent mathematicians. Further, we offer evidence for which classroom practices facilitated their border crossing toward self-described success in mathematicians. Future research may continue to explore border crossing, including how classroom teachers assist students in countering deficit discourses and how students' ways of knowing are related to what counts as meaningful mathematics.

LOOKING AT VERSUS LOOKING THROUGH: WHEN DESIGNS UNDERMINE STUDENT REASONING

Melissa Sommerfeld Gresalfi	Isaac Nichols	Panchompoo Wisittanawat

melissa.gresalfi@vanderbilt.edu	isaac.nichols9@gmail.com	pwisittanawat@gmail.com

This paper reports on two rounds of a design-based research study whose goal was to support mathematical problem solving in the context of an immersive game using the concepts of rate, ratio, and proportion. Findings from these implementations suggest that while all students learned in both years, students in year 1 scored significantly higher than students in year 2. Based on this analysis, we concluded that the changes from year 1 to year 2 had a negative effect on student reasoning about ratio, particularly due to the ways that a ratio tool focused students' and the teacher's attention on separate versus coordinated reasoning about ratio.

Keywords: Design Experiments, Middle School Education, Instructional Activities and Practices

Introduction

A persistent challenge of complex problem solving involves balancing between problem solving activity and underlying conceptual understanding. Complex problem solving involves what is often described as a *dance of agency* (Pickering, 1995) between the conceptual agency of decision-making and the disciplinary agency of leveraging appropriate methods and strategies to solve the given problem. Successful problem solving therefore fundamentally requires conceptual understanding of strategies; that is, understanding not just *how* to execute a procedure, but also what a procedure might tell you and why it might be useful in a particular situation (Gresalfi, 2015; Gresalfi & Barnes, 2015; Santos-Trigo, 2007; Schoenfeld, 2007). This kind of conceptual understanding is notoriously difficult to support, for reasons that range from the complexity of underlying ideas, to more mundane challenges such as instructional time.

This paper reports on two rounds of a design-based research study whose goal was to support mathematical problem solving in the context of an immersive game using the concepts of rate, ratio, and proportion. There is significant agreement that the concepts of ratio and proportion are critical topics of mathematical study and also notably challenging for students to understand (Beckmann & Izsák, 2015; Behr, Harel, Post, & Lesh, 1992). Great attention continues to be focused on the nuances of understanding ratio and proportion (Beckmann & Izsák, 2015) and how to best support student learning of those topics (Lobato, Ellis, & Zbiek, 2010). Although there are myriad elements that compose the concepts of ratio and proportion, many learning goals in schools involve articulating definitional distinctions and setting up an algorithm that can be resolved using cross multiplication. Like any procedural approach to mathematics, students can remember steps but struggle with the underlying conceptual ideas (Cramer & Post, 1993; Lesh, Post, & Behr, 1988; Lobato et al., 2010).

Project Overview

We report overall findings of the first two round of design and implementation, and present a detailed analysis of the second round of implementation, focusing in particular on the design of a *ratio tool* intended to support students' conceptual understanding of proportion.

Problem Solving Game

We studied mathematical reasoning and problem solving in the context of an educational video game called *Boone's Meadow,* based on a project-based mathematics activity from the *Adventures of Jasper Woodbury* (Bransford, Zech, Schwarz, Barron, & Vye, 2000; Pellegrino et al., 1992). The game begins when students are told that an endangered eagle has been shot in Boone's Meadow—a

place that cannot be reached by car and takes 6 hours to hike by foot. Multiple decisions need to be made to rescue the eagle, including which route to take, which plane to fly, the length and time of the journey, how much gasoline will be required (and where to stop to get it), and whether any additional cargo is necessary (or feasible) given the weight limit of the small aircraft.

Ratio tool. The first iteration of the game did not include an explicit scaffold for proportional reasoning based on earlier pilots with 9-10 year olds, who successfully engaged with problem solving tasks in the game using multiplicative comparisons. However, in year 1 we discovered support was needed, as described below. We thus design a *ratio tool* to support proportional reasoning as a double number line (see Figure 1) for the following reasons. First, a double number line makes clear the *coordination* between two quantities. We included an additional design feature to attune students to this coordination—the paired numbers are enlarged when the slider is moved to their position (see 30 and 20 in Figure 1). Second, compared to cross multiplication, a double number line has a spatial component making the *co-variation* between the two quantities more explicit (Confrey & Smith, 1995; Thompson & Carlson, in press).
Figure 1. The Ratio Tool Designed for Round 2.

Methods

Participants and Data Collection

Data come from two years of implementation in the same 7th grade teacher's classroom (Ms. Lynn) at a diverse middle-school (92% free and reduced lunch, 30% English language learners) in a southeastern U.S. city. The students generally performed at least two grades below level; in both years students struggled with fundamental understanding of multiplication and relied on a multiplication chart when conducting calculations.

Although the game changed slightly from year 1-2, the flow of the implementation was similar. Four days of class time were devoted to game play both years. Each day, class began with a warm-up and a discussion before computers were given to students. These discussions varied in length, lasting as long as 50 minutes of a 1.5-hour class period. Follow-up discussions after game play occurred some days, but not all. During both years, data was collected in the form of pre/post tests, video of pairs of a subset of students working with the game, and video of the teacher in whole class discussion and working with individual students during gameplay.

Analysis

For years 1 and 2, pre and post tests were scored by a minimum of two coders, and compared for gain within year and difference across years. To examine how students were interacting with the ratio tool (year 2), we examined videos from two thirds of focus groups (six pairs), selected randomly. Transcripts were made of interactions with the ratio tool while conducting six unit rate calculations, and coded to determine whether students were reasoning with ratio in a separate or coordinated way. This distinction came from literature, which has identified seeing ratios as a single coordinated unit

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

rather than two separate units moving together as a core concept in order to build proportional reasoning (Lobato et al, 2010). In addition, transcripts of the teacher's talk about ratio were coded using the same separate vs. coordinated coding scheme.

Results

A simple t-test revealed that all students learned in both years ($t=6.00$, $p<.001$). There was a significant effect for year of study on posttest scores, although not in the hoped for direction; a multiple regression revealed that students in year 1 scored significantly higher than students in year 2 ($t= -2.31$, $p <.05$). This was surprising, as we observed higher levels of engagement in year 2, and were asked help far less frequently. To better understand why the ratio tool might have contributed to lower post test scores in year 2, we examined videos of student and teacher interactions, focusing specifically on times when the ratio tool was the object of activity.

Student Interactions

Of the 36 questions (6 questions per group) that students solved while playing the game, six questions were lost due to video malfunction loss, and 12 were coded as copy answer, meaning that students had recorded answers from prior discussions or other groups. The remaining 19 questions were coded as separated reasoning (11) or coordinated reasoning (7), see Table 1. However, the difference between coordinated versus separate was more disparate than it might seem at first glance; a single pair of students (second row of Table 1) was responsible for 5 out of the 7 questions coded as coordinated (2 of which were prompted by Ms. Lynn or a researcher). The other 2 questions coded as coordinated reasoning were in separate groups and both heavily depended on help from researchers. Thus, students did not seem to naturally use the tool in a coordinated manner. Instead, many students cued into separate patterns within the tool, that the ratio tool was undermining a basic property of ratio, attending to and coordinating two quantities (Lobato et al, 2010). Rather than building the conceptual understanding of proportion, the tool became the object to look at and solve, not learn with (Greeno & Hall, 1997).

Table 1: Counts Of Student Solved Problems

	Total questions	Separate	Coordinated	Copy Answer	Lost
All Groups	36 (6 per 6 groups)	11	7	12	6
One Group	6	1	5	0	0

Teacher Interactions

As seen in Table 2, the ratio tool also seemed to reorient Ms. Lynn's discourse from dominantly coordinated with twice as many coordinated utterances as separate, to dominantly separate with half as many coordinated utterances as separate.

Table 2: Counts Of Utterances Coded As Separate Or Coordinated

	Separate	Coordinated
Without Ratio Tool	23	49
With Ratio Tool	70	35

Discussion

The overall goal of this research project is to support mathematical problem solving that involves making decisions about how to solve problems, and considering the impact of those mathematical decisions. The data shared here describe two rounds of a design-based research study that attempted to support student conceptual understanding by building in a tool that, we hoped, would support students' reasoning about ratio. Based on measures of pre-post change, we found that although students learned, they did not learn as much with the addition of the ratio tool. Although it is not

clear that the introduction of the tool caused this lower level of learning, the results of our in-depth analyses around the tool, documenting the dominance of separated talk about the proportion, suggest that the tool did not support understanding of proportion.

It is possible that this problem is particular to this population of students due to their lack of facility with multiplication. Perhaps the tool attunes students to the relationship between numbers only when the relationships that are being identified are easily uncovered; that is, students might notice that the relationship between 2:10 and 5:25 only if they are easily able to identify both 1:5. Thus, it is possible that the ratio tool undermines *some students'* reasoning about ratio, but not all. This is a topic of continued investigation as we work with more teachers and students. Regardless, our next round of design needs to consider whether and how we can support students' whole-number multiplicative reasoning while simultaneously supporting them to connect that reasoning with a focus on invariant (i.e. proportional) relationships.

UNDERSTANDING UNDERGRADUATES' MATH-RELATED PERCEPTIONS

Xiaoxia Huang	Jennifer Cribbs	Katrina Piatek-Jimenez

In this study, we surveyed 323 undergraduate students at a large public university in the Northeastern region of the United States. We explored the relationship between these students' career interest in STEM with their beliefs and self-perceptions related to mathematics, including: mindset, anxiety, identity, and efficacy. Our findings suggest statically significant correlations between the four mathematics constructs. In addition, mathematics identity and self-efficacy were positive predictors for students' STEM career interest. Furthermore, family interest and gender are important measures for predicting student career interest.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Gender, Post-Secondary Education

Introduction

The goal of this study is to understand the relationship between mathematics related affective measures, including mindsets in math, math anxiety, math identity, and math self-efficacy, and to investigate the predictive nature of these constructs toward students' career interest in STEM. Previous research has identified these affective factors important to understanding people's choice, behavior or learning in mathematics (e.g, Bandura, 1997). Mindset orientations in math have been defined to include fixed mindset and growth mindset: people with a fixed mindset tend to view math intelligence as unchangeable while people with a growth mindset view math intelligence as malleable that can grow with effort (Dweck, 2000). Math self-efficacy focusses on one's perceived confidence in performing math related tasks. Math anxiety, a concept closely related to math self-efficacy, normally refers to one's unpleasant feelings (e.g., fear) associated with math task performance (Ashcraft, 2002). Finally, math identity refers to how students see themselves in relation to mathematics based upon their perceptions and navigation of everyday experiences with mathematics (Enyedy, Goldberg, & Welsh, 2006).

Prior work related to mindset, anxiety, identity, and self-efficacy have shown the constructs to play an important role toward students' engagement in math. For example, it has shown that math self-efficacy affects students' math course choices and math-related career choices (e.g., Anjum, 2006; Hackett, 1985). Research has also found that mindset is not only predictive of math achievement in adolescents (Blackwell, Trzensiewski, & Dweck, 2007) but also predicts the level of math courses that students take as they transitioned through middle school (Romero, Master, Paunesku, Dweck, & Gross, 2014). Likewise, math anxiety has been shown to influence students' self-perceptions related to their math ability, expectancies for success in math, and perceived value of math (Meece, Eccles, & Wigfield, 1990). Other work indicates that math anxiety is correlated with which math courses students take in high school (Ashcraft, Krause, & Hopko, 2007).

