Land Acknowledgement:

The PME-NA 44 Conference is held on unceded Indigenous land including the traditional homelands of the Cherokee, Shawnee, and Yuchi. The connections of Indigenous Peoples to this land continues to the present day. As we begin our conference it is important to acknowledge our place, both geographically and historically, paying tribute to the land and our ancestors—and honoring both. We note that just speaking the word Tennessee is a tribute to a first nations' word for "where the river bends." The genocide, forced displacement, and cultural erasure of indigenous peoples resulting from the colonization of this land is particularly felt here, where the Trail of Tears cut through Middle Tennessee. In the midst of this history, Native American Indians tell their story today—including the joy of return. Founded in 1980, the Native American Indian Association of Tennessee is working to improve the quality of life for Indigenous People in this state. This includes raising funds to one day build the Circle of Life Indian Cultural Center, which will showcase a research library, exhibit halls, emergency relief support, job training, and education. These efforts help to close the circle of hatred and prejudice so that all Tennesseans can come together in freedom and pride.

An important goal of land acknowledgments is to increase support of local Indigenous communities. You can support the work of the Native American Indian Association of Tennessee by donating at naiatn.org. You can also learn more about the history of Tennessee's Indigenous communities by visiting the First Peoples exhibit at the Tennessee State Museum, which is about 3 miles from the conference site. More information is at tnmuseum.org.

This statement was created in conversation with local Indigenous leaders and informed by the Native Governance Center's Guide to Indigenous Land Acknowledgment.

PME-NA History and Goals

PME came into existence at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany, in 1976. It is affiliated with the International Commission for Mathematical Instruction. PME-NA is the North American Chapter of PME. The first PME-NA conference was held in Evanston, Illinois in 1979. Since their origins, PME and PME-NA have expanded and continue to expand beyond their psychologically oriented foundations.

The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers; and
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME-NA Membership

Membership is open to people who are involved in active research consistent with PME-NA's aims or who are professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website at http://pmena.org. For information about membership in PME, go to http://www.igpme.org and visit the "Membership" page.

PME-NA Steering Committee

Elected Members

Karl W. Kosko (Chair) – Kent State University (2019 – 2022)
Doris Jeannotte (Chair Elect) – L'Université du Québec à Montréal (2021 – 2024)
Julie Amador – University of Idaho (2019 – 2022)
José Martínez Hinestroza – Texas State University (2019 – 2022)
Alyson E. Lischka – Middle Tennessee State University (2019 – 2022)
Oyemolade Osibodu – York University (2020 – 2023)
Angeles Dominquez – Tecnológico de Monterrey (2021 – 2024)
María S. García González – Universidad Autónoma de Guerrero (2020 – 2023)
Xiangquan (James) Yao – Pennsylvania State University (2021 – 2024)
Brent Jackson (graduate student rep) – Michigan State University / WestEd (2021 – 2022)
Megan M. Parise (graduate student rep) – University of Minnesota (2021 – 2022)

Appointed Members

Aaron Brakoniecki (Webmaster) – Boston University
Yi-Yin (Winnie) Ko (Treasurer) – Indiana State University

Conference Chairs

Past Conference Co-Chairs (2019 – 2022)

Sandy Spitzer
Towson University
sspitzer@towson.edu

Dana Olanoff
Widener University
dolanoff@widener.edu

Kim Johnson
West Chester University of Pennsylvania
Kjohnson2@wcupa.edu

Current Conference Co-Chairs (2020–2023)

Alyson Lischka
Middle Tennessee State University
Alyson.Lischka@mtsu.edu

Elizabeth B. Dyer

Strand Leaders

The Local Organizing Committee is extremely appreciative of the following people for serving as Strand Leaders. They managed the reviewing process for their strand and made recommendations to the Local Organizing Committee. The conference would not have been possible without their efforts.

Preface

On behalf of the 2022 PME-NA Steering Committee, the 2022 PME-NA Local Organizing Committee, and Middle Tennessee State University, we welcome scholars to Nashville, Tennessee, USA, for the Forty-Fourth Annual Meeting of the International Group for the Psychology of Mathematics Education – North American Chapter, held at the Loews Vanderbilt Hotel.

The goal of PME-NA is to promote the international exchange of research on the psychology of mathematics education and to promote an ever-deepening understanding of the psychological aspects of teaching and learning mathematics. Psychology, the study of mind and behavior, encompasses biological influences, social pressures, and environmental factors that impact how learners think and act. As members of PME-NA, it is necessary that we attend both to the contexts in which the teaching and learning of mathematics takes place and to the experiences of individual participants, while considering the multiple voices, histories, systems, and social structures present in our learning spaces. In recent years, our contexts and experiences have been forever impacted by the world-wide COVID pandemic and a renewed struggle for civil rights in many of our communities.

This year's conference theme, ***Critical Dissonance and Resonant Harmony,*** reflects not only the time and place that we gather, but also the time and place in which we conduct our academic work. Dissonance can be jarring to experience, whereas harmony can be pleasing. We gather in Nashville - Music City - which is no stranger to both dissonance and harmony. Walk the streets and you will experience both, as vibrations felt in your body or heard in your ear. Look closer and you will see both, knitted in the very fabric of our identity. We are not only the site of lunch counter sit-ins, Freedom Rides, the final approval for women's suffrage (the 19th Amendment to the U.S. Constitution), the Teens for Equality Black Lives Matter rally, and the Annual March for Black Women in STEM, but also The Trail of Tears, countless acts of oppression, and reactionary legislation limiting citizen's rights—most recently those of LGBTQIA+, BIPOC, and Immigrant communities. We know that dissonance is necessary for change and liberation, and so has a critical component. We also know that harmony occurs when multiple voices and forces join simultaneously to amplify and enrich, achieving a resonance that pushes through to the other side and finds a better way. Still, in reality, dissonance and harmony cycle, neither seemingly fully formed, and often sharing contiguous or overlapping spaces. The PME-NA community will gather in this place in 2022, traveling from locations across North America that are experiencing similar dissonances and harmonies.

It is in this context that we conduct our work in the field of mathematics education, as researchers who value the contributions and experiences of each and every person. In preparation for PME-NA 44, we invited all presenters to reflect on how their work impacts the contexts and experiences of members in mathematics learning communities, particularly those who are on the margins of these communities, and to address what these reflections mean for their work. Reflection may have included consideration of the following questions: How does your work challenge a settled mathematics learning status quo? How does your work help to create more socially just contexts for learning and teaching mathematics? How does your work have an impact on society more broadly, beyond individual mathematics classrooms and school districts? How does your work improve learning conditions for each and every mathematics learner? Whose voice does your work center in the mathematics learning process? What can be learned from reflecting on this question? This proceedings represents the work of mathematics education scholars as they took up this call for reflection.

We hope the PME-NA 44 conference provides a communal space for critical reflection and conversation on how our individual and collective work contributes to dissonant and harmonious movements in our field as it relates to the psychological aspects of teaching and learning mathematics. We recognize that what is perceived as dissonant or harmonious varies among cultures and even individuals and is by no means universal. And so, we look forward to the opportunities for conversation and learning across our international community as we share instances of dissonance and harmony that can serve to propel research toward action and change.

This year's conference will be attended either in-person or remotely by close to 600 researchers, faculty members, and graduate students from around the world including Canada, Mexico, Colombia, and the USA. Approximately 800 authors are represented by the papers in this volume. Each paper was reviewed by multiple referees in a double-blind process. After initial reviews were submitted, Strand Leaders reviewed feedback and made selections for papers to include in the conference. Finally, the local conference committee made decisions based on reviewer and strand leader feedback and constraints of the conference space. The result was an overall acceptance rate of 66% with the final papers comprised of 101 research reports, 140 brief research reports, 84 Posters, and 16 Working Groups. In addition, we conducted a doctoral consortium in conjunction with the conference during which 23 late-stage doctoral researchers engaged with mentors and each other to support their research. These scholars presented their in-progress work as posters during our poster sessions.

In 2021, the PME-NA Steering Committee voted to require all working groups wishing to continue their work at a subsequent conference to produce a report on their work following the conference. Therefore, this proceedings contains a report of work conducted in 2021 along with a proposal for the work to be conducted at the 2022 conference for each returning working group. These reports are found in Chapter 17.

This conference and publication would not have been possible without the support of many in our field: strand leaders who put forth efforts to ensure the quality of the papers selected for the conference program, colleagues who supported the local organizing committee as we navigated the unchartered territories of planning a conference during a pandemic, plenary speakers who took up our vision for the theme, a Steering Committee which supported us while allowing space for us to follow our own vision, and the many scholars who share their brilliant work with our field through this outlet. We thank Middle Tennessee State University for supporting our efforts to lead this conference. We also thank Samantha Drown and Sarah Johnson for their work in compiling this proceedings.

The local organizing committee hopes that you engage with this research by looking for both dissonances and harmonies within these papers that enrich the ways in which your own work can continue to support the learning and teaching of mathematics.

RE-MEMBERING PLACE: MATHEMATICAL ACTIONS FOR INNOVATIVE, RESILIENT, AND CULTURALLY RICH COMMUNITIES

Florence Glanfield

jethom@uvic.ca

How might mathematics educators recognize discourses as resonating harmonies in their practices as researchers? In this paper we share individual experiential narratives guided by Ojibway author Richard Wagamese's Medicine Wheel teachings in the four directions of East (humility), South (trust), West (introspection), and North (wisdom). As we journey through (re)membering place we offer opportunities for recognizing resonating harmony(ies) and algo-rhythms in our practices as mathematics education researchers and for engaging with critically dissonance discourses and actions. This (re)membering supports relating with each other, mathematics, communities, and place in ways that are more sustainable, inter-connected, and kincentric.

Keywords: place and land education, Indigenous perspectives, ecological perspectives, mathematics education

Introduction

We, Florence, Cynthia, and Jennifer, all mathematics educators and researchers, use Ojibway author Richard Wagamese's (2011) four direction Medicine Wheel teachings to share our individual research journeys. We use stories (Clandinin & Connelly, 2002) to re-member and re-think our individual actions and the ways those individual actions have woven together to become collective work. Wagamese's teachings follow the direction that Earth travels each day. Just as humans have said that the start of the day is in the East, Wagamese's Medicine Wheel teachings also begin in the East. This paper is written in the four directions; East, South, West, and North. Wagamese's Medicine Wheel teachings start the section; followed by stories of each of the authors.

East

> **THE OLD ONES** say that humility is the foundation of everything. Nothing can exist without it. Humility is the ability to see yourself as an essential part of something larger. It is the act of living without grandiosity. Humility, in the Ojibway world, means "like the earth." The planet is the epitome of a humble being, with everything allowed the same opportunity to grow, to become. Without the spirit of humility there can be no unity, only discord. Humility lets us work together to achieve equality. Humility teaches that there are no greater or lesser beings or things. There is only the whole. There is only the great, grand clamour of our voices, our spirits, raised together in song. (Wagamese, 2011, p. 9)

Humility: The Power of Place (Cynthia)

It's common for cliffs on Haida Gwaii along Canada's Pacific northwest coast to receive 10m high waves, for spruce trees to dance in a southeast storm, and for the ocean to leave platters of cockles, clams, crab, and octopi on its beaches when the tide is out. Haida Gwaii is a land between sea and sky where the worldview Gin 'waadluuwan uu gu dil adiidaa "everything depends on everything else" speaks to the synergetic relationship between humans and nonhumans, natural and Supernatural Beings. It is a place where "culture" says Haida artist and activist Guujaaw "actually is our relationship to land" (Guujaaw as quoted in Jones, 2006 p. 29). The inlets and shores of Haida Gwaii are nutrient-rich and tempered with warm offshore currents feeding a diversity of life. In spring grey whales migrate between their winter breeding areas in California and their summer feeding waters in the Bering Sea. From our little log cabin on Haida Gwaii's North Beach, living without electricity or running water, we could see the whales along their route, releasing their breath with spectacular spray as they prepared for the next dive.

One spring afternoon out in our 12 ft Zodiac boat, we found ourselves surrounded by a pod of grey whales. A kilometre off-shore with no other boats in sight, we shut down the motor as the greys circled. Maybe they were curious about who had ventured into their territory. Maybe the bottom of our Zodiac looked familiar from a whale's perspective, but different enough to make them curious, take notice, and check us out. Three maybe four barnacled backs rose from the water, one flipping a tale wider than the length of our dwarfed boat. Their breath lingered while we held our own.

Without warning one broke from the circle and swam directly toward us. Grey whales can reach 15 m (about 50 ft) in length. I imagined this massive being flicking us in the air like a dog playing catch with a ball. We sat still, as still and humble as what Atleo calls an "insignificant leaf floating in a spring well" (Atleo 2011, p. 98). The power in this moment lay with this whale. As the whale slipped smoothly and quietly – planned and precise – under our boat and rose on the other side we acknowledged our respect with thanks. And, as if this magnificent animal heard us, the whale circled back. Resting its head on the water's surface, we met eye-to-eye, feeling once again the power of this relationship and our place within it. This whale's gaze and 'playful' interaction reminded us of our own fragility as visitors in their realm.

Haida oral stories speak of interactions between humans and nature and Supernatural Beings as sharing skins. Under our skins, both human and nonhuman, we are reminded that we are all connected, sharing this power of place.

Humility and Earth (Jennifer)

"Humility, in the Ojibway world, means 'like **the earth**. …[H]umility ... is **the foundation of everything. Nothing can exist without it.**" (Wagamese, 2011, rearranged, p. 9).

These words which describe the Ojibway world re-mind me of my Chinese grandmother's family name. "Chan" written as Chinese characters 陳 (see also Figure 1) animate familiar meanings of place, direction, and temporality to those of Ojibway meanings for East. 陳 means earthly place, landscape, ancient, and abundant. 東 as the sun rising from behind the tree is East which infers morning but also spring as the first season of the new year. Thus, not only does the direction of East locate Earth as place but it also posits Earth as originary and foundational. Just as light appears, day breaks night, and from winter comes spring, it is from the East where new beginnings and possibilities emerge.

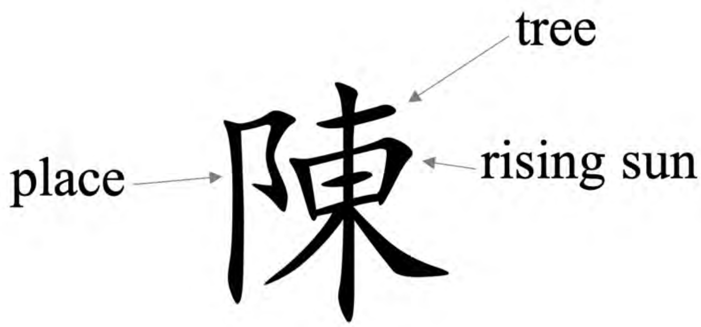

Figure 1. Chinese characters for "Chan"

"Humility, in the Ojibway world, **means 'like the earth.** …**[H]umility ... is the foundation of everything. Nothing can exist without it.**" (Wagamese, 2011, rearranged, p. 9).

Deeper within the layers of Wagamese's description, I hear the wor(l)ds of Japanese-Canadian curriculum scholar Ted Aoki. Aoki (2004a) remembers and reminds that the word *humility* is etymologically akin to earth. From *humilis* meaning "on the ground", *dhghem* or *humus* as "earth", and *don* as "place" (Humility, 2022), the very word has originated and evolved from *earth*. Humility as described by Aoki (2004a) is "concerned with lived space[s] where people dwell communally ... with others [and] earth under the sky." (p. 300) And just as *hum*ility comes from *humus*, Aoki (2004a) remembers and reminds that we *hum*ans do too.

While East marks first light, new beginnings, and starting points, humility calls for contemplation of what has come before. Humility makes returning to and reconsidering onto-epistemologies of place possible. In doing so, it allows for movement and change. *Returning* then is not simply 'turning around' or 'going back' but 'turning again'. Further, from the East turning again conceptually conjures notions of a turning point or starting anew.

For me, East signifies the first part of my journey as graduate student. Asked by my supervisor why I decided to pursue further studies in mathematics education, I explained to her that: "When I am in the mathematics classroom, there are certain things and events I can see and theoretically explain through constructivism. However, there are all sorts of other things and events I know or sense are happening but all I can do is point to them. I have no means by which to describe them yet I desperately want to understand them." Digging deeper, I was also conflicted with the idea that if "WE ARE CONNECTED TO THIS EARTH" (Thom, 2012, p. 2) then why is it that school mathematics feels so disconnected. These "things" and "events" were just a few of the items on what was becoming an ever-growing list. Many were contradictions I experienced between my home life and life lived as mathematics student and teacher. From ontologies to epistemologies to cultural discourses to the metaphorical nature of language to meanings of place. My hope was that these questions would be the start of a new journey for me. A journey that would require me to re(-)turn and explore the place of classroom mathematics and if necessary, bring forth possibilities for 're-rooting the learning space' and develop an understanding for what it means to 'mind where children's mathematics grow' (Thom, 2012).

Understanding Humility in Relation to the Boreal Forest (Florence)

I grew up on a ranger station in what is now called northeastern Alberta. My father was a forest officer and grew up in the prairies. My Métis mother was born and raised in the North primarily living in a variety of small communities around a huge fresh water lake. The ranger station was located on the edge of boreal forest and farmland. A boreal forest is full of deciduous and coniferous trees; land that includes muskeg (or bogs), freshwater lakes, rivers, and streams.

The land sustains a vast number of animal and plant species - species that also sustain human life. I grew up eating “wild meat” such as moose, deer, partridge, ducks, goose, and fish. I grew up picking and eating wild berries and learning about some medicines that were available in the forest.

I also grew up being in the boreal forest, learning from my Métis grandparents and from my parents about what it means to pay attention to the land. I grew up learning how to ‘find my way’ through the forest and learning to pay attention, for example, to the ways in which moss grows on trees as you might need the moss to build a fire for warmth. A large part of these early years was understanding forest fires. Forest fires were feared and at the same time celebrated. Forest fires were feared because of the way that they could impact human life. My father would be called away when a fire was spotted in order to begin to work with others on the initial attack; hoping that the fire could be contained in order to protect humans and human properties. At the same time there was a contradiction because a boreal forest relies on a forest fire for rejuvenation and growth. Nutrients are released, seeds are released for some species of trees, and fires open the canopy to allow new growth (Natural Resources Canada, 2022).

It was always fascinating to me to watch the way that a forest ‘rejuvenated’ following a fire. The years following a forest fire would mean that we needed to pay attention to reading the land in a different way because there would be new growth. You would notice the new jack pine seedlings that could now grow because of the fire. We would pay attention to the places that fireweed would grow across the burned area as fireweed was often the first ‘new growth’ we would see. We would spend time ‘reading’ the changes in the land after a fire and noticing the changes in the ways that the animals would live around the land that had been burned. Sometimes it would mean hunting in a new place for the moose or deer because the growth of the plants had changed because of the fire.

Often throughout these early years of my life we were taught to live with the forest because it was a way to learn about how to ‘survive’ with the forest. Even though we learned a lot about reading the land we also learned about respecting the land as the land can be changed quickly and dramatically by rain or no rain, fire or no fire, and extraordinary winds. Learning about ‘surviving’ taught me about humility; I was taught to respect the land, the weather, and the species that sustained our family. As I reflect on these early years now, I was learning about uncertainty and interdependence of humans and nonhumans living with earth or land.

South

> **TRUST IS THE** spiritual by-product of innocence. My people say that innocence is more than lack of knowledge and experience, it's learning to look at the world with wonder. When we do that, we live in a learning way. Trust, the ability to open yourself to teachings, is the gateway for each of us to becoming who we were created to be. All things bear teachings. Teachings are hidden in every leaf and rock. But only when we look at the world with wonder do the teachings reveal themselves, and trust is also the ability to put those teachings to work in our lives. Trust is, in fact, our first act of faith and our first step towards the principle of courage that will guide us (Wagamese, 2011, p. 57).

Trust: Relations Take the Time it Takes (Cynthia)

As shapeshifters, Supernatural Beings appear in Haida stories told for generations. They’re carved into poles, masks, and jewelry, and painted on bentwood boxes, woven into cedar hats, and tattooed on bodies. I’ve learned from Haida Elder Gwaaganad Diane Brown that it is here, Haida Gwaii, where multispecies kinship between human and nonhuman, natural and Supernatural is honored – where, for example, "we treat the ocean as our relative."

Supernatural Being Kugann Jaad (Figure 2) appeared for Haida artist Billy Yovanovich when working on his ideas for mathematics education on Haida Gwaii. It is Kugann Jaad, says Billy, who is known for her ability to restore balance and equity "with her strength, wisdom, and vision she guides us, speaking with both her hands and her eyes with knowledgment of what is to happen, what will happen, or even provide resources to meet challenging situations (Nicol et al., 2020, p. 17-18).

Figure 2. Kugann Jaad by Billy Yovanovich

Kugann Jaad for me helps tell the story of working with Haida communities, first as a beginning teacher, and then for the past 17 years as an academic to connect community, culture, and mathematics within the culture and place of Haida Gwaii. The task, when first started, seemed challenging but doable: work with six teachers (Indigenous and non-Indigenous; elementary and high school; from the north and southern parts of the Island; beginning and experienced) and the Principal of Indigenous Education to create practices and resources that ground and strengthen relationships between people, mathematics, and place. Teachers with more than 20 years of experience found themselves questioning their own assumptions, challenging what they noticed as deficit perspectives, and recognizing the complex work needed. We were excited about these modest results and humbled by the time it took. With community we took two years to develop a common workable set of questions that we called the PAIRS approach to highlight place, relationships and Indigenous storywork with mathematics, and another three years to develop a book as a collection of community Elders' stories alongside mathematical adventures.

Our efforts seemed to move forward and backward at the same time. Off-Island teachers typically left the Islands within 5 years, new teachers joined the project, and the work would begin again. Kugann Jaad loves a good puzzle, and as shapeshifter can slip into the skins of others to lend a hand when needed. Perhaps it was Kugann Jaad who helped us accept that the strength of this work was felt not within a couple years, or 5 years, or even 10. It came with intergenerational teachings – when for instance I found the daughter of one of my former Haida students in my university teacher education mathematics class. I had taught her mom, her aunties, and some of her uncles, all of whom, I have since learned, shared with her their good stories of learning mathematics in my class many years ago. Now here she was in my university class eager and ready to embrace mathematics as a new teacher. Kagann Jaad reminds us to trust the time some learnings take.

Trusting Wonder (Jennifer)

"[O]nly when we look at the world with wonder do the teachings reveal themselves" (Wagamese, 2011, p. 57).

Wonder as Wagamese (2011) explains allows for an openness to the world, opportunity to receive its teachings, and inspires hope as well as promise to "live in a learning way" (p. 57). For me, his teachings evoke insights and sensibilities which resonate with 詩 (see also Figure 3). Pronounced "shi" in Japanese and Cantonese, 寺 can be interpreted as "tera (sic) [or] [E]arth/measure [as] 'temple,' a sacred place where one may be allowed to hear the true measure of earth beings, mortals in the nearness of divinity." (Aoki, 2004d, p. 374) 言 is "to speak/to sound [w]ithin the 'mouth' that sounds forth or sings, over layered with three echoes and a lingering note." (Aoki, 2004d, p. 374). 詩 expresses reverence and awe for Earth as place and teacher. Moreover, given the opportunity to learn by "listening to the land" (Glanfield et al., 2021, p. 258), "to hear .... the inspirited beat of earth's rhythm" (Aoki, 2004d, p. 374-375) as "*land-guaging* algo-rhythms" (Glanfield et al., 2021, p. 258) opens possibilities for humans to speak and sound them forth into the world so they may endure. In trusting wonder, I am learning that "to [hear] and read the (con)texts of the natural world intimately and openly implies that 'language … is not a specifically human possession, but is a property of the animate earth, in which we humans participate' (Abram, 2010, p. 11)" (Thom, 2019a, p. 252).

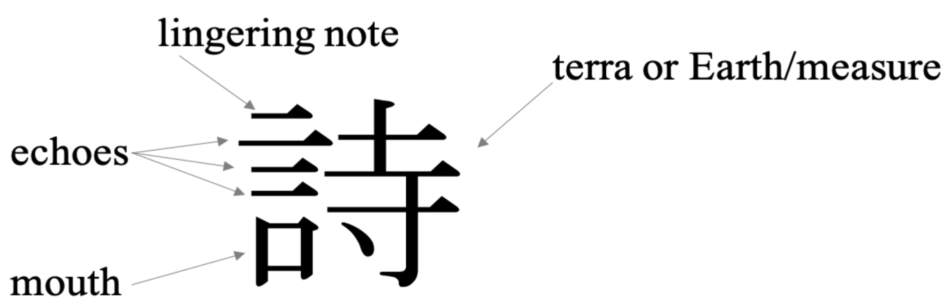

Figure 3. Chinese characters for "shi"

Doing so prompts me to revisit Alan Bishop's "assertion that all human cultures 'do' mathematics—that is, count, measure, design, play, locate, and explain (Bishop, 1988)" (It's Spring, 2022, p. 6). Here it is as if in its resurfacing, Bishop's assertion asks to be re(-)turned. Wondering as Wagamese does and as 詩 implies, I wonder:

[W]hat [inspirited algo-rhythms might be heard if] such a focus [for mathematics education] recognizes not only human activities as mathematical but emphasizes ways of knowing, doing, and being which are inherently grounded in and come from the land and Earth [such as when]:

~ Sun and moon rise (and set)
~ Seasons change
~ Spiders web
~ Raindrops dance upon the water's surface
~ Maple seedlings spin and spiral from tree to ground
~ Bat and fish and tree and pea tendril ... just "know" where they are and how to get to where they need to be (It's Spring, 2022, p. 6)
~ Humpback whales work together to net and feed.

Lischka, A. E., Dyer, E. B., Jones, R. S., Lovett, J. N., Strayer, J., & Drown, S. (2022). Proceedings of the forty-fourth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Middle Tennessee State University.

What do I Trust (Florence)

The south direction in my life are the years that I was in formal postsecondary education. I first of all began to not trust as I was provided with implicit and explicit messages about silencing the teachings I had with my family in relation to the boreal forest. I wanted to be a mathematics teacher so when I finished high school I entered university to study mathematics first and then education second. Through those first two degrees I was taught a lot of different theories and practices. Theories about ways that children learned, theories about why humans act the way they do, theories about relationships, theories about the 'best' way to teach mathematics, theories about the best ways to assess student learning, and theories about the actions of the 'best' teachers. It felt like the years of formal education were a different world as I did not know or could not 'see' the ways in which the interdependencies that I learned about in my early years belonged in this world of theories that suggested an "if then" philosophy. That is, if x action is taken then y event will happen. This was contradictory to the philosophy that I grew up with as I was learning to 'read' the land, a philosophy that paid attention to interdependence and relationships.

As I began my teaching career I felt like I needed to implement all that I learned through my formal education. I often think about how, in my first 1.5 years of teaching, I spent hours and hours reviewing the "cumulative files" of each youth that were registered in my mathematics classes prior to the beginning of each school term. I did this because I believed that if I 'knew' about the youth in my classes then I could plan the 'best' program for each. I think about how I would spend hours and hours to make sure I could solve every mathematics problem in the assignments I planned to give because I thought that the "best" mathematics teacher was the mathematics teacher that had all of the correct answers. I think about how I would plan well in advance and how I wanted to keep up with my teaching colleagues in order to make sure I covered the curriculum in the same time frame. I wanted to quit teaching after those first 1.5 years because it was not anything like I had imagined.

As I began to learn about the youth that were with me in the classroom, I started to notice that the "cumulative files" didn't really tell me anything about who the youth were as individuals. The "cumulative files" often shared information about what the youth could not do and rarely did those notes reveal what the youth could do. I began to wonder if I was thinking about the youth in a deficit way. I began to realize that all of my planning ahead did not pay attention to what was happening with each collection of humans in any one class. So while planning ahead was important I also noticed I had to be prepared for the different observations from the youth in each class. I realized that my planning ahead did not recognize the interdependence of a classroom. I began to realize that questioning my practices was moving me away from the predominant "if then" philosophy of my university years and moving closer to the "interdependence and relationship" philosophy of my early years.

West

> **ON THE MEDICINE** Wheel, introspection is the "looks within place." Humility and trust offer many teachings, and introspection is a means of seeing how those apply to our lives. It's a place of vision. It's a resting place where the story, the song each of us has created up to this moment can be inspected and those things deemed unnecessary be let go. It's a place of courage, because the hardest place to look is within. Many people stop here, deterred by the trials of the journey and the sudden hurts that sometimes make life hard. But introspection is meant to bring us to balance. It is the place where all things are ordered, where all things ring

> true at the same time. Balance allows us to move forward, and when we do, the journey becomes wondrous again by virtue of our ability to see the whole trail. (Wagamese, 2011, p. 107).

Introspection: What are you? (Cynthia)

At a community potlatch feast in a northern BC Indigenous community a young girl sitting next to me turned and proudly declared her heritage: "I'm Nisga'a!" Then, with what seemed an obvious question to her, and looking straight at me asked, "What are you?"

What am I? I could answer *who* am I? or *Where* are you from? But *what* am I? It's taken a few years for me to learn how to respond to that question. Growing up as a non-Indigenous/settler in the Kootenay territory of southern British Columbia, in a predominantly white Euro-centric community, my heritage was rarely questioned and certainly invisible. We were taught nothing about the system of residential schools, lasting for over 160 years, involving more than 150,000 children in an education that offered more abuse than teaching. How is it possible that such atrocities occurred but then were erased from Canadian education? Even while I taught on Haida Gwaii these experiences were rarely spoken or only whispered.

My work with rural and Indigenous communities continues to deepen my own self-gaze to "disrupt molded images" (Dion, 2007), and settler colonial logics (Donald, 2012). This involves working with communities toward building relationships with land through personal experience, drawing upon stories and ancestral knowing through listening to Elders, and (re)membering respectful and responsive mathematical learning environments by connecting math, community and culture.

Through the teachings of Haida Elder Gwaaganad and Haida artist/activist Guujaaw I'm learning more about "what" I am. Gwaaganad spoke at our project meetings of the need to treat the ocean as our relative, as a member of the family. The ocean is neither an object, nor unending resource, nor even something that needs protection. The ocean is a relative, the ocean is kin. Similarly, Guujaaw spoke of the importance of ancient cedar trees to the Haida people. If "the trees are gone [due to industrial logging]" said Guujaaw, "then we're just like everyone else." The trees and the land including the ocean and waterways define what it means to be Haida.

Learning about relationships with the ocean and forests, as relatives, opened pathways for listening to the possibilities the land and waterways offer as teachers. Gwaaganad and Guujaaw led us in (re)membering long views of time and experiences of food harvesting with the changing ocean life, changing harvesting practices, and the revitalizing of ancient pedagogies of place. Opening myself up to embrace these kinds of obligations to the land/ocean, to be respectful and responsible for caring for the non-human world brings me closer to understanding what I am.

What am I? I'm still not sure I have a full response to this question, but I do know that it speaks to a more kincentric (Salmón, 2001) way of being, one that supports living in the world in more relational and emergent ways.

Simultaneous Complementarities (Jennifer)

"Introspection... 'looks within place.' ... [A] place of vision... where ... the song each of us has created up to this moment can be inspected .... [W]here all things ring true at the same time." (Wagamese, 2011, p. 107).

As I sit, "keeping watch" (Thom, 2012, p. 363), reflectively circling back and reflexively circling forth, I can appreciate and more deeply understand the onto-epistemological meanings of place that connect and (in)form my journey as mathematics education researcher. Now from the West, it is my Chinese grandfather's family name 譚 "Tàahm" and my surname "Thom" that appears, inviting my further contemplation. Similar to 詩 or “shi”, 言 depicts a mouth which sounds or sings forth, echoes, and holds a lingering note. 覃 translates as “early west.” (see also Figure 4). (How curious it is that 譚 foretells my grandfather’s journey from Hoiping China to Vancouver Island, singing forth as it echoes my family’s history in the “early west” during the turn of the 20th century onward.)

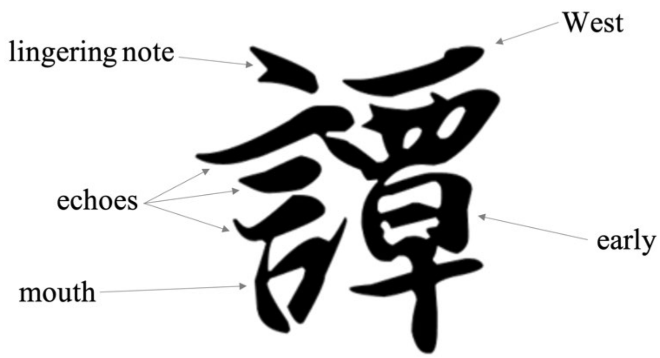

Figure 4. Chinese characters for Tàahm/Thom

Looking again, the Chinese characters for West bare other meanings which suggest reflection. For example, “dusk” as the time of day when the sun disappears below the horizon and the season of autumn. Both resonate with Wagamese’s description of West as “a resting place” and “a place of vision” that affords “look[ing] within place” and “introspection” (Wagamese, 2011, p. 107). Perhaps more intriguing is how the idea of “early west” presents as “all things ring[ing] true at the same time.” (Wagamese, 2011, p. 107). That is, *sunrise* and *sundown*; *early* or *soon* and *late*, *morning* and *evening*; even *beginning* and *end*. And as well, while autumn signifies a time of ripening, harvest, and plenty, it is also a time of decay, death, and decline.

These ‘opposites’ which could be viewed as contradictory can also been understood as wonderous spaces in which to “see the whole trail” (Wagamese, 2011, p. 107). Not as distinct or separate parts that compete with one another but in the harmonious *and* discordant ways they come together to dialectically (in)form “a space of conjoining and disrupting, indeed, a generative space of possibilities, a space wherein in tensioned ambiguity newness emerges.” (Aoki, 2004b, p. 318). So understood, dwelling within such edgy yet fecund spaces inspires my inquiry and occasions my learning into: how STEM *and* the cultural commons (Bowers, 2016) enable eco-centric intelligences within communities (Thom, 2019b); conceptualizing modern *and* ecological discourses in ways other than an impasse (Thom, 2021); alternative meanings and purposes for STEM within Indigenous *and* ecological perspectives (Glanfield et al, 2021); dynamics of mathematical ideas as individual *and* collective phenomena (Thom, 2012); mathematical drawings as act *and* artifact (Thom & McGarvey, 2015); mathematical perception *and* representation (Thom et al., 2021); and bodily experiences *and* mathematical conceptions (Thom, 2017, 2018; Thom et al., 2015; Thom & Hallenbeck, 2021; Thom & Pirie, 2002; Thom & Roth, 2011).

Indigenous Knowledge Systems and University Teachings (Florence)

I turn to university and to teachings of Indigenous knowledge systems in the west. After years of teaching I return to study a graduate degree in educational administration as I want to learn more about schools and how schools and school systems come to see youth as deficit. I imagine that I will become a school administrator that will make a change in the school system. I never become a school administrator. When I finish the graduate degree I begin to work with the provincial ministry of education in developing and implementing provincial mathematics programs and developing student assessment materials. I also began to notice that who I am as an Indigenous person made a difference when I was working with communities across Northern Canada around mathematics programs. I remember being invited to sit with Indigenous community members in the northwestern part of the Northwest Territories, outside of the normal mathematics program activities, when the community learned I was Métis. At another community in the Northwest Territories an Elder talked with me about how the number system in the Dene dialect was not a base 10 system when she learned I was Métis. The Elder told me about how numbers were important in communities traditionally but that it was about ‘enough’ and not always needing ‘more.’ These were ideas that I had not previously learned. Indigenous community members would tell me how they were working to have Indigenous languages present within schools. I was asked about the languages that my family spoke and I began to inquire within my family about the Indigenous languages that were spoken, as I could not remember Indigenous languages being spoken.

What I was learning through my living is that the predominant “if then” philosophy so evident in much of my formal education and the policy work was being replaced in my living with the “interdependent relational” philosophy of my early years. As I entered into a PhD program I searched for theoretical frameworks and methodologies that more closely aligned with an “interdependent relational” philosophy. The searching was not easy; but I had the opportunity to learn about narrative inquiry (Clandinin & Connelly, 2004) and an enactivist view of cognition (Maturana & Varela, 1992; Varela, Thompson & Rosch, 1991). These views ‘aligned’ with what I was learning from Indigenous knowledge holders as I was making sense of doctoral studies and aligned with an “interdependent relational” ontological stance.

North

> **TO BE TRULY** wise is to understand that knowing and not knowing are one. Each has the power to transform. Wisdom is the culmination of teachings gleaned from the journey around the circle of life, the Medicine Wheel. Circles have no end. We are all spirit, we are all energy, and there is always more to gain. This is what my people say. When the story of our time here is completed and we return to spirit, we carry away with us all of the notes our song contains. The trick is to share all of that with those around us while we're here. We are all on the same journey, and we become more by giving away. That's the essential teaching each of us is here to learn. (Wagamese, 2011, p. 151).

Our journeys traveling through Wagamese’s Medicine Wheel teachings, East (humility) to South (trust) to West (introspection) bring us to North (wisdom) and our questions of what this journey means for mathematics education. We are aware of the colonizing role mathematics and mathematics education has played and continues to play as “one of the most powerful weapons in the imposition of Western culture … [and] a secret weapon of cultural imperialism” (Bishop, 1990, p. 51). And so, we ask: How does (re)membering place give rise to discourses and actions that are both resonating harmonies and critically dissonant in mathematics education? How can (re)membering place help challenge more dominant ways of being in relation – from exploitation, violence and oppression over land, animals, humans, language and cultures (Calderon, 2014; Seawright, 2014) to more intimate experiences of dwelling together humans and more-than-humans for the wellbeing of all (Abram, 2011).

We acknowledge calls in the literature to re-imagine mathematics education to address current global challenges (e.g., Adams, 2018; Barwell, 2018; Glanfield et al., 2019; Nicol et al., in press; Wolfmeyer et al., 2017). For instance, critiques of educating for STEM, are gaining attention in teacher education (Khan, 2020; Nicol et al., 2020), curriculum (Wolfmeyer et al., 2018a; Thom, 2021) and communities (Thom, 2019b; Wiseman et al., 2020); design (Glanfield et al., 2020), interdisciplinarity (Yaro, Amoah & Wagner, 2020), social justice (Davis & Renert, 2013; Wolfmeyer et al., 2018b); and mathematical formatting (Barwell, 2018; Skovsmose, 2021).

In addition, there are calls to address issues such as equity and the need to rehumanize mathematics education (Guitérrez, 2017, 2018); to teach and assess in ways that build upon the strengths of students from marginalized groups and communities (Aguirre & del Rosario Zavala, 2013; Celedón-Pattichis, Musanti & Marshall, 2010); and to recognize intersectionality (Bullock, 2017; Gholson 2016).

Yet, with Wagamese (2011), we have traveled the four directions to offer narratives for mathematical ways of being that support a more holistic engagement with human and natural environments. Where place, and land, is teacher.

In the Chinese language:

> wisdom is inscribed in a family of words: *human, humility, humus, and humor*, all etymologically related as they are, too, in our language. The Chinese characters of a wise leader read *sei-jin* 聖人–a person who, indwelling with others 人, stand between heaven and earth 土, listening 耳 to the silence, and who, upon hearing the wor[l]d, allows it to speak 口 to others so others may follow. (Aoki, 2004c, p. 214).

> What kind of a place is this? A place where there is room for words like *humor, human, humus, humility* to live together. In such a place, to be humiliated is to be reminded that we are communally ecologic, that the rhythmic measures of living [with] Earth come forth polyphonically in *humor* and *human* and *humus* and *humility*. (Aoki, 2004a, p. 300)

We end as we began with questions …

1. What are the conditions that make possible ethical and rigorous engagement across communities in resonant harmonies and critical dissonances that can help us move together towards improved relationships and wiser futures, as we face unprecedented global and local challenges?
2. What are some guidelines, approaches, and practices for ethical and respectful engagement with communities that can help us to work together in holding space for each other human and more-than-human in the place of mathematics education?
3. How do we learn together, to co-construct and learn to be with each other, the land and our more than human kin, in ways that are compassionate, sensory, interconnected, and with humility, courage, wonder and trust in caring for life over the long haul? And what is the role of mathematics education in this?

DECENTERING TO BUILD ASSET-BASED LEARNING TRAJECTORIES

Amy B. Ellis
University of Georgia
amyellis@uga.edu

The development and use of learning trajectories is a body of research that has made enormous contributions to the field of mathematics education, offering insight into the teaching and learning of topics at all levels. Simultaneously, the work of building learning trajectories can benefit from explicitly adopting an anti-deficit stance, incorporating ways to center student voices from an asset-based perspective. In this paper I propose two related constructs to support this work: decentering and second-order models. In decentering, researchers work to set aside their own knowledge to understand students' reasoning as viable. This can support models of student mathematics that position student thinking as rational, powerful, and productive. I provide one example of the work of decentering and discuss ways to build learning trajectories that emphasize students' strengths and competencies.

Learning trajectories research has played a prominent role in the field of mathematics education, and it continues to exert influence on the teaching and learning of mathematics. In a recent plenary address to PME-NA, Steffe (2017) remarked that the construction of learning trajectories is "one of the most daunting but urgent problems facing mathematics education today" (p. 39). The influence of this sphere of research is evident in funding priorities at the NSF and the IES, in special journal issues (Duncan & Hmelo-Silver, 2009), in topics conferences (e.g., the learning trajectories panel held at the VARGA 100 Conference in 2019), and in special reports (Daro et al., 2011; Taguma & Barrera, 2019). For instance, the National Research Committee (NRC) issued a special report in 2009 identifying a set of goals for young children based on learning trajectories, which ultimately led to the use of learning trajectories as a foundation for the Common Core standards in mathematics (Clements et al., 2019). We also see the prominence of learning trajectories research for PME-NA as reflected in plenary paper topics (e.g., Battista, 2010; Confrey, 2012; Sarama, 2018; Steffe, 2017).

Researchers have defined and theorized learning trajectories in a variety of ways. Simon (1995) initially coined the term "hypothetical learning trajectory" to describe "the learning goal, the learning activities, and the thinking and learning in which students might engage" (p. 133). Clements and Sarama (2012) described a learning trajectory as a depiction of students' thinking and learning in a specific mathematics domain and a "related, conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children though a developmental progression of levels of thinking" (p. 83), and Confrey and Maloney (2010) described a learning trajectory as a progression of cognition that represents ordered, expected tendencies developed through empirical research aimed at identifying the likely steps students follow. There is variation in the degree to which researchers characterize learning trajectories as being (a) connected to particular task sequences, (b) influenced by specific teaching actions or other contextual factors, and (c) depictions of strategies, skills, or performances versus concepts and operations; for a more expanded discussion of these differences, see Battista, 2010, or Ellis et al., 2014. For my work, I have found Steffe's (2012) characterization to be particularly useful. He described a learning trajectory as a model of students' initial concepts and operations, an account of the observable changes in those concepts and operations as a result of students' interactive mathematical activity in the situations of learning, and an account of the mathematical interactions that were involved in the changes. I consider task sequences to be a part of mathematical interactions, but the emphasis is on the interactions themselves, including particular teaching moves, students' activity and conversation with one another, and students' interactions with tools, artifacts, and representations.

As a body of research, learning trajectories have made enormous contributions to the field. They have offered insight into major milestones of students' conceptual development for a variety of topics, including measurement (Battista, 2010; Clements & Sarama, 2009; Sarama et al. 2011), composition of geometric figures (Clements et al., 2012), fractions (Maloney & Confrey, 2010; Steffe, 2012b; Steffe & Olive, 2010; Wright, 2014), early algebra (Blanton et al., 2015; Hackenberg & Lee, 2015), geometry (Fitri & Prahmana, 2020), function (Ellis et al., 2016; Fonger et al., 2020), and probability (Rahmi et al., 2020; Wijaya & Doorman, 2021), among others. Learning trajectories research informs not only standards development, but also curriculum, pedagogical decision making, teacher noticing, and professional development (Clements, 2007; Confrey et al., 2014; Hackenberg & Sevinc, 2022; Liss, 2019; Meyers et al., 2015; Suh et al., 2021; Steffe, 2004). However, this body of research has also weathered critiques. These critiques include concerns about an overfocus on tasks, cautions about the need to better attend to variation in students' progression, scrutiny of the basis for the construction of learning trajectories, and calls to more explicitly address equity and inclusion.

An overfocus on tasks can occur when learning trajectories offer only task sequences paired with learning goals, without attending to the teaching actions and other contextual factors that are important for supporting students' development. Relatedly, learning trajectories can be construed as generalizable or transportable from one situation or context to the next, as if students, teachers, classrooms, and cultures were interchangeable. It is important to recognize that trajectories developed in one context may not always appropriately depict students' learning in a markedly different context. Additionally, not all students will progress in the same way throughout any given trajectory. Learning is more individualized, context-dependent, and idiosyncratic than what could ever be depicted in a neat, ladder-like sequence. Certainly, many researchers who construct learning trajectories are aware of these constraints. For instance, Clements and Sarama (2012) wisely reminded the reader that their task sequences are not necessarily the only or even the best path for learning and teaching, but are instead merely hypothesized to be "one fecund route" (p. 84). Nevertheless, learning trajectories have, at times, been interpreted in overly broad or simplified ways.

A more central issue that I would like to tackle in this paper is the models that constitute the basis of learning trajectories. In particular, it is worth considering the affordances and constraints of these models for developing and using learning trajectories to highlight students' competencies. In order to do so, I now turn to a consideration of first-order and second-order models, advocating for the use of second-order models to advance an asset-based perspective.

The Potential Pitfalls of Building Learning Trajectories from First-Order Models

Learning trajectories that are built on the foundation of the researcher's understanding of the discipline are based on what we call first-order models (Steffe & Olive, 2010). First-order models, or first-order knowledge, are the models that one constructs "to order, comprehend, and control his or her own experience" (ibid, p. xvi). There is robust evidence of reliance on researchers' first-order knowledge of mathematics in learning trajectories research. For instance, Clements and Sarama (2012) described a hypothetical learning trajectory as one involving conjectures about a possible learning route that aims at significant mathematical ideas, and a specific means to support and organize learning along this route. Those mathematical ideas are the researcher's ideas: "The trajectory is conceived of through a thought experiment in which the historical development of mathematics is used as a heuristic" (p. 82). To offer a few other examples, Confrey and colleagues (2014) used the term learning trajectory to refer to "clusters and sequences of standards and their related descriptors" (p. 720), Baroody et al. (2022) depicted the goals of a learning trajectory to be based on "the structure of mathematics, societal needs, and research on children's thinking about and learning of mathematics" (p. 195), and Andrews-Larson et al. (2017) described their hypothetical learning trajectory as content-specific documentation of common milestones and learning environments supporting students' progression across those milestones. Certainly, not all studies reporting on learning trajectory development conceive of learning trajectories in this manner. For instance, Confrey (2006) underscored the importance of the learner in guiding this work, emphasizing the centrality of students' voices and disciplinary perspectives, and others have published learning trajectories that reflect this aim (e.g., Fonger et al., 2020; Steffe, 2012; Steffe & Olive, 2010). Nevertheless, there remains a strong emphasis on learning trajectories that are based on researchers' own mathematics as starting points.

Building learning trajectories from first-order knowledge can offer important affordances. Such trajectories reflect the researcher's nuanced, in-depth understanding of the relevant content and key learning goals, as well as research-based knowledge of how to support student learning. At the same time, trajectories developed from first-order knowledge may also position students in terms of how they measure up against researchers' knowledge of the discipline. Moreover, this framing runs the risk of depicting students in terms of falling short. Adiredja (2019) characterized this stance as "epistemological violence", particularly towards minoritized students and students from marginalized communities, when the research we conduct positions students' knowledge as inferior or problematic. Furthermore, such a stance centers the perspective of the expert rather than that of the student. Certainly, many thoughtful scholars are careful to consider these issues in both their construction and use of learning trajectories, emphasizing the potential of learning trajectories to be asset-based models (e.g., Clements & Sarama, 2012; Hunt et al., 2020; Meyers et al., 2015; Suh et al., 2021). There is nothing inherent in a learning trajectory that requires it to be constructed as a deficit-based tool. Nevertheless, learning trajectories built from first-order models may fail to identify, sufficiently explore, or acknowledge the competence and brilliance of student thinking. In fact, as a field we run the risk of learning trajectories being used to bolster deficit stances towards minoritized and marginalized students, particularly when the trajectories over-privilege formal language, consistency in understanding, or straightforward and direct change in understanding (Adiredja, 2019). Adiredja pointed out that it is not that these mathematical goals are bad, but rather, an inflexible privileging of such goals can interact with deficit master-narratives to devalue the mathematical sensemaking of students, particularly students of color.

Learning trajectories built from first-order knowledge can also run the risk of encouraging teachers and other stakeholders to use them in a manner that places students on a continuum, with some positioned as more advanced and others positioned as deficient. Such an emphasis is reminiscent of the studies focused on achievement gaps, which allow researchers to "unconsciously normalize, the 'low achievement' of Black, Latina/Latino, First Nations, English language learners, and working-class students without acknowledging racism in society or the racialization of students in schools" (Gutiérrez, 2008, p. 359). Moreover, this treatment of learning trajectories may miss important nuances, not only about student thinking and reasoning, but also about the ways in which students may shift from one understanding to another based on complex, interrelated factors.

What, then, is the alternative? Researchers can instead psychologize students' mathematics by constructing second-order models, which are the hypothetical models observers construct of their students' knowledge in order to explain their observations of students' states and activities (Steffe & Olive, 2010). They are referenced to the researcher's first-order mathematics, as well as the researcher's conceptions and interpretations of the language and actions of students. These second-order models are sometimes referred to as the mathematics of students; students' first-order models (their own models of mathematics) are referred to as students' mathematics (Steffe, 2017).

Building Learning Trajectories from Second-Order Models

In building learning trajectories that are elaborations of second-order knowledge, we concern ourselves with identifying the mathematics of students and elaborating students' mathematical concepts and operations. I consider these learning trajectories to be *coproduced* by students and researchers (Steffe, 2012). Although initial hypothetical learning trajectories may be informed by a researcher's first-order mathematical knowledge, in combination with their knowledge of student thinking, these trajectories are nascent, ill-formed, and flexible. The learning trajectories that are consequently built out of teaching actions with students are accounts of students' initial concepts and operations, an account of the observable changes in those concepts and operations as a result of teaching and learning actions, and an account of the teaching and learning actions that led to the changes.

Building learning trajectories as second-order models encourages, or perhaps even requires, a different epistemology of mathematics, one that deviates from Western naïve realism traditions. Drawing on Piaget's epistemological beliefs, von Glasersfeld (1982) wrote that "The cognitive organism is first and foremost an organizer who interprets experience and, by interpretation, shapes it into a structured world" (p. 612). This one sentence conveys a radical departure, as von Glasersfeld put it, from traditional ideas of not only knowledge, but of reality itself. Knowledge is not a more or less accurate representation of reality. We construct our conceptions of reality through perception, not directly, and we cannot maintain a belief about knowledge being a reflection of reality by simply acknowledging that our reflection may not always be very accurate. This is not to say that von Glasersfeld denied reality; rather, he considered it to emerge only through bumping up against constraints. From this perspective, it does not make sense to judge knowledge based on its accuracy; in fact, this would be impossible, because it would require comparing one's knowledge to an independently existing reality and judging the closeness of the match. How can any human do this without direct access to that reality? Instead, knowledge is successful if it is viable, i.e., when it is not impeded by constraints.

Within this framing, there is no such thing as a mathematics that resides outside of human experience. The very concept of the second-order model is based on an epistemology that considers mathematics to be a product of the functioning of human intelligence. Students' mathematics *is* the mathematics. Certainly, we can compare our second-order model of the mathematics of a student to our first-order model of our own mathematics. In doing so, it is productive to understand that there are two mathematics, and both are legitimate. This requires a rejection of the Platonist knowledge traditions that frame mathematics as universal and objective. It also requires one to position students' ways of knowing and thinking as rational, rather than inferior when compared to standard strategies, procedures, and conventions (Louie et al., 2021). As L. Steffe explained, "students are 'never wrong' even though their thinking may not appear as viable with respect to certain situations or ways of thinking. Mistakes are always an observer's concept" (personal communication, October 5, 2022). Louie and colleagues argued that a failure to position students' reasoning as legitimate can discourage teachers from attending closely to unconventional ways of thinking and seeking to understand them, much less valuing or inviting them. I argue that this can also be true of researchers' treatment of students' ideas. In contrast, if we understand that students' mathematics *is* the mathematics, then we will be compelled to take students' reasoning and competencies as the starting point for building any learning trajectory.

One way to build second-order models is through the process of conceptual analysis, which is a process guided by the question, "What mental operations must be carried out to see the presented situation in the particular way one is seeing it?" (Steffe, 2017, p. 78). Thompson and Saldanha (2000) described conceptual analysis as articulating the conceptual operations that, "were people to have them, might result in them thinking the way they evidently do" (p. 315). Engaging in conceptual analysis draws on a researcher's ability to decenter, and can support the development of the epistemic student. Below I discuss each of these constructs in turn.

Decentering

Piaget (1955) introduced the idea of decentering to characterize the actions of an observer attempting to understand how an individual's perspective differs from their own (Teuscher et al., 2016). Piaget developed this idea to describe an aspect of a child's development: when a child learns to decenter, they begin to abandon egocentrism and develop the capacity to consider another's perspectives, thoughts, and feelings (Piaget & Inhelder, 1967). Steffe and Thompson (2000) then extended Piaget's construct to characterize a teacher's stance towards a student, particularly in terms of a teacher's ability to adjust their actions in order to understand a student's thinking.

Arcavi and Isoda (2007) described decentering as:

> the capacity to adopt the other's perspective, to 'wear her conceptual spectacles' (by keeping away as much as possible our own perspectives), to test in iterative cycles our understanding of what we hear, and possibly to pursue it and apply it for a while. Such a decentering involves a deep intellectual effort to be learned and exercised (p. 114).

Decentering is a stance that attends to both mathematical thinking and social interactions. It entails interacting with students reflectively, in a conscious attempt to set aside one's own knowledge to understand a student's reasoning as viable (Thompson, 2000). This reflective stance towards interactions with students is crucial for creating viable second-order models, and such efforts are hampered if a teacher – or a researcher – does not make concerted efforts to differentiate the mathematics of students from one's own mathematics. Steffe and Ulrich (2020), in distinguishing between responsive / intuitive interaction and analytic interaction, described the latter as a process of stepping out of analyzing students' thinking in ongoing interaction. All of the researcher's attention is absorbed in trying to think like the students, and produce and experience mathematical realities that are intersubjective with their own first-order models.

If researchers do not decenter, students' thinking and reasoning may not be considered worthwhile models of the environment in their own right, and instead may be positioned only in relation to standard models (i.e., the researcher's models) of mathematical knowledge. The construction of learning trajectories that are not a consequence of decentering may then position students as falling short, with insufficient attempt to understand or model students' thinking as viable, powerful, and potentially productive, even in times when it deviates from canonical mathematics. In contrast, a decentering researcher "always assumes that a student has some viable system of meanings that contribute to her or his actions" (Teuscher et al., 2016, p. 439).

Teuscher and colleagues went on to point out that the ideas of correct versus incorrect become largely irrelevant beyond informing one's future actions. This is not to suggest that correctness is unimportant. Rather, when engaged in the hard work of decentering, correctness is not a notion that contributes utility to building second-order models. A student does not position their own knowledge as incorrect, and decentering means seeing the world with the student's mathematical eyes.

The Epistemic Student

Hackenberg (2014) defined an epistemic student as an organization of schemes of action and operation that undergo change over time. The epistemic student is a model, one that is composed of the ways of operating common to all students at the same level of development "whose cognitive structures derive from the most general mechanisms of co-ordination of actions" (Beth & Piaget, 1966, p. 308). I see the epistemic student as a useful model of characteristic mathematical activity that is developmental, generalized, and dynamic (Ellis, 2014). It is an abstraction (Piaget, 1970), meant to explain some ways of operating that we suspect may be common across students.

The epistemic student is a helpful construct because students who share initial concepts and operations often respond in somewhat common ways to thoughtful instructional interactions. This does not mean that every student will respond identically, but typically there are a manageable number of ways of reasoning that bubble up repeatedly across participants and contexts. The epistemic student can be a useful model for trying to walk the tightrope between overgeneralization and over specificity. I acknowledge that it is not appropriate or even accurate to claim that my second-order models and resulting learning trajectories, which are developed from small numbers of students in specific contexts, would extend to all students in all contexts. To do so would ignore the variation in students' experiences, backgrounds, and positionalities, as well as the variation in classrooms, schools, and cultures. Simultaneously, the work of building learning trajectories necessarily entails a belief in the value of creating scientific (rather than experiential) models with the potential of being useful across different students and contexts.

Learning Trajectories Built from Second-Order Models Emphasize Anti-Deficit Stances

The body of learning trajectories research has been critiqued for not adequately considering equity or addressing student diversity (e.g., Zahner & Wynn, 2021). Some may even be used in ways that can reinforce deficit perspectives. A deficit perspective is "a propensity to locate the source of academic problems in deficiencies within students, their families, their communities, or their membership in social categories (such as race and gender)" (Peck, 2021, p. 941). In contrast, an anti-deficit perspective begins with the assumption that students are capable of reasoning mathematically and that they bring productive resources for learning mathematics. It acknowledges that learning is time-consuming, and that "imperfect articulations of mathematical ideas and some inconsistencies in the student's current conception are a natural part of the process" (Adiredja, 2019, pp. 416-417). Furthermore, adopting an anti-deficit perspective means locating the source of students' academic challenges within the racist, sexist, and ableist institutional structures that restrict, or even actively oppose, access to high-quality educational opportunities. When considering student thinking, a researcher considers and identifies the assets and competencies that students possess, rather than what students lack.

A goal of learning trajectory construction must be to position student thinking as rational, powerful, and viable, and from that position, seek to understand why students reason the way they do. It is our job, as researchers, to construct second-order models that reflect a value that student thinking is sensible and intelligent. In constructing learning trajectories, we must begin with that stance, identify student concepts and operations so that we can meet students where they are, and then consider productive teaching interactions that can support students' shifts from one way of thinking to the next. In doing so, we must also understand and acknowledge that these shifts may be idiosyncratic, time-consuming, and messy, as is learning itself. By starting from a model of the mathematics of students, we can then construct models for how teachers might interact with students to bring forth productive changes in their concepts and operations.

The learning trajectories that my colleagues and I produce (e.g., Ellis et al., 2016; Fonger et al., 2020) emphasize students' strengths and competencies, even when student thinking differs from canonical mathematics. We see an important outcome of our learning trajectory work to be that of highlighting those strengths and competencies with stakeholders. The goal of our work is to understand why students reason the way they do, and to show how students can and do think in ways that are thoughtful, reasonable, and nuanced, even if, at first glance, one might only see an incorrect answer or a puzzling strategy. Like many others (e.g., Clements & Sarama, 2012), our learning trajectories provide multiple viable paths and do not claim to represent the only (or even the best) route to learning. Centering the mathematics of students is explicit in our theoretical framing and constitutes the starting point for creating and refining trajectories.

An Example of Building a Learning Trajectory from Second-Order Models

Our learning trajectories are depictions of concepts and mental operations, in concert with teaching interactions and in relation to task sequences, set in specific teaching and learning concepts. The concepts and mental operations *are* the mathematics in our trajectories. As an example, my colleagues and I constructed a learning trajectory of students' understanding of exponential growth from a covariation perspective (Ellis et al., 2016). That trajectory in its entirety is beyond the scope of this paper, but I will highlight here four of the operations we identified: (1) Explicit coordination of change in y-values for 1-unit change in x-values, (2) Coordination of change in y-values for multiple-unit changes in x-values: repeated multiplication imagery, (3) Coordination of change in y-values for multiple-unit changes in x-values: exponentiation imagery, and (4) Coordination of change in y-values for any unit change in x-values, for any Δx. Mathematically, from our perspective, these are all the same operation. For an exponential function $y = ab^x$, it is possible to coordinate the change of any two y-values with any two corresponding x-values according to the relation $\frac{y_2}{y_1} = b^{x_2 - x_1}$, and the value of Δx is immaterial. Conceptually, however, these are not the same operation. In our work with students, my colleagues and I found that coordinating changes in x-values and corresponding y-values for unit changes in x is different from coordinating for large changes in x. Additionally, one can engage in coordination for large changes in x either by appealing to repeated multiplication imagery, or by appealing to a different set of stretching or scaling images. Furthermore, managing this type of coordination for cases when the change in x is less than 1 draws on a different set of concepts, and students can engage in operations (1) – (3) long before they can do operation (4).

What students can do and how they can reason is always rational from their perspective. Not yet being able to engage in operation (4) is something that a researcher would describe as a constraint for the student. But, from the student's perspective, there does not exist a more "advanced" way to coordinate exponential growth. Students are always reasoning with their available conceptual operations. For teachers, then, it is advantageous to understand how students may be operating, so that they do not impose ways of thinking on the students that run counter to the students' reasoning. Curricular treatments of exponential growth, however, to the extent that they might address a coordination approach at all, do not distinguish these forms of reasoning, because they can all be handled with the same formula. In contrast, my teaching interactions with students revealed that it is sensible for students to draw on different imagery when constructing these operations, and that transitioning from one form of reasoning to another can be effortful and may require specific instructional support. In short, such a transition is a significant intellectual achievement. Without this knowledge, teachers and textbooks will not distinguish them, and students may consequently experience challenges in making sense of expressions such as $2^{(1/7)}$; after all, when the meaning of exponents presented to students in school is only that of repeated multiplication what does it mean to engage in such multiplication 1/7 times? Now that we are aware that these operations are mathematically different for students, we can help improve the teaching and learning of exponential growth ideas.

As an example of the decentering work that supported our understanding of the mathematics of students, consider a task in which students are provided with a table of height values at certain times for a special plant called a Jactus, which grows exponentially (Figure 1).

This is a table for a Jactus that doubles every week. The entries are approximate. How much taller will the plant grow in a quarter of a week?

Week	Height
0	1"
0.25	???
0.5	1.414214"
0.75	1.681793"
1	2"
1.25	2.378414"
1.5	2.828427"

Figure 1: Table of Week and Height Values for a Doubling Jactus

If I were to solve this problem, I would take the ratio of any two consecutive height values in the table that were a quarter of a week apart. That ratio is approximately 1.189, and so I can divide the height at week 0.5 by 1.189 to find the missing height value. The question is written in an unusual way, because it asks students about how the plant grows in a quarter of a week, but the table has an empty spot for the height value at a specific time, 0.25 weeks, which is actually a slightly different question. This was a "serendipitous mistake" (Tasova et al., 2021), because it enabled us to identify a form of reasoning about which we had been unaware prior to students encountering the task. Our initial intention was to support the idea that the ratio of height values for any quarter-week gap will always be the same.

When working with 8th-grade participants who had never before had school instruction on exponential growth, we initially expected that they would use a strategy like the one I described, because they had already used that strategy with prior tables. For instance, when encountering tables with uniform gaps of 1 week, 2 weeks, or 5 weeks, our students had divided height values to determine the plant's growth for the corresponding amount of time. But in this case, they did not leverage this strategy. For instance, consider the work of one of our participants, Uditi (a self-chosen pseudonym). In describing herself, Uditi discussed her experiences as an immigrant to the midwestern United States from India. She shared that she enjoyed mathematics and science, which was why she had volunteered for our research study, and she preferred expressing her ideas in small groups rather than with the whole class. When encountering the task in Figure 1, Uditi wrote the expression "$1 \times \_\_\_\_^{0.5}$". She then proceeded to use a cumbersome guess and check strategy to determine the missing value that would go in the blank to yield the plant's height at 0.5 weeks, which she knew had to be approximately 1.414. By doing this, Uditi determined that the growth factor was 2, and then laughed ruefully as she saw that the task description had already told her that the Jactus doubled each week. She then wrote the equation, "$\text{Height} = 1 \bullet 2^{\text{week}}$", and then substituted 0.25 for the exponent to determine the height at 0.25 weeks.

Uditi's strategy was correct, and it was also creative. It revealed an understanding of many important ideas, including the idea that she could write a correspondence relation of the form $y = 1b^x$ because the initial height at Week 0 was 1 inch. Her strategy, however, also surprised me and my colleagues, because it was different from what she had done before, and it was also more cumbersome and difficult than just dividing. Moreover, Uditi was not the only student who approached the problem in this surprising way. Other students across two different teaching experiments did as well, which suggested to us that there was an important conceptual issue with that task that we had not anticipated. In combination with other students' responses to similar tasks, we began to realize that the value of Δx was critical. If one week is the period of time for the plant to double its growth, then it became clear that asking students to determine what happened *within* a week was a conceptually different task than asking students what happened across a span of multiple weeks – even though, from our perspective as researchers, the two tasks were mathematically identical.

Part of the job of creating second-order models is to engage with students reflectively, attempting to decenter in order to understand why their behavior and reasoning is sensible. Uditi and other students could already write expressions such as $y = x^{0.25}$, therefore presumably using decimal and fractional exponents to determine a fixed height value. What puzzled us was that they could also divide two height values to determine an amount of growth for a given time span. Why, then, did Uditi not do so with this task? Our goal was to now try to understand Uditi's reasoning that drove the unanticipated strategy. In doing so, we hypothesized that it was because Uditi could attribute two meanings to an equation such as height = 2^3, but only one meaning to an equation such as height = $2^{0.25}$. The expression 2^3 in the first equation meant two things to Uditi: It could be a static height value, such as the plant's height at 3 weeks, or it could be a measure of growth, i.e., how many times larger the plant grows in height for a time span of 3 weeks. But the expression $2^{0.25}$, we hypothesized, could be the plant's static height value at 0.25 weeks, but not how many times larger the plant would grow in a time span of 0.25 weeks. We suspected two reasons for this, both related to students' meanings for multiplication. The first is that determining growth across multiple weeks entails generalizing the operation of multiplication to an exponential context. This is fairly easy to do, as many students hold an expectation that multiplication makes bigger (Greer, 1987). They can extend their meaning of doubling by mentally repeating the operation multiple times across multiple weeks. In contrast, 0.25 weeks is less than a week, and there is no easy way to extend the operation of doubling to a fraction of a week. Furthermore, Uditi and the other students we worked with had all received school instruction that described exponential growth as repeated multiplication. The image of repeated multiplication does not easily lend itself to decimal exponents, as it is difficult to imagine such an operation.

Our efforts to construct a second-order model of Uditi's mathematics via her activity with this and related tasks led us to realize that constructing exponents less than 1 as a representation of growth is its own separate mathematical concept. This is not something I understood prior to working with Uditi and other students. We learned that in order to make sense of non-natural exponents as representations of growth, it is useful to invite students to shift to images that do not entail repeated multiplication. For our participants, this meant creating an image of change in the plant's height between weeks that represented an action of stretching, or scaling. For instance, Pei's drawing (Figure 2) shows a Jactus stretching as it doubled from Week 1 to Week 2 to Week 3, on the right, and then he was able to reverse his doubling operation to imagine halving the Jactus's height to see how tall it would be at Week ½ on the left. Once Uditi developed a similar scaling image, she was then able to answer the following question: "Say a plant grows 3 times as tall every week. How many times taller will it grow in 1 day?". Uditi wrote "$3^{.14}$" and explained, "There are seven day(s) in a week. So, I divided one week into seven parts, which represent one day." She could now conceive of an expression such as $3^{.14}$ to represent a measure of growth, not just a static height value.

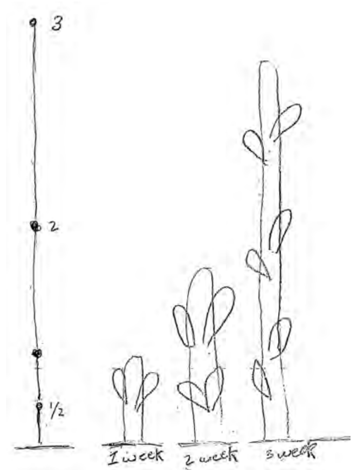

Figure 2: Pei's Drawing of a Doubling Jactus

Before my teaching interactions with Uditi, I was unaware that an expression such as $y = ab^x$ could represent two different ideas, a static value or an expression of growth. Certainly, this is not a big idea, and its truth is obvious to me now. Nevertheless, the concept was not originally part of my own first-order knowledge, nor was I aware that the mental imagery needed to undergird the second idea would need to be different from the first in order to accommodate non-natural exponents. Thus, my participants' mathematics served as a source of novel mathematics for me as a researcher, as it could also do for teachers who make use of the learning trajectory.

This approach toward the creation of learning trajectories shifts mathematical authority to the students. Uditi's mathematics served as a source of new mathematics for me. As a researcher, it was my job to understand her mathematics, why it made sense conceptually, and then determine ways to support her to create the meanings and images that would be productive for fostering an understanding of nonnatural exponents. This work centers student thinking as the core of our activity. Moreover, a productive stance to aid in my own decentering is to ask the question why. Why did Uditi's activity make sense? Why did she use the strategy that she did? Researchers must ask these questions with the assumption that there is always a sensible reason driving the student's activity. We simply need to be careful enough in our own research to find it. Moreover, in doing that work, we as researchers can grow in our own first-order knowledge: knowledge of the mathematics itself, of student thinking about mathematics, of the concepts and operations needed to make sense of particular ideas, and of the kinds of tasks and teaching moves that can support the development of those ideas.

I would like to close this extended example by pointing out that this model of a learning trajectory, with the four operations I shared, differs from learning trajectories that are (a) a proposal of the kinds of reasoning we should expect from students based on content analysis, (b) a specification of target performances, (c) a set of strategies, (d) a network of constructs that one might encounter through curriculum and/or instruction, or (e) a set of tasks that could be provided as stand-alone problems. An elaboration of a learning trajectory built from second-order models will identify student concepts and operations in relation to both tasks and teaching actions. I do not mean to denigrate or minimize the incredibly valuable contributions that prior learning trajectories have made, but rather, to articulate and clarify my vision of what a learning trajectory could be when it is built from second-order models.

Learning Cannot be Separated from Activity and Context

Helping our students develop stretching and scaling images for exponential growth turned out to be a productive route for their learning. Furthermore, because we saw the type of reasoning Uditi demonstrated in other students, our construction of the epistemic student from Uditi and her peers supported a model in which one may need explicit support to shift from a repeated multiplication image to an alternate image. Sharing second-order models in this manner can also help mathematically experienced adults, such as curriculum authors and teachers, understand and appreciate a different mathematics from the one they already know. In this manner, learning trajectories research can play a role not only in helping the field better understand how to support student learning of particular mathematics topics in the curriculum, it can – and should – determine what mathematics should be in the curriculum to begin with.

Nevertheless, emphasizing stretching and scaling images may not necessarily be a universally productive route. The degree to which it proves to be fruitful for other students in other contexts is an open question. As I alluded to above, researchers have raised concerns about the need to attend more explicitly, and more theoretically, to the role that teaching interactions play in influencing student learning (Empson, 2011; Simon et al., 2010). This body of work challenges the assumption that features of learning are transportable, or that it is possible to study effective teaching and learning in a particular context and tease out some key aspects that can then be generalizable to other contexts. Mathematics learning occurs in interaction, not only via teaching actions, but also via tasks, tool use, student discourse, classroom norms, school and community settings, and in relation to students' identities, histories, and positionalities (Nasir et al., 2008). Because mathematics learning does not occur in isolation from these sociocultural contexts, it is wise to avoid overly strong claims about the transportability of any particular finding. Learning trajectories research is a worthwhile endeavor not just for its potential to broadly improve the teaching and learning of particular topics (Baroody et al., 2022), but also to develop a set of contextualized, specific case studies of the types of reasoning that can exist and can be supported in particular ways.

Build Learning Trajectories that are Engines of Equity

I have advocated for the usefulness of the epistemic student as a construct that can help researchers navigate a balance between over generalizability and over specificity. In what might seem like an odd turn, I am now going to argue against my own argument, or, at least, consider an alternate stance. That stance is this: If the epistemic student is an idealized abstraction, a model composed of common ways of operating, this leads me to question what type of student we imagine when evoking the epistemic student. Analyzing student reasoning without attending to sociocultural diversity runs the risk of reinforcing deficit narratives about minoritized students and students from marginalized communities (Zahner & Wynn, 2021). And yet, the construct of the epistemic student may encourage this form of analysis.

Studies of cognition and equity are frequently positioned as separate areas of research in mathematics education (Adiredja, 2019). For instance, Adiredja has pointed out that racial and gender inequities are seldom considered in cognition studies, and, furthermore, engaging in analysis that does not include these positionalities of the students we study does not make our research apolitical: "Rather, it has the impact of maintaining the status quo that is the dominant master-narrative about White male exclusive membership in mathematics and centering education around their needs and concerns" (ibid, p. 426). One way to begin to address this limitation can be to extend the notion of the epistemic student to understand the identities and positionalities of our research participants who contribute to the epistemic student model. We can invite studies highlighting the powerful reasoning of marginalized and minoritized students, including being deliberate about who we include as participants in research opportunities, being thoughtful about the ways in which we engage our participants in research, and being explicit about our participants' positionalities.

We must build learning trajectories that are explicitly and theoretically organized from an asset-based perspective. Such trajectories can begin with efforts to understand our students' cultural competencies, and by drawing on our students' backgrounds and out-of-school knowledge and practices, rather than ignoring or even excluding them. Deliberately creating learning environments that leverage students' cultural and linguistic strengths supports their mathematical reasoning (Abdulrahim & Orosco, 2020). This means, then, broadening our starting point for the construction of hypothetical learning trajectories. Rather than beginning only with our first-order knowledge of mathematics, combined with research and pilot studies about student learning, we can also incorporate (a) hypothesized second-order models, (b) research on students' funds of knowledge relative to the topic at hand, and (c) information about our participants' values, interests, and knowledge. In this manner, learning trajectories research can meaningfully center student voices, and can serve as a bridge connecting research on cognition and equity.

Acknowledgments

The research reported in this paper was supported by the National Science Foundation (award no. 1920538). I would also like to thank Maria Blanton, Marrielle Myers, Leslie Steffe, and Jennifer Suh for their helpful conversation and feedback on the ideas in this paper, as well as Joel Amidon, Muhammed Fatih Dogan, Nicole Fonger, Torrey Kulow, and Zekiye Özgür for their contributions and brilliance in collaboratively constructing, refining, and writing about learning trajectories with me.

THE ROLE OF LEARNING PROGRESSIONS IN "DEMOCRATIZING" STUDENTS' ACCESS TO ALGEBRA

Maria Blanton
TERC
Maria_Blanton@terc.edu

Learning progressions have become an important construct in educational research, in part because of their ability to inform the design of coherent standards, curricula, assessments, and instruction. In this paper, I discuss how a learning progressions approach has guided our development of an early algebra innovation for the elementary grades and provide examples of how this approach can help challenge a settled mathematics learning status quo about the kind of algebra students can learn, when they can learn it, and how all students can be successful. Empirically derived learning progressions are an important part of designing early algebra innovations that can open new curricular pathways for teaching and learning algebra, creating accessible and effective avenues of learning for all students.

Keywords: Algebra and algebraic thinking, learning trajectories and progressions, elementary school education

Using a Learning Progressions Approach to Develop an Early Algebra Innovation

Over a decade ago, my research interests turned towards a question that I view as critically important in teaching and learning algebra: Does early algebra matter? Since I assume early algebra *does* matter, perhaps a better way to frame this question is to what extent does early algebra matter, in what ways does it matter, and how might we capture or measure this? There are deep implications for the answers to these questions. A truly effective integration of early algebra (or, algebraic thinking in the elementary grades) would entail significant costs because it requires "deep curriculum restructuring, changes in classroom practice and assessment, and changes in teacher education—each a major task" (Kaput, 2008, p. 6). Such costs highlight the need for carefully constructed models of early algebra instruction—models that have been missing from elementary grades mathematics. However, these models, as curricular roadmaps for developing children's algebraic thinking across elementary grades in a deep, systemic way, are essential to understanding early algebra's impact.

To build such a model, our research team turned to a *learning progressions approach*. Learning progressions have become an important construct in educational research (Clements & Sarama, 2004, 2009; Confrey et al., 2014; Simon, 1995; Stevens et al., 2009), in part because of their ability to inform the design of coherent standards, curricula, assessments, and instruction (Daro et al., 2011). We focused our work on the development of several core components aligned with this approach (e.g., Clements & Sarama, 2004; see also Fonger et al., 2018): (1) empirically-derived learning goals around algebraic thinking in elementary grades; (2) grade-level instructional sequences designed to address these learning goals; (3) validated assessments to measure students' understanding of core algebraic concepts and practices as they advance through the instructional sequences; and (4) progressions that specify increasingly sophisticated levels of thinking students exhibit about algebraic concepts and practices in response to an instructional sequence. A learning progressions approach served two purposes in our work. It provided an over-arching "large-grain-size-level" framework to guide our design of a Grades K–5 early algebra intervention from which we might measure the impact of early algebra on children's algebra readiness for middle grades. It also provided a theoretical mechanism for identifying "small-grain-size-level" cognitive foundations in children's algebraic thinking that, along with other existing research in the field, could inform the development of our intervention.

At a large-grain-size level, we used a learning progressions approach (e.g., Shin et al., 2009, Stevens et al., 2009) in the development of learning goals, grade-level instructional sequences, and grade-level assessments for K–5. Using Kaput's (2008) content analysis of algebra as a set of *key aspects* (ways of thinking algebraically) and *core strands* (content domains where algebraic thinking occurs), we identified core algebraic thinking practices of *generalizing*, *representing*, *justifying*, and *reasoning with* mathematical structure and relationships as an underlying conceptual framework for the design of our goals, sequences, and assessments (Blanton, Brizuela et al., 2018). We viewed a conceptual framework organized around algebraic thinking *practices* as critical to avoid designing instructional sequences based simply on the use of ubiquitous "algebra" tasks (e.g., solving equations) and not cohesively grounded in what it means to think algebraically.

To develop our learning goals, we analyzed the treatment of the core algebraic thinking practices in several dimensions: (1) empirical research on Grades K–8 students' algebraic thinking; (2) national curricular frameworks and standards such as the *Principles and Standards for School Mathematics* (National Council of Teachers of Mathematics [NCTM], 2000) and *Common Core State Standards* (National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010); (3) Grades K–8 curricular materials (e.g., *Everyday Mathematics*, *Singapore Math, Investigations)*; and (4) formal algebra content at both secondary and postsecondary levels. We then organized early algebra content to align with strands in Kaput's (2008) algebra content analysis, in particular, "the study of structures and systems abstracted from computations and relations" (Strand 1) and the "study of functions, relations, and joint variation" (Strand 2) (p. 11). These strands also aligned with core content around which the early algebra research base had coalesced. Based on this, we structured our findings on early algebra content within several "Big Ideas" (e.g., Stevens et al., 2009), or content domains, where core algebraic thinking practices can occur: Generalized Arithmetic; Equivalence, Expressions, Equations, and Inequalities; and Functional Thinking. We then unpacked the role of algebraic thinking practices within each Big Idea by delineating core algebraic *concepts* related to the practices, *claims* that specify the nature of skills or understandings expected of students regarding a specific concept, *evidence* in students' work that would indicate they had developed the skills or understandings specified in our claims, and research-based *difficulties and misconceptions* that students have with a concept (Shin et al., 2009). The concepts, claims, evidence, and difficulties or misconceptions associated with the algebraic thinking practices within each Big Idea informed the development of grade-specific learning goals.

Using our learning goals, we then constructed grade-level instructional sequences for each of Grades K–5 by designing specific task structures that connected the algebraic practices with related claims about the skills or understandings that might reasonably be expected of students. For example, for Generalized Arithmetic we designed sequences of tasks that created opportunities to *generalize* arithmetic relationships, to *represent* these relationships in different ways, to develop appropriate general arguments for *justifying* the arithmetic relationships students observed, and to use arithmetic generalizations students developed as objects (Sfard, 1991) for *reasoning with* novel problems or properties of arithmetic that make computational work more efficient. Grade-level learning goals were used to guide content for these task structures. For example, the types of arithmetic relationships addressed at a particular grade, the types of representations used to express them, or the nature of arguments students might develop to show relationships were valid, were guided by our learning goals. We then used design research (Cobb et al., 2003) to field-test and refine our proposed grade-level instructional sequences. Finally, we used these task structures to develop validated, grade-level assessments by which we could measure within-grade and across-grade (longitudinal) growth in children's algebraic thinking in order to understand early algebra's impact.

Our effort to design a broader, multi-year (Grades K–5) approach to developing students' early algebraic thinking—essentially, components (1)–(3) above—aligns with what is sometimes characterized as "learning progressions" (Stevens et al., 2009). At the same time, a smaller grain size approach was needed to fill in "gaps" in empirical research on our understanding of children's algebraic thinking (essentially, component (4) above), particularly in the early elementary grades where the research base was less developed than that for Grades 3–5. Because of its narrow scale in terms of a focus on specific algebraic concepts or practices within short instructional timelines (e.g., weeks), this second aspect of our work might be seen as more akin to learning trajectories (e.g., Stevens et al., 2009). This "small-grain-size-level" research was critical for identifying increasingly sophisticated levels in students' thinking about a particular practice or concept within a Big Idea. For example, we identified trajectories in students' thinking about concepts such as a relational understanding of the equal sign (Blanton, Otalora Sevilla et al., 2018) and variable and variable notation (Blanton et al., 2017), as well as for practices such as generalizing functional relationships (Blanton, Brizuela et al., 2015; Stephens et al., 2017), generalizing arithmetic relationships (Ventura et al., 2021), and justifying claims about arithmetic relationships (Blanton et al., 2021).

Regardless of the nomenclature used or whether focusing on "big" ideas over a broad span of time (e.g., multiple years) or "small" concepts in a narrow span of time (e.g., weeks), a learning progressions approach has provided a flexible theoretical paradigm with key features aligned with our core research goals: identifying increasingly sophisticated ways students come to think about an algebraic concept or practice in response to an instructional sequence (Duschl et al., 2007; Simon, 1995; Smith et al., 2006); attending to specific content domains rather than general cognitive structures in how we design our instructional sequences to study early algebra's impact (Baroody et al., 2004); organizing content within these domains to facilitate the development in students' understanding of algebraic concepts and practices over time (Smith, et al., 2006); and relying on classroom-based empirical research, rather than just a logical analysis of the discipline, to understand how students' early algebraic thinking develops (Stevens et al., 2009).

The value of this approach extends beyond its role as a research paradigm, however. One of the organizing questions of the PME-NA 2022 conference—*How does your work challenge a settled mathematics learning status quo?*—is at the heart of early algebra's goal of "democratizing" students' access to algebra. By democratizing access to algebra, we mean opening up pathways to students for whom the traditional "arithmetic-then-algebra" approach—teaching arithmetic in elementary grades, followed by formal algebra in secondary grades—has been unsuccessful (e.g., Hiebert et al., 2005) and has limited students' access to STEM career and workforce opportunities (e.g., LaCampagne, 1995; NCTM, 2000). These challenges have been particularly felt among students from historically underserved communities (e.g., Moses & Cobb, 2001; Museus et al., 2011). For example, elementary grades students from lower socioeconomic (SES) backgrounds are two times more likely to be deficient in mathematics than students from higher SES backgrounds (U.S. Dept. of Education, NCES, 2007). This makes such students especially vulnerable in later formal algebra courses, which impacts their chance for success in college (U.S Dept. of Education, 2008) and access to STEM-related disciplines and careers. The promise of early algebra, then, is to address existing inequities in school mathematics and broaden students' access to STEM disciplines. In what follows, I consider a few examples of how our work, built around learning progressions, has helped challenge the status quo of settled mathematics learning around the kind of algebra students can learn, when they can learn it, and how all students can be successful.

Representing Generalizations Using Variable Notation

The traditional "arithmetic-then-algebra" approach to teaching and learning algebra has entailed certain views about what kind of algebra content should be taught and when. One aspect of algebra that has historically been largely outside the purview of elementary grades is variable and variable notation. Our work takes the view that variable notation is a useful tool that children can begin to understand and use from early elementary grades. From this perspective, we have sought to understand trajectories in students' thinking about variable and the use of variable notation to represent arithmetic and functional relationships. While the act of symbolizing a generalization is central to algebraic thinking, the way in which a generalization is represented can vary. In elementary grades, non-conventional forms such as natural language and drawings—symbol systems whose meanings are already available to young children—have historically been prioritized as a more productive way to represent generalizations (Resnick, 1982).

Part of the hesitation for the use of variable notation with young children has likely been due to strict interpretations around Piaget's formal stages of development, along with the concern that premature formalisms (Piaget, 1964) might lead to meaningless actions on symbols (Blanton et al., 2017). It is reasonable to assume that the well-documented challenges adolescents have with the concept of variable and the use of variable notation (e.g., Knuth et al., 2011; Küchemann, 1981) would be even more prominent among younger, elementary grades children. Yet, unlike younger children, adolescents are expected to build a mathematical understanding of literal symbols to notate variable quantities *after* they have deeply developed ways of thinking about letters in linguistic contexts (e.g., Braddon et al., 1993). This suggests that difficulties with variable notation may be more related to conflicts generated by students' use of literal symbols in mathematical contexts that rely on the understandings they already have about literal symbols in non-mathematical contexts (McNeil et al., 2010).

Research, however, increasingly supports that variable notation can be a valuable tool for young learners (e.g., Blanton, Stephens et al., 2015; Brizuela et al., 2015; Carpenter et al., 2003; Cooper & Warren, 2011; Dougherty, 2008; Fuji & Stephens, 2008). Learning progressions have helped us better understand why this might be the case. In a recent study (Blanton et al., 2017), we explored a trajectory in first graders' understanding of variable and use of variable notation to represent functional relationships. The conceptual space of interest here is the level at which children do not yet understand the concept of variable quantity nor how to use variable notation to represent a variable quantity, a level we characterize as *pre-variable/pre-symbolic*. The close analysis involved in mapping out a learning trajectory helped surface a more nuanced view of students' understandings about variable and variable notation. In particular, we observed that students' whose thinking was "pre-variable" did not yet *perceive* a variable quantity in a mathematical situation. As such, they naturally searched for other tools and ways of understanding within their conceptual field to make sense of a situation involving an unknown.

How might this manifest in students' mathematical actions? When young learners at a pre-variable/pre-symbolic level of thinking encounter a situation with a variable quantity, they typically assign a numerical value to the quantity, either randomly or based on some numerical feature of the situation. They might also propose (hypothetically) that the quantity be measured or counted to determine a specific value, even though it cannot be. This is not an unreasonable approach, given that students' mathematical experiences are, typically, fully centered on arithmetic at this point, where quantities are known or can be counted or measured and represented by a numerical value. Moreover, a child whose thinking is pre-variable (that is, the child cannot imagine or does not "see" an unknown within a situation) would not reasonably be expected to *look for* literal symbols (or even non-conventional representations such as natural language) to symbolize a quantity. Instead, we would expect them to use the tools and ways of understanding already available to them, which are arithmetic in nature.

As students progress in their thinking, some pick up the use of algebraic notation before they can perceive variable quantities. Such cases are indicated by the use of literal symbols as labels or to represent objects rather than quantities. That is, students recognize that a literal symbol can be used to recognize *something*, but not a variable quantity, since this is outside of their conceptual field. However, once variable and variable notation co-emerge in children's thinking, children begin to use variable notation in meaningful ways to symbolize variable quantities (Blanton et al., 2017). Through our construction of a learning trajectory around variable and variable notation, we came to see that the challenge was not that young learners cannot understand (and, thus, should not be exposed to) variable notation. It is, rather, that they have learned to interpret mathematical situations through an arithmetic lens which leads to certain ways of (arithmetic) problem solving that are inadequate for situations involving variable quantities. Instead, if they first learn to perceive a variable quantity, this motivates the need for a symbol system—whether conventional or not—to represent the quantity. Once they perceive a variable quantity, the symbolic system—including the use of literal symbols—can be meaningfully used to represent unknowns.

Our findings elsewhere support that children can learn to use variable notation in meaningful ways. For example, in a large-scale, randomized (CRT) study in 46 elementary schools on the effectiveness of our Grades 3–5 instructional sequences (i.e., early algebra intervention), we found significant differences in how treatment students, who were taught the intervention as part of their regular curriculum, were able to represent functional relationships with variable notation in comparison to control students, who were taught only their regular curriculum. Figure 1 compares treatment and control students' use of variable notation and natural language (words) to represent a functional relationship they observed using data they had culled from a problem situation. Not only were treatment students significantly better able to represent a function with variable notation (as well as with words) than control students, treatment students were also significantly better able to use variable notation than words. (Even students in control schools were better able to use variable notation than words, although the differences were not significant).

The point here is that a learning progressions approach has enabled us to better understand potential challenges to young learners' understanding of variable and variable notation and to design instruction that can significantly improve their understanding, both of which call into question the long-held view that young learners should focus on representational tools that are already available to them (e.g., natural language, diagrams). While we strongly support young learner's use of representational systems such as natural language, we equally support the introduction of variable and variable notation in appropriate ways to young learners and view learning progressions research as a means to help shift perceptions that variable and variable notation is beyond the grasp of young children.

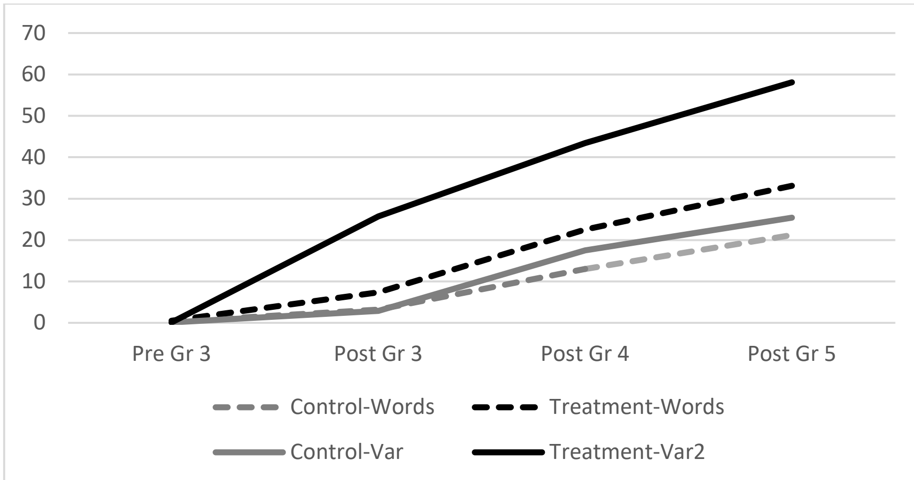

Figure 1. Comparison of treatment and control students use of variable notation to represent a functional relationship.

Developing Mathematical Arguments

Justifying claims about mathematical relationships is central to early algebraic thinking, yet the role of justifying or proving in school mathematics has historically been limited, particularly in elementary grades (Ball et al., 2002; Stylianides, 2016). However, studies suggest that deductive reasoning emerges in the elementary grades (Falmagne, 1980) and that with appropriate instruction, students can learn to use deductive—rather than empirical—reasoning to develop mathematical arguments (Stylianides & Stylianides, 2008). This challenges the long-held view that children's lack of ability to reason deductively is due to a developmental constraint and, instead, points to limited classroom opportunities as the more likely cause for their challenges with building good, grade-appropriate mathematical arguments (Stylianides, 2016; see also, e.g., Ball & Bass, 2003; Carpenter et al., 2003; Lampert, 1992; Maher & Martino, 1996). Studies suggest that the lack of argumentation in elementary grades has far-reaching implications in that it detaches students from sense-making (Staples et al., 2012) and can promote difficulties with proof and proving in high school (e.g., Coe & Ruthven, 1994; Knuth et al., 2002; Stylianides & Stylianides, 2008).

Stylianides and Stylianides (2008) and Stylianides (2007) suggest that research that details trajectories in children's thinking in response to instructional sequences focused on argumentation can help us understand how young children come to reason deductively in response to specific instructional conditions. Because justifying mathematical relationships is a core practice in our conceptual framework, we are interested in how students' come to build strong mathematical arguments in response to instruction. We recently conducted a study in which our goal was to identify progressions in Grades K–1 children's understanding of parity arguments and underlying concepts (e.g., even and odd numbers) in response to our Grade K and Grade 1 instructional sequences (Blanton et al., 2021). Our particular focus was on how children's understanding of representation-based proofs (Schifter, 2009)—versus empirical arguments—developed from the start of formal schooling, before their introduction to any parity concepts.

While our sample was small due to the design nature of our work, our findings were similar to those of other researchers who have conducted extensive work in this area (e.g., Schifter et al., 2009; Stylianides, 2007; Van Ness & Maher, 2019). For example, even in kindergarten, we found that students were able to construct informal structural parity arguments that did not rely on the use of specific or even generic numbers. What we found even more surprising was how rare empirical arguments were in these early grades, even though such arguments are a predominant proof strategy in secondary grades (Coe & Ruthven, 1994; Staples et al., 2012). For example, kindergarten students were unfamiliar with the concepts of pair and even and odd numbers prior to our instructional sequence in Grade K, but by Grade 1 pre-test (i.e., after the Grade K sequence), many students routinely used a pairs strategy (where numbers that can be represented as pairs of cubes are even and those that cannot be represented in this way are odd) to reason about the parity of numbers represented in concrete, visual, and abstract forms. More importantly, out of a group of 10 students interviewed, no student used an empirical argument to justify why the sum of an even and an odd would be odd. Six out of ten were able to correctly use a structural argument involving a pairs strategy (three students could not build either type of argument; one student was not asked this question).

In developing trajectories in children's thinking about particular algebraic concepts or practices, we have found that introducing algebraic thinking earlier—even as early as kindergarten—can help mitigate the development of misconceptions in students' thinking that can occur within an arithmetic-focused approach to instruction. We have observed this in students' understanding of variable quantity and variable notation, where engaging students in mathematical tasks that first help them perceive variable quantities can support their use of variable notation in meaningful ways. We have seen that the early introduction of representation-based arguments can help offset entrenched forms of empirical reasoning by providing students with an accessible, grade appropriate process for justifying their claims. We have seen early attention to functional relationships between quantities mitigate an ingrained focus on recursive patterns in function data that makes it difficult in later elementary grades to re-focus students' thinking on co-varying quantities. We have seen concrete and visual tools help students begin to think relationally about the equal sign even before symbols and equations are introduced, thereby disrupting the operational thinking that is often fostered through arithmetic work focused on standard forms of representations (Blanton, Otalora Sevilla et al., 2018). In this way, learning progressions in early algebra research has helped challenge historically settled notions (even some of our own) regarding what algebraic concepts should be addressed and when. But early algebra's mission to democratize access to algebra is broader than "what" or "when." It is ultimately about "who." In what follows, I briefly touch on some of our evidence around this.

Challenging Perceptions of *Who* Can Do Algebra

The underlying premise of early algebra is that developing children's informal notions about mathematical structure and relationships, beginning in kindergarten, will better prepare them for success in formal algebra in later grades. As described earlier, our work has focused on the use of a learning progressions approach to build the tools with which we could explore this premise, and we are starting to see the contours of an answer to the question of whether early algebra "matters." Our recent 3-year randomized (CRT) study on the effectiveness of the Grades 3–5 early algebra "intervention" (i.e., grade-level instructional sequences) offers some evidence of this. The study was conducted in 46 schools across urban, rural, and suburban settings, where the intervention was taught by classroom teachers as part of their regular mathematics instruction. We found overall that, at each of Grades 3–5, students who received the intervention as part of regular instruction significantly outperformed their peers who received only regular instruction in both their knowledge of algebraic concepts and practices and their use of algebraic strategies to solve tasks (Blanton et al., 2019). Moreover, treatment students maintained a significant advantage over control students in middle grades, one year after the intervention ended (Stephens et al., 2021).

Algebraic thinking in the elementary grades is now codified as essential to algebra education in frameworks such as the *Common Core State Standards for Mathematics* (NGA Center & CCSSO, 2010). Through the adoption of these standards, many states have elevated the role of algebra, leaving students potentially vulnerable to a persistent marginalization in school. With students from underserved communities already underrepresented in STEM professions (Oscos-Sanchez et al., 2008), the long-term implications for the inequity of access to educational on-ramps for students around early algebra are significant. As such, early algebra innovations should be designed to ensure that they are inclusive of learners across diverse classrooms. So, while our overall results are promising, it was (and continues to be) important for us to further unpack our findings for students in different demographics and learning conditions. One example of this was our comparison in the performance of a subset of participating treatment and control schools for which the majority of students were from underserved communities (i.e., 100% low SES, 94% underserved racial minorities). We found that, like our overall population, treatment students again significantly outperformed control students at each of Grades 3–5 on both their knowledge of algebraic concepts and practices and their use of algebraic strategies to solve tasks (Blanton et al., 2019). To visualize the significance of this finding, Figure 2 compares the performance of students in treatment and control schools for this subset of schools along with the performance of the overall control group. In addition, it also shows that, while treatment students from schools with underserved communities did underperform the overall control group prior to the intervention, by the end of Grade 3 they outperformed even the *overall* control group (although not significantly) and maintained this advantage throughout the end of the intervention in Grade 5.

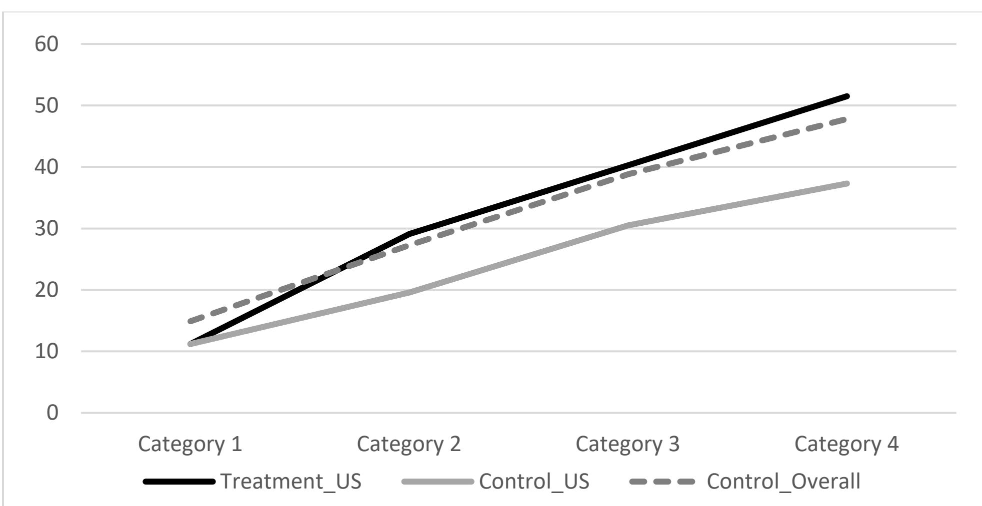

Figure 2. Comparison of performance for underserved students (US) in treatment and control schools with control students overall.

These promising results support findings from other studies that show providing students from historically underserved communities with more challenging learning environments in elementary grades can increase mathematics proficiency (Lee, 2011; Zilanawala et al., 2018). While it's difficult to tease out whether the role of a learning progressions approach was sufficient for these results, we can say that *when* a learning progressions approach was used, we have found a significant improvement in *all* learners' ability to think algebraically.

Building on this, we are continuing to explore how to develop a more inclusive early algebra intervention in Grades K–2. We expanded our recent design work around instructional sequences and assessments in Grades K–2 to include a more intentional focus on students with learning differences in order to understand how these students make sense of the algebraic concepts and practices in our intervention and how its features (e.g., concrete and visual tools) support learning. We have found that tools such as balance scales helped students analyze equations and reconsider unfamiliar equation forms (Stephens, Sung, Strachota et al., 2022), even prior to developing strong computational skills. Further, we have documented how these tools mediated the abilities of diverse learners to generalize and represent what they notice about structure and relationships involving parity concepts (Strachota et al., 2021)

While this work is ongoing, our Grades K–2 instructional sequences already show promise overall in developing children's algebraic thinking. We recently conducted a small, one-year cross-sectional study ($n = 80$) in each of Grades K–2 that examined the potential of each grade-level sequence when taught by classroom teachers. After only a one-year intervention in each grade, we found a marginally significant interaction between treatment condition and performance that showed gains favoring treatment students in their understanding of early algebra concepts such as the structure of evens and odds, mathematical equivalence and equations, properties of arithmetic, the representation of varying unknown quantities, and functional thinking [$F\ (1, 58) = 3.794$, p=.056] (Stephens, Sung, Blanton et al., 2022). Further, we found no significant three-way interaction among treatment condition, performance on the assessment, and grade level, suggesting that the impact of the intervention was similar across grade levels. With these findings for Grades K–2 and our more fully developed findings about the effectiveness of our Grades 3–5 intervention, we are optimistic about the innovation's potential to positively impact all students' experiences in algebra.

Conclusion

A learning progressions approach has been central in our efforts to develop an empirically grounded model for teaching and learning algebra that can increase all students' opportunities for success in algebra. It has provided both a framework for developing an innovation to measure early algebra's impact and a mechanism to examine fine-grained details in how children's algebraic thinking develops. It has also helped us think about how to reframe learning around an asset-based perspective in which instruction can build on the rich ways students think about algebraic concepts and practices, rather than from a deficit model built around students' misconceptions. Designing innovations from a perspective of what students *can* do (or, as Jim Kaput used to say, the "happy stories") can minimize the need to design for the purpose of "undoing" misconceptions in students' thinking that arise when elementary grades instruction does not attend to algebraic concepts and practices. Early algebra innovations based on learning progressions can open new curricular pathways for teachers and create effective avenues of learning that can democratize all students' access to algebra. We are hopeful that such models can continue to challenge the national discourse on teaching and learning algebra around the kind of algebra students can learn, when they can learn it, and how all students can be successful.

INTENTIONALITY IN USING LEARNING TRAJECTORIES TO "REFRAME" TEACHER NOTICINGS TOWARDS ANTI-DEFICIT AND ASSET-BASED INSTRUCTION

Jennifer M. Suh
George Mason University
jsuh4@gmu.edu

Learning Trajectories have the potential to be used as a tool to advance equity by explicitly connecting to anti-deficit framing and asset-based instruction. This plenary paper highlights research on three use cases for learning trajectories (LT) with an intentionality around promoting equity: 1) the use of LT based Lesson Study with vertical teams of teachers to position students as capable and teachers as knowledgeable, 2) the use of LT coupled with anti-deficit framing in curriculum design research to provide students with access to rigorous educational resources and asset based instruction, 3) the use of LT with formative assessment to develop preservice teachers' equitable teaching practices to advance students understanding. The presenter invites the PMENA community to consider how learning trajectories can be coupled with powerful equity-focused research and frameworks to disrupt the status quo, broaden the notion of learning mathematics, eliminate labeling, and dismantle inequitable structures and hierarchy in the mathematics classroom.

Keywords: Learning Trajectories and Progressions, Anti-deficit Orientation, Asset-based Instruction, Teacher Noticing, Professional Development, Preservice Teacher Education

Introduction

In this paper, I discuss how learning trajectory (LT) research should attend to equity by providing access to rigorous educational resources, positioning students as capable and teachers as knowledgeable, and questioning the curriculum and high stakes assessment practices. I do this work by engaging and privileging the voices of teachers and coaches as co-designers and researchers in Lesson Study and Curriculum Design Research with the focus on rehumanizing mathematics for students (Gutiérrez, 2018).

I am a first generation Korean American mathematics education scholar, who attended my formative years of elementary schools in the 70s between two countries, experiencing Korean as a second language and also what was at the time called, English as a second language. I experienced first-hand differential learning experiences (NCTM, 2020; Jong et al., 2020) where some students were centered and others marginalized. Experiencing schooling in two countries, I also noticed the differential treatment of the teaching profession, one where it is a revered and noble profession and the other where the teacher's professional judgment is constantly questioned and viewed where anyone can teach. This has motivated me to focus my work on elevating the voices of teachers and the teaching profession in the US and building on students' mathematics strengths, particularly those who are marginalized in the mathematics classroom. My research is informed by a commitment to equity and culturally sustaining pedagogy in mathematics education. I work mostly with schools that are racially, culturally, and linguistically diverse and receive title 1 funding. My research has focused on LT use in Lesson Study and Community-based Math Modeling to connect mathematics to students' lived experiences, attending to both cognitive and socio-cultural perspectives. I lean on the work of Aguirre et al.'s (2013) centering their definition of equity where,

> All students in light of their humanity – personal experiences, backgrounds, histories, languages, physical and emotional well-being–must have the opportunity and support to learn rich mathematics that fosters meaning-making, empowers decision-making, and critiques, challenges and transforms inequities/injustices. Equity demands responsive instruction that promotes equitable access, attainment, and advancement for all students" (p. 9).

Given my research orientation, my plenary paper focuses on two questions-1) How do we use LT with teachers and coaches as a tool to deepen teacher knowledge and promote asset-based instruction, especially for students who have been historically marginalized? 2) How might we use LT to "reFrame" teacher noticings towards an anti-deficit orientation?

Shifting from Deficit to Anti-deficit Orientation by "reFraming" Teacher Noticings

This PMENA Plenary event in 2022 marks a significant time in our society, where we experienced the struggles and pain due to the Pandemic as well as systemic racism and escalation of racial tension leading to the Black Lives Matter movement. The pandemic unleashed hate, xenophobia and scapegoating leading to AAPI Hate with racist rhetoric. Labeling the "Asian" community as a monolith with an erasure of individual identity and the myth of the model minority or that "Asians are good at math" perpetuates a stereotype that is racist and dehumanizing (Shah, 2019), ignoring the huge diversity of linguistic, socio-economic, political and cultural backgrounds. It also masks the issues that different communities may need different supports in the school setting to succeed and excel. The Pandemic magnified the inequities that have long-existed in our society, education and communities. Deficit framed discourse streamed the media with outcries of "learning loss", while educational organizations worked hard to fight against this harmful language and discourse (i.e., Where is Manuel? A rejection of 'Learning Loss' TODOS, 2020). In addition, the danger in the discourse that marks the achievement of marginalized students being "more behind" in their learning, again perpetuates a pernicious mindset of achievement gap that our community has worked tirelessly to move away from (Gutierrez, 2008). Our professional organizations showed solidarity in fighting against systemic racism and this deficit framing and advocated for the "Mo(ve)ment to Prioritize Antiracist Mathematics: Planning for This and Every School Year" (TODOS, 2020), and AMTE's (2022) statement on "Equitable and Inclusive Mathematics Teaching and Learning" and the press release on systemic racism advocating for practices that draw on students' mathematical, cultural, and linguistic resources/strengths, and challenge policies and practices grounded in deficit- based thinking. The voices from our leading mathematics educational organizations (NCSM, NCTM & ASSM, 2020, 2021) "In Continuing the Journey: Mathematics Learning 2021 and Beyond", and "In Centering Our Humanity: Addressing Social and Emotional Needs in Schools and Mathematics Classrooms" (TODOS, 2020) advocated for math educators and school leaders to keep our focus on teachers, families and students well being, during this contentious socio political climate and Pandemic.

Rather than returning to the pre-pandemic status quo, Ladson-Billings (2021) argued for a "hard re-set" for a new "post-pandemic pedagogy" stating,

> In a re-set school environment, we will begin a school year with an accurate assessment of what students already know. The school year will have varied and regular formative assessments to determine how well students are understanding what they are taught, and an end of the year assessment would be keyed to what was actually taught in their classrooms. Assessment would no longer be a punitive tool to "catch" students but rather a diagnostic and

developmental tool that will tell teachers and schools how to adjust their curriculum and pedagogy (p. 74).

And yet, we know the opposite is happening where teachers are again being pressured to “catch students up” so that they can once again administer high-stakes tests. This is problematic as we know as scholars like Louie et al. (2021) describe the danger when a teacher with a framing around “closing the racial achievement gap” implicitly frames Black, Hispanic, and Indigenous students as mathematically lacking and White students’ achievement as the standard by which they should be measured (Gutiérrez 2008; Martin 2009). This framing makes one more likely to attend closely to Black, Hispanic, and Indigenous students’ errors without attending to their knowledge or strengths, to interpret these errors as evidence of misconceptions and failures, leading to deficit noticing.

Instead, we should be focused on varied and regular formative assessments to holistically determine how well students are understanding what they are taught and focus on asset based pedagogy like Complex Instruction (Horn, 2012; Cohen et al., 1999; Eli & Wood, 2016) where we develop teachers skills in assigning competence in student work. Research from Cohen et al.’s (1999) work on Complex Instruction showed that when teachers praised low-status students publicly for a task-related accomplishment, those students' participation increased; their status differences were mitigated or eliminated; and ultimately, their achievement increased.

When teachers better understand the learning trajectory continuum and anticipate a broader range of strategies, teachers can spot the strength of students along the LT continuum who may typically not get highlighted (Suh et al., 2018). In fact, Empson (2011) reflected on the 2010 PMENA and noted how LT impacts teacher professional noticings, “As teachers interact with students and decide how to proceed, there are many types of decisions to be made – how to gather information about children’s thinking, how to respond to it appropriately in the moment, how to design tasks that extend it, and even what to pay attention to” (p. 587).

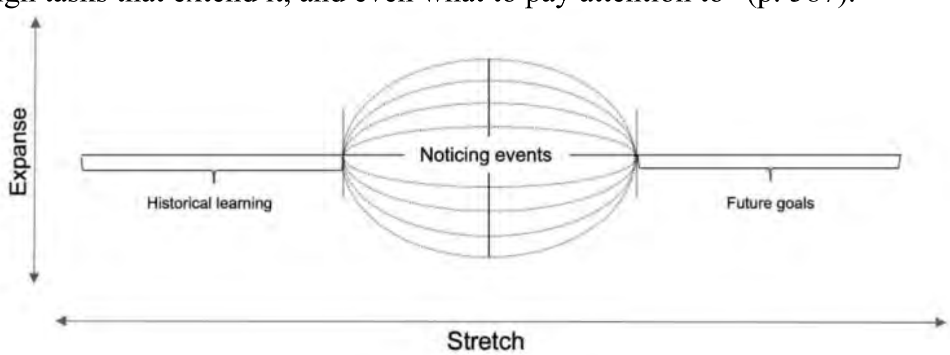

Figure 1: Reflecting Multi-dimensional Noticing for Equity (van Es et al., 2022)

Developing teachers' ability to assign competencies requires specialized skills of equitable noticing (Jacobs et al., 2010; Jacobs & Spangler, 2017; Kalinec-Craig et al., 2021; Jilk, 2016; Jong, 2017; Wager 2014). More recently, van Es et al. (2022) described a framework for Multidimensional Noticing for Equity, a system of noticing to disrupt inequities. Their framing towards a more multidimensional noticing for equity include the perspective of “taking account for how the histories and cultures of teachers, learners, and mathematics —and the broader historical, cultural, and political contexts in which they exist—are at play in moment-to-moment classroom interactions” (van Es et al, 2022, p.115 citing Louie, 2018; Mendoza et al., 2021; Shah & Coles, 2020). In their more expansive framework, the multidimensional noticing was used to interpret teachers' enactment of culturally sustaining instructional practices organized around a) Stretch, which captures the relation of teachers' noticing to both their own and students' past and futures, and (b) Expanse, which reflects the breadth and range of what teachers identify as noteworthy in moments of classroom interaction teaching and teacher noticing (see Figure 1).

Louie et al. (2021) discuss the importance of framing as a way to challenge deficit discourses about marginalized students that devalue the knowledge and abilities of students of color in classrooms in the US. They note,

> Deficit discourses may give rise to deficit noticing, wherein teachers attend almost obsessively to the errors and shortcomings of students of color; interpret errors and shortcomings as evidence of deficiencies in students, their families, or their cultures; erase students' assets; and disregard schooling practices and social structures that limit students' opportunities to learn and thrive. (p. 96)

Louie et al.'s (2021) most recent work framed anti-deficit noticing explicitly emphasizing how **F**raming is critically important in the ways teachers **A**ttend, **I**nterpret and decide to **R**espond (see Figure 2)

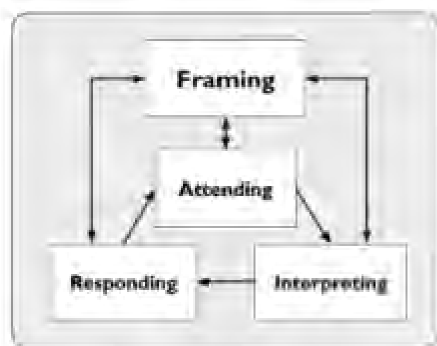

Figure 2: FAIR framework for Anti-deficit Noticing (Louie et al., 2021)

These two frameworks helped our research team think more broadly as we worked with our teachers in how we needed to frame anti-deficit orientation and asset-based instruction when working with learning trajectories. An important implication that we gleaned from the Multi-dimensional Noticing for Equity (van Es et al., 2022) is that although noticing captures the moment-to-moment events, what teachers notice and attune to is multidimensional in that it takes into account historical knowledge of the student, class and context and attends to the complexity of the instruction at play (i.e. Culturally Sustaining Pedagogy). The FAIR framework for Anti-deficit Noticing (Louie et al., 2021) noted the importance of being intentional and explicit when framing toward anti-deficit orientation to shift teachers noticing from deficit to anti-deficit noticing (See Figure 1). In particular, this FAIR framework's emphasis on framing allowed our team to pay close attention to *"how we notice"* students as full human beings with many mathematical strengths and resources, framing math learning as a creative exploration of ideas and framing interaction and interpersonal relationship as integral to learning (Louie et al., 2021).

Expanding the Notion of Math Competence using LT and Students' Assets

We emphasize in our LT PD work that teachers bring these multiple aspects and framing into view as they engage in multidimensional noticing. We focus on encouraging narrative that emphasizes the strengths students bring to the classroom including their mathematical thinking as well as their disposition and mathematics practices. LT has a long history in mathematics education research (Battista, 2011; Blanton et al., 2015; Clements & Sarama, 2004, 2009; Confrey et al., 2009, 2011; Ellis, 2014; Hackenberg, 2013; Ebby et al., 2020; Petit et al., 2020; Simon, 1995; Steffe & Olive, 2010; and others cited in the synthesis by Lobato & Walters, 2017) and well featured in past PMENA proceedings and has many metaphors and descriptors including a climbing wall (Confrey et al., 2021), in a conceptual corridor (Confrey, 2006);and levels of sophistication plateaus (Battista, 2004), just to name a few. Confrey and Maloney (2010) describe learning trajectories as

> a researcher-conjectured, empirically-supported description of the ordered network of constructs a student encounters through instruction (i.e. activities, tasks, tools, forms, of interaction and methods of evaluation), in order to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time. (p. 968)

Clements and Samara (2004) describe learning trajectories for early childhood mathematics for narrow sequences of topics as “a conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children through a developmental progression of levels of thinking” (p. 83).

The affordance of using LT deepens teachers' understanding of the progression of student learning-drawing upon their knowledge of the learning trajectories to make instructional decisions. More specifically, LTs have been used with teachers and researchers to better understand how students come to understand concepts (Battista 2004; Hackenberg & Tillema 2009) and to use “the learning goal, the learning activities, and the thinking and learning in which the students might engage” (Simon 1995, p. 133) to provide direction for teachers as they plan learning activities and predict the potential reasoning, misconceptions, and learning of students. Hypothetical learning trajectories (Simon 1995) have also been used in professional development settings to enhance instructional practices. Wilson et al. (2015) reported on a study using professional development where LTs bridged “guidelines for student-centered instruction with domain-specific understandings of students’ thinking for teachers” (p. 227).

According to Sztajn et al. (2012) existing research on teachers’ use of learning trajectories “shows that as teachers make sense of trajectories, these trajectories can support growth in mathematical knowledge, selection of instructional tasks, interactions with students in classroom contexts, and use of students’ responses to further learning” (p. 149). Research on Learning Trajectory based Instruction (LTBI, Sztajn et al., 2017) and the specific design decisions (Sztajn, 2010) the team attended to revealed the importance of setting discursive norms to focus on student thinking and teaching from a strength-based perspective particularly “at a time when deficit perspectives and language of differentiated instruction (such as having “high”, “medium”, and “low” children) to express ideas about student learning have been normalized.” (Sztajn et al., 2017, p. 30). With the many descriptors that include terms like “trajectory”, “progression”, “increasingly complex”, “levels of sophistication” (Battista, 2010), some caution that translated LT research can be misused as hierarchical levels that teachers use to sort students and dangerously place labels on students as being high or low. In fact, Myers et al. (2014) concluded that learning about LTs without additional support was insufficient to challenge deeply rooted ideas about student abilities. Even with attention to the design of PD, Myers (2014) found that teachers with severe deficit orientation used LTs to talk about what students could not do as opposed to thinking about moving students forward. Through discourse intervention, teachers started to use ability as a temporary descriptor to present students' current mathematical performance and used language from the LT to support these claims. The explicit attention to having teachers refer to the LT language instead of labels for students demonstrated the potential of LTs to support equitable instruction.

Celedòn-Pattichis et al. (2018) asset-based approaches to mathematics education are a conscious way to move away from deficit perspectives by teaching in ways that view students' language and culture as well as families', and communities' ways of knowing (Civil 2007; Bartell et al., 2017) as intellectual resources to engage with mathematics in the classroom. Asset based approaches offer a more humanizing view of student thinking that extends beyond school mathematics and recognizes that mathematics thinking and learning happens at home and in communities but is often unrecognized in school settings. Opening up learning trajectories to be able to recognize other forms of math thinking and experiences is key. Celedòn-Pattichis et al. (2018) also cautioned the community to recognize that not all communities and families focus on counting and operations in the specific way that Cognitively Guided Instruction (CGI) has described. Studies that combined CGI with culturally responsive instruction improved the mathematics performance of Native American students with learning disabilities (Hankes, et al., 2013) and other studies with culturally and linguistically diverse students engaged in complex CGI problem solving where teachers drew from language and culture as intellectual resources showed positive outcomes (Celedón-Pattichis et al., 2010; Turner et al., 2008).

Below I share use cases with LT PD and curriculum design research where coupling LT with asset-based approaches yielded anti-deficit teacher noticings. I detail how the use of vertical lesson study teams and other PD structures focused on learning trajectories and multidimensional noticing supported the development of anti-deficit professional noticings. I will refer to my research team as "we" in the case studies to represent the collaborative efforts of multiple researchers and doctoral students from the VDOE projects called TRANSITIONS and Bridging for Math Strength and an NSF project called IMMERSION.

Case #1: Synthesizing Previous Research on using Learning Trajectory-based Lesson Study- Appreciating Students' Robust Understanding

For over a decade, my colleagues and I used Learning Trajectory based Lesson Study (LTLS, Suh et al., 2021; Suh et al., 2019a; Suh et al., 2019b; Suh et al., 2018; Suh et al., 2017; Suh & Seshaiyer, 2014) in a series of multi-year state funded project called TRANSITIONS, where we worked with vertical teams of K-8 teachers, studying, planning, implementing and reflecting on teaching through rich tasks. In the Study phase of the Lesson Study (Lewis, 2012) instead of focusing on grade level standards, we used Confrey's (2012), five elements to unpack the LTs and to plan and anticipate strategies for a rich task starting with discussing: 1) the conceptual principles and the development of the ideas underlying a concept; 2) strategies, representations, and "conceptions"; 3) meaningful distinctions, definitions and multiple models; 4) recognizing coherent structure or pattern in the development of progressively complex mathematical ideas ; and 5) bridging standards or identifying the underlying concepts.

In Suh et al.'s article (2019a) we detailed a LTLS with a group of teachers ranging from Kindergarten to six grade, at an elementary school near a military base with the highest mobility rate of 33% in the district. With this transient population, the LTLS team wanted to use LT to bridge coherence in their curriculum. The team chose the often used submarine sandwich sharing task related to equipartitioning (Confrey et al., 2021; Confrey et al. 2009) typically used in Grades 3 or 4. They decided to launch the first lesson iteration in the Kindergarten classroom to study how very young students might approach this task. We framed the LTLS using elements from the Teaching for Robust Understanding (TRU) Framework (Schoenfeld & The Teaching for Robust Understanding Project, 2016), particularly focusing on the dimensions of *equitable access to content* using the LT and *agency, ownership, and identity* described as " the extent to which students are provided opportunities to contribute to conversations about disciplinary ideas, to build on others' ideas and have others build on theirs—in ways that contribute to their development of agency (the willingness to engage), their ownership over the content, and the development of positive identities as thinkers and learners" (p. 9).

Though teachers studied the Equipartitioning LT during the Study phase of the LTLS, seeing how students approached equipartitioning through the Lesson Study surprised the educators and brought the LT to life. They noticed the strength in Kindergarten students being able to halve equal sized parts and share among friends, and understand the context of fair share. One group split the 6 sandwiches into 12 halves and made sure everyone of the 8 friends had equal sized parts (halves) and decided to remove 4 halves not eaten. Another group contributed the idea that there were some extras and wanted to use up the whole set of sandwiches and gestured cutting the halves into another half (fourths). Knowing how students approached this task allowed teachers to think about how to advance students to exhaust the whole without leaving any part of the sandwich unused. We used the LT "look fors" to help us better understand criteria for equipartitioning:

1. Having the correct number of parts
2. Exhausting the whole, leaving no parts unused
3. Having equal-size parts

(LT TurnonCC website, Confrey et al., n.d.).

Through lesson study, this vertical team saw this same lesson enacted in second, fourth and sixth grade classrooms. In our debrief, instead of focusing on grade level standards, the focus of the conversation came from observing how the students responded to the task related to the equipartitioning LT 'look fors' as well as using language from like non-anticipatory sharing, additive coordination to multiplicative coordination (Empson & Levi, 2011) as shown in Figure 3.

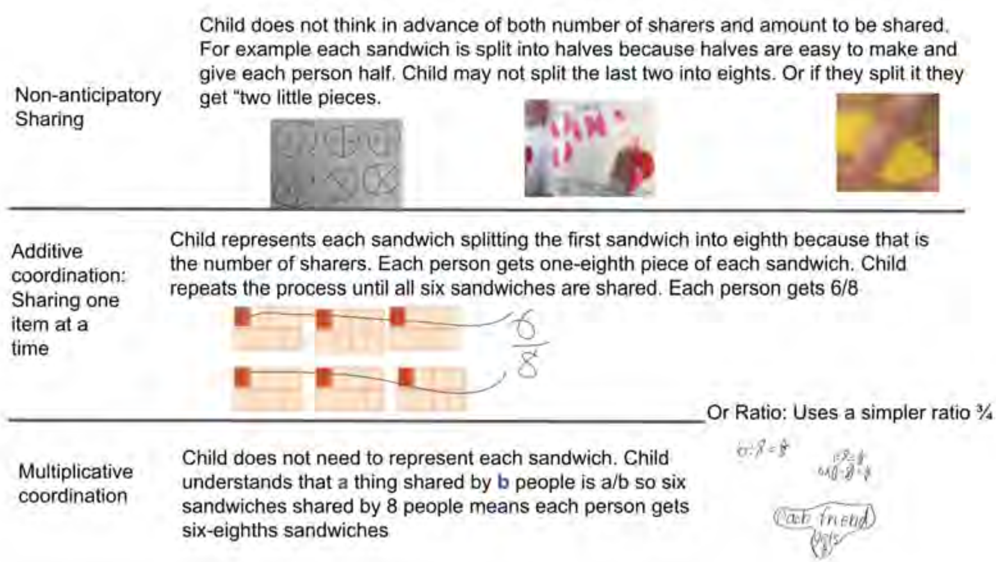

Figure 3: Analysis of Student Thinking using Equipartitioning LT on Sharing Tasks

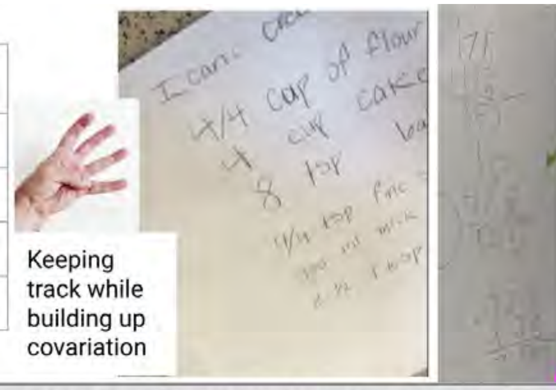
The kindergarten teacher was proud to share the brilliance of her students and the LTLS team acknowledged and appreciated the informal understandings that emerged in earlier grades as valuable prerequisites for building more complex ideas.

In another vertical lesson study through an NSF project called IMMERSION (Suh et al., 2022), a team of 3rd through 6th grade teachers wanted to celebrate the Lunar New Year by making mooncakes with the many Asian students who celebrated the holiday. This school with its culturally and linguistically diverse student population identified 71% Latinx, 14% Asian, 11% White, 2 % Black and 3% others with 73% qualifying for free and reduced fee, embraced culturally sustaining pedagogy viewing students' home and community cultural practices as resources "to honor, explore, and extend" (Paris, 2012, p. 94). Scaling up a recipe is a rich task, typically classified as a middle grade proportional reasoning task but because there was a real need to scale up a recipe that was set for 6 servings, the teachers chose this task and decided that the first iteration would be launched in a 3rd grade classroom. As teachers discussed the learning trajectory continuum, they identified the skills that students have already developed like skip counting, as well as emerging skills like repeated addition and multiplication, connecting to future learning goals like scaling up using a ratio table. They discussed the connection to students' assets in terms of cultural funds of knowledge (Moll et al., 1992) and family practices in cooking and emphasized bringing in realia for measurements as well as the ingredients to connect to students' multiple knowledge bases (Turner et al., 2013). They anticipated some students using manipulatives/realia to make sense of figuring out how many times their recipe might have to be scaled up based on the serving size, in addition to repeated addition, using multiplication facts as well as using as manipulatives and tables. Just like the previous task with the sharing sandwich, students in third grade used their multiple knowledge bases (Turner et al., 2013) to figure out how much of the ingredients they would need to make enough mooncakes. Teachers noted how students used manipulatives to figure out how many batches they would need (the scale factor) and noted how they used their fingers or notes on paper as they scaled up the ingredients. This coordination through iterative skip counting is the precursor to recognizing the covariation nature of early proportional reasoning (Steinthorsdottir & Sriraman, 2014).

With this in mind, teachers recognized that these emergent ways of keeping track with their fingers and scaling up was a brilliant way of thinking and reflected formative strategies to show covariation. Teachers were seeing the LTs in action as they observed student work and thinking (see Figure 4).

batch	servings
1	6
2	12
3	18
4	24



Build-Up (repeated addition)	The given ratio of first-measure-space quantity to second-measure-space quantity is repeated and combined using addition or multiplication as a form of repeated addition.	
Multiplicative	A multiplicative relationship is explicitly used.	
	Between-Measure Space	The given between-measure-space ratio is maintained in the target ratio.
	Within-Measure Space	The scale factor is determined and applied within each measure space, a reduced rate is scaled, or a unit rate is scaled.

Figure 4: Analysis of Student Thinking using Early Proportional LT on Scaling up a Recipe with LT Chart from Riehl & Steinthorsdottir, 2014

Through both of these LTLS, we found that,

1. The observers as well as the host teacher acknowledged and appreciated the brilliance and quality of students' fraction and proportional reasoning and positioned students' conceptions and multiple strategies as strengths.
2. The coach facilitated a productive debrief with the participating teachers to verify, validate and sometimes dispute the hypothetical learning trajectories based on their observations noting that they saw some attributes of more advanced thinking with earlier formative strategies.
3. Bridging the learning trajectories through a rich task across multiple grade levels allowed teachers to better focus on LT and talk less of grade level standards. Seeing the students work vertically across grades k-6 allowed teachers to appreciate informal understandings as valuable prerequisites for building more complex ideas.
4. Teachers can play an active role in validating LTs with researchers and at times disrupt notions of traditional sequencing of mathematics prescribed by standards.
5. Rich tasks can go beyond the realm of standards and provide a low floor and high ceiling where teachers can use their knowledge of LT to highlight students' strengths and position students as capable along the LT.

Lessons learned from LTLS informed our most recent work below with LT based professional development and curricular design activities that highlight the ideas of using LT as a tool to build on students' assets and promote anti-deficit framing in our work.

Case #2: Using LT with Formative Assessment to Build on Math Strength- Multi-dimensional Professional Noticing focused around Anti-deficit Framing

This case study began in 2020 at the start of the pandemic when mathematics leaders in the state department of education approached our team to create curriculum resources for teachers to support deep conceptual learning around essential concepts. One of the problems of practice presented was that teachers were skillful at finding what gaps students had in their understanding but did not always know where to go next to advance student thinking. In reflecting on this problem of practice, I thought back to Shaun Harper's (2010) paper called *An Anti-Deficit Achievement Framework for Research on Students of Color in STEM*, where he states that the kinds of questions we ask can focus on failure and not successes. For example, we can reframe the question- "Why do so few pursue STEM majors?" (Deficit-Oriented Questions) to "What stimulates and sustains students' interest in attaining degrees in STEM fields?" (Anti-deficit reframing). He notes that it is both important to unearth systemic inequities and barriers as well as identify structures and strategies that support students of color to thrive. In this same vein, we wanted to reorient this problem of practice from, "How do we work with students once we know the gaps in their understanding?" to "How do we spot students' strengths and use that to advance their learning in mathematics?"

In our design research, we invited teachers and coaches as our co-designers, tapping into the geniuses in our schools (Wiseman et al., 2013) to build an LT based curricular resource site for educators. The key design components for our design institute included asset-based instruction, knowledge and integration of learning trajectories as our teacher designers created formative assessment with bridging activities. Bridging for Math Strength design work engaged teachers to unpack LT, use formative assessment to articulate the 'look-fors' for building on math strength and purposeful questions to advance student learning through a designed set of learning activities along that continuum. The participants in our Math Strength Design team included twenty-seven K-8 teachers and coaches working as teacher designers in teams of three. The summer design institute took place in June of 2020 with Implementation Cycles in Fall 2021 and Spring 2022. We used a rapid prototyping method with iterative design and refinement through implementation cycles.

Using a variety of research-based strength building strategies in our Design Institute, we equipped our teachers with the knowledge and research on Learning Trajectories and concrete strategies to support asset-based thinking. This included:

1) Locating relevant usable LT research translated for practitioners – (https://www.learningtrajectories.org/, http://www.ogapmath.com/, https://www.sudds.co/ Blanton, 2008; Empson & Levi, 2011; Ebby et al., 2020; Hackenberg, 2013; Petit, st al., 2020; Steffe & Olive, 2010)
2) Broadening the notion of math competence and smartness with Complex Instruction (Kobett, & Karp, 2020; NCTM, 2020; Jilk, 2016; Kalinec-Craig, et al., 2021; Horn, 2012; Lotan, 2003; Cohen et al., 1999; Featherstone et al, 2011)
3) Anti-deficit & Multi-dimensional Noticing frameworks (Louie et al., 2021; van Es et al., 2022)
4) Lesson Study to collectively learn about students' brilliance in thinking and strategies competence (Lewis, 2022; Suh & Seshaiyer, 2014)
5) Evaluating and sequencing learning activities to advance students' thinking

We used the data sources including the designed module, implementation narrated through Flipgrid, a recording platform, debrief webinars about the implementation cycles and interviews with teacher designers.

Our research questions focused on 1) How can we use LT with teachers and coaches as a tool to deepen teacher knowledge and promote asset-based instruction for students? 2) How might we use LT to "reFrame" teacher noticings towards anti-deficit orientation?

Each of the fall follow- up sessions with teacher designers included debriefs around implementing the modules and analyzing student work. Using Flipgrid, the teacher-designers narrated their implementation so other teachers could follow their process. They started by sharing the formative assessment they chose, and then outlined the sequence of activities picked based on the student work on the formative assessments. Knowledge of LT helped them sequence learning activities for students. These voices centered teachers and coaches in the LT and focused the lesson implementation to elevate the strengths of students.

Below Kelly shares her implementation of the LT based curricular resource with some of her students. The excerpt brings to life how a coach might use LT as a tool to build on students' strengths. In her noticings (see Figure 5), she honored this student's funds of knowledge when he shared with her, "Well I like 7s because I watch a lot of football so I'm good at counting by 7s". She interprets his strengths then decides that she would respond by asking questions to see how he might recognize patterns and apply reasoning strategies. She planned for questions such as, "What do you notice about the relationship of 7x2, 7x4, and 7x8? You mentioned you felt comfortable with 7s. What other numbers feel friendly to you? How could you use them to solve more challenging facts?" In deciding on rich educational learning experiences to strengthen his reasoning, she proposed a center activity called Strive to Derive which is a game that shows arrays that students can break apart to rehearse the strategy of using known derived facts or distributive property. In addition, she proposed visual number strings to build on patterns and relationships for multiplication.

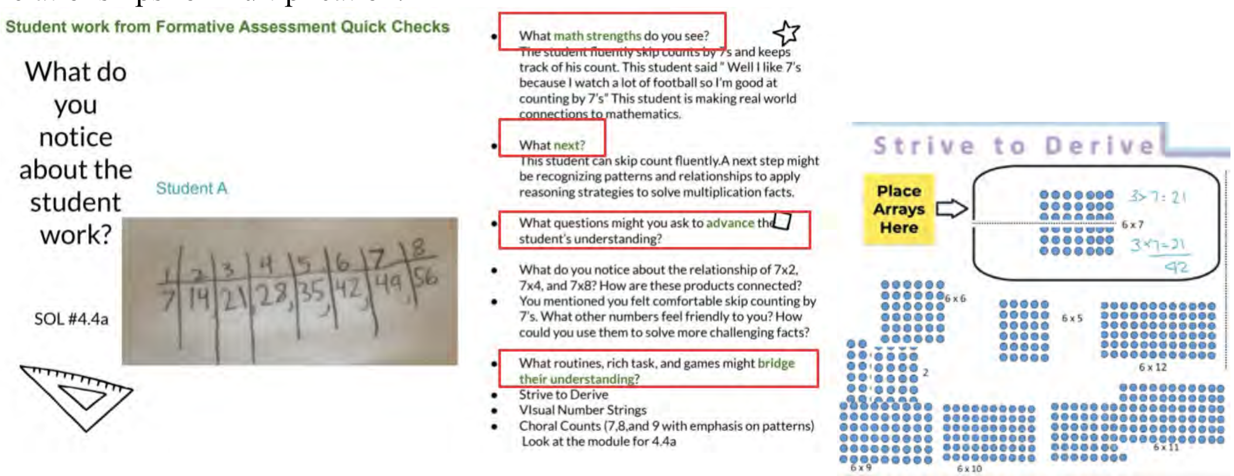


Figure 5: Providing question prompts to support asset based/anti-deficit noticings

In our analysis we found that using formative assessment and LT based bridging activities as a curricular resource during the pandemic revealed the power of removing high stakes testing and letting teachers use formative data in meaningful and humanizing ways. One of the teachers shared, "It was *liberating* because I didn't think so much about grade level standards and the state assessment. Instead, I focused on the LT and where students showed strength and built on their strength through routines, rich tasks and games." The LT-based curricular structure supported teachers and coaches in reframing how they view student learning beyond grade levels- moving away from language like "below grade level" and "at risk". Sienna, an instructional coach, found that the LT structure helped teachers see their students' learning as a progression and consider next steps rather than visualizing a gap between students' current understanding and the "final goal of the standard". Kara had a similar epiphany in her second grade classroom. She found that the LT structure allowed her to focus on conceptual understanding in her second grade students' work rather than simply quantifying the number of incorrect answers, stating "When you go to grade something or check it over, I'm not necessarily looking at 'Oh, they got 15 out of 20. They're missing a bunch.' ...I'm really zoning and honing in on what patterns I can find. I feel like that's what this cycle has taught me is that there are patterns in student work." Kara's attention to patterns in her students' work allowed her to identify their position on the LT and plan targeted instruction to support their learning as well as identify strengths and growth areas.

Case #3:PST Teachers Use of LT to Assess Student Thinking and Design Sequence of Activities

This next case illustrates ways LTs can be used with preservice teachers to prepare them as competent mathematics teachers. The term "learning trajector(ies)" appears at least sixty-three times in the document for the Standards for Preparing Teachers of Mathematics (SPTM) published by the Association of Mathematics Teacher (AMTE, 2017). For example, Standard EC3 and EC7 emphasizes the importance of LT in curricular knowledge as well as for assessment.