Mathematics identity is also an important construct that explains students' persistence in STEM. Research in the area of math identity has shown two factors as having a direct, positive effect on students' math identity development (Cribbs, Hazari, Sadler, & Sonnert, 2015). Recognition is one of the factors and is defined as how individuals view themselves in relation to mathematics. The second factor, interest, is defined as an individual's desire to think about and learn mathematics. While research has shown connections between math identity and students' career goals (Cribbs, Cass, Hazari, Sadler, & Sonnert, 2016), there is limited work exploring how math identity correlates with other affective measures that influence students' engagement with mathematics. As math anxiety and math identity both have the potential to influence students' choices for future engagement in math or

math-related activities, it is possible that these constructs are correlated in some way. Likewise, students' math self-efficacy could also be correlated with math identity, particularly when considering the strong correlation that students' perceptions about their ability to perform in and understand math has to the sub-constructs of math identity, recognition, and interest (Cribbs et al., 2015). How the above constructs correlate to mindset orientations in math is also worth exploration as little research has focused on this question. In addition, we are interested in examining which of these math related constructions are better predictive of student interest in STEM-related careers.

The following research questions were used to guide this study: 1) Are students' self-perceptions and beliefs about mathematics correlated, and 2) What is the relationship between students' career interest in STEM and math mindset, anxiety, identity and self-efficacy?

Methods

Data were collected through surveying undergraduate freshman in the fall of 2015 at one university in the northeast region of the United States. A total of 323 completed responses were received. The survey was piloted and revised in the spring of 2014 and includes questions on student demographic information, career goals, and perceptions related to mathematics, including math mindset (Dweck, 2000), anxiety (Betz, 1978), identity (Cribbs et al., 2015) and self-efficacy (Fennema & Sherman, 1976). Previous research has established the validity and reliability of each affect construct measured. In addition, the internal consistency for each construct was calculated and found to be appropriate in the present study: mindset (0.90), anxiety (0.87), identity (0.95) and self-efficacy (0.95). Before the construct variables were calculated, all negatively worded items were reverse coded so that a higher score indicates a more malleable view of intelligence (growth mindset) and a higher level of anxiety, identify, or self-efficacy.

Pearson correlation tests between each of the four mathematics beliefs and self-perception constructs were run to address the first research question. The second research question was addressed using logistic regression, where a model was developed for each math construct. Students' STEM career interest, which is a dichotomous variable, was the dependent variable. Table 1 summarizes the number of responses to the career interest variable.

Table 1: STEM Career Interest

Are you interested in pursuing a STEM-related career?	Female	Male	Total
Yes	69	42	111
No	175	37	212

For the correlation analysis and regression models, a proxy for each mathematics construct was developed by averaging participants' responses. Furthermore, the following demographic information was entered as control variables: gender, mother and father's highest level of education, family support and interest, and race. List-wise deletion was used for missing data.

Results

Table 2 details the results for research question 1: Are students' self-perceptions and beliefs about mathematics correlated? Each of the mathematics constructs had statistically significant correlations with the others: growth mindset and anxiety were moderately negatively correlated, $r(313) = -.35$, $p < .001$; growth mindset and identity were weakly positively correlated, $r(313) = .29$, $p < .001$; growth mindset and self-efficacy were moderately positively correlated, $r(311) = .46$, $p < .001$; anxiety and identity were strongly negatively correlated, $r(317) = -.72$, $p < .001$; anxiety and self-efficacy were strongly negatively correlated, $r(315) = -.84$, $p < .001$; and identity and self-efficacy were strongly positively correlated, $r(316) = .81$, $p < .001$.

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Table 2: Correlation Test Results

Construct	Mean	SD	Mindset	Anxiety	Identity	Self-efficacy
Mindset	3.48	.83	-			
Anxiety	2.92	.94	-.35***	-		
Identity	2.99	.19	.29***	-.72***	-	
Self-efficacy	3.44	.97	.46***	-.84***	.81***	-

***p<0.001

In order to address research question 2, what is the relationship between students' career interest in STEM and math mindset, anxiety, identity and self-efficacy, a series of regression models were created. Mindset and anxiety were not significantly predictive of students' career interest. However, identity and self-efficacy were both predictive of students' career interest in STEM as shown in Table 3 and 4. Additionally, gender, mother's highest level of education, and family interest in math as a career (my family saw math as a way for me to have a better career) were all positive predictors for students' career interest in STEM.

Table 3: Relationship between students' career interest in STEM and identity (N=314)

	Estimate	SE	Odds Ratio	Sig.
Intercept	-4.212	0.653		***
Controls				
Gender (Male=1, Female=0)	1.061	0.316	2.890	***
Mother's Highest Education	0.281	0.124	1.325	*
Family Interest in Math as Career	0.349	0.084	1.418	***
Mathematics Identity	0.273	0.120	1.313	*

*p<0.05 **p<0.01   ***p<0.001

In addition to indicating that self-efficacy is predictive of students' career interest in STEM, several control variables were also positive predictors, gender and family interest in math as a career (my family saw math as a way for me to have a better career).

Table 4: Relationship between students' career interest in STEM and self-efficacy (N=315)

	Estimate	SE	Odds Ratio	Sig.

Mathematics Self-efficacy	0.313	0.147	1.368	*

*p<0.05 **p<0.01   ***p<0.001

Discussion

Results from this study indicate that math-specific mindset, anxiety, identity and self-efficacy are all correlated with one another. However, some of the variables are more highly correlated than others. Specifically, the strong correlation between math self-efficacy and anxiety supports previous theoretical and empirical research on their relationship (e.g., Bandura, 1997; Griggs, Patton, Rimm-Kaufman, & Merritt, 2013). In addition, the strong correlation between math identity and self-efficacy was not surprising either given prior work related to the constructs of self-efficacy and math identity (Cribbs et al., 2015). Math identity and math anxiety also had a strong yet negative correlation. The strongest correlation that mindset had was with self-efficacy, followed by anxiety

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

and identity. When investigating how predictive each of the affective measures were with students' STEM career interest, mindset and anxiety were not found to be predictors. However, mathematics identity and self-efficacy did significantly predict students' STEM career interest.

No prior research has integrated these math related affective factors into one model and explored their relationships with each other and with STEM career interest, as explored in the present study. Additional research is needed to better understand the relationship between math-specific mindset, anxiety, identity and self-efficacy by exploring possible mediating effects among the variables to STEM interest. Particularly, structural equation modeling could provide important information as to how the constructs are related.

LEARNING FROM TRANSGENDER INDIVIDUALS IN STEM EDUCATION

Elizabeth Kersey
Purdue University
ekersey@purdue.edu

This paper outlines a gender-complex framework and narrative research methods to investigate how transgender and gender non-conforming students' experiences in STEM education have varied as their gender presentation has evolved. The theoretical framework draws from post-structural feminism, queer theory, and gender performance theory. This is summarized in the gender oppression plane, in which one axis measures gender category privilege or oppression, and the other axis measures gender conformity privilege or gender transgression oppression. Feminism addresses the former axis, and queer theory addresses the latter axis. Gender performativity theory helps to explain an individual's placement on the plane, and how that placement can change with time or context. Proposed research methods include interviews and reflective journaling, which will then be analyzed narratively.

Keywords: Gender, Equity and Diversity, Post-Secondary Education

Gender is a category that pervades almost every aspect of our lives. To most people, the fact that the world is divided into two groups – male and female – is seen as unproblematic, even among those opposed to discrimination against one group. This practice of taking gender and sex (which are often equated) for granted is one that pervades many research studies seeking to discover or explain gender differences in mathematics education (Damarin & Erchick, 2010). The borders between sex and gender, between male and female, and between man and woman need to be questioned. Motivated by a desire to interrogate these borders and an interest in telling the stories of those who have crossed them, I outline a framework and methods to explore the following research question: "How have transgender and gender non-conforming students' experiences in STEM education varied as their gender presentation/performance has evolved?" My framework draws from post-structural feminism, queer theory, and gender performativity theory.

Rationale

It is an oft-cited fact that women are underrepresented in STEM fields (National Science Foundation, 2015). There have been many theories to try to explain this fact, such as stereotype threat (e.g., Brown & Josephs, 1999) and differences in learning styles (e.g., Geist & King, 2008). Nearly all of these studies take gender as a well-defined, unproblematic, binary category (Damarin & Erchick, 2010). However, studies that include gender identity have found it to be a better predictor than sex (e.g., Hackett & Betz, 1989; Severiens & ten Dam, 1997). This study will examine the experiences that transgender students have had in STEM education, and focus on their interactions with others in that setting.

Definitions

A framework that includes many subtleties surrounding the concept of gender necessitates the careful definition of such terms as gender identity, gender presentation, and gender attribution. *Gender identity* refers to an individual's "sense of self as a boy or girl, woman or man (or, as we are increasingly realizing, as a nongendered, bigendered, transgendered, intersexed, or otherwise alternatively gendered person)" (Tranzmission, n.d., p. 10). *Gender presentation* refers to the intentional and unintentional ways that an individual communicates their gender to others. *Gender attribution* is the way in which an individual interprets the myriad cues available to designate an

individual as male, female, indeterminate, etc. It is gender attribution rather than gender presentation that determines a person's gendered treatment by others.

I define a *transgender* person as anyone whose gender identity is not the same as their assigned sex at birth. Defining transgender in this way includes those who are intersex and were forcibly assigned a gender with which they do not identify, those with a non-binary or fluctuating gender, and those do not present as their preferred gender identity.

Theoretical Framework

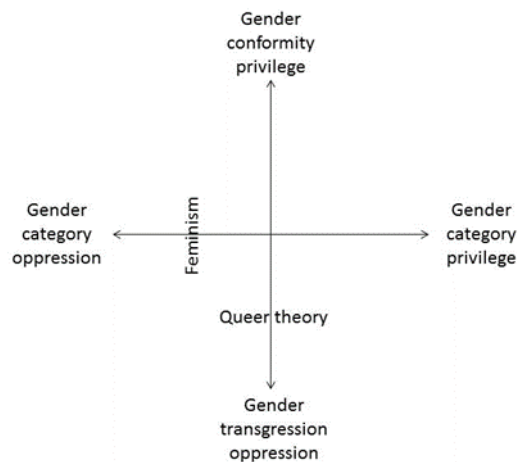
I borrow the concept of a gender oppression plane from Kathleen Rands (2009), although the visual depiction of it is my own (see Figure 1). In this approach, there are two dimensions along which one might experience privilege or oppression based upon one's gender. The first, *gender category oppression*, describes the ways in men experience systematic privilege and women experience systematic oppression. This is based on whether one is perceived as a man, a woman, or another gender category. The second dimension is *gender transgression oppression*. This refers to the systematic privilege experienced by those who do not challenge heteronormativity, and the systematic oppression of those who do. While my focus is on these two types of gender oppression/privilege, it is important to also acknowledge that they interact with other types of oppression and privilege, such as that based on race or class. Race and class (and other bases on which our society discriminates) would be on axes perpendicular to the gender oppression plane.


Figure 1. Gender oppression plane. Privilege and oppression based on gender category interact with that based on gender conformity/transgression.

My theoretical framework is a critical one, since I am interested in issues of privilege and oppression, and especially how those are operationalized by those who have power (such as instructors and administrators). The four pillars of my theoretical framework are the gender-oppression matrix (Rands, 2009), feminism, queer theory, and gender performativity theory. Feminism is concerned with the gender category axis of the gender oppression matrix, and queer theory is concerned with the gender transgression axis of the gender oppression matrix. Gender performativity theory helps to explain where an individual might be situated on this plane, and how that position may change with context, time, or circumstances.

Judith Butler (1993) conceives of gender as performativity, an idea which I incorporate into my own framework. In this theory, one's gender presentation is an act of communication, both conscious and unconscious, but always present and always political. It is likely to be dynamic rather than static. But like any act of communication, it is dependent upon the reception and subsequent interpretation

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

of social signals as much as upon the sending of those signals. Thus, the gender attribution is dependent upon the observer as much as the actor.

Methods

Narrative inquiry is a type of qualitative research that focuses on telling the stories of people's lived experiences, or their biography. In narrative inquiry, the focus is on empowering the research subject – not as someone who is subjected to research, but as a subjective human being whose experiences are considered to be valuable (Chase, 2011).

Participants

My participants will be individuals whose gender presentation has significantly changed during their experiences in STEM education. This may include gender nonconformists as well as transgender students. I will primarily recruit graduate and undergraduate students, but I also welcome the participation of transgender faculty members in STEM fields and recent alumni of STEM programs. I will use snowball sampling, relying heavily on gatekeepers and insiders in the LGBTQ community, similar to the process described by Winkle-Wagner (2009).