> EC.3. Mathematics Learning Trajectories: Paths for Excellence and Equity: Well-prepared beginning teachers of mathematics at the early childhood level understand learning trajectories for key mathematical topics, including how these learning trajectories connect to foundational knowledge, curriculum, and assessment frameworks. [Elaboration of C.1.4]
>
> EC.7. Seeing Mathematics Through Children's Eyes: Well-prepared beginning teachers of mathematics at the early childhood level are conversant in the developmental progressions that are the core components of learning trajectories and strive to see mathematical situations through children's eyes. [Elaboration of C.3.1]

Supporting PSTs on how to use LT and formative assessment to strengthen student thinking is a priority in a mathematics methods course. Focusing on these two standards, I designed an assignment called *Learning Trajectory-based Formative Assessment & Sequenced Digital Math Activities.* In this assignment, PSTs planned and enacted asset-based solutions that included digital tools as learning activities. The goal of the tasks was to re-engage students in mathematics as the students worked to develop their sense of agency, identity, and ownership in their mathematical learning. This case focuses on how PSTs used learning trajectory research to analyze formative assessment data and then sequenced bridging activities using digital technologies to enrich mathematics instruction for individual and collective learning. PSTs also learned to use digital technology teacher dashboards, which allowed them to be responsive by providing ease of analysis of student proficiency, facilitating immediate feedback, and providing information to form targeted small groups to support student learning. The *Learning Trajectory-based Formative Assessment and Digital Math Activities* (Suh et al., 2022) assignment was designed using two important frameworks, Learning Trajectory Based Instruction (LTBI, Sztajn et al., 2012) and Technological Pedagogical Content Knowledge (TPACK, Mishra, P., & Koehler, M. J., 2006))

Sara mapped out her learning trajectory concept map with the core idea of 'unitizing' (Lamon 1994, Steffe 1992, 1994) as "operating with singleton units to coordinating composite units" (Singh 2000, p. 273) highlighting the array as part of the development of spatial and numeric composite (Battista, 2012) necessary for multiplicative reasoning.

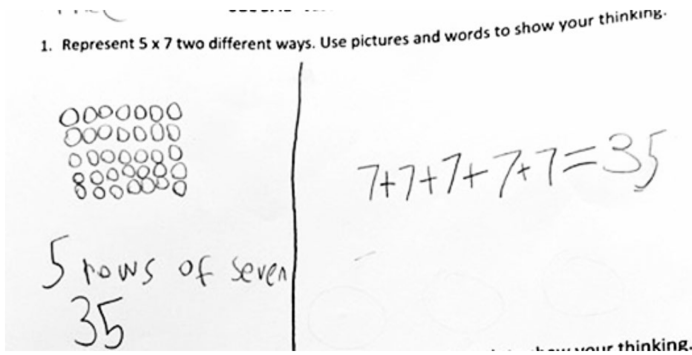

Figure 6: Sample Formative Assessment that Puzzled the Preservice Teacher

Sara, had been working with a student named Selena who could draw rows and columns with dots to model multiplication, and use repeated addition (see Figure 6), but oftentimes she would be off by 1 or 2 with her final answer. Sara was curious how to support Selena. She watched her during a formative assessment and noticed that for every problem, she would count every dot. Knowing that she wanted to move the student from counting all to seeing "many as one" as a composite unit, she found a technology tool called Bunny Times (see Figure 7) that worked with an array model with an added feature. Her analysis of the tool highlighted the affordance of the "fog feature" actually helped Selena advance to other strategies that were more efficient like skip counting or adding on from a known fact. She liked this applet because the visual helps students make connections between rows and columns. The game can be scaled in the size of math facts. Additionally, 'fog' can settle over the field obscuring some of the answers disallowing counting. Facts can be differentiated when starting the game.

Figure 7: Learning activity that supports unitizing and skip counting

Sara stated in her assessment report,

> For my target student, I plan to use Bunny Times math after working with her on skip counting. Bunny Times allows for multiplication facts to be scaled to learner readiness. Additionally, it can be played with all rows and columns visible or with some hidden under a layer of fog. For my student, with practice on unitizing, skip counting, and counting on, I hope that she will be able to complete problems using the "fog" feature.

Through the assignment, Sara learned that she could lean on her clinical faculty, a math coach in the school as well as her course instructor to assess where her student was in the multiplicative learning trajectory. She reflected on this practice-based assignment stating,

> I think this assessment will prove to be one the most important things which happened to this

> student in 3rd grade. Because of her fabulous math disposition and other areas of proficiency, it is likely that her struggles with unitizing and counting would have been masked and not observed. This project allowed for data collection, meeting with a math specialist, testing, and ultimately transferring that into specific intervention. -Sara, the PST

This PST noticed many strengths in this child's mathematical understanding related to multiplication and the intervention built on those strengths to stretch the student to be a stronger mathematician.

Implications for Mathematics Teacher Educators and Researchers

In reflecting on PMENA 2022's Theme on Dissonance and Harmony, I share some concluding thoughts and implications for mathematics teacher educators and researchers. First, we need to take the notion of a "hard reset" (Ladson-Billings, 2021) seriously to dismantle inequitable structures and practices that exist in mathematics teaching and learning and challenge the status quo. We found in our LTLS research how teachers can play an active role in validating researcher-conjectured LTs and at times challenge the traditional sequencing of mathematics prescribed by standards. We have viewed LT as a tool to help reframe teachers thinking about what students are capable of doing and finding a strength based asset orientation to instruction (Bartell et al., 2017). Building on the work of LTBI and our previous work around LTLS (Suh et al., 2018), the project that began during the pandemic called "Bridging for Math Strength" with the professional development and design research study continues to go through iterations of refinement with our model and products to support teachers teaching and student learning. With this work, we focused on changing the narrative and mindset of teachers, moving away from looking at gaps and solely focusing on error patterns (deficit-approach) to finding strengths in student thinking and using the LT to advance student thinking based on strengths and growth areas. Working on explicitly noticing and assigning competence (Gresfali et al., 2009) to shift classroom status and using LT has helped look for the strengths and where to move students forward in their learning. Too often data-talk focuses on looking at gaps using white performance as a standard to show how marginalized students are performing. Bridging the learning trajectories through a rich task across multiple grade levels allowed teachers to better focus on LT and talk less of grade level standards as the final arbiter of learning.

In order to create more socially just contexts for learning and teaching mathematics, we propose a paradigm shift in learning more deeply about the LT so that we can assess student strength and make a path of learning activities through rich tasks, place more emphasis on formative assessment and move away from gap gazing that continues to persist with state assessment (Gutierrez, 2008). Catalyzing Change Early Childhood (NCTM, 2020) - shows that students often marginalized are not given rich tasks instead given more rote learning. We advocate moving away from a "my students can't" narrative and the opportunity gaps that exist from students engaging in rigorous tasks. Continuing with data meetings with state assessments to "close the achievement gap" and catch students up will perpetuate deficit discourses, deficit noticing, obsession over errors and shortcomings of students of color blaming deficiencies in students, their families, or their cultures (Louie et al., 2017). Instead, Celedon-Pattichis et al., (2018) urges researchers and mathematics teachers to embrace asset-based approaches to mathematics education and to consciously move away from deficit perspectives that view students, parents, and communities as lacking in different aspects that enable them to be ready for schooling (Coleman et al., 2016). They encourage the mathematics education community to appreciate the math knowledge/experiences that students bring from home and communities and by doing so students bring ways of thinking that broaden mathematics beyond what is written in standards or embodied in curriculum.

To impact society more broadly, beyond individual mathematics classrooms and school districts our work must improve learning conditions for each and every mathematics learner. With a hard reset and a focus on asset-based instruction and anti-deficit noting with the intentional use of learning trajectory (LT) with equity focused PD, our work revealed that teachers felt liberated and empowered to open up varied and expansive ways to discuss students' mathematics competencies, name students' strength and position students as capable. LTLS allowed teachers to be researchers and share their expertise and validated research-conjectured LT with real classroom data. This positioned them as knowledgeable and elevated their status as learning scientists. With the Bridging for Math Strength project, the use of LT coupled with anti-deficit framing in curriculum design research provided teachers with a tool and the language to analyze student thinking and plan rigorous educational resources and asset-based instruction for their students.

Lastly, the use of LT with formative assessment in the practice-based assignment for preservice teachers provided a scaffolded learning experience in the field with multiple educators supporting them with LT research and equitable teaching strategies to advance students' understanding. As I close this paper, I invite the PMENA community to consider how learning trajectories can be coupled with powerful equity focused research (Gutierrez, 2007; Celedon-Pattichis et al., 2018; Hand, 2012; Wager, 2014) and frameworks (Aguirre & Zavala, 2013; Bartell et al., 2020; Yeh et al., 2020) to disrupt the status quo, broaden the purposes of learning mathematics (NCTM, 2020), eliminate labeling, and dismantle inequitable structures and hierarchy in the mathematics classroom. In continuing this work, I invite mathematics researchers and math teacher educators to consider border crossing (Silver & Lunsford, 2017) as boundary spanners (AACTE, 2018) to not only translate but engage teachers and researchers in the viewing the relationship between research and practice in education as bidirectional rather than unidirectional so that "research could/should influence/inform practice, but also that practice could/ should influence/inform research" (Silver & Lunsford, 2017, p. 36) while centering the voices of students who are at the margins and attending to the socio-political lens with their LT research.

Acknowledgments

I would like to acknowledge Dr. Toya Frank and Dr. Julia Aguirre for reviewing this plenary paper and for both being an awesome mentor and friend, Dr. Theresa Wills, Dr. Courtney Baker, Dr. Padhu Seshaiyer and our many doctoral students and colleagues at GMU who have been partners on these projects and my EQSTEMM research team, Erin Turner, Mary Alice Carlson, Elizabeth Fulton and Julia Aguirre who enrich my thinking every day. In addition, I acknowledge the funding agency, NSF STEM-C 1441024 and VDOE for the project mentioned above.

LEARNING TRAJECTORIES RESEARCH NEEDS A HARD RE-SET: USING PCTM TO CENTER COGNITION, CONTEXT, AND CULTURE

Marrielle Myers
Kennesaw State University
mmyers22@kennesaw.edu

Research on LTs remains a central topic in mathematics education. In this plenary paper, I argue that LT-based research needs a hard re-set if it is to play a role in creating more equitable and anti-oppressive experiences for historically marginalized students. I begin with an overview of LT-based research presented during PME-NA plenary sessions, which I examine through a lens of cognition, context, and culture. I assert that a continued focus on cognition reproduces the status quo and causes dissonance for many learners. I then discuss equity in LT research and how it has evolved throughout the years. Next, I offer Political Conocimiento in Teaching Mathematics (PCTM) as a framework that can support us in asking the complex sociopolitical questions needed to create liberatory spaces in mathematics teaching and learning. I end by inviting the field to commit to centering equity in their LT-based research as a political act.

Keywords: Equity, Inclusion, and Diversity; Social Justice; Teacher Educators; Learning Trajectories and Progressions

Introduction

For many of us, the past two years have been challenging mentally, emotionally, physically, and spiritually. There are multiple pandemics affecting our students. And while news of a looming recession and midterm elections may be dominating media outlets, the pandemics of racism, cisheteropatriarchy, redlining, xenophobia, ableism, wealth inequality, food insecurity, and climate change are still alive and well. Right-leaning states, politicians, and media are openly attacking supports aimed at remedying these pandemics. Capitalism continues to thrive at the expense of the very Black and Brown people whose ancestors built this country. Wars and threats of wars are happening around us. And while the United States stands ready to send money overseas to maintain its interests, it fails to protect its own citizens from police brutality or ensure clean drinking water as a human right.

Teachers and schools are also facing some of the greatest attacks we have seen in decades. Texas, Georgia, and Florida continue to compete in a "race for the bottom" as they seek to define and ban "divisive topics," create anti-woke laws, ban books, whitewash this nation's history, and further marginalize students who identify as LGBTQIA+ by developing policies intended to destroy their safety. Teachers are left exhausted by the pandemics, ongoing attacks, and fears of being sued or otherwise humiliated in any attempt to support students specifically harmed by these pandemics. Education remains a political pawn. Schools are underfunded. And politicians would rather spend tax dollars enforcing racist laws instead of paying teachers what they deserve. These conditions further exacerbate teacher burnout leading many school districts to start the year with an unprecedented number of vacancies.

Instead of critical mathematics education scholars being consistently asked to defend the relevance of their work as if the context of concurrent pandemics doesn't impact the teaching and learning of mathematics, we need to shift the conversation to examining how each of these cells of mathematics education research serves to maintain or liberate us from the multiple pandemics plaguing our nation. As we meet on these stolen lands, I implore our community to take up Aguirre et al.'s (2017) call for engaging in equity-oriented mathematics education research as a political act as well as what Ladson-Billings (2021) termed a "hard re-set." Ladson-Billings (2021) used the term hard re-set as a mantra and called for us to center students and culture in an effort to build a more humane future. Specifically, she stated:

> We must re-think the purposes of education in a society that is straining from the problems of anti-Black racism, police brutality, mass incarceration, and economic inequality. The point of the hard re-set is to reconsider what kind of human beings/citizens we are seeking to produce. (Ladson-Billings, 2021, p. 72)

LT-based research needs a hard re-set that can only be achieved if our community adopts a critical stance that centers equity. Doing so requires holding cognition, culture, and context together while using a critical lens. To date, LT research has privileged cognition at the expense of culture and context, and that disregard has led to inequitable uses. To make this point, I first discuss the history of LTs in plenary sessions at PME-NA in relation to cognition, culture, and context. Next, I establish my positionality and history with LT-based research. I then discuss the current state of equity-based approaches in LT research, and offer Political Conocimiento in Teaching Mathematics (PCTM) as a framework for our field to consider in order to enact the hard re-set needed (Gutiérrez, 2017). I end with questions and implications for the field.

Learning Trajectories at PME-NA

The North American Chapter of the Psychology of Mathematics Education (PME-NA) has a detailed history of centering LTs in its conference. In his 2010 plenary session and paper, Mike Battista spoke about the similarities and differences between Learning Progressions (LPs) and LTs, and what it meant for students to move through LPs/LTs (e.g., milestones, levels of sophistication). After highlighting differences in theoretical framings, the nature of levels, and the inclusion of instruction as a way to differentiate LTs and LPs, Battista turned to his work with Cognitive Based Assessments (CBAs). He noted that a CBA LP outlines students' conceptions, obstacles, plateaus, and mental processes needed to advance for a given topic (2010, p. 66). While Battista notes that movement through progressions is not unilateral because "students' learning backgrounds and mental processing differ[s]," there was no specific mention or acknowledgment of the sociocultural and political environment this instruction, assessment, and research validation occurred in. We are also left to wonder how Battista defines learning backgrounds and to what extent, if any, that definition captures the rich knowledge students bring from their homes and communities. Battista ended his paper by calling on researchers to exercise caution when using quantitative techniques to develop and validate LPs so as to not misapply such techniques or ignore how this thread of work interacts with research on learning (Battista, 2010, p. 69). It is noteworthy that Battista's caution to the field centered cognition and upholding principles of research methodology while tangentially addressing context and ignoring culture.

Susan Empson (2010) questioned the novelty and usefulness of LTs in Battista's plenary in an invited critique and reaction. After offering a summary of LTs and drawing on Simon's (1995) discussion of a hypothetical learning trajectory, Empson pondered LTs' place in teaching and research. In addition to posing questions for consideration, Empson acknowledged the importance of context when she cautioned the field not to underestimate the role of tasks, teachers, and teaching in LT research. She also reminded us to acknowledge disciplinary practices in the same way we focus on content, which is critical since LTs are tools used for teaching and ultimately derive meaning from classroom contexts. Finally, this paper noted that LTs ultimately need to be useful for teachers and that the creation and use of LTs must be an interactive process that involves careful study of how teachers use them. Empson's paper reminded us of the importance of context in cognition-based research. This paper did not explicitly address culture.

In 2012, Confrey offered a plenary paper summarizing how LTs were used in the development of the Common Core State Standards for Mathematics (CCSM). A major premise of this work was to support state leaders in distilling elements of the new standards into smaller pieces of information supported by research on student learning over time. Another key element of her paper was presenting components of LTs in ways that were useful for teachers, resulting in the creation of a hexagon map of K-8 mathematics standards. As Confrey described the hexagon map, she provided a rationale for its design, noting how different big ideas were connected (e.g., counting, addition, and subtraction), how some content supported the learning of other ideas (e.g., equipartitioning supporting the development of division and multiplication), and why some topics were visually clustered between others (e.g., length area and volume are nestled between equipartitioning on one side and shapes/angles on the other). This plenary offered a detailed analysis of a multiplication and division LT coupled with figures, strategies, and multiple representations. Confrey and team unpacked each trajectory by articulating conceptual principles, strategies, representations, misconceptions, meaningful distinctions in language, coherent structure, and bridging standards, which centered cognition.

Confrey explicitly stated that the hexagon map did not address the standards for mathematical practice (which could have inserted relevant connections to culture and context) but noted that students would surely use various practices as they progressed through the trajectory (2012, p. 8). She then posited that when LTs are properly unpacked and coordinated with standards, teachers can be better supported to connect underlying mathematical principles. She ended this paper by inviting the field to consider the usefulness of the hexagon maps as one example of what coherence across standards could look like, with the ultimate goal of supporting teachers as they transitioned to using the CCSS (Confrey, 2012). While the hexagon maps and associated unpacking offered valuable information related to cognition, a sociopolitical lens was not evident. As such culture was not discussed and context was not addressed. Given the social and political nature of teaching and how the CCSS were created, such connections would have been valuable as they could have contextualized this national movement and addressed teachers' concerns around new mandated curricula and tests that accompanied these standards.

The next plenary talk on LTs featured Julie Sarama in 2018. In a response to the conference theme, *Looking back, looking ahead: Celebrating 40 years*, Sarama discussed how mathematical knowledge developed in young children and shared brief highlights from her work. Her definition of LTs, which she noted is rooted in constructivism, acknowledged the importance of instruction and mathematical tasks. As Sarama unpacked the tenets of *Hierarchic Interactionalism*, she noted several points that were central to young childrens' innate skills and environment. She ended this chapter by offering an example of a student named Justin progressing through the LT-based *Building Blocks* curriculum. Sarama highlighted this student's growth in counting, addition, and subtraction as one example of how student thinking across multiple LTs is interactive and can grow concurrently (Sarama, 2018). Again, this plenary paper, and the original paper from which the example was drawn, centered cognition (and cognitive science) and did not provide insight on the context of Justin's "growth," his culture, who the teacher was, and the broader sociopolitical context this study occurred in.

In reflecting on these plenaries, Battista's took a cognitive approach. Empson pushed back and acknowledged context but left much unsaid about culture. Using a constructivist paradigm, Confrey and Sarama attend to context in limited ways (e.g., standards, curriculum) but did not include culture or other sociopolitical factors. My goal in providing this brief historical overview through a lens of cognition, context, and culture was not to freeze any of these scholars in time as working toward equity is a journey and not a destination. Rather, I sought to highlight how each of the plenary papers privileged cognition (when written) at the expense of context and culture, thus casting equity to the sidelines. While these scholars moved the field forward in monumental ways by disrupting understandings of how mathematical content is organized and reframing students as capable of rich mathematical thinking, they did not go far enough to disrupt other problematic strongholds in mathematics teaching and learning (e.g., tracking, low expectations). This review of previous LT-focused plenaries at PME-NA highlights the timeliness and necessity of the current conference theme, as scholars were specifically invited to consider their work through a sociopolitical lens. I hope this paper and resulting discussion contribute to a collective examination of why a hard re-set is needed in LT-based research if it is to play *any* role in leading toward a more "antioppressive and equitable human experience" in mathematics teaching and learning (Aguirre et al., 2017, p. 127).

Positionality

Before moving forward, it is important that I provide context on who I am and how I came to this work. I am not an outsider to LT-based research. In fact, I have an intimate history with LTs, and most of my time as a graduate research assistant for my master's and doctoral programs was spent on large-scale, NSF-funded, LT-focused grants. Earlier in my program, I worked on a research team to develop LTs for equipartitioning and rational numbers. As a graduate assistant, I conducted numerous clinical interviews and worked with my teammates to construct and validate LTs. Our team regularly met and engaged with other LT experts in the field, many of whom I cite in this paper, and worked to support the development of our state's mathematics standards. During that time, several concerns began to arise in the field around the construction and validation of LTs. Many of these questions were aimed at the diversity, or lack thereof, of the student population upon whom LTs were constructed and validated. Our team considered that feedback and began to intentionally recruit research participants in various settings to diversify our student sample. I recall being curious about this critique and wondering if students from different racial, cultural, and linguistic backgrounds would demonstrate different pathways through our sets of tasks. At that time, my equity lens was not sophisticated enough to recognize that engaging diverse students in a fairly "rigid" set of tasks was unlikely to produce different outcomes. In fact, as I reflect on this approach to diversifying the student sample in our research, I now see that we worked to accumulate more in the sample, rather than pause and fundamentally reorganize the research design. I was also only beginning to understand the impact of context and interlocking systems of oppression. And as such, I was not yet able to a) question the rationale for centering cognition, b) form arguments about how the clinical interview structure excluded context, c) understand how students intersectional identities influenced their work on our tasks, or d) understand how the social and political context of standards, funding, and other external forces impacted our research work.

After transitioning to another project, my focus shifted from developing and validating LTs in rational numbers to designing LT-based professional development. While on this project, our team worked on translating and coordinating early grades LTs focused on number, counting, addition, and subtraction, into useful tools for teachers across grades K-5. This research project, titled *Learning Trajectories Based Instruction* (LTBI), served as the basis for my dissertation. As we sought to understand and develop a model for *how* teachers learned to use LTs, I, along with other team members, became interested in how teachers' implementation of LTBI looked different across various subsets of their student population. I had grown as a person and a scholar and was much more aware of equity, justice, and how the systemic nature of marginalization in schools maintained opportunity gaps and systematically excluded minoritized learners.

After ending my high school teaching career to complete my doctorate full-time, I was much more attentive to culture and context. I had also grown increasingly frustrated with the ways "new trends" and "innovative curricular materials" in mathematics teaching and learning yielded the same results year after year (e.g., opportunity gaps, tracking). Because of the national attention LTs were receiving at the time, and how they were being used to develop curriculum and assessment, I wanted to be proactive in considering how they could be used equitably. Therefore, I worked with my team to articulate a theory of Equitable Learning Trajectory Based Instruction (E-LTBI), which I then investigated in a case study of four teachers for my dissertation (Myers, 2014). This E-LTBI framework resulted from simultaneously considering Gutiérrez's (2007) four dimensions of equity and our existing LTBI framework (Myers et al., 2015). I share more about this work in my review of LTs and equity after providing a brief overview of LTs/LPs and critiques.

Learning Trajectories

Several definitions of LTs have been offered in the field. Clements and Sarama (2004) define LTs as

> descriptions of children's thinking and learning in a specific mathematical domain and a related, conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children through a developmental progression of levels of thinking, created with the intent of supporting children's achievement of specific goals in that mathematical domain. (p. 83)

Confrey and Maloney's (2010) definition of LTs features similar language but notes that trajectories a) are empirically supported, b) include activities, tools, and assessments in addition to tasks, and c) highlight the iterative nature movement, reflection, and refinement as students move from informal understandings to formal ideas (p. 2). Research around LTs exists in three primary areas: development and validation (constructing LTs in different domains and content strands) (Battista, 2004; Blanton et al., 2015; Confrey et al., 2009; Maloney & Confrey, 2010; Gravemeijer et al., 2003; Fonger et al., 2020), informing instructional tools (e.g., standards, curriculum, and assessment) (Clements, 2002; Clements & Sarama, 1998; Confrey, 2012; Daro, Mosher, & Corcoran, 2011; Mosher, 2011), and, more recently, professional learning for teachers (Bargagliotti & Anderson, 2017; Clements & Sarama, 2009; Edgington, 2012; Sarama et al., 2016; Suh & Seshaiyer, 2015; Sztajn et al., 2012; Wickstrom, 2014; Wilson et al., 2013; Wilson et al., 2015; Wilson et al., 2017). Lobato and Walters (2017) conducted a detailed review of research on LTs and LPs in mathematics and science education. They produced a taxonomy of approaches to learning trajectories and progressions, which they refer to as LT/Ps. At each level, they described the approach, offered an example, highlighted the features, outlined the methods used, and discussed the purpose, benefits, and tradeoffs. I invite readers to study the full paper to learn more about the breadth and depth of research around developing and validating various LT/Ps.

It is important to note that I do not seek to offer a distinction between LTs and LPs nor advocate for one over the other. I encourage readers interested in the LT vs. LP discussion to read Battista (2010) and Ellis, Weber, & Lockwood (2014), as both papers offer a detailed account. The relevant similarity from my perspective is that while LTs and LPs center cognition and narrowly reference context (in noting the importance of carefully selected tasks and pedagogical moves), neither body of research explicitly addresses the social, cultural, or political context in which the research, validation, creation, and intended uses occurred. Moreover, I argue that both LTs and LPs offer a narrow definition of what mathematics is, whose mathematics is privileged, and why we engage with it, thus missing an opportunity to expand the view of what counts as mathematics (Aguirre et al., 2017).

Critiques of LTs (and LPs)

Critiques of LTs and LPs in mathematics and science education are not new. In the National Research Council (NRC) report *Taking Science to School*, the authors provide an overview of teaching and learning science in grades K-8. In their chapter on learning progressions, much of which aligns with LTs mathematics education, the committee highlighted how LPs can be used to map students' understandings and unify science topics that have previously been disconnected. The committee ended this chapter by discussing the design challenges of LPs and stated,

> No single learning progression will be ideal for all children, since they have different instructional histories, bring different personal and cultural resources to the process of learning science, and learn in different social and material environments. The best learning progressions are those that make effective use of the resources available to different children and in different environments. This is the challenge that we are farthest from responding to effectively with the current research base. (NRC, 2007, p. 222)

The committee later noted that although they recognized inequities in science education and the dire need to address them, they were unsure about what recommendations to make related to modifying instruction for diverse learners. Their suggested agenda for future action included focusing on the effectiveness of different instructional strategies, the unpacking of systemic inequities across schools, and the need for specific research that examined the complexity of culture, language, and socioeconomic status (NRC, 2007). This report summarized the cognitive aspects of LPs in science and pointedly expressed the absence of context, culture, and other sociopolitical constructs.

In a 2011 paper, an expansion of her 2010 plenary response, Empson questioned what LTs afforded, foregrounded, and obscured, which parallels the current conference theme of dissonance and harmony. I appreciated that this more detailed analysis considered both promises and pitfalls of LTs by making the case that learning is as much contextual and social as it is cognitive. Empson went on and acknowledged that teaching was a relational act that "depends fundamentally on interpersonal relationships of trust and respect." (Empson, 2011, p. 587). What was underdeveloped in this paper was the explicit unpacking of the word *contextual* and the historical and political nature of those contexts. Additionally, when children's differences were alluded to in the text, the words race, gender, culture, language, sexual orientation, or ability were not explicitly mentioned. When we do not intentionally name the different elements of students' intersectional identities we can inadvertently reify some scholars' beliefs that LTs only need to focus on "cognitive differences." I argue that while this critique pushed for the inclusion of context (and culture to some degree) in LT research, a sociopolitical could have strengthened this critique. Just as Empson argued that learning cannot be separated from teaching, I argue that teaching cannot be separated from the teacher. Since teachers hold a range of beliefs and biases about who can do mathematics and who should be afforded opportunities for “rigorous” mathematics, neglecting to use a sociopolitical lens secures an oppressive, anti-black, anti-immigrant, anti-poor, anti-LGBTQ, ableist system. We must explicitly engage teachers’ beliefs as we center context and culture in conversations about LTs.

In their examination of equity in LT/LP research, Delgado and Morton (2012) analyzed existing research using a cognitive constructivist framework. They noted that this framework was aligned with their definition of equity. These authors pushed against “equity for all” (or dominant framing of equity) and embraced a postmodern definition of equity that “acknowledges existing inequities in society [and] proposes responsive, individualized attention to students in order to compensate for past lack of opportunities and to promote social justice” (Delgado & Morton, 2012, p. 205). As they examined LT/LP research that explicitly considered “issues of equity,” the authors found that student populations lacked diversity (or didn’t report any demographic information), only focused on common themes amongst students’ mathematical ideas instead of capturing all students’ ideas, and failed to consider how students’ family and community knowledge shaped their engagement in tasks and resulting movement through a trajectory. The authors concluded their paper and stated,

> Research groups developing LPs and LTs should ideally include advocates for certain groups of students, for example, an expert on special education and team members that are deeply knowledgeable about the culture of minority students. Developing learning progressions and learning trajectories that do not address inequity in educational opportunities in math and science for students will only exacerbate the current problem. As the learning sciences, science education, and mathematics education fields continue to negotiate and define the nature of LPs and LTs, an expansion to include equity concerns at the forefront can greatly benefit groups that have been traditionally underserved. (Delgado & Morton, 2012, p. 209)

LTs and Equity

In this section, I present three ways “equity” has been addressed in LT-based research. First, I highlight Sarama & Clements’ body of work as an example of a dominant framing of equity as it primarily focuses on access and achievement (Gutiérrez, 2007). I also discuss how their attention to equity has shifted over time to include some critical framings of equity. Next, I discuss equitable uses of LTs by highlighting two cases: LTBI and Suh et al. (2022). After showing how Clements and Sarama’s work influenced my dissertation study and led to the development of the E-LTBI framework, I transition to the work of Suh and colleagues who built from our LTBI findings and intentionally embedded equity in their LT-based PD model. I conclude by highlighting the work of Zahner and Wynn (2021), who centered equity in an attempt to address gaps in representation in LT development.

Dominant Framing. One area of LT & equity research focuses on how LTs can offer access and support achievement for minoritized students. The body of work of Clements and Sarama represents decades of research and tens of millions of dollars of grant funding from large-scale funders (e.g., The National Science Foundation and Institution of Education Sciences), which led the development of curriculum (Clements & Sarama, 1998; Sarama & Clements, 2019), conferences, and the creation of research centers. Because these scholars' definition of LTs and the resulting body of work has been so influential in LT-based research, I draw on it as one example of a dominant framing of equity. Consider the large-scale randomized trial that was conducted and published in several venues (Clements et al., 2013; Sarama et al., 2012). The authors noted that they chose their research site because “children from low-resource communities and who are members of ethnic and linguistic minority groups demonstrate significantly lower levels of mathematics achievement than children from higher-resource, nonminority communities" (Clements et al., 2012, p. 2). The authors went on to note that their LT-based PD model, "include[d] guidelines for promoting equity through the use of curriculum and instructional strategies that have demonstrated success with underrepresented populations" (Clements et al, 2012, p. 4). Findings from this and similar studies indicated that African-American students in their experimental groups scored significantly higher than their counterparts in control groups. One conclusion of this study was that "centering instruction around LTs may focus teachers' attention on students' thinking and learning in mathematics rather than their memberships in ethnic groups and thus avoids perceptions that negatively affect teaching and learning" (Clements, Sarama, Wolfe & Spitler, 2012, p. 26). In their 2014 book chapter, Clements and Sarama stated, "several "gold standard" randomized control trial studies have shown that curricula and professional development based on learning trajectories increase children's achievement more than those that do not." (p. 7). They went on to say, "learning math at an early age is critically important for young children, especially those from disadvantaged communities" (Clements & Sarama, 2014, p. 8).

Clements and Sarama's attention to and expression of equity continued to grow and expand throughout the years. They sharpened their perspective by explicitly addressing six myths about LTs, three of which are germane to this analysis (Clements & Sarama, 2017/2019). First, they argued that LTs are asset-based because they help teachers recognize and build upon students' thinking. Next, they defended critics' notions of LTs being narrowly focused by noting that LTs are "deeply constructivist" and address broad ranges of ideas. Finally, they stated, "Learning trajectories are expressly built to be adaptable to different cultures, groups, and individuals. One important adaptation is for different cultures. Learning trajectories take funds of knowledge from all communities seriously and encourage using such funds" (Clements & Sarama, 2017/2019, p. 2).

More recently, Clements et al. (2020) suggested that teachers who know how to use the three components of an LT are better suited to understand the complexity of early mathematics content and offer instruction that is more closely aligned with students' current conceptions, thus providing more robust mathematics experiences for all children. They stated that such environments are necessary for "vulnerable children who live in poverty, are members of linguistic and ethnic minority groups, or…children with disabilities" (Clements et al., 2020, p. 1). They suggested that early-childhood teachers could benefit from sustained PD focused on learning trajectories that also included direct support for engaging children with learning disabilities. The authors ended this paper by announcing their STEM Innovation for Inclusion in Early Education Center, which they noted is a critical step in ensuring equity and excellence in early STEM experiences. Ongoing work from this team continues to suggest that LT-based PD positively impacts students from "low-resource communities" (Sarama, Clements & Guss, 2021).

As I followed this and other bodies of LT-based research over the years, I observed how the discussions of context and culture have both evolved by expanding the attention given to equity and, in some cases, remained stagnant by only considering equity in relation to student achievement. I have paid particular attention to how students were described and positioned in these and other studies. I would encourage Clements and Sarama to consider how the language they used to dispel myths in their 2017/2019 resource document may be at odds with how often students and their communities are referred to as low resource, vulnerable, and minority. Although those phrases were often used as demographic descriptions, doing so without a sociopolitical lens may serve to reify the deficit orientations Clements & Sarama seek to disrupt. It is also important to note how context was included (e.g., as a description or as a mediating variable in a statistical model, etc.) and whether or not the context of the study was situated in the historical context of schools and schooling in the United States (e.g., critical explanations of sociopolitical factors that intentionally created disadvantaged or low-resource communities). Finally, I invite the reader to carefully consider how this dominant view of equity and its evolution was inextricably tied to cognition, which overwhelmingly excluded critical discussions of context and culture.

Equitable Usage of LTs. A second area of equity and LT research focuses on the ways LTs are used in instruction. The Learning Trajectories Based Instruction (LTBI) research project (for which I was a graduate research assistant) is one such example (Sztajn et al., 2012). This study used Clements and Sarama's early number, counting, addition, and subtraction LTs in a multi-year research project with K-2 teachers. In our 2015 paper *From implicit to explicit: Articulating equitable learning trajectories based instruction*, my colleagues and I argued that although we initially considered our LT-based research with teachers to attend to issues of equity, what we learned in our work caused us to reconsider some of those assumptions (Myers et al., 2015). Similar to other cognition-focused teacher learning models, our project centered students' thinking, disrupted notions about the "traditional sequencing of mathematics," and created space for students' individual thinking to emerge and be positioned as valuable along various trajectories. Teachers in our study deepened their knowledge of K-2 mathematics content, appreciated the language the trajectory afforded them, and began to recognize and value a range of students' mathematical contributions (Edgington, 2012; Myers, 2014; Wilson et al., 2015). In this sense, one assumption of our work built on Clements et al. (2012) suggestion that by using LTBI, teachers would see that all children were capable of mathematics, potentially reducing their focus on other demographic factors.

Unfortunately, the suggestion that focusing on cognition could reduce attention to other factors did not hold true in our work, highlighting how good intentions and race-evasive approaches are not enough to effect radical change across diverse groups (Rodriguez, 2003). As a result, we saw LT language taken up and used oppressively such as when teachers replaced the language of "low students" and "high students" with LT-based vocabulary (e.g., the low students being renamed the direct counters). Results from my dissertation highlighted that most LT-based work aligned with a dominant approach to equity (Myers, 2014) and that the elements that connected to Gutiérrez's (2007) critical axis were shallow or maintained dominant framing. Moreover, in my paper titled, *The unintended consequences of a learning trajectories approach*, I reported on a teacher, Elizabeth, who possessed several deficit orientations about her students. This teacher also shared that she wasn't confident in her own mathematics knowledge and therefore taught science instead of mathematics to her kindergarten students. Although this teacher made "gains" in her content knowledge and began offering LT-based instruction in her classroom, several issues emerged. A primary concern was that this teacher's deficit orientations about students overshadowed what she learned about LT-based instruction. This teacher ultimately used knowledge gained in the PD to justify retaining kindergarten students from minoritized groups, and the LT-based language she acquired in our sessions provided "credibility" to her decisions as a teacher (Myers, 2015).

It is important to note that my dissertation study sought to examine what equity may look like as a *by-product* of participating in LT-based PD, as equity was not explicitly centered in the PD design. Building upon findings from LTBI-based research, Suh and colleagues considered that

LT-based PD was not enough to disrupt teachers' beliefs about minoritized students. Therefore, she and her team intentionally embedded equity in their LT-based teacher learning study design, simultaneously centering cognition, context, and culture. They engaged teachers in professional development focused on LTs, asset-based instruction, and cognitive demand (Suh et al., 2022). They hypothesized that pairing LTs with equity-oriented and anti-deficit frameworks for noticing (Louie et al., 2021; van Es et al., 2022) would help teachers recognize students' multiple knowledge bases. They suggested that this framework would support teachers to assign mathematical competence to their students. The authors noted that teachers in their study moved beyond discussing "gaps" in students' understanding to using what they referred to as "strength-based language" (Suh et al., 2022). It is unclear from these findings if the shift from "gap-based language" to "strength-based language" reflected a change in teachers' beliefs or if teachers were merely using the "new language" that had become normalized in the professional learning space, potentially as a proxy for previously held viewpoints (Myers et al., 2013; Wilson et al., 2017). The field can benefit from continued research that examines how similar findings (e.g., strength-based language) relate to broader conceptions of socially just and anti-oppressive learning environments.

Representation in LT Development. A final area of equity and LT research focuses on who is used in constructing LTs. In noting the absence of diversity in the student population of much LT-based work, Zahner & Wynn (2021) conducted clinical interviews with 23 multilingual students using LT-based tasks focused on proportional reasoning and linear functions. This study of twenty-five ninth-grade students (primarily Latinx, Asian, and African American), ten of which were multilingual, provided valuable insights into how the linguistic complexity in mathematics tasks impacted how students approached tasks and explained their reasoning, thereby influencing their potential "ranking" or placement on a content-focused LT. Their findings call into question the role of language in previous large-scale work conducted to create, norm, and validate LTs. Given that many initial LT-based studies did not consider language or the linguistic complexity of tasks in the study design, we are left to wonder how students interpreted tasks. Even when scholars acknowledged demographics (e.g., language status) in large-scale studies they typically neglected to present analysis around how language mediated performance on standardized tests. Zahner and Wynn's research is an example that culture and context can be centered while simultaneously investigating cognition.

Summary

For organizational purposes, I presented these two sections (critiques of LTs and equity in LT-based research) separately. Readers should note that some of this work occurred concurrently and that some of the shifts in how equity was presented in LT-based research were in direct response to the ongoing critiques of equity in LT research (e.g., Empson, 2010, NRC, 2007, Sztajn and Wilson, 2019), LT-based conferences and working groups, and other conversations that have continued in the field. Despite a small shift in how scholars have attended to equity in their LT work, cognition is still the focus, and I argue that we have not yet met the call of centering equity in LT research as both a political act and a collective responsibility. I also note that in order for an LT-based re-set to happen in ways that honor Aguirre et al.'s (2017) call, we must pause to unpack a) how discussions of "equity" have (or have not) evolved in LT-based work, b) whether we have been intentional about acquiring the knowledge necessary to make the shifts in genuine ways, c) if our work focuses on the full humanity of students' experiences and moves beyond acknowledging their test scores, and d) how we have chosen to foster and cultivate critical collaborations that value the expertise of a range of scholars, colleagues, and families. In what follows, I describe PCTM and suggest that this framework can help us ask the complex, sociopolitical questions needed (Gutiérrez, 2013) for us to examine LT-based as we consider how cognition, context, and culture are necessarily entangled.

Using PCTM to Critically Consider Cognition, Culture, and Context

In honoring the conference theme and Aguirre et al.'s (2017) call to be intentional about discussing interlocking systems of oppression with colleagues, I suggest that Political Conocimiento in Teaching Mathematics (PCTM) can provide the field with a lens to examine LT-based research and ask complex questions. Because PCTM explicitly engages content, pedagogy, social context, and politics, it is suitable for examining LT-based research across its three primary domains (e.g., development and validation, informing instructional tools, and professional learning with teachers). For too long, large-scale research projects (e.g., LTs and Cognitively Guided Instruction) have been conducted in mathematics education and taken up by the mainstream without engaging a sociopolitical lens during conception. Equity-oriented scholars have then dedicated their careers to proving how the initial work was not grounded in equity while also considering how to "re-mix" the research and curricula to meet their justice-oriented agendas (Maldonado et al., 2022). My goal in offering this framework is to call for an end to this two-phased approach that centers cognition first and then leaves equity-oriented scholars to consider culture and context. After describing PCTM, I unpack questions posed in the conference theme to illuminate the power of this theoretical framework.

Political Conocimiento in Teaching Mathematics

PCTM is a theoretical framework that highlights the unique ways that mathematical knowledge for teaching (MKT), pedagogical content knowledge (PCK), knowledge of students, and political knowledge are entangled (see Figure 1) to produce a unique way of *knowing* that teachers (and researchers) need to consider as they teach and conduct research, especially with historically marginalized students. Here, I list two elements of this framework that make it useful to critically analyze LT-based teaching and learning. First, PCTM explicitly links content, pedagogy, knowledge with students and communities, and political knowledge (e.g., power dynamics) and situates the entanglement of each of these in a social and historical context (Gutiérrez, 2012). This linkage does two things. One, it dispels the "false dichotomy" between mathematics and equity that some scholars assert (Aguirre et al., 2017), making it inconceivable to conduct research on cognition and teaching without attending to context and culture. Two, this linkage asserts that political knowledge is not merely added to the other dimensions. On the contrary, engaging a political lens causes us to re-examine the other components (Gutiérrez, 2012). As such, one would not consider developments related to content and pedagogy (e.g., develop a LT-based curriculum) and then question how to use it with diverse learners. Instead, this framework embraces the tensions that exist when these individual pieces are entangled, thereby allowing us to ask richer questions and reflect on decisions we make to foreground or background different dimensions (Myers, Gutiérrez & Kokka, in press). Using such a framework at the onset of LT-based research would have eliminated many of the critiques that came later since culture, race, language, communication patterns, task design, teacher and researcher identity, etc., would have all been considered in the development and validation phases. Embracing this tension allows us to see that dissonance and harmony can coexist while we also question who experiences dissonance and who experiences harmony (Gutiérrez, 2009a).

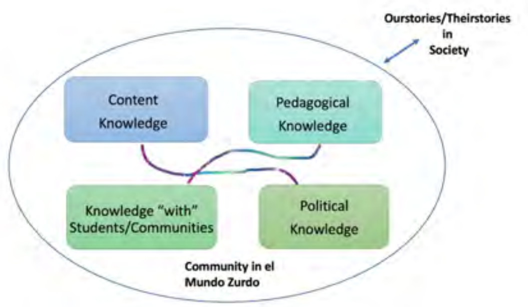

Figure 1. Political Conocimiento in Teaching Mathematics (Gutiérrez, 2012)

Second, the word conocimiento is drawn from the Spanish verb conocer. The Spanish word *saber* represents a "fixed" kind of knowing (e.g., to know facts, how to follow steps, to know a piece of information). The verb *conocer,* however, represents a fluid type of knowing that is contextual (e.g., to know a person, to know of a place). This distinction is critical as *conocer* asserts that context and conditions are essential to framing *how* we know (Gutiérrez, 2017). This kind of knowledge prevents us from objectively knowing "low-income students," "minority students," or "English language learners" in a fixed or homogenous way and, as such, applying a "best practice" to that population with the hopes of minimizing an achievement gap. A teacher or researcher using PCTM as a lens would first question how a "best practice" was developed. That person would ask, "best for whom? Best under which conditions? Best to what end? Best for what outcome?" Using this type of framework also problematizes the treatment of groups of students as static objects of our research and suggests that knowledge must be co-constructed with learners, families, and community partners. Reframing knowing as relational also reminds us that how we *know* is always changing because our environments and sociopolitical contexts are ever-changing. Moreover, as scholars, our *knowing* about LTs is also fluid as we continue to re-negotiate our work in light of new understandings about our intersectional identities, new scholarship, etc. PCTM is undoubtedly a powerful theoretical framework that the field can use to consider complex questions similar to those posed in this year's conference theme. In the next few paragraphs, I consider two of the thematic questions through the lens of PCTM.

How does LT-based teaching challenge a settled mathematics learning status quo?

Using PCTM allows us to answer this question in two ways. First, it is important to acknowledge the historical and political contexts that afforded the "mathematics learning status quo" to be created and maintained for so many years, leading to dissonance. Our field can benefit from engaging in discussions around how mathematics has been socially constructed in a way to maintain systems of oppression (Gutiérrez, Myers & Kokka, 2022, in review). Using PCTM forces us to unpack the political nature of the status quo, understand who is negatively affected by it, and develop a comprehensive approach to address the problem instead of accepting it as the norm or rushing to a "quick fix."

Second, PCTM allows us to consider how questioning mathematical content (thereby questioning mathematical content knowledge) can lead us to work toward harmony. Given that the four elements of the PCTM framework are entangled and that the resulting knowledge is relational, pulling one thread in an attempt to disrupt a status quo necessarily challenges our ways of knowing, allowing us to consider the other dimensions and reimagine mathematics learning more broadly. For example, several studies demonstrated that LT-based professional development supported teachers in understanding the complexity of mathematics content, how underlying ideas were connected, that mastery was not a prerequisite for more sophisticated ideas, and that informal understandings were valuable prerequisites for building more complex ideas. This work is important. What was missing from those conversations is specific research on how changes in teachers' MCK interacts with the other elements of PCTM, to potentially disrupt other status quos in mathematics teaching and learning. For example, does the “asset-based” lens teachers acquired during LT-based PD support them in reframing their understanding of the mathematical practices (e.g., centering a range of communication and argumentation styles, debunking traditional notions of precision) through a sociopolitical lens? Moreover, even when teachers develop an “asset-based” lens as a result of LTs and constructed counternarratives about students’ thinking, what did this mean for how teachers recognized and valued students’ humanity? Did “disrupting inequity” in mathematics thinking lead teachers to advocate for greater change? And did changes in beliefs, if any, persist over time? If LT-based teaching continues to treat mathematics as disconnected from students, families, communities, and contexts, how can we expect to truly eradicate inequity in mathematics teaching and learning?

How does LT-based teaching have an impact on society more broadly, beyond individual mathematics classrooms and school districts?

This question naturally engages each element of the PCTM framework as we consider how LT-based teaching and learning (content and pedagogical knowledge) *might* impact society (students, communities, politics) more broadly (our/theirstories). I argue that, to date, much of what we have seen in LT-based teaching supports long-standing notions that mathematics is a neutral and culture-free domain. As we examine mainstream curricula and approaches to teaching mathematics, we see that there is still a focus on drill and memorization, even though worksheets have been traded for digital tools. PCTM helps us see that school-based mathematics is still privileged at the expense of home, community, and place-based mathematical knowledge. We have not considered how to use our collective power to disrupt standardized testing and its oppressive effects. Instead, much LT-based work has been advertised in support of helping our students perform better on tests. PCTM can support scholars in thinking about using LT-based research to “play the game” and “change the game” (Gutiérrez, 2009b). This question reminds us that because teaching happens in classrooms, which are housed in schools, which are located in communities, which are a part of society, any classroom level teaching and research ultimately has an impact on these other spaces. Whether that impact upholds the status quo or redistributes power is a question scholars delve into while remembering our moral obligations (Stephan et al., 2015) and embracing a “productively self-critical” disposition (Kilpatrick, 2013, p. 73 as cited in Larnell et al., 2016).

Conclusion

Before I close, I return to the case of Elizabeth, who used what she learned in LT-based PD to justify retaining historically marginalized students in kindergarten. As I mentioned, this teacher showed growth in her content knowledge. She also used what she learned to attend to students’ thinking and plan next steps aligned with the trajectory. But when her “content-focused reform efforts” didn’t produce the results she expected to see on students’ quarterly benchmark tests, deficit narratives entered the conversation (e.g., if they weren’t eating free breakfast in the morning we could do extra practice, their parents don’t spend enough time with them at home). What was missing? How did Elizabeth need to be supported to question the usefulness of an LT-based approach across all students? What tools did Elizabeth need to support her so that she could ask *questions about the nature of standardized testing* instead of asking *questions about her students and their families*? Was Elizabeth ever providing “equitable and high-quality instruction” if these comments were indicative of her beliefs about students? And what does it mean that Elizabeth chose to retain students instead of advocating for them? Frameworks like PCTM help us ask these questions about Elizabeth's case. Part of our moral obligation as scholars is to ensure that we consider how cognition, context, and culture are entangled and the type of professional learning experiences teachers need to understand the political nature of their work, not just the cognitive aspects. LT-based PD alone is insufficient for ensuring equity and justice.

Mathematics teaching, learning, and research are political acts (Aguirre et al., 2017; Larnell et al., 2016). And as such, we must use care in conducting our work and consider what's at stake when we don't approach our research critically. In this paper, I built the case for using PCTM as a theoretical framework to examine LT-based research to support the hard re-set needed if LTs are ever going to be relevant in creating a more humane and just mathematics experience for historically marginalized students. I also submit that it is necessary to pause, reflect, and engage in the self-work and education needed to prepare for this re-set. This paper contributes to that pause by adding to critical discussions about LT-based research and suggesting a theoretical framework that can support our collective efforts. Despite increasing explicit attention to equity in LT research, a sociopolitical lens is still needed as we grapple with considering LTs at the intersection of cognition, context, and culture. We need to continue to unpack the various definitions of equity that guide our work and engage in conversations across research paradigms to build critical LT-based research models. And while we cannot change the LT research that has come before us, we can strengthen our commitment to equity and justice by asking more complex questions that critically hold cognition, context, and culture together.

UNDERGRADUATE LATIN* QUEER STUDENTS' INTERSECTIONALITY OF MATHEMATICS EXPERIENCES: A BORDERLANDS PERSPECTIVE

Luis A. Leyva
Vanderbilt University
luis.a.leyva@vanderbilt.edu

The cisheteropatriarchal climate of STEM education shapes oppressive experiences for queer and trans (QT) students majoring in the sciences. Intersectionality of STEM experiences for QT students of color is missing in the literature. Thus, it has been unexplored how undergraduate STEM as a racialized space shapes variation in experiences among QT students. Such intersectional analyses are especially necessary in mathematics -- a discipline socially constructed as 'neutral' despite being a gatekeeper to STEM degrees for historically marginalized groups. To address this area of needed research, this paper presents findings from an analysis of undergraduate Latin* QT students' intersectionality of mathematics experiences as STEM majors with a focus on peer relationships. I conclude with implications for research and practice to disrupt mathematics education as white, cisheteropatriarchal space.*

Keywords: gender, intersectionality, Latin*, sexuality

Introduction

Ximena (they/them), a Mexican agender[1] pansexual person in their senior year of college studying mechanical engineering, considered dropping the major due to invisibility of their identity that made them question their ability. They saw mathematics education as valuable for increasing historically marginalized populations' access to engineering and other STEM careers.

> A lot of it [dropping engineering] had to do with imposter syndrome. And I think a big influence within that was lack of visibility. I really felt like I didn't fit in because everyone in my class is a male or white… When I was going to drop out, I was going to switch to math teaching… Even when I become an engineer, I want to help students understand math because I feel math can be a way to gatekeep these really good jobs… Math should be accessible, so that's why I was like, 'I'll just pursue that'… I want to inspire people of color and people in the Latinx community and queer folks to go into these STEM jobs… I want to stop it from being all just straight white men.

This perspective reflecting Ximena's use of their role as a mathematics educator to diversify scientific professions was shared during their individual interview as a participant in my research study about the experiences of queer and trans*[2] (QT) students of color in STEM majors. The narratives of undergraduate QT students of color in STEM like Ximena are central to the study's analysis to understand their experiences of intersectionality (Crenshaw, 1991), which refers to

[1] *Agender* is a gender identity of being genderless.

[2] *Queer* refers to all marginalized sexual and nonnormative gender identities. *Trans** describes individuals who depart from their assigned gender at birth and move across socially-constructed boundaries in normative views of gender, including those who do and do not pursue medical gender-affirming treatment as well as those who identify with binary and nonbinary genders (Nicolazzo, 2017). The term's asterisk, much like in computer searches, ensures broad inclusion of gender identities and expressions (e.g., transgender, transfeminine, trans man, transsexual). To avoid reinforcing trans* erasure, I use the phrase *queer and trans** and the corresponding acronym *QT*.

multiply-marginalized people's unique forms of oppression and agency at the juncture of racism and other overlapping systems of power. Ximena's quote conveys agency to use mathematics education in addressing the systemic issue of limited diversity in STEM, which transpired into a distinctly intersectional experience of invisibility as a Mexican queer engineering student.

Prior research has importantly shown how cisheteropatriarchy (i.e., a system of oppression that marginalizes QT people and cisgender women by reinforcing heterosexual and cisgender identities as normative and upholding misogyny) shapes undergraduate STEM as oppressive for QT students (Cech & Waidzunas, 2011; Miller et al., 2020). However, QT students of color were underrepresented in study samples, and the lack of intersectional analyses left implicit how racism figured into QT students' experiences of cisheteropatriarchy in STEM. The present analysis addresses these limitations in extant research by exploring variation in experiences of oppression and agency among undergraduate Latin*[3] queer STEM majors like Ximena. This analysis comes from a larger study that exclusively sampled Black, Latin*, and Asian QT students in STEM to examine variation in intersectionality specific to race, gender, and sexuality.

My analysis pays particular attention to the influence of mathematical contexts on Latin* QT students' experiences while pursuing STEM majors. As raised in Ximena's opening quote, mathematics has played a long-standing role in higher education as a gatekeeper to STEM degrees and careers for historically marginalized groups. For example, research has shown that Latin* students' racialized experiences in undergraduate mathematics have a major influence on perceptions of their academic ability and decisions to continue coursework required for STEM majors (e.g., Leyva, 2016; Oppland-Cordell, 2014). Epistemologies of neutrality and objectivity in mathematics, which are rooted in ideologies of antiBlack racism (e.g., colorblindness) and cisheteropatriarchy (e.g., gender neutrality), insidiously reinforce the discipline's oppressive nature through educational opportunities that frame social identities and experiences as irrelevant (Gutiérrez, 2017; Leyva, McNeill & Duran, 2022; Martin, 2009). Constructions of mathematics as 'neutral,' therefore, also marginalize QT learners who may internalize that their queerness is distracting or unwelcome due to pervasive silence about their identities (Kersey & Voigt, 2020; Yeh & Rubel, 2020), which may negatively impact their STEM persistence (Leyva, McNeill, Balmer, et al., 2022). Mathematics education must be interrogated to inform instructional and support practices that affirm historically marginalized identities in STEM. An intersectional lens of analysis allows for complex insights that are essential to developing such practices, which are less readily attainable when attending to only a single axis of social oppression. The present study advances such inquiry in undergraduate mathematics research where QT students' racialized experiences went unaddressed (e.g., Voigt, 2022) and intersectionality among Latin* students specific to QT learners was an unexplored area of study (e.g., Oppland-Cordell, 2014).

The PME-NA 44 conference theme, "Critical Dissonance and Resonant Harmony," addresses how experiences of dissonance are "necessary for change and liberation" in struggles for justice across educational and societal contexts. Harmonious justice is characterized as resonance in multiple stakeholders amplifying each other's voices in disrupting oppressive forces tied to racism and overlapping systems of power. Applying the PME-NA 44 theme as a lens to interpret Ximena's opening quote, the invisibility of Latin* and queer students in engineering and STEM more broadly shaped dissonance between their intersectional identity and mathematical contexts

[3] The asterisk in *Latin** considers fluidity in gender identities across the Latin American diaspora (Salinas, 2020). The term *Latin** responds to (mis)use of Latinx, a term reserved for gender nonconforming peoples of Latin American origin and descent (Salinas & Lozano, 2019).When describing student participants in the present analysis who did not identify as trans*, I use the phrase *Latin* queer*. Otherwise, I used the broader descriptor *Latin* QT*.

that produced feelings of imposter syndrome. Ximena's agency through their motivation to teach mathematics depicts an effort to seek justice by dismantling gatekeeping to STEM careers. Such effort fosters resonance for future generations of Latin* QT students between their identities and STEM pursuits. The following research questions for the present study are framed to examine dissonance and agency across Latin* QT students' intersectionality of mathematics experiences:

1. What oppressive contexts of mathematics education contribute to Latin* QT students' experiences of dissonance as STEM majors?
2. What agency do Latin* QT students exhibit to manage intersectional oppression from dissonant experiences in mathematics and protect their identities while pursuing STEM?

In what follows, I present the study's guiding theoretical perspective and methods to address the research questions. This paper presents findings specific to peer relationships in mathematics that shaped Latin* QT students' intersectionality of experiences. I conclude by discussing the study's scholarly significance and implications for educational research and practice.

Theoretical Perspective

The theory of *borderlands* (Anzaldúa, 1987/2007) from Chicana feminist thought served as the guiding theoretical perspective for the study. As a theory of the flesh (Moraga & Anzaldúa, 1981/2021), Gloria Anzaldúa drew on her lived experience to develop borderlands as a lens for theorizing intersectional oppression and agency. Borderlands theory captures how an individual at the juncture of multiple, contradictory systems of power (e.g., racism, misogyny, homophobia) can experience an oppressive sense of liminality and ambivalence that can also be a site for transformative resistance. Anzaldúa, a sixth-generation Chicana lesbian born in Texas near the U.S.-Mexico border, described this push-pull dynamic between racialized constructions of nation-state and cisheteropatriarchy at the juncture of these two power systems:

> As a mestiza, I have no country, my homeland cast me out; yet all countries are mine because I am every woman's sister or potential lover. (As a lesbian, I have no race, my own people disclaim me; but I am all races because there is the queer of me in all races). (p. 102)

This experience of liminality for Anzaldúa and other multiply-marginalized individuals is theorized to be existing at the borderlands, wherein la frontera (the border) is a "metaphor for all types of crossings – between geopolitical boundaries, sexual transgressions, and the crossings necessary to exist in multiple linguistic and cultural contexts" (Cantú & Hurtado, 2012, p. 6). Borderlands theory "seek[s] enlightenment of the ambiguity and contradiction of all social experience" (Cantú & Hurtado, 2012, p. 5) to generate complex insights into multiply-marginalized individuals' intersectionality of experiences.

There are three key constructs from borderlands theory that provided a foundation for the present study. First, *Nepantla* (liminality) refers to the space of being neither here nor there and the multiplicity of realities, as depicted in Anzaldúa's quote above, where new knowledge is produced. This space is characterized by la mezcla (the hybridity) at the borderlands of competing sources of power, which generates new understandings of the world that inform multiply-marginalized individuals' ability to engage in border-crossings. Second, *mestiza consciousness* refers to individuals' outsider-within knowledge at the borderlands. This critical awareness of not being fully accepted on either side of the border is an empowering source of knowledge for challenging oppressive dualities and coming into one's full, intersectional identity. Anzaldúa (1987/2007) argues that mestiza consciousness provides individuals with a sense of conocimiento (familiarity with) that allows for an interconnected understanding of others' experiences at the borderlands. This knowledge production is a foundation for building coalitions and advancing collective action against intersectional injustices. Finally, *la facultad* (ability) refers to individual agency in leveraging knowledge produced through a sense of liminality at the borderlands to engage in border-crossings and resist oppressive systems.

Borderlands is a foundational theoretical perspective in scholarship advancing justice for QT people of color (Brockenbrough, 2015; Ferguson, 2004; Kumashiro, 2001), including work specific to Latin* QT communities (Aguilar-Hernández & Cruz, 2020; Hames-García & Martínez, 2011; Hernández et al., 2021; Rodríguez, 2003). To illustrate, the concept of mestiza consciousness provided an orientation for the development of gay Latino male studies from a space of solidarity with Chicana and Latina lesbian scholarship (Hames-García & Martínez, 2011). Latin* trans and nonbinary scholars have extended borderlands theory by disrupting its binary conceptualization of gender and sexual oppression to make visible the intersectional realities of border-crossing among Latin* gender nonconforming people (Cuevas, 2018; Hernández et al., 2021). Thus, borderlands theory offers a promising foundation for the present study of Latin* QT students' intersectionality of mathematics experiences as STEM majors.

Methods

The analysis presented in this paper comes from a larger study exploring intersectionality of experiences among undergraduate queer and trans* (QT) students of color pursuing STEM majors. A total of 39 students who identify as Black, Latin*, and Asian, including mixed-race, are included in the sample. The larger study examines students' narratives of oppression and agency to elucidate features of STEM classroom instruction and co-curricular support spaces experienced as affirming or marginalizing of their intersectional identities. For the present paper, I focus on an analysis specific to Latin* QT participants' mathematics experiences.

Study Context and Participants

Participants in the larger study were recruited across four U.S. universities in 2019-2021. The study began in 2019 at Lorde University– a large, research-intensive, elite, and private historically white institution (HWI; see Leyva, McNeill, Balmer, et al., 2022). The research team expanded the study in 2020 to include three large, research-intensive, and public HWI contexts – Ferguson University, Moraga University, and Rivera University. The three public HWIs were purposefully selected for their strong records of success with enrolling and granting bachelor's degrees to Black and Latin* students according to recent higher education policy reports (Excelencia in Education, 2018; Harper & Simmons, 2019). Rivera University received the federal designation as a Hispanic-Serving Institution (HSI). In addition, Moraga University and Rivera University were selected as institutions recognized for their efforts in promoting positive campus life experiences for QT students (Campus Pride, 2020). Ferguson University was also selected for its institutional legacy of preparing undergraduate students from racially minoritized backgrounds to pursue STEM graduate degrees and professional careers.

The purposeful selection of university sites made space for variation in how different institutional contexts and student support offerings shaped intersectionality of STEM experiences among QT students of color. For example, the multi-institutional study design allowed our team to look across student experiences in private and public HWIs across different U.S. regions. Inclusion of the three public universities with strong records of racial equity, including Moraga University as a HSI and Ferguson University with its history of addressing racial inequities for STEM access, served to explore the extent to which culturally-affirming institutional missions and efforts provided intersectional support in STEM for queer of color identities. Our selection of Moraga University and Rivera University allowed us to consider how nationally-recognized support for minoritized gender and sexual identities impacted QT students of color in STEM.

For participant recruitment, the research team asked staff and student leaders for university offices and organizations to share information about the study with undergraduate networks. These offices and organizations had missions relevant to the scope of the study, including those of social affinity (e.g., queer student alliances), STEM (e.g., American Society of Civil Engineers chapters), and intersections of social affinity and STEM (e.g., Society for the Advancement of Chicanos/Hispanics and Native Americans chapters). See Leyva, McNeill, Balmer, et al. (2022) for details about recruitment across the four universities. The analytical sample for the present paper includes all 16 Latin* QT students from the study. This sample reflected variation in ethnoracial identity (e.g., Colombian, Mexican, Puerto Rican), queer sexual identity (e.g., bisexual, gay, pansexual) and STEM major (e.g., computer science, mathematics, mechanical engineering). Six Latin* participants held gender-expansive identities, such as agender, female/questioning, genderfluid, nonbinary, and transmasculine. Four students attended Lorde University, three attended Ferguson, four attended Moraga, and five attended Rivera.

Data Collection

The research team used five data sources for rich, multidimensional portraitures of Latin* QT students' intersectionality of STEM experiences. First, participants completed a demographic survey to collect information about their identities (race, gender, and sexuality), year of study, STEM major, course enrollment, and campus involvement. For participants recruited in 2020-2021 during the COVID-19 pandemic and the transition to remote learning in higher education, the survey asked participants to indicate any preferred accommodations of the study design to ensure comfort with their participation (e.g., addressing privacy concerns about discussing their gender and sexuality via Zoom from home). Second, each participant submitted a STEM autobiography. The autobiographies were written reflections about being QT students of color in STEM, including responses to prompts about memorably positive and negative experiences, socially-affirming academic and co-curricular spaces, and influential people. One autobiography prompt asked participants to reflect on the role that mathematics played in their STEM trajectories as QT students of color and vivid memories from their experiences. The third data source was event journaling (Leyva, Quea, et al., 2021; Leyva, McNeill, Balmer, et al., 2022). Throughout the study, participants kept an ongoing record of events across STEM spaces (e.g., classrooms, study groups) experienced as supportive/encouraging or unsupportive/discouraging of their identities (see Leyva, McNeill, Balmer, et al., 2022 for more details about journaling).

The two final data sources were an individual interview (60-90 minutes) and group interview (90-120 minutes). Participants completed the survey and autobiography prior to the individual interview (Interview 1). Interviews with Lorde University participants were completed in person and before the start of the COVID-19 pandemic. Interviews with participants enrolled in other universities were scheduled after the start of the pandemic in 2021 and completed on Zoom. All interviews were semi-structured, audiotaped, and transcribed. Two research team members conducted each interview. To the extent possible, we matched participants and interviewers with similar racial, gender, and sexual identities. Such matching was an effort to increase comfort in discussions about racism, misogyny, cissexism, and heteronormativity in STEM.

Interview 1 explored participants' perspectives on being QT students of color in and out of STEM, major influences on their STEM pursuits, coping strategies for STEM persistence, and recommendations for queer of color inclusion in STEM. The protocol revisited excerpts from participants' STEM autobiographies and event journaling related to these themes. For participants interviewed during the pandemic, we also explored participants' views on the influence of COVID-19 on their STEM experiences. In particular, participants were asked about standout moments in online/hybrid classrooms that positively or negatively impacted their identities, nature of their campus involvement, and relationships with peers and family members.

After Interview 1, participants completed a group interview (Interview 2). I adopted my group interview methodology of presenting 3-4 prompts for stimulated-responses to explore variation in participants' intersectionality of STEM experiences (see Leyva, 2021 and Leyva, McNeill, Balmer, et al., 2022 for more details about the interview methodology). The prompts in Interview 2 featured excerpts from research about QT students' STEM experiences (e.g., Cech & Waidzunas, 2011; Kersey & Voigt, 2020) and intersectionality of campus experiences among QT students of color (e.g., Nicolazzo, 2016; Vega, 2016). The excerpts provided concrete starting points to stimulate group dialogue about emergent themes from preliminary data analysis, including cisheteronormativity in STEM instruction and perceptions of STEM ability linked to race and gender. To explore variation in opportunities for intersectional support across different universities in our study, one prompt included excerpts that featured reflections from QT students of color in prior research about their experiences of campus climate and identity-related support offerings at their institutions. We followed the presentation of these excerpts with statements about the advancement of diversity and equity at participants' home institutions. These statements were used to probe the extent to which participants perceived opportunities for identity support in their broader campus contexts influencing their STEM pursuits. After participants were presented with each interview prompt, we asked them about their general interpretations, degree of perceived relevance to their experiences, and recommendations for increasing queer of color inclusion in relevant practices of STEM education.

To the best of our ability, each participant who completed Interview 2 was paired with at least one other participant of a similar race-gender identity. Such identity-matching across the group interviews was an attempt to avoid participants feeling their perspectives were tokenized and create space for variation in responses to interview prompts among students with a similar intersectional identity. When we conducted Interview 2 via Zoom with participants after the onset of the COVID-19 pandemic, we also tried to have representation of participants enrolled in different universities for each interview to allow for discussion of similarities and differences in their STEM experiences across institutional contexts. We completed three group interviews with Latin* QT participants who attended different universities but shared a similar race-gender identity (namely, Latina cisgender women, mixed-race Hispanic and Latina cisgender women, and Latine gender-expansive people). For example, the group interview for mixed-race Hispanic and Latina participants included Erica (mixed, cisgender, bisexual Latina of Brazilian descent[4] in Rivera University), Laura (Mexican and Chinese pansexual female at Ferguson University) and Tamara (mixed-race Hispanic, Peruvian/white masculine woman lesbian at Moraga University).

Data Analysis

The research team used the framework of *STEM Education as a White, Cisheteropatriarchal Space* (WCHPS, Figure 1; Leyva, 2021; Leyva, McNeill, Balmer, et al., 2022) to guide data analysis. The WCHPS framework provides a lens for examining how interplay between racism and cisheteropatriarchy in STEM educational contexts shapes intersectional experiences of oppression and agency for multiply-marginalized individuals, including QT students of color.

[4] I use wording from participants in describing their identities.

Each framework dimension (ideological, institutional, and relational) attends to a level of influence in STEM education at which white cisheteropatriarchy (the juncture of white supremacy and cisheteropatriarchy) impacts multiply-marginalized individuals' experiences. The ideological dimension addresses beliefs, norms, and values that organize STEM educational practices. The institutional dimension explores structural inequities that constrain opportunities for achievement and participation in STEM, in addition to forms of individual agency in navigating such oppressive structures. The relational dimension addresses interactional forms of oppression and agency in STEM education. These dimensions are interconnected, thus allowing the WCHPS framework to examine how white cisheteropatriarchy shapes intersectionality of STEM experiences in complex ways. Elsewhere (Leyva, McNeill, Balmer, et al., 2022), I provide more details about developing the WCHPS framework.

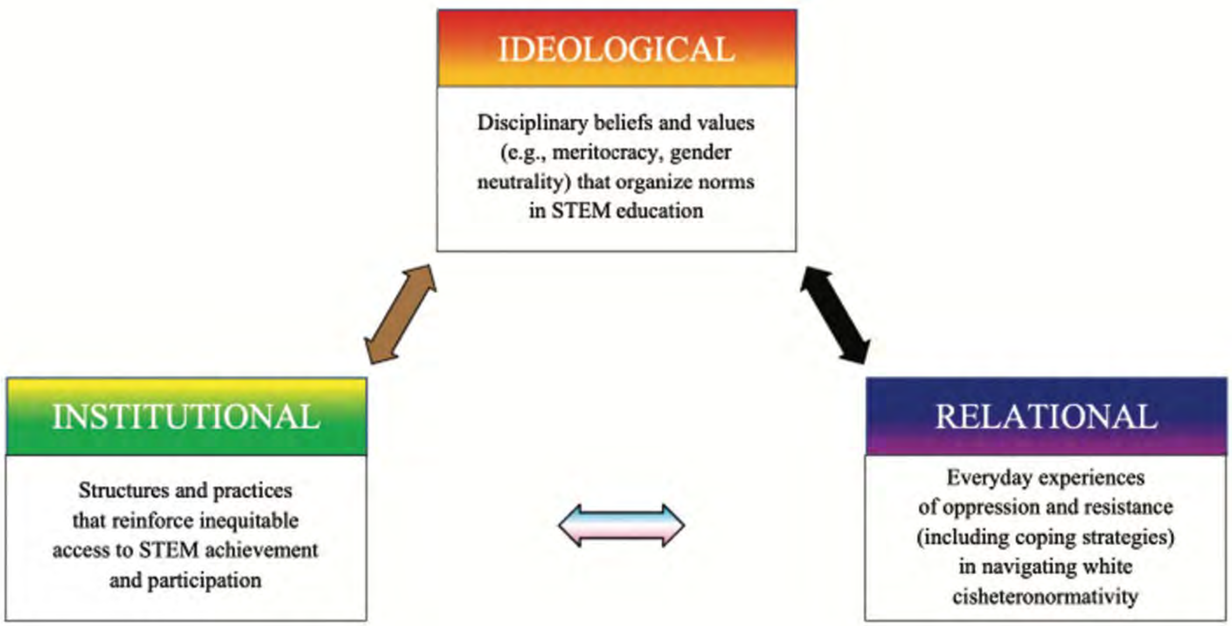

Figure 1: Framework of STEM Education as a White, Cisheteropatriarchal Space

Data analysis was completed in four stages. First, the research team inductively coded participants' data to flag aspects of their mathematics experiences corresponding to each WCHPS dimension. We coded for instances of oppression, supportive forms of structural disruption, and agency across ideological, institutional, and relational levels of Latin* QT students' experiences. (See Leyva, Balmer, et al., 2021 and Leyva, McNeill, Balmer, et al., 2022 for more details about coding.) The second stage of analysis was constructing an analytical narrative for each participant of navigating white cisheteropatriarchy in mathematical spaces as Latin* QT students majoring in STEM. These narratives were developed by following the critical race methodology of counter-storytelling (Solórzano & Yosso, 2022), which centers racially minoritized people's experiences of oppression for theorizing resistance to racism and other interlocking systems of power. Each participant's counter-story was structured around oppression, structural disruptions, and agency across WCHPS dimensions identified in coding.

The third stage of analysis was identifying themes across the 16 Latin* QT participants' counter-stories that address our two research questions. To address the first research question, we identified themes about oppression through experiences of dissonance between participants' identities and mathematical contexts. We addressed the second research question by identifying themes of agency specific to participants' behaviors and motivations for navigating dissonance to protect their Latin* QT identities and success as STEM majors. The fourth and final stage of data analysis was interpreting the themes through the lens of borderlands theory (Anzaldúa, 1987/2007) and its uptake in Latin* queer studies with an expansive theorizing of gender (e.g., Cuevas, 2018). In particular, the borderlands concept of Nepantla served to elucidate how dissonance in Latin* QT participants' mathematics experiences reflected liminality at the juncture of power systems that limited full affirmation of their intersectional identities. Mestiza consciousness supplied a lens to account for participants' critical awareness of how white cisheteropatriarchy operated in mathematical contexts, including how it was reinforced through dissonant educational practices. The construct of la facultad elucidated Latin* QT students' agency to manage dissonance in mathematics as a white, cisheteropatriarchal space. Overall, our analysis captured how white cisheteropatriarchy in STEM educational contexts shaped the borderlands of Latin* QT students' intersectionality of mathematics experiences.

To sharpen our data analysis, the research team conducted member-check interviews with available participants after data collection was complete. Eleven of the 16 Latin* QT students in the study sample completed a member check. We structured member-check interviews in three parts corresponding to each of the framework dimensions. During each interview part, the interviewers read a section from the participant's counter-story to convey our understanding of oppression, disruptions, and agency at each level of the WCHPS framework. Participants, who were positioned as experts of their lived experiences during the interviews, were prompted to suggest edits and add content to ensure an accurate analysis in their counter-stories. The interviewers also asked participants a series of questions to clarify and further elaborate on important ideas raised in each counter-story section read to them.

Positionality

Our research team (one faculty member, three doctoral students, eight master's students, and two undergraduate students) are members of the Power, Resistance and Identity in STEM Education (PRISM) Lab at Vanderbilt University. The team has robust social diversity across intersections of race (African American, Black, Latin*, biracial, white), gender (cisgender, nonbinary, transmasculine), and sexuality (demipansexual, gay, lesbian, pansexual, queer, heterosexual, unsure). Most of the team collected and analyzed data from Latin* QT participants. Milner's (2017) framework on positionality in educational research guided the team's self-reflections to avoid dangers of approaching our study without consciousness for the influence of our identities and experiences. These reflections avoided the seen danger of not interrogating our respective areas of privilege and oppression. The team adopted an asset-based research approach by making space for understanding Latin* QT participants' agency and resistance in mathematical contexts, thus avoiding the unforeseen danger of readers perceiving QT students of color as powerless victims of oppressive educational systems. To mitigate the unseen danger of misinterpreting participants' sensemaking about intersectionality of their experiences, we completed interviews and coding in pairs to have multiple researcher perspectives present in data collection and analysis procedures. We also completed member checks described earlier to strengthen the trustworthiness of our findings. Team members bracketed their lived experiences from those of participants to avoid the unseen danger of distorting participants' realities, all while remaining critical of oppressive STEM structures and systems through use of the counter-storytelling methodology. I avoided the unseen danger of flattening variation in oppression and agency that Latin* QT students experienced by infusing voices from multiple participants in the findings, including a cross-case analysis of counter-stories for two participants with different ethnoracial, gender, and sexual identities. Although this is a solo-authored piece, I solicited feedback from team members who analyzed Latin* QT participants' data to ensure the final draft of our analysis accurately reflects our collective work.

Findings

Themes across the 16 Latin* QT participants' counter-stories reflected how two mathematical contexts shaped experiences of dissonance and agency: (i) curricula and instruction and (ii) peer relationships. To respect space limitations, I present themes about peer relationships in this paper. I develop themes for curricula and instruction elsewhere (Leyva, 2022, 2023).

Half of the participants (Daniela, Erica, Koyotl, Laura, Ros, Steven, Teresa, Ximena) reflected on how peer relationships produced dissonance with their Latin QT identities across mathematical contexts. One theme was the lack of social diversity in STEM majors and mathematics classrooms, which brought forth feelings of isolation and imposter syndrome as well as struggles to build identity-affirming networks of support. Koyotl (he/him; Indigenous American, gay, transmasculine person of Mexican descent; third-year computer science major in Rivera University), for example, shared how the main impact of mathematics on his experience as a computer science major was making him feel "lonely as a LGBTQ+ student in STEM" (Autobiography). Being in mathematics classrooms, where he was the only queer student to his knowledge and often felt "alone in a room full of white students" (Autobiography), brought him to feel academically inferior to students from majority groups. Similarly, Erica (she/her; mixed, cisgender bisexual Latina of Brazilian descent; third-year computer science major in Rivera University) managed a sense of imposter syndrome due to a lack of peer diversity, which was not the case at the community college from where she transferred and "actively [saw] older students or more students of color" (Interview 1). She reflected on building a strong connection at the community college with an older student who identifies as a lesbian in her pre-calculus course, "We were able to connect over the fact that she was also around my age and came from an arts [background]… That was a really great way of [feeling like] 'Okay, well, clearly I'm not the only older student or I'm not the only queer one'" (Interview 1). Opportunities to build diverse networks of peer support in STEM were limited, which shaped dissonance in Erica's experience.

The second theme specific to peer relationships was marginalization through interactions during collaborations with peers in mathematical contexts, including microaggressions of ability as well as instances of cisgender women being fetishized or hypersexualized. To develop this theme, we look across counter-stories from two Latin* queer STEM participants (Ros and Daniela). The counter-stories are structured in three parts. I open each counter-story with a short biographical sketch of Ros and Daniela. To address the study's first research question about experiences of dissonance, the second part of each counter-story depicts peer relationships that limited affirmation and support for Latin* queer participants' identities as mathematics learners. The final part of each counter-story answers the second research question about agency. In this portion of the counter-stories, I account for participants' behaviors and motivations for managing and resisting dissonance through peer relationships to protect their identities and STEM success. I conclude the findings section by applying borderlands theory and the WCHPS framework in a cross-case analysis of Ros's and Daniela's counter-stories.

Ros's Counter-Story

Ros (they/she/he) is a Mexican, bisexual, and genderfluid person majoring in mechanical engineering as a senior in Rivera University. They saw themself as being female-presenting and recognized their privilege of passing as white. Family played a central role in Ros's motivation to succeed as a future engineer. They perceived their academic accomplishments as giving back to their parents for their sacrifices, including how their mother was unable to use her computer engineering degree from Mexico after immigrating to the U.S. Success in mathematics allowed Ros to serve as a role model for younger cousins aspiring to become engineers, "The only introduction my cousins and I had to it [calculus] was through media, and now it's nice to be one of the family members they can come to for help" (Autobiography). Ros felt a strong sense of acceptance as a queer person from his family, which he described as different from "traditional Latino ones" (Interview 1) where homophobia and transphobia rooted in religious beliefs resulted in some of her Latin* friends being disowned or having their queerness disregarded.

In addition to family, peer relationships that affirmed Ros's full identity as a Mexican queer engineering student were important for Ros's persistence in navigating the cisheteropatriarchal culture of STEM. His most positive STEM educational experience was having a peer network of support in high school engineering classes, which he described as "all Latinx and a few were LGBTQ+ as well so [he] always felt like [they] were all on the same plane" (Autobiography). Establishing such peer connections was more difficult as an engineering major with students largely coming from white, wealthy backgrounds and where the space felt "very cishet male-dominated… [and] very masculine" (Interview 1). As further developed in the remainder of Ros's counter-story, the exclusionary space of undergraduate STEM contributed to Ros's sense of vulnerability when meeting and working with unfamiliar peers in different contexts (e.g., study groups, engineering organization meetings). The constant threat of facing homophobic and transphobic microaggressions about their academic ability and queer identity in peer interactions shaped dissonance for Ros in mathematical spaces. To navigate such dissonance as a Latin* queer student, Ros carefully studied unfamiliar STEM peers' interactions to assess if they would be accepting of their queerness before sharing their pronouns and discussing their identities.

Dissonant influences. Dissonance in Ros's mathematics experience as a mechanical engineering major arose from navigating cisheteronormativity in peer interactions. Ros described how their queerness was often overlooked or stigmatized and how they felt underestimated in terms of their academic ability. Ros described facing peers' microaggressions about her mathematical ability couched in humor, "I have heard some jokes along the lines of people finding it interesting that I am skilled in math when 'Queer people are bad at math' is apparently a stereotype" (Autobiography). He expressed uncertainty if such peer humor was coming from a space of homophobia and transphobia or whether it served as a coping mechanism for fellow queer students in STEM, "If you're saying that weird gay joke, does that mean that you're going to be against my identity? Or is it one of those things where… you're also queer and you're just joking about it to cope?" (Interview 1). The ambiguity of humor that invoked microaggressions of mathematical ability produced dissonance in Ros's experience as a queer engineer.

Queer oppression in peer humor was one aspect of a broader culture of cisheteronormativity that Ros experienced in mathematical and scientific spaces. This oppressive culture made Ros feel vulnerable to facing homophobia and transphobia when joining new STEM study groups with unfamiliar peers. To illustrate, Ros recounted their most negative experience as a Latin* queer student in STEM as being when they were misgendered and assumed to be straight during a small study group session for an introductory calculus or physics course.

> I went out of my comfort zone to sit at a group with people I didn't know… all of which seemed like cis men minus one woman. As we were getting along, the woman turned to me and said something along the lines of 'It's nice to see another regular girl at these things, it's

> always all guys or the girls who come are lesbians.' It was really jarring to me because I neither identify as a woman nor am I straight so as she said this to me I had to sit with the knowledge that my identity was something she was bothered by. And because I wasn't familiar with this group, I just chuckled awkwardly and switched the topic. (Autobiography)

The groupmate's assumption that Ros was a cisgender, heterosexual woman suggests a feeling of relief from patriarchal, male-dominated STEM spaces. At the same time, this assumption points to the cisheteronormative culture of STEM that erases queer people as well as produces undue labor for queer students like Ros about disclosing or concealing their gender and sexuality. Building peer networks in STEM was a taxing endeavor for Ros in terms of constantly preparing themself for students "making assumptions based on what you look like… [and] mak[ing] comments that are probably going to be hurtful and homophobic and transphobic" (Interview 1).

The dissonance that Ros experienced as a queer person navigating cisheteronormativity in STEM peer relationships also took form in campus meetings for identity-based engineering organizations and programs. Although Ros felt a reprieve from the hypermasculinity of their major in events for women in engineering, the focus on cisgender women produced tensions about sharing their genderfluid identity and made them feel like an imposter, "When I do go to events that are specifically for women, I'm kind of like, 'Do I say that I don't identify as a woman? Does that make me not belong in this space even though I appear female?'" (Interview 1). Ros also felt conflict with her queer identity in the university's chapter for the Society of Hispanic Professional Engineers (SHPE). He described how SHPE's strong focus on racial affinity, in addition to traditional, culturally-mediated views on gender and sexuality among student members, made expression of his queer identity inaccessible in this Latin* affinity space.

> With SHPE, I didn't so much expand on my gender and sexual identity because… everybody in those spaces bonds over the fact that they identify as Hispanic or Latino, so it's not as prioritized. They are a little bit better about having pronouns available and all of that at some of their meetings, but most of them, it's just traditional. And there's also this stigma... with people who are more traditionally Hispanic… especially first-generation immigrants aren't always onboard and as progressive when it comes to gender and sexuality. (Interview 1)

SHPE, as a single-identity affinity space that left cisheteronormative beliefs of gender and sexuality in Latin* culture uninterrogated, limited opportunities for Ros to find community with Latin* peers that embraced her full identity. With Ros having received the "biggest backlash… from people with Latino backgrounds against [his] sexuality" (Interview 1), including family members in Mexico, he chose not to engage his queerness with SHPE peers. Dissonance between Ros's Latin* queer identity and STEM peer groups, including study groups and spaces for identity affinity in engineering, limited peer support that affirmed their intersectional identity.

Agency. One strategy that Ros adopted to navigate cisheteronormativity in peer relationships when working in study groups was not disclosing their queerness right away to protect themself from homophobia and transphobia, "If I do go into these spaces, I'm not really like, 'Hey, these are my pronouns. Please respect them. Please respect me.' I'll let you assume whatever you want to assume" (Interview 1). Ros described entering new spaces of STEM peer collaboration as "learning how to read the room and learning… what's going to be acceptable and what's not going to be acceptable" (Interview 1) in terms of identity expression. Although Ros also experienced transphobia during groupwork in high school, the presence of Latin* QT peers in her engineering classes who "reaffirmed what [she] was feeling and helped [her] work through that whole gender identity thing" (Interview 1) mitigated oppression in collaborations. With the challenge of building diverse networks of peers who would provide similar forms of support in the engineering major, Ros readily concealed his queerness, much like he did when misgendered in the study group, to cope with the dissonance experienced in STEM peer relationships.

Another behavioral strategy that reflected Ros's agency in managing dissonance as a Latin* queer engineering student was entering new spaces with unfamiliar individuals alongside peers with whom they feel comfort and trust. Ros reflected on the significance of such peer connections as a STEM major, "Making connections has been the biggest thing in finding support with people that you feel comfortable with. It is one of the most essential things I've found to try to get through college with my identities" (Interview 1). To illustrate, Ros developed a close relationship with a queer classmate and SHPE leader whose openness about her identity increased her comfort with attending SHPE meetings. This strategy of "mak[ing] a connection first with the person before going into a space" (Interview 1) depicts Ros's agency in protecting himself from cisheteronormativity at intersections of STEM and Latin* cultures to overcome dissonance that limited access to peer support networks across mathematical spaces.

Daniela's Counter-Story

Daniela (she/her) is a bisexual, mixed-race Latina (Colombian/Cuban and white) in her third-year as a computer science major at Lorde University. Being a mixed-race queer woman meant that "the thing that impacts a lot of [her] experiences is a lack of identity" (Interview 1), especially as someone who sees herself as "be[ing] a part of two cultures and then a part of neither culture at the same time" (Interview 1). This sense of liminality in Daniela's experience made it initially difficult for her to find community on campus as a STEM student. At the same time, Daniela faced peers' racialized and gendered assumptions that her accomplishments were not based on merit but rather affirmative action. This "recipe for imposter syndrome" (Journal) as a mixed-race Latina in STEM made her feel constantly devalued and defeated.

In managing identity-specific challenges and academic struggle in computer science as a difficult major, Daniela built a supportive community of diverse, like-minded peers in and beyond the engineering school. She reflected on how such community supported her STEM persistence as a mixed-race queer Latina, "If there are people that are like you, you can ask them for help and form a community… If I didn't have an engineering community, I don't know what I would do. I'd probably fail" (Interview 1). She identified three sources of peer community: (i) the university's SHPE chapter; (ii) a professional engineering fraternity; and (iii) a group of women of color who met at a conference for gender equity in technology. Representation of queer people and opportunities to exchange stories of identity-based struggles created space for Daniela to comfortably engage her bisexuality in these STEM collectives, which contrasted her STEM classroom experiences where "you leave yourself at the door" (Interview 1). SHPE was also a space where she could be open about the "feeling of not fully being able to own up to [being] Latinx" (Interview 1) and could learn more about Latin* culture, which she felt was taken from her as a child raised to believe that being white was more socially acceptable. The collective of women of color in technology fields, which included another queer student, was a space for openly sharing and processing personal histories of misogyny in STEM. Daniela described how this community of healing and empowerment in STEM conveyed how "from the struggle you can form really good bonds with people" (Interview 1), which they sustained through regular check-ins and sharing professional development resources.

I now highlight how peer relationships in mathematical contexts (namely, fetishizing and sexualizing behaviors from male peers) contributed to Daniela's experiences of dissonance as a mixed-race bisexual Latina in STEM, which exemplifies the gendered struggles she processed in the women of color collective. Next, I address Daniela's agency in coping with such dissonance.

Dissonant influences. Daniela reflected on how the overrepresentation of white male students in her mathematics classes made her hyperconscious of being fetishized and hypersexualized when interacting with them. Such hypersexualization felt racialized to Daniela as a mixed-race Latina, "In terms of my sexuality… I've had to be very conscious of people fetishizing. So, it's very common for guys to be, 'Oh, I think Latinas are really hot, and I want their mom to make me tacos,' which I find super offensive and creepy" (Interview 1). Daniela described the risk of being hypersexualized when seeking male peers' support with mathematics, "I typically have to [ask] a man, who always makes a sexual advance on me… These advances make it really hard to focus and feel comfortable in math classes. This is especially annoying because math classes are incredibly difficult" (Autobiography). The discomfort Daniela felt from being hypersexualized added to the challenge of understanding content in mathematics courses.

As a computer science major, Daniela was often one of the only women in collaborative groups, which made her feel vulnerable to being hypersexualized, "If I'm working on an assignment with a group of people, that group of people is going to be predominantly male, and they're all going to be making advances, typically. And that's something that's pretty obnoxious" (Interview 1). To depict how "mathematics has always been an awkward experience" (Autobiography) navigating male peers' fetishization and hypersexualization, she recalled being the only woman in a study group where one male placed his foot on hers to keep her from moving away, another invited her to study in his room, and another asked for her phone number. Male peers' behaviors capture how Daniela was perceived as a sexual object before she was seen as a mathematics classmate. Despite this discomfort, she reflected on the "pressure to not turn guys down" (Interview 1) in her study groups and classes because rejecting their sexual advances jeopardized access to peer support in mathematics. In the following section addressing Daniela's agency, I highlight how she strategically used her bisexuality to keep male peers interested in helping her with mathematics despite their oppressive advances. The white, heterosexual male gaze in mathematics, thus, shaped Daniela's experience of dissonance as a bisexual Latina navigating racialized fetishization and hypersexualization in peer relationships.

Agency. Agency in Daniela's experience to protect her academic success in the masculinized spaces of mathematics courses is reflected in strategic expressions of her sexual identity. She shared how although claiming to be a lesbian could stop male peers from hypersexualizing her, presenting as bisexual ensured that they would remain interested in her and continue to help her.

> Maybe it would be easier if I just told them that I was a hundred percent lesbian, not interested in them, and they wouldn't make advances at all. But then I also consider, maybe then they wouldn't help me study, you know? And then they wouldn't be interested in assisting me anymore, or interacting with me anymore. (Interview 1)

Daniela used her bisexuality strategically by playing into male classmates' fetishization and hypersexualization as a way of maintaining access to peer support in mathematics. Such agency, while protective of Daniela's academic success, reinforced dissonance in her STEM experience.

Another way that Daniela exhibited agency in managing unwanted sexual attention was toning down feminine self-expression through dress, particularly in STEM classrooms where she was underrepresented as a femme Latina. Daniela described preferring to wear crop tops and artsy, quirky clothing that departed from what she described as the "engineering uniform" (Interview 1), a hoodie and T-shirt. However, she worried that her preferred dress would make her hypersexualized and subjected to negative judgment from STEM peers and faculty as "some dumb girl that is dressed inappropriately for class" (Interview 1) who put more attention into her appearance than academics. As a result, Daniela saw sacrificing her femininity through dress as protecting her not only from being hypersexualized, but also having her intellect undermined.

> One thing I leave of myself behind is… I don't wear the clothes I wanted to wear to school a lot because… I don't want other students to think I look dumb… If you look like you took care of yourself [as an engineering student], people say you're not smart… I also don't want to be wearing anything that could possibly be sexualized by people. (Interview 1)

Making intentional choices of dress was a strategy that Daniela adopted to protect herself from the dissonance between her intersectional identity and masculinized environments of STEM classrooms. By "going for as asexual as possible in classes" (Interview 1), Daniela's dress captured a self-preserving form of agency in response to how femininity was disassociated from STEM ability as well as male peers' racialized hypersexualization in mathematical contexts. Although Daniela's selectivity in dress alleviated dissonance rooted in the white, heterosexual male gaze in classrooms, she had to sacrifice aspects of her identity for such self-preservation.

Cross-Case Analysis

Looking across Ros's and Daniela's counter-stories through the lens of borderlands, their experiences of dissonance in peer relationships demonstrate Nepantla through a sense of liminality about bringing their full Latin* queer identities into mathematical contexts, especially collaborative settings like study groups. Ros's and Daniela's experiences at the juncture of racism and cisheteropatriarchy (e.g., navigating culturally-mediated tensions of disclosing queerness in SHPE, managing racialized fetishization from male peers) made them feel a sense of being "neither here nor there." The counter-stories also depict mestiza consciousness through critical awareness of the white, cisheteropatriarchal gaze in peer interactions that shaped dissonance across the intersectionality of their experiences. This awareness also informed agency or la facultad in using their motivations and strategic forms of self-expression to protect their Latin* queer identities and ensure academic success. In what follows, I develop two conclusions from a cross-case analysis of Ros's and Daniela's counter-stories through the lens of borderlands and the WCHPS framework. These conclusions address how Latin* queer students' experiences of dissonance and agency exemplify navigating the borderlands of mathematics education as a white, cisheteropatriarchal space across ideological, institutional, and relational levels.

First, the counter-stories show how dominant constructions of mathematics and STEM as neutral can leave racialized, cisheteropatriarchal climates of educational contexts unchallenged. Daniela's perception of STEM classrooms as disconnected from identities and social experiences, for instance, left her grappling with the liminality of being a mixed-race queer Latina struggling to find socially-affirming community as a computer science major. She ultimately found relational support in STEM co-curricular contexts, including SHPE and a conference for gender equity in technology fields, that made space to process her experiences of Nepantla and coming into her intersectional identity. These spaces, thus, disrupted ideological notions of STEM as neutral to offer Daniela opportunities to heal from the dissonance of being a mixed-race queer Latina in computer science. Unfortunately, such ideological disruptions were absent in formal institutional contexts, including peer collaboration in mathematics courses, that subjected Daniela to being fetishized and hypersexualized as a queer woman of color working with predominantly white, heterosexual male peers. Daniela's awareness of the white, cisheteropatriarchal gaze across classrooms and groupwork in mathematics illustrates mestiza consciousness that guided her agency (la facultad) through strategic self-expression in dress and disclosure of her queer sexuality. Ros's counter-story similarly depicts such awareness of facing intersectional marginalization as a Mexican genderfluid, bisexual person in STEM peer interactions where homophobic and transphobic perspectives went unchecked (e.g., jokes about queer people lacking mathematics ability, having their queer identity overlooked in SHPE meetings). Both counter-stories capture how ideological assumptions of neutrality in mathematical spaces can perpetuate Latin* queer oppression in exclusionary climates of peer relationships linked to a lack of social diversity (institutional influence) and toxic interactions involving microaggressions of ability and sexual harassment (relational influences). Therefore, being at the borderlands for Daniela and Ros as Latin* queer STEM majors meant managing oppressive peer relationships reinforced through assumptions of mathematics as a neutral space.

Second, both Latin* queer students' counter-stories portray the undue cognitive labor placed upon them to adopt strategies for protecting their identities and success across oppressive contexts of peer relationships in mathematics. To illustrate, Ros's keen awareness of how homophobic and transphobic ideologies influenced peer interactions, such as their most negative STEM experience of being misgendered and assumed to be straight in a study group, taxed them with the burden of concealing their queerness until peers said or did something that signaled being accepting of their genderfluid and bisexual identities. Ros exhibited similar awareness of the cisheteropatriarchal culture in the SHPE organization that informed her decision to attend meetings when accompanied by a peer with whom she can confide her queer identity. Critical awareness of study groups and SHPE meetings as potentially oppressive spaces depicts Ros's mestiza consciousness that led to investing cognitive energy in determining how to present himself with unfamiliar peers and ensuring the presence of queer-affirming peers for his safety. While these behavioral strategies depict agency or la facultad from Ros in managing queer marginalization through peer relationships, such self-protection came at a cost with Ros only being able to embrace certain aspects of their identity as a Latin* queer student in STEM. Daniela faced a similar reality in terms of sacrificing her gender expression through feminine dress to protect herself from hypersexualization in mathematics classrooms. Furthermore, Ros's counter-story conveys how institutional spaces of identity support for STEM majors often failed to account for experiences of queerness and intersectionality. The cisnormative framing of gender support in programs for women in engineering left Ros with a sense of liminality as a genderfluid person who presents as female and the labor of concealing their queerness to avoid being deemed as not belonging. She described how tensions of being a queer SHPE participant were due to traditional views of gender and sexuality in Latin* culture that also shaped dismissal of her sexuality from family, specifically cousins living in Mexico who were also sources of motivation for excelling in mathematics. Ros's liminality in SHPE and programs for women engineers captures his experiences of Nepantla in terms of being "neither here nor there" as a beneficiary of institutional support. The affirmation that Ros felt for their full identity from immediate family and in high school engineering with Latin* queer peers was missing. Ros, thus, was taxed with the same cognitive labor of protecting their queerness in peer collaborations for mathematics coursework even in institutional spaces like SHPE designed to resist oppression in formal STEM contexts. The labor imposed on Ros and Daniela to cope with intersectional oppression across peer relationships in groupwork and co-curricular programs reflects realities at the borderlands with needed disruptions of white cisheteropatriarchy in mathematical contexts.

Discussion

The present study's scholarly significance is twofold. First, the focus on Latin* queer students contributes insights about intersectionality that went unexamined in research about Latin* students and QT students in undergraduate STEM (e.g., Convertino et al., 2022; Hughes, 2017 McGee, 2016). Findings uncovered intersectional forms of dissonance that Ros and Daniela managed between their Latin* queer identities and peer relationships in mathematical spaces. For example, Daniela's counter-story depicts her strategic ways of sharing her queer sexuality and expressing her gender through dress to navigate the white, cisheteropatriarchal gaze in mathematics courses, which subjected her to unwanted sexual attention from male peers who were also sources of academic support. Second, representation of Latin* gender nonconforming students in the study extends understandings of gender equity in mathematics education. Over the years, equity-oriented research in mathematics education has framed gender as a binary and disconnected from other dimensions of social experience, including race and sexuality (Leyva, 2017; Leyva & Mahtab, in press). By centering intersectionality of mathematics experiences for Latin* students with queer gender identities, this study disrupts the long-standing erasure of trans* and nonbinary students of color in mathematics education for more complex insights on how racialized forms of trans* oppression impact gender equity. To illustrate, Ros's counter-story conveys struggle in finding peer support across study groups and pre-professional engineering societies that affirmed their genderfluid identity. Along with feeling like an imposter in programs for women in engineering that mainly catered to cisgender women, Ros felt tensions about participating in SHPE where cisheteronormative ideologies of gender and sexuality in Latin* culture influenced their perceptions of peers' acceptance of their queer identity.

Findings from the present study raise implications for research to generate more nuanced insights into Latin* QT students' intersectionality of mathematics experiences. One implication is exploring how differences in ethnoracial backgrounds, immigration history, and ability to pass as white, cisgender, and/or heterosexual shape variation in intersectional oppression and agency. Although Ros and Daniela both identified as members of the Latin* community, their racialized experiences differed. Social norms of gender and sexuality in Mexico shaped Ros's concerns about facing homophobia and transphobia from cousins living there, which can be likened to the vulnerability he felt about engaging his queerness with Latin* engineering peers. Daniela's upbringing in a mixed-race household with Colombian-Cuban and white parents, who she felt distanced her from Latin* culture, produced conflict in identifying as Latina. Peer relationships in SHPE helped her come into her intersectional identity and overcome struggles in finding community as a mixed-race, queer woman in STEM. Future research that continues unpacking within-group differences in participants' racial backgrounds, including mixed-race experiences, disrupts monolithic representations of Latin* QT students in mathematics and contributes robust understandings of intersectionality for this population. A second implication for research is further exploring variation in Latin* QT students' intersectionality of mathematics and STEM experiences across different types of higher education institutions, including HSIs. Although Ros attended a HSI with a mission for providing culturally-affirming opportunities to Latin* students, the cisheteropatriarchal culture of STEM environments, even in spaces of racial affinity like SHPE, limited their access to networks of peer support like they had in high school engineering, This finding illustrates the importance of future research that continues to explore how structures and practices at HSIs and other institutions with missions for serving minoritized populations (e.g., women's colleges) disrupt intersectional marginalization in mathematics classrooms and other STEM contexts for Latin* QT students. Such research in HSIs responds to calls for insights about queer-affirming institutional support that serve Latin* QT students (Vega et al., 2022).

The study's findings also raise implications for educational practice. Both counter-stories addressed peer collaboration for mathematics coursework as a context where participants experienced dissonance with their Latin* queer identities. This finding points to the importance of instructors co-constructing norms of collaboration with their class that resist influences of white cisheteropatriarchy and expand Latin* QT students' comfort with groupwork. Examples of norms include students reflecting on how much space they have occupied, checking in on students who have not shared ideas, using peers' chosen names and pronouns, and avoiding assumptions of peers' gender, sexual, and other identities. These norms foster accountability to ensure that group members, including Latin* QT students, feel safe and comfortable to participate. This accountability alleviates the vulnerability that Ros and Daniela reported about navigating racialized-gendered judgments of ability, possibilities of being hypersexualized, and uncertainties of homophobia and transphobia that negatively impacted their experiences in peer collaboration. Instructors can ensure students engage in alignment with co-constructed norms by re-visiting them as a class when they observe groups departing from them, modeling norms through behavior and discourse during instruction, and encouraging adoption of these norms to structure collaboration in peer study groups and other contexts outside of the classroom.

Another practice implication is adopting an expansive approach to identity-based support in affinity spaces for STEM majors from historically marginalized groups. Findings captured limitations to peer support that participants experienced in spaces like SHPE and programs for women in engineering, where they were unable to bring their full intersectional identities as Latin* queer individuals. Leaders for STEM affinity spaces must interrogate how they frame gender inclusion to avoid reinforcing cisnormative exclusion like Ros had experienced. In addition, the design of STEM affinity spaces for Latin* students (e.g., SHPE) and QT students (e.g., Out in STEM) must give explicit attention to experiences of intersectionality to ensure a robust sense of inclusion and support for Latin* QT students. Daniela's ability to process complexities of being a mixed-race queer Latina in SHPE exemplifies how such intersectional support was available to her in a space for racial affinity.

Conclusion

This study portrays undergraduate Latin* QT students' experiences at the borderlands as aspiring STEM majors navigating white cisheteropatriarchy in mathematical contexts. Ros's and Daniela's counter-stories shed light on dissonance between their intersectional identities and exclusionary peer relationships, in addition to their individual agency for coping with such dissonance to protect their identities and success in STEM. With participants' accounts of agency involving the sacrifice of their queer identities, disruptions of mathematics education as a white, cisheteropatriarchal space are needed to advance intersectional justice for Latin* QT students.

Acknowledgments

Thank you to the organizers of the PME-NA 44 conference for the invitation to deliver a plenary based on the study presented in this paper. The reported research was funded by the National Academy of Education/Spencer Foundation Postdoctoral Fellowship and the Vanderbilt-Peabody College Small Research Grant initiative. I am grateful for feedback from Elsie Kindall, Taylor McNeill, and fellow PRISM Lab members on an earlier draft of the paper.

Curriculum, Assessment, and Related Topics

“MIRROR LOGIC”: A PRESERVICE MATHEMATICS TEACHER’S THINKING ABOUT RADIAN IN THE CONTEXT OF LIGHT REFLECTION

Hanan Alyami
Purdue University
alyamih@purdue.edu

Lynn Bryan
Purdue University
labryan@purdue.edu

Integrated science, technology, engineering, and mathematics (iSTEM) education allow learners to utilize multiple disciplinary perspectives. However, the discipline of mathematics remains underrepresented in iSTEM curriculum. To explore the nature of mathematical thinking with an iSTEM curricular approach that emphasizes mathematics, we investigated the thinking of a preservice mathematics teacher, Alex (pseudonym), who engaged in a task-based digital activity involving radian angle measure in the context of light reflection. Findings suggest that Alex’s ways of thinking comprise mathematical terminology, concepts, and processes, including mathematical ways of thinking about light reflection. The findings in this report suggest that emphasizing mathematics in this iSTEM context provided an opportunity for new ways of thinking about radian angle measure, and about how angle measure relates to light reflection.

Keywords: curriculum, geometry and spatial thinking, integrated STEM

Despite more than a decade of science, technology, engineering, and mathematics (STEM) reform initiatives toward integrated STEM (iSTEM) approaches (National Academy of Engineering [NAE] and National Research Council [NRC], 2014; National Council of Supervisors of Mathematics [NCSM] and National Council of Teachers of Mathematics [NCTM], 2018; NRC, 2013), the underrepresentation of mathematics in iSTEM education curriculum remains (English, 2016; Fitzallen, 2015). Given the need to develop iSTEM curriculum where mathematics holds equal importance as other disciplines (Baker & Galanti, 2017), it is incumbent upon educators to find ways of foregrounding mathematics within iSTEM experiences to better develop learners’ understanding not only of core mathematics content and practices but also about how core mathematics content and practices meaningfully relate to other disciplines. English (2016) and Fitzallen (2015) called for approaches that address how mathematical concepts and practices contribute to the learning and understanding of other STEM disciplines in iSTEM instructional contexts. Additionally, Li et al. (2019) called for research that attends to how thinking in content-based approaches relates to thinking in other disciplines. We take up these calls (English, 2016; Fitzallen, 2015; Li et al., 2019) with purposeful attention to situating mathematics as pivotal in the iSTEM experience. We argue that iSTEM experiences that foreground mathematics can contribute to mathematical thinking, and we consider how mathematical thinking relates to other STEM disciplines. We specifically explore a preservice mathematics teacher’s [PMT’s] thinking about the mathematical concept of radian angle measure in the context of light reflection. The research question guiding this report is “What ways of thinking does a PMT demonstrate upon interacting with a digital task that involves radian angle measure and light reflection?”

Theoretical Framing

To answer the research question, we took a constructivist perspective (Schunk, 2012) on the construct of thinking, and spatial thinking in particular, which we describe in the following sections. Additionally, we clarify our perspective and definition of iSTEM curricular approaches.

iSTEM Curriculum

Curricular approaches that involve iSTEM have been defined in various ways in the literature (Navy et al., 2021), with teachers, administrators, and policy makers having different views on iSTEM education (Breiner et al., 2012; Holmlund et al., 2018). In this report, our perspective of iSTEM curriculum involves instructional activities with learning goals of content and/or practices from one or more of the STEM disciplines, as anchors, along with engineering and/or engineering design practices, as integrators. Additionally, iSTEM curriculum activities involve opportunities to emphasize twenty-first century skills in a real-world, authentic context, to be solved through collaboration, communication, and teamwork (Bryan & Guzey, 2020).

There are many challenges when it comes to implementing iSTEM curricular approaches (English, 2016; Fitzallen, 2015). One of these involves distinctions in the knowledge base between disciplines (Williams et al., 2016). For example, discipline-specific words have explicit definitions and are used in unique ways in that discipline (Morgan & Sfard, 2016) despite use and overlap of such words in other disciplines. For example, the light reflection principle (Figure 1) is understood as the equality of the angle of incidence and the angle of reflection relative to a perpendicular to the mirror known as the normal ($\alpha = \beta$). The light reflection principle can also be understood as the equality of the angles of incidence and reflection relative to the mirror ($\gamma = \delta$). In this context, the term *normal line* refers to perpendicularity in relation to the scientific phenomenon of light reflection. A person with a mathematical perspective might refer to the normal line in the context of light reflection, using its mathematical property of perpendicularity, rather than using the term itself.

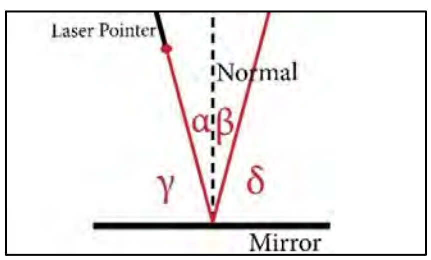

Figure 1. Demonstration of the principle of light reflection

Despite the challenges, research and reviews have reported the effectiveness of iSTEM education approaches on learners' engagement, motivation, interest in STEM, and increased mathematical achievement (Honey et al., 2014; Stohlmann, 2018; Zhong & Xia, 2020). However, little is known about learners' mathematical thinking as they engage in iSTEM instruction (Li et al., 2019). Hence, this study focuses on the ways of thinking that are involved in an iSTEM task that involves radian angle measure and light reflection.

Ways of Thinking

Our definition of ways of thinking builds on Harel's (2008) description of thinking as a learner's established cognitive characteristics, and Thompson et al.'s (2014) extension of Harel's (2008) definition, where thinking is the consistency in a learner's reasoning about mathematical situations. Building on these descriptions, we interpret ways of thinking as the thought patterns a learner demonstrates when reasoning about a particular concept given a specific situation that evokes such reasoning. For example, researchers demonstrated that PMTs think of radian angle measure as angles expressed in terms of π (Akkoc, 2008; Fi, 2003). Additionally, Moore et al. (2016) reported that PMTs' thinking about radian angle measure incorporates a unit circle diagram (Figure 2) to perform calculations. These studies suggest that through their prior coursework and experiences, PMTs may have developed a thought pattern to reason about radian angle measure. Such reasoning makes the use of special angles expressed in terms of π, and/or using calculational strategies an established way of thinking about radian angle measure.

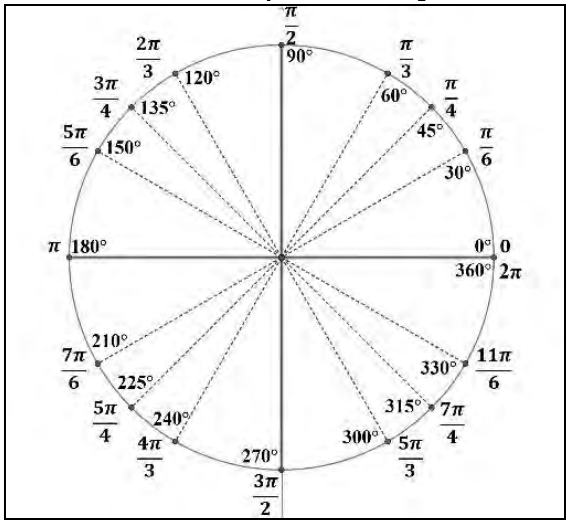

Figure 2. A typical diagram of the unit circle

Spatial Thinking

We characterize ways of thinking with particular attention to spatial ways of thinking. Commonly known as spatial reasoning, we use the term spatial ways of thinking to refer to thought patterns that include “the ability to recognize and (mentally) manipulate the spatial properties of objects and the spatial relations among objects” (Bruce et al., 2017, p. 146), through “a collection of cognitive skills comprised of knowing concepts of space, using tools of representation, and reasoning processes” (NRC, 2006, 12). Spatial thinking is associated with various disciplines and is correlated with achievements in both mathematics (e.g., Clements & Sarama, 2009; Mix, 2019; Mulligan et al., 2018), and other STEM disciplines (e.g., Newcombe, 2010, 2013; Newcombe & Shipley, 2015; Pruden et al., 2011). However, there are few opportunities for students to engage in spatial thinking in school (Clements & Sarama, 2011; Sinclair & Bruce, 2015; Whiteley et al., 2015). Because spatial thinking is associated with achievements in mathematics in addition to achievements in other disciplines (Bruce et al., 2017), it is appropriate to investigate the ways of thinking involved in an iSTEM curricular approach with attention to spatial ways of thinking.

While spatial thinking is usually associated with visualization, Whiteley et al. (2015) suggested addressing and legitimizing broader spatial ways of thinking, including symmetrizing, comparing, decomposing-recomposing, situating, orienting, and scaling. We describe these spatial ways of thinking in the methods section (Table 1), however, we note that the spatial ways of thinking we mentioned do not represent all spatial ways of thinking, nor do they exist in isolation of each other and/or other ways of mathematical thinking (Davis et al., 2015). For example, Munier and Merle (2009) built on NCTM’s (2000) recommendation to interrelate geometry and spatial thinking to provide 3-5 graders the opportunity to explore angle measure through physics-based teaching sequences, one of which included light reflection. Through an iterative process of spatial experimentation and geometric knowledge development, the 3-5 graders were able to discover light reflection principle, by attending to the symmetry between the angle of incidence and the angle of reflection relative to the mirror (γ = δ in Figure 1). This illustrates students’ use of symmetrizing as a form of spatial thinking in conjunction with the notion of angle as a form of mathematical thinking to discover light reflection principle.

Methods

Research Design

We employed a qualitative case study design (Flyvbjerg, 2011) to examine a PMTs mathematical thinking during a lesson that was part of an iSTEM unit embedding the design of a periscope (Alyami, in-press). The lesson entailed a digital task that involved radian angle measure in the context of a light reflection scenario (described further in the following section).

Participant and Task

The PMT participating in this study was Alex (pseudonym), who was enrolled in a mathematics teacher preparation program at a large Midwestern university. Alex volunteered and was compensated for his time after the first author briefly presented the opportunity in his secondary mathematics methods course. While Alex likely encountered the concepts of radian angle measure and light reflection during his K-16 schooling, he was not offered a formal learning session about radian or light reflection prior to participating in this study.

A Desmos activity (i.e., *Radian Lasers*) comprised the task in this report, where Alex typed values of angle measure (in radian) to adjust a laser and one or two mirrors so the laser beam would successfully pass through three stationary targets at once (Figure 1). The angles of the laser and the mirror are relative to the horizontal and in standard position, where positive angle values are counterclockwise and negative angle values are clockwise. The task consisted of two warm-up activities to familiarize Alex with the functionality of the digital interface, followed by six challenges. A benefit of the *Radian Laser* task is that the angles needed to situate the mirror were not limited to the common special angle (e.g., π/6, π/3, π/2). For example, one way of solving Challenge 1 is by positioning the laser upwards at an angle that is 5π/6 radian, with the mirror angled at a 5π/12 radian, which is not a common special angle (Figure 4).

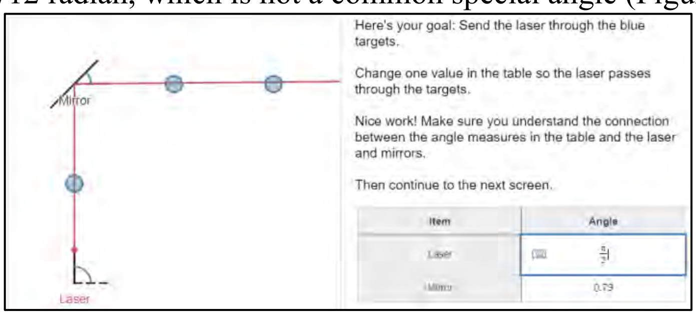

Figure 3. A challenge from the *Radian Lasers* activity

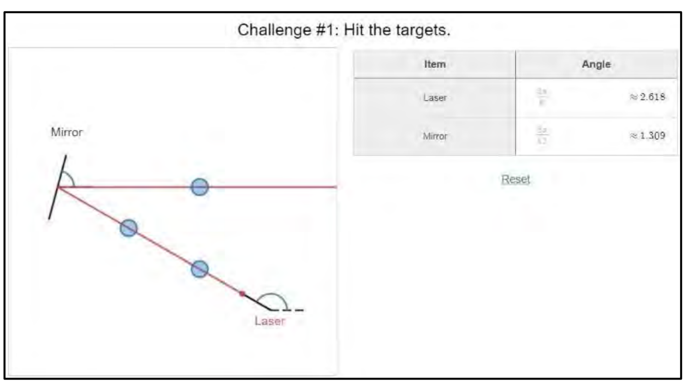

Figure 4. Challenge 1, where the angle of the mirror is not a common special angle

Following principles of structured, task-based interviews (Goldin, 2000), Alex engaged with the *Radian Lasers* task in a semi-structured, think-aloud interview setting, where he could use his own language to make sense of the task (van Someren et al., 1994). The semi-structured setting provided an opportunity to ask for elaborations (e.g., How do you know that? How would you represent your thinking?), which were informed by the responses Alex provided throughout the interview to encourage him to clarify his thinking.

Data and Analysis

The think-aloud, semi-structured interviews, led by the first author, took place virtually, were video recorded, and lasted approximately one hour. The interview video and time-stamped transcript comprise the data for this study. To analyze the data, the first author used a whole-to-part inductive approach for coding (Erickson, 2006), beginning with playing and watching the whole video without coding, stopping, or pausing. Then, NVivo software was used to code the media file, as described by Wainwright and Russell (2010). At this stage, the unit of analysis consisted of one or more sentences that formed coherent statements in which Alex described his thinking about how to reposition the angle of the laser and/or the mirror. To further analyze these statements, we used thematic analysis, which is a coding strategy that involves identifying themes in the data that are informed by the research questions, theoretical framework, and literature review (Saldaña, 2013). Specifically, we coded Alex's statements with attention to spatial ways of thinking described in Whiteley et al. (2015). As part of thematic analysis, we were open to the development of new categories that emerged from the data. Table 1 contains the codes that were evident in the data.

Table 1: Coding Scheme of All Spatial Ways of Thinking Utilized by Alex

Code	Description
Locating	Thinking about *where* objects are situated and/or positioned.
Orienting	Thinking of *how* objects are situated and/or positioned in relation to each other.
Comparing	Thinking about angle size in relation to itself or another angle (bigger, smaller, etc.)
Decomposing-Recomposing	Thinking of a whole as spatially broken into a specific number of parts, and/or spatially adding up parts to form a specific whole.
Symmetrizing	Thinking and applying properties such as congruence and symmetry with similar parts spatially facing each other around an axis.
Visualizing	Thinking visually of geometric objects and managing their characteristics. Includes: Managing both visible and imagined visual information.
Diagramming	Thinking of and managing geometric objects and patterns through drawing Includes: Gestures depicting semantic content (e.g., tracing angles as if to represent the angles on a typical unit-circle diagram) (Sinclair et al., 2018).

After coding all the transcript, the first author reviewed statements that were coded with multiple codes to provide a meaningful interpretation of the coded data "so that more can be gleaned from the data than would be available from merely reading, viewing, or listening carefully to the data multiple times" (Simon, 2019, p. 112). To answer the research question and provide evidence for our argument, the interpretation of the data focused on Alex's ways of thinking in relation to radian angle measure, and in relation to light reflection.

Findings

We describe in this section the mathematical and spatial ways of thinking Alex demonstrated upon engagement with the digital task, *Radian Lasers*. To argue that this iSTEM experience, which foregrounds mathematics, contributes to mathematical thinking and brings mathematics in relation to other STEM disciplines, we organize the two sections of the findings to start with Alex's ways of thinking in relation to radian angle measure. We then describe his ways of thinking in relation to making sense of light reflection.

Ways of Thinking about Radian Angle Measure Beyond the Special Angles

Since the angles needed in *Radian Lasers* are not limited to common special angle (e.g., π/6, π/3, π/2), Alex needed to think beyond the special angles commonly represented on a typical diagram of the unit circle (Figure 2). When a challenge required a noncommon angle, Alex estimated the measure of angle based on spatial comparisons and estimating the angles in between. For example, to reason about Challenge 1 (Figure 4), Alex initially situated the mirror at π/3 radian (left side of Figure 5), and noted that "the laser is hitting the mirror at a perpendicular angle … and that tells me that this angle needs to be slightly bigger." The previous statement suggests that Alex is observing the result of situating the mirror at π/3 radian angle, and then comparing the size of the resulting angle in relation to the angle that would lead the laser to hit the third target. Alex then entered π/2 for the mirror (right side of Figure 5), as he stated that "maybe π/2 would increase the angle," which caused the laser to reflect beyond where the third target is located. Upon missing the third target, Alex said "Okay, so I know it's between π/3 and π/2."

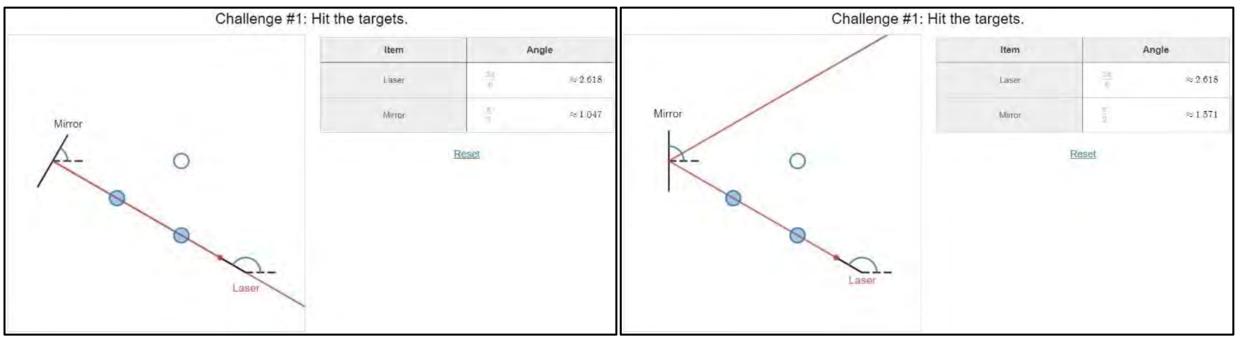

Figure 5. Alex's trials of π/3 & π/2, sending the laser respectively below & above the target

However, Alex was not familiar with a special angle that is between π/2 and π/3, and asked the first author if he could try an input such as 2.5π/6 for the angle. When he entered 2.5π/6, he observed the laser hit the third target. The interviewer asked Alex to explain why he questioned his ability to use the fraction, 2.5π/6. Alex explained:

> The 2.5π/6 was not like an option in my head because that's not, like one of the things that are usually mentioned or like associated with like radians. The reason why I got there is because I knew it was in between π/2 and π/3 but with the list of all, like the radians that I know, π/2 and π/3 are, like right next to each other, and there's, like no whole number π over anything in between those two numbers.

Alex's explanation is in reference to a typical diagram of a unit circle (Figure 2), where π/3 and π/2 are represented without depicting other angles between them. Alex recognized the need for an angle between π/3 and π/2, which led him to try the value between 2π/6 and 3π/6. He concluded that the angle would be 2.5π/6.

Mathematical Ways of Thinking about Light Reflection

In this section, we provide an analysis of Alex's ways of thinking as he makes sense of the scientific phenomenon of light reflection. We describe Challenge 3 of the *Radian Lasers* which could be solved by positioning the laser downward at an angle that is -π/6 radian, with the mirror being angled at a 5π/12 radian, to reflect the laser beam to the third target at the bottom (Figure 6).

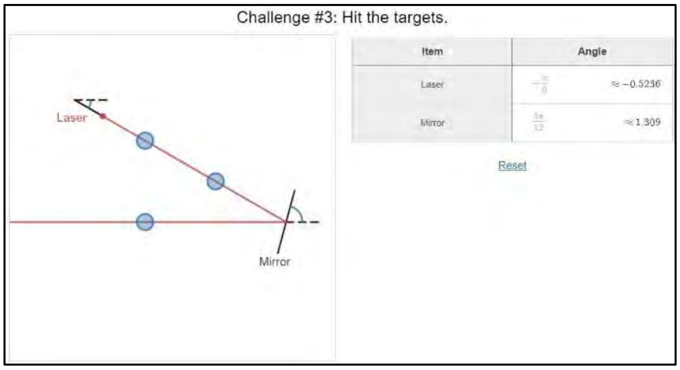

Figure 6. A possible solution for Challenge 3 from the *Radian Lasers* task

Alex used diagramming to represent his visualization of the challenge as alternate interior angles, then extended his diagramming with a focus on the mirror (Figure 7). Alex explained that "this entire thing [points to the mirror in Figure 7] is π, and so then I tried to find out what these two [the angles of incidence and reflection relative to the mirror] would be remaining, and I got … 5π/12 because there's two of them so I have to split the angle in half, because these two angles are equal." Alex's explanation of the mirror as a straight angle where its measure represents the "entire thing is π," suggests his thinking about the straight angle as a whole. Alex then decomposed the straight angle into π/6, which he concluded from the alternate interior angle theorem, and two angles that "would be remaining." Alex's elaboration demonstrates his attention to symmetry as he has "to split the angle in half because these two angles are equal."

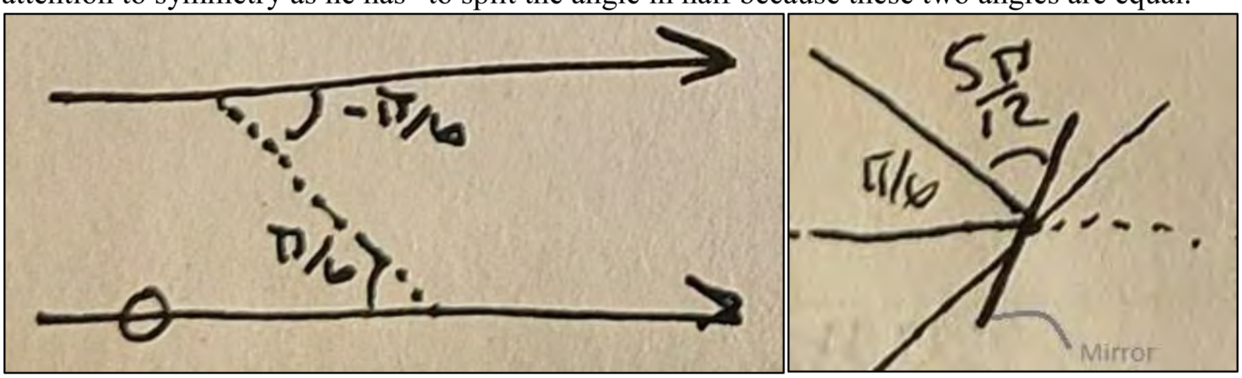

Figure 7. Alex's diagramming of Challenge 3 of the *Radian Lasers*

This example illustrates Alex's mathematical ways of thinking to make sense of the angle at which to situate the mirror. Alex's ways of thinking involved mathematical concepts (i.e., alternate interior angles), as well as various spatial ways of thinking (i.e., diagramming, decomposing, and symmetrizing). Alex went further to describe the light reflection principle from a mathematics perspective. Specifically, when Alex described his diagramming for Challenge 3 (Figure 7), he pointed at the angle the laser makes with the mirror upon reflection and stated, "this whole entire angle is π/6. I know the bisector, it, each angle would be like π/12. Then I know that this angle bisector is perpendicular with, you know, the mirror." Alex's description of the bisector of π/6 as "perpendicular" to the mirror illustrates his mathematical thinking about the science of light reflection, which he referred to as "adjust[ing] for mirror logic." The significance of the angle's bisector is because the angle the laser makes upon reflecting from the mirror (i.e., π/6) is the sum of the angles of incidence and reflection relative to the normal ($\gamma = \delta$ in Figure 1). However, Alex described the mathematical property of the

normal line as perpendicular to the mirror, instead of using the science terminology. Alex's explicit description of the science of light reflection through his mathematical perspectives was not elicited by the interviewer. Alex utilized his mathematical ways of thinking to make sense of the principle of light reflection. While Alex did not explicitly use the terminology, "angle of incidence" or "angle of reflection," he was meaningfully incorporating mathematical thinking to make sense of the science of light reflection.

Discussion

To date, there are few iSTEM curriculum materials that emphasize mathematical concepts as the anchor discipline (English, 2016; Fitzallen, 2015), despite evidence of the benefits of iSTEM curricular approaches on mathematical achievement and development of mathematical understanding (Stohlmann, 2018). Additionally, there are few opportunities to engage in spatial thinking in schools (Clements & Sarama, 2011; Sinclair & Bruce, 2015; Whiteley et al., 2015), despite the role of spatial thinking in understanding both mathematics (e.g., Mix, 2019) and other disciplines (e.g., Newcombe & Shipley, 2015; Pruden et al., 2011). Our report illustrates a purposeful integration approach with a focus on mathematics in the context of science within an iSTEM unit. We argue that iSTEM experiences that foreground mathematics can meaningfully contribute to mathematical thinking, in addition to enhancing how mathematics relates to other STEM disciplines. The *Radian Lasers* as an iSTEM approach that emphasized mathematics provided Alex, a PMT, the opportunity to utilize mathematical and spatial ways of thinking about radian angle measure (e.g., alternate interior angle, perpendicular lines, angle bisector, visualization, diagramming, comparing), and to relate angle measure to light reflection principle.

Previous studies suggest that PMTs' thinking about radian angle measure is limited to special angles expressed in terms of π (Akkoc, 2006; Fi, 2003) and calculational strategies using the unit circle (Moore et al., 2016). Similarly, Alex initially referred to some of the special angles on the unit circle. However, the *Radian Lasers* task constrained these established ways of thinking as Alex was not able to only depend on few special angles. Alex used spatial comparison to think beyond the special angles that are associated with the unit circle. This suggests that the *Radian Lasers* as an iSTEM activity that focused on radian angle measure in a science context provided an opportunity for Alex to reason about radian angle measure beyond the special angles. Alex's use of multiple spatial ways of thinking reflects Davis et al.'s (2015) discussion that the spatial ways of thinking do not exist in isolation of each other and/or in isolation of other mathematical ways of thinking. Specifically, to reason about the functionality of the mirror, Alex used diagramming as a spatial way of thinking in relation to a mathematical concept (i.e., alternate interior angle theorem), and in relation to other spatial ways of thinking (i.e., Symmetry and Decomposing-Recomposing).

Alex's mathematical ways of thinking assisted him in not only applying mathematical content and processes (e.g., alternate interior angles, spatial thinking), but also in making sense of light reflection. The iSTEM activity in which Alex engaged brought mathematics to bear in a situation that represents a scientific phenomenon, which allowed for the construction of a relationship between a scientific phenomenon and a mathematical concept. Our findings align with English (2016) and Fitzallen's (2015) call for educators and curriculum developers to capitalize on iSTEM approaches that emphasize mathematics, as well as Li et al.'s (2019) call for research that explores thinking in iSTEM contexts. The report illustrates how iSTEM approaches that foreground mathematics have the potential to support learners' thinking of not only mathematical content, but also meaningful mathematical applications and connections to other STEM disciplines.

COLLECTIVE CURRICULAR NOTICING WITHIN A MATHEMATICS PROFESSIONAL LEARNING COMMUNITY

Erin Barno
Boston University
ebarno@bu.edu

Leslie Dietiker
Boston University
dietiker@bu.edu

This paper explores how a professional learning community (PLC) redesigns high school mathematics lessons towards a shared commitment. We describe the nature of a PLC's collective curricular vision to illuminate how teachers can come to new understandings as a group in order to shift the ways students experience mathematics. Using the curricular noticing framework (attending, interpreting, and responding), we analyzed the meetings of a PLC with six teachers as they individually presented lessons to be redesigned with a focus on the group's shared commitment. Findings indicate three ways ideas were introduced that led to expansive responses, which suggests this analytic approach could identify ways in which a PLC can work towards new curricular decisions.

Keywords: Curriculum, Teacher Noticing, Teacher Beliefs

A central part of mathematics teaching is the design of lessons within a system of constraints (Brown, 2009). After teaching a lesson, teachers may reconsider specific design decisions based on their individual interpretations of the enacted lesson (what we refer to as *redesign*). Recognizing new curricular opportunities, however, is then limited to what prior experiences this individual teacher has had and what personal frameworks they use to make sense of their curriculum (what we refer to as *curricular vision*) (Darling-Hammond et al., 2005; Drake & Sherin, 2009). Teachers work under the demands of larger systemic constraints (e.g., policy, social messages of learning loss) as well as local constraints (e.g., administrative agendas with standardized testing, co-planning opportunities, curriculum access). Teachers, therefore, are limited within their redesign decisions — not by choice, but by pressure.

We are concerned that these constraints on curricular decision-making may prevent teachers from making ambitious changes to their teaching, thus maintaining the status quo for their students' experience and learning. Redesigning a lesson with other teachers that reimagines a given individual's curricular vision by challenging the given constraints can enable different types of experiences to inform teacher curricular decisions. When teachers are members of a professional learning community ("PLC") committed to a shared curricular vision, individuals then have new things to consider, negotiate, and think about in their own redesign choices. Therefore, we are interested in understanding the nature of collective redesign to illuminate how PLCs can come to new understandings as a group with a shared commitment in order to shift the ways students experience mathematics.

In this paper, we begin to answer the questions: (1) *What is the nature of curricular decision making for teachers with a shared design commitment in a PLC?* and (2) *What enables an expansive curricular decision?* We will illustrate how a group of teachers collectively arrived at and engaged with decision decisions that expanded potential opportunities for students. With better understanding of the potential ways groups of teachers can collectively redesign lessons, we hope to inform how PLCs with a shared commitment can potentially catalyze broader opportunities for students in mathematics classrooms.

Theoretical Framework

We use the *curricular noticing framework* (attending, interpreting, and responding) as a way to trace and describe the nature of lesson redesign in the PLC individually and across a group.

Curricular Noticing

Any decision that a teacher makes as part of the profession is shaped by the lenses (*interpretation)* with which they engage. Additionally, teachers' designs are also influenced by the phenomena (e.g., student work, textbook tasks, assessment data) to which they pay attention (*attending)*. Together, these contribute to a teacher's professional decisions to act (*responding*). Teacher's shifting lenses can contribute to teachers *attending* to, *interpreting*, and making pedagogical *responses* consistent with a particular goal when reflecting on a lesson enactment (Baldinger, 2017; Louie, 2018; Louie et al., 2021; van Es et al., 2014). *Curricular noticing* builds on the teacher noticing framework to describe how the phases of noticing (attending, interpreting, and responding) take place when teachers are designing or adopting any form of curricular materials (e.g., textbooks, enacted videos of lessons) (author, year). Although teachers may pass through a sequence of attending-interpreting-responding ("A-I-R"), the phases are not strictly sequential so that, for example, an interpretation may cause a teacher to redirect their attention. In addition, not all may lead to curricular decisions. For example, a teacher's interpretation that follows their attention may lead them to decide to not move forward with a particular action (i.e., response).

Increasingly, the noticing framework has begun to provide insight into how teachers identify patterns towards challenging systemic inequities in mathematics classrooms. Research in teacher noticing has begun to explore how individual teaching stances, such as deficit perspectives (Louie, 2018; Louie et al., 2021) or particular goals (Hand, 2012) can influence the extent to which teachers' interpretations lead to disrupting or perpetuating inequitable practices via responses. However, curricular noticing has not yet explored how a teacher's frameworks (i.e., curricular vision) can impact possible curricular responses. We argue that curricular noticing can support our understanding of how teachers challenge and disrupt systematic patterns of thinking due to the structural systems of schooling and testing, particularly within mathematics education.

Curricular Vision as a Commitment within PLCs

An individual's curricular vision, when interacting with others' own curricular vision, can create disruptive *responses* within group lesson design. Because curricular noticing happens from the standpoint of an individual's curricular vision (Dietiker et al., 2018), a group of individuals working together in a PLC means there are multiple curricular visions (potentially overlapping or shared in some cases). These curricular visions are positioned to interact and influence what responses are possible from individuals within the PLC and the PLC as a collective. When a group of teachers choose to align their own curricular visions towards new possibilities (which we will call *collective curricular vision*), their collaboration can support curricular responses related to students' potential mathematical learning experiences in new ways.

We conceptualize this shared stance for a collective curricular vision as a form of *commitment*. Evidence of a member's commitment to the collective curricular vision, therefore, is the explicit intention of aligning to a shared stance based not only on personal frameworks but also shared frameworks. The connection between a groups' shared commitment and the alignment to that commitment can either make space for new types of curricular responses (what we will call *expansive* responses) or prevent curricular responses from taking form during a group conversation (what we will call *restrictive* responses).

Methods

This study is a qualitative analysis of a lesson redesign meeting with a group of teachers with a shared commitment for how their interactions led to potential expansive opportunities for students. Pairs of teachers from three high schools (one urban comprehensive public school, one suburban comprehensive public school, and one urban private charter) in the Northeast were selected to participate. The 6 teachers, along with 2 researchers, participated in the redesign meeting. At this meeting, teachers took turns sharing video clips and data from a lesson they had taught the previous year and which they wanted to redesign. The data used here is based on audio recordings of workshops between the teacher who shared the lesson (the "lead teacher") and other teachers in the professional learning community. This design group was part of a larger project aimed at creating aesthetic opportunities for their students. Using video of enacted lessons as a form of curricular materials allows for curricular noticing to take in embodied, emotional, and verbal expressions of mathematics engagement.

Case Selection Process

Of the six redesign meetings, two were selected to be analyzed. To select, we looked for three qualities: (1) the participation of multiple members of the group; (2) conversation that specifically attended to the shape of content (i.e., curricular); and (3) conversation that included reference to the shared commitment: improving students' aesthetic opportunities.

In one session, Ms. Elm presents a lesson she previously designed and taught about the Rational Root Theorem (RRT). In another, Ms. Willow, presented an introduction to inverses lesson that she designed, taught, and wanted to redesign. Both of these audio recordings met the above three criteria, and had 5-minute segments that included all three pieces of criteria. These 5-minute segments were chosen for in-detailed analysis because of clear evidence of individual's members noticing and the noticing across members of the PLC. Therefore, the described segments show examples of exchanges towards expansive or restrictive responses.