Data Sources and Collection

I will draw from a series of three open interviews with each participant and reflective journals in order to help construct my participants' narratives. I will conduct three phenomenological interviews with each participant, as in Seidman (2013). Each interview will focus on a different time period: the first focused on the past, the second focused on the present, and the third focused on the future and connections across time. I expect each interview to be approximately 90 minutes long. For the reflective journals, I will provide prompts, such as, "What does it mean to be treated as a man in STEM education? What does it mean to be treated as a woman?" Participants will also be free to write about topics other than the prompts. These will be completed between interviews. All interviews will be audio-recorded in order to capture the exact words of the participants as exactly as possible.

Data Analysis

All interviews will be transcribed and reviewed by the participants for the faithfulness of the interpretation. I will use the restorying process described by Cresswell (2008). This process involves three steps. First, the researcher transcribes the interviews. This is the raw data. Second, the data is re-transcribed with codes added for each element of the story: setting, characters, action, problem, and resolution. Finally, the researcher presents these key elements in a sequence, such as setting, characters, and then events in chronological order. I will debrief with peers and conduct member checks for the themes, in order to ensure that they are both analytically rigorous and true to the intended meanings of the participants.

My research will be framed by Clandinin and Connelly's (2000) three-dimensional space of narrative inquiry as consisting of interaction, continuity, and situation. These are derived from Dewey's theory of experience. Interaction entails both the personal and the social. This involves movement inward and outward: inward toward internal conditions, and outward toward the environment. Continuity entails the past, present, and future. This involves movement forward and backward, chronologically. Situation entails place. This involves the physical and cultural locations of participants. Researchers can look at any of these dimensions individually, or at the intersections of them. This could include intersections within a dimension as well, such as the intersection of the personal with the social. Since it is a critical study, I will pay particular attention to any actionable findings, such as institutional bias that could be remedied by a change of policy. Participants will also have the chance to reflect on the final version of the narratives and discussion, particularly

because confidentiality may be an important concern for them, but also because I want to include their opinions on the final analysis.

Conclusion

This study will shine a light on a neglected area of study, the experiences of transgender students in STEM education. I will use a critical lens informed by feminism, queer theory, and gender performance theory to investigate issues of privilege and oppression associated with gender category and gender transgression. By telling these stories, I hope my audience will question the border between male and female and gain more respect and understanding for those who cross that border.

Parents, K-8 teachers, and 4th-8th grade children partnered as learners in math-focused parental involvement through the Math and Parent Partners (MAPPS) program. We hypothesize that participation in MAPPS improved parent attitudes towards mathematics motivating children to learn at school.

Keywords: Informal Education, Affect, Emotion, Beliefs, and Attitudes

Background and Research Questions

Low parental involvement in disadvantaged schools has been related to a gap in mathematics achievement (Jackson & Remillard, 2005) while strong parent-child communications and parents' aspirations for their children's mathematics education have been found beneficial for student achievement (Aldous, 2006; Robinson & Harris, 2014). A school district and university in the Southeast partnered to boost student achievement in Title I schools through the Math and Parent Partners (MAPPS) Program. Knapp, Jefferson, and Landers (2013) found standardized test scores to rise significantly over a three year period for those participants attending regularly for at least one Minicourse. To build on this result, we ask, *How might improvement in student understanding and achievement occur within a standards-based mathematics PI program such as MAPPS? In particular, do parents' attitudes related to mathematics improve?*

Theoretical Framework: Funds of Knowledge

From its inception, MAPPS has been grounded in the socio cultural theory of Funds of Knowledge/Communities of learners (Rogoff, 1994; Allexsaht-Snider & Bernier, 2003). The assumption that families possess bodies of knowledge used for daily living, "is critical in terms of reconceptualizing households, not as the source of barriers to educational attainment, but as repositories of resources that can be strategically tapped" (González, 1996, p. 3). Civil (2007) refers to these resources as "Funds of Knowledge". According to Civil, Funds of Knowledge build on students' and parents' knowledge and experiences as a resource for schooling and values community-based teaching as well. Such Funds involve pedagogically mathematizing household knowledge such as carpentry, repair, or folk medicine for classroom use.

Participants and Context

In this vein, the Math and Parent Partners (MAPPS) program engages parents in mathematical tasks to equip them as mathematical resources for children and schools. The five-part MAPPS curriculum was developed with National Science Foundation project ESI-9901275 funding K-8 parents to collaboratively explore mathematics learning at school as well as connecting to parents' existing Funds of Knowledge. A particular MAPPS program located in the Southeast invited all parents, instructional staff, administrators, and children from certain schools to participate in the study (Knapp, Jefferson, & Landers, 2013). Children in 4th-8th grade accompanied their parents for Mini-courses comprised of eight weeks in two hour sessions while young children participated in childcare with mathematical activities and games. Eight separate Mini-courses on number, geometry, algebra, and data were offered over the course of three years. Instructors were practicing teachers studying mathematics education. MAPPS Mini-course structure followed the National Council of Teachers of Mathematics (2000) process standards by engaging participants in content

and pedagogy through learning communities of parents, children, and teachers to solve tasks, use manipulatives, and present solutions to the entire group (Knapp et al., 2013). In total, 59 parents, 33 teachers, and 115 children from four main Title I elementary schools attended at least one Mini-course on a regular basis. About double attended less regularly. Most attendees were single mothers and held low-income jobs. They were approximately 40% Caucasian, 40% African-American, and 20% Hispanic.

Methods, Data Analysis, and Coding Tallies

Impacts of the MAPPS Mini-courses were ascertained through pre/post attitude inventories taken by parents and teachers. A focus group of parents, teachers, and children also participated in 95 pre/post interviews lasting approximately 15 minutes probing for improvement in mathematical knowledge and on parents' ability to assist their children in mathematics. Interviews were coded for factors that might affect their mathematics achievement, including aspects of the home environment related to Funds of Knowledge. Code identification examples are given in bold in the results section. After coding the interviews and pre/post surveys, we tallied the 59 codes to identify areas of participant growth as well as factors prompting that growth. For quantitative attitude analysis, the researchers administered a modified version of the Attitudes Toward Mathematics Inventory (ATMI) (Tapia & Marsh, 2004) to parents and teachers before and after each Mini-course. The inventory consisted of 25 items to reflect five affective mathematics dimensions (confidence, anxiety, value, enjoyment, and motivation). The ATMI was found to be reliable (alpha = .948) for parents and teachers. Parents were asked to rate statements such as "Mathematics is a very interesting subject" on a Likert scale (Tapia, 1996). Attitude surveys were analyzed using paired samples *t*-tests. This mixed methods study was of quasi-experimental design as parents self-selected to the program.

Results and Discussion

Question #1: How might improvement in student understanding and achievement occur?

The MAPPS **learning community** environment yielded many benefits. First parents, teachers, and children assisted one another in learning mathematics. At times**, children helped parents** figure out problems, which became a source of pride and motivation for the children, especially when they could present their solutions to the group. **Enjoyment** of mathematics was the second product of the learning community. "Before you leave, you're laughing because you've learned. The average 8 and 78-year-old learning together," said one parent. She explained that people come to MAPPS for the enjoyment of learning. Children also expressed enjoyment such as in seeing their teacher and parent interact. The third product of the learning community included **motivation**. The learning community motivated parents to increase parent-child interaction around mathematics as they observed other parents engage with their children. As one parent put it, she was motivated to explicitly budget time at home for helping her child with mathematics. Motivational factors for children included 1) parental presence at MAPPS, 2) parental interest in what the children were doing, 3) a non-traditional, ungraded learning environment at the university, and 4) a location that they found exciting. Seeing their parents **value mathematics** also motivated children to value it. The MAPPS-fostered learning community among parents, teachers, and children motivated children not just to learn mathematics at MAPPS and at home, but in school as well. One teacher reported:

> I think as they [children] saw things that we did outside of class [at MAPPS] in our class, it motivated them because they could share their experience with their peers. They could say, 'I understand this because I've seen it before.' It built their confidence because when they knew how to do something, people [MAPPS participants] looked to them for help.

A child expressed her gained mathematical confidence and motivation by saying, "You would get smarter and feel more confident. You would just have fun with that". Thus, parental involvement in mathematics along with the MAPPS learning community appeared to spawn increased motivation and confidence for children to learn in the school setting. Analysis of the qualitative data appears to show that the MAPPS environment improved classroom learning for children, an improvement which may have impacted student achievement over time.

Question #2: Do Parents' Attitudes Related to Mathematics Improve?
The quantitative attitude survey supports the qualitative evidence gathered about improved **confidence** and **motivation** of parents with respect to their own mathematics learning and teaching of their children. Mean **attitude** scores improved during most sessions (See Table 1).

Table 1: Parent and Teacher Attitude Surveys- Mean Scores out of 125

	n	Pre	Post	Change
2008-2009 Session1	18	100.5	101.6	1.1
2008-2009 Session 2	32	97.2	98.6	1.4
2009-2010 Session 1	24	90.7	85.5	-5.2
2009-2010 Session 2	20	92.6	98.3	5.7
2010-2011 Session 1	4	90.8	95.0	4.2
All years 1st Mini-course taken	65	93.0	94.2	1.2
All years 1st-Last Mini-course	65	93.6	96.2	2.6

Parents showed improved attitude toward mathematics when comparing the first time the inventory was taken to the last (some participants took several Mini-courses and thus took the survey multiple times) ($p = 0.101$, $d = 0.160$). Adults (parents and teachers) analyzed together improved significantly when comparing the first time they took the inventory to the last ($p = 0.084$, $d = 0.125$). We chose *alpha* = 0.1 as the limit level due to the small sample size. Thus for the p-value of 0.101, we have moderate evidence to say it is significant and the p-value of 0.084 is considered significant (Borenstein, 2012). An increase in parent attitude toward mathematics may have contributed to the improved motivation of children to learn mathematics (See Table 2).

Table 2: Parent and Teacher Attitude Scores- 125 points possible

	n	Pre	Post	Change	Result
1st-Last Mini-course Parents	46	93.6	96.2	2.6	*p*=.101
		sd	sd		*d*=.160
		14.1	11.3		
1st-Last Mini-course Parents & Teachers	65	93.1	95.2	2.1	*p* = 0.084
		sd	sd		*d* = 0.125
		17.7	16.0		

Conclusions
In conclusion, parents' improved attitudes toward mathematics and their confidence in explaining it appeared to impact **parent-child interactions** and thereby impacting student achievement. Parent-teacher relationships forged through the MAPPS learning community also impacted student motivation and consequently sustained mathematics learning. *Children's interactions with parents fueled by the MAPPS learning community prompted children's motivation and confidence to learn mathematics at school, possibly leading to student achievement gains.* The *familial bond* to and with the child may channel motivation to learn mathematics. Indeed, top codes from data analysis

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

revealed improved parent-child interaction around mathematics and parent enjoyment and valuation of MAPPS; certainly children would have picked up on these cues. Through mixed methods, this mid-sized quasi-experiment points to parental attitude toward mathematics as a possible predictor of student achievement. Other possible factors in the study may have been changes in parent and teacher knowledge and parent-child interaction among other factors (See Knapp et al., 2013; Knapp & Landers, 2012). Further quantitative study is needed on larger scale and in multiple contexts relating parent attitude and student achievement. Additionally, a correlation study is needed to compare parental attitude towards mathematics and student attitude toward mathematics.

INTERVENTION IN PARTICIPATION SUPPORTING STUDENTS WITH LEARNING DISABILITIES IN STANDARDS- BASED MATHEMATICS CLASSROOMS

Rachel Lambert
Chapman University
lambertr@chapman.edu

Understanding learning disabilities (LD) through neurodiversity, this literature review found that students with LD were supported towards equal participation in standards-based mathematics through teachers trained in Mathematical Knowledge for Teaching and multi-modal curriculum that was responsive to individual student thinking. Rather than focusing solely on intervention in content, research in the mathematical learning of students with LD must address participation gaps with intervention in participation, striving to deepen the participation of students with LD in meaningful mathematics.

Keywords: Equity and Diversity, Classroom Discourse, Instructional Activities and Practices, Problem Solving

Introduction

Considering the creativity and entrepreneurship of individuals with LD (Von Karolyi, Winner, Gray, & Sherman, 2003), increasing participation of students with LD in these fields will not only benefit those individuals, but society as a whole. Understanding LD as a natural and beneficial aspect of *neurodiversity* (Boundy, 2008), this presentation presents the results of an integrative research review (Torraco, 2005) describing studies that investigated the participation of students with LD in standards-based mathematics classrooms, presenting findings across the studies and future directions for research.

This review takes a sociocultural view of participation as engagement in practices such as discourse and problem solving (Nasir & Hand, 2008). Building proficiency in mathematics for all learners means sustained and deep engagement in practices such as problem solving, reasoning and critique. However, students with disabilities have less access to these mathematical practices (Jackson & Neel, 2006; Kurz, Elliott, Wehby, & Smithson, 2010). Even when students with LD are given access to standards-based mathematics, without additional support, there may exist a *participation gap* between students with and without LD. Differences in participation could account for achievement differences, as participation in mathematical practices predicts mathematical learning (Ing et al., 2015, Webb et al., 2009).

LD can be understood through multiple perspectives. From a medical model, LD is a processing deficit. Through the social model, LD may be better understood as a mismatch between students and inflexible classrooms (Reid & Valle, 2004). LD can be understood as interactional in mathematics, produced through a series of iterated interactions that position learners in relationship to mathematics (Lambert, 2015; Heyd-Metzuyanim, 2013).

To be included in this integrative research review, studies need to be 1) standards-based mathematics curriculum, 2) a naturalistic classroom setting rather than a separate intervention, 3) include students with documented LD and 4) qualitative data on student participation. Studies were found through searches of "special education" and/or "disability" in combination with any one of the following terms: "participation," "mathematical practices," and/or "engagement."

Findings

In a study of the participation of students in a standards-based mathematics curriculum, students with LD did not participate in whole group mathematics discussion, and tended to focus on non-mathematical tasks such as materials management during small group work (Baxter, Woodward, &

Olsen, 2001). In another study, students with LD were called on fewer times than other students, and were less involved in small group work (Bottge, Heinrichs, Mehta, & Hung, 2002). After documenting this disparity in participation, both the research teams led by Baxter and Bottge designed future studies to explore increasing engagement and participation of students with LD in standards-based mathematics (Baxter, Woodward, & Olson, 2005; Bottge, Rueda, Serlin, Hung, & Kwon, 2007). Instead of designing intervention only in specific mathematical topics, they designed *intervention in participation*.

While some research studies offered evidence that students with LD were not participating equally in standards-based mathematics (Baxter et al., 2001; Bottge et al., 2002), other studies offered evidence of promising practices to deepen the participation of students with LD (Baxter et al., 2002; Bottge et al., 2007; Foote & Lambert, 2011; Moscardini, 2010). Some of these studies offered glimpses of classrooms in which participation in mathematical discussion and problem solving could not be predicted by whether or not a student had a disability.

The design of curriculum may be critical. Students were supported in standards-based mathematics classrooms in which they were presented with tasks that offered multiple solution paths (Bottge et al., 2007; Foote & Lambert, 2011; Moscardini, 2010). Students were supported by curriculum that was responsive to student thinking, so that teachers designed the tasks based not on a predesigned sequence but on the current understandings of their students (Carpenter et al., 1999/2014). Students were supported when mathematics curriculum provided multi-modal representations of content, and multiple ways of engaging in mathematical activity (Baxter et al., 2005; Bottge et al., 2007; Foote & Lambert, 2011).

These studies suggest that teacher moves are critical in increasing student participation. While some studies documented significant differences in participation between students with LD and those who were not (Baxter et al., 2001; Bottge et al., 2002), there were classrooms in which participation was equalized (Foote & Lambert, 2011). In these classrooms, teachers supported student problem solving through strategies such as supporting student participation in discussion. Other strategies included rewording problems during problem-solving (Moscardini, 2010) and supporting equity in small group work (Bottge et al., 2007). Teachers supported the equal participation of students with LD by giving equal status to presentations that included the notebook and manipulatives as supports (Foote & Lambert, 2011). Researchers noted that consistency in classroom routines may have increased the participation of students with LD.

Effective use of teacher moves are predicated on mathematical knowledge for teaching (MKT) or developing understanding of how learners come to understand complex mathematical ideas (Hill, Rowan, & Ball, 2005). All studies that reported successful participation of students with LD either provided professional development in MKT for teachers, or used teachers with already developed MKT. The issue of MKT is particularly relevant to special education. Special education training for teachers has long focused on understanding learner characteristics rather than content-specific pedagogy (Woodward & Montague, 2002). Based on their training, special education teachers often see pedagogy as generalized strategies that work across content areas, such as using flashcards to support memorization both for math facts and letter recognition. These generalized strategies are quite different from discipline specific strategies, such as in mathematics, supporting students' ability to build on known facts using the properties of operations. This situation continues even as research in mathematics education has demonstrated the importance of MKT for effective mathematics teaching (Hill et al., 2005). The studies reviewed here suggest that shifts in the training of special education teachers could allow students with LD greater access to successful participation in standards-based mathematics. While special education teachers are not trained sufficiently in MKT, general education teachers report being underprepared for including students with disabilities in their classrooms. Moscardini (2013) found that the general education teachers in his study reported that basing instructional decisions on the thinking of children was more effective with students with

learning disabilities, and these general education teachers reported being more receptive to including learners with disabilities in their mathematics classrooms.

Research in the mathematical learning of students with learning disabilities must focus attention on *intervention in participation*. This review included only a small number of studies that suggest a future direction for research in this area. Such research could provide a much needed focus on what learners who are labeled LD *can* do within standards-based mathematics, rather than what they *cannot* do. With increasing evidence that such students can construct effective strategies on their own (e.g. Peltenburg, Heuvel-Panhuizen, & Robitzsch, 2012), educators can no longer assume that standards-based mathematics will not work for these students based on perceived deficits. Nor can we assume that simply including students with learning disabilities in standards-based mathematics classrooms will lead to higher achievement. Instead, we must learn more about how to support all learners for full participation in standards- based mathematics classrooms. These supports are likely to be helpful for a wide range of learners, assisting teachers in making standards-based mathematics more equitable for all.

PARENTS' INVOLVEMENT IN EARLY YEARS MATHEMATICS LEARNING: THE CASE OF JAPANESE IMMIGRANT PARENTS

Miwa Aoki Takeuchi
University of Calgary
miwa.takeuchi@ucalgary.ca

A meaningful collaboration between schools and homes can enhance students' opportunities to learn mathematics. The goal of this study is to understand how parents experience their involvement in children's mathematics learning and how they describe their relationships with schools and teachers. This study utilizes the data collected from semi-structured interviews with Japanese immigrant families in Canada. Findings identified active parental involvement in children's mathematics learning among this population. At the same time, findings also suggested the invisibility of school mathematics learning for those parents. This study proposes creating boundary objects that can meaningfully bridge homes and schools.

Keywords: Equity and Diversity, Informal Education

Background and Literature Review

Parents can influence mathematics education, especially in a child's early years and in elementary schools. For example, in Canada, which is the context of this study, a group of parents recently organized a petition to the Alberta government to push mathematics curriculum "back to basics" (Tran-Davies, n.d.). Understanding parent's discourse surrounding mathematics learning is important for mathematics teaching.

This study investigates how parents experience their involvement in children's mathematics learning and how parents, particularly immigrant parents in this case, describe their relationships with schools and teachers. Previous research tells us how certain forms of parental involvement affect students' academic achievement in school (Galindo & Sonnenschein, 2015; Organisation for Economic Co-Operation and Development, 2012). According to those studies, influential forms of parental involvement include engaging in discussions that facilitates critical thinking and setting a good example for academic engagement. Because parental involvement can affect students' academic performance, it is important to identify how parental involvement at home is promoted or hindered.

The current study focuses on Japanese immigrant families living in an urban city of Canada. Previous studies on the topic of immigrant parents' engagement in mathematics learning shed light on immigrant parents' mathematics knowledge and resources embedded in their cultural practices (Civil, 2007; Willey, 2008). This line of research has also highlighted the conflicts and struggles that immigrant parents experience in their relationships with schools (Abreu & Cline, 2005; Civil & Bernier, 2006; Crafter, 2012). This study adds a new cultural and historical context to this body of literature. Based on the experience of Japanese immigrant families, I will explore possible ways to facilitate a meaningful collaboration between homes and schools.

Theoretical Framework

In order to investigate the relationship between schools and homes/communities for students' mathematics learning, I will examine the presence or the lack of boundary objects. The concept of boundary objects was proposed by Star and Griesemer (1989) and defined as:

> Boundary objects are objects which are both plastic enough to adapt to local needs and the constraints of the several parties employing them, yet robust enough to maintain a common identity across sites. (…) They have different meanings in different social worlds but their

structure is common enough to more than one world to make them recognizable, a means of translation. The creation and management of boundary objects is a key process in developing and maintaining coherence across intersecting social worlds (p.393).

Boundary objects can connect communities together for a common goal (Wenger, 1998). Boundary objects allow us to examine how collaboration among different parties become possible without a prior consensus (Star, 2010).

Method and Methodology

The data are derived from the ethnographic study I conducted with Japanese immigrant families in an urban city of Canada. Here I focus on findings gained from the interviews with 14 Japanese parents, first generation immigrants to Canada. All the parents were raising school-aged children. Each interview lasted approximately 60 minutes and elicited backgrounds of the parents (education, language, and immigration), involvement in children's school education, education at home, mathematical cultural practices in which parents were involved in Japan and in Canada, and sense of belonging and social networks in Canada.

For the current analysis, I focused on the following two aspects described in the interview: 1) how parents were involved in their children's mathematics learning at home and 2) how parents described their relationships with their children's schools and school teachers. The following findings section is organized around these two aspects and I will first describe how the participants in this study were involved in their children's mathematics education. Subsequently, based on the concept of boundary objects, I will discuss whether and how boundary objects existed between schools and homes for immigrant families.

Drawing from the framework of Discourse (with a capital D) proposed by Gee (1990), my analysis focuses on identifying common threats that characterizes the collective discourse of Japanese immigrant parents living in Canada. Discourse recognizes that people's ways of talking and acting signifies their involvement in certain social groups. By using Discourse as an analytic tool, I tried to shift my focus from individuals who speak, to socially and historically defined discourses identified in Japanese parents' accounts on mathematics teaching and learning.

Findings

Overall, Japanese parents in this study were actively involved in their children's mathematics education at home and in their community. There were forms of parental involvement described both at the community level and at the individual level. At the community level, Japanese immigrant parents were organizing space for children to learn arithmetic. Many elementary school children were learning to use the Japanese abacus in informal settings, from Japanese immigrant parents. One of the teachers (who is also a parent) of the community abacus class explained that the class started spontaneously based on the needs from parents. The teacher/parent also explained that it was a way of making a contribution to the community: "My strength I can use to contribute to the Japanese Canadian community is abacus, so…(laughter)." In addition to teaching abacus and arithmetic, parents also hoped to teach Japanese language through the abacus classes. The arithmetic children learn at the abacus class is advanced, compared to the regular school curriculum. For example, when I visited one of the abacus classes, Grade 3 students were working on 6-digit multiplication.

Similarly, at the individual level, many parents were teaching mathematics by using Japanese mathematics textbooks or workbooks that they brought back from Japan. Parents were concerned that their children might fall behind academically due to their limited exposure to English at home. They decided to provide additional support to enrich their children's mathematics learning opportunities. For example, a parent explained, "I was concerned that my children might academically suffer or might come to dislike school because their English is not strong. So, I wanted to teach mathematics

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

even for a bit, for them to gain confidence academically, even when they don't understand English well."