Analytical Methods

The audio recordings were transcribed and analyzed for their curricular noticing (Dietiker et al., 2018). To identify instances of *curricular attending*, we analyzed the discourse for evidence of teachers "taking in" (ibid, p. 525) what was under discussion (e.g., presented by the lead teacher or introduced by another member of the PLC). To identify instances of *curricular interpreting*, we analyzed the discourse for evidence that a teacher made sense of what was attended to using their knowledge base in relation to their goals (e.g., evaluating a suggestion for its benefits). Finally, we identified instances of *curricular responding* by looking at decisions of action, both proposed and accepted (i.e., selecting a polynomial).

For each coded utterance, we analyzed how it related to the prior coded utterances. For example, when analyzing a coded utterance, we asked "was there a prior moment of attending, interpreting, or responding to another utterance that supported this utterance?" After compiling these threads of connected utterances, we identified the types of threads that emerged most frequently and connected to the groups' expansive responses.

Findings

With a collective curricular vision in a PLC, we found that the curricular noticing of the group of teachers were collectively shaped as follows: 1) prior responses were pulled back into the discourse as something to attend to, 2) prior interpretations were pulled back into the discourse as something to attend to with new interpretation, and 3) prior responses were impacted by the shifts in collective attending and interpreting. These characteristics, in turn, enabled this group to generate expansive responses. To show this, we present two exchanges from different parts of the design meeting to illustrate each of these characteristics, and describe how those either led to restrictive or expansive responses. In the first, based on a lesson on the RRT, all three characteristics were present and described. In the second, focused on redesigning a lesson that is an introduction to inverse functions, two of the three characteristics were present and described. In the first, based on a lesson on the RRT, all three characteristics were present and described. In the second, focused on redesigning a lesson that is an introduction to inverses, two of the three characteristics were present and described.

The Collective Redesign of Ms. Elm's Lesson on the Rational Root Theorem

Summary of Design Meeting. [1] At the start, the group watched an abbreviated video of key moments of the lesson enacted the prior year, selected by Ms. Elm. In this lesson, Ms. Elm had students use guess and check to test potential roots of given polynomials (cubic functions and quartic functions) in order to conjecture the RRT. Within this context, Ms. Elm presented the guess and check process as identifying "suspects" towards solving the mystery of the corresponding polynomial roots. She grappled with a tension; how could the lesson have students eliminate roots in such a way that they have time to understand the concept behind the RRT while keeping the aesthetic potential of mystery intact.

[2] After viewing the video, Ms. Spruce says:

> I loved the four guesses part…that was where you could definitely see like the kids [snapping], getting excited. What I wondered was... could you implement that earlier? To like generate more excitement…as you go up in degree and complexity, start taking away the number of guesses, because I think that would also generate the sense of…excitement, but in between there do some stuff to facilitate…better guesses

[3] Immediately after this comment, Mr. Palm points out that there was no evidence of students' verbally articulating what the learning objective is, and raises a question about the curricular goal of the lesson (ex: "do you want them, by the end of this…?"), offering multiple potential learning objective goals. [4] Ms. Elm replies:

> I mean ideally, I would love them to do all the things you said…that's really a tall order for one period...the key piece…sometimes there are so many potential factors that [the RRT] doesn't seem very efficient, but as the polynomial becomes more depressed, like that process is super-efficient when you're looking at your new *p* and *q*… If there's any way... um... but like I don't know if we ever got to that idea, so, um...I just don't know.

[5] As the conversation progresses, Ms. Spruce continues thinking aloud about the polynomial's leading coefficient (*p*) and its constant (*q*), suggesting that students, although not yet understanding the relationship between the roots and the polynomials, might get a sense of what could be a root. Ms. Willow and Ms. Elm continue to discuss how students' intuitive sense of numbers can lead them to making connections. [6] Ms. Willow suggests changing the polynomials to encourage students to focus on the coefficients. [7] Ms. Elm builds on this by saying that the new choice of coefficients should not visually mislead students (such as having p=1 and q=5 when the roots are not 1 and 5. [8] Ms. Spruce jumps in and describes this option as "kinda interesting," which [9] is echoed by Mr. Ash as a potential moment of "beauty."

Characteristic 1: Attending to a Prior Response. In [2], Ms. Spruce drew *attention* to the students' embodied reaction to the prior design choice of guesses. This focus on students' emotional and aesthetic reaction is connected to the larger groups' commitment toward captivating lessons. Then in [5], Ms. Spruce *attended* to her prior *response*, interpreting it as a way to connect to students' intuitive sense around numbers (i.e., connecting roots with the coefficients). Others continue *attending* to students' aesthetic reactions via numerical attunement [6, 7] and embodied excitement [9]. Collectively, these responses change the direction of the redesign; the focus on the original lesson in terms of students' articulating learning objectives shifted toward how the problems can make space for an increased aesthetic experience in a way that also contributes to students' learning.

Alternatively, this characteristic can limit curricular responding, such as in the case of Ms. Elm [4] attending to Mr. Palm's response [3]. The expansiveness of future responses began to close — her use of "I don't know" signifies that Mr. Palm's utterance overwhelmed her from responding at all. Unlike the previous example, here an A-I-R chain begun in [2] was interrupted.

Characteristic 2: New Attending and Interpretation of a Prior Response. Ms. Willow's prior *response* in [6] suggests that coefficients should be selected in such a way that students are learning through their intuitive sense. However, Ms. Elm in [7] *attends* to and *interprets* numerical attunement as misleading and unsupportive of sensemaking. This leads to a new *response* of a lesson design that does not have the potential to mislead students. Although this example can be read as one that restricts responses, the fact that the utterance [7] named a design challenge actually positioned the group to consider responding in two ways one, to either resolve that problem through a design-related response, or two, to shift what was attended to how it was interpreted that allows for a new expansive response. Therefore, the act of attending and interpreting a prior response enabled the group to name a problem, creating an opportunity to think more deeply about lesson redesign towards the shared commitment of student aesthetic experience [8-9].

Characteristic 3: Attending to Prior Interpretation. When Ms. Elm's *interpretation* in [7] was then *attended* to by Ms. Spruce [8], a new opportunity for students' aesthetic responses was created (i.e., the tension could potentially lead to a moment of excitement when students are able to find a pattern). This made space to consider aesthetic opportunities within the redesign. So, although the interpretation of the problem set in relation to students' numerical intuition was named as a potential issue [7], that interpretation was expansive because it was considering aesthetic characteristics within a lesson redesign. So, not only did that initial interpretation encourage continued noticing around aesthetic, but also made space for the reframing of the interpretation as an opportunity [8], which, in turn, acts as an example of enabling a subsequent expansive response.

The Collective Redesign of Ms. Willow's Lesson on Introduction to Inverses

Summary of Design Meeting. [1] In the beginning of this episode, the PLC is discussing how to adapt the opening task from the original lesson. [2] Ms. Dogwood proposes prompting students to compose $x^2 + 3$ and $\sqrt{x-3}$. [3] Ms. Spruce follows by saying, "Do you want them to have that in their minds when they go to [Problem] three?", which asks students to match functions that are inverses from a list of linear functions. Ms. Willow share this concern, saying:

[4] Ms. Willow: Oh, I see, because then I might be giving them stuff that has squaring…
[5] Ms. Spruce: Which isn't necessarily the end of the world, if you allow yourself to have awareness…
[6] Mr. Ash: You could just ask for linear(s). Like on [Problem] 3…you could restrict [the given types of functions].

Following this moment, the group discusses the difficulty students might have with simplifying the composed functions. This includes [7] Ms. Dogwood wondering if students would know to "square out" a radical, [8] Ms. Willow naming that doing so would be "really hard," and [9] Ms. Dogwood describes this process as "ugly."

[10] Ms. Willow then suggests creating a problem within the set that requires three operations to simplify the composed functions. She continues [11] by saying the three steps could more clearly illustrate the "doing and undoing" that is key to inverse functions, compared to prior suggestions that potentially resulted in the composition not "coming out nice." [12] Ms. Dogwood, in turn, articulates how inputs could influence whether the composition is "nice" and responds by suggesting that the group thinks of problems that would have a "nice" composition with the original problem's "yucky" elements (such as fractions). Ms. Willow continues:

> [13] Ms. Willow: I'm worried though, because if they try composing these…it would be three halves times two-thirds *x* plus one minus one… they're gonna be like, 'Oh, okay, so that's like *x* plus one minus one, it cancels out…
>
> [14] Mr. Ash: But that would be a nice opportunity for you to…because that's a common mistake that you saw happening later on…[say] maybe 'here's an opportunity, don't forget to distribute.'
>
> [15] Ms. Dogwood: But I think Ms. Willow's wondering…how can [the students] trouble that's not right? Then your question begs, like, 'how come? We have to distribute."
>
> [16] Ms. Willow: I don't know how that will make them feel when we do all the canceling…like, if they just tried to cancel and it didn't work, then suddenly all this canceling *does* work, does that feel better or worse?
>
> [17] Ms. Cherry: Well maybe they understand *why* it's so special, like *woah*, you know? Because everything cancels out.

Characteristic 1: Attending to a Prior Response. When considering Mr. Ash's [6] use of the prior *response* [3], we see how he encouraged the PLC to design in such a way that considers students' intuitive number sense to understand why the functions are inverses. When bringing Ms. Spruce's [3] response back into as something to *attend* to, Mr. Ash [6] opens the community to consider how clarifying what students have in their minds could be influenced by a restriction to the types of problems being presented. So, Mr. Ash *responds* by suggesting that restricting the problem set to linear equations (as opposed to incorporating quadratics and square root functions as inverse pairs) could serve as a better way to focus students' attention.

In another moment, we see a sequence of utterances where what is attended to stems from a prior utterance's response. An example of this starts when Ms. Willow [13] *attends* to Ms. Dogwood's *response* in [12] to create a pair of functions that, when composed, is "nice," although the coefficients may be "yucky." Ms. Willow *responds* [13] by naming that students' intuitive sense of what cancels could also be an issue towards their understanding of inverses and what actually cancels. Then Ms. Willow's *response* [13] was then attended to by Mr. Ash in [14], where this could be leveraged to support their conceptual understanding of the need to distribute [16]. This illustrates how prior responses that are pulled back into the discourse can result in expansive responses when the process is compounded by happening multiple times in a row.

In another example, the PLC *attends* to prior *responses* of multiple members of the group at the same time. Ms. Dogwood [15] draws *attention* to both Ms. Willow's [13] and Mr. Ash's [14] prior *responses* about students' intuitive sense by interpreting students' need to challenge their intuitive sense of canceling (as opposed to just refocusing the attention). This happens again when Ms. Cherry [17] *attends* to the same two *responses* that Ms. Dogwood just *attended* to. Here, Ms. Cherry interprets those responses by naming the importance of students understanding why the expressions cancel in order to have a positive aesthetic experience while canceling. This interpretation results in a new response where Ms. Cherry suggests that some of the tensions named in the prior responses could potentially be a moment where students "understand why [composing inverses] is so special."

Characteristic 2: New Attending and Interpretation of a Prior Response. Ms. Spruce, in [3], *responded* when she suggested clarifying what the lead teacher (Ms. Willow) wanted students to have in their minds while solving the subsequent problems. Ms. Willow [4] *attended* to Ms. Dogwood's original *attending* in [2], but *interprets* it using Ms. Spruce's [3] *interpretation* of how prior problems in the set could influence their approach to new problems. Ms. Willow's *response* [4], in turn, becomes the same *response* that Ms. Spruce previously had — that is, that the lead teacher (here, being Ms. Willow herself) needs to clarify what she wants students to have in their mind. So, although it could be said that Ms. Willow did not contribute anything novel to the conversation, she was able to elevate the prior response in a way where members of the PLC could recognize the design challenge as Ms. Willow was *interpreting* it in relation to the commitment.

Another instance where prior *responses* are reimagined with new *attending* and *interpreting* is when Ms. Willow [16] refines the *response* of students' intuitive sense of what cancels as an issue. Here, she highlights the need to design problems that do not confuse students by *attending* to students' embodied feelings of when canceling "works" or "doesn't" work. So, Ms. Willow brings in the *interpretation* that students can feel better or worse when there are "inconsistent" responses with canceling. This new *attending* and *interpreting* of prior *responses* now brings in students' affective reactions when considering their intuitive sense of numbers and the relationship to the problem set. So, instead of only focusing on how students can mislead themselves or on the "ah-ha!" moments that students might have due to their intuition, Ms. Willow draws *attention* to the tensions that might arise during the lesson. This reimagining oriented teachers to the broader affective experience that students may have when engaging with this topic through new expansive *responses*. Students' opportunities to have positive aesthetic experiences, on the other hand, may have been restricted if the PLC had not considered the broader affective experience as presented within the redesign.

Discussion

By highlighting the role of collective curricular vision, this paper argues how teachers who collectively redesign lessons with a shared commitment can shift their attention and interpretation of what other teachers offer towards more expansive views of mathematics learning. When a PLC's collective curricular noticing is guided by a commitment that intentionally disrupts constraints within the design process, such as attending to students' emotional reaction to a mathematical concept over attending to standardized testing scores, the way in which noticing functions within the collective can lead to *expansive* responses. In addition, when a PLC's curricular noticing, despite being guided by a shared commitment, tends to stray away from the collective beliefs in any capacity (such as reinforcing design habits that are traditionally inequitable, redirecting the group from an expansive response), *restrictive* responses can emerge. In terms of the curricular noticing framework, we can see an alignment to the collective curricular vision's commitment through (a) what an individual decides to attend, interpret, or respond to with during PLC conversations, and (b) the expansiveness or restrictiveness of resulting responses. This, in turn, informs curricular responses toward reimagined ways for students to think about, engage with, and experience mathematics.

Analyzing curricular noticing as a collective practice within the curricular noticing framework sheds light on the way in which teachers are listening to each other, considering different ideas, and hearing other teachers' own attending, interpreting, and responding to the *same* noticing within the same discussion. Being able to trace the way in which members of a PLC build upon each other's contributions shows that a response helps move the group towards deeply understanding what they care about in terms of the shared commitment; we are now able to see how this is done by tracing the process of fine-tuning the question they are *really* vexed with to ensure the PLC's commitment is salient in how decisions are made within the redesign. Although individuals in a PLC bring in their own interpretations through their experiences, they are being exposed to and building off of the noticing that is happening within the collective.

This analysis illustrates that, through the product of years of teaching, collective sensemaking around aesthetic, and co-design work as part of a PLC, expansive curricular responses are possible through emergent discourse. Identifying this contributes to the mathematics education field by shedding light on the nature of collective curricular noticing and how expansive curricular responding develops in response to a shared commitment and a space to design lessons aligned to that commitment. Knowing this, there is a call for PLCs to develop a curricular vision around a shared commitment, such as increasing aesthetic opportunities for students. With this in place, we can begin to think about the emergence of expansive curricular noticing across redesign sessions between educators. This focus opens up potential opportunities for students — when a teachers' curricular noticing is including and expanding beyond content goals, a students' learning experience can begin to include a wider range of experiences is equally if not more important towards shaping an enjoyable, expansive, and engaging learning experience for young people in a space that typically marginalizes them. A shared attunement to an expansive ideology (be it aesthetic, or another touchstone towards a more equitable learning space), and the resulting curricular responses, has the potential to become expansive when rooted in a professional learning community.

Validity and validation is central to conducting high quality quantitative mathematics education scholarship. This presentation aims to support scholars engaged in quantitative research by providing information about the degrees to which validity evidence related to their instrument use or interpretation, were found in mathematics education scholarship. Findings have potential to steer future quantitatively focused scholarship and support equity aims.

Keywords: assessment, research methods

The inferences and interpretations drawn from quantitative assessments are largely grounded in the validity evidence and their associated claims (AERA et al., 2014; Carney et al., in press; Kane, 2016). Mathematics education scholarship using quantitative assessments has not consistently adhered to strong validity and validation practices as seen by the limited presence of validity evidence related to many instruments used with K-12 students and teachers (Bostic et al., 2019, Bostic et al., 2021; Krupa et al., 2019). A purpose for the present study is to serve as an educative piece for mathematics educators who intend to develop or use quantitative assessments in their research. We offer results about the degree to which validity has been taken up in mathematics education scholarship that uses quantitative instruments.

Related Literature

The *Standards for Educational and Psychological Testing* ([*Standards*] AERA et al., 2014) describe five sources for validity: test content, response process, relations to other variables, internal structure, and consequences from testing. Reliability is a related but not sufficient condition of validity (AERA et al., 2014; Kane, 2012). While the *Standards* describe some approaches for each source, those descriptions are not intended to be exhaustive. A special issue of *Psicotherma* (2014, 26(1)) includes articles related to each of those sources. Here again, the authors of those articles indicate that their description of each validity source is to introduce readers to that source and are not intended to be comprehensive. Thus, there is a need for a more comprehensive list of data collection approaches related to each validity source.

Mathematics education scholarship has started to address validity within the context of quantitative research across K-20 students, as well as preservice and inservice teacher settings (e.g., Bostic & Sondergeld, 2015; Carney et al., 2017; Gleason et al., 2019; Hill & Shih, 2009; Melhuish & Hicks, 2019; Walkowiak et al., 2014; Wilhelm & Berebitsky, 2019). These authors provide discussions about how they explored validity evidence and serve as potential roadmaps for others doing validation work. There are some common approaches to gathering validity evidence. The present study intends to summarize literature about approaches to gathering validity evidence so that quantitative assessment developers, users, and reviewers have a more comprehensive understanding of what has been done previously, and what approaches are viable. Our research question was: In what ways is validity evidence and arguments present in mathematics education scholarship that uses quantitative instruments between 2000-2020?

Methods

Context for study

In 2019, 39 mathematics education scholars convened at a 2-day conference led by the authors. Scholars included mathematics educators, psychometricians, special educators, and policy experts who had previously conducted quantitative mathematics or statistics education assessment work. Conference leaders asked attendees to form small groups and brainstorm viable data collection approaches that might generate validity evidence for that source. After sharing ideas, groups rotated to each approach and left feedback, followed by whole-group discussions. The product was an extensive list with at least five unique approaches to gathering validity evidence for each validity source. There were still questions about whether there were other approaches and how to define some of these approaches for a broad audience (e.g., factor analysis). To that end, the authors of this submission reviewed literature and sought definitions to create an Evidence Types Guidebook. The definitions were sent to conference attendees for feedback and revised as needed. Independent of that work, conference attendees have been conducting syntheses of literature across a variety of contexts including teacher education, elementary and secondary students, and statistics education.

An Evidence Types Guidebook served to facilitate the identification of approaches typically utilized within a validity evidence type. For each of the evidence types (i.e., test content, response processes, internal structure, relation to other variables, and consequences of testing) within the Guidebook, a general definition of the type was given, followed by a list of methods commonly used to support a validity claim within the respective category. For example, the internal structure section included approaches such as factor analysis, item response theory, latent class analysis, and other approaches commonly used to assess and support claims of validity related to the internal structure of a quantitative instrument. Each of these methods also contained definitions and citations for further exploration and information. The Guidebook content was aligned with the validity evidence repository framework and served to support participants, in general, throughout the framework application process.

Data Sources and Analysis

Our data collection and analysis process is summarized here; more details are provided in Bostic et al. (2022). The PRISMA statement guided the literature search (Rethlefsen et al., 2021). The top 24 mathematics education journals (Williams & Latham, 2017) were searched for studies using quantitative instruments. Articles that included quantitative instruments were culled to create a list of instruments. Next, validity evidence was sought for each instrument through a literature search using google scholar. Instrument names and keywords were used to generate an appropriate sample space. As an example from teacher education, over 3,000 articles were examined, which led to over 300 instruments Evidence was coded as being connected to a validity source or reliability. Validity claims in support of arguments were also coded. We share results from those syntheses as a means to illuminate the frequencies of various approaches as well as opportunities for use of new approaches.

Findings

Overall, synthesis groups searched for validity evidence of 190 instruments and found 278 articles with descriptions of validity evidence (see Table 1). The majority of articles (83%) did not contain an interpretation statement or a use statement. In addition, 73% of the articles that contained validity evidence did not specify any claims. An example of a use statement comes from the Statistics Education synthesis group: "The availability of an instrument such as the Attitudes Toward Research (ATR) scale which has been designed for students, may provide information concerning motivational aspects associated with learning research, and might also have potential for identifying distinctive attitude profiles of students who find research problematic. Overall however, this study's results validate the utility of the ATR scale in measuring student attitudes toward research" (Papanastasiou, 2005, p. 23).

Table 1. Instrument and Article Overview

	Elementary (K - 6) Tests & Instruments	Secondary (7 - 12) Tests & Instruments	Statistics (K - 20) Tests & Instruments	Teacher Education Instruments	Combined
Number of instruments	59	27	16	88	190
Number of articles	92	36	52	98	278
Articles with an interpretation statement	17 18.48%	4 11.11%	19 36.54%	7 7.14%	47 16.91%
Articles with a use statement	18 19.57%	2 5.56%	20 38.46%	2 2.04%	42 15.11%
Articles with a claim	37 40.22%	6 16.67%	15 28.85%	15 15.31%	73 26.26%

Considering the distribution of the five types of validity as well as reliability: Internal structure, reliability, and test content were the most frequently located. Table 2 shows the frequency of each evidence type across different areas. The most frequently used method for each evidence type is displayed in Table 3. Some frequencies are quite high (e.g., alignment with frameworks) whereas the mode for other validity sources was quite low (e.g., quantitative DIF analysis).

Table 2. Evidence Type Frequency

	Elementary (K - 6) Tests & Instruments	Secondary (7 - 12) Tests & Instruments	Statistics (K - 20) Tests & Instruments	Teacher Education Instruments	Combined
Consequences of Testing	4 1.73%	0 0.00%	5 2.81%	1 0.69%	10 1.71%
Internal Structure	48 20.78%	7 21.88%	34 19.10%	29 20.14%	118 20.17%
Relations to Other Variables	33 14.29%	1 3.13%	27 15.17%	19 13.19%	80 13.68%
Reliability	68	9	29	53	159

	29.44%	28.13%	16.29%	36.81%	27.18%
Response Process	27 11.69%	3 9.38%	13 7.30%	6 4.17%	49 8.38%
Test Content	51 22.08%	12 37.50%	70 39.33%	36 25.00%	169 28.89%
Total Number of Evidence Types	231	32	178	144	585

Table 3. Mode of approach for each validity source and reliability

Validity Source or Reliability	Most common type of approach	(count, %)
Test content	Alignment with frameworks	n = 45, 26%
Response Process	Student written work	n = 19, 38%
Relations to Other Variables	Correlation analysis	n = 41, 51%
Internal Structure	Confirmatory factor analysis	n = 41, 34%
Consequences of Testing	Item functioning such as DIF	n = 3, 30%
Reliability	Internal consistency, alpha	n = 19, 38%

Discussion

It is clear from analyzing the validity evidence from this sample of instruments that modern notions of validity and validation arguments (AERA et al., 2014; Author, in press; Kane, 2016), have not necessarily been taken up by the field. We do not blame authors for this omission. It may be that validity evidence is removed during the editing process. Authors may not be prepared to conduct validation work. It has also been shown that 75% of mathematics education graduates take two or less quantitative research courses, where validity and validation might be discussed (Shih et al., 2019). Few instruments presented in existing scholarship are accompanied with an explicit statement describing the intended interpretation and use of test scores. Further, we found little validity evidence based on consequences of testing and response processes. Given current equity issues in mathematics education, it is a concern that there is not more evidence of consequences from testing and bias, especially to ensure fair use of the score interpretations from the tests.

Validity is naturally an equity issue (AERA et al., 2014; Cronbach, 1988). Otherwise, tests may have bias and test scores may be used unfairly. Cronbach (1988) proclaimed, “Tests that impinge on the rights and life chances of individuals are inherently disputable” (p. 6). Furthermore, the inferences drawn from tests that lack a validity argument may not be accurate (Carney et al., in press). To yield accurate inferences about student learning or teacher practice, it is critical for scholars to have tests and instruments with strong validity evidence and robust validity arguments.

INVESTIGATING ELEMENTARY MATHEMATICS TEACHERS' ADAPTATION OF ACTIVITIES FOUND ON VIRTUAL RESOURCE POOLS

Lara K. Dick
Bucknell University
lara.dick@bucknell.edu

Amanda G. Sawyer
James Madison University
sawyerag@jmu.edu

Over the past decade, teachers have increasingly turned online to supplement their mathematics curriculum and some research regarding where and how teachers search has been completed. However, there are many open questions regarding this rising phenomenon, one of which is learning more about what teachers do after finding a mathematics activity online. We report on a subset of a survey of elementary school teachers across the United States about their use of elementary mathematics activities found via virtual resource pools; for this manuscript, we share results on two questions related to teachers' adaptation of elementary mathematics activities they obtained.

Keywords: Curriculum; Elementary School Education; Instructional Activities and Practices

Prior to the rise of the internet, most schools adopted elementary school mathematics textbooks and provided teachers with associated teaching materials with the understanding that this was "all" teachers needed to have at their disposal to teach mathematics successfully (Browne & Haylock, 2004; Remillard, 2005). However, over the last decade, many teachers have turned online to various virtual resource pools to supplement their elementary mathematics curriculum. Teachers may search for activities on online teacher marketplaces such as Amazon Inspire, Pinterest or TeachersPayTeachers, or they may search on more vetted sites such as professional organizations like the National Council of Teachers of Mathematics. Recent research shows ever-increasing popularity of teachers' curriculum supplementation via virtual resource pools (Hu & Torphy, 2020) but overall, this supplementation is not well-understood by the mathematics education research community. According to Silver who completed a literature review on online resource supplementation, most research "tends to center phenomena closely related to supplementation (e.g. virtual resource use, teacher social media use) rather than supplementation itself" (2021, p. 2). This paper seeks to study the act of supplementation, specifically that of adaptation of supplemental mathematics activities found online by elementary teachers.

Literature Review

To situate this work, we share literature related to lesson supplementation with resources found on virtual resource pools and lesson adaption more generally. We then share the focus of this study.

Lesson Supplementation from Virtual Resource Pools

Teacher supplementation can be described as any change teachers make to curriculum resources provided by officials at their schools or districts (Silver, 2021). Teachers have always supplemented their classroom resources but Hodge et al. (2019) discusses the increase of teacher supplementation as a recent phenomenon due to increasing internet use and the implementation of the Common Core Standards. With the rise of the internet came a variety of virtual resource pools which Silver (2021) defines as "websites that host curriculum resources for download by teachers to use either alongside or instead of their school-adopted textbooks" (p. 1). Thus, VRPs include websites hosted by textbook companies, professional organizations, open educational resources, online teacher marketplaces and more general sharing sites like Pinterest that teachers use to search for supplementary curriculum resources.

One finding of a recent review of research is that "teachers curriculum supplementation is massive in scope" (Silver, 2021, p. 6). Surveys of teachers looking at their VRP supplemental usage has shown this increase with Davis et al. (2013) reporting 60% of teachers reporting supplementing their curriculum to more recent studies reporting over 80% (e.g. Sawyer et al., 2019a; Carpenter & Shelton, 2021; Tosh et al., 2020). Research shows that teachers often also turn to social media sites such as Instagram and Twitter as spaces to search for materials on various VPRs (e.g. Carpenter & Kruka, 2014: Carpenter et al., 2020) which is further complicated by the number of teacherpreneurs who promote their self-created resources on these and other social media sites (e.g. Hu & Torphy, 2020; Shelton & Archambault, 2019).

One question researchers have studied is teachers' reasons for supplementing their classroom curriculum. From his synthesis of research Silver (2021) describes teachers' reported motivations are largely to fill holes they perceive with their provided curriculum, to assist their students or make teaching better for themselves. Sawyer et al. (2019a) found that teachers reported alignment to standards and student engagement to be the most important factors for teacher supplementation via VPRs. In contrast, Schroeder et al. (2019) found "idea gathering" as the main purpose for teacher supplementation with other reasons related to improving the classroom environment and increasing student engagement (p. 171). Specific to the TeachersPayTeachers VRP, teachers cited the following reasons for supplementation: to fill gaps in existing curriculum related to concepts or skills, to make learning fun, to provide additional practice for students and for inspiration when they were not sure how to approach a particular lesson (Carpenter and Shelton, 2021). Taking together, these results point to teachers' carefully searching for and choosing supplementary resources that meet their curricular needs and the needs of their students. For this study, we are interested in what happens after teachers choose a supplemental curricular resource. Specifically, do they use the supplement as they found it or do they adapt it in some way.

Lesson Adaptation

For the purpose of our study, we utilize Davis et al.'s (2011) description of adaptation, "Adaptations can include insertions, deletions, or substitutions, for example, and may be based on aspects of the teachers' contexts, their students' needs and strengths, and their learning goals, knowledge, beliefs, identities, and orientations" (p. 797). Studies researching adaptation have focused on teachers' reasoning (e.g. Choppin, 2011; Drake & Sherin, 2006; Carpenter & Shelton, 2021) with results showing reasons for adaptation falling into two main categories: improving instruction for students and making teaching better for teachers.

Methods of adaptation vary across elementary school subjects; researchers have investigated methods of adaptation in reading (e.g. Parsons, 2012), science (e.g. Forbes, 2011), as well as the subject studied for this paper, mathematics (e.g. Choppin, 2011; Remillard, 1999; Sherin & Drake, 2009). Sherin & Drake (2009) found that mathematics teachers typically adapt their activities in a three-step cycle: omit, replace, and create. They explain that teachers first remove items from a mathematics activity and then replace it with something that they find useful and that they believe will better support their students' learning. If this is not deemed sufficient, mathematics teachers create new curricular elements to support student learning in their classroom (Sherin & Drake, 2009). In a more recent study, elementary preservice and inservice teachers reported adapting resources they found on Pinterest often with the top reported reason for adapting given as "meeting student needs and attending to grade-level standards." (Schroeder et al., 2019, p. 173). Because Schroeder et al.'s (2019) study was not subject specific and was specific to teachers searching for supplemental resources on one particular VRP, Pinterest, the current study both broadens and narrows the question of adaptation by looking at elementary teachers' supplemental mathematics activities found on any VPR. Specifically, this study seeks to answer the following two research questions:

1. How often do US elementary teachers report adapting mathematics activities they find on VPRs?
2. How do US elementary teachers describe how they adapt mathematics activities they find on VPRs to fit the needs of their students?

Conceptual Framework

For this study, we adopt the Teacher Curriculum Supplementation Framework (Silver, 2021) that includes four dimensions surrounding teacher supplementation as a tool to guide research: the teacher's reasons for supplementation, the supplement's source, the teacher's supplemental use pattern and features of the supplement itself. In the literature review, we discussed what is currently known about teacher's reasons for supplementation, the fact that teachers' use of supplemental resources is massive and have indicated that for this study, we are not considering specific VRP sources from which supplements are sought. We are, however, interested in the supplement itself, specifically how often and how teachers choose to adapt a supplemental elementary mathematics activity.

When considering the supplement itself, researchers may study features like the visual appeal, educational quality and how these affect student learning. Silver (2021) notes that most research in this area is researcher determined meaning researchers use their expertise to study the curricular supplements. Research in these areas regarding elementary mathematics supplemental activities have shown supplements tend to be low in quality (e.g. Hertel & Wessman-Enzinger, 2017; Sawyer et al., 2019b; Shapiro et al., 2021), but that does not mean teachers use the supplement as they find it. Because of this, Silver (2021) suggests that more work is needed looking at "a teacher's supplementation process from start to finish" (p. 24). While this study does not follow teachers' full process, it does begin to consider what happens to a supplement after it is chosen which meets the call by Hu and Torphy (2020) to focus more on the compilation, distribution and diffusion of supplements into the classroom.

Methodology

This study reports on a subset of a survey conducted in June 2018 that asked teachers 23 questions about their elementary mathematics VPRs search practices including how often, where they searched, what they were looking for when they searched, and how often and how they adapted resources they found. Results on how often, where and what teachers reported looking for when searching for supplemental activities was reported in Sawyer et al. (2019a).

Data Collection

To distribute the survey, we emailed the presidents of all 50 state affiliates for both the National Council of Teachers of Mathematics and the Association of Math Teacher Educators, thus obtaining our participants through a snowball sampling technique (Weiss, 1994). We also posted the survey link on multiple social media sites including Twitter, Facebook, and Instagram using #elemmathchat, #edchat, #mathchat, #elemchat, #mtbos, #iteach, #iteachmath, and #numbersenseroutines. After the emails and social media posts were sent, the survey was open for seven weeks. 601 teachers responded; they hailed from 48 states, excluding Delaware and

South Dakota, as well as three US territories. They were currently teaching kindergarten through sixth grade and had between zero and 36+ years of teaching experience.

There were two survey questions specifically focused on teacher adaptation. The survey questions that we report on in this paper include:

1. How often do you adapt mathematics activities you find online?
2. How do you adapt activities you find online to fit the needs of your students?

For responding to frequency of adaptation, teachers choose one of the following five scaled responses, “Always; Most of the time; About half the time; Sometimes; Never”. For responding to how they adapt, we purposefully did not define what we meant by what constitutes “how” to not limit our study to a specific definition of the term. However, we did focus the question on how teachers adapted to fit student needs which is in line with Schroeder et al. (2019)’s finding that the majority of adaptions focused on student needs. We were interested in how adaptations were made to elementary mathematics supplements for students, not for teachers.

Of the 601 elementary teachers who responded to the survey, 496 answered the question about how often they adapted online elementary mathematics activities but only 290 teachers provided a descriptive narrative about their adaptation process. We therefore answer research question 1 using the 496 teacher responses, but answer research question 2 with the 290 teacher responses.

Data Analysis

This mixed methods study used both quantitative and qualitative data analysis. We implemented descriptive statistics when describing how often teachers reported adapting elementary mathematics activities. We applied the constant comparative method through grounded theory to analyze qualitative data provided by the teachers in their descriptive narratives explaining how they approach adapting to meet the needs of their students (Glaser & Strauss, 1968; Miles, Huberman, & Saldaña, 2013). For the qualitative analysis, we used Qualtrics’s coding tool. First, we ran a keyword analysis of the open-ended responses. We then used the most common terms along with the constant comparative method through grounded theory to allow for additional terms to emerge (Glaser & Strauss, 1968; Miles, Huberman, & Saldaña, 2013). One researcher did this initial work. Once data saturation was reached, an additional researcher worked with the coder to collapse keywords and identify overarching themes. At this point, keywords were collapsed into larger categories. Teachers whose responses did not include common keywords were individually coded into the four overarching categories by the two researchers. Questions about responses or instances where the two researchers could not agree were brought to a third researcher for consultation.

Findings

Research Question One: How Often

Less than 1% of the teachers (n=4) said that they never adapt a supplemental math activity. The majority of the teachers reported that they adapt sometimes (21.6%, n=107), about half of the time (21.6%, n=107) or most of the time (40.9%, n=203). 15% (n=75) of the teachers reported adapting their supplemental mathematics activities all of the time. Taken together, these results show adaptation to be a common practice with 78% of the teachers indicating that they adapt elementary mathematics activities found on VRPs at least half of the time.

Research Question Two: Teacher’s Reported Reasons for Adapting

While the teachers were asked how they adapt supplemental activities to fit the needs of their students, the four overarching categories regarding teacher responses did not all relate specifically to student needs. The four categories were 1) Adapted for different learning needs;

2) Adapted for classroom implementation; 3) Adapted for mathematics content; 4) Adapted for visual appeal. Keywords and definitions for each of these categories are provided in Table 1.

Table 1: Teacher's Collapsed Adaptation Categories with Keywords and Definition

Category (count, %)	Keywords	Definition
Adapted for Different Learners	English Language Learners Needs** Special Education Level of Difficulty** Easy/Hard/Difficult/Levels/ Rigor/Advance/Struggle Differentiation** Scaffold	The teachers adapted the activities to meet different learner needs.
Adapted for Classroom Implementation	Manipulatives Directions* Time Structure** Independent/Group/Partner /One-on-One/Centers Technology Video/PowerPoint/iPad/ Smart Board/Computer/Tech	The teachers adapted the activities by adding elements or taking elements away by altering the implementation of the activity in their classroom.
Adapted for Mathematics Content	Standards Common Core/ District/State Numbers* Content Alignment Curriculum	The teachers adapted the activities by adding elements or taking elements away to by altering the mathematical content.
Adapted for Visual Appeal	Format Font Design Size Picture/Image Visual	The teachers adapted the visual aesthetics of the activity.

*The keyword was coded in 10% or more of responses. **15% or more

Adapted for different learning needs. We found 64% (n=191) of the teachers reported adapting elementary mathematics to meet the needs of different types of learners. This category included teacher descriptions about adapting the online activity through differentiation or through making accommodations for students with special needs, often involving discussions of levels of difficulty. For example, a teacher stated that they adapted online mathematics activities by "Change[ing] level as necessary, add[ing] scaffolding and modeling" which we coded as adapting for different learning needs. Multiple teachers reported focusing adaptations on “increasing the rigor,” and others reported adapting “to differentiate.” Other teachers discussed adaptation for specific student groups (e.g. English-language learners (ELLs)) or based on cultural needs as seen in the following response, “I rewrite to provide access for English learners. I remove unnecessary language to assure that I am measuring math, not language. I also rewrite lame attempts at ‘multiculturalness,’”. Responses such as these highlight the main finding that these teachers are sensitive to their different learners’ needs both mathematical and outside of the mathematics itself and place these needs at the forefront of their minds when they consider how to adapt elementary mathematics activities they find on VPRs.

Adapted for classroom implementation. While not necessarily specific to student needs, we found that 45% (n=134) of the teachers reported adapting supplemental activities to adjust to the teachers’ facilitation or more specifically, how they would implement the activity in their classroom. Responses in this category included reported adaptations such as adding manipulatives, changing directions, modifying suggested timing, or changing the activity from individual to a group game. These examples show implementation changes that directly affect student engagement with the activity. For example, a teacher stated they adapted by, “adding follow up activities, or changing the directions.” Others teachers described changing methods of implementation to meet their teaching style or classroom structure such as the following teacher who described, “If it is a PDF, I may turn it into a Smart Notebook that I can utilize for whole group instruction,” or another teacher who reported adapting to “tie it [the activity] to a lesson or activity from our current math standard and another subject we might be studying, such as science, social studies, health, etc.” While there were additional responses similar to the previous two, the majority in the classroom implementation category related to changing implementation structure regarding directions such as “cross out questions” or “extending time” … and “print them on task cards for a game.” These examples show minor adaptations allowing the teacher to change a task to make it structurally work in their classrooms but also point to structural changes that they deem necessary to assist student learning and engagement.

Adapted for mathematics content. We found that 26.5% (n=79) of teachers reported adapting their supplemental materials specifically for the mathematics content. These teachers indicated they changed the specific mathematical ideas represented in the online activities. For example, one teacher stated that they, “Use larger or smaller numbers in place of what’s provided [or] use fractions or decimals instead of whole numbers.” These adaptations allow for the structure of the activity to be used across mathematical topics. Another teacher reported that they “change numbers to fit a more appropriate range for students” thus altering the mathematics specifically. Yet others reported changing the mathematics to make activities easier or more difficult depending on their students’ needs.

Teachers also identified changing content to address specific standards. A teacher stated that they adapted the activities for different standards, “to ensure alignment.” Teachers also indicated adapting activities by changing the style of questions that were presented. For example, one teacher stated, “I reformat questions so they align with the style of questions students will see on State tests.” Another teacher reported,

> The advertised grade level items I find online tend to be too easy for my grade level. If I go up a grade level those tend to not totally align with my state standards. Usually I can only use about 70% of what is provided [from VRPs].

These show teachers adapting the level of the mathematics content and the way questions are posed to students because of state or district requirements.

Adapted for visual appeal. The least common thematic category was adaptation for visual appearance accounting for only 22 teacher responses (7.4%). Responses in this category included teachers who described their adaptations regarding superficial aspects of the activities not related to content or implementation. For example, a teacher described changing "color to black and white" and another referred to making activities "more durable by laminating," and yet another, "Sometimes I retype it to make it in a format I like." One teacher provided reasoning for visual changes related to student needs; they explained that they adapted by adding "larger spacing, fonts and pictures. I made it easier for my students to see it and fill it in." Most of the responses in this category were accompanied by descriptions that fell into the other three categories as well, such as this one that explicates visual appeal along with adapting for different learners. Importantly, only two teachers, including the first one presented in this paragraph, only discussed adaptations based on visual appeal.

Overall. Many teachers provided short, simplistic responses when describing how they adapt their supplemental elementary math activities for their students' needs, but despite their brevity, the responses indicated an overlap between the four identified thematic categories of adaptation for many teachers. For example, one teacher described their adaptation process as, "Increase the rigor and retype it". Other teachers provided additional details, such as the following teacher who explained,

> I may make the activity whole group so everyone can benefit. I also will sometimes change or clear-up the directions. I find that I need to often increase the rigor. I use TpT [TeachersPayTeachers] a lot and there tends to be a 3-5 band that is often too basic.

This response was unique, not because of the overlap of various ways they adapt, but because the response provides rationale for the need to adapt the rigor.

Discussion

These results indicated that 99% of teachers identified some form of adaptation of their classroom activities. When asked how they adapt these activities to meet student needs, 64% of the teachers who responded indicated adapting elementary mathematics activities found on VPRs to meet the needs of specific learners, such as English-language learners or special education students. This is a promising result because research has shown online supplements can cause harm to certain students, with Polikoff and Dean (2019) specifically discussing this issue for ELLs and Harris et al. (2020) discussing supplements that embody racist ideas. These studies were for history and English supplements, but we find it encouraging that some elementary teachers report adapting for these specific learners for mathematics.

Many teachers discussed changing the implementation structure of supplemental activities which mirrors an often-cited reasons teachers provide for searching for supplemental activities (e.g. Sawyer et al., 2019a; Carpenter and Shelton, 2021) regarding searching to increase student engagement. Teachers also reported adapting the mathematics content. Given that the quality of elementary mathematics supplements themselves tends to be low (Sawyer et al., 2019b; Shapiro, 2021), it is good to learn that teachers are adapting the mathematics content. These results also mirror the finding that teachers (Schroeder et al., 2019) and preservice teachers (Schroeder & Curcio, 2022) often adapt supplemental resources to align with state or district standards. The findings seem to indicate that teachers are not finding what they want when searching for elementary mathematics activities on VRPs. We find it interesting and encouraging that teachers appear to be taking a critical stance when evaluating and selecting supplemental elementary mathematics activities and that they expect to adapt what they find to better meet the needs of their students.

Through this study, we have gained further insight into what teachers do with elementary mathematics curricular supplements they find on VRPs and the answer is that they tend to adapt these supplements prior to classroom implementation. We agree with Silver (2021) that "it is essential that we understand teachers' supplementation decisions in order to develop teachers who supplement skillfully and responsibly" (p. 17). We believe the teachers would benefit from training regarding mathematics supplementation that goes beyond how to search and includes information on the adaptation process, but also moves further and follows teachers to the implementation process of these supplemental activities.

Limitations

This research does come with limitations. For example, it must be noted that a teacher's perception of what an activity is suggesting to do in a classroom could be incongruent with the creators' intent for the activity. Because we did not have access to either the supplemental activities that the teachers originally found or to teachers' adapted supplemental activities, we are unable to compare. The research field could learn from a comparative study to learn whether or not teachers are, for example, successful at increasing the rigor of a supplemental activity or if an adaptation for a specific learner actual increases the student's learning. Finally, this investigation was conducted prior to the pandemic; it is possible that teachers' adaptation of supplemental activities has changed how they adapt elementary mathematics activities in their in-person classrooms. More research is needed in this area.

Conclusion

Teachers have become their own curators of supplemental curricular resources and part of this curation process involves adaptation. Our research suggests that, in general, teachers adapt the supplemental elementary mathematics activities they find on VPRs. They adapt for various reasons related to student support but the most reported reasons relate to different learners and classroom implementation. Given the wide variance of student needs and structural parameters within each classroom, adaptation seems perhaps inevitable for effective teaching, but more remains to be learned about how adaptations are enacted and the effects on student learning. We believe it would benefit teachers to be explicit about their adaptation processes and discuss it with fellow teachers as a way to provide more information to the overall VPR supplementation process.

INTERACTIVE DYNAMICS IN TASK-BASED CURRICULAR MATERIALS

Allison L. Gantt
University of Delaware
agantt@udel.edu

Given the importance of students' interactions to their opportunities to learn mathematics, I investigate the interactive dynamics that are encouraged in two U.S. high school task-based written curricular materials and the purposes for interaction that they communicate. I conduct a thematic analysis to organize the functions of dynamics that encourage students to interact with peers' ideas (e.g., through dialogue) and with their own ideas (e.g., through reflection). Peer-interactive dynamics in this sample focused on sense-making, negotiation, and comparison. Self-interactive dynamics focused on developing awareness of thinking, formalization of new algebraic ideas, exploration, and precise language. I discuss how patterns among these themes, across who interaction is designed for and across curricular materials, could generate future lines of inquiry connecting the design of curriculum to student learning.

Keywords: Curriculum, Instructional Activities and Practices, Metacognition

Written curricular materials can organize the landmarks of subject matter together with a plan for learners' thinking and development (e.g., Remillard & Heck, 2014); in other words, they can communicate intended opportunities to learn for students (Brown et al., 2009). The actualization of opportunities to learn mathematics, however, is strongly linked with the quality of students' *interactions* with mathematical ideas in the classroom (Cohen et al., 2003; Gresalfi, 2009; Haertel et al., 2008; Hiebert & Grouws, 2007). Because of the strong influence of written curricular materials on teachers' enactment and students' experiences (Choppin et al., 2018; Remillard & Heck, 2014), we could better understand how curriculum connects to learning by examining the interactions curricular materials encourage.

In the following paper, I present findings from an analysis of the types of student interactions recommended in two U.S. high school mathematics curricula (i.e., *interactive dynamics*). I chose to examine task-based curricula as their approach depends upon students' activity as a primary instructional method. I was guided by the following research question: *What functions can be ascribed to the interactive dynamics in teachers' guides of task-based curricula?* I begin with a review of what is known about the relationship between interactions and mathematics teaching learning and follow with a description of my method and results. I use these findings to exemplify some of the current purposes of interaction in task-based curricula, discussing some of the patterns in results and connecting with literature to recommend areas for future exploration.

Interactions in Mathematics Teaching and Learning

Hiebert and Grouws (2007) argue that opportunities to learn mathematics are generated through interacting and grappling with key conceptual ideas. In classrooms that center student discourse and activity, students may grapple as they engage their peers' contributions. Webb et al. (2014) found that students' engagement with one another's thinking (beyond giving explanations) was significantly related to student achievement. Moreover, they found that teachers' actions (namely, their follow-up questioning strategies) were influential in establishing a classroom where such engagement could develop. Research has shown, however, that even in classrooms with consistent discourse among students, not all students experience the same potential for interactions with peers' ideas (Gresalfi, 2009; Reinholz & Shah, 2018). These findings suggest open questions about how curricular materials could support and structure teachers to facilitate all students' high-level engagement with their peers' contributions.

Interaction that promotes learning in the classroom may not be limited to students engaging others' ideas; research has also shown the importance of students interacting with their own thinking around mathematics content (e.g., Cohen et al., 2003). Piaget's theory of reflective abstraction (2001), for example, suggests that a learner must engage with their own thinking after accommodating a new idea to encourage stable meanings. Furthermore, Jansen (2020) suggests that teachers play an active role in designing instructional structures that encourage consideration of how one's own ideas have changed over time and through experiences with revision and reflection. Although these interactions are considered to be central to teaching practice, studies have yet to explore how curricular materials might support or communicate particular strategies.

Method

To respond to my research question, I conducted a qualitative content analysis (Mayring, 2015) and accompanying thematic analysis (Terry et al., 2017) of the interactive dynamics constructed in teachers' guides of one unit each in two task-based curricular materials: *Illustrative Mathematics* (IM) and the *Interactive Mathematics Program* (IMP). I selected these texts as they each satisfied my conditions for a task-based curriculum: 1) the student-facing materials took the form of bounded activity with an established instructional goal (i.e., a task), and 2) the teacher's guide encouraged facilitation of student activity and dialogue as the primary mechanism of instruction (i.e., learning was framed as task-based). Moreover, the two curricula selected each contained an instructional unit focused on the same content. Specifically, I examined an instructional unit from each set of curriculum materials that encouraged students' work with standard form linear equations, systems, and inequalities ("Unit 2: Linear Equations, Inequalities, and Systems" in IM Algebra 1 and "Cookies" in IMP Year 2). This choice allowed me to account for variation in teacher's guide recommendations due to mathematical topic.

I analyzed the teacher's guide text surrounding a task. In IM, I considered each numbered activity within a lesson (except the cool-down) a task. In IMP, I considered each titled activity listed in the table of contents to be a task. I focused on the text for each task that was marked as an expected component of teacher's facilitation (e.g., "Activity Synthesis" or "Doing the Activity" sections). I omitted sections that were described as additional supports.

To begin my analysis, I first coded sentence-by-sentence within a task for *interactive dynamics*. I assigned this code if the teacher's text described enactment in a way that would explicitly encourage a student (or students) to respond to a contribution related to the algebraic content of the mathematical task. For example, a request for a student to share a content-related response to a peer's mathematical contribution would constitute an interactive dynamic; a request for a student to simply share an idea with the class would not (e.g., Webb et al., 2014).

After that, I assigned additional codes to sentences describing interactive dynamics. First, if the text expected a teacher to encourage their students to respond to their peers' ideas (e.g., a dialogue), I coded it as a *peer-interactive dynamic*. A response to students' own ideas (e.g., a reflection) would constitute a *self-interactive dynamic*. I also coded if an interactive dynamic encouraged teachers to engage *all* of their students or *some* of their students. If such engagement was not specified (e.g., the teacher asks a question to "students"), it was classified as intended for some students, as no structure was described that would ensure reaching all.

Once interactive dynamics had been catalogued in both curricula, I constructed themes from the data to identify patterns and relationships across and within codes (Terry et al., 2017). Through my themes, I sought to explore structures that were common and unique to each task-based curriculum and considered what they expressed about learning mathematics. In the results that follow, I describe and exemplify these themes. I note that these findings are preliminary.

Results

In my results, I characterize themes in the functions of peer-interactive and self-interactive dynamics in the sampled texts. Peer-interactive dynamics in this sample focused on sense-making, negotiation, and comparison. Self-interactive dynamics focused on developing awareness of thinking, formalization of new algebraic ideas, exploration, and precise language.

Peer-Interactive Dynamics: Sense-Making, Negotiation, and Comparison

In the teachers' guides of these task-based curricula, I found that peer-interactive dynamics directed toward *all* students emphasized understanding each other's ideas. Teachers' guide prompts in both IM and IMP encouraged teachers to facilitate *making sense of one another's solutions* (e.g., "Have students discuss their solutions in groups and try to understand one another's work," IMP, 2010, p. 25). In IM specifically, this sense-making process was always accompanied by a request for *reaching consensus around solutions*. For example, the "Launch" of one lesson gave teachers the following instruction:

> Tell students that when one student explains, the partner's job is to listen and make sure that they agree and that the explanation makes sense. If they don't agree, the partners discuss until they come to an agreement. (IM, 2019, p. 140)

As this quote shows, this peer-interactive dynamic centered a negotiation-based process (i.e., "discuss until they come to an agreement") and engaged all students with partners in the process. Peer-interactive dynamics reaching *some* students, however, occurred frequently in full-class discussions facilitated by the teacher and less commonly encouraged consensus-building. Rather, I identified one central theme in such peer-interactive dynamics: *looking for similarities and differences*. This theme was common across both curricula.

Examples of peer-interactive dynamics encouraging some students to look for similarities and differences ranged from short, general requests to more specific, task-focused requests. For instance, a prompt in IM encouraged the teacher, "After each student presents, ask if others solved it in the same way" (IM, 2019, p. 244). I note how this prompt, aimed to engage student volunteers, could be applicable across a variety of tasks. Other prompts, however, encouraged student volunteers in full-class discussions to center on "the variations among the graphs for each inequality" (IMP, 2010, p. 26) or "whether these equations all represent the same relationship" (IM, 2019, p. 53). In contrast, none of the peer-interactive dynamics described for *all* students (as shown above) were task-specific requests.

Self-Interactive Dynamics: Awareness, Formalization, Exploration, and Definition

Self-interactive dynamics reaching *all* students differed between IM and IMP texts. In the IM sample, self-interactive dynamics promoted *metacognitive awareness* for all individuals during full-class Math Talk routines. Math Talk routines encouraged students to engage a short series of mental math exercises to launch a central idea of the lesson. All Math Talks included the following instruction: "Give students quiet think time for each problem and ask them to give a signal when they have an answer and a strategy" (IM, 2019, p. 49). In this way, despite the full-class setting of the activity, IM encouraged all students to reflect on their own ideas and included a structure to support this behavior.

IMP, on the other hand, employed self-interactive dynamics of *developing new algebraic structures* for all students, which was strongly connected to the structure of the curriculum around a unit problem. In IMP, students begin the "Cookies" unit working an open problem and recording their progress; they then re-engage that problem at checkpoint moments during the unit as they build related mathematical ideas through other tasks. For example, students' first engagement with the "Cookies" unit problem asks teachers to "have groups use the inequalities to check that the combinations discussed earlier really do satisfy the constraints" (IMP, 2010, p. 4). This self-interactive dynamic for all students (through groups) could support students to transition from open strategies to the application of an algebraic structure (i.e., inequality statements), supporting their progress in the unit problem task.

I identified self-interactive dynamics reaching *some* students primarily in the form of questions the teacher could pose to individuals or the full-class during group work or discussions. Such questions were most often highly task-specific. Moreover, many of the themes for self-interactive dynamics reaching some students reflected the same themes reaching all students, falling again along curricular lines. IM continued to include prompts that encouraged *metacognitive awareness* (e.g., "How do you know that the expression gives us the liters of water in Tank A after *m* minutes?" IM, 2019, p. 165). IMP continued to include prompts directed toward *developing new algebraic structures* (e.g., "Encourage students to keep plotting points…until they realize that the boundary between satisfying the inequality is the line corresponding to the equation P + I =140," IMP, 2010, p. 19).

However, I also interpreted new themes in the samples of self-interactive dynamics reaching *some* students: namely, *exploring current algebraic structures* and *defining terminology and concepts*. Exploring current algebraic structures could be found in both curricula, encouraging students to investigate, apply, or interpret the situations and structures of the problem (e.g., "Ask whether there is any way to adjust the statement 4(-2) > 3(-2) to make it true," IMP, 2010, p. 9). Defining terminology and concepts, on the other hand, was most salient in IM: "If students refer to edges and vertices as 'lines' and 'points,' ask if they remember the 'math names' for these things" (IM, 2019, p. 51). As the example illustrates, these self-interactive dynamics in IM pressed students who used these terms to interact with ideas to develop precise language skills.

Discussion

My findings highlight how two task-based curricular materials communicate the functions of students' interactions in the classroom, both with students' peers' ideas and their own. Collectively, these findings illustrate what interactive dynamics can be designed to achieve with students; they also generate new questions about how interactions can be structured to support all students' opportunities to learn. I described that, although peer-interactive dynamics for all students encouraged general understanding and negotiation, dynamics for some students encouraged comparison in task-specific scenarios. Given that opportunities to learn may be experienced differentially across classrooms (e.g., Gresalfi, 2009), this finding suggests a factor of influence and leverage. Future research could investigate how peer-interactive dynamics in curricula could support goals of both sense-making and comparison through structures that support all students to engage with specific mathematical ideas.

Self-interactive dynamics, on the other hand, differed by curriculum, suggesting that interactive dynamics may also support curricular priorities. IM emphasized building students' metacognitive awareness and precision of mathematical language. IMP strived to leverage students' own ideas to build new algebraic structures. Future study could examine the relationship between these interactive goals and teachers' enactment (e.g., Brown et al., 2009) and students' ultimate experiences of opportunities to learn in the classroom. By examining the intentions for interactive dynamics in written curriculum, we can better understand how to design support for the interactions that occur during student learning.

HOW THE TEACHER AND STUDENTS IMPACT THE UNFOLDING OF MATHEMATICAL IDEAS ACROSS A LESSON

Amanda Huffman	Leslie Dietiker	Andrew Richman
Purdue University	Boston University	Boston University
huffma33@purdue.edu	dietiker@bu.edu	asrich@bu.edu

By highlighting the curriculum modifications that lead to maintaining, or enhancing, the mathematical quality of an algebra lesson introducing the substitution method for solving systems of equations from an algebra textbook, we present an analysis of how a teacher and her students impact how the mathematical ideas unfold across the lesson and how they are experienced. Using a narrative-based analytical approach to write the stories of the written and enacted lessons, we found key similarities and differences in the lessons. In comparing the mathematical plots, we found evidence of how the teacher and students alter the unfolding story with the incorporation of more jamming than seen in the text and more questions developed based on the students' needs and their responses.

Keywords: Curriculum; Teaching Practice; Algebra and Algebraic Thinking

Research has demonstrated that teachers combine pedagogical practice, contextual factors, and the curriculum when teaching a lesson (e.g., Remillard & Heck, 2014). Teachers make pedagogical and contextual decisions (e.g., restricting calculators) based on the needs of their students, the context of learning, and their own prior experiences. While the text offers resources for the lesson and can certainly impact the teacher's instruction and students' learning (Remillard et al., 2014), what happens in the classroom often appears quite different than what the textbook authors intended since the actions of both teachers and students are influenced by a variety of prior experiences, goals, and perspectives. Ben-Peretz (1990) refers to the set of intended and unintended curricular uses of written curriculum materials as *curriculum potential* and describes the subset of these that are viewed favorably by its authors in the *curriculum envelope*. This theoretical framing implies there are a range of appropriate and beneficial interpretations and uses of all written curriculum materials.

However, there is little understanding of the ways in which lessons can vary within the curriculum envelope. Therefore, in this study, we illustrate how complex interactions between teachers and students in an enacted lesson shifts how the lesson unfolds while still drawing from the elements of the textbook lesson and maintaining its overall intentions. We present the case of one enacted algebra lesson implemented to a group of students from a set of written materials that were explicitly designed to increase the mathematical quality of courses by providing students access to rich, conceptually connected mathematical ideas. In this case, the enacted lesson maintained (or even enhanced) the mathematical quality of the lesson as written and thus is within the curriculum envelope. By highlighting the curriculum modifications that lead to maintaining, or enhancing, the mathematical quality of the written materials (e.g., its aesthetic opportunities, rigor), we begin to address the research question: *In an enacted lesson that is within the curriculum envelope, in what ways can the teacher and students impact how the mathematical ideas unfold across the lesson and how they are experienced?* We present a new methodology to comparing enacted and written curriculum that focuses not only on content, but also on how the content unfolds across the lesson. This comparison allows us to see how enacted lessons can maintain or even enhance the mathematical quality of the lesson for students and could reveal potential strategies for taking advantage of the design of the curriculum.

Theoretical Framework

To compare mathematics lessons how mathematical ideas unfold, we interpret the lessons as a form of narrative. Similar to how literary stories can captivate a reader by the withholding and revelation of information (Nodelman and Reimer, 2003), mathematics lessons can similarly structure how information emerges, enabling curiosity and encouraging a reader to build interest in learning more (Dietiker, 2015). A *mathematical story* is a metaphorical interpretation of how the mathematical ideas unfold across a lesson, connecting the beginning with the end. Note, however, that mathematical stories are not limited to contextualized word problems, but rather describe the twists and turns of the mathematical revelations throughout a lesson. As with literary stories, mathematical stories have characters (i.e., mathematical objects, such as algebraic expressions) that are manipulated and changed through *action* (i.e., mathematical transformations, such as substituting an expression to make an equivalent equation). In addition, these mathematical characters and actions play out in one or more mathematical *settings* (i.e., the representational space, such as symbols on paper or manipulatives) (Dietiker, 2015).

In a literary story, the text communicates via a narrator, and its interpretation focuses on how the text communicates to a reader in ways that are both logical (i.e., what makes sense) and aesthetic (i.e., what it makes a reader feel) (Bal, 2009). Mathematical stories in written curriculum materials operate similarly; the text narrates the story, and it can be read for how it communicates to potential readers—who in this case are teachers and students. Reading a written mathematical story for how it communicates requires identifying how the mathematical ideas, which are assumed to be unknown from the start, emerge and change as the story proceeds. For example, if a new definition or a theorem is presented that has not yet entered the story, it is interpreted as a new revelation even if it is already familiar to the researcher.

Enacted mathematical stories (i.e., those that unfold within classroom) also have narrators and can be interpreted by how the mathematical ideas emerge and change across a lesson. However, in this case, the narration occurs both by the written curriculum (e.g., when a task is read from a worksheet) or by a human (e.g., when a teacher introduces a topic or when a student describes how they solved a problem). Thus, enacted mathematical stories are more like guerilla theater, where the teachers and students are both actors and audience members contributing to and experiencing the story (Dietiker et al., in progress). The teachers in enacted mathematical stories can also have a role in *storytelling*, as they may have specific intentions for how the mathematical story will progress, which impacts their decisions in the moment. For example, when a student raises a new mathematical idea that alters what is known at that point in a story, the teacher can choose what to do with that information (e.g., suppress, elaborate) based on how they want the mathematical story to progress.

The way a mathematical story unfolds has a potential aesthetic impact on its readers, what we refer to as its *mathematical plot*. A mathematical plot "describes the aesthetic response of a reader as he or she experiences a mathematical story, perceives its structure, and anticipates what is ahead" (Dietiker, 2015, p. 298). The way in which the mathematical ideas play out over time can spur curiosity in a reader, leading them to pose new questions (e.g., asking *how can that be?*) and seek information (e.g., recognizing that two equations are equivalent) that answer them. As new facts are revealed, a reader has an opportunity to make progress on what is known about the questions they have adopted at that point in the story. According to literary theory, stories that offer numerous sustained questions simultaneously are more compelling (Barthes, 1974). The transition of what is known about a question, from when it opens to how it is answered is referred to as a *story arc*. A story arc can be short-lived when a question is answered quickly after being asked, or can be longer when a question remains unanswered and is still in consideration throughout portions of the lesson. Since some questions may never be resolved, some story arcs may remain open at the end of the story. Others may be abandoned when it is clear to a reader that the story has moved on. With multiple story arcs open, a student may sense a growing mystery, while a decrease may cause a reader to sense relief (Dietiker, 2015).

Methods

This study is part of a larger exploratory study that initially examined the different ways experienced (i.e., more than five years of experience) Algebra I teachers enacted the same textbook lessons. Using the mathematical story framework, this study compares one teacher's enacted lesson juxtaposed with the written lesson through a narrative-based analytical approach. In this section, we describe the context of the written and enacted lessons and describe how we interpreted and compared their mathematical plots. Note that we share our interpretations and they may vary from other groups completing this same process. Therefore, a key to this analysis is that both the written and enacted stories were analyzed using a consistent process. Our interpretation of these mathematical stories represents a consensus of a diverse mixture of mathematics education researchers, practicing teachers, mathematicians, and graduate students, and thus were informed by a mixture of perspectives regarding curriculum, mathematics, and teaching. Our interpretations represent a *potential* interpretation of a novice learner, as we took into consideration the story's previous revelations while setting aside our prior knowledge.

Sources of Data

The written lesson in this study, Lesson 4.2.1 from the *CPM Core Connections Algebra* textbook (Dietiker et al., 2006), introduces the substitution method for solving a system of linear equations. All elements of the lesson as provided in the teacher's edition were analyzed, which includes the student-facing materials (i.e., tasks, explanations) and suggestions to the teacher.

The enacted lesson, which was based on lesson 4.2.1 from the *CPM Core Connections Algebra* textbook (Dietiker et al., 2006), was observed in Ms. Turner's (all names are pseudonyms) Southern United States high school Algebra I course for special education students during the Fall of 2015. Ms. Turner's classroom consisted of six students, all of whom were Black, seated in small groups. The lesson was videotaped using three cameras: one facing the front board and two facing the students. In addition, audio recorders were placed on student desks about the room. The main video recording facing the front board, along with the audio recorders, was used to build the lesson transcript.

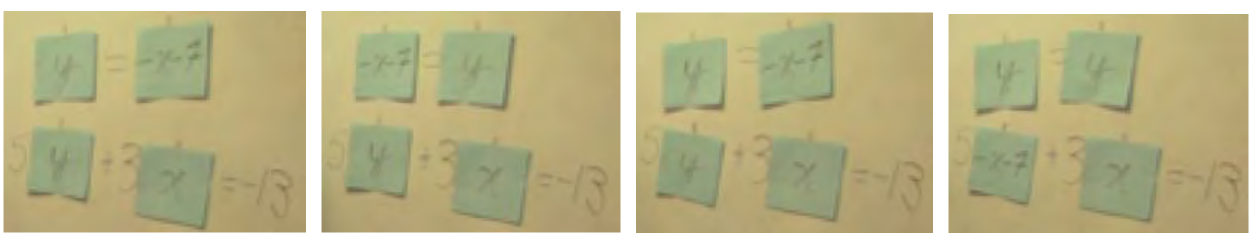
Ms. Turner, who is White, was in her 19th year of teaching and was selected to be observed for this study based on her expertise. For six years prior to this study, Ms. Turner led professional development for mathematics teachers in addition to coaching fellow teachers in her district for the previous seven years. Prior to the observation of this lesson, Ms. Turner was interviewed for information on her school demographics, her goals for the lesson, and her anticipated challenges during the lesson. According to Ms. Turner, from the pre-interview, the learning goal for this lesson was for students to rewrite the two equations with two variables as a single equation in a single variable by using a suitable substitution expression. After the observation, she was interviewed again about her reflections and was asked to discuss her curricular decisions that were made throughout the lesson.

The Written Mathematical Story

The lesson begins with the students solving the system $y = -x - 7$ and $5y + 3x = -13$ using a method that was introduced in a prior lesson, namely, the *equal values method* (i.e., a process that involves solving each of two equations for the same variable and then setting the two resulting expressions equal to each other). After providing the students a few minutes to solve the system of equations, the teacher is encouraged to stop the students and launch a discussion about whether it would be useful to have an easier method. A task then introduces the substitution method for the same system of equations, and the teacher is encouraged to use strips of paper with parts of the expressions to build the equations to aid in a discussion of the logic of the new method. Four more systems of equations are then given for students to solve using this new method. One of these results in a new situation (i.e., no solution). The lesson concludes with the task prompting students to figure out a way to know if the solution of a fictional student is correct or not.

The Enacted Mathematical Story

Ms. Turner started the lesson by reviewing the equal values method. She then prompted students to solve a system of equations (i.e., $y = -x - 7$ and $5y + 3x = -13$) with this method. After the students struggled to solve the problem for a few minutes, Ms. Turner stopped the students and offered a new method to the students with a reasoning of why this new method was beneficial (i.e., you can avoid ugly numbers). Using the paper switching method described in the teacher's guide, Ms. Turner introduced the students to the substitution method. Figure 1 shows the paper switching process with (a) the original system of equations formed by cards and symbols, (b) the system after switching the cards in the top equation, (c) the same systems with the *y* cards switched in the top and bottom equations, and (d) the same system after switching the bottom *y* card with the $-x - 7$ card in the top. Before Ms. Turner even started through the process one student indicated insight, but she quickly quieted the student. She continued to guide the students through the substitution method with the paper switching visual. After "showing her (Ms. Turner's) magic" (i.e., the substitution method), the students practiced solving two more systems of equations using their new method.



(a) (b) (c) (d)

Figure 1: Paper switching process.

Interpreting the Mathematical Story and Plot

In order to analyze and compare the mathematical plots of the written and enacted lessons, the researchers analyzed each portion of both stories for opportunities for new understanding. To interpret the stories, we analyzed the text of the story; the text of the written lesson included the suggested components of the lesson in the teacher's guide including all tasks and statements, while the text of the enacted lesson was the transcript from the classroom.

Analyzing the mathematical plots required three passes through each text. Each pass was first performed individually and then the group of researchers met to resolve differences. First, the researchers divided the text into agreed upon *acts*, where each act represented a portion of the story during which the mathematical story advanced and different acts were marked by changes in the mathematical characters, actions, or settings. Second, the researchers identified all the questions raised, either explicitly or implicitly, by the curriculum, teacher, or students in the text.

Third, we used Barthes' (1974) codes to describe the transition from question to answer and any suspense or surprise in between: *question formulation, promise of an answer, snare* (misleading information), *jamming* (unanswerable question), *suspension* (delayed answers), *partial answer* (progress), and *disclosure of the answer* (endorsing the answer).