Overall, parents in this study were actively involved in mathematics teaching at home. At the same time, they expressed concerns regarding the disconnection between home and school. One of the concerns was the difference in mathematics pedagogy between what parents experienced in Japan and what their children were learning in Canada. For this issue, a parent said, "In Canadian schools, I don't think they place so much value on quick computing, because computation is just a tool. It's more important to know how to use the tool and why the particular tool is used in a particular situation."

At the same time, parents felt there were limited opportunities to learn about what children are learning at school. For all the parents in this study, school mathematics was invisible in Canada. Recalling the Japanese education system, parents named several culturally-specific practices that made Japanese school curriculum visible to parents. For instance, there were opportunities for parents to join a regular class to observe (*jyugyou sankan*). During these occasions, teachers often explained the curriculum and pedagogical goals to parents. Also, in Japan, each child receives a textbook and studies at home. Parents and children are generally able to communicate about what is learned at school, via textbooks (if parents and children have the time and capacity to do so). Most of the parents in this study were interested in supporting their children's academic success, especially in mathematics in early years. However, they felt limitations in supporting their children because they did not have a clear idea about the curriculum and pedagogy at school. All the parents I interviewed felt these culturally-specific practices were missing in Canadian contexts and the lack of these practices were contributing to the invisibility of school mathematics for parents.

Discussion and Implications

Parents in this study were actively involved at home and in their communities to support children's learning mathematics, especially during the early years. Parents' academic involvement tended to focus on number sense and computation, as represented in the community abacus classes. Some parents were concerned about the pedagogical gap between what children are learning at school and what they are teaching at home and in the community. All the participants expressed the invisibility of school mathematics due to the lack of organized practices, which could help to make school mathematics visible to parents. This finding is compelling especially that parents can have considerable impact on mathematics curriculum and pedagogy. This finding suggests the need to build a bridge between schools and homes/communities and to facilitate a dialogue between teachers and parents.

Designing boundary objects is one way of filling this gap. Parents' interviews in this study revealed some effective boundary objects they observed in Japan. For example, *jyugyo sankan* (lesson observation) can allow teachers to explain and enact their teaching philosophy and curriculum goals by going through the details of a lesson. Communicating via textbook is another example. Parents hoped to learn more about what children were learning at school so that they could provide appropriate academic support to them. As Stigler and Hiebert (1998) maintain, teaching is a cultural activity that is situated and deeply rooted in history, policy and everyday practices. It will be important to understand the history, policy and practices that surround these boundary objects. Designing boundary objects that can bridge homes, communities and schools in a meaningful way can enrich the dialogue and collaboration for students' mathematics learning.

This study examined a new context, which has not yet fully been investigated in the body of immigrant parents' engagement in mathematics (e.g., Abreu & Cline, 2005; Civil & Bernier, 2006; Civil, 2007; Crafter, 2012; Willey, 2008). Several unique issues were revealed through this study on Japanese immigrant parents living in Canada. One of the issues was discussed above and all the parents in this study acknowledged the boundary objects that could bridge homes and schools, by

referring to their experiences in Japan. Another interesting initiative observed in this community was the abacus classes that parents organized. Further examination will be beneficial to understand how these children experience mathematics learning across the mainstream mathematics classes in Canada, the community abacus classes and learning at home.

WHAT CONTRIBUTES TO POSITIVE FEELINGS TOWARDS MATHEMATICS?: EXAMINING MATHEMATICS AUTOBIOGRAPHIES

Miwa Aoki Takeuchi
University of Calgary
miwatakeuchi@ucalgary.ca

Jo Towers
University of Calgary
towers@ucalgary.ca

Lyndon Martin
York University
LMartin@edu.yorku.ca

In this paper, we present how the participants in our study (post-secondary students) described what contributed to fostering their positive feelings towards mathematics. Drawing from mathematics autobiographies completed by the participants, we present some of the contexts wherein participants described positive feelings toward mathematics. We discuss a) encounters with teacher dispositions and pedagogical practices, b) experiencing the joy of engaging in mathematics, and c) external validation from teachers and parents, and consider whether each of these contexts sustained participants' positive feelings towards mathematics.

Keywords: Affect, Emotion, Beliefs, and Attitudes

Literature Review and Theoretical Framework

The interplay between the affective domain (beliefs, attitudes, and emotions) and teaching and learning mathematics has been explored over the past 30 years. Many of the studies investigating affect and mathematics in the field of cognitive psychology tend to focus on negative aspects, such as "math anxiety," associated with mathematics (e.g., Ahmed, Minnaert, Kuyper, & van der Werf, 2012; Young, Wu, & Menon, 2012). Also, when conducting large survey-based studies on the affective domain of mathematics learning (e.g., Vandecandelaere, Speybroeck, Vanlaar, De Fraine, & Van Damme, 2012), treating emotion as fluid, dynamic and changing becomes a methodological challenge so the construct tends to be portrayed in static ways and as an attribute of an individual. As Di Martino and Zan (2011) maintain, the mathematics education community tends to treat emotion in a more holistic way by considering a wider range of emotions and the importance of social aspects. For example, researchers in the mathematics education community pay close attention to the conditions and instructional contexts in which students' emotions towards mathematics can be changed (e.g., Evans, Morgan, & Tsatsaroni, 2006; Hannula, 2002). However, such investigation is still often limited to single case studies.

Our study further extends these earlier investigations by analyzing a large number of autobiographical narratives from Kindergarten to post-secondary level students. In this paper, we focus in particular on the data from participants enrolled in post-secondary level education, in order to give us a longer-term view of the contexts that influenced students' feelings about learning mathematics in schools and the factors that helped them to sustain positive feelings into their post-secondary years. Because the majority of research on emotions and mathematics, especially when drawing from a psychological paradigm, focuses on negative emotions, we hoped to examine other aspects of emotions, such as positive feelings and a change in feelings.

This research is framed by enactivism, a theory of embodied cognition that emphasizes the interrelationship of cognition and emotion in learning (Maturana & Varela, 1992). Enactivist thought reorients us to the significance of this mathematical milieu in shaping not only what students learn in school but also their emotional connections with the discipline.

Method

This study is part of our larger project, which investigates students' experiences learning mathematics in Canadian K-12 schools and post-secondary institutions. The data we present here were gathered by using an online submission form. We asked participants (ages 18 and older) to submit mathematics autobiographies, wherein they described their histories of learning mathematics

and their relationships with the discipline of mathematics. We also asked participants to contribute demographic information including age, gender identity, education history, and current profession. To date, we have analyzed 70 submissions, 48 of which were submitted by pre-service teachers, and 26 are multimodal autobiographies using visuals, sounds, and videos. Our data collection and analysis are still ongoing. The analysis of this paper focuses on positive feelings towards mathematics described by participants. Positive feelings were coded when linguistic markers to describe positive emotions (e.g., "like" "love" "enjoy") were used.

Findings

In this section, we present how the participants described the factors that contributed to fostering their positive feelings towards mathematics. Mainly, participants described a) an encounter with particular kinds of teacher dispositions and pedagogical practices, b) experiencing the joy of engaging in mathematics, and c) external validation from a teacher and parents.

Encounters with Teacher Dispositions and Pedagogical Practices

One of the recurring themes was how teachers made an impact on participants' feelings towards mathematics. Many participants acknowledged teachers who appreciated various ways of solving mathematical problems rather than strictly following a set of predetermined procedures. For example, a participant said: "The best teachers I had for math taught to my learning style (and this happened rarely). For me, math is highly intuitive, and I loved the idea that math answers could be arrived at using different methods." Other aspects of teaching that changed participants' disposition towards mathematics were teachers' commitment to students' success and providing sufficient help when needed. A participant recalled high school mathematics classes and said, "At lunch one could frequently find students from both classes crammed into his (the mathematics teacher's) classroom, clamouring for help."

Teachers' dispositions toward mathematics can also influence students' feelings. The following description, by a participant who considered herself to be "math anxious," is informative in showing how teaching approaches can make a difference in students' feelings.

> Specifically, I LOVED algebra!….I remember when Ms. W. spoke about algebra. She reminded us throughout the unit that doing algebra is like doing a puzzle; have fun with it!…Ms. W. had always given us extra time to complete tests, which I needed being the ball of nerves I was and still am. I, the former math anxious student, received the highest grade in the class (92%). More importantly, I approached the test as a puzzle, something I needed to take time with and figure it out. I was given that time. Time to play around with letters and numbers. Time to experiment with math!

This quote shows the significance of a teacher's dispositions towards mathematics—the importance of communicating the joy of mathematics and validating the time in which students "play around with" and "experiment with" mathematics. While many participants acknowledged great teachers, they also described encounters with a good mathematics teacher as a rather rare experience.

Experiencing the Joy of Engaging in Mathematics

In contrast with findings from our Kindergarten to Grade 9 student dataset where very few participants reported liking mathematics because of an intrinsic appeal (Hall, Towers, Takeuchi, & Martin, 2015), a third of post-secondary participants reported an intrinsic love of mathematics itself. Interestingly, the descriptions of the internal joy of engaging in mathematics described by these participants painted two very different portraits of "mathematics." Some participants conceived of mathematics as a discipline consisting of a set of procedures and correct answers to be discovered and it was this apparently "one right answer" vision of mathematics that they found compelling. The

following quote represents this stance: "I liked that I was given a formula to follow and that there was always only one right answer to each question. Everything was straight forward and to the point in my eye." These participants appreciated how the mathematics with which they engaged at school was "simple" "reasonable" and "concrete." Notably, those who perceived mathematics as a set of procedures did not further pursue a post-secondary degree that heavily involves mathematics.

Others perceived mathematics to be like a "puzzle," "an elegant language," "something beautiful," and "patterns." Many of these participants further pursued a post-secondary mathematics education through the degrees in the areas of engineering, astrophysics, biology, chemistry, and computer sciences. For example, the following quote is one representation of this group of participants: "I have associated mathematics with puzzles.…To me it is a game, with each level of increasing difficulty add[ing] another layer of beauty and technique." For these participants, mathematics was much broader than a set of procedures to follow. Another participant described the joy of mathematics as: "I actually really like doing math; it is an elegant language and I wish I could speak more of it. When I hear the word 'mathematics' I see the Universe and all of the matter within it." It is noteworthy that we observed quite opposite ways of describing the joy of engaging in mathematics among the participants.

External Validation from Teachers and Parents

External validation, appraisal, and positive evaluations received from teachers and parents contributed to participants' positive feelings to some extent. For example, a participant said, "When we had "mad minutes" (a minute to complete a sheet of multiplication questions) in grade three, I always tried to be the first one done." For some participants, the speed with which they could operate computation was rewarded in school and that contributed to their positive feelings towards mathematics. But the feelings of excitement were inconsistent for these participants. For example, the same participant said, "in Grade two, I couldn't understand at first how to subtract numbers and 'borrow' ones...I was just about in tears and felt really stupid." This participant associated her confusion with her identity. Similarly, when participants were relying on external validation from others, positive feelings towards mathematics could be easily swung to become negative ones.

> As a mathematics student in elementary school I remember liking mathematics because I liked solving problems and I was quite good at it. In junior high, I liked math even more because my family was amazed that I was able to get quite good marks in math.…I kept persisting in achieving high marks because I liked the acknowledgement that I received from teachers and my family.

This participant's grade dropped in Grade 12 and she received 65%. She said she "was very ashamed of this grade" and "I discovered that math no longer had a purpose in my life, so the hard work needed to get through the class didn't feel worth my time anymore." As clearly described in this case, positive feelings about mathematics backed up merely by external validation could be drastically changed to negative feelings towards mathematics as soon as the external validation of good marks and acknowledgement from others disappeared.

Discussion and Implications

Our analysis adds to the existing literature by detailing some of the factors contributing to students' positive relationships with mathematics. This analysis adds to earlier investigations on the complexity and dynamics of emotion (e.g., Evans, Morgan, & Tsatsaroni, 2006; Hannula, 2002) by demonstrating that an encounter with a mathematics teacher, who embodies the joy of mathematics and encourages students to explore and experiment with mathematics, can affect students' feelings towards mathematics in a positive way. However, we also came to learn that such an encounter was described as rather rare. In addition, our study suggested that positive feelings backed up merely by

external validation from teachers and parents could easily shift to negative feelings in the absence of such validation. This finding suggests the significance of teacher education where teachers can foster a wider range of mathematical dispositions and teaching methods that can positively influence students' relationships with mathematics.

Our study also suggests the importance of attending to the details and contexts when participants describe positive feelings towards mathematics. For such investigations, participants' autobiographical narratives provided contextualized accounts of how participants' feelings have changed over time and whether participants pursued mathematics-rich further education and careers. Our analysis revealed that those who enjoyed mathematics because it was perceived as straightforward, simple, and a set of procedures, did not further pursue post-secondary mathematics education. In contrast, those who were attracted by its beauty, challenge, and elegance further pursued mathematics. This is an important finding that should be further explored by mathematics education researchers.

TEACHERS REPORT FREQUENT INTERACTIONS WITH STUDENTS TO EVALUATE PROGRESS

Ahmet O. Akcay	Rachel A. Ayieko	Elif N. Gokbel
Duquesne University	Duquesne University	Duquesne University
akcaya@duq.edu	ayiekor@duq.edu	karalie@duq.edu

Formative assessment during instruction makes a difference in students' learning outcomes (Black & Wiliam, 1998) and provides information about students' learning needs, learning styles, and development that can be used by teachers to adjust their instruction (Greenstein, 2010). Additionally, Black and Wiliam (1998) concluded that effective learning is based on active student classroom involvement. "Learning requires active and frequent interaction between teachers and students" (Black et al. 2004, p.47). In particular, teachers should determine effective teaching strategies for their students' learning needs and discuss these strategies with the students so as to maximize the quality and quantity of student achievement.

This poster provides preliminary findings of the relationships between teachers' reports on their frequent interactions with students to evaluate students' progress and algebra achievement. The data was withdrawn from the National Assessment of Educational Progress (NAEP) data across selected ten states between the years from 2009 to 2015. The dependent variable was the eighth-grade students' average algebra scale scores. The independent variables are the teachers reports on the frequency of interacting with individual students to evaluate their progress in mathematics, in the following activities: (a) Determining how to adjust teaching strategies to meet student's current learning needs and to reflect student's future goals (b) Discussing student current performance level (CPL)". The responses were given on a 5-point Likert scale: Never or hardly ever (1), a few times a year (2), one or twice a month (3), once or twice a week (4), every day or almost every day (5). Also, "teachers were asked to specify the frequency with which they interact with students in various ways to evaluate their progress" (Coley, 2010, p.9).

A one-way analysis of variance (ANOVA) was conducted to examine the differences in the students' algebra scores based on the frequency of teachers' interactions. There were no significant differences in the frequency of interacting with individual students to evaluate their progress in algebra, in the following activity: "determined how to adjust teaching strategies to meet student's current learning needs and to reflect student's future goals". However, there was a significant difference in eighth grade students' algebra scores based on the teachers' frequency of discussion of students' CPL. Notably, the eighth grade students whose teachers never discussed students' current performance level had significantly lower algebra scores when compared to students whose teachers discussed students' current performance levels "a few times year, one or twice a month, one or twice a day", or "every day or almost every day".

EXPLORING COLLECTIVE CREATIVITY IN ELEMENTARY MATHEMATICS CLASSROOM SETTINGS

Ayman Aljarrah
University of Calgary
aaljarra@ucalgary.ca

In the field of education, and following the argument that students will need to be better equipped to successfully navigate the increasingly complex and ill-defined nature of life in the twenty-first century (Wells & Claxton, 2002), there is full agreement on the importance of creativity, and the need to reconceptualize pedagogy for purposes like teaching for creativity, learning creatively, and promoting creativity in classroom settings. But for such reconceptualization to be possible and applicable, it is important for us as researchers and educators to understand the nature of creativity in classroom settings, and to develop a description of it as it may emerge in such settings.

Although scholars in pedagogy, mathematics education, and teacher education have generated a good literature based in promoting learning for individual creativity, the fostering of individual creativity, and characterizing mathematical creativity, only a few of the current definitions for creativity are suited to the distributed and collective enterprise of the classroom. This claim doesn't mean that earlier accounts are wrong nor are they unfruitful, on the contrary they do provide food for thought on creativity. They may be just incomplete, given that they mostly restrict themselves to one path, or one vision, or one description, or one experience of creativity.

For the purpose of overcoming such an incompleteness, and based on the claim that doing and understanding mathematics are creative processes that should be considered at both the individual and the collective levels (Martin, Towers, & Pirie, 2006), my study explores possibilities and potentials of integrating a combination of theories related to creativity and theories related to collectivity with other teaching and learning practices in mathematics classroom settings in order to: investigate the nature of collective creativity in mathematics learning, offer needed empirical findings concerning collective creativity in elementary schools, explore ways in which collective creativity might be fostered in such settings, and generate understandings about the role of teachers in this endeavor. Collective creativity in elementary mathematics classroom settings is investigated in the classroom within a problem based curriculum, using a design-based research methodology.

My study is driven by the following questions: 1) what can be learned from the process of developing and refining an emergent definition of collective creativity for the elementary mathematics classroom? 2) Does collective creativity emerge in elementary mathematics classroom settings? 3) How can we foster collective creativity in elementary mathematics classroom settings? 4) And what is the teacher's role in fostering collective creativity?

DEVELOPMENTAL MATHEMATICS STUDENTS' AGENCY IN AN IN-CLASS COMPUTER-CENTERED CLASSROOM

Geillan Aly
Hillyer College, University of Hartford
geillanaly@gmail.com

Keywords: Affect, Emotion, Beliefs, and Attitudes, Equity and Diversity, Post-Secondary Education, Technology

Developmental mathematics students in community college, particularly those of color, are disproportionately unsuccessful and fail to reap the benefits of higher education (Bahr, 2008, 2010). Despite the intentions of course instructors, course designers, and students, developmental courses frequently fail to adequately support students. In-class computer-centered (ICCC) classes, where at least 80% of the content is supplied via stand-alone software, are a possible solution to this social justice issue. Such courses provide students with individual pacing and a flexible learning model. However, these courses also limit students' mathematics agency by limiting their ability to demonstrate knowledge. This paradox of limited mathematical agency and unlimited student agency provides a tension likely to yield findings on student actions.

This study explored student actions and behavior to answer the research question *how do disadvantaged students draw upon their experiences to navigate the ICCC classroom to achieve their goals* using agency–defined by Bandura (2008) as the capacity to understand, predict and alter the course of one's life's events–as an analytic framework. Students' past experiences and future goals were considered in the analysis (Emirbayer & Mische, 1998). Using agency in such a manner is novel in mathematics education research, which traditionally explored the type and extent of student agency in mathematics classes. In this study, three students were interviewed and observed working in a developmental mathematics class using MyMathLabs software.

Findings suggest that students established reasonable plans to successfully navigate their courses. However, these plans were based on assumptions, resulting from students' past experiences and ultimately undermined their intentions. These assumptions could have been formed from students' cultural capital not being aligned with the culture of community colleges.

Student success was also adversely affected by the hyper-linear environment where students could not advance in the course if they did not pass their immediate exam. Hyper-linearity prevented students from using later concepts to reinforce and further understand previous ideas, limiting opportunities for students to make conceptual connections.

This research explored how the reasonable design in ICCC mathematics classroom levied a burden on as-yet-unsuccessful students. Eliminating substantial feedback and requiring independent learning for a difficult subject, affected student's overall success, thus preventing them from gaining necessary college-level mathematical skills.

TEACHING ASSISTANTS' AFFECT INFLUENCES STUDENT PERCEPTIONS

Katie Bjorkman
San Diego State University; University of California, San Diego
kbjorkman2@gmail.com

Keywords: Affect, Emotion, Beliefs, and Attitudes, Instructional Activities and Practices, Post-Secondary Education

While graduate teaching assistants (TAs) are usually evaluated by students as part of a course evaluation, these evaluations are often vague or entirely quantitative and may not correlate with student outcomes (Patitsas & Belleville, 2012). While students are known to prefer male lecturers (MacNell, Driscoll, & Hunt, 2014) this may not be the case for TAs (Patitsas & Belleville, 2012). There is a known bias against TAs who are non-native English speakers (Lenio et al., 2014). The present study does not seek to address such biases and does not control for them. The focus of this poster is on student responses to open-ended questions asking students to describe their best and worst TAs. The results should be interpreted in the light of possible actions taken by existing programs to inform a TA selection, training, or evaluation process.

Method

Participants were 78 respondents to an anonymous internet survey sent in the early summer of 2015 to all students enrolled in first-quarter calculus in the fall of 2014 at a large, public, southwestern university, the intervening year assured that most had experienced multiple TA-led mathematics discussion sections at the school. This institution has professor lecturers and utilized TAs for breakout sections. Participants filled out a short survey about their experiences in TA-led mathematics discussion sections including describing what made a TA the "best" or "worst" of the TAs they had experienced. Open coding was utilized for data analysis.

Results

The greatest number of descriptors of best TAs were of personality, TA interest in students and/or the subject, or of the TA's ways of interacting – that is, of affective traits. Similarly, students describing their worst TAs frequently described affective traits such as condescending attitudes. Based on this analysis, it seems that affective and not just didactic or mechanical aspects of teaching and interacting with students would be appropriate to include in both TA training and assessments. The first and second-most mentioned TA factors mentioned – affect and preparedness/clarity– for both positive and negative TA experiences are likely related. If a TA cares about and therefore prioritizes their classes it will be obvious to their students, as will the reverse. It is of note that few students expressed gender, ethnic, or language preferences in this study, instead expressing similar views of action and attitude across TA demographics.

WHAT ABOUT ME? EXPLORING THE IMPACT OF REMEDIAL COURSEWORK ON POST-TRADITIONAL LEARNERS' SELF BELIEFS

John Bragelman
University of Illinois at Chicago
Jbrage2@uic.edu

Setting the Stage

More than 50 percent of students entering two-year colleges are placed into non-credit bearing remedial (NCBR) courses, a large leap over the almost 20 percent placed at four-year institutions (Complete College America, 2012). As community colleges offer flexibility to students who wish to pursue a college education but do not have the financial resources or available time to attend conventional, four-year institutions, they appeal to adults seeking to further their education. The American Council on Education (ACE) defines adult, or post-traditional, learner as the population of working age, adult students (ages 25 to 64).

Post-traditional students seek out community colleges for access and flexibility, and many are placed into non-credit bearing remedial courses, in part due to gaps in their educational careers. This study seeks to understand how NCBR courses affect post-traditional students mathematics self-efficacy and identity, and what relationship, if any, mathematics self-efficacy and identity have with their successes and struggles as they attempt to transition to college-level coursework. Bandura (1977) defined self-efficacy as the beliefs students hold about their academic abilities. Mathematics self-efficacy is the belief a person holds about her mathematics ability. This study draws on the work of Usher and Pajares (2009) to explore mathematics self-efficacy across these domains. Including identity into this analysis allows a broader focus beyond students' beliefs about their academic ability to do math, following Martin's (2000) framework for mathematics identity formation and socialization.

Findings

This poster presents preliminary findings on the effects of remediation on post-traditional students' mathematics self-efficacy and identity. Quantitative results will include changes in self-efficacy using an adapted version of Usher and Pajares (2009) instrument for mathematics self-efficacy ($\alpha = .798$). Results from a repeated measures ANOVA will show that post-traditional students exhibited a significant improvement in mathematics self-efficacy over a 16-week, NCBR course ($F[1,34] = 7.683, p < .01$), with significant differences in the domains of vicarious experience and social persuasion. Relationships to course completion and success will be presented, as well as the impact of the course on enrollment of post-traditional students in a mathematics course for the subsequent semester. Interview results are presented in the form of vignettes, illuminating struggles and successes post-traditional students experience in NCBR courses with the intent that future reform and innovation in remediation include the ever-increasing population of post-traditional students frequently left underserved.