With both the written and enacted mathematics lessons coded for their mathematical plots, the researchers analyzed how the mathematical plots of the written and enacted stories were similar and different.

Findings

The mathematical plots, which reveal how the stories unfolded in the lessons, are provided in Figure 2 (as written) and Figure 3 (as enacted). The acts (in columns) are presented in order from left to right, while the mathematical questions are listed in the order they emerged in the left column. The shaded cells, representing the story arcs, contain letters for Barthes' (1974) plot codes, where a: Question by Teacher or Environment, b: Question by Student, c: Promise, d: Progress by Teacher or Environment, e: Progress by Student; f: Snare, g: Jamming, h: Suspension, and i: Disclosure.

Figure 3: The Mathematical Plot of the Enacted Lesson.

In comparing the mathematical plots, we found evidence of how the teacher and students alter an unfolding story within the curriculum envelope for the benefit of student experiences. Specifically, we discuss three shifts in the enacted mathematical story: (a) additional jamming by Ms. Turner's added questions and interactions with her students, (b) Ms. Turner's students' increased engagement through her verbal declaration of knowing what mistake her student was about to make and evidence of her understanding of her students and the rapport she has built with them, and (c) added questions asked by the teacher in response to her students' needs while addressing the algebraic processes of solving the systems of equations.

Added Jamming in the Enacted Story

In the enacted lesson, specifically in Act 5, Ms. Turner's actions of posing the problem to solve a system of equations (i.e., $y = -x - 7$ and $5y + 3x = -13$) using the equal values method created multiple instances of *jamming*, or an experience where you think you are going to get an answer and then the story threatens and drops hints that you may not get the answer. Both the written lesson Question 5 and the enacted lesson Question 4 (*What is the solution to the system of equations* $y = -x - 7$ and $5y + 3x = -13$*?*) created a similar instance of jamming as the posed problem became too messy to solve. However, Ms. Turner added additional questions around this problem which added more jamming to the enacted story:

3	How do you solve a system of equations with the equal values method?
8	How do we isolate *y* in the equation $5y + 3x = -13$?
10	How do we use algebra tiles to help us solve equations?
12	What does that student mean by "you put it in the place of the *y*"?

That is, these additional questions (i.e., Question 3, Question 8, Question 10) offered support for her students as they tried to solve the given system of equations using the equal values method. Then, when Ms. Turner stopped the class as the problem became too messy, abandoning the equal values method to solve the given system of equations, this simultaneously disrupted Question 3, Question 4, and Question 8. As Ms. Turner moved on to introduce the substitution method, Question 12 was introduced by a student, but this question was quickly jammed in order for Ms. Turner to walk through the entire process of the substitution method step-by-step with the paper switching method.

During the paper switching demonstration, beginning in Act 5, another element of jamming occurred as one student quickly picked up on what to do. Ms. Turner stopped the student from sharing his complete thought, to continue explaining the process and to ensure the other students followed the substitution method. Ms. Turner enabled this aesthetic moment in her classroom by deciding in the moment to quiet her students' *aha* moment, as the other students in the class would benefit from a guided introduction to substitution. After Ms. Turner explained a little more, she returned to the student who was eager to share and quickly saw how the substitution method worked when doing the paper switching visual provided by the curriculum. These added elements of jamming and Ms. Turner's deviations enhanced the lesson for her students while providing her students access to rich, conceptually connected mathematical ideas as the author(s) intended in the written lesson.

Predicting a Student's Error in the Enacted Story

In Act 11, Ms. Turner's response, "I guarantee you've made a mistake and I'll eat my words if you didn't," while the students are solving for y to finish solving the system of equations after as a class they found the value for x created question 23. Question 23, *What mistake is she predicting?* is not in the written lesson, but enhanced the lesson as Ms. Turner knew what her student was going to do. This student had mixed up the double negative in the problem, and this student action led to the formulation of Question 26, *What is -x when x is negative?* These two questions were added to the enacted story based on the teacher's predictions and the student's mistake. Again, these questions were created in the moment and based on the context of the lesson and Ms. Turner's students, something not seen in the written story.

Additional Questions to Solve the System in the Enacted Story

In the enacted story, Ms. Turner also added questions not found in the written story. These added questions supported the students as they worked to understand the substitution method and solve systems of equations, as the students needed reminders and guidance in solving the equation for one variable once they made the substitution (e.g., reviewing the distributive property). These additional questions demonstrate how Ms. Turner's pedagogical practice and contextual factors impacted the enacted lesson. The first occurrence of added questions is at the very beginning as Ms. Turner guided the students in recalling the equal values method from the previous lesson. Ms. Turner added the following questions:

6	Can I set these two equations equal to each other and start solving?
7	What do we need to do to one of these equations to solve with equal values?
8	How do we isolate y in the equation $5y + 3x = -13$?
9	What should I do with -13 and -3x, and why?
10	How do we use algebra tiles to help us solve equations?

These additional questions helped students to start solving the system of equations. These questions were not raised when the written substitution lesson was analyzed, since both the equal values method and how to solve an equation for one variable were presumed prior knowledge. Seeing Ms. Turner's introduction of these questions indicates the need for the students' prior knowledge to be recalled as a class. This also demonstrates how Ms. Turner knew her students and the context of the lesson and made adjustments to meet them where they were in supporting their development of the substitution method.

This is not the only time Ms. Turner added additional questions to the enacted lesson. The next occurrence was seen when guiding the students through the substitution method. Ms. Turner added additional questions (i.e., Questions 18 - 21) to assist the students in solving the system of equations using substitution. Ms. Turner even referred back to a visual representation, algebra tiles, and also discussed the distributive property while solving the equation for x after substituting in the expression for y. These added questions made the lesson fit the students and allowed the students to engage in the rich mathematical task.

18	How do we solve this new one variable equation?
19	Why do we have to use the distributive property?
20	How do I multiply 5 by $-x$?
21	How do I solve $-2x=22$?

Discussion

Our findings reveal how, in the enacted lesson, the teacher's questioning and the questions and responses of the students altered the story of the written lesson while still maintaining its overall intentions. The students' needs were known by the teacher and the students' responses and actions (i.e., "I already know what y is", forgetting a negative) enhanced the lesson. Ms. Turner's use of the introductory problem, the paper switching visual, and the practice problems showed her use of the curriculum when teaching the lesson, while the added jamming, prediction of a students' error, and added questioning demonstrated Ms. Turner's use of pedagogical practice and contextual factors when teaching the lesson. These experiences enhanced the lesson for these students and allowed these students to complete the mathematical task and learning goal envisioned by the authors. Ms. Turner's crafting and improvisation of the lesson in the moment supported the written lesson.

Through our narrative-analytical approach, we illustrated how complex interactions between a teacher and students in an enacted lesson shifted how the lesson unfolded while the lesson still drew from the elements of the textbook lesson. We demonstrated how one enacted lesson maintained, and even enhanced, the lesson for the students. Additional research is needed to highlight other enacted lessons also maintaining, and possibly even enhancing, the written lesson. Additionally, further research is needed to explore how to support teachers in recognizing the potential strategies of implementation that take advantage of the design of the curriculum materials so that more enacted lessons maintain or enhance the mathematical quality for students.

MATHEMATICS EDUCATION DESIGN PRINCIPLES TO BUILD AN EVIDENCE BASE FOR FRACTION INTERVENTION

Jessica H. Hunt, Ph.D.

Kristi Martin, Ph.D.
Sam Houston State University
Kxm138@shsu.edu

We report the results of the second of two pilot studies from an intervention designed and developed based on a validated trajectory of students' fraction concepts. Results suggest that designing and developing interventions that draw upon practices based in mathematics education and theory (e.g., utilizing students' own problem-solving actions, basing activities on learning trajectories, and supporting students to notice and discuss their problem-solving strategies) was an effective means of bolstering conceptual understanding and performance for the students we learned from in this work.

Keywords: students with disabilities; curriculum, equity, inclusion, and diversity.

Designing fraction instruction to meet the needs of diverse learners is a challenge facing educators today. One need often outlined in the literature is designing and testing curricular materials that build conceptual understanding, especially for students with learning difficulty (MD) and learning disability (LD). Observed performance differences that students with MD experience are concerning because conceptual knowledge mediates differences in overall performance in fraction skills between students with and without MD (Vukovic, 2012). Yet, we contend that the inadequate progress is likely the result of an opportunity gap caused not by a lack of knowledge or sub-optimal cognitive ability but instruction that does not provide these students access to their conceptual capacities or advance their understanding.

One innovative approach to bolstering access and advancement of conceptual knowledge of fractions is the use of learning trajectories as a grounding for intervention design and innovation. Learning trajectories include a goal, developmental stages of thinking, and activities designed to explicitly promote the stages of thinking to bolster concepts of fractions (Clements et al., 2020). Unfortunately, although basing instruction on learning trajectories is often recommended, "there is little direct evidence to support this approach" (p. 3).

We report the results of the second of two pilot studies (see Hunt et al., 2020) from an intervention designed and developed based on a validated trajectory of students' unit fraction, partitive fraction (i.e., non-unit fractions less than one), and iterative fraction (i.e., non-unit fractions greater than one) concepts. The research questions for this study are: (a) To what extent does a supplemental fraction intervention implemented in a school intervention setting and based on trajectories of students' fraction learning demonstrate evidence of increased student outcomes, defined as conceptual advance evidenced by units coordination, for students with LD and MD? And (b) Is there a statistically significant increase in score on a standardized measure of fractional concepts and operations after participating in a supplemental fraction intervention implemented in a school intervention setting for students with LD and MD?

Conceptual Framework

The learning trajectory utilized in the current study addresses the concepts of fractions as a coordination of units. Units coordination is defined as the number of units children can bring into fraction problems to think and reason with (Hackenberg et al., 2016) and involves the processes of partitioning, iterating, and the eventual combination of partitioning and iterating into a single process (Hackenberg, 2007; Norton & Wilkins, 2010; Wilkins et al., 2013). Partitioning is the mental or enacted action of dividing a unit into equal-sized parts. As students become more fluid with partitioning, they can mentally pull out a created fractional unit from the whole and understand it in relation to the whole without destroying the whole. They begin to iterate, or repeat, the fractional unit to make larger units (e.g., use $\frac{1}{3}$ to make $\frac{2}{3}$).

At first, students make sense of larger fractional units within the bounds of the whole (two-level units coordination). Over time, students will learn to combine partitioning and iterating into a single process called splitting. Splitting involves anticipating the results of partitioning a whole concurrently with iterating a fractional unit (Hackenberg, 2007; Norton et al., 2018). When students can split, they can understand larger fractional units outside of the bounds of a whole (three-level units coordination). Students will often combine the two processes sequentially before combining them into a single operation. We hypothesized students with LD could utilize similar processes to build a concept of fractions toward the learning goal, "Fractions are numbers that have magnitude determined by the coordination of the numerator with the denominator."

Methods

Participants and Data Sources

The pilot study took place in one suburban elementary school located in the Southeastern United States. The school enrolled approximately 1,050 students: of these students, 5.1% received special education services and 75.8% were from underrepresented groups. Students were selected based upon five criteria: (a) currently in fourth or fifth grade, (b) previously identified as requiring at least Tier II intervention in mathematics in response to sustained low performance and poor progress on grade-level curriculum, (c) have a weakness is fraction concepts and applications as identified by the classroom teacher, (d) performance of less than 30% on a screener of fraction concepts from the state's end-of-grade test, and (e) provide information parental consent and student assent. When students who met the criteria were identified, the school selected participants.

The process yielded a total of 10 students – two of whom received Special Education services (LD) and four who received 504 or Tier 3 services for math difficulty (MD) - participated in the study. These 10 students comprised two intervention groups, with five students in Group 1 and five students in Group 2. Of the 10 students, three were females, seven were males, nine were People of Color, and one was White. Students were between nine and 11 years of age. Intervention attendance for the nine out of the 10 students was high (100%).

Our intervention was designed to support the fraction learning of students with LD. Yet, schools often include both students with LD and MD in supplemental mathematics instruction. We included students with LD and MD to match school norms and procedures.

Data sources for conceptual advance included video data, accompanying student work, and researcher field notes for each session. For performance change, 16 items pulled from the 2018-2019 North Carolina Department of Public Instruction (DPI) released third, fourth, and fifth grade End-of-Grade (EOG) Exams were used as a distal measure of performance because they measured the Number and Operations Fraction Standards students were assessed upon across elementary school. The measure was also group-administered and included six items measuring third grade standards, two items measuring fourth grade standards, and eight items measuring fifth grade standards. Internal consistency ranged from 0.90 to 0.94.

Study Design & Data Analysis

A one phase, mixed methods quasi-experimental approach drove this research (Creswell & Plano Clark, 2018). Qualitative data were considered primary in the design, consistent with the study emphasis on changing students' conception and appropriate with small sample sizes.

Data analysis to detect conceptual change was done on several levels. First, constant comparison methods (Leech & Onwuegbuzie, 2007) and classical content analysis (Grbich, 2007) were used to document and quantify students' partitioning and iterating processes within each problem for each student. Researchers examined each student's (a) partitioning and iterating actions used to solve each problem (b) the student's utterances as they solved problems along with how they named, or quantified, their solution, (c) whether the student appeared to have a plan/strategy before having to act, and (d) any observable evidence related to the student's units coordinating. We used peer debriefing and collaboration to search for evidence that confirmed or refuted claims made across the data to build reliability and validity in the coding process. We had 86% interrater reliability for individual analyses of codes across the entire set. Researchers then quantified the number of occurrences for each code (e.g., how many times partitioning was observed) by dividing the totals by the total number of all codes.

Second, researchers used emergent coding to document how students' observable processes across the tasks and after the second, fourth, sixth, and tenth instructional sessions were or were not consistent with the stages of units coordinating learning trajectory confirmed in previous years of the project. Generally, researchers looked for evidence of the stages of units students could either (a) describe before activity in the problems or (b) used with activity in the problems. The analysis was iterative and included multiple perspectives to make confirmatory claims about patterns in the data consistent with conceptual advance. We established 100% interrater reliability after peer debriefing and collaborative work. Finally, to detect initial differences in performance on fraction state standards as a result of the instructional trajectory (i.e., before and after the intervention within the same group of students), a one-tailed paired sample t-test was used to evaluate statistically significant differences on the distal measure. The IV was time; the DV was score. The level of significance was set at 0.05.

Results

Three nuances in partitioning consistent with our learning trajectory were coded across the intervention sessions: (a) In action halving (i.e., students engaging in halving strategies in the midst of problem-solving), (b) In action linked (i.e., students engaging in partitioning linked the number of sharers in the midst of solving problems), and (c) Before action linked partitioning (i.e., students describing a partitioning plan that was linked to the number of sharers before solving the problem). After session two of the intervention, 56% of students used in action halving-based partitioning, and 23% and 21%, respectively, used in action planned or before action linked partitioning. After Session Four, 11% of students continued to use in action halving-based partitioning, 34% of students used in action linked partitioning; before action linked partitioning (55% of students) became the dominant method. After the eighth session, only 23% of students were in action partitioning. The final session showed a slight uptake in students' use of in action (33%) versus before action (67%) partitioning. The two students with LD both started the intervention using in-action halving partitioning. After session two, one continued to use in-action halving while the other progressed to in action linked partitioning. After session six, both progressed to and consistently used before action linked partitioning. Increased use of sophisticated partitioning alongside decreases in rudimentary partitioning showcases growth.

The forms of iteration uncovered and coded in the analysis were (a) in action trial and error (i.e., students created an equal share and did not correctly adjust it longer or shorter), (b) in action adjustment (i.e., students created an equal share and corrected adjusted its magnitude) and (c) planned (i.e., students accurately created an equal share and used iterating to confirm the part as $\frac{1}{n}$). After Session Two, 45% of students used in action trial and error iteration, 55% used in action adjustment, and 0% used planned iteration. After Session Four, the percentage of students using in action adjustment for iteration increased to 34%, and students using planned iteration increased to 22%, and the use of in action trial and error iteration was relatively unchanged (44%). After the eighth session, trial and error iteration was used by only one student (11%), while in action adjustment and (44%) planned (45%) iterating was dominant. Both students with LD began the sessions iterating in action trial and error. After session four, one student progressed to a stable use of planned iterating for the remaining sessions. The other student evidenced planned iteration in the tenth session.

Advances in units coordination emerged in the data that were consistent with students' advances in conceptual processes. After Session 4, most (89%) of students coordinated two levels of units in action (i.e., had to act within a problem to think about fractions as coordinated in magnitude with a whole), while one student (11%) came into the problems coordinating one level of units. After Session 8, students who bring in two levels of units into problem activity increased to 33%; students coordinating two levels of units in action fell to 56%. In the final session, 67% of students (inclusive of both students with LD) brought two levels of units into the problems. Process advances and units coordination mark students' conceptual advances.

A paired-samples t-test was conducted to compare performance score on a distal measure of students' fraction knowledge before and after participating in the instructional trajectory. A histogram confirmed the normality of the data. There was a statistically significant difference in group scores from pre-test ($m = 4.56$, $sd = 2.07$) to post-test ($m = 6.78$, $sd = 3.87$), $t = 2.23$, $p = 0.03$. Our results suggest that engaging in our fractions intervention positively impacted students' performance. When examining the performance of the students with LD on an individual basis, there was a statistically significant difference in scores from pre-test to post-test, $t = 2.24$, $p = 0.03$ and $t = 7.85$, $p < 0.0001$, respectively, for both students. Our results suggest that our intervention also positively impacted the performance of students with LD.

Discussion

Very few studies in mathematics education or special education evaluate the effectiveness of student-centered interventions based on mathematics education instructional practices and theory on improving student outcomes (see Hwang et al., 2019; Shin & Bryant, 2015). We provide evidence regarding an intervention designed and developed based on a validated trajectory of students' unit fraction, partitive fraction, and iterative fraction concepts (Hunt et al.., 2020). Designing and developing interventions that draw upon practices based in mathematics education and theory (e.g., utilizing students' own problem-solving actions, basing activities on learning trajectories, and supporting students to notice and discuss their problem-solving strategies) was an effective means of bolstering conceptual understanding and performance for the students that we worked with in this study. More work is needed to substantiate our findings.

Traditionally, mathematics is taught without a connection to the real world which makes it abstract and difficult for students to understand, thereby resulting in low mathematics achievement. This study investigated the learning experiences of Grade 8 students as they participated in project-based learning (PBL) as part of an interdisciplinary mathematics education (IdME) unit of study. Qualitative data were collected in the form of student self-reflections and interviews. Findings suggest that students were able to improve their mathematics knowledge and understanding by implementing mathematics concepts in real-world contexts. We argue that students not only understand mathematics better but also realize its importance as a discipline when it is taught through real-world projects.

Keywords: Instructional Activities and Practices, Middle School Education, High School Education, Integrated STEM / STEAM

Mathematics knowledge and processes are used in everyday life. Furthermore, skills developed through engaging with mathematics, such as logical thinking and problem solving, are critical in tackling complex global problems of the 21st century. Despite the importance of mathematics in our society, Canadian secondary students' mathematics achievement is declining (Allison & Geloso, 2021). A majority of the students find mathematics education vague, abstract, and detached from reality and real-life situations (Mosvold, 2008). Indeed, in secondary schools, mathematics has traditionally been taught without any connection to other subjects (Chi, 2021) despite curricula calling for interdisciplinary approaches to teaching and learning (e.g., Ontario Ministry of Education, 2016; Québec Education Program, 2001). Moreover, there is a dearth of literature that provides concrete examples and evidence of mathematics being taught in connection to other subjects, especially in the context of Canada. This paper presents a case of interdisciplinary mathematics education (IdME) being implemented in a Grade 8 mathematics course at a small, independent school in the province of Québec. Specifically, our study is guided by the following research question: How does IdME contribute to students' learning experiences with mathematics?

Perspectives

An interdisciplinary approach to teaching and learning involves curriculum organized around common learning across various disciplines where students learn concepts and skills that are common to two or more than two disciplines (Costley, 2015; Helmane & Briška, 2017). Specifically, in IdME, mathematics is taught in an interdisciplinary way (Chao-Fernández et al., 2019). IdME presents mathematics in a wider context (Chi, 2021), combined with one or more disciplines and everyday knowledge to encourage problem solving and inquiry (Williams et al., 2016). In IdME, mathematics can be combined with a wide range of disciplines including science, arts, or languages (Brante & Brunosson, 2014; Lovemore et al., 2021; Serrano Corkin et al., 2020). Studies indicate that IdME increases students' engagement (Madkins & Morton, 2021; Satterthwait, 2019; Serrano Corkin et al., 2020) and improves students' mathematics knowledge and understanding (Altin et al., 2021; Brante & Brunosson, 2014); both serving as crucial predictors of students' mathematical achievement.

A common approach for IdME is project-based learning (PBL)(Chi, 2021). PBL is an instructional method that allows students to engage with the content at a deeper level and bridge theory and practice (Condliffe, 2017). In PBL, students engage in complex tasks based on challenging questions or problems in authentic contexts (Bell, 2010; Laur, 2013). Students design, problem-solve, make decisions, and investigate topics of personal interest (Aydın-Günbatar, 2020; Lin et al., 2015). PBL helps students in "establishing conceptual associations between the learnt knowledge" (DemiRel, 2010, p. 48) and hence, improves their academic achievement in mathematics (Gürgil & Çetin, 2018). Indeed, a study by Holmes and Hwang (2016) found that students who initially had little belief in their mathematics skills "expressed mastery or learning goals" as result of engaging with PBL (p. 459). PBL has also shown to increase students' understanding of mathematics concepts by making students capable of applying mathematics knowledge to real-life situations (Boaler, 1997; Fain et al., 2015; Holmes & Hwang, 2016).

Research Context and Methods

The study took place within a context of a research-practice partnership with a small, independent girls' school in Québec. The Grade 8 mathematics teacher, Stephanie (all names are pseudonyms), was keen to integrate IdME into her teaching practice, and more specifically, used PBL as a means to achieving this goal. As such, she developed the "Lifestyles Project", comprised of three tasks: the Hobby, Careers and, Bedroom Design tasks. Tasks were purposefully interdisciplinary and designed in collaboration with teachers from other subject areas (science, English language arts, and visual arts, respectively). In the first task, students chose a hobby of personal interest and identified and explored science and mathematics concepts associated to the hobby. The second task required students to select a future career, find a job in this career, and calculate the salary that they would receive (given required tax deductions). In the final task, students designed a 3D, scaled model of the bedroom of their dream apartment considering mathematical constrains like size and surface area. Tasks were interspersed throughout the academic year, each spanning 2-3 weeks in length. Study participants were all of the students in Stephanie's Grade 8 mathematics course (*n*=16).

A qualitative case study method (Denzin & Lincoln, 2011; Stake, 2006), was used to explore the Grade 8 students' experiences with the Lifestyles Project. There were two sources of data for this study: 1) student self-reflections, and 2) student interviews. Students completed written self-reflection after most PBL classes to capture their experiences during the Lifestyles Project. Semi-structured interviews (Gubrium & Holstein, 2002) were conducted at the end of the year in which students were asked about their thoughts and feedback about the Lifestyles Project and IdME more generally. Interviews were audio-recorded and transcribed verbatim. Interview transcripts and student self-reflections were coded in a series of coding cycles using an inductive thematic analysis approach (Guest et al., 2011). Qualitative data analysis software NVivo was used to efficiently organize and code the data using a code book developed by the research team. We then selected codes specific to students' learning experiences in mathematics through an iterative process and categorized this data by seeking out emerging patterns and themes.

Findings

The aim of this study was to explore how IdME, as enacted through the Lifestyles Project, supported Grade 8 students' learning experiences with mathematics. In this section, we present two major themes that emerged from the data: 1) how the Lifestyles Project allowed students to connect mathematics to the real world, and 2) how real-world contexts supported the students' mathematics learning.

Connecting Mathematics to the Real World

Through the Lifestyles Project, students applied mathematics to realistic contexts. Students reflected on how the Lifestyles Project allowed them to see how mathematics could be used in the real world. For example, Raza shared,

> I learned that interior designing has math in it, because interior designers need to know how much the total surface area is of something. And they can't just pick up like, go buy a couch or something, and hope it fits. They really need to measure it, so it fits.

Or as another example, Cymbi described how the Careers task allowed her to learn about taxes. She said, "I loved learning new things like what QPIP (Québec Parental Insurance Plan) taxes were and why were they used. Because I never knew about these things, it was all so new!" Students recognized and discovered that many mathematics concepts are immediately applicable and helpful in problems and tasks that they may encounter in their daily lives.

Real-World Contexts to Support Students' Mathematics Learning

In addition to allowing students to see the usefulness of mathematics, real-world applications helped the students deepen their mathematics knowledge. Students' mathematical understanding was strengthened when they could connect mathematics with real-world applications relevant to their own lives. For example, in reflecting on the Bedroom Design task, Junan said,

> I think [the task] was also really good for understanding total surface areas a lot. On a paper, I don't count the backside (of furniture)…we can't see it. But, like actually seeing it (in 3D) because now if I were to look at my closet or something, I could say like, oh, I wouldn't count this because I can't see it is touching the wall.

Here, Junan described how calculating the surface area of a real 3D model instead of a 2D drawing on a paper allowed her to better understand the concept of surface area. Similarly, Cymbi described how designing her bedroom reinforced the importance of mathematics knowledge. She said, "Measurements really are important and proportions because like, I found myself making a table that was like, shorter than the bed and then I was like, oh my god, that doesn't make any sense." Here, Cymbi shared how measurement errors would result in major problems in this real-world context. Indeed, through the Lifestyles Project, students realized the value and importance of both mathematics and mathematics knowledge in broader, non-academic contexts.

Students also shared that the Lifestyles Project provided them an opportunity to develop a stronger understanding of mathematics concepts that they had previously learned in the course. For example, Junan said, "I was okay at [surface area] before, but especially now, like when I was looking at the actual shape, I was like, 'Oh, wait, I don't count this, I don't count that." A similar response was given by Aura who felt that the Bedroom Design task "helped with like, what we were learning in class was like, lateral area and total surface area."

Although the majority of students enjoyed the Lifestyles Project, some felt that the real-world contexts were a hinderance to their mathematics learning. As Rose said, "I wouldn't want [class] always to be these projects, because I would want to learn some math and stuff...I would prefer the majority of the year to be math". This response indicates that some students drew a clear boundary between 'mathematics' and these '(Lifestyle) projects'. These students did not see the Lifestyles Project as incorporating mathematics, whether it be the mathematics concepts or processes that they previously learned, or the students' conceptions of what mathematics is and how to do it. Kobu explained, "We're learning about stuff [in a way] that we wouldn't like, conventionally learn about in math class." Indeed, for some students, learning mathematics in a way that they were not accustomed to was challenging.

Discussion and Conclusion

The focus of this study was to explore how interdisciplinary mathematics education (IdME), implemented through project-based learning (PBL), contributed to the students' learning experiences with mathematics. In the "Lifestyles Project", Grade 8 students participated in a variety of tasks that involved integration of mathematics with other disciplines (i.e., science, English language arts, visual arts). Findings suggest that the students were able to make sense of mathematics concepts by applying them to real-world contexts, which provided them with an opportunity to enhance their mathematics learning and improve their mathematical understanding.

The relevant and authentic contexts of the Lifestyles Project allowed students to realize how mathematics can be implemented in the real world (Brante & Brunosson, 2014). Furthermore, these contexts underscored the importance of mathematics as a discipline that is inherently present and correlated to all disciplines. When engaging in IdME through the Lifestyles Project, the students recognized the need to apply integrated mathematics knowledge to engage in real-world design and problem solving tasks. Indeed, the students seemed to "understand how mathematics inter-relates with other school subjects and with the real life" (Chi, 2021, p. 667). We argue that IdME encouraged students to learn by "demonstrating the real-world relevance of their education" (Newell, 2010, p. 11). In connecting mathematics to real-world contexts, the students seemed to be better able to understand mathematics concepts that were initially perceived to be complex and abstract. This strengthened understanding of new and previously learned mathematics concepts, in turn, improves students' academic achievement, both in mathematics and more generally across disciplines (Applebee et al., 2007). Despite its positive impact on students' mathematics learning, some students found IdME to challenge their perception of mathematics education. Indeed, some students had preconceived notions that mathematics should be taught in isolation and not connected to real-world contexts. This is in contrast to research indicating that students are generally more positively inclined towards an interdisciplinary learning approach as compared to traditional approaches to teaching and learning (Ghisla et al., 2010; Zhan et al., 2017).

While these findings may not be generalizable to wider contexts, our study provides further evidence of the positive potential of IdME as a means to enhancing students' learning experiences with mathematics. We encourage researchers and educators alike to further consider the ways that IdME can be used to transform mathematics instruction and allow students to thrive.

Utilizing an innovative and theoretically-grounded approach, we extend the work of cognitive scientists and mathematics educators who have previously documented the impact of comparison on students' learning in algebra with the goal of transforming the learning that occurs in eighth-grade geometry classrooms. The purpose of this paper is to examine the types of comparisons participants made during think aloud interviews when engaging with curricular materials that have them examine multiple solution strategies. This research seeks to extend the work of using comparisons in algebra to determine if using comparisons in geometry will help improve students' mathematical understanding.

Keywords: Curriculum, Geometry and Spatial Reasoning, Middle School Education

Introduction

Dissonance is defined, in part, as "an instance of such inconsistency or disagreement" (Merriam-Webster, 2022). There is much to be learned through these inconsistencies, especially in regards to learning mathematics, for it is through this dissonance that students work to make sense of the inconsistencies and develop stronger mathematical arguments. By simply comparing different solution strategies to a mathematics problem, students can draw out inconsistencies to deepen their mathematical thinking.

Utilizing an innovative and theoretically grounded approach, we extend the work of cognitive scientists and mathematics educators who have previously documented the impact of comparison on students' learning in algebra (Star, Pollack, et al., 2015), with the goal of transforming the learning that occurs in middle grade geometry classrooms. Comparing and contrasting objects is a powerful learning tool with deep roots in cognitive science literature. Goldstone, Day, and Son (2010) stated, "research has demonstrated that the simple act of comparing two things can produce important changes in our knowledge" (p. 103). There is empirical support from cognitive scientist literature for the use of comparing contrasting examples for learning about business negotiations (Gentner et al., 2003), heat flow in science (Kurtz et al., 2001), children's learning (Loewenstein & Gentner, 2001; Namy & Gentner, 2002), and in studies of infants 4 to 6-months old (Oakes & Ribar, 2005). In mathematics education, research on comparing has proven effective in learning: estimation (Star & Rittle-Johnson, 2008, March, 2009), the concept of an altitude for a triangle (Guo & Pang, 2011), and equation solving (Rittle-Johnson & Star, 2007, 2009; Rittle-Johnson, Star, & Durkin, 2012).

Theoretical Framework

Comparisons are a powerful way to improve learning across disciplines; having students compare and contrast different strategies has produced gains in students' knowledge of algebra (Lynch & Star, 2014; Star, Newton, et al., 2015; Star, Pollack, et al., 2015). Furthermore, comparison of multiple strategies also plays a prominent role in policy documents. In particular, one of the five recommendations for improving mathematical problem solving for middle grade students noted in the released Practice Guide from the U.S. Department of Education

(Woodward et al., 2012) was to have students examine multiple problem solving strategies. Similarly, one of the Common Core State Standards for Mathematics (NGA, 2010) mathematical practice standards is for students to be able to construct viable arguments and critique the reasoning of others, specifically that, “Mathematically proficient students are also able to compare the effectiveness of two plausible arguments” (p. 10). When students share their ideas and evaluate the thinking of others in class discussions, they develop the ability to construct mathematical arguments; the practice of critiquing peers is thought to enhance mathematical understanding (Lampert, 1990; Silver, Ghousseini, Gosen, Charalambous, & Strawhun, 2005).

Researchers have developed contrasting case materials to address typical Algebra I content that students struggle with or that elicit student misconceptions (see Star, Pollack, et al., 2015; Star, Rittle-Johnson, & Durkin, 2016). Star and colleagues’ Algebra I curriculum is focused around worked example pairs (WEPs), where each WEP shows two fictitious students solving one or more algebra problems. The intent of each WEP is for students to directly compare and contrast, line-by-line, the methods that the two fictitious students use in solving each problem. Star and colleagues (2015) have demonstrated that teachers’ implementation of the contrasting cases materials, including whole class and small group discussions around the WEPs, can lead to increased procedural knowledge, procedural flexibility, and conceptual knowledge of Algebra I topics.

The research in this proposal seeks to extend this work to geometry content and to further enhance the effectiveness of this approach for geometry by creating digital materials with animations. Because a major goal of the project is to establish a scientific foundation for animated contrasting cases as a basis for the learning of geometry, this paper seeks to answer an initial question: *What types of comparisons between mathematical strategies do students make?*

Design of Materials

Our digital curricular materials center two fictitious students’ voices at the center of mathematics learning, and each lesson includes five unique features: a page for the first fictitious student’s solution strategy on a given geometry task, a page for the second fictitious student’s solution to a geometry task (which could be the same or different task shown on first student’s page), a page with both students’ strategies side-by-side, a discussion sheet with four questions for the students to answer, and a thought bubble page summarizing the key mathematical concepts in the problem. The discussion sheet and thought bubble page are designed to make the instructional goal of each WEP more explicit and for students to summarize their work from the WEPs (Star, Pollack, et al., 2015).

There are four units, each containing either five or six WEPs, that cover the geometry content in the 8th grade CCSSM (NGA, 2010). Each unit introduces two new characters; for this paper we will refer to the characters as Jaxon and Maxine. As we created the materials, we considered several design features: animations and colors to draw student’s attention to the geometric content in meaningful ways, characters’ methods purposefully selected to spark comparisons, geometric thinking of the WEP characters, and diversity of characters throughout the units.

Methods

After fully developing the 8th grade geometry materials, and due to shifts in classroom-based research due to COVID, we conducted 56 hour-long open-ended semi-structured clinical interviews (Piaget, 1976; Opper, 1977), in the form of think alouds, with individual participants ($n = 42$). Our goal was to elicit student thinking as participants engaged with the materials and discussion questions, not to get them to a “correct” response (Opper, 1977). Consistent with

Opper's description of the clinical method, we used the students' language, paced the interview to each student's speed, and encouraged students to elaborate on their thinking. In order to engage participants in each phase of the WEP during the interviews, we followed a detailed protocol: examine Jaxon's method, examine Maxine's method, horizontally compare Jaxon and Maxine's methods, solve the problems on the discussion page, and read the thought bubble at the end. If needed, we had questions for each phase of the protocol to probe student thinking. At the end, we asked if they had any questions for us or any final thoughts on the materials.

We transcribed each interview and began *a priori* (Saldaña, 2013) coding based on our key design features (Animations, Colors, Comparison Between Characters, Diversity of Characters, Geometric-Thinking of WEP Characters). We then added emergent (Saldaña, 2013) Level 1 codes for the students' geometric thinking and curricular form and Level 2, 3, and 4 codes as appropriate. We met to develop the codebook and then each coded several interviews individually. We then met to discuss any discrepancies and came to agreement on all codes. Once we had finalized our codebook, two coders independently coded each transcript and the third researcher resolved all disagreements. The average initial agreement between the pairs of coders was: 88.92% for Level 1 codes, 82.76 for Level 2, 81.04% for Level 3, and 88.09% for Level 4. This paper specifically analyzes the Level 1 Comparison Between Characters codes to determine what types of comparisons the participants made regarding Jaxon and Maxine's solutions strategies. Below, we report on the types of comparisons they made and give examples of each type.

Findings

Comparisons Between Characters

We observed 756 (23.27% of all Level 1 codes) instances where students were making comparisons between the WEP characters (Table 1). Most often they were discussing differences between the characters ($n = 484$), but they also noted similarities ($n = 267$) and used both WEP characters' strategies to verify a mathematical idea ($n = 5$). Looking at the Level 3 codes, regardless if students were pointing out a similarity or difference in Jaxon and Maxine's strategies, participants often referred directly to the method they were using to solve a problem.

Specifically, when pointing out differences, students most often described differences in the methods the characters used to solve a problem ($n = 380$). For example, when analyzing strategies related to translating a figure, one student stated, "Jackson is more plotting it out, while Maxine is subtracting the values to go left or down. They both had it in the same spot, which is good; I think that's the idea." This student realized Jackson is using a visual geometric method, while Maxine is using an algebraic approach, yet they arrive at the same answer. This student was attending to the visual/algebraic aspects of Jaxon and Maxine's approaches. Students noted differences in the students' methods regarding WEP specific content. For example, in a WEP designed to have students understand why the interior angle sum in a triangle is 180 degrees, one student said, "Alex like ripped his triangle apart and… what did Morgan do? And Morgan, just drew the line and just used like the parallel cut by transversal stuff to figure everything out. To figure out that it was 180 degrees." Here the student is attending to specific mathematics content in the WEP.

Students noted similarities based on the method students were utilizing in the WEP. In a WEP focused on verifying similarity using transformations, one student noted, "they both show that the triangle is similar, I guess. They both did show that the side lengths are proportional. As you can see." Another student, working in a WEP focused on reflections, stated, "They're both, they're both flipped to the other side, depending on if it's the x or y axis, they're both being flipped." Here the student noticed that Jaxon reflected his triangle over the x-axis, whereas Maxine reflected hers over the y-axis. This student was later able to make a generalization about what happens to the coordinates of a figure when it is reflected over the x-axis and y-axis. These comparisons helped students analyze benefits and drawbacks of the WEP characters' methods and make informed decisions about their preferred strategy for solving similar problems.

Table 1: Number Codes at Each Level

Level 1	*n*	Level 2	*n*	Level 3	*n*	Level 4	*n*
Comparison Between Characters	756	Similarities	267	Answer	55		
				Method	162		
				Problem	50		
		Differences	484	Answer	69		
				Method	380	Liked Better	37
						Same Result	20
						Way I Would Do It	33
						Easier	55
						Unsure	3
						Visual/Algebraic	26
						WEP Content Specific	206
				Problem	35		
		Led to Understanding	5				

Conclusions and Implications for Future Work

We have begun to document the types of comparisons students made during think aloud interviews regarding fictitious student methods to mathematics problems. This research shows a viable scientific basis for using comparisons to explore multiple solution strategies of students, as students were able to note similarities and differences in the strategies. Given critiquing reasoning is important to deepening mathematical understanding (Lampert, 1990; Silver, Ghousseini, Gosen, Charalambous, & Strawhun, 2005), these findings are a step towards documenting the ways in which contrasting cases can be used in geometry. Future research will analyze if these comparisons of the fictitious students' solution strategies advance students' knowledge of geometry content, provide them with more flexible solution strategies, and equip them to better critique the reasoning of their peers.

ANALYZING CURRICULUM FOR LEARNING TO PROFESSIONALLY NOTICE: A VARIATION THEORY OF LEARNING APPROACH

Alees Lee

John Bragelman
University of North Georgia
john.bragelman@ung.edu

Teaching teachers how to notice student mathematical thinking has received growing attention over the years. While descriptions of preservice teachers' experiences while learning to notice have been documented, there are still questions about how the curriculum can afford preservice teachers the best opportunities to develop their skill to professionally notice. In this paper, we examine a curriculum designed to teach preservice teachers how to professionally notice through the lens of Variation Theory of Learning. We posit Variation Theory of Learning provides insight into critical elements preservice teachers should be exposed when learning to professionally notice.

Keywords: Preservice Teacher Education; Content Courses; Professional Noticing; Variation Theory of Learning

Research on prospective teacher noticing has grown considerably over the past decade (Amador et al., 2021; Dindyal et al., 2021). Like practicing teachers, prospective teachers are required to understand children's mathematical thinking, interpret what their thinking implies for their current understanding, and decide where children need to go next in order to advance their learning (Jacobs et al., 2010; Leatham et al., 2015; Van Zoest & Stockero, 2012). The skill of attending to, interpreting, and responding to children's mathematical thinking is known as professional noticing (Jacobs et al., 2010). Intentionally developing the aforementioned skills in content courses for preservice teachers has shown mixed results (Superfine et al., 2015), and there are still questions regarding what experiences preservice teachers should have in content courses in order to grow their capacity to professionally notice students' mathematical thinking.

In this paper, we examine an experimental curriculum designed to start preservice elementary teachers on their journey to learning how to professionally notice. To investigate the potential learning opportunities afforded by the designed curriculum, we adopt Variation Theory of Learning (Marton, 2015). We argue Variation Theory of Learning (VTL) provides a useful lens for analyzing curriculum in order to determine what could be made possible to learn about professionally noticing.

The Context and Curriculum

Development of preservice teachers' capacity to professionally notice typically occurs within methods courses (e.g. McDuffie et al., 2014; Schack et al., 2013); however, the intricate relationship between what teachers notice and their content knowledge for teaching (Dick, 2017; Jong et al., 2021) suggests preservice teachers may benefit from intentional experiences to develop noticing skills simultaneously with content knowledge. As the integration into content courses is relatively new, designing instruction with professionally noticing in mind needs careful thought and consideration.

The noticing curriculum discussed in this paper is experimental and contains multiple content modules. Each module has four phases designed to weave the learning of content and the learning of noticing together. The focus of this paper is on the potential learning of professional noticing provided by the structure of the various modules within the four phases of module 1 as examined through the lens of VTL. We discuss the potential learning within the context of the first content module: counting strategies related to addition and subtraction as used with word problems.

Within Phase 1, the preservice teachers are prompted to solve a task (Figure 1) in as many ways as possible. The various solution strategies will then be shared and discussed as a class, and together they will hypothesize other ways students might solve the task. The goal of this phase is for preservice teachers to see and understand multiple counting strategies related to a single task their future students might use.

Professor Peabody took a sample of sixteen beans from a container. He recorded two lima beans and nine pinto beans. He forgot to record the number of navy beans before he dumped them back into the container. How many navy beans were in his sample?

Figure 1: Task from Counting Strategies Module

In Phase 2, the preservice teachers watch a video case of a teacher implementing the same task with her elementary students in Phase 2. The preservice teachers read a description of the elementary classroom context and are encouraged watch the video twice: first without a specific purpose and again to answer reflecting questions. The goal of this phase is to support the preservice teachers in noticing children's mathematical thinking, attending to the various solution strategies and making interpretations about them, and in providing evidence to support their claims. Phase 3 has preservice teachers analyze student work samples for a task with the same context but new numbers. The work samples came from the same students in the video case. The purpose of this phase is to have preservice teachers recognize there are multiple representations within which they can notice and attend to student mathematical thinking. Finally, in Phase 4, the preservice teachers review student work samples from the same students of a new task with a different context, but accessible using similar counting strategies. The intent of this phase is to extend preservice teachers' noticing of student work related to counting strategies with respect to other problem contexts.

The Variation Theory of Learning

A theory developed from empirical research in the classroom, the Variation Theory of Learning (VTL) (Marton, 2015) is uniquely suited to the investigation of learning opportunities in a postsecondary classroom for prospective teachers. VTL has two main tenants: humans discern elements of our world by attending to difference against a background of sameness; and one cannot learn unless there is something to be learned, which is called the *object of learning* (OL). VTL examines learning through the lens of variation that occurs with respect to the OL (Runesson, 2005). To discern the OL, one must see the OLs necessary *dimensions of variation* and their *features*. Dimensions of variation (DoVs) are important components to understand in order to make sense of the OL, while features are characteristics of the DoVs (Figure 2).

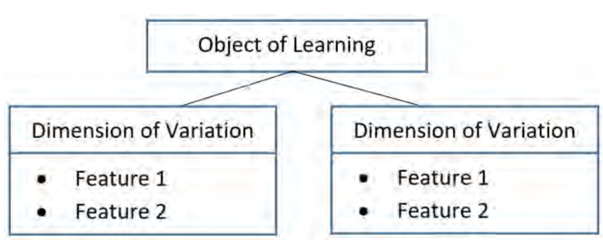

Figure 2: Structure of VTL Terminology

Marton (2015) describes four types of variation: 1) contrast, 2) generalization, 3) fusion, and 4) repetition. The type of variation depends on which dimension is in focus for the learner (Table 1). In order to discern the OL, one must first separate the necessary DoVs from each other. To separate a dimension from the others, the learner must experience a contrast followed by a generalization in relation to that DoV. The progression from contrast to generalization separates the focus DoV from the others, which is best done one dimension at a time (Pang & Marton, 2013). The learner must then bring the dimensions back together again with a fusion.

Table 1: Types of Variation

Type of Variation	Dimension in Focus	Other Dimensions
Contrast	Variant	Invariant
Generalization	Invariant	Variant
Fusion	Variant	Variant
Repetition	Invariant	Invariant

Beyond articulating the relationships between the object of learning, dimensions, features, and types of variation, Marton (2015) describes the various perspectives from which one can see these elements. An OL can be identified or determined from three different perspectives: the intended object of learning, the enacted object of learning, and the lived object of learning. The distinctions between these three elements are akin to recognizing what the teacher or curriculum designer intends to be learned (intended OL) is potentially different from what is made possible to learn during instruction (enacted OL) and from what the individual students actually learn (lived OL). In this paper, we analyze the curriculum from the perspective of the intended OL.

Seeing the Curriculum through the Lens of Variation Theory of Learning

In this section, we analyze the elements of the curriculum from the lens of VTL in order to articulate what the curriculum could afford the preservice teachers to learn about professional noticing. To that end, we establish the intended OL as: professionally noticing student thinking related to counting strategies and consider how the variation within the curriculum addresses that intended OL.

For the aforementioned intended OL, we envision two necessary dimensions (Figure 3). The first dimension relates to a teacher's understanding of counting strategies (DoV1), while the second dimension is the act of noticing student mathematical thinking (DoV2). Whether or not prospective teachers have opportunities to learn the OL depends on the careful structuring of variation which make the dimensions and OL visible to learners in the curriculum.

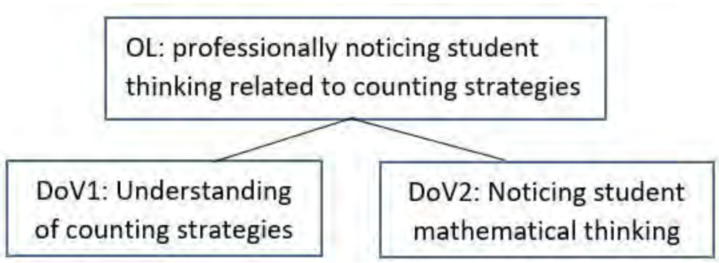

Figure 3: Learning to Notice VTL Structure

To uncover what the curriculum affords preservice teachers to learn about professional noticing, we examined the phases through the lens of VTL. Specifically, we considered the variation that could arise both within and across DoV1 and DoV2 as the preservice teachers progress through the four phases (Table 2). We hypothesize preservice teachers will have ample opportunity to discern elements surrounding DoV1. In particular, experiences within and from Phase 1 and Phase 2 surface a contrast and a generalization related to the idea that the strategies elementary students might employ to solve problems differ from how the preservice teachers themselves would solve the problem. Furthermore, the preservice teachers have opportunities to grapple with and understand the multiple counting strategies students might employ.

On the other hand, the curriculum does not explicitly provide the preservice teachers an opportunity to separate DoV2, noticing student thinking, from other dimensions through a contrast. To provide a contrast and open DoV2, one could encourage preservice teachers to see the authentic classroom instruction through various lenses such as classroom management, or how the students are grouped, or who is given authority to talk, in order to discern what it means to notice a specific element of instruction. The curriculum does afford the preservice teachers an opportunity to experience the dimension in Phase 3 through an induction, which is the same type of variation as a generalization without a contrast happening first. Finally, the curriculum provides an opportunity for preservice teachers to bring the dimensions together through a fusion in Phase 4.

Table 2: Variation across Phases

Variation Type	DoV1: Counting Strategies	DoV2: Noticing of Student Thinking
Contrast	Phase 1 – preservice teachers see different solution strategies for the same task. The solutions are from their classmates.	Does not occur
Generalization	Phase 2 - When watching the classroom video, the focus is still on the different solution strategies, however actual elementary students are now surfacing those strategies.	Phase 3 – Moving from Phase 2 to Phase 3, solution strategies and students remain invariant, but representations of student thinking (verbal/written) changes. ***Technically an induction.
Fusion	Phase 4 – A new task context is provided that allows for the solution strategies and what the preservice teachers notice to vary.	

Conclusion and Discussion

In this brief, we show how VTL as a lens to examine curriculum explicitly identifies and illuminates what the preservice teachers could have the opportunity to learn about professional noticing through engaging with the phases in the curriculum. Furthermore, the theory provides insight into elements that may be missing from the curriculum, such as providing an opportunity for students to learn what it means to notice a particular element emerging during instruction, like student thinking. In this, we offer insights into how VTL may support researchers and teacher educators in their development of preservice teachers' professional noticing of children's mathematical thinking.

In this paper, we report findings from an analysis of four triangle congruency lessons from a grade 8 mathematics textbook from China, using the Mathematics Curriculum as A Story framework developed by Dietiker (2015). We found that the Chinese textbook organized the four lessons under a four-level-plot structure to answer only one overarching explorative question: "Can we guarantee triangle congruence using a sub-set of conditions?" which connects triangle congruence criteria well for easier sense making. We also found that the textbook provides students with varied reasoning and proof opportunities by embodying rich actions and real-life context in the tasks. The findings of this study demonstrate the illuminating power of the Curriculum as a Story framework to fill the gap of current textbook analysis research.

Keywords: Curriculum, Geometry and Spatial Reasoning, Middle School Education

Objectives

Mathematics textbooks have long been regarded as a bridge between the intended curriculum, such as national curriculum standards, and the implemented curriculum, i.e., the actual teaching in the classroom (Valverde et al., 2002). They determine, to a high degree, what teachers teach and what students learn (Stein et al., 2007). Fan et al. (2013) proposed a framework for classifying the literature on mathematics textbook research studies that includes four main categories: role of textbooks, textbook analysis and comparison, textbook use, and other areas. The primary goal of all these analyses is to provide a proxy measure for the potential learning opportunities afforded by each textbook.

Using approaches described above, research on mathematics textbooks have made significant contributions to identify and report features that can be used as the basis for comparisons. However, these findings collectively, still fail to provide a sense of the changes and flows of the mathematical content throughout a textbook nor are they able to account for the aesthetic of sequencing and presenting ideas in one way verse another way. As an old Chinese fable says, it would not be possible for a group of blind people to get an idea of what an elephant looks like by just sharing their individual experience obtained from touching parts of the real elephant. Recognizing this limitation of the current research on mathematics textbook analysis, Dietiker (2015) proposed a conceptualization of mathematics textbook as a story that provides a holistic view of curriculum to examine the connections as well as sequences between mathematical ideas. Thus, applying Dietiker's (2015) narrative framework, our current investigation is guided by a general question, "how does a textbook tell a story of triangle congruency?" Specifically, we focus on understanding how an eighth-grade mathematics textbook published by People's Education Press (PEP, 2013) in China tell the story of triangle congruency.

We chose the concept of congruency as the content focus for this study for two main reasons. First, it is an important and common topic in geometry curriculum worldwide (Jones & Fujita, 2013). The idea that a partial set of all angle and side length measures can guarantee congruency between two given polygons is a unique property of triangles, which provides a rich setting for developing students' geometric intuition and ability to perform deductive proof (Wang et al., 2018). Second, previous studies found triangle congruence a challenging topic for students worldwide (e.g., Wang et al., 2018). A recent review comparing the introduction of triangle of congruency in a Chinese and a U.S textbook found that while both textbooks introduced the same set of congruent triangle conditions to their students, the sequence of how these criteria were introduced were quite different (Lo, Zhou & Liu, 2021). The findings of the present study on Chinese lessons will lay the beginning of the groundwork for the future investigation on the effect of different approaches mathematics textbooks use to present triangle congruence theorems on students' learning.

Theoretical Perspectives

According to Dietiker (2015), a mathematics story contains four main elements: mathematical characters, mathematical actions, mathematical setting, and mathematical plot. Mathematical characters are "figures" that were brought into existence by descriptive naming that could be in a variety of forms such as words, graphs, tables, or symbolic forms. In a story, mathematical characters can take on multiple forms via the process of mathematical character development which could be the main focus of the story. In addition, a story can also be about the relationships among multiple mathematical characters. Mathematical actions are manipulations taken on a mathematical character that results in a mathematical change. Other than moving a mathematical story forward, mathematical actions can create a new mathematical character for a story. Dietiker (2015) gave an example of a story of counting to find the quantity of the number of remaining objects after removing one at a time. This sequence of action will result in a surprising result of naming a quantity when nothing is left to be counted.

Dietiker (2015) defines mathematical setting as the space in which the mathematical character emerged and developed via mathematical actions. One way to conceptualize a mathematical setting is the mathematical representation in which mathematical characters move about which can affect both the richness and the interpretations of the story. For example, a "function" character that lives in a mathematical setting of multiple representations afford richer learning opportunities for students to know this character.

A mathematical plot is the "potential temporal dynamics of the story that encourages (or discourages) a reader to continue to advance through the mathematical story" (Dietiker, 2015, p. 299). Dietiker and Richman (2017) identify two main features of a mathematical plot: the sequence of the events unfolded within the story, and both the known and unknown felt by the reader as they were propelled to read on by the moment-to-moment tension. Dietiker (2015) suggested that a careful analysis of a mathematics curriculum via mathematical characters, actions, settings, and plots would help teachers and curriculum developers identify the potential challenging spots for the students which could then guide the future curriculum improvement.

Methodology

The design of the study was informed by the theoretical perspectives and framing outline above and the analysis was conducted by the constant comparative analysis (Stake, 2000).

Setting:

The Chinese education system is highly centralized. There is only one set of national mathematics curriculum standards: Compulsory Education Mathematics Curriculum Standards (CMCS) (Ministry of Education, 2012) which have to be followed strictly by all textbook series. In CMCS, the content of triangle congruence is considered as a part of a larger topic, Triangles. Under the topic of Triangle, CMCS has six expectations: 1) understand special lines in triangles, 2) explore and prove triangle sum theorem and its deduction, 3) master triangle congruence, 4) explore and prove the properties of angle bisector line and perpendicular bisector, 5) explore isosceles triangle and right triangle, and 6) explore the Pythagorean theorem and its converse theorem. In this study, the lessons we focused on belong to third expectation: master triangle congruence.

Data Set

An eighth-grade math textbook published by People's Education Press (PEP, 2013) was selected for this analysis. Among Chinese textbook publishers, People's Education Press has the longest history in developing K-12 curriculum in all subjects, and their mathematics textbooks were most widely analyzed (e.g., Cai & Jiang, 2017; Fan & Zhu, 2007). The primary data set for this study is the section 12.2 of the eight-grade mathematics textbook. PEP Math devoted four lessons to the five congruent triangle criteria: side-side-side (SSS; Lesson 1), side-angle-side (SAS; Lesson 2), angle-side-angle and angle-angle-side (ASA & AAS; Lesson 3), and hypotenuse-Leg (HL; Lesson 4). There was also additional investigation of the criteria that did not work such as side-side-angle (SSA) in Lesson 2 and in angle-angle-angle (AAA; Lesson 3).

Data Analysis

The analyses of the congruent triangle units were carried out jointly by the three authors based on the narrative framework developed by Dietiker (2012, 2015). Each of the authors first read the textbook unit independently following the reading practices discussed in Dietiker (2012) as discussed below. We each wrote a story summary based on our notes taken during this first-read with an eye toward prompts, questions and anticipations, as well as character development. We shared and discussed our interpretations multiple times to meet a consensus. Constant comparisons (Stake, 2000) were used throughout the process to look for emerging themes and evidence that either support or inconsistent with our ongoing narrative. Then we met on-line to develop the first joint story summary by combining all the distinct details as well as resolving any differences in our own reading of the story. The same process was repeated to fine-tuning each story by focusing on the other constructs of the framework, like actions and settings.

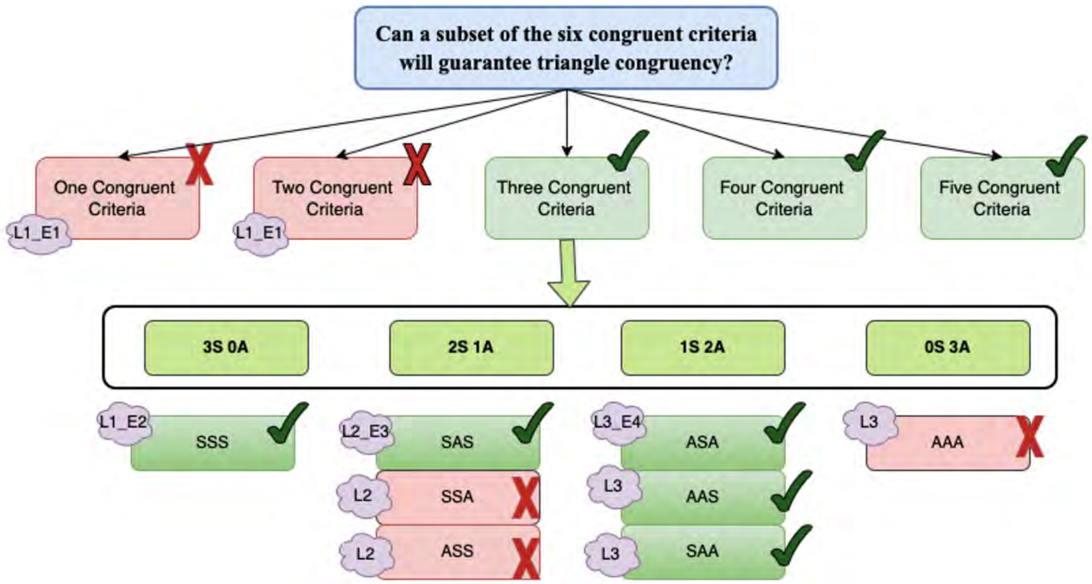
The mathematical story of triangle congruency we will be sharing with you is influenced by our own unique prior experiences with textbooks, mathematics, and education systems and cultures. All of us received K-16 education in Chinese education systems and came to the United States for our graduate degrees in mathematics education. Crossing cultural learning and teaching provided us a comparative perspective on mathematics curriculum which motivates us as mathematics teacher educators to conduct curriculum analysis and provide suggestions for developing effective curriculum. when we developed our knowledge and skills of mathematics curriculum analysis.

Findings

Because of the space limitation, we will limit our findings on the plots and actions of the stories. We will first describe the four-level plots of the congruent triangle story. Then, we will take a closer look at the plots around the introduction and development of the first explored condition: SSS. Finally, we identify several different types of actions employed by the students when investigating various mathematical characters: triangles with various types of properties.

Plots

PEP Math introduces the congruent triangles as a special case of congruent figures that have the same sizes and shapes. Therefore, when two triangles are congruent ($\triangle ABC \cong \triangle A'B'C'$), their three corresponding sides and angles are congruent. That is, the following six conditions exist: $AB=A'B'$, $BC=B'C'$, $CA=C'A'$; $\angle A=\angle A'$, $\angle B=\angle B'$, $\angle C=\angle C'$. Our read of the story uncovered four levels of plots as seen from Figure 1.



Note: L1_E1 means Lesson 1 Exploration 1; 2S1A means two pairs of congruent sides and one pair of congruent angles; A tick off means could guarantee triangle congruency; Cross means could not guarantee triangle congruency.

Figure 1: Four level mathematical plots of the congruent triangle story

First-level plot. The students were invited to explore the first-level, the overarching, plot via the following question: "Is it possible to identify various subsets of these six conditions that will also make two triangles congruent?"

Second level plots. In order to answer the questions posted in the first-level plot, students need to identify the potential subsets of these six conditions. Using a listing strategy, students may know the possible subsets including only one set, two sets, three sets, four sets, and five sets of congruent sides or angle conditions may guarantee triangle congruency. Therefore, to support the development of the first-level plot, there are five potential second level plots: will one, two, three, four, or five sets of congruent sides or angle conditions guarantee triangle congruency. The textbook first invited the students to ponder the following question "Will one or two sets of congruent sides or angle conditions guarantee triangle congruency?" by a series of drawings: "Start with an arbitrary triangle △ABC. Then draw a triangle △A'B'C' with just 1 criteria (one pair of congruent sides or one pair of congruent angles) or 2 criteria (two pairs of congruent angles, two pairs of congruent sides or one pair of congruent angles and one pair of congruent sides) of △ABC. Is △A'B'C' guaranteed to △ABC? (p. 35). The students were expected to provide counterexamples to reach the conclusion "no".

Third-level plots. The story then asked students to explore the question: "Will three sets of congruent conditions guarantee triangle congruency?" Answering this question led to an exploration of the third-level of plots. There are four kinds of combinations of three subsets of these six congruent conditions could be three pairs of congruent sides (3S0A), two pairs of congruent sides and one pair of congruent angles (2S1A), two pairs of congruent angles and one pair of congruent sides(1S2A), three pairs of congruent angles (0S3A). For each kind of combination, different order of congruent conditions leads to different arrangements, which leads to the fourth-level of plots.

Fourth-level plots. As Figure 1 shows, we identified eight different arrangements, including SSS; SSA, SAS, ASS; SAA, ASA, AAS; and AAA, all these can be considered different characters of the story. However, because a triangle is a closed figure with three sides and three angles, SSA can be understood as ASS, SAA can be understood as AAS. Therefore, we shaded ASS and AAS in grey, which are not explored by the textbook. After exploring all the six general arrangements, the textbook explored hypodense-leg (HL) which was a special case of SSA that was rejected earlier. Specifically, PEP confirmed five triangle congruency criteria in the following sequence: SSS, SAS, ASA, AAS, and HL It also rejected two criteria: SSA along with SAS, and AAA right after AAS.

The story ends with an exploration of a special case of right triangles (HL), a new character. The text invited students with the following question "With a pair of right triangles that already shared a pair of congruent right angles, what other conditions would be needed to establish their congruency?" The story then pointed to the students that based on the triangle congruent theorems already learned, two right triangles will be congruent if either 1) the pairs of two sides of the right angles were congruent or 2) there is a pair of congruent sides and a pair of congruent acute angles. Notice that the first condition will lead to SAS with the right angles be the congruent angles, and the second condition will lead either to ASA or AAS. However, the textbook did not provide these reasoning directly. Those two conditions were left for the students to explore. After those two conditions were confirmed, there was only one case left: What if the two right triangles shared a pair of congruent hypotheses and another pair of side. Note that this is the condition of SSA which was rejected as a valid congruency condition in the earlier lesson, so the students were likely to be intrigued.

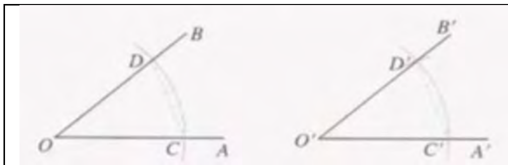
A Closer Look at the Plots of The First Lesson on SSS

The story asks students to conduct the following exploration: Draw an arbitrary triangle. Then draw another triangle such that their three side measures are equal. Cut the triangle out and place it on top of the original triangle. Are they congruent? While the narrative initially leaves it open to the various approach students may use to answer this question, the story soon provides detailed step-by-step straight-edge & compass constructions to create a new triangle that has three sides congruent to those of the original triangle. Then students are asked if their steps are as same as the narrative and what conclusion they can reach from this exploration. The story then affirms the SSS condition. Further, the students are reminded of a previous experiment of creating a triangle with three wooden sticks. Once the triangle is created, both the shape and size of the triangle is determined.

The story then provides two worked-out examples to help students apply the newly learned SSS condition. The first example can be seen in Figure 2.

In $\Delta ABC, AB = AC,$ $Segment\ AD\ connects\ A\ and\ D,$ $where\ D\ is\ the\ midpoint\ of\ BC.$ $Prove\ that\ \Delta ABD\ \cong \Delta ACD$	
Figure 2. The first worked-out example after SSS is introduced (p. 36, PEP, 2013)

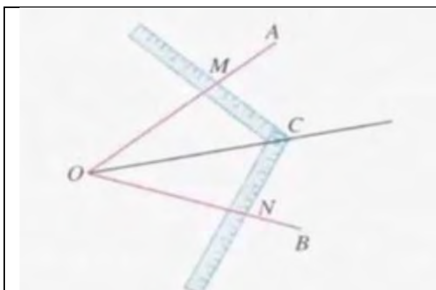
Before showing students the complete proof, the story first provides a pre-analysis, asking students to identify SSS conditions in the given problem. One pair of congruent sides, AB=AC, was already given. Segment AD, as a shared side, provides the second pair of congruent sides, AD=AD. The condition that D is the midpoint of side BC provides the third pair of congruent sides, BD=CD. The second worked-out example shows students how to construct a congruent angle with the straightedge & compass -using the SSS condition as follows (Figure 3).



1) As in the figure, use O as the center of the circle, arbitrary length as the radius, draw an arc that intersects OA and OB at points C and D.
2) Draw a ray $O'A'$. Use O' as the center, the length of OC as the radius, draw an arc intersects $O'A'$ at point C'.
3) Use C' as the center, the length CD as the radius, intersects the arc drawn in Step 2 at point D.
4) From D', draw a ray $O'B'$. Then$\angle A'O'B' = \angle AOB$.

Figure 3. The second worked-out example after SSS is introduced (p. 37, PEP, 2013)

The story of the SSS ends with two exercises that could be completed by students. The first exercise is another deductive proof similar to the worked-out example in Figure 2. The second exercise is a construction of an angle bisector of a given angle in the context of a construction trade as seen in Figure 4.



Construction workers often use a carpenter square to bisect an arbitrary angle. They used the following method as shown in the diagram: $\angle AOB$ is an arbitrary angle. On the segments OA and OB, pick OM=ON. Move the carpenter square so that the same distance markers on the two legs of the carpenter square will coincide with M and N. Then the ray formed by the vertex of the carpenter angle, C, and point O will be the angle bisector of $\angle AOB$. Why does this method work?

Figure 4. The second exercise at the end of SSS story (p. 37, PEP, 2013)

Actions

The story of congruent triangles in PEP Math engaged students in several different types of actions when exploring conjectures, establishing congruent criteria, constructing deductive proofs or to solving problems embedded in the real-life context that require the use of triangle congruent criteria they have just learned. Table 1 includes the frequency of each action type needed for the 20 tasks analyzed in this units. All tasks require multiple actions to complete.

Table 1. Frequency of each action within the story

Action Type	Drawing and direct comparison	Straight-edge & compass construction	Translating	Applying	Corres-ponding	Joining & separating
Frequency	9	6	28	18	11	2

The first action is “drawing and direct comparing”. When a conjecture was first posted, the students were advised to draw a triangle with the given condition to see if different ones could be created. If so, the original condition was rejected. If no different triangle could be drawn, the story then guided students to the second action, “the straight-edge & compass construction.” This action was used to prove SSS, SAS, ASA and HL. The third action is “translating”, for example, when students read the statement “…D which is the midpoint of AB” in Figure 2, they need to translate that statement into the existence of two congruent line segments, AD and BD. And when they see the diagram in Figure 2, they need to translate the image of a “shared side” of two triangles into the existence of a congruent side relationship in these two triangles.

The fourth action is “applying”. This includes both applying various congruent conditions to perform conductive deductive proofs as well as solve word problems embedded in real-life context. It also includes applying previous learned properties such as vertical angles are congruent and sum of the three interior angle measures of any triangle is 180° were used to identify pairs of congruent angles. The vertical angle property was first used in a worked-out example in Lesson One and then in an exercise in Lesson Three. And the property that the sum of the three interior angle measures of any triangle is 180° was used in a worked-out example in Lesson Three when applying ASA condition to prove AAS.

The fifth action is “corresponding”, students need to mentally manipulating the figures in the problem in order to establish the corresponding sides and angles correctly. The sixth action is “joining or separating”, for example, a pair of congruent sides of two triangles could be constructed from two congruent sub-segments and a shared segment via either the addition or subtraction property. Example in Figure 5 requires both the fifth and the sixth actions. The problem statement already contains a pair of congruent sides, AB=DC, and one pair of congruent angles, $\angle B = \angle C$. It is likely that students would think of using the SAS condition. They needed to mentally orient those two triangles given in the figure based on the locations of the corresponding angles and sides to identify the pair of two triangles, ΔABF *and* ΔDCE, that are likely to be congruent. To establish the congruency between these two triangles, they would need an additional pair of congruent sides: BF and CE. Here is where they need to use the constant addition property BE=CF on a shared line segment EF so that BE+EF=CF+FE. Thus, BF = CE.

The points E and F are on the segment BC, BE=CF, AB=DC, ∠B=∠C. Prove ∠A=∠D	
Figure 5. An example of an exercise requires two different actions p. 39, PEP, 2013)

Conclusion and Implications

In this paper, we tell a story of how a Chinese textbook, PEP Math, helps their students to develop their concepts of triangle congruency based on the “Mathematics curriculum as a mathematical story” framework outlined by Dietiker (2012, 2015). The main plot started with SSS, a condition with three congruent sides, and proceeded systematically through the conditions with two sides and an angle, one sides and two angles, and three angles. Both the valid and invalid conditions were investigated under a specific case. The entire story ended with an investigation on right triangles which is a special case as one congruent condition was guaranteed. A variety of mathematical actions were used both in real life context and deductive proofs to provide students with rich opportunities to make conjectures, conduct systematic investigation, and apply what they have learned in new explorations.

These findings have two significances. First, it shows that using the curriculum as a story framework, especially the plot component, brought new affordance for examining curriculum coherence in a structural perspective that went beyond tasks analysis. Second, it shows the possibility of organizing the exploration of different triangle congruence criteria as an inquiry that could be systematically examined. All the lessons we analyzed are designed and organized to answer only one overarching explorative question: can we guarantee triangle congruence using a sub-set of conditions? Doing so, the criteria are well connected which is easier to make sense of.

This story is told from the perspectives of three mathematics education researchers who grew up with Chinese education systems. We acknowledge the influence of this background. The mathematics story framework provided us a holistic lens to investigate the topic of congruency. Even though we are familiar with the content, the story framework not only allow us to view mathematics content through a literary lens but also help us to capture nuance information that were hidden from us before this investigation. For example, PEP follows the similar lesson structure and provide multiple opportunities for students to use the same sets of mathematical actions while investigating conjectures and solving problems that are embedded in a variety of different settings. Using straightedge & compass construction as the only action to establish the congruent condition makes it necessary to start the story with SSS condition. These approaches reflect a distinct philosophy of the curriculum design including how the content is organized to follow the logical sequence and how the topic connects with other previous mathematical ideas and prepare for the future learning. They also open a variety of research questions that worth investigation. For example, how might our read of the congruent triangle story similar or different from the reads by teachers and students? Do stories on other important mathematics topics such as quadratic functions told by PEP math share the same design features such as arranging content based on logical sequence and high intensity of repeatedly utilizing the same mathematical actions? Similar investigation on the stories told by other mathematics textbooks may uncovered more curriculum design features that can be used to create appealing and have the high potential to help students. particularly those who are on the margins of these communities, to reach the learning goals as called by the 2022 PMENA Conference Theme.

Future studies could use these kinds of rich textbook analyses to develop assessment items that are more sensitive to the variations in the story told by different mathematics textbook that might contribute to the difference in student performances. For example, Common Core State Standards defines congruent figures via rigid transformations, which is different from the straightedge & compass construction typically used by the Chinese textbooks. Fan et al. (2017) found no significant difference in students' ability to solve general proof questions from their quasi-experimental study with two groups of eighth-grade Chinese students. The control group received regular instruction based on straight-edge & compass constructions, while the transformation instruction was integrated into their regular lessons on writing proof in the experimental group. However, the experimental group performed much better than the control group on challenging problems involving constructing auxiliary lines. More stories of the introduction and development of other important mathematics topics would make it possible to deepen the investigation on the link between textbook and student learning, suggested by Fan et al. (2013) as a critical research area that needs more work.

Over the past few decades, researchers have adopted forms of abstraction introduced by Piaget to build explanatory models of student and teacher knowledge. Although Piaget's forms of abstraction have proved productive for developing models of knowledge, their broader applicability to mathematics education remains an open question. In this brief report, we extend these forms of abstraction in order to analyze hypothetical outcomes of teachers' enactment of instructional materials.

Keywords: Cognition, Learning Theory, Curriculum

Piaget's (1970, 2001) genetic epistemology has played a critical role in mathematics education via researchers adopting his theory to develop models of students' mathematics, models of teachers' mathematics, and models of student-teacher interactions. Researchers carrying out this work have provided important insights into those meanings that prove productive for students' mathematical development, as well as those meanings that constrain students' mathematical development (Steffe & Olive, 2010; Thompson, 2013). Furthermore, these researchers have provided useful ways to characterize teaching in terms of teacher knowledge necessary to build upon students' ways of thinking (Liang, 2021; Tallman, 2015).

An important construct spanning these contributions is that of abstraction. Stated generally, abstraction is the process by which an individual develops stable, generalized knowledge structures. To Piaget, abstraction provided a vehicle to developing precise accounts of knowledge development while also articulating generalized differentiated characteristics of knowledge structures. Piaget proposed several forms of abstraction including empirical, pseudo-empirical, reflecting, and reflected abstraction (Montangero & Maurice-Naville, 1997; Piaget, 2001). Mathematics educators have adopted these forms to provide differentiated accounts of student and teacher knowledge in numerous contexts (Ellis et al., in preparation; Tallman & O'Bryan, in preparation; Thompson, 1994).

Given the usefulness of Piaget's forms of abstraction for developing accounts of student and teacher knowledge, it is plausible that the forms of abstraction are productive for analyzing other aspects contributing to the teaching and learning of mathematics. In this brief report, we extend Piaget's forms of abstraction in order to analyze instructional materials. Specifically, we analyze two secondary teachers' instructional materials for teaching quadratic growth in order to develop hypotheses of the knowledge students may abstract from engaging in those materials. Because this is a brief report, we close with potential implications of this work and future directions building on this preliminary analysis.

Background

Ellis et al. (in preparation) and Tallman and O'Bryan (in preparation) synthesized Piaget's forms of abstraction and described how mathematics education researchers have adapted these forms of abstraction to be viable in their areas of research. Empirical abstractions primarily concern observables and foreground sensory-motor experience, and reflected abstractions rest on a subject's consciousness of their ways of operating. These two forms of abstraction are critical aspects of knowledge development, but they are less relevant to the analysis of secondary mathematics instructional materials when compared to the two forms of reflective abstraction that are pseudo-empirical abstraction and reflecting abstraction.

Speaking on pseudo-empirical abstraction, Piaget (1977) explained, "When the object has been modified by the subject's actions and enriched by the properties drawn from their coordinations…the abstraction bearing upon these properties is called 'pseudo- empirical' because…the facts it reveals concern, in reality, the products of the coordination of the subject's actions…" (p. 303). To Piaget, a critical aspect of pseudo-empirical abstraction is that such an abstraction requires the presence of perceptual material or observables and foregrounds actions on that available material. Drawing on the work of Moore (2014), Ellis et al. (in preparation) argued for extending Piaget's construct of pseudo-empirical abstraction so that "perceptual material" or "observables" includes the products of activity, even if these products of activity are purely cognitive. As they illustrated, such an extension of pseudo-empirical abstraction is productive for developing viable models of students' mathematics at numerous levels.

Piaget's distinction between pseudo-empirical abstraction and reflecting abstraction rested on the extent perceptual material or observables are required. Ellis et al. (in preparation) noted that the broader interpretation of pseudo-empirical abstraction provided above requires a more restrictive framing of reflecting abstraction. A primary difference between these two forms of abstraction is that while the source material for pseudo-empirical abstractions is perceptual material or the result of actions, the source material for reflecting abstractions is the coordination of a subject's actions themselves. Reflecting abstractions thus involve differentiating an action from the effect of an action so that the actions themselves can be projected to a level of representation and taken as objects of thought (Ellis et al., in preparation; Tallman & O'Bryan, in preparation; Thompson, 1994). As we illustrate with our task analysis, these differences in the source material for a subject's abstractions have important implications for their learning.

Project Setting and Methods

The current work is situated in a multi-year project investigating students' generalizing including the ways in which teachers support generalizing in their teaching (Ellis et al., in press; Ellis et al., 2017). Our approach to generalization is cognitive, drawing on an actor-oriented perspective as detailed by Ellis et al. (in press). The project's guiding research questions are: What are the opportunities for generalizing in classroom settings? Specifically, what types of instructional moves, student engagement, and enacted tasks support classroom generalizing? The current paper addresses these questions by investigating the abstractions potentially supported during the implementation of instructional materials.

The project involves two high school teachers and two middle school teachers. We concentrate this paper on the two high school teachers' instructional materials in order to restrict our focus to one content area. We analyzed the instructional materials using conceptual analysis (Thompson, 2008) with a guiding framework of the forms of abstraction identified above. At its most general level, conceptual analysis involves answering the question, "What mental operations must be carried out to see the presented situation in the particular way one is seeing it?" (von Glasersfeld, 1995, p. 78). With respect to analyzing curricular materials, conceptual analysis involves developing hypothetical accounts of *realized curriculum* (Kilpatrick, 2011) or *conveyed meanings (Tallman & Frank, 2020)*. This is accomplished via generating and interpreting “typical” solutions to the instructional materials using the lens of abstraction in combination with ways of reasoning held by secondary mathematics students as suggested by research (Ellis, 2011; Ellis & Grinstead, 2008; Fonger et al., 2020; Moore et al., 2019).

Tasks and Task Analysis

The two secondary teachers’ instructional activity focused on quadratic growth. The instructional activity explored a sequence of discretely growing shapes (see one example in Figure 1) with the intention that students identify patterns in quantities’ values including their first- and second-differences. The primary goal and generalization of the activity was to identify that for successive equal increases in Q_A of a situation (e.g., sail size), Q_B (e.g., sail area) increases by constantly increasing amounts, and that such a covariational relationship is modeled by a quadratic relationship. We discuss hypothetical pseudo-empirical and reflecting abstractions against the backdrop of the aforementioned goal. Underscoring that the forms of abstraction are cognitive constructs, we discuss each form of abstraction using a typical solution that involves a student generating a table of values, first-differences, second-differences, and a formula.

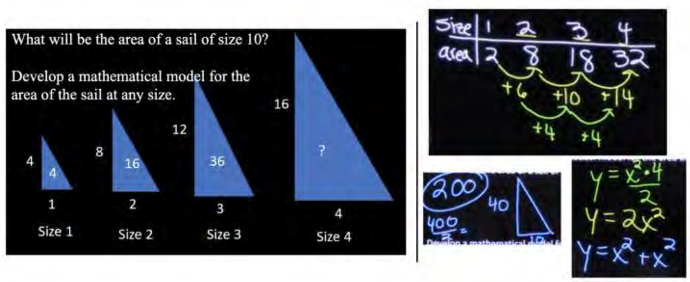

Figure 1: Example Activity (left) and a “Typical” Student Solution (right)

Pseudo-Empirical Abstraction

After working a series of activities like that presented in Figure 1, a student might observe that each time they obtain constant second-differences in a quantity, a quadratic formula models the situation. Recall that pseudo-empirical abstractions are those abstractions that foreground “perceptual material” or “observables” including the products of activity. In the case of the example activity (Figure 1), the products of activity include a table of values and a quadratic formula. Thus, the observation of the student would be a pseudo-empirical abstraction if their association is strictly based on noticing that constant second-differences were accompanied by a quadratic formula. The abstraction consists of an indexical association between constant-second differences and a quadratic formula with no logico-mathematical operations forming the basis for that association. The actions that produced the table of values and formula are inconsequential to the abstraction except in that they yielded an outcome or product to act as source material for the student’s abstraction. We contrast this with a reflecting abstraction in the next section.

Reflecting Abstraction

A limitation of pseudo-empirical abstractions stems from the abstraction foregrounding the products of actions rather than the actions themselves. For instance, and based on our experiences with students, the abstraction described in the previous section often results in the student associating a quadratic formula with constant second-differences regardless of how the other quantity’s values are ordered in a table (e.g., non-constant first-differences in Q_A that produce constant second-differences in Q_B). In the case of the example activity and solution in Figure 1, a reflecting abstraction that foregrounds the coordination of actions and their results would involve a student reflecting upon both the quantitative referents of their tabular activity, as well as how their relationship necessitates a quadratic formula.

With respect to the tabular activity, this would involve the student conceiving first-differences as the amount by which a quantity increases (or decreases) and second-differences as the amount by which a quantity's increase increases (or decreases) as shown in Figure 2. Furthermore, because a reflecting abstraction foregrounds the coordination of actions as opposed to the products of actions, the student's abstraction would include awareness that the constant "+1" increases in size are intrinsic to the constantly increasing increase in area. With respect to a quadratic formula model, a reflecting abstraction involves understanding how the aforementioned quantitative relationship necessitates a second-degree polynomial. Although the connection between the two is not trivial, researchers (Ellis, 2011; Ellis & Grinstead, 2008; Fonger et al., 2020) have illustrated its feasibility for students including those in middle grades.

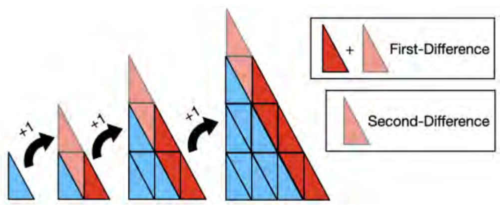

Figure 2: Conceiving first- and second-differences quantitatively

Discussion and Future Work

Although we are not aware of studies that have used the aforementioned forms of abstraction to develop hypothetical accounts of student activity in the context of teachers' instructional materials, mathematics education researchers and teachers have been sensitive to the role of abstraction in instructional design. For example, it is impossible to read the collective works of Steffe or Thompson and not sense the forms of abstraction directly informing their work even when not explicitly mentioned. As another example, Oehrtman (2008) provided a more general description of how Piaget's notion of abstraction can inform a layered sequence of activities so that students have the opportunity to reflect upon and identify common structures in their actions across a variety of contexts. In each of these cases, researchers leveraged abstraction in the context of their own research-based work and design. We find it important to include a complementary focus on teachers' extant instructional materials, as those materials play a significant role in students' educational experiences.

We illustrated that an abstraction framing provides a way to analyze instructional materials and produce differentiated accounts of knowledge development. Moving forward, we envision several productive avenues to continue investigating the viability of this framing. First, the current report is limited to one content area. Future work should look to extend the framing to other content areas including those not within secondary mathematics. Second, our analysis of the instructional materials consists of *hypotheses*. A more holistic account should include a focus on students' realized abstractions, as well as the role of teacher knowledge and instructional moves in students' construction of those abstractions. Third, we envision that an abstraction framing can provide a cognitive-focused approach to modifying instructional materials and their implementation. For instance, based on analysis like that provided here and then investigations into students' realized abstractions and aspects of instruction contributing to the construction of those abstraction, researchers and teachers can look to modify instructional materials to better support students' reflecting (and reflective) abstraction of productive meanings.

Designers of critical mathematics instruction have documented difficulties in simultaneously fostering the development of critical consciousness while supporting students in developing understandings of new mathematics. However, confining justice-oriented tasks to applications of previously learned mathematics limits the degree to which these tasks will be taken up by teachers. We describe our attempt to employ heuristics from the instructional design theory of realistic mathematics education [RME] to create a sequence aimed at developing students' critical and ethical reasoning while also developing new mathematical understandings of ratio, proportion and percents. We propose emergent adaptations to two of the realistic mathematics education design principles then propose an additional ethical principle to guide the development of future RME sequences.

Keywords: Curriculum; Learning Trajectories and Progressions; Rational Numbers & Proportional Reasoning; Social Justice

Ernest's work in the philosophy of mathematics education has set the stage for the argument of ethics as its first philosophy (Ernest, 2013). For Ernest (1998) "ethics arises from the ways in which persons live together and treat each other" (p. 9) including what is deemed right or wrong when making decisions and how we generate knowledge. He proposes that ethics should serve as the foundation for mathematizing and philosophizing and calls for "an ethics of mathematics" that acknowledges its social responsibility as well as its implications for freedom, justice, and cooperation (Ernest, 1998, 2013). "Ethics in mathematics education supports, and lays the foundation for, concerns about social justice" in that issues of social justice are concerned with the social activity of groups and the fair enjoyment of social benefits, while issues of ethics are concerned with interactions between people more generally (Atweh & Brady, 2009, p. 268). From this perspective, ethical considerations are based upon people's moral responsibility to one another, establishing "social justice concerns as a moral obligation, rather than charity, good will or convenient politics" (Atweh & Brady, 2009, p. 268). Accordingly, we view ethical reasoning as notions of what is right or wrong in social contexts, with considerations of social justice as one of its key components.

A primary goal of an ethical mathematics education is fostering students' epistemological empowerment through mathematics (Ernest, 2002). In other words, developing both mathematical and social empowerment in which the learner establishes a sense of self-efficacy in "the language, skills and practices of using and applying mathematics" in school settings, and their ability to use mathematics to "participate more fully in society through critical mathematical citizenship" (Ernest, 2002, p. 1). Such an education concerns the individuals' growth of confidence in using mathematics, creating knowledge, validating it, and transforming the world through mathematics (Ernest, 2002). Educators have attempted to develop students' awareness of the power that mathematics holds to both help and harm society through the teaching of critical mathematics, which aims to develop students' critical consciousness, or awareness of social, political, and economic oppression (Frankenstein, 1983; Freire, 1970; Gutstein, 2006). If ethical reasoning is primarily concerned with notions of what is right or wrong, we see critical consciousness as the component of ethical reasoning concerned with identifying oppressive systems. While critical mathematics focuses on responding to these systems, ethical mathematics also includes the responsible creation of mathematical products. Many efforts at implementing critical mathematics have done so with students who experience intersecting oppressions; this is understandable, given that developing critical consciousness is a pillar of culturally relevant teaching (Ladson-Billings, 1995). Some scholars, though, have argued for the importance of developing critical consciousness of students from communities of privilege, proposing that without such consciousness, students from these communities may, wittingly or unwittingly, abuse the disproportionate power they wield, which continues the dehumanizing effects of oppression on both the powerful and those with less power (Kokka, 2020; Stephan et al., 2021). These scholars propose that critical mathematics, like any critical pedagogy, works toward liberating the oppressed and oppressors (Freire, 1970).

Tensions in Designing for Ethical and Mathematical Reasoning

Reports on efforts to design and implement critical mathematics lessons aimed at developing students' mathematical power and critical consciousness highlight the difficulty of the work. One primary tension, raised by numerous scholars, involves balancing the goals of developing students' mathematical power so that they can succeed in dominant mathematics while also developing their critical consciousness (Gutiérrez, 2002). Gutstein (2006) proposes that productively navigating this tension is possible but admits that he relied primarily on a reform-based but non-critical textbook series, *Mathematics in Context*, to develop students' mathematical power. Brantlinger (2013) also grappled with the tension between the two goals. After finding himself unable to navigate the tension by simultaneously addressing social justice and mathematical concepts, he then tried separating them hoping for later syntheses. Brantlinger ultimately concluded that he was unable to resolve the tension between the two goals, at least in the secondary mathematical setting of geometry which the project addressed. Other scholars document teachers' (rather than their own) efforts to implement social justice themed mathematical lessons and their attempts to navigate the tension by separating social justice contexts and the development of mathematical ideas (Turner et al., 2009; Bartell, 2013) or simply focusing primarily on either the mathematical goals or social justice goals, leaving the other goal as more of a background possibility if the opportunity arises (Bartell, 2013).

In our reading of the literature on critical mathematics and teaching math for social justice, we noticed that studies of implementation were well grounded in the literature on critical mathematics and tenets of teaching math for social justice, but these studies tend not to cite instructional design theories for developing mathematical ideas. In other words, while the social justice aspect of these lessons was grounded in theory, the mathematical aspect relied on the intuition of the teachers or instructional designers rather than an established instructional design theory. We hypothesized that this theoretical imbalance may contribute to the difficulty in designing for new mathematical concept development simultaneous with critical consciousness. In our attempt to address the goals of developing new mathematical ideas through ethical and critical contexts, we relied heavily on an instructional design theory that uses realistic contexts to ground the development of mathematical ideas.

Instructional Design Principles

To reconcile the aforementioned tensions, we anchored our study to critical mathematics frameworks (Frankenstein, 1983; Gutstein, 2006; Skovsmose, 1994) as well as the Dutch instructional theory of realistic mathematics education [RME] (Gravemeijer, 1994), which provides a robust set of design principles for developing sequences that develop students' mathematical understanding. Van den Heuvel-Panhuizen and Drijvers (2014) present six core teaching principles which correspond to instructional design heuristics: activity, reality, level, intertwinement, interactivity, and guidance. Rather than elaborate all six, we focus on the reality and level principles to illustrate how we foregrounded these particular heuristics in our design activity when confronted with critical and ethical challenges.

The *reality* principle advises that instructional sequences begin in *experientially real scenarios*. The term experientially real does not mean that problem contexts need to be authentic, or real-world, but rather the problem context needs to be imaginable, so that students can act on the problem elements in sensible ways. An earlier interview study of similarly aged students (Stephan et al., 2021) inspired an initial conjecture of how this principle might be adapted for critical mathematics instruction: we hypothesized that problem contexts in which students felt like they themselves were targets of oppressions could be a more experientially real starting point for students than situations where others were targeted.

The *leveling* principle describes the notion that students' understanding passes through various stages. Their early conceptions often involve concrete, context-bound solutions to initial problems. As their understanding develops, their *models of* these situations become more abstract and less attached to these problem situations, and become *models for* use in other, mathematically isomorphic situations (Gravemeijer, 1999). Our earlier work provided a hypothesis of how this principle might be adapted for the development of critical mathematics instructional sequences as well; we conjectured that students' initial understandings *of* how they themselves were targeted might lead to an empathy *for* other vulnerable populations.

Given our experience in designing RME sequences, we were hopeful that we could develop an instructional sequence that simultaneously developed students' understanding of new mathematical concepts (namely proportional reasoning and percent change) while also developing their critical and ethical reasoning. The following questions guided our study:

Research Question

When designing a mathematics instructional sequence for developing ethical and critical reasoning,

1. What adaptations to the existing RME design heuristics emerged and why?
2. What additions to the existing RME design heuristics emerged and why?

Method

Setting

In identifying a suitable context for our study, we drew on Kokka's (2020) conceptualization of privilege as the "set of advantages one group has over others, granted because of membership or perceived membership in social categories" (Kokka, 2020, p.3). This conceptualization considers race, socioeconomic status, and educational privilege, as well as other intersectional identity traits including, but not limited to, sexual orientation, gender, and ability status, that are both interrelated and influence students' experiences of privilege and marginalization (Kokka, 2020, p.3). As such, the instructional sequence was designed with partners who work at a school we refer to as Lakeview Charter Middle School (LCMS). The student population at LCMS is approximately 68% White, 13% Black, 8% Asian or Pacific Islander, 6% multiracial, 6% Hispanic and less than 1% Native American. Families are responsible for providing transportation for their students to and from school. There is no possibility for students to have free or reduced lunch due to the requirement that students bring their lunch from home. Due to these requirements, the student population generally draws students from economically advantaged families. The Design Team consisted of the three co-authors (two white females and a white male in comfortable socioeconomic positions) as well as two LCMS teachers (one male and one female) and their principal (female), all three being people of color. The team met four times over the summer to brainstorm contexts and develop an outline of the unit, then the three co-authors worked and met intermittently over two months to develop the unit.

Data Analysis

Data for this paper consisted of field notes that captured design decisions as well as 13 different iterations of the instructional sequence, which aimed to develop students' understanding of ratio, proportion, and percent change within a context of nicotine vaping. To analyze our design decisions related to ethical and critical challenges, two co-authors independently coded the documents by marking each instance in which an ethical or critical challenge was raised. We then compiled the results and resolved any inconsistencies. For instance, both coders identified tensions related to a task asking students to analyze a graph showing the correlation between the amount of nicotine users ingest per day and the proportion of those users who meet the established criteria for addiction; students were asked "how many mg of Nicotine would you say leads to addiction in most people?" One author coded this as an *ethical* challenge, recalling the team's discussion of whether the idea of a threshold might encourage students who are interested in vaping to try to vape 'just under the amount' they think would get them addicted. The other author noted a *critical* tension with this same task recalling that the 5 mg threshold proposed by epidemiologists seemed somewhat arbitrary to the design team, who did not want the students to accept this threshold uncritically. Upon discussion, both codes were deemed appropriate.

Findings

Our analysis suggests some extensions to the RME reality and leveling design principles as well as the inclusion of an additional principle. We first discuss some new perspectives on the reality and leveling principles and then introduce the ethics principle.

Navigating the Reality Principle in Choosing Critical Contexts

When searching for an experientially real context to serve as the semantic grounding for the instructional sequence, we found ourselves rejecting many of the contexts that would have been rich for critical investigation because they were not *didactically rich,* in the mathematical sense. For example, the mathematics involved in water contamination, lead poisoning, and air pollution were too complex to support our ratio and percent learning goals. At other times, the context may have been didactically rich, and from the designers' point of view, *critically rich*, but when considering it from the students' points of view, they would not be engaging or may produce anxiety in students. Exploring critical issues around SAT [a college entrance exam] scores was one such context that the teachers rejected for two reasons. First, at this middle school, the SAT is introduced very early to students and is a topic that students are confronted with frequently. The teachers felt that students hear about it so often that they may not be interested in it. Furthermore, they felt their students are overly pressured to perform well on the SAT and this might produce anxiety.

After two brainstorming sessions, we decided on developing a unit related to the context of vaping, because we deemed the context to be both didactically rich and critically rich from the students' perspective. Because researchers had documented efforts to target teenagers with candy and fruit vaping flavors as well as sensational advertising (e.g., Center for Disease Control, 2016), the context also fit our initial hypotheses about how an experientially real situation, where students themselves were targeted, could provide initial access to critical perspectives. Tobacco companies' targeting of African American communities with advertisements and promotions for highly addictive menthol cigarettes (Henriksen et al., 2012) and their efforts to attract Native American customers with ethically questionable promotions (Lempert & Glantz, 2019) provided potential opportunities for students to practice empathy and critical intuition about situations where other populations are targeted.

Navigating the Leveling Principle in Choosing an Entry Point

Once we settled on the vaping contexts, we grappled with the joint goals of staying authentic to the context, while also following the RME modeling principle of beginning with more informal models and progressively introducing more formal models. In our attempt to find an accessible starting point for the unit, we initially looked for authentic ratios related to vaping that students could visualize using contextual imagery. We learned that nicotine channels require two molecules of nicotine to open the receptor, but quickly realized that that particular 2:1 ratio was likely too simple to prompt students to develop creative informal solutions; furthermore, the ratio does not change, so that particular relationship did not support an instructional sequence. Aware of the frequent use of varying concentrations of lemonade or other beverages at the beginning of ratio instructional sequences, we also attempted to begin the sequence by investigating the concentration of nicotine in e-cigarette cartridges, but we could not find a way to avoid the use of fractions or decimals because of the small concentration of nicotine relative to the other ingredients, so the authentic situation proved too complex.

Ultimately, we decided that the ratio of puffs per hour presented an accessible and rich possibility. Students could draw pictures of puffs of smoke and either hourglasses or small clock faces to represent hours, so that they could visualize and iterate the ratio. Once we had identified an accessible entry point, we attempted to identify realistic problems that involve this relationship.

- Given the data for an individual, can we determine if they are puffing more than they were? In other words, is the individual possibly becoming addicted?
- Who puffs more, one individual or another?
- How long would one cartridge last, given a set puff rate?

Navigating both Reality and Leveling Principles in Developing the Sequence

Given our desire to use the puff per hour ratio and a dearth of authentic data for individual vapers, we decided that for the outset of the instructional unit, we would not use actual data. Rather we would create fictional data within the vaping context, to provide maximum flexibility to meet our needs in developing the mathematical concept. Leaning on the RME principle of experientially real or imaginable scenarios, we created a fictional story of a teen named Sara, who tracked her puffing using a smartphone app. This fictional story allowed us the flexibility to start with appropriately accessible ratio (3 puffs:1 hour), ask a variety of questions (How many puffs would she take in 8, 24 hours?) and adjust that ratio as needed to increase complexity (5 puffs:2 hours) Although we incorporated real-world data (one cartridge contains enough vape liquid for approximately 200 puffs), much of the data was hypothetical, yet positioned students as friends, wondering if Sara should worry about increases in her puffing.

Once we had progressed from informal (pictorial) to preformal (long ratio tables) to formal (short ratio tables analogous to formal proportional notation using equations) representations of ratios, we then made a design decision to transition to an authentic and not hypothetical scenario: determining a reasonable puff rate threshold for different concentrations of vaping liquid that would correlate to a scientifically-backed definition of addiction.

An emergent design heuristic. The tensions between authenticity and the desire to attend to the leveling principle and our decisions in navigating the tension illustrate an emergent design heuristic that represents our efforts to adapt the reality and leveling principles to a critical mathematical instructional sequence. When the authentic data and mathematical relationships proved more complex to provide an accessible and didactically rich starting point, we employed the use of relevant, believable, fictional stories in early stages of the progression to provide access to informal strategies and more accessible number choices. Then, once students were able to use more formal representations that could be used for other situations, we transitioned to more authentic, non-fictional inquiry.

Our efforts to design with and for ethical reasoning resulted in a number of situations for which existing RME principles provided little guidance. In response, we propose an additional principle.

The ethics principle: A seventh principle

In designing mathematics instruction for ethical and critical reasoning, we found ourselves facing design challenges that were not addressed in the six principles. The analysis of our design field notes indicated that we were attending not only to the nature of the problems we chose to provoke students' ethical awareness, but also calling into question the ethics of our choices as designers. Thus, we humbly introduce the ethics principle that has emerged from our work. The *ethics principle* refers to the fact that mathematics is done by human beings and thus has the potential for bias, at best, and oppression, at worst. Conversely, doing mathematics can be liberatory and students must learn to recognize the impact that their mathematical solutions may have on the world. This principle can be viewed in two ways. First, designers must intentionally build ethical problem solving into instruction to provide opportunities for ethical decision making to arise. Second, designers themselves must problematize the ethical dimensions of their design activity and products. The ethics principle manifested itself in two ways during our design work: attending to ethics in the grounding context and attending to ethics when writing problems.

Attending to ethics in the grounding context. Using the context of vaping presented our first ethical challenge. We wondered if it was ethical to have discussions about vaping with teenagers, and worried in particular about introducing a potentially harmful practice to students who may not have been aware of the practice before our instruction. We considered whether we should use the names of actual companies, such as JUUL, in our materials, as that might promote the company's product to students. Another ethical consideration that emerged was that some students might be vaping and become anxious when they learn of the potential negative health consequences.

Potential design solution. We resolved these ethical dilemmas by consulting outside stakeholders such as the school's principal, teachers, and teenagers. As a member of the design team herself, the principal agreed that vaping might be a controversial topic for some parents, but revealed that the health teacher teaches about nicotine, and many students will already know about it. The teachers on the design team talked with other teachers, one of whom had a child in the class. The teacher-parents indicated that they did not think the vaping context would be harmful to their children. Finally, we talked with some teenagers who indicated that most teens know about vaping, adding that many middle schoolers they know are actually engaging in the practice. This feedback from stakeholders at the school led us to settle on the vaping context.

Attending to ethics in the problems. Once we committed to vaping as the context, there were ethical issues that arose as we wrote specific problems. We considered launching the instructional sequence with a video from the Truth Initiative (Shank, n.d.) that shows teens glorifying vaping, participating in vape challenges, and getting a buzz from the nicotine. Our intention was to acknowledge upfront that teens are vaping and to invite them into a serious conversation. From an ethics perspective however, we worried that the content of the video might inadvertently encourage teens to vape because it *looks cool and fun.*

A second time we were confronted with an ethical dilemma as designers occurred when we were considering introducing the idea of a "nicotine threshold" amount. A nicotine threshold refers to the minimum amount of nicotine an individual could ingest without becoming addicted. We worried that students who want to vape might think that, as long as they stay under this threshold, they can vape without getting addicted.

A third ethical issue arose as we were writing problems that might help students see themselves as the target of vaping companies. We created an instructional task that showed actual advertising photos by vaping companies. These advertisements contained pictures of candy flavored vape juice products, the Sesame Street Muppet Elmo encouraging vaping, young people partying with vape products, and famous entertainers holding vape pods. Our intent was to have students analyze the advertisements to see that vape companies were intentionally promoting their product to youth, but we worried the ads would attract students to the product. They might be inclined to think that *vaping looks cool;* or *if my favorite stars do it, it must be ok*.

Potential design solution. One way we attended to these ethical dilemmas involved creating what we refer to as a *contextual storyline*. We intentionally introduced a fictional character named Sara who became increasingly aware that she might be vaping enough to become addicted to nicotine. The mathematical problems we introduced not only supported our conjectured *mathematical* learning trajectory, but were couched in an ongoing narrative of Sara thinking about her vaping habit. We weaved the mathematical and contextual trajectories together so that students would develop proportional reasoning as they helped Sara and other fictional teen characters think about addiction. As the mathematical learning goals shifted to percent, the storyline changed to using a fictional app called the iVapeless meter so students could analyze how close Sara was to her self-imposed vaping limit. In this way, we used Sara's storyline to both develop students' mathematical understanding of ratio and percent while also learning about how vaping, even in small amounts, might lead to nicotine addiction. We also elicited students' knowledge from health class about the potential health consequences of nicotine throughout the storyline. In this way, we hoped the storyline we created would, at minimum, de-glorify vaping and maximally, deter students from using nicotine.

Discussion and Implications

In this study, we attempted to address an identified tension from previous studies of critical mathematical lessons: the difficulty in simultaneously teaching new mathematical concepts as well as ethical/critical reasoning. Unable to find critical mathematics studies that utilize established mathematics instructional design theories, we attempted to use tenets of realistic mathematics education to support our design toward the mathematical goals, while also attending to critical mathematics frameworks. One notable difference that emerged between the lessons we developed and lessons present in the existing literature is that we designed a *sequence* of lessons, built on researched *learning* trajectories for ratio and proportion (Civak, 2020; Stephan, 2021) and critical *contexts*. Our instructional sequence also began with contexts that positioned the students we worked with as targets of oppressive acts, and then proceeded to inquiries into how tobacco companies targeted populations with marginalized identities that many of our students did not possess. Prior reports and published resources tend to represent individual lessons, rather than carefully sequenced tasks built upon learning trajectories.

Through our work, we found that the RME design heuristics were helpful for supporting our design efforts, yet we needed to adapt two of the existing principles (the leveling and realistic principles) and add a new principle. First, our adaptation to the reality principle led us to a better understanding of the demands of selecting an appropriate anchoring, experientially-real context. Others have identified the step of determining justice-oriented contexts for a given student population and determining the mathematical topics that are relevant to that context. In addition to this, we also needed to determine whether contexts were didactically rich, meaning that problems inherent to the context lent themselves to develop a variety of models, from informal, context-bound models to more formal models. Furthermore, we needed to identify contexts that presented a variety of critical and mathematical questions; vaping for instance, had many different considerations including how to determine whether someone is vaping more, data related to teens' vaping practices, and the targeting of various groups with advertising.

Our second adaptation involved the leveling principle. Once we had determined a didactically rich, critical context, we found ourselves oscillating between posing problems with complete fidelity to the context and fictionalizing certain aspects of the situations. For example, we attempted to use real stories and actual data from social media and research articles for problem contexts, but sometimes the numbers and procedures in the reports were too complex to support students at that particular point in the mathematical learning trajectory. Thus, in order to develop a sequence that adhered to the leveling principle, we needed to fictionalize aspects of that context at times.

Finally, in addition to adapting the leveling and reality principles to design instruction with authentic critical contexts, we found the need for an additional RME heuristic. Ernest (2013) argues that the ethical considerations of problem contexts must be considered and should be the foundation for mathematization, yet none of the current RME principles provide much guidance to designers who create instructional sequences with attention to ethics and social justice. We illuminated the ways in which ethical considerations emerged for us during the design process and presented several instances when the design team encountered ethical dilemmas and the ways we resolved them. Consequently, we suggest the addition of an ethics design principle to RME and argue that, not only should instructional materials support students' development of ethical reasoning but that designers themselves must also be alert to and problematize the ethical dimensions of their designs for students.

In our description of these adaptations and additions to the RME heuristics, we must also clarify that these are proposals at an early stage of the design research project. We have developed and piloted an initial version of the instructional sequence, but we have yet to analyze the data on implementation. Thus, we are careful not to propose that the adaptations to the RME principles are final, rather they are emergent and likely to need further revision. As our work progresses, it will be important to apply and continue to revise these principles in other settings with other students, mathematical topics, and justice-oriented contexts.

A STUDY OF THE CONSISTENCY IN NEW YORK STATE FIRST YEAR MATH EXAMS

Stephanie Schaefer
American College of Education
stephanie.schaefer@ace.edu

Deborah Moore-Russo
University of Oklahoma
dmr@ou.edu

As standards documents have been introduced over the past 20 years, many states have seen an evolution in both the standards and related high stakes exams. For many teachers across the U.S., the rollout of standards and exams has not been an experience that builds trust in state education leaders. In this study, we consider three major changes in the first-year high school math exams in New York State since 2002, looking at consistency in item types, topics addressed, and student performance. Shifts in all were noted, but the changes in topics, especially when not obvious by the names given to standards, are suggested as the mostly likely to misinform or misguide teachers. We consider how state educational leaders are working to build trust for the next iteration of standards. While this study is particular to one state, the methods and findings should be of interest to others who study curriculum and testing in high schools.

Keywords: Algebra and Algebraic Thinking; Assessment; High School Education; Standards

The National Council of Teachers of Mathematics (NCTM, 1989) introduced its first standards document just over 20 years ago. This launched an evolution of mathematics curriculum standards and related assessments. NCTM (2000) published a subsequent set of standards in just over 10 years, and the Common Core Standards were published 10 years later (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). While having a national organization, such as NCTM, put forth standards helped bring more coherence to mathematics instruction across the United States, this led to significant disruptions at the state level. State education leaders subsequently made changes in their standards and state assessments that were rolled out to teachers, while legislation (e.g., No Child Left Behind, 2002) put in place mandates that implemented state assessment accountability.

Researchers report that state assessments have been associated with intense stress for teachers, and teachers report feeling that the high-stakes state exams often undermine meaningful learning and instruction (Barksdale-Ladd & Thomas, 2000). This feeling of pressure is regardless of the state in which teachers work (von der Embse, Pendergast, Segool, Saeki & Ryan, 2016), and studies have reported on state assessment accountability and its impact on teacher stress and teachers' intentions to leave the teaching profession (e.g., Ryan et al., 2017).

A reconstitution of the mathematics curriculum based on standards has brought about research that compares states' curricula and adoption (Senk & Thompson, 2020) as well as research that considers states' suggested coverage and placement of key topics in the curricula (e.g., Nagle & Moore-Russo, 2014; Stanton & Moore-Russo, 2012). However, little has been published about the high-stakes state exams themselves. How much did changing standards impact state assessments, particularly those that were being administered for the first year of high school mathematics? In order to consider this question in light of a new set of state mathematics standards that will soon impact state assessments, the overarching research goal of this study is to look at changes in first-year high school mathematics state exams in New York State (NYS) over the past 20 years. The three specific research questions include:

1. How consistent have state exams been over the past 20 years, in terms of the topics covered, types of items included, and student performance on the exams?
2. How do previous exam topics compare to current first year mathematics state standards?
3. How are state education leaders preparing teachers for the upcoming changes in standards and state exams?

Theoretical Framework

Social capital theory can focus on notions ranging from power (Fine, 2001) to economic transactions (Hardin, 1999) to mechanisms that build common values (McNiell, 2007). In all of these, there is interconnectivity that involves some level of trust. *Trust* is the belief that an entity (be it an institution or an individual) will act in ways that are consistent with one's expectations of positive behavior (Algan, 2018). It is an expectation that arises that is based on shared norms (Fukuyama, 1996). Trust helps reduce uncertainty (Luhmann, 1979) and helps deliver optimal outcomes by strengthening relationships and preventing defection (Six, van Zimmeren, Popa & Frison, 2015). Hardin (2002) suggests that norms produce trust, which he describes in the first person as the perception that you have "an interest to take my interests in the relevant matter seriously…you value the continuation of our relationship" (p. 2).

In organizations, subordinates' trust in those over them has been found to be related to employee commitment and job satisfaction (Colquitt, Scott, & LePine, 2007; Dirks & Ferrin, 2002). Burke, Sims, Lazzara, and Salas (2007) suggest that this trust is based on aspects such as accountability, transparency, and consistency (Kim & Lee, 2018). Consider the mathematics education community in a state as an organized entity with teachers in roles that might be considered subordinate to those who create high-stakes exams. The state's educational leaders show trust in teachers with their administration and marking of the exams. However, if one has listened to teacher lounge grumblings or has read media reports (Domanico, 2021; Strauss, 2012; Taylor, 2016), it calls to question how much this trust has been reciprocated. To begin to understand teacher trust in state education leaders and mandated state testing, there are many aspects that could be studied. A logical initial investigation is to study how consistent state exams have been looking at different measures of consistency. For that reason, this study considers looks the three iterations of the NYS exams for first-year high school math in terms of consistency and using the current math standards as a lens. It also considers how NYS education leaders are preparing teachers for future revisions to the standards and related exams.

Current Study

Since this study focuses on a particular state, we first detail the sequential shifts that have occurred in first-year high school mathematics in NYS. Next, we situate ourselves and experiences as researchers for this study.

Context.

From 2002 to 2020, there were three changes in standards that affected the first-year math exams in NYS: the *old* standards (Math A) from 2002-2009, the *recent* standards (Integrated Algebra) from 2008-2015, and the *current* standards from 2014-2020. Each exam administration occurred in January, June, and August. Each exam consisted of multiple choice and constructed response items corresponding to the relevant standards. In some years, two versions of the exam were available during transitional periods between standards. There were a total of 2287 items that were graded and publicly available on the NYS Regents' website (NYS Office of State Assessment, 2021): 764 *old* items (2002-2009), 857 *recent* items (2008-2015), and 666 *current* items (2014-2020).

Research team.

The research team consists of two members who have firsthand experience with the changes in NYS standards and assessments in high school mathematics. The lead researcher is a former NYS secondary mathematics teacher who experienced: the *old* exams as a student, the *recent* exams as a pre-service teacher, and the *current* exams as an in-service teacher. As part of her dissertation work (Schaefer, 2020), Schaefer did an in-depth study of NYS state assessments focusing on readability. While focusing on readability, other changes across the years became obvious. The second researcher worked in a Department of Learning and Instruction in a university located in NYS; she taught the secondary mathematics education classes for pre-service teachers from 2004 to 2014, a period that overlapped the *old*, *recent* and *current* standards.

Data Collection and Standard Classification

All items from first-year *old* (n=764), *recent* (n=857), and *current* (n=666) NYS exams were used as data. A sample of 10% of *current* exam items were classified using the *current* standards to obtain interrater reliability with NYS standard classification (Schaefer, 2020). Cohen's κ was calculated to determine agreement ($\kappa = 0.903$, $p < 0.05$). Discrepancies were then analyzed, and the NYS classification was accepted in each area of discrepancy. All *old* and *recent* items were then coded by the first using the *current* standards. Both authors discussed any items that were difficult to code until consensus was reached.

Findings

In this section we present findings in the order of the research questions. The findings are then followed by relevant discussion.

Exam Consistency

We first consider how consistent the first-year mathematics exams have been in NYS. We look at the topics covered by the exams in light of the standards that applied at the time of the exams. We then consider the types of items on the exams. Finally, we investigate any changes in student performance.

Item Topics. The *old*, *recent*, and *current* exams had a wide variety of topics based on their individual standard systems. Table 1 notes the different topic areas for each of the exams in terms of the distributions by the relevant standards at the time. The *recent* standards show the emphasis on an integrated curriculum, with the inclusion of a Geometry standard, that was not present in either the *old* or *current* standards. The *old* exams had the greatest difference in topic names as compared to *recent* and *current* exams. Consider the *current* standard of Number and Quantity. On *old* exams, the Number and Numeration standard was the focus for 8% of exam items, and the Operations standard was the focus for 19% of exam items. On *recent* exams, Number Sense and Operations was the focus of 8% of exam items. On *current* exams, Number and Quantity was the focus of 5% of exam items. Measurement decreased from being the focus on 19% of items on the *old* exam to 6% on *recent* exams, and it was not considered a high school mathematics standard and was therefore not the focus of any items on the *current* exam. The emphasis on functions shifted from accounting for 18% of the items on *old* exams, under the Patterns/Functions standard, to being melded in with Algebra in *recent* exams. Functions is a standard by itself and represented the focus of 37% of the items on *current* exams.

Table 1: Topic Areas and Relative Distributions of Exams.

Old Exam		*Recent* Exam		*Current* Exam	
Standard	Dist.	Standard	Dist.	Standard	Dist.
Math Reasoning	7%	Algebra	54%	Algebra	50%
Operations	19%	Geometry	16%	Functions	37%
Number & Numeration	8%	Number Sense & Ops	8%	Number & Quant	5%
Model/Multiple Reps	20%	Stats & Probability	16%	Stats & Probability	9%
Measurement	19%	Measurement	6%		
Uncertainty	8%				
Patterns/Functions	18%				

Item Types. Exams since 2004 but prior to *current* exams seemed to be more heavily weighted toward multiple-choice items. When the *old* exams were initially administered, the relative weighting (in terms of point distribution) of multiple-choice items was 47%. Then, the *old* exam was revised so that the relative weighting of multiple-choice items was 71% of exam points. *Recent* exams had a similar 69% relative weighting of multiple-choice items. The *current* exams relative weighting decreased to 56% of the total points. Most notably, there was also a six-point constructed response item added to *current* exams, replacing the three-point items that were on previous exams. Table 2 outlines the differences in item type distributions with the relative weighting for each item type in relation to the overall total exam point value.

Table 2: Item Type Distributions and Relative Weighting to Total Point Values for Exams

Item Type & Value	*Old* Exam Jun02-Jun03		*Old* Exam Jan04-Jun09		*Recent* Exam Jun08-Jun15		*Current* Exam Jun14-Jan20	
	n	Rel Wt*	*n*	Rel Wt	*n*	Rel Wt	*n*	Rel Wt
Multiple-Choice (MC Items)								
2-point	20	47%	30	71%	30	69%	24	56%
Constructed Response (CR) Items								
2-point	5	12%	5	12%	3	7%	8	19%
3-point	5	18%	2	7%	3	10%	0	0%
4-point	5	24%	2	10%	3	14%	4	19%
6-point	0	0%	0	0%	0	0%	1	7%

Student Performance. In order to consider exam consistency, we now look at student performance on the exams. For the NYS Regents, passing an exam is equivalent to receiving at least 65% of the total points on an exam. However, some students with disabilities are given a 55% passing rate, depending on their Individualized Education Programs (IEPs). A score at or above 85% is considered passing with distinction. For this reason, Table 3 displays the passing rates at or above 65% and 85% for all students taking the first-year math exams in NYS as well as the passing rates at or above 55%, 65%, and 85% for students with documented disabilities who took these exams (NYS Education Department, 2022).

Note the passing rate of scores that are 65% or higher on exams has decreased for all students going from 73% on *old* exams to 72% on *recent* exams to 70% on *current* exams. The passing with distinction rates (i.e., scores of 85% or higher) have decreased more markedly for all students going from 25% on *old* exams to 16% on *recent* exams to 13% on *current* exams. Now consider only the population of NYS students with disabilities and their performance on the *old*, *recent*, and *current* exams. Students with disabilities' passing rates of 55% or higher have increased from 64% to 66% to 67%, respectively, while passing their passing rates of 65% have decreased from 45% to 42% to 39%, respectively. There has also been a decline in student with disabilities who pass with distinction (i.e., with scores of 85% or higher) from 6% to 2% to 1% respectively.

Table 3: Relative Passing Rates on Exams for All Students and Students with Disabilities

Item Type & Value	*Old* Exam n = 1,552,177			*Recent* Exam n = 1,933,213			*Current* Exam n = 1,324,731		
	$\geq$55%	$\geq$65%	$\geq$85%	$\geq$55%	$\geq$65%	$\geq$85%	$\geq$55%	$\geq$65%	$\geq$85%
All Students n = 4,980,809	-	73%	25%	-	72%	16%	-	70%	13%
Students with Disabilities n = 700,048	64%	45%	6%	66%	42%	2%	67%	39%	1%

Comparison to *Current* Standards

We now use the *current* standards as a lens to consider shifts in the topics covered on exams for the past 20 years. When considering the items on *old*, *recent*, and *current* exams (as displayed in Table 4), it is obvious that there have been shifts in the topics that are covered. This is most notable when looking that the number of items that were on the *old* exams (73%) and *recent* exams (57%) that do not apply to the *current* standards. For example, measurement and geometry are no longer part of the first-year mathematics curriculum in NYS. For the Algebra standard, there has been a respective shift from 22% to 29% to 50% respectively on *old*, *recent*, and *current* exams, with the items on the *current* exams primarily focusing on this standard. For the Functions standard, there has also been a notable increase from 1% to 4% to 37% respectively on *old*, *recent*, and *current* exams. This is due to introducing the concept of function as well as an emphasis on introducing and using functional notation (rather than only considering equations, such as $y = 2x + 3$). There have been less dramatic shifts in the percentages of items that address the Number and Quantity and the Statistics and Probability standards. There have also been some shifts within individual topics as to which subtopics are emphasized. However, most of these shifts are based on the large increases in all the subtopics under the Algebra and Function standards.

Table 4: Counts of Items on Exams by Current Standards' Topics/Subtopics

	Old		*Recent*		*Current*	
Topic and Subtopic Areas	*n*	%	*n*	%	*n*	%
Algebra	**166**	**22%**	**248**	**29%**	**331**	**50%**
Arith w/ Polynomials & Ratl Expressions	19	2%	21	2%	34	5%
Creating Equations	22	3%	38	4%	82	12%
Reasoning w/ Equations & Inequalities	109	14%	139	16%	144	22%
Seeing Structure in Expressions	16	2%	50	6%	71	11%
Functions	**7**	**1%**	**34**	**4%**	**244**	**37%**
Building Functions	-	-	1	< 1%	37	6%
Interpreting Functions	7	1%	25	3%	153	23%
Linear, Quadratic, & Exponential Models	-	-	8	1%	54	8%

The Real Number System	2	< 1%	-	-	18	3%
Quantities	17	2%	27	3%	15	2%
Statistics and Probability	**13**	**2%**	**58**	**7%**	**58**	**9%**
Interpreting Categorical & Quantitative Data	13	2%	58	7%	58	9%
None Applicable	**559**	**73%**	**490**	**57%**	**-**	**-**

Preparations for Upcoming Changes in Standards

Another change in NYS is coming, with the Next Generation Math Standards (NYS Education Department, 2017a). When the *old* curriculum evolved to the *recent* curriculum, there was a significant shift in topic areas covered in the standards. In the shift from the *recent* to the *current* curriculum, similar topic areas were used; yet standards were condensed and there was a move away from an integrated curriculum. Now, from the *current* to the *future* Next Generation Math Standards, NYS educational leaders have created resources (i.e., a snapshot document and a crosswalk) to better explain how standards have been added, modified, or removed.

In the Snapshot document (NYS Education Department, 2019a), there were three categories that highlighted the major changes from *current* to *future* standards. These categories including mapping the *future* standards to the *future* curriculum, outlining which standards moved to another level of the mathematics curriculum, and additional clarification on *current* standards pertinent to the *future* curriculum. The Crosswalk document (NYS Education Department, 2019b) included detail clarifying the standards based on input from conference calls hosted by the NYS Education Department. These comments included notes that clarified more information about the standards. For instance, there was specific information regarding fluency expectations and how the first-year standards differed from those for the third-year math course, Algebra II.

The NYS Education Department created two committees that included both educators and parents for the *future* standards. There were also opportunities for public commentary on the draft document with over 750,000 comments from more than 10,500 people on the AIMHighNY 2016 survey (NYS Education Department, 2017b). This information was first used to create an initial version of the future standards in 2017 that has since been revised and disseminated in June 2019.

Probably most importantly, there has also been a longer roll-out period for the *future* standards than existed in past years when transitioning between standards. Initial information on the *future* standards was provided to teachers in 2017. The NYS Department of Education has also considered the impact of the pandemic and are taking its impact into account regarding the implementation of the *future* standards, which are not slated to be implemented and used for Algebra 1 exams until September 2023 (NYS Education Department, 2021).

Discussion

In conclusion, there have been some shifts in first-year high school math exams in NYS over the past 20 years. This is noted both in the item types and their weightings. It is also noted in student performance on the exams, especially in students passing with distinction. However, the areas where the revisions have been the most dramatic, especially in the impact on teachers, are in the topics that are covered on these exams.

Much of the discontent with the roll out of standards in the past is likely due to the lack of communication and a disruption in the continuity of topics that were included in the standards and on the exams. Change, by its very nature, disrupts consistency. However, there are mechanisms that can make change easier. There are also practices that can downplay change so that it is less evident initially, but this has consequences when it is realized that the change was more dramatic than initially believed. Having standards with similar topic names helped teachers transition from *recent* to *current* standards. However, what counted as Algebra for the *recent* exams was not the same as what counted as Algebra in the *current* exams. While 54% of the *recent* exam items were classified as addressing Algebra topics under the *recent* standards; only 29% of the *recent* exam items were classified as Algebra topics under the *current* standards. For example, ratios and proportions (including the three basic right triangle trigonometric ratios) were considered part of the subtopics covered in the *recent* Algebra standards, but they are not part of the *current* Algebra standards. Using the same topic name for a standard that represents different subtopics misinforms and can misguide teachers. When Algebra means one thing for a few years and then something else, it could have felt like a breach of trust for many teachers.

It is heartening that the NYS Department of Education has been more transparent and open to suggestions from teachers (and others) in the transition to future math standards that will be adopted soon. One way that this is noted in the inclusion of accessible documents that carefully map out the continuity across and evolution in topics. Optimistically, the research team is hopeful that the rollout of the future standards will be smoother than it was for past transitions of standards in NYS.

The input of teachers (as well as of other constituents in the learning process) is key to building trust. But bi-directional communication between teachers and state education leaders is not all that is needed to help teachers transition between curricular standards. There needs to be a logical, coherent evolution that builds on, rather than totally replaces, existing standards. Moreover, this evolution needs to be clearly communicated to all, but especially to teachers. Consistent transparency as to the coming changes and how they are line up with, build on, and improve the current standards would be of benefit and would help develop more trust between teachers and state education leaders.

Limitations, Future Study

While an obvious limitation is that this study only looks at NYS, the methods used and the underlying message are pertinent to those who study high school mathematics in other states, especially those interested in curricular standards and state exams. Other studies that investigate how different states have handled curricular shifts in standards and state assessment exams would be of great value. It would be interesting to see how future work could springboard from studies such as this to delve into more qualitative work on how trust is built or breached between teachers and state education leaders, especially in light of high stakes testing.

HOW DO MULTI-DIGIT MULTIPLICATION PROBLEMS PROMOTE PROCEDURAL FLEXIBILITY? AN ANALYSIS OF TWO FOURTH GRADE TEXTBOOKS

Elena M. Silla
University of Delaware
esilla@udel.edu

Procedural flexibility promotes efficient problem solving in mathematics. However, it is unclear whether and how elementary-grades textbooks promote this skill. The current study investigated lessons within two fourth grade math textbooks to determine how math tasks promote procedural flexibility within the domain of multi-digit multiplication. I developed and applied two frameworks to analyze the multiplication strategies and instructional strategies that might promote procedural flexibility that were presented in textbooks The textbooks differed in the number and types of multiplication strategies included. Neither textbook showed much variability in terms of instructional strategies, and there was little alignment between multiplication and instructional strategies. Future research could investigate additional textbook features such as teachers' guides study additional avenues for promoting procedural flexibility.

Keywords: Elementary School Education, Curriculum, Number Concepts and Operations, Standards

Historically, students in the United States have underperformed in mathematics (see the National Center for Educational Statistics, 2021). This lack of proficiency in math leaves many students unprepared for more advanced math courses such as Algebra. To remediate this, math researchers and educators have been targeting strands of mathematical thinking that may help students develop deeper understanding of mathematical concepts as well as more effective problem-solving skills (National Research Council, 2001).

One such strand of math learning is procedural flexibility. Procedural flexibility refers to students' abilities to think flexibly and adaptively about strategies for problem solving, thereby facilitating students' abilities to discern between multiple strategies and apply the most efficient strategy (Digital Promise Global, 2021; National Research Council, 2001; Star, 2005; Verschaffel et al., 2007). Procedural flexibility is a crucial skill for later math subjects such as Algebra (Rittle-Johnson et al., 2020; Star, 2005). Recent research has also emphasized the importance of procedural flexibility in its relation to both procedural and conceptual knowledge of problem solving (see Newton et al., 2020; Schneider et al., 2011). Having the procedural knowledge to accurately and fluently solve problems allows students to discern efficient problem-solving strategies and thus evoke procedural flexibility when selecting which strategy to use (Star, 2005). Similarly, conceptual knowledge of a topic can help students reason flexibly about problems (Durkin et al., 2017; Schneider et al., 2011). For example, a student who does not understand the standard algorithm for multi-digit multiplication but who has conceptual understanding of multiplication might be able to think flexibly and develop their own strategy for solving the problem. Improvements in procedural flexibility is also associated with increases in conceptual understanding (DeCaro, 2016; Durkin et al., 2017, 2021; Newton et al., 2020). Thus, procedural flexibility is an important aspect of mathematical thinking.

Procedural flexibility is also embedded in the Common Core State Standards for Mathematics (CCSS-M; 2016) and is emphasized across grade levels, with standards stating that students should have "skill in carrying out procedures flexibly, accurately, effectively, and appropriately" (CCSS-M, 2016). Its prominence both in the CCSS-M and in research suggests procedural flexibility may be a crucial skill to emphasize in mathematics instruction.

Conceptual Framework

While procedural flexibility is integral to math learning, it is unclear whether and how students learn procedural flexibility in the classroom. A central artifact to a math classroom is the textbook, which provide curricular materials that guide teachers' instruction (Lloyd et al., 2017). Therefore, this analysis will examine textbooks to explore in what ways textbooks promote the use of multiple strategies and procedural flexibility in problem solving.

Procedural Flexibility and Multiple Strategies

The ability to use and apply multiple strategies while problem solving is intricately tied to procedural flexibility. The CCSS-M (2016) emphasize the use of multiple strategies in problem solving. For example, the standard 4.NBT.B.5 mentions five different multiplication strategies students should be able to apply when solving problems. Other standards similarly include multiple strategies, implicitly emphasizing the importance of procedural flexibility. Equally important is the ability to apply strategies effectively. DeCaro (2016) found that students who were primed to use a specific strategy solved later problems less efficiently than those who were not primed, suggesting that this mental constraint affected students' abilities to efficiently apply strategies to solve problems. Promoting flexibility in thinking, then, may help students apply strategies more efficiently when problem solving.

Instruction of Procedural Flexibility

Researchers and educators have developed ways for procedural flexibility to be taught through instruction. One method is through comparing multiple strategies (Durkin et al., 2021; Rittle-Johnson et al., 2020), often through comparing two worked examples that show the same problem solved in two different ways. In one study, Durkin et al. (2021) tested curricular materials designed to foster comparison between multiple strategies for solving linear equations. They provided teachers supplemental worked example pairs (WEPs) that presented multiple strategies for solving the same problem as well as questions that prompted students to compare and analyze each strategy. Students whose teachers used multiple strategies in instruction and asked students to compare multiple strategies performed better on the posttest, particularly in the domains of procedural flexibility, than students whose teachers did not engage in these practices.

Other instructional strategies could be associated with increased procedural flexibility as well. A method often used in textbooks is to require students to solve a problem using a specific strategy, allowing students to engage with a multitude of strategies while problem solving (see Great Minds, 2016; MacMillian-McGraw Hill, 2009 for examples). Other techniques include encouraging students to reflect on strategies used during problem solving (Star et al., 2015; Woodward et al., 2012) and asking students to choose between strategies when problem solving.

Multi-Digit Multiplication

The current study of multiple strategy use and procedural flexibility is situated in the domain of multi-digit multiplication. Prior work on procedural flexibility has been done at the pre-Algebra or Algebra level (e.g., Durkin et al., 2021; Rittle-Johnson et al., 2020; Star, 2005), and less work has been done at the elementary level. Yet there is reason to believe that procedural flexibility is important for early grades, as well. As mentioned above, the CCSS-M standards (particularly for fourth and fifth grade) emphasize procedural flexibility through prompting students to perform operations fluently (CCSS-M, 2016). In particular, standards for multi-digit multiplication include multiple problem-solving strategies, suggesting this may be a fruitful domain to introduce strategy choice. Additionally, developing procedural flexibility when solving multiplication problems can help students solve problems more accurately and quickly (Digital Promise Global, 2021), which can help students solve more complex problems in later subjects. Finally, the role of procedural flexibility in developing conceptual knowledge (Rittle-Johnson et al., 2015; Schneider et al., 2011), as well as the prominence of flexible thinking in more advanced problem-solvers (Star & Newton, 2009) makes it a crucial skill for students to learn early on. Thus, it is important to explore in what ways procedural flexibility is taught in elementary mathematics classes and how curricular materials such as textbooks might promote this skill.

Research Questions

The current study examines the viability of two novel frameworks, consisting of multi-digit multiplication strategies and instructional strategies promoting procedural flexibility, through applying them to two fourth grade mathematics textbooks. My specific research questions are:

1. What strategies do fourth grade mathematics textbooks specify for students to use when multiplying multi-digit numbers?
2. In what ways do problems in fourth grade mathematics textbooks promote procedural flexibility of multiplication strategies?
3. How aligned are strategies used for solving multi-digit multiplication problems and practices promoting procedural flexibility?

Methods

Data Sources

Two textbooks were analyzed for this study: *Math Connects* (MacMillian-McGraw Hill, 2009) and *Eureka Math* (Great Minds, 2016). These textbooks were selected because of their accessibility to classrooms; *Math Connects* is written by a major U.S. textbook manufacturer, and *Eureka Math* is available for free online. Lessons within each textbook that focused specifically on multi-digit multiplication were selected for analysis. Within those lessons, I coded all independent practice problems for whether they contained multi-digit multiplication. These problems, hereby called math tasks, included both arithmetic problems that students had to solve and worked examples that asked questions about a worked-out problem.

Analytic Framework

To analyze what multiplication strategies and instructional techniques promoting procedural flexibility were promoted in fourth grade mathematics textbooks, I developed two frameworks with which to code math tasks. Math tasks were coded holistically, meaning that both the instructions and the task itself were included in the codes and analysis. Additionally, codes were additive, and a math task could have more than one code from each framework. Codes within the two frameworks were both research-based and data-based (DeCuir-Gunby et al., 2011). An initial list of codes was developed from prior literature. Additional codes that emerged through patterns in the data were then added to the frameworks, and previously coded problems were recoded to align with the updated framework. These frameworks are detailed below.

Strategies for Multi-Digit Multiplication. Math tasks were coded as prompting a specific multi-digit multiplication strategy if the strategy was explicitly included in the instruction (e.g., “Solve this problem using the standard algorithm”) or prompted via a visual scaffold (e.g., inclusion of an area model). Codes generated from prior literature included codes based on memorization (Lampert, 1986) and mental math (Rathgeb-Schnierer & Green, 2018), the use of physical objects when solving problems (Lampert, 1986), the use of area models (Kwon & Son, 2019), and the use of conceptual strategies such as the distributive property and other multiplication properties (e.g., the commutative property, decomposition; Ambrose et al., 2003; Lampert, 1998), and additional abstract strategies (Baek, 2006). Emergent codes included multiplication strategies such as the standard algorithm, using partial products, using a place value chart, or using drawings to solve the problem, all of which were common in the data sources (e.g., Great Minds, 2016; MacMillian-McGraw Hill, 2009) but were not represented in the literature. Finally, repeated addition was added based on the author's prior knowledge of multiplication strategies.

Instruction Promoting Procedural Flexibility. Math tasks coded as including instructions promoting procedural flexibility if there were specific instructions (e.g., "Choose a strategy to solve the problem below") instructing students to *how* to apply multiplication strategies to solve the problem. Initial codes emerging from the literature included asking students to compare strategies (Durkin et al., 2021) and reflect on strategy use (Star et al., 2015; Woodward et al., 2012). Later codes that emerged from the data sources included specifying a strategy for use while solving a problem and choosing between multiple strategies (Great Minds, 2016; MacMillian-McGraw Hill, 2009).

Connection Between Strategies and Procedural Flexibility. To address the third research question, the multiplication strategy framework and the instructional strategy framework were aligned to determine if there were patterns in co-occurrences of multiplication strategies and instructional strategies. It is plausible that some multiplication strategies may align better with certain instructional techniques to promote procedural flexibility. For example, more advanced strategies may be paired with promoting strategy choice because students have a greater repertoire of strategies from which to choose. Likewise, strategies that employ visual scaffolds often promote student reflection on the strategy used to help students align the scaffold with the numerical representation.

Results

Lessons in *Math Connects* ranged from having 21 to 47 multi-digit multiplication tasks, while lessons in *Eureka Math* ranged from having 4 to 19 multi-digit multiplication tasks. There were 302 math tasks in the specified *Math Connects* lessons, compared with 142 tasks in the specified *Eureka Math* lessons. Of those, multi-digit multiplication was included in 266 tasks in *Math Connects* (266 problems, no worked examples) and 140 tasks in *Eureka Math* (138 problems, two worked examples). These were the math tasks used in the analyses that follow.

Research Question 1: Fourth Grade Multiplication Strategies

First, I examined whether the strategies included in the framework appeared in the textbooks. The number of math tasks that explicitly included a multiplication strategy differed between the two textbooks. Overall, 14.3% (n = 38) of multi-digit multiplication tasks in *Math Connects* included multiplication strategies, while 74.3% (n = 104) tasks in *Eureka Math* contained at least one multiplication strategy for student use. Table 1 shows the number and proportion of multiplication strategies that appear in each textbook. Twelve out of the 14 strategies included in the framework were found in at least one of the textbooks. Two strategies, repeated addition and physical objects, were not found explicitly in the tasks in either textbook.

The amount and distribution of multiplication strategies differed between the two textbooks. Within the nine coded lessons in *Math Connects*, four different strategies were explicitly stated, with only two (Memorization and Mental Math) stated more than once. In contrast, among the 14 *Eureka Math* lessons coded, ten different strategies were evident, and all were present multiple times. The types of strategies varied between the two textbooks, as well. *Math Connects* contained a high number of math tasks that prompted students to use memorization (n = 27) or mental math skills (n = 9), strategies that were not stated in *Eureka Math*. The most prevalent strategies in *Eureka Math* were related to decomposition and visual aids, including partial products (n = 45), use of a place value chart (n = 28), and use of an area model (n = 24). These strategies were largely absent from *Math Connects*. *Eureka Math* also suggested that students use the standard algorithm (n = 23), often in conjunction with other strategies, such as using a place value chart. This strategy was similarly absent from *Math Connects*. Finally, the number of math tasks that included multiple strategies differed between the two textbooks, as well. Half of the 104 math tasks in in *Eureka Math* (n = 52) included multiple strategies. This included asking students to choose between strategies, including multiple strategies to solve the problem, or specifying multiple strategies to solve the problem. No math tasks in *Math Connects* included more than one strategy.

Table 1: Number and Percentage of Math Tasks that Suggest Specific Strategies

	Textbook	
Strategy Code	**Math Connects (n = 38 tasks)**	**Eureka Math (n = 104 tasks)**
Memorization	27 (71.1%)	-
Mental Math	9 (23.7%)	-
Standard Algorithm	-	23 (22.1%)
Physical Objects	-	-
Area Model	-	24 (23.1%)
Place Value Chart	-	28 (27.0%)
Other Drawings/Symbols	-	9 (8.7%)
Partial Products	1 (2.6%)	45 (43.3%)
Repeated Addition	-	-
Distributive Property	-	9 (8.7%)
Relational Comparison	-	10 (9.6%)
Decomposition	1 (2.6%)	8 (7.7%)
Additional Abstract Strategies	-	7 (6.7%)
Other Strategies	-	6 (5.8%)

Note. Percentage add up to more than 100 because some tasks prompted students to use more than one strategy.

Creating overall categories of strategies. As strategies were coded, patterns emerged between the categories. Some categories required memorization, some included visual scaffolds, some required the use of underlying conceptual knowledge, and some simply required use of a rote procedure. To facilitate comparison, I created four overarching categories within which strategies were sorted. Strategies were sorted by similarities in knowledge needed by students to apply the strategies. The four categories of Memorization, Procedures, Visual Scaffold, and Conceptual Understanding can be seen in Table 2.