ANALYZING MATHEMATICS IDENTITIES IN AN UPPER-LEVEL UNDERGRADUATE MATHEMATICS COURSE

Elizabeth Fleming
University of Maryland
fleming1@umd.edu

Real Analysis is a course that often presents a shift in content toward constructing definition-based proofs, and is recognized to be a conceptually difficult course (Weber, 2008). At the large U.S. public research university where this study was conducted, it acts as a gateway, as it is the only upper-level course that is required for all mathematics majors regardless of concentration. Given its high stakes, this course offers an important opportunity for examining the development of students' mathematics identities, which may help contribute ideas for both improving student learning and fostering identities of belonging (Solomon, 2007).

This study consisted of classroom observations as well as interviews with 11 students in one section of Real Analysis (initial enrollment of 27 students). All 11 students confirmed the make-or-break nature of the course; as one student described it, "I heard that it is terrible. I heard that it's very hard and very challenging. But the general consensus is, after you've taken it, it's like you're like a veteran math student." This poster specifically examines students' responses to an interview question asked at both the beginning and end of the semester about how they see themselves in relation to mathematics.

First, these data were coded using Anderson's (2007) four faces of math identity (engagement, imagination, alignment, and nature), in order to see generally how students responded to the open-ended question, and what aspects of identity were most relevant to them. All 11 students commented on aspects of *engagement*, largely in positive ways such as "I actually think it would be fun to continue proving stuff in other classes." Interesting differences arose in that juniors in the course tended to focus on *alignment* (e.g., "I'm a real math major now") whereas seniors tended to focus on *imagination* (e.g., "My job isn't going to use stuff from the math major specifically"), suggesting that the course served different roles depending on students' stage in their degree. The *nature* component of students' responses was the most complicated and conflicted, requiring further analysis, and suggesting that students were wrestling with their own narratives about their ability and confidence in mathematics.

Second, students' responses were analyzed for change over time. Students in the pure math concentration and those who were double majors (5 of 11) tended to have the most positive shifts (e.g., "I feel like I can do anything in math now"), whereas students in statistics, education, or who were math minors (6 of 11) expressed decreases in confidence (e.g., "when it comes to this class I don't think I'm good at math"). These findings suggest the need to re-evaluate the structure and goals of critical gateway courses like this one in order to better support students beyond traditional mathematics majors in developing positive and productive math identities.

CLARITY, COMPASSION, INTEGRITY: A MODEL FOR SOCIAL JUSTICE MATHEMATICS PEDAGOGY

Manjula Peter Joseph
University of Wisconsin-Eau Claire
josephm@uwec.edu

Teaching mathematics for social justice is understood in multiple ways - teaching about social justice issues using mathematics, teaching mathematics with a social justice lens, or teaching students to use mathematics to challenge social injustices (Gutierrez, 2002; Gutstein, 2006). In order to do this, besides having fairly in-depth content and pedagogical knowledge, teachers need to be familiar with real-world contexts (Ball, Lubienski, & Mewborn, 2001) and be able to facilitate 'bringing the world into the classroom' (Gutstein, 2006). Teachers often reject the idea because of the perception that paying attention to social justice issues means moving away from rigorous content and academic achievement for which they are held accountable (Erchick & Tyson, 2011). This poster provides findings from a study undertaken to push the boundaries of such perceptions and provide vivid descriptions of effective social justice pedagogical practices.

The Study: Methodology, Context, Data Analysis

A two-year longitudinal ethnographic case study was conducted in a 5th grade classroom in a culturally, ethnically, and linguistically diverse school with 90% low SES students. Researcher provided support to Ms. Lara (pseudonym) in teaching mathematics to ELL students. Ms. Lara is experienced, with Special Education, Educational Philosophy and Montessori Education background. Video-recorded lessons, student work samples, field notes, audio-recorded and transcribed interviews with Ms. Lara provided data. Data were coded using a codebook grounded in research and developed over three studies, covering a range of equitable instructional practices in teaching mathematics for equity and social justice.

Findings

Key features of Ms. Lara's pedagogy surfaced: (a) critical thinking as a personal process; (b) informative assessment; (c) intentionality in knowing students' context, aspirations, and using knowledge to make instructional decisions; (d) building mathematical and social identities; (e) students as locus of authority; (f) attention to "connected knowledge". Findings led to developing the model. (Codebook and framework displayed on poster.) The "codebook" and the framework can inform understanding of and teaching about, with, and for social justice.

VOICES OF MARGINALIZED YOUTH: AN EXPLORATION OF LIMITED CHOICE, HIGH MOBILITY, AND MATHEMATICAL LEARNING

Jennifer Y. Kinser-Traut
University of Arizona
jkinser@email.arizona.edu

Keywords: Equity and Diversity, Policy Matters, High School Education

School choice is touted as a solution to alleviate inequities in students' schooling experiences, but just like in mathematics, inequities persist. School choice can be seen as a way out of under-performing neighborhood schools. However, due to students' and parents' limited knowledge of charter schools and credit recovery schools catering to marginalized students, it can be very challenging for marginalized students to leave an under-performing neighborhood school and transfer into a school of choice (Rangel, 2013). Therefore, as marginalized students try to understand the school choice landscape, they may engage in strings of transfers increasing the chance that they will drop out (Rumberger & Larson, 1998). What is not well understood is the impact transferring has on students' mathematical learning. This poster examines how highly mobile, marginalized youth describe their experiences learning mathematics.

Using an analytic framework that foregrounds students' mathematical empowerment (Alsop, Bertelsen, & Holland, 2006), I analyzed one student's experiences engaging in high mobility and mathematical learning. The data included eighteen study sessions, a pre- and post-interview, and the student's school records. Using interpretive methods, I analyzed talk in each interview transcript, coding for components of my analytic framework, and wrote analytic memos across the data, striving to understand the individual student's empowerment cycles.

In this poster, I will focus on my findings of Felix, a seventeen-year-old junior at the time of the study. He was a Hispanic American who emigrated from Cuba with his parents when he was two. Felix did not receive equitable mathematics instruction, as he was often passed along without learning mathematics. In turn, Felix often experienced mathematical passing empowerment without considering his limited mathematical learning. The opportunity structures of his elementary and middle schools allowed him to "never think about" his mathematical knowledge (post-interview, line 387). When Felix became highly mobile, transferring five times, during his first two years of high school, his limited mathematical empowerment only intensified. It was not until Felix transferred to a charter school of good fit that he was finally mathematically empowered both in terms of learning mathematics and earning mathematics credit. For the first time since third grade, Felix experienced both passing and learning empowerment. In summary, this study sought to reveal some of the challenges highly mobile, marginalized youth face learning mathematics. These findings are important for mathematics educators, policy makers, and school officials as students' mathematical learning experiences are evolving with increased school choice.

BLURRING THE BOUNDARIES BETWEEN HOME AND SCHOOL: SUPPORTING PARENT AND STUDENT LEARNING WITH FAMILY MATH

Michael Lawson
University of Tennessee, Knoxville
mlawso13@vols.utk.edu

Lynn Liao Hodge
University of Tennessee, Knoxville
lhodge4@vols.utk.edu

Keywords: High School Education, Informal Education

Parent involvement has been identified as an important factor in the academic success of students (Sheldon & Epstein, 2005). However, DePlanty et al. (2007) found that parent involvement declines as students' progress through secondary school, citing intimidation and a lack of content knowledge as potential barriers. In addition, Becker and Epstein (1982) suggest that fewer parent involvement strategies are being used by secondary educators, and Abreu and Cline (2005) found that parent's confidence may be shaken when their mathematical approaches are not equally valued by the school. Finding a strategy for high schools to overcome these barriers for parents is often overlooked in the literature, and provides the purpose of this study.

In reviewing parent involvement strategies, Family Math Night (FMN) emerged as a potential fit for our purpose. FMNs have been described as opportunities for families to enter a non-threatening environment where they can demystify a subject and share in new challenges (Schussheim, 2004), and as a means to address curriculum needs, make school resources available, or celebrate mathematics (Szemcsak & West, 1996). With FMN as our selected strategy, we asked the following questions: (1) Is FMN appropriate and welcomed by parents and students in an urban high school? (2) What are parent and student takeaways from FMN?

To address these questions FMNs were implemented at an urban high school over the course of four years. Critical to the development of the FMNs were the following design features: inform parents about changes to students' curriculum and assessments, and provide activities and materials that emulate *open tasks* and the standards for mathematical practice. After each FMN parent and student survey data were collected. The data were analyzed using descriptive statistics and open-coding to better understand participants' perspective and voice.

From preliminary analyses, we have found a shift in parents' and students' views about mathematics to a subject that is useful and approachable. In addition, parents' expressed how they did not realize that mathematics included much more than problems found in textbooks. Parents and students also suggest that FMN was welcomed, beneficial, interesting, challenging, and informative. We see FMN as a parent involvement strategy that challenges many of the potential barriers to parent involvement in high school and helps blur the boarders between the home and school.

EMOCIONES EN LA RESOLUCIÓN DE PROBLEMAS MATEMÁTICOS EN ESTUDIANTES DE BACHILLERATO

HIGH SCHOOL STUDENTS' EMOTIONS ON MATHEMATICAL PROBLEM SOLVING

José Gabriel Sánchez Ruiz
FES-UNAM

Palabras clave: Cognición, Afecto, Emoción, Creencias y Actitudes, Resolución de Problemas

Importancia de las emociones en el ámbito escolar

Entre otros, Collell y Escudé (2003) plantean que gran parte del fracaso escolar de los alumnos no es atribuible a una falta de capacidad intelectual, sino a dificultades asociadas a experiencias emocionalmente negativas que tienen múltiples manifestaciones, por ejemplo, comportamientos problemáticos y conflictos interpersonales.

Dada la complejidad de los aspectos emocionales, diversos autores han propuesto su definición para la emoción, de las cuales se adoptó para este trabajo la conceptualización que ofrecen Ortony, Clore & Collins (1989): las emociones surgen como resultado de la interpretación de situaciones por parte de quienes las experimentan, pueden ser consideradas como "experiencias valoradas de eventos, agentes u objetos, es decir, están determinadas por la forma en que se interpreta la situación construida".

Las características de la estructura cognitiva de las emociones aluden a términos como "cualidad emocional" e "intensidad emocional" y son, por lo tanto, dos parámetros generales con los que se intenta definir una reacción emocional (Cano, 1989).

McLeod (1989) menciona que en resolución de problemas los estados emocionales se caracterizan por su brevedad, los alumnos experimentan un bloqueo en el plan de acción puesto en marcha para llegar a la solución de un problema, experimentan de forma casi inmediata respuestas emocionales intensas pero muy breves.

Considerando el rechazo a la resolución de problemas matemáticos que se observa en los estudiantes y el correlato emocional que el sujeto experimenta como resolutor de problemas, este trabajo tuvo como objetivo: Analizar las emociones de estudiantes de nivel medio superior cuando resuelven problemas de matemáticas.

Método

Está investigación es de tipo cuantitativo. Participaron 87 estudiantes de nivel medio superior de un instituto privado de la ciudad del Estado de Puebla, México. Sus edades eran 16-17 años. Para evaluar las emociones de los estudiantes al resolver problemas de matemáticas se empleó la Prueba de Positividad de Fredrickson (Cortina & Berenzon, 2013) la cual está compuesta por 20 reactivos que evalúan las emociones con base en la proporción entre el afecto positivo y el negativo, cabe mencionar que esta prueba se modificó al contexto de resolución de problemas matemáticos.

Resultados

Se encontró que las experiencias emocionales más frecuentes, y por lo tanto más constantes en situaciones de resolución de problemas son el orgullo, asombro, estrés y culpa por no estudiar. Los resultados del estudio muestran que el estudiante no tiene un manejo adecuado de emociones positivas, los cual es un aspecto importante ya que predominan las emociones negativas como estrés y culpa al resolver problemas matemáticos, lo cual es una implicación en el proceso de enseñanza-aprendizaje de la materia.

Keywords: Cognition, Affect, Emotion, Beliefs, and Attitudes, Problem Solving

Importance of Emotions in Schools

Among others, Collell and Escudé (2003) suggest that much of the students' school failure is not attributable to a lack of brainpower, but difficulties associated to emotionally negative experiences that have multiple manifestations, for example, problem behaviors and interpersonal conflicts.

According to the complexity of the emotional aspects, several authors have proposed their own definition for emotion, which was adopted from Ortony, Clore, & Collins (1989): Emotions arise as a result of the interpretation of situations by those who experience them, they can be considered as " valued experiences of events, agents or objects, that is, they are determined by the way the built situation is interpreted."

The characteristics of the cognitive structure of emotions refer to terms such as "emotional quality" and "emotional intensity" and are, therefore, two general parameters with which one attempts to define an emotional reaction (Cano, 1989).

McLeod (1989) mentions that in problem solving, emotional states are characterized by their brevity. Students experience a blockage in the action plan to reach the solution of a problem. They experienced intense but very brief emotional responses immediately.

Considering the rejection of solving mathematical problems observed in students and the correlative emotion that the subject experiences as a problem solver, this study aimed to analyze the emotions of high students when solving math problems.

Method

This study is quantitative. Eighty-seven students of higher average level from a private institute located in Puebla, Mexico participated in the study. Their ages were from 16 to 17 years old. We evaluated the students emotions to solve math problems with *Fredrickson's Positivity Test* (Cortina & Berenzon, 2013) which has 20 items that assess emotions based on the ratio of positive and negative affect, it is important to mention that the test was modified to fit the of mathematical problem solving context.

Results

We found that the most frequent and therefore more consistent emotional experiences in problem solving situations are pride, amazement, stress, and guilt for not studying. Results show that students have no proper management of positive emotions, which is an important aspect as it is dominated by negative emotions such as stress and guilt while solving mathematical problems. This has implications for the teaching and learning process of the subject matter.

LAS IDEAS DEL "NOLANO" GIORDANO BRUNO, CONDICIÓN NECESARIA (QUIZÁ SUFICIENTE) PARA MATEMATIZAR EL MOVIMIENTO

THE IDEAS OF "NOLAN" GIORDANO BRUNO, NECESSARY (AND MAYBE SUFFICIENT) CONDITIONS TO MATHEMATIZE MOVEMENT

Felipe de Jesús Matías
CINVESTAV
fmatias@cinvestav.mx

Aurora Gallardo
CINVESTAV
agallardo@cinvestav.mx

Palabras clave: Educación Primaria, Educación Secundaria, Resolución de Problemas

Deseamos evidenciar la importancia de ideas descritas por el Nolano contemporáneo de Nicolás Copérnico y Galileo Galilei, sugiriendo que aparezcan en los programas y libros de texto quizá desde nivel básico. Encontramos similitud en lo que hoy conocemos como "Relatividad de Galileo" basada en el movimiento de un barco (Hacyan, 1999, p. 13). Este hecho fue descrito por Bruno en "La Cena de las Cenizas", con años de anticipación (Schettino, 1972, p. 161). Compartimos la idea de lo expuesto por De Angelis y Espirito (2015) respecto a la contribución de Bruno al principio de la relatividad espacial (p. 246). El reconocimiento del movimiento de los cuerpos, debería lograrse antes de la resolución de problemas vía fórmulas, considerando el desarrollo histórico de las ideas que dieron paso al establecimiento de las mismas. Partimos de la pregunta, ¿Qué ideas describen los estudiantes de nivel básico, que permitirían descubrir las relaciones involucradas en el movimiento de los cuerpos?

Usaremos la teoría de los Modelos Mentales y Modelos Conceptuales en la enseñanza de las ciencias, aporte de Greca, Moreira y Rodríguez (2002), al explicar que: "Las personas operan cognitivamente con los modelos mentales. Entender un sistema físico o fenómeno natural, por ejemplo, implica tener un modelo mental del sistema que le permite a la persona que lo construye explicarlo y hacer previsiones con respecto a él" (p. 37). Un ejemplo que hace referencia a la cinemática encontrada en Giordano es el siguiente: "Con la tierra se mueven, por tanto, todas las cosas que se encuentran en ella. Por consiguiente, si desde un lugar fuera de la tierra se arrojara algún objeto hacia ella, perdería la rectitud debido al movimiento de ésta". (Schettino, 1972, p. 161) Elegimos un estudio cualitativo, aplicado en tercer grado de Primaria donde estudian las Ciencias Naturales y en segundo grado de Secundaria, en la materia de Ciencias II con énfasis en Física. Usaremos situaciones encontradas en la historia que permitieron despertar el interés de los antecesores del Nolano sobre el movimiento de los cuerpos. Nos interesa establecer que el uso de ecuaciones sobre el movimiento en la resolución de problemas de cinemática, debe hacerse una vez comprendida la situación física, poniendo énfasis en la comprensión del movimiento. Es necesario resaltar la importancia del Sistema de Referencia al resolver problemas de cinemática, causa de la existencia de valores negativos en velocidad, aceleración, tiempo y signo del valor de la gravedad. Categorizaremos los Modelos Mentales surgidos en estudiantes de nivel básico al dar respuesta a las situaciones históricas planteadas.

Keywords: Elementary School Education, Middle School Education, Problem Solving

We aim to highlight the importance of ideas described by "Nolan," contemporary of Nicolaus Copernicus and Galileo Galilei, suggesting that these appear in programs and textbooks, perhaps, since the very basic level. We find similarity in what is now known as "Galileo's Relativity" based on the movement of a boat (Hacyan, 1999, p. 13). This fact was described by Bruno in "The Supper of Ashes" years in advance (Schettino, 1972, p. 161). We share the idea of the comments made by De

---

Wood, M. B., Turner, E. E., Civil, M., & Eli, J. A. (Eds.). (2016). *Proceedings of the 38th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Tucson, AZ: The University of Arizona.

Angelis & Espirito (2015) regarding Bruno's contribution to the principle of spatial relativity (p. 246). The recognition of the movement of bodies should be achieved before solving problems via formulas, considering the historical development of the ideas that gave way to the establishment of these. We begin with the question: what ideas do basic-level students describe which would allow them to discover the relationships involved in the movement of bodies?

We will use the theory of Mental Models and Conceptual Models in science education, contribution made by Greca, Moreira and Rodriguez (2002), explaining that: "People operate cognitively with mental models. Understanding a physical system or natural phenomenon, for example, involves having a mental model of the system allowing the person who builds it to explain it and make predictions in relation to it" (p. 37). An example that refers to the kinematics found in Giordano is as follows: "Together with the Earth, all things that are in it move. Therefore, if from a place off the Earth an object was thrown to it, it would lose the straightness due to its movement" (Schettino, 1972, p. 161). We chose a qualitative study, applied to third graders where they study natural science and eighth grade in secondary schools, in Science II with emphasis on Physics. We use situations encountered historically that allowed to spark the interest of Nolan's ancestors on the movement of bodies. It is important to establish that the use of equations of movement in solving kinematics problems should be carried out once the physical situation is understood, with an emphasis on understanding such movement. It is necessary to emphasize the importance of the Reference System to solve kinematics problems because of the existence of negative values in velocity, acceleration, time and sign of a gravity value. We categorize the Mental Models emerged in basic-level students to respond to the referred historical situations.

FACILITATING CONVERSATIONS ABOUT EQUITY THROUGH IMAGERY

Laura Kondek McLeman
University of Michigan-Flint
lauramcl@umflint.edu

Eugenia Vomvoridi-Ivanovíc
University of South Florida
eugeniav@usf.edu

Zandra de Araujo
University of Missouri
dearaujoz@missouri.edu

Increasingly there have been calls for mathematics teacher educators (MTEs) to address issues of equity and diversity (e.g., Strutchens, et al, 2012). Addressing issues of equity in the context of mathematics teacher preparation, however, can be a challenging task (Vomvoridi-Ivanovíc & McLeman, 2015). One of the most discussed challenges is that of resistance (e.g., Aguirre, 2009). Aguirre noted that pre-service teachers (PSTs) can resist discussing issues related to race or power. Even when PSTs are willing to examine biases present (e.g., in curriculum), they might still be resistant to examine how race and other physical characteristics might provide people advantages in the world.

To counter some of these challenges and in an attempt to cross borders between the literature world and the mathematics world, we explored the use of comics to facilitate conversations about equity in our courses. Mallia (2007) argued that comics have the intrinsic potential of being a valuable affective and cognitive tool and can be used in instruction for, among other things, motivational and retention purposes. As such, we engaged in an exploratory study to address the following question: How does the inclusion of visual imagery, comics in particular, help MTEs facilitate classroom discussions about issues of equity?

As MTEs of courses in various contexts, we selected comics that depicted conceptions of equity and equality and included them in our syllabi. Further, we used the comics to frame discussions about key course objectives. Utilizing components of grounded theory (Glaser & Strauss, 1967), we analyzed course artifacts, student work, and our self-reflections.

In this poster, we present initial findings regarding the use of comics in our differing contexts. Preliminary findings show that the images enabled us to engage our students in difficult dialogues about equity in mathematics. Furthermore, our findings suggest that the use of comics allowed students from multiple contexts (e.g., education level, major, course focus) to meaningfully enter into conversations about equity in a safe manner.

LA COMPRENSIÓN TEXTUAL DE PROBLEMAS MATEMÁTICOS VERBALES EN NIVEL BÁSICO

TEXTUAL COMPREHENSION OF BASIC LEVEL VERBAL-MATHEMATICAL PROBLEMS

Representaciones Mentales

En 1986, W. Kintsch presentó un estudio, en el que niños de primaria resuelven problemas aritméticos y se ocupa de cómo los niños de este nivel entienden problemas aritméticos verbales. Con ese trabajo, el autor concluyó que las modificaciones lingüísticas menores afectan en gran medida la capacidad de los estudiantes para resolver un problema, comentó que no sólo la formulación lingüística del problema es importante, también es necesario comprender la situación descrita en el problema. Mencionó un problema de aritmética con dos formulaciones: "(1) Hay 5 pájaros y 3 gusanos, ¿Cuántos pájaros hay más que gusanos?", "(2) Hay 5 pájaros y 3 gusanos, ¿Cuántos pájaros no obtendrán un gusano?". El problema 1 fue resuelto correctamente por el 39% de los sujetos, mientras que el problema 2 por el 79%. En el problema 2, la expresión lingüística permitió a los sujetos formar un modelo situacional definitivo (pájaros comiendo gusanos) que les proporcionaba la estructura aritmética correcta para llegar a la solución. En el problema 1, sin embargo, el término relacional abstracto "más que" no proporcionó tal ayuda. Dado lo anterior, nuestro objetivo es analizar cómo ciertas modificaciones en el texto base influyen en la construcción del modelo situacional de un problema verbal de matemáticas en el nivel básico y la pregunta de investigación que nos planteamos es: ¿Cómo influye la modificación en el texto base en la construcción del modelo situacional y en la solución del problema?

Método

Para alcanzar el objetivo planteado se aplicaron dos problemas con modificaciones en su estructura lingüística y matemática y se compararon los modelos situacionales representados en los dibujos que se les solicitaron a los alumnos inmediatamente después de haber leído los problemas. En esta investigación se analizaron las construcciones mentales de los estudiantes a través de los dibujos. El análisis es de tipo cualitativo. Se aplicaron los dos problemas que mencionamos de Walter Kintsch (1986) a 117 estudiantes de los tres grados de secundaria y a 87 estudiantes de los primeros tres grados de primaria. El estudio se realizó en la ciudad de Puebla, México.

Análisis y Conclusiones

Las respuestas obtenidas en secundaria no coinciden con las de Kintsch, ya que la mayoría de los estudiantes contesta correctamente ambos problemas, esto se debió seguramente al grado de estudio, ya que el autor trabaja con niños de primaria y esto se nota en el estudio que se hizo en primaria, donde nuestros resultados coinciden con los del autor. Al analizar los modelos situacionales en los dos niveles, se logra ver un modelo más coherente en estudiantes que trabajan con el segundo problema, en donde la claridad de la expresión lingüística es mucho mejor. Podemos concluir lo mismo que Kintsch, que la complejidad del modelo del problema requerido para la solución del problema 1 confunde a los sujetos.