Table 2: Multiplication Strategies Categorized by Knowledge Needed

Category	**Explanations**	**Strategies/Original Codes**

Memorization	Relies on memorized facts or prior knowledge	Memorization, Mental Math
Procedure	Using a rote procedure to solve problem	Standard Algorithm
Visual Scaffold	Requires use of a visual scaffold (either physical object or symbolic)	Area Model, Place Value, Physical Object, Other Drawings/Symbols
Conceptual Knowledge	Incorporates conceptual knowledge or understanding of multiplication	Repeated Addition, Partial Products, Distributive Property, Decomposition, Additional Abstract Strategies
Other Strategies	Strategies that do not fit into one of the four above strategies	Relational Comparison, Other

The overall strategy categories presented in Table 2 were then graphed to display the number of problems within each category presented in *Math Connects* and *Eureka Math*, depicted in Figure 1. The *Math Connects* column shows primarily Memorization strategies; indeed, these strategies make up 94.7% of coded strategies in the textbook (n = 36). In contrast, the Memorization category does not appear explicitly in *Eureka Math*. Instead, most problems coded involve conceptual understanding (n = 69, 66.9%) or present visual scaffolds (n = 54, 51.9%).

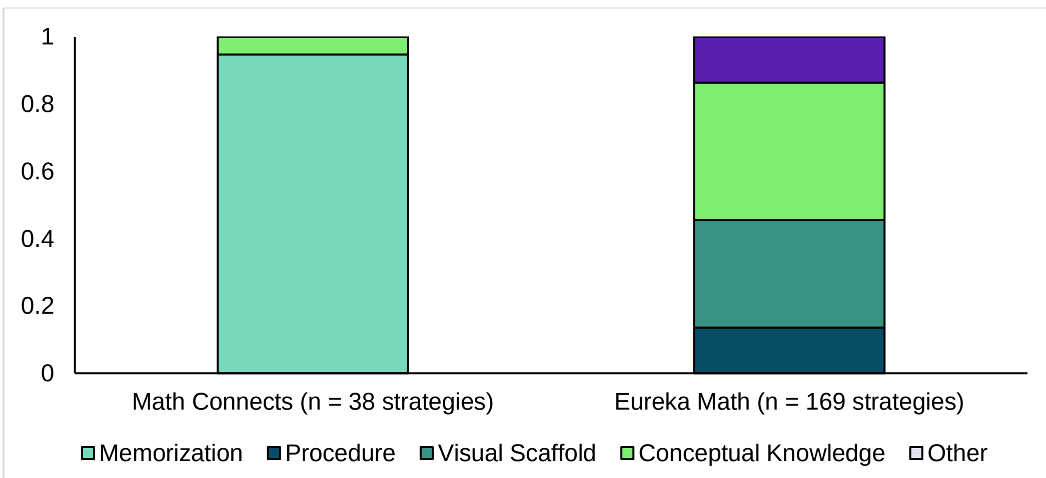

Figure 1: Percentage of Multiplication Strategies within Overall Categories

Note. The number of strategies in *Eureka Math* totaled to more than 104 because some math tasks prompted the use of multiple strategies.

Research Question 2: Instructional Strategies that Promote Procedural Flexibility

I next looked at whether the math tasks incorporated instructional strategies that promoted procedural flexibility. Figure 2 shows the percentage of tasks in each textbook that included problems that might promote procedural flexibility. All instructional techniques included in the framework were seen in the two textbooks; however, the percentages of instructional strategies differed. Within *Math Connects,* 28.3% (n = 47) of tasks employed instructional strategies that may promote procedural flexibility, compared with 69.0% (n = 98) of tasks in *Eureka Math.* In both textbooks, the most frequently used instructional component was to specify a strategy for students to practice (e.g., use the standard algorithm to solve this problem). The distribution of the other types of instructional techniques between the two textbooks was similar, with little variability between the techniques.

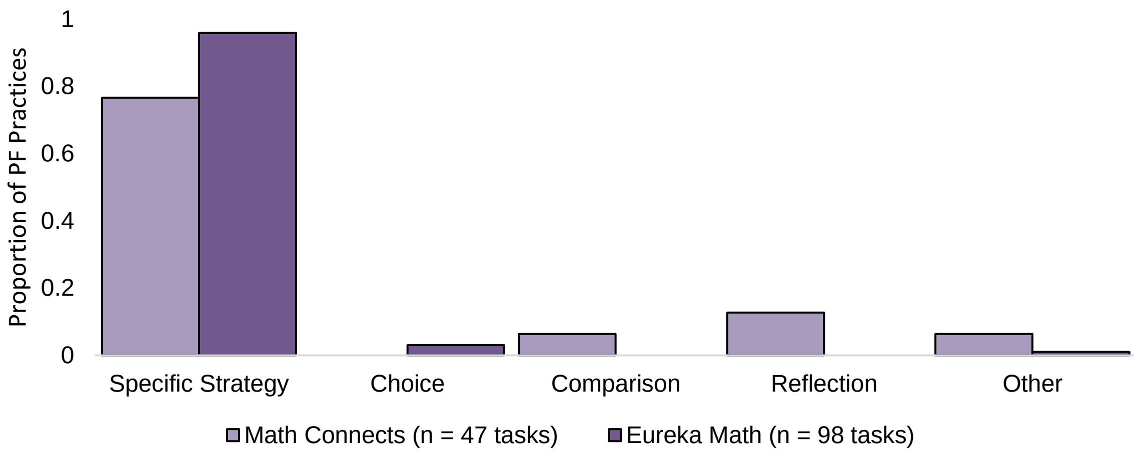

Figure 2: Number of Instructional Techniques that Promote Procedural Flexibility

Research Question 3: Alignment of Multiplication Strategies and Procedural Flexibility

Finally, I looked at whether there were relationships between instructional strategies multiplication strategies. Table 3 shows the alignment between these two axes in both textbooks. Overall, there was not a certain strategy that was paired a certain instructional strategy. However, the two strategies that were paired with reflecting on strategy (partial products and decomposition) in *Math Connects* were categorized as Conceptual Strategies. Interestingly, three tasks in *Eureka Math* promoted students to choose between four different strategies (standard algorithm, partial products, student-created area model, and distributive property).

Table 3: Alignment Between Instructional Strategies and Multiplication Strategies

Instructional Strategy	*Math Connects* Multiplication Strategies	*Eureka Math* Multiplication Strategies
Specify Strategy	Memorization (n = 36)	Conceptual Strategies (n = 61) Visual Scaffold (n = 56) Procedural (n = 20) Other (n = 12)
Choice	-	Conceptual Strategies (n = 6) Visual Scaffold (n = 3) Standard Algorithm (n = 3) Other (n = 1)
Comparison	No Strategy (n = 1)	-
Reflection	No Strategy (n = 6) Conceptual Strategies (n = 2)	-

Discussion

The current study explored what multiplication strategies and instructional strategies promoting procedural flexibility are presented in fourth grade mathematics textbooks and whether the presentation of multiplication strategies and instructional strategies were related. Using novel frameworks developed through prior literature and patterns in the data, I found that most multiplication and instructional strategies included in the frameworks were found in at least one of the two textbooks. Some multiplication strategies included in the framework, such as repeated addition and using physical objects, were not explicitly included in either textbook. Additionally, there was not much variability in the instructional techniques, nor was there overall alignment between multiplication strategies and included and instructional techniques to promote procedural flexibility. These results illustrate what can be learned from applying these frameworks to examine curriculum materials.

The frameworks illuminated great differences between the two textbooks coded. The majority of math tasks coded in *Eureka Math* prompted students to use at least one multiplication strategy when solving problems, yet over 85% of math tasks coded in *Math Connects* did not specify a strategy, instead often asking students simply to “Multiply.” Additionally, although both textbooks overwhelmingly used the “Specify Strategy” instructional technique, the other instructional strategies promoted in the two textbooks differed, with tasks in *Eureka Math* prompting student strategy choice and tasks in *Math* prompting reflection and comparison. Interestingly, neither textbook showed a strong alignment between multiplication strategies and instructional techniques for procedural flexibility. This was likely because there was not much variety in instructional techniques, as both textbooks primarily promoted the “Specify Strategy” technique and did not have many tasks that promoted other techniques. Although presenting multiple strategies for solving multiplication problems might inadvertently promote procedural flexibility, pairing this with instructional strategies that explicitly promote procedural flexibility might lead to greater gains in this skill. Future research might investigate whether this alignment is present in other parts of the textbook or within parts of the enacted lesson.

Limitations and Future Directions

A limitation of this study is that only two textbooks were used to demonstrate the viability of the constructed frameworks. Using a broader variety of textbooks as well as including more recent textbooks as data sources for the developed frameworks would give a more complete picture of what multiplication and instructional strategies are presented in fourth grade mathematics textbooks. Additionally, only independent practice problems were considered in the described analyses. Multi-digit multiplication problems also appeared in other parts of the lessons, such as parts developed for whole-class instruction. Future studies should consider analyzing these textbook features, as well as prompts included in teachers’ guides, to analyze how procedural flexibility is promoted through curriculum enactment.

Conclusion

Procedural flexibility is an important, yet often underemphasized, facet of mathematics learning. This skill can be emphasized explicitly in textbooks, and teachers may be able to further emphasize it through instruction. Small changes in the multiplication and instructional strategies seen in textbooks would likely be beneficial to students in helping them think flexibly and adaptively about problem solving. In learning flexible thinking at an early age, students may be better able to think flexibly about problem solving throughout their mathematics careers.

The purpose of this study is to examine how proportional reasoning is introduced and developed in two widely used U.S. and Korean mathematics textbooks for grades 6-7. Seven research-based frameworks that identify student learning opportunities for understanding of proportional reasoning were used to analyze the textbooks. The results showed that American textbooks include more problems that require explanations and make use of more effective contextual and number structure of problems than Korean textbooks. In contrast, Korean textbooks make a shift from providing highly contextualized problems to presenting abstract and purely computational problems, which aligns with the process of concreteness fading. In addition, Korean textbooks contain more unique types of topics and representations.

Keywords: Proportional reasoning, textbook analysis, cognitive demands of math tasks

Proportional reasoning has been recognized as a key concept in mathematics for middle grades students to develop (Common Core State Standards Initiative, 2011). However, research indicates that students have considerable difficulties understanding proportional reasoning because they tend to apply additive or subtractive thinking processes rather than multiplicative processes (Karplus, Pulos, & Stage, 1983). Students' difficulties with proportional reasoning may be largely attributed to the quality of their learning environments, such as textbooks that influence what is to be taught and what students learn (Alajmi, 2009; Stigler, Fuson, Ham, & Kim, 1986; Weiss, Pasley, Smith, Sanilower, & Heck, 2003). Given the important role of textbook in mathematics teaching and learning, this study, focusing on the case of proportional reasoning, examines learning opportunities presented in representative American and Korean textbooks. The study aims to compare various aspects of the structure and sequence of the lessons on proportional reasoning, and the characteristics of the problems presented in the lessons in American and Korean textbooks. Specifically, the study addressed the following questions: (1) When and how are ratios, rates, and proportional reasoning introduced and developed in American and Korean textbooks?; (2) What similarities and differences are observed in the content of ratios, rates, and proportional reasoning in American and Korean textbooks?

Theoretical perspectives

Student difficulties and recommended strategies for proportional reasoning

Proportional reasoning has been seen as a cornerstone of secondary mathematics curricula because it is important for understanding of percentages, gradient, trigonometry, and algebra

(NCTM, 2006). Accordingly, students' concepts of proportion have long been a focus of mathematics education research and have been explored about students' errors and difficulties in relation to proportional reasoning tasks (Lo & Watanabe, 1997). One of the roots of difficulties with proportional reasoning is that students have a weak understanding of the part/whole relationships described in fraction notation. Students often struggle with solving some proportional reasoning problems that involve the use of fraction notations (Norton, 2006).

Research has consistently emphasized students' difficulties with proportion and proportion-related tasks and applications and explored pedagogical ways to improve students' development of proportional reasoning (Behr, Harel, Post & Lesh, 1992; Lo & Watanabe, 1997). First, research has recommended to contextualize problems in real-life situations, as it can activate students' familiar experiences and informal knowledge for sense-making (Resnick & Omanson, 1987). Representing proportion concepts by using various models rather than numbers and symbols may increase students' conceptual understanding. Thus, concreteness fading, which refers to the process of beginning with concrete representations and then fading into more abstract ones, is found to be effective in developing students' conceptual understanding (Goldstone & Son, 2005). In addition, providing problems with high levels of cognitive demand gives students more opportunities to think and reason in given mathematical tasks. Research indicates that using high-level and cognitively complex tasks is important to develop the capacity to think, reason, and solve problems (Stein & Lane, 1996). Furthermore, it is also recommended to provide proportion tasks in a wide range of contextual (e.g., part-part-whole, scaling, well-chunked) and number (e.g., integer or non-integer answers) structures so that students can apply multiplicative thinking into various types of situations (Lamon, 1999). We use these research-based instructional strategies to identify student learning opportunities for understanding of proportional reasoning.

Textbook comparison

Analyses of mathematics textbooks have examined textbooks across countries and have brought many alternatives and insights to the field for improving instruction on challenging mathematical ideas. Prior international comparative studies have shown that curricula in Asian countries contain more tasks that are framed in concrete and real-life situations and provide more cognitively difficult problems, compared to the U.S. For example, Murata (2008) examined the presentation of addition and subtraction in the U.S. and Japanese textbooks and found that Japanese textbooks included more contextualized problems than the US textbooks, which mainly utilized computation problems. Similarly, Ding and Li (2010) compared Chinese textbook series with the two U.S. series on the topic of distributive property and found that the main problem context was computation problems in the U.S. textbooks, whereas it was word problems in the Chinese textbooks. Son and Senk (2010) also compared Korean and American textbooks with standards-based and traditional American textbooks and found that Korean textbooks include more problems that required students to explain than American textbooks. However, some studies have shown inconsistent results [see Fan and Zhu (2007), Li (2000), Hong and Choi (2014), Son and Senk (2010)]. While some studies revealed that American textbooks contained more problems with higher level cognitive demand, problems that required students to provide explanation, and multiple representation than either Chinese or Korean textbooks, other studies reported different findings. Examining whether these findings are consistent with the results of the previous international comparative textbook studies in the present study will enhance the current understanding of what students learn in the U.S. and Korea.

Methods

Representative and widely used American and Korean textbooks were chosen for this international comparative analysis. For American textbooks, *Eureka Math* or Engage NY modules (EM) (www.engageny.org) were chosen for its popularity (Opfer, Kaufman, & Thompson, 2016). There is only one set of textbook series developed on the national Korean curriculum standards by the Ministry of Education (KM).

The textbook analysis in this study focused on two aspects of textbooks: (1) the structure of the lessons and topics, and (2) the nature of the problems. For the analysis of the textbooks' structure of the lessons and topics, the introduction and development of the concepts of ratio, rate, and proportional reasoning as well as topics arrangement were examined. The analytical framework shown in **Table 1** was utilized to analyze the nature of the problems in depth. The analytical framework consists of the following seven categories: concrete fading (Ding & Li, 2010), cognitive demand (Stein, Smith, Henningsen & Silver, 2000), perspectives (Beckmann & Izsak, 2015; Shield & Dole, 2012; Thompson, 1994), task types (Cramer, Post, & Currier, 1993), contextual and number structure (Lamon, 1993), response types (Charalambous et al., 2010; Mayer et al., 1995), and problem solving difficulty (Hsu & Silver, 2014).

Table 1. Categories and subcategories of analytical framework

Analytical framework	Subcategories
1. Concreteness Fading	Word Problem Visual Representation Word Problem with Visual Representation Abstract
2. Cognitive Complexity	Memorization Procedures without Connections Procedures with Connections Doing Mathematics

4-a. Contextual Structure	Well-chunked Part-part-whole Associated Sets Stretcher/Shrinker Symbolic
4-b. Number Structure	I-I-I I-W-I I-B-I I-B-N N-B-N N-N-I N-N-N

Lischka, A. E., Dyer, E. B., Jones, R. S., Lovett, J. N., Strayer, J., & Drown, S. (2022). Proceedings of the forty-fourth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Middle Tennessee State University.

4-c. Response Type	Numerical Answers Only Algebraic Expressions Required Explanation Required
5. Problem-solving Difficulty	Easy Medium Hard

Problems are coded as instances, according to the definitions of each analytical framework. After coding, we counted the frequency of all the problems in each subcategory of the analytical frameworks. A Microsoft Excel spreadsheet was used to record the frequency and percentage. The number and percentage of problems that were demonstrated in each subcategory were recorded in the spreadsheet. The counts and percentages of problems were summed, and are reported in the Findings section.

Summary of findings

The nature of problems with ratio, rate, and proportional reasoning

Table 2 presents the total number of problems in both textbooks counted. In total, there are 679 problems and 236 problems in EM and KM, respectively. Further, when the frequency and percentage distribution of total problems were categorized per concept, EM present percent problems most frequently and ratio problems least frequently. In contrast, KM include proportional reasoning problems most frequently and percent problems least frequently.

Table 2. Total frequency of problems in Korean and EM

EM (n=679)						KM (n=236)					
Grade (Module)	Ratio (%)	Rate (%)	Percent (%)	Proportional reasoning (%)	Total	Grade (Vol.)	Ratio (%)	Rate (%)	Percent (%)	Proportional reasoning (%)	Total
6 (1)	80 (34)	109 (47)	45 (19)	0 (0)	234 (100%)	6 (1)	48 (53)	25 (28)	17 (19)	0 (0)	90 (100%)
7 (1)	15 (9)	28 (16)	0 (0)	133 (75)	176 (100%)	6 (2)	5 (6)	0 (0)	0 (0)	80 (94)	85 (100%)
7 (4)	0 (0)	0 (0)	269 (100)	0 (0)	269 (100%)	6 (2)	0 (0)	0 (0)	0 (0)	61 (100)	61 (100%)
	95 (14)	137 (20)	314 (46)	133 (20)	679 (100%)		53 (22)	25 (11)	17 (7)	141 (60)	236 (100%)

Concreteness fading and visual representation types

Table 3 shows the frequency and percentage of concrete and abstract problems in EM and KM. The results showed that both textbooks provide most problems in concrete contexts (e.g., EM: 93% and KM: 81%). For abstract problems, only 7 % of the total problems in EM were situated in purely mathematical contexts, while 19 % in KM were framed in abstract contexts. It may seem that EM used more concrete problems than KM. However, it should be noted that the majority of problems in KM was word problems with visual representation, whereas the greater part of problems in EM was word problems. In KM, there were 45 % word problems with visual representation, 33% word problems, and 3% visual representation problems. In EM, 50 % word problems, 28% word problems with visual representation, and 15 % visual representation problems. This may indicate that KM situate the majority of their problems in concrete situations by using visual representation, while EM contextualize their problems through word problems.

In addition, the process of concreteness fading is not obvious in EM. Although concrete representations outnumbered abstract ones in EM, word problems were used most frequently (50%) followed by word problems with visual representation (28%) and visual representation problems (15%). This trend indicates that the frequency of concrete representation types used may not necessarily indicate the transfer from concreteness to abstractness. In contrast, the frequency of concrete representation types used in KM decreases in the following order: word problem with visual representation (45%) - word problem (33%) - visual representation problem (3%). This may show that there is a concreteness fading process within the concrete problems in KM. Moreover, given that KM contained 45% word problems with visual representation, 33 % word problems, and 19% abstract problems, there was a gradual fading process from concrete to abstract representations across problem types. Research shows that although providing learning opportunities in more concrete representations may activate students' familiar experiences for sense-making (Resnick & Omanson, 1987), making connections between concrete and abstract representations than just using concrete representations is found to be more effective in developing students' conceptual understanding (Goldstone & Son, 2005). This may imply that KM may be more advantageous in facilitating students' conceptual development on such abstract concept as proportional reasoning.

Table 3. The frequency and percentage of concrete and abstract problems

	Concrete				
	Word problem (%)	Visual representation (%)	Word problem with visual representation (%)	Abstract (%)	Total (%)
			EM		
Grade 6 M1	98 (42%)	37 (16%)	70 (30%)	29 (12%)	234 (100%)
Grade 7 M1	65 (37%)	28 (21%)	72 (41%)	2 (1%)	176 (100%)
Grade 7 M4	177 (65%)	28 (10%)	51 (19%)	16 (6%)	269 (100%)
Total	340 (50%)	103 (15%)	193 (28%)	47 (7%)	679 (100%)
			KM		
Grade 6 Vol.1	38 (42%)	5 (6%)	37 (41%)	10 (11%)	90 (100%)
Grade 6 Vol. 2	25 (29%)	1 (1%)	21 (25%)	38 (45%)	85 (100%)
Grade 6 Vol. 2	15 (25%)	1 (1%)	45 (74%)	0 (0%)	61 (100%)
Total	73 (33%)	7 (3%)	98 (45%)	47 (19%)	236 (100%)

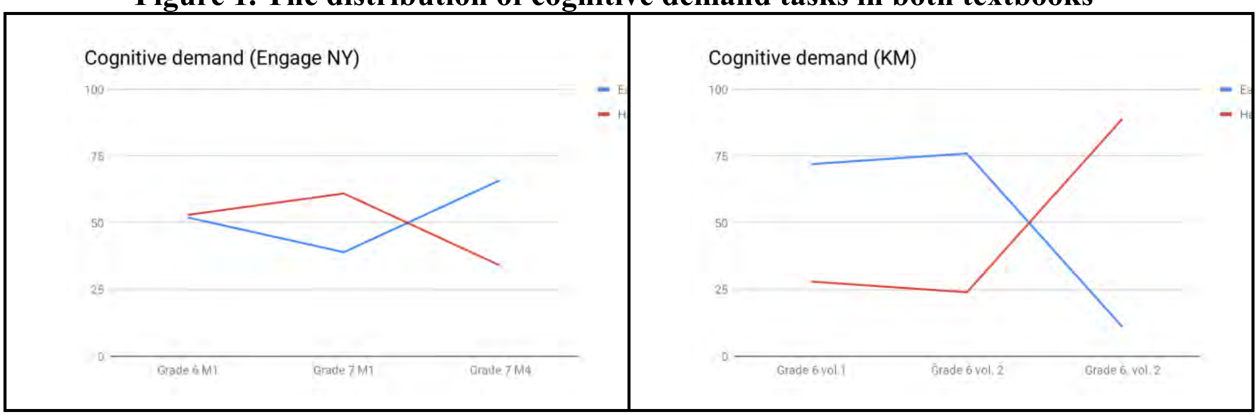
Lischka, A. E., Dyer, E. B., Jones, R. S., Lovett, J. N., Strayer, J., & Drown, S. (2022). Proceedings of the forty-fourth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Middle Tennessee State University.

Cognitive demand and problem-solving difficulty

The majority of the tasks is procedures without connections and procedures with connections in both textbooks. Problems with the highest level cognitive demand, doing mathematics, are little represented in both textbooks. EM have a higher percentage of low cognitive demand tasks (54%) than that in KM (42%). This result does not align with the finding from Hong and Choi (2013) reporting that the majority of problems in American and KM require lower level cognitive demand and more than 80% of problems only require simple algorithms or formulas.

Note that EM have more “procedures without connections” (43%) than “procedures with connections” (37%), while KM have more “procedures with connections” (39%) than “procedures without connections” (36%). This may show that KM contain more cognitively challenging problems that require students to use their understanding of concepts and underlying principles and procedures. However, it also should be noted that the problems in KM are generally either a problem with a series of easy subproblems. For example, the subproblems require students to follow at least four steps to complete the problem in EM, while the subproblems in KM ask for one step to complete the problem. Also, based on the analysis of problems in terms of problem solving difficulty, the majority of problems in KM (88%) are easy-level, which requires only one step to complete the problem, whereas EM contain four times more problems that are at least medium-level (49%), which consisted of two or four steps, than KM (12%). This indicates that EM are expected to complete tasks with more steps than Korean students.

Figure 1. The distribution of cognitive demand tasks in both textbooks



Perspectives: Multiple Batches vs Variable Parts

Table 4 illustrates the percentage distribution of problems based on the perspective of multiple batches and variable parts drawn from Beckman and Izsak (2015). A higher percentage of problems that utilized the multiple batches perspective than the variable parts perspective in both textbooks. EM included a higher percentage of problems with the multiple batches perspective (61%) than KM (24%). By contrast, KM included a higher percentage of problems that utilized both the multiple batches and variable parts perspective (36%) than EM (5%). This may show that EM focus on the development of the multiple batches perspective, while KM intend to develop both perspectives. Different from Beckman, the results of our study show that KM, as the curriculum of one of the mathematically high-performing countries, not only utilized the multiple batch perspective, but also the variable parts perspective in developing students’ proportional reasoning ability through providing the problems that utilized both perspectives.

Table 4. Frequency and percentage of multiple batches and variable parts perspectives

		EM			
Grade	Multiple Batches	Variable Parts	Both	Neither	Total
6 (1)	95 (41%)	13 (6%)	29 (12%)	97 (41%)	234 (100%)
7 (1)	93 (53%)	0 (0%)	0 (0%)	83 (47%)	176 (100%)
7 (4)	229 (85%)	7 (3%)	3 (1%)	30 (11%)	269 (100%)
Total	417 (61%)	20 (3%)	32 (5%)	210 (31%)	679 (100%)
		KM			
6 (1)	25 (28%)	0 (0%)	35 (39%)	30 (33%)	90 (100%)
6 (2)	3(4%)	6 (7%)	49 (57%)	27 (32%)	85 (100%)
6 (2)	52 (85%)	0 (0%)	2 (3%)	7 (12%)	61(100%)
Total	80 (24%)	6 (3%)	86 (36%)	64 (27%)	236 (100%)

Contextual and number structure

We further explored contextual and number structure in missing value problems to explore the learning opportunities for proportional reasoning concepts. We found that the main contextual structure of missing value problems in EM is the stretcher/shrinker problems (47%), whereas the symbolic problems (1%) were minimally represented. In KM, the majority of problems are well-chucked (32%) and part-part-whole (30%) problems, while the least frequently represented problems were associated sets (9%). In EM, all four semantic types were evenly utilized in grade 6. The well-chunked and stretcher/shrinker type were most frequently utilized in grade 7. This may suggest that EM began with a balance of all four semantic types and then moved to the stretcher/shrinker problem type in missing value problems. In contrast, KM initially used the stretcher/shrinker problem type, and then heavily relied on using the part-part-whole and the well-chunked problem type. This finding may show that that EM utilized more appropriate contextual structures of their missing value problems than KM, as their students develop conceptual understanding of proportional reasoning, based on the level of difficulty.

Table 5. Percentage of contextual structure of missing value problems in both textbooks

			EM (n=192)			
Grade (Module)	Well Chunked (%)	Part-Part-Whole (%)	Associated Sets (%)	Stretcher /Shrinker (%)	Symbolic (%)	Total (%)
6 (1)	28 (32)	18 (21)	18 (21)	20 (23)	3 (3)	87 (100)

6 (2)	22 (92)	0 (0)	1 (4)	1 (4)	0 (0)	24 (100)
Total	29 (32)	27 (30)	8 (9)	17 (19)	9 (10)	90 (100)

Discussion and Implications

This study showed notable similarities but also striking differences between EM and KM. The goal of cross-cultural comparison is to know in what measure the learning opportunities provided by textbooks get enacted in classroom practice and student learning. Our findings indicated that how this comparative study of textbooks may contribute insights to improve the learning environments of proportional reasoning. Korean textbooks' emphasis on the process of concreteness fading and skillful use of high level cognitive demanding problems are consistent with prior findings that Asian students are involved in more meaningful and desirable material to learn mathematics. Korean approaches in developing students' explicit understanding, such as the unique construction of lessons, may be helpful for textbook designers in America and other countries. Our study also showed that EM provide more opportunities for students to solve mathematics problems with complex number structures, but also to explain and reason about the problems than KM. EM encourage their students to be independent in solving mathematics problems by asking them to create visual representations to justify their reasoning. These findings seem to conflict with the findings that Asian textbooks present more problems requiring explanation and problems with multiple visual representations than American textbooks. Developers of KM can benefit from EM' approaches in using various strategies, such as a wider range of number structures and visual representations, and stressing more critical thinking.

INFLUENCE OF CONTEXT ON TEACHERS' ASSESSMENT PRACTICES

Kamie K. Stack

eebaldinger@umn.edu

The process of assessing students is a fundamental part of teaching and learning mathematics. The assessment practices a teacher chooses are shaped by their values while also being shaped by the context of the school, district, state, and country where the teaching takes place. This can result in gaps between teachers' values and practices. In this study, we use student work sample interviews with five secondary mathematics teachers to illustrate their values around assessment, the factors that influence their assessment practices, and how their agency influences their assessment decisions. We focus on the important role contextual factors can play in shaping teachers' agency and assessment choices. These findings have implications for teacher education and further research around how assessments are used.

Keywords: Assessment, teacher beliefs

The process of assessing students is a fundamental part of teaching and learning mathematics. The assessment practices a teacher chooses are shaped by their values while also being shaped by the context of the school, district, state, and country where the teaching takes place. Enacting high-quality assessment practices has been identified as a key factor in preparing future mathematics teachers (Association of Mathematics Teacher Educators, 2017). Prior research has highlighted teachers' assessment practices and their values related to assessment within and outside of mathematics education (e.g., Barnes et al., 2014; Beswick, 2011; Brown, 2004; Davis & Neitzel, 2011; Remesal, 2007). Just as there may be gaps between mathematics teachers' values and instructional practices more generally (Beswick, 2011), such gaps may extend to assessment practices in particular. Despite this, teachers' assessment practices are used as factors in measuring teaching effectiveness (e.g., Sato, 2014; Sato et al., 2008).

Given these conditions, researchers in the Network for Excellence in Teaching (NExT) sought to investigate multiple measures of teaching effectiveness (NExT Teacher Effectiveness Work Group, 2018). One such measure built on D'Souza's (2012) Teacher Assessment/Pupil Learning Protocol (TAPL) which was used to examine assessment practices and how they evolve with early career high school English teachers over a period of five years. Using D'Souza's TAPL, NExT created a student work sample interview protocol to measure teacher effectiveness across disciplines. As part of our participation in NExT, we implemented the student work sample interview with recent graduates of the secondary mathematics licensure program in a Midwest University.

In a student work sample interview, teachers select student work from a recent assessment they implemented and then discuss the pieces of student work with an interviewer. Through piloting this interview protocol, we gathered important data for the NExT consortium and the teacher preparation program. Beyond programmatic evaluation, we also noticed interesting patterns related to teachers' values and assessment practices. We therefore engaged in a process of open coding, drawing on the principles of grounded theory (Charmaz, 2006). We arrived at two research questions: (1) What factors influence how secondary mathematics teachers enact assessment practices? (2) How does their enactment align with their values about assessment?

Literature Review

In this section, we highlight relevant literature related to assessment and teacher agency. These two constructs are key to understanding the themes that emerged from our interviews.

Assessments Serve Multiple Purposes for Multiple Audiences

Assessments generate artifacts that serve multiple purposes for multiple audiences (Davis & Neitzel, 2011; Remesal, 2007). In addition to students and teachers, audiences for assessment artifacts include parents, caregivers and what Davis and Neitzel (2011) call the "higher-ups"—people such as school administrators, district leaders, and policy makers. With multiple and potentially conflicting audiences come multiple conceptions of the purposes of assessment. Teachers' conceptions exist along a continuum from a focus on the pedagogical purposes of assessment to a focus on the accountability purposes of assessment (Barnes et al., 2014).

At the pedagogy end of the continuum, students and teachers are the primary audiences for assessments. Pedagogical purposes of assessment include informing instruction, facilitating learning, and providing evidence of student understanding. For students, assessments align with the content in the curriculum (Davis & Neitzel, 2011), demonstrate their progress toward learning goals (Karp & Woods, 2008), and offer an opportunity to receive feedback. On the alternative extreme of the continuum, the "higher-ups" are the driving audience. Here, assessments are used as measures for teacher and school accountability (Brown, 2004). As an example, teachers may choose to use classroom assessments as intentional preparation for high stakes, standardized assessments to adhere to expectations from the "higher-ups" audience and their focus on accountability (Davis & Neitzel, 2011). In this example, the audience of the "higher-ups" and their beliefs about the purpose of assessment influence classroom assessment practices. The accounting role of assessment is punctuated in mathematics education because most students in the United States take a high stakes mathematics assessment at the end of every school year starting in third or fourth grade.

Enacting Assessment Values

Teacher values around assessment, including where such conceptions might fall along the continuum, influence classroom decisions (Biesta et al., 2015). However, a teacher may hold competing goals and values for their approach to assessment (Thomas & Yoon, 2014). For instance, a mathematics teacher may value teaching practices that support a deep conceptual understanding of essential learning goals. They may also value preparing their students for success on high stakes assessments. The first value may require teachers to allocate extended instructional time to a single learning goal. The second value may require teachers to follow a particular curriculum or set of standards within a specific time frame. These two values may come into conflict when students need more time to master a particular learning goal but also need to move on to the next learning goal to complete the curriculum before the high stakes assessment. How a teacher decides which value to prioritize depends on teacher agency. Teacher agency is the degree to which teachers can enact their values in classroom practices within the culture and context of the school (Biesta et al., 2015).

Teacher agency is situated by context and a complex relationship between educational theory, practice, and environment (Biesta et al., 2015). Thomas and Yoon (2014) found that teachers prioritized their pedagogical values when making instructional decisions until one of three conflicting values came into play: (1) requirements about time, curriculum, or assessment; (2) potential success for future learning; and (3) respect for students' cultures. For instance, a secondary mathematics teacher who was committed to student-centered learning might not enact that value when it came in conflict with preparing students for assessments by completing the national curriculum in the available time. In this case, the teacher switched to teacher-led instruction and limited the time allocated for a specific learning goal, despite their personal feelings that the concept was important, because it was not part of the required curriculum.

When there is tension between conflicting assessment values, particularly between pedagogical and accountability purposes, teachers may feel less agency around the accountability purposes of assessment. As a result, teachers may prioritize accountability purposes even to the detriment of their pedagogical values. Teachers' choices related to navigating conflicting values are influenced by the amount of agency they perceive in decision making. In this study we connect the research by Barnes et al. (2014), Thomas and Yoon (2014) and Biesta et al (2015) to discuss agency and how it relates to assessment values and practices with early career teachers in mathematics.

Methods

This study emerged as a result of piloting the student work sample interview protocol from the NExT digital handbook (NExT Teacher Effectiveness Work Group, 2018). The interview protocol was based on D'Souza's (2012) case study of early career teachers' assessment practices. D'Souza found that a student work sample interview protocol encouraged reflective practices with early career teachers that supported growth and development around assessment practices. Those findings motivated our choice to pilot this interview protocol, in particular because we were interested in how a protocol designed to work across disciplines might be used in the context of early career mathematics teachers. Unlike D'Souza, who implemented the TAPL with participating teachers routinely over five years, we piloted the NExT student work sample interview protocol once with each of our participating mathematics teachers.

Data Collection

Participants for this study were drawn from the approximately 40 secondary mathematics teachers who were in their first three years of teaching and had graduated from the secondary mathematics teacher licensure program at a Midwest university. All 40 teachers were invited to participate in the study and five teachers elected to participate. Four teachers taught at middle or high schools in the same Midwest state as the licensure program; the fifth taught in a school in the southeast United States.

Each teacher selected a recent assessment they had used in their mathematics courses and submitted a set of student work samples to the researchers prior to an individual interview. The only parameters for the teachers in this study was to select an assessment that had enough student work to drive a conversation about the learning that was present. The selected assessments ranged from two questions on a single skill to a summative unit test or project. The student work samples were graded and represented a range of student mastery.

The semi-structured interview included five main sections: (1) context questions focused on understanding the school setting, (2) description of the assessment, (3) discussion of student work samples, (4) implications for advancing student learning, and (5) a final reflection. The context questions asked teachers to share anything they felt was important for the researchers to know about their students and school. In the second section, teachers described the assessment and the learning activities that led to or followed the assessment. The majority of the interview time was dedicated to the third section, reviewing and analyzing the student work samples. During this portion of the interview, teachers were asked to organize the student work into three categories: *demonstrated mastery, approaching mastery,* and *still needs support*. The teachers then described what they noticed in each sample and explained why they categorized the student work as they did. Teachers were then asked about the next steps they wanted to take to further student learning. Finally, each interview concluded with an opportunity to reflect on the experience of participating in a student work sample interview, as well as any reflections about the licensure program. Each interview lasted approximately 60-90 minutes. All interviews were video recorded and transcribed for analysis.

Data Analysis

To analyze the interviews, we used two distinct but complementary approaches. The first approach followed the NExT digital handbook (NExT Teacher Effectiveness Work Group, 2018) which suggests using rubrics provided to measure the effectiveness of teachers' assessment practices. These rubrics were adapted from edTPA. They evaluated (1) assessment planning, (2) analysis of student learning, (3) feedback on student learning, and (4) analysis of student learning to inform teaching. Using these rubrics for the initial purpose of piloting the materials from the handbook, we began to notice additional patterns in the data.

These initial observations led us to engage in a more systematic, open analytic process. Our second approach applied grounded theory to code and analyze the interviews. Grounded theory starts with a general area of research interests and uses the coding of qualitative data to identify patterns (Charmaz, 2006). Those initial patterns inform subsequent research questions and coding to arrive at a theory from the data. We concluded by looking at the results from these two analytic approaches to identify any further patterns evident in the data.

Results

Our analysis resulted in three key findings. First, we found that the mathematics teachers demonstrated high-level indicators of effectiveness relative to the pre-existing rubrics. In particular, they demonstrated values related to assessment that align with high-quality instructional practices. Second, through our use of open coding, we identified a wide variety of factors that influence how teachers enact their assessment values. Finally, we describe how teachers revealed tension between their assessment values and their perceived agency to enact those values.

Teachers' Assessment Views

We found evidence that all five teachers in the study demonstrated assessment practices and values that aligned with high-level indicators described in the NExT handbook. Teachers demonstrated that they (1) believe all their students can do well on mathematics assessments, (2) can differentiate feedback and analysis based on knowledge of individual students, (3) view assessment as ongoing, and (4) can design and implement assessments that provide students with opportunities for deep mathematical learning.

Mastery and ongoing assessments. A high-level performance indicator states that teachers use an "assets-focused approach to describing student progress towards learning goals". We found that all five teachers demonstrated this indicator in how they responded to interview prompts to discuss the student work samples. The interview protocol asked teachers to categorize their work samples based on student mastery. Despite this prompt, all five teachers resisted grouping the samples and instead discussed each piece of student work individually. The teachers consistently tailored their discussion and ideas for further instruction based on their knowledge of each individual student. They described the student understanding they saw demonstrated in the work and discussed how that aligned with the individual's progress towards their overall mathematics goals. We found their collective decision to discuss students individually rather than as a group to be evidence that the teachers were focused on each students' mastery level on the assessment and their progress toward the learning goals. The teachers discussed student work in a way that consistently indicated that they believed all students would master the learning goal eventually.

Tied to the concept that all students would eventually master the learning goal, we also found that teachers approached assessment as ongoing. Teacher A, for example, said, “I like giving at least two chances on each test.” This teacher went on to describe how additional opportunities for students to take assessments combined with standards-based grading provides Teacher A with a more comprehensive understanding of student mastery. Like Teacher A, all participants discussed intentionally providing ongoing assessment opportunities that enable students to demonstrate mastery of the learning goals beyond the first assessment.

Assessments as opportunities for deep mathematical learning. Another indicator of productive assessment practices from the student impact rubrics was opportunities for deep learning. To demonstrate valuing deep mathematical learning through assessment practices, teachers might require students to communicate mathematical arguments through their work and/or develop mathematical ideas. Teachers in our study demonstrated this in multiple ways. Teachers C and D analyzed student learning based on the ability to communicate valid arguments to support their work. Teacher B designed assessments that encouraged students to construct new mathematical ideas alongside checks for understanding.

To Teacher D, having the correct steps in a geometric proof was only part of demonstrating learning mastery. They also felt students must be able to create and communicate a valid argument through their work in a way that others can understand. Teacher D explained that they were not only looking for an accurate answer. “I also want them to understand that this is communication and it should be written to be read. I'm looking to motivate the idea that we're doing math as both a deductive and social activity.” To assess that, Teacher D designed an open-ended project with student choice that allowed students to prove geometric theorems using paragraphs, annotated diagrams, or a two-column format. Teacher B’s assessment design also encouraged students to think critically and advance conceptual understanding. Their assessment included questions that asked how a data summary would change if a new value was added to the data table. Students were also asked to make predictions about outliers, which served as a pre-assessment to the next lesson. These examples demonstrate that these early career teachers were prepared to design assessments with opportunities for deep learning by developing mathematical ideas and communicating mathematical arguments rather than focusing assessments solely on procedural fluency.

Factors that Influence Enactment of Assessment Values

The teachers indicated that there are a variety of factors that influenced how they enact their assessment values in practice. These factors included influence from administration, influence from their teacher preparation program, and their perceived agency in classroom decisions.

Influence from the teacher preparation program. All five teachers discussed assessment practices and values that were influenced by their teacher preparation program. These influences include practical elements of teaching and learning of mathematics, such as implementing multiple forms of assessments, incorporating unit plans they designed during their university coursework, and considering specific examples of student misconceptions in assessment design. They also demonstrated theoretical understanding of assessment practices by citing specific readings they had studied and the socioemotional needs of students.

For example, Teacher C reflected on their assessment and discussed designing assessments that were accurate measures of student understanding, which requires questions that can tease out misconceptions. The assessment selected by Teacher C was part of a routine created by the mathematics team at their school to improve student skills on selected standards. In this assessment, students solved two questions using the distance formula. Both questions involved finding the distance of a horizontal line segment from the origin to another point. Teacher C critiqued their assessment, referencing a specific task from their teacher preparation program which revealed that students can develop misconceptions about triangles when the base is always horizontal to the x-axis. They applied that experience to this assessment and explained that future versions of this assessment should include questions that solve for the distance of both horizontal and diagonal lines. This example highlights the high-level indicators of designing and implementing assessments that are accurate measures of student understanding and using evidence in student work to measure nuanced growth towards the learning goal.

Teacher C explained, however, that adjusting assessment questions created a new set of challenges for department collaboration and measuring student growth. Their assessment was designed as an intervention strategy with multiple opportunities for reassessment. As such, one of the goals was consistency both in assessments/reassessments and across classrooms. Teacher C described the complexity of wanting to design assessments collaboratively and implement assessments that were consistent enough to support student growth through reassessments, while also varying the questions to be a true measure of what the students know. Teacher C's commitment to each of these values were influenced by their program, but the reality of navigating those values while collaborating with a department sometimes created tension.

Influence from school administrators. The interview data revealed that the teachers' assessment practices were strongly influenced by their school administrators' view of assessment in mathematics teaching and learning. The teachers expressed feeling tension between their assessment values and the assessment practices encouraged or enforced by their school administrators. The teachers described a complex and contextualized reality that influenced their ability to implement high level assessment practices.

Multiple teachers described tension between the values developed during their program and their administrator's views on assessment. For example, Teacher E discussed how their district's "data driven" assessment plan felt at odds with the values learned during their program. "We were taught about all the awesome ways that you could do things. Which is great...But I don't know if that effectively prepared me for walking into a school where that's the exact opposite of what they do". Teacher E felt that pressure from the district to maximize student performance on standardized tests influenced instructional and assessment decisions that went against the practices learned as a pre-service teacher.

Similarly, Teacher C shared that their school leadership viewed mathematics learning through a procedural lens.

> The program prepared me wonderfully for actually teaching mathematics, but navigating [my] district's and administration's attitude towards mathematics is more difficult...the decision makers in our administration conceptualize mathematics as all procedural. [...] How to navigate that while pushing towards the ultimate goal of making mathematics education about understanding is a thing that I feel like I don't know.

Through their work in the teacher preparation program, Teacher C learned to value understanding in mathematics teaching and learning, yet their administration viewed mathematics as "all procedural". Both Teachers C and E described feeling frustrated about how the "higher ups" views of assessment purposes influenced their ability to enact practices that align with their personal assessment values. They offset those tensions by creating ongoing assessment opportunities that provided students with additional chances. The teachers explained that in their respective departments, the mathematics teachers chose to integrate reassessments and test corrections to better align their values with the required assessment expectations.

Finite learning time. Limited learning time also appeared to be a significant factor for how teachers enacted their assessment values. We define *learning time* as available time for instruction and intervention based on scope and sequence constraints. All five teachers talked about learning time. The teachers described immense pressure to maintain scope-and-sequence pacing for the year. This is particularly notable since our interview questions focused strictly on assessment without any reference to instructional time. Teacher B reflected on this from their position as the sole mathematics teacher at their school, saying, "I feel kind of blessed almost to be the only teacher because I get to work on my own schedule...and really use data from assessments to help guide my teaching." This contrasts with teachers who felt bound by their pacing guides. These teachers described feeling pressure to "push through the content" faster than the students could handle and having to "hustle to convince" students to get extra help during lunch or after-school. These time barriers also affected how much time teachers felt they had to provide feedback and modify their instruction based on assessment data.

These influences from the teacher preparation program, school administrators, and learning time all contributed to situations where teachers found themselves with competing goals relating to assessment. In the next section, we turn to the construct of agency to help us understand how teachers navigated these competing values.

Complex and Contextualized Teacher Agency About Assessment

Despite our finding that these five teachers demonstrated high-level indicators with respect to their assessment values, how they were able to enact those values was contextualized through the complex realities of their schools. Our data highlights complexities around administrators' view of assessment purposes in mathematics and the relationship between learning time and instructional decisions. Teachers navigated these contexts based on their perception of agency over teaching practices. In some circumstances teachers felt agency to align their assessment values with practices, such as using assessment data to inform classroom decisions and designing assessments with opportunities for deep mathematical learning. At the same time, all of the teachers described situations where they felt pressure to enact assessment practices that went against their values. One area where teachers demonstrated agency was in designing year-long assessment plans with ongoing assessments. All of the teachers were required to meet assessment expectations set by the "higher ups". This included weekly department-wide skill assessments, a minimum of two summative assessments every four weeks, or administering assessments that were closely tied to high stakes standardized assessments. However, all five teachers also incorporated ongoing assessment practices or assessments designed to allow solutions in multiple representations within their school's larger assessment plan. Teachers were able to find space within those expectations to enact their assessment values based on the degree of agency.

Discussion

Our study had three findings. First, all five teachers demonstrated high-level performance indicators for assessment values. Second, factors influenced how teachers enacted their values - including tension created by the "higher ups" views and expectations about assessments in mathematics. Third, teachers navigated this tension by agency that was contextual. A key finding from this study showed that mathematics teachers recognized a misalignment between their assessment values and their agency to enact those values.

We argue that the degree of teacher agency to enact assessment values depends on where the conflicting values lie on the continuum of purposes of assessment (Barnes et al., 2014). When the purpose of assessment was at the pedagogical end of the continuum, teachers were doing the assessing and had agency to align their values with classroom practices. In our study, we saw this when teachers used multiple forms of assessment, created ongoing assessment practices, and individualized feedback. However, when the conflicting values were between accountability purposes from the "higher ups" and pedagogical purposes, teachers yielded their values to conform to expectations. At this end of the continuum, teachers were *being assessed* while they were assessing student understanding. The "higher ups" use assessment as a form of control and accountability to evaluate teacher effectiveness (Barnes et al., 2014). When there is tension between the teachers' assessment values and higher ups views of mathematics assessments, teachers are put in a position where they must choose between their evaluation of teacher effectiveness or pedagogical practices that align with their values.

One of the most striking themes from our data was the influence learning time had on teachers' assessment practices. All of the teachers in our study cited the pressures of learning time as a driving factor for instructional decisions that misalign with their values. Thomas and Yoon (2014) found that time was one of three factors that influenced a teacher to abandon their pedagogical values in order to conform to accountability purposes of assessment. In that study, time was grouped with curriculum and assessment. Echoing Thomas and Yoon, we posit that required curriculum and high stakes assessments, as well as learning time, are factors that influence teachers' agency to enact their assessment values. Furthermore, we argue that teachers felt pressured to disregard their values because time, curriculum, and high stakes assessments are at the accountability end of the continuum of assessment purposes.

"Higher ups" make decisions and set policies that they believe will help students learn mathematics, such as scope-and-sequencing and departmental teaching strategies. However, their lens of understanding these practices is often driven by standardized assessments, which means that it is still largely procedural. Mathematics teachers, through their licensure programs, have a complex and nuanced understanding of teaching mathematics for conceptual understanding that align more strongly with pedagogical purposes of assessment. Our findings support research that continues to think about ways to use available learning time for deep learning rather than focusing solely on procedural skills. Our data shows that less pressure around maintaining a scope-and-sequence may enable teachers to better enact their assessment values.

Our study piloted a teacher interview protocol that was adapted from D'Souza's (2012) TAPL with early career mathematics teachers. Similar to D'Souza, we found that this protocol was an effective tool in understanding teachers' practices and values around assessment. We found that when implemented with secondary mathematics teachers, the student work protocol revealed both indictors of high-level assessment practices and contextual factors that might prevent teachers from enacting those practices. We posit that teacher agency is a key component to enacting assessment values and is tied to the continuum of purposes of assessment (Barnes et al., 2014). Since accountability purposes influence teachers' agency, evaluations of teacher effectiveness should include opportunities for teachers to identify when they felt pressured to act against their values. The NExT student work sample protocol is one alternative to evaluate teachers' assessment values and practices.

HOW DO TEACHERS AND DISTRICTS IMPLEMENT STATEWIDE CO-DESIGNED INSTRUCTIONAL FRAMEWORKS?

We report the findings from our efforts to co-design statewide instructional frameworks to support elementary and middle school mathematics teachers' and leaders' implementation of state standards in ways that align with visions of high quality mathematics instruction. In this paper, we explore whether districts as well as individual teachers took up the instructional frameworks, their reasons for doing so, and the ways they used them to support instruction. Our findings indicate that the instructional frameworks were widely adopted across the state, supported teachers' pacing and sequencing efforts, and provided opportunities for professional learning. However, school/district leaders and classroom teachers had different views on why their district decided to take the frameworks up, indicating a communications divide that needs to be addressed in future co-design efforts.

Keywords: Systemic Change, Curriculum, Design Experiments

The notion of vision has long been researched as an important part of a teacher's ability to enact thoughtfully adaptive teaching (Duffy, 1998). Additionally, a shared vision of high-quality instruction among administrators, teachers, and other stakeholders, is essential for professional development and collaborations to be effective in schools (Birkeland & Feiman-Nemser, 2012; Fulton, et al., 2010) and for the implementation of new programs or policies (Gamoran, et al., 2003). The importance of common vision of mathematics instruction is reflected in Cobb and Jackson's (2011) theory of action for large scale instructional improvement in mathematics, which includes vision of high quality mathematics instruction (VHQMI) underlying a coherent instructional system as one of five key elements. What counts as "high quality" in mathematics education is debatable, but a large body of research suggests that HQMI involves listening to students and building on their representations and strategies to encourage sense making. Teachers who aspire to this vision are often constrained by district policies (e.g., scripted curricula, strict pacing and sequencing) and state mandates (e.g., assessments, standards). Although these conditions have constrained mathematics teachers across the country, we describe a research-practice partnership (RPP; Coburn, et al., 2013) that aims to co-design infrastructures and resources that support North Carolina mathematics teachers to develop and enact common visions of high-quality mathematics instruction (VHQMI). In this paper, we report the findings from our efforts to co-design statewide instructional frameworks to support elementary and middle school mathematics teachers' and leaders' implementation of state standards in ways that align with VHQMI. Specifically, we explore whether districts as well as individual teachers took up the frameworks and why.

Co-designing for Shared VHQMI Through Instructional Frameworks

Research suggests that pacing guides are often viewed as a constraint to enacting visions of practice (Duggan, et al., 2018). They undermine teachers' flexibility to meet individual student needs as district expectations of strict adherence to weekly or daily schedules contribute to the need to "cover everything," often by dropping conceptual-based, student-led activities in favor of teacher-directed activities (Bauml, 2015). In North Carolina [NC], school districts had each created their own pacing guides to sequence instruction based on statewide standards. Differing levels of capital and expertise among districts resulted in widely varied pacing guides, some co-created by district-wide teams of elementary math specialists and, in other districts, created by K-12 district curriculum leaders with no particular expertise in mathematics education. North Carolina teachers and leaders identified this as a problem of practice that could be leveraged to build towards a more coherent vision across the state. Thus, we convened teams including teachers, instructional coaches, administrators, and curriculum leaders from 19 diverse and representative school districts, higher education faculty from eight universities and state leaders from the NC Department of Public Instruction [NC DPI] to co-design an elementary and a middle school pacing guide that would be grounded in research on learning progressions (Common Core Standards Writing Team, 2013) and could be adapted *statewide*. The co-design teams decided to address their concerns about common VHQMI, and the productive vs. non-productive uses of pacing guides by envisioning a pacing document that goes beyond "what to teach when." Focused on the idea that curriculum materials can themselves can be educative (Drake, et al., 2014; Davis & Krajcik, 2005) the co-design teams set a goal of promoting a shared instructional vision by developing suggested state-wide, grade-level pacing guides, re-named **instructional frameworks** (IFs) to denote their role beyond traditional pacing documents that: 1) Emphasize curriculum guidance, not prescriptive pacing, 2) Focus on central ideas with links to exemplary curriculum materials, lessons, and instructional strategies, 3) Allow for flexibility and unpredictability based on differences in teachers, students, and contexts, 4) Address development of student reasoning and how to build upon it (i.e., learning progressions), and 5) Are adjusted frequently based on feedback from teachers. The co-design teams completed first drafts of the IFs in fall 2017, sought feedback through a statewide survey from stakeholders, made revisions and rolled the IFs out in spring 2018. Importantly, the NC DPI adjusted the content of their free, optional interim assessments [Check-Ins] to align with the IFs sequencing and pacing. Like the Check-Ins, districts had the option to use the IFs to guide implementation of the mathematics standards for the 2018-2019 school year. At this time, the elementary and middle school IFs have been available and adapted statewide for three years. In this paper, we share findings related to three research questions:

RQ1: For districts that adapted the IFs, what did participants think was the reason for uptake?
RQ2: What aspects of the frameworks did individual teachers report were their favorite?
RQ3: How did teachers report using the frameworks?

Research Methods

This work is part of an ongoing Design-based Implementation Research (DBIR) state-wide project that is in its seventh year, having partnered with hundreds of NC mathematics educators. In 2019, a survey was distributed through the state agency's listservs to approximately 20,000 mathematics teachers, school administrators, and district mathematics leaders. Of the 813 educators that responded to the survey, we analyzed only the responses of participants who worked with grades that would potentially use the IFs. These 538 responses represented 74% of the NC school districts. Of the respondents, 60 were School-based Coaches/Curriculum Facilitators, 38 District Curriculum Personnel, 4 Principals/Asst. Principals, and 436 Classroom Teachers. The respondents worked in elementary (320), middle (181), elem/middle (11), middle/high (16), and elem/middle/high school (10) settings. In this report, we analyzed the answers to a block of questions/prompts related to implementation of the IFs:

1. **Question 1:** Did your district use the instructional frameworks?
2. **Prompt 1:** If you know what influenced your district's decision to use the IFs, rank and order the reasons below: match/align to the state quarterly assessments, match the textbook or math program used in my district, align to State resources, match our current sequencing and pacing of instruction, address the development of student reasoning and how to build upon it based upon research, were co-designed by a large number of people, were created with feedback from teachers and leaders, and I do not know.
3. **Question 2**: What are your favorite aspects of the instructional frameworks? (Pick up to 3 choices): [same choices as Prompt 1].
4. **Question 3**: How did you use the IFs (Select all that apply): as a resource among a variety of resources, a resource to supplement a textbook or math program, to determine pacing and/or to sequence instruction, to gain a better understanding of what the standards mean, to gain a better understanding of the mathematics, to understand vertical alignment.

Findings

Of the 75 district leaders, school coaches, and principals/asst. principals who answered question 1, 85% (n=64) reported that their district was using the IFs, 13% (n=10) said they were not using the IFs, and 2% (n=1) said that they did not know. These 75 mathematics leaders represented 53 of 115 districts or roughly 46%. We used responses from district and school leaders only because we believe they have the most accurate knowledge of the district's decisions, whereas a teacher does not always have direct knowledge of their district's intentions. Interestingly, of the 227 classroom teachers who answered this question, 78% of respondents say that their district uses the IFs, 8% say that they do not, and 14% do not know. This suggests some coherency between teachers' and leaders' knowledge of whether the IFs are being used within their districts. The fact that 14% report that they do not know whether their district adapted the IFs or not suggests there may be a communication challenge between districts and teachers. Overall, we are encouraged by the high number of districts that report using the IFs.

Why Did Districts Take Up the Instructional Frameworks?

We separated responses to survey prompt 1, if you know why your district decided to use the IFs, by education role. According to district leaders, school coaches and principals/asst. principals, the top three ranked reasons that districts chose to use the IFs were that they matched the state quarterly assessments, matched the district's textbook/curriculum and incorporated feedback from teachers and leaders. In contrast, classroom teachers reported that their district chose to use the IFs because they matched the textbook/curriculum, matched their district's current pacing guide, and aligned to the State's resources. In this case, teachers and teacher leaders only agree that the district used the IFs because they match the textbook/curriculum of their district. Otherwise, there is little agreement. It is significant to notice that educators who are closer to their district's decision making process, report that assessments were an important part of their decision while classroom teachers ranked assessments in the bottom three reasons they thought their district used the IFs. This finding indicates that there is miscommunication between districts and teachers and suggests infrastructuring as a potential problem to address in working towards shared VHQMI.

What Were Individuals' Favorite Aspects of the IFs?

Of the 302 respondents to Question 2, approximately 50% chose *matched the state quarterly assessments* as one of their top three favorite aspects of the IFs. Not far behind was the fact that the IFs *address the development of student reasoning and how to build upon it based on research*

(40%) and that they *match their district's current pacing guide* (36%). Disaggregating the responses by role group (teachers and leaders), there is no difference which suggests regardless of role responsibilities, participants valued the same aspects of the IFs. In particular, the IFs seem to be valued for their intended purpose: suggested pacing of standards. Second, the IFs are valued for aligning standards with the assessments. Surprisingly, the second most valued characteristics of the IFs involved the fact that they are based upon the development of student reasoning and research. Taken together, these findings suggest that educators value the resources for addressing their practical challenges, *assessments and pacing,* and must be attended to in resource design. Further, grounding resources in research was a characteristic that was valued by those who took it up.

How did individuals use the IFs?

Question 3 asked participants to select among a variety of ways that they used the IFs in their classroom instruction or professional work (if leaders). From the 226 responses, the three most prevalent uses of the frameworks were to gain a better understanding of what the standards mean (51%), as a resource among a variety of resources (51%), and to determine pacing and/or to sequence instruction (47%). Less common responses included using the frameworks to gain a better understanding of the mathematics (36%), to understand vertical alignment (31%), and as a resource to supplement a textbook or math program (14%).

Discussion

The goal of this DBIR project was to work towards statewide shared VHQMI by co-designing instructional frameworks to address the shared problem of practice of non-productive uses of pacing guides and the many disparate, district-created pacing guides across the state. The IFs were taken up widely and served their purpose as a guide for sequencing and pacing and also as a tool to promote professional learning. Findings about why and how districts used the IFs and what was most valued about the tool have implications for future co-design. First, perceptions about why districts took up the IFs differed between leaders and teachers, indicating a lack of communication. Continued co-design to promote shared VHQMI needs to support communication across role groups. Second, respondents valued that the IFs addressed the development of student reasoning and how to build upon it based on research, and yet this component was not among the top reasons respondents perceived as a reason districts chose to use the frameworks. In other words, respondents valued that the tool was research-based and focused on student reasoning, but it was not a determiner of uptake in the way that alignment to state assessments was. Thus, the co-design process needs to include negotiating the existing structures within the communities for which tools are being created. Finally, intentionally seeking feedback from all role groups in the system is essential in co-design. In the case of the IFs, getting feedback at multiple levels allowed for attention to the differing needs that were expressed, resulting in high uptake and buy-in, opportunities for learning, and movement toward shared VHQMI. As one respondent noted:

> The instructional frameworks could be the beginning of a powerful movement in North Carolina towards Student Centered Mathematics Instruction. The frameworks are so detailed regarding rationale for clusters that it serves to support teacher professional learning. I think that we need so many more professional learning opportunities where teachers from all over the state can come and collaborate and learn from each other.

This research report describes a Learning Trajectory-based Curricular Design project that engaged teachers and coaches in the design and implementation process. As the project team, we focused on deepening teacher designers' understanding of the learning trajectory (LT) while situating student learning along a continuum to advance student thinking. Analysis of the design and implementation cycle demonstrated that teacher designers used their professional judgment and knowledge of LTs to assess the quality and appropriateness of curricular resources as they made instructional decisions to meet the needs of diverse learners. School-based coaches used these teaching resources as a type of professional development for identifying student strengths and "packaged" the resources for teachers who were overwhelmed from teaching during the pandemic. We discuss the importance of applying LT research for asset-based instruction.

Keywords: Learning Trajectories and Progressions, Teacher Knowledge, Instructional Activities and Practices, Standards (Strand: Curriculum, Assessment, and Related Topics; Mathematical Knowledge for Teaching)

COVID-19 interrupted teaching and learning in unprecedented ways and presented multifaceted challenges for students and teachers. As educators worked hard to support student learning in mathematics, the field looked for innovative ways to mitigate the challenges. In the spirit of PMENA 44's theme, Critical Dissonance and Resonant Harmony, we share how researchers and teacher designers worked collaboratively in design-based research to move beyond the "dissonance" created by COVID to build a curricular resource framed by learning trajectories (LT) and asset-based instruction to bring "harmony" to educators striving to meet the needs of every student.

The Need to Translate Learning Trajectory Research to Practitioners

We situate our work in uncertain times, as Ladson-Billings (2021) calls in a "re-set school environment", where she asks educators to use an accurate assessment of what students already know with varied and regular formative assessments to determine how well students are understanding what they are taught. In this way, assessment is not a "punitive tool to 'catch' students but rather a diagnostic and developmental tool that will tell teachers and schools how to adjust their curriculum and pedagogy"(Ladson-Billings, 2021, p.75). This re-set requires teachers to be deeply knowledgeable about the learning trajectory (LT). It is critically important to introduce LT research to practitioners due to the scale of disruption and overwhelm of teachers in the post COVID-19 learning environment. Teaching that incorporates an understanding of LTs has the potential to make instruction more efficient and supportive of learning mathematics for understanding (Suh et al., 2014; 2021). Clements & Sarama state that a LT describes:

> Children's thinking and learning in a specific mathematical domain, and a related, conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children through a developmental progression of levels of thinking, created with the intent of supporting children's achievement of specific goals in that mathematical domain. (Clements & Sarama, 2004, p. 83)

In many academic and practitioner resources, the terms LTs and learning progressions are used interchangeably with the emphasis on the developmental progression of levels of thinking within a conceptual domain. Confrey's notion of LT/progression is described as:

> A researcher-conjectured, empirically-supported description of the ordered network of constructs a student encounters through instruction (i.e. activities, tasks, tools, forms of interaction and methods of evaluation), in order to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time. (Confrey & Maloney, 2010, p. 1)

According to Confrey (2012), there are five elements of LTs that teachers need to understand: 1) the conceptual principles and the development of the ideas underlying a concept; 2) strategies, representations, and "conceptions"; 3) meaningful distinctions, definitions and multiple models; 4) recognizing coherent structure or pattern in the development of progressively complex mathematical ideas; and 5) bridging standards or identifying the underlying concepts that "bridge the gap" between standards. Focusing on the five elements of LTs can improve instructional planning as teachers anticipate student strategies, representations, and conceptions that can be attributed to students' strengths and resources for building on their understanding. The potential of Learning Trajectory-Based Instruction (LTBI) in professional development (PD) settings has also been explored by the collective work of Sztajn et al. (2012), Wilson et al. (2015), and Myers et al. (2015), who examined how teachers' discursive patterns about students as mathematics learners changed as the teachers engaged with the LT in PD. In particular, they noted that teachers initially voiced expectations about students' mathematical ability related to student age or grade level. But as teachers' understandings of LT developed, their voiced expectations began to acknowledge that students' prior experiences influenced students' performance.

Asset-based instruction and the use of rigorous mathematics were central to the framing of our project and aligns with one of the key recommendations in *Catalyzing Change in Early Childhood and Elementary School* (NCTM, 2020) to develop "deep mathematical understanding" and build students "as confident and capable learners" (p. 11). Using Asset-based approaches to planning instruction is a conscious way to move away from deficit perspectives (Celedón-Pattichis et al., 2018). Teachers' explicit attention to focusing on strength in students' thinking and what children are capable of doing helps teachers in avoiding biases that impair teaching and learning. According to Gresalfi et al. (2009), what counts as "competent" gets constructed through an interaction between the opportunities that a student has to participate in a particular mathematics classroom and the student's uptake of those opportunities, meaning that structures that promote equitable participation and interaction are key. Positive and discourse-rich classrooms (NCTM, 2000; Stein & Smith, 2011) allow each student to have feelings of success and pride (NCTM, 2020). The instructional decision to formatively assess and highlight student thinking during discussions has important implications for assigning competence, as it suggests *what* students are accountable for and to *whom* they are responsible for sharing their thinking with (Gresalfi et al., 2009). We believe that by finding strength in students' multiple knowledge bases (Turner et al., 2016; Kobett & Karp, 2020), teachers are better able to assign competence in student thinking, while broadening the notion of what competence means and building student agency and a positive sense of identity (Civil, 2007; Gonzalez, Moll, & Amanti, 2005; Aguirre et al., 2013; Lotan 2003; Cohen et al., 1999; Gresalfi et al., 2009).

Figure 1: Mathematics Learning Trajectory-based Curricular Design Framework

Context for our Math Learning Trajectory-based Curricular Design for Practitioners

The professional development design institute used a LT-based Curricular Design framework (Figure 1) which incorporated LT research, asset-based instruction, and rigorous instructional resources with high levels of cognitive demand. The team of teacher designers curated curriculum modules aligned to state-selected bridging standards. Bridging standards connect content across units within grade levels and articulate prerequisite knowledge for standards in future grades. The modules designed for each bridging standard consisted of five components: a) a zoomed-in LT bridge that illustrated the connection between students' strengths, bridging concepts, and the targeted learning standard; b) "big ideas" about the principles and development of each LT; c) important assessment "look-fors" that included strategies, representations, and "conceptions" to use for formative assessment; d) purposeful questions to assess, clarify, and advance students' mathematical ideas; and e) cognitively-demanding bridging activities, specifically routines, rich tasks, and games.

The LT research embedded in the modules provided direction for teachers to predict their students' potential reasoning, misconceptions, and learning. The modules were designed to support teachers in examining student thinking according to levels of cognitive proficiency rather than age or grade level. The curricular focus on asset-based instruction was intended to challenge and expand what teachers value and consider to be mathematical competence. Based on formative assessment of students' strengths, the modules guide teachers to select targeted activities in response to students' understandings and to support further learning.

Methods

Context and Participants

Using design-based implementation research, this qualitative case study (Stake, 1995) followed six early elementary mathematics educators from a professional development program to understand how these teacher designers applied a LT framework and asset-based lens while designing and testing curricular materials through two implementation cycles. After each implementation cycle, teacher designers attended an implementation debrief meeting to share their experiences and change recommendations.

The teacher designers were purposefully recruited for the professional development based on their leadership and teaching experiences. The design process began in the midst of the Pandemic in the summer of 2021 with a 30 hour-one week Design Institute. Teacher designers then implemented the design modules in their classrooms during the fall of 2021 with iterative cycles of refinements. We met three sessions online to debrief each cycle of implementation. In the spring of 2022, we interviewed a core group of our teacher designers to learn about how they continued to use the LT based instructional modules to support diverse learners. This case study followed six total participants: three math coaches, Jana, who taught 11 years in the classroom and 7 years as an instructional coach; Mia, who taught 14 years as a classroom teacher and 14 as a coach; and Sienna, who taught 9 years as a classroom teacher and 18 years as a coach; a first grade teacher, Rebecca, who has taught 3 years, and two second grade teachers, Kara, who has taught 9 years, and Naomi, who has taught for 8 years.

Data Collection and Analysis

Three data sources were analyzed for this case study: video clips from implementation debrief meetings that served as focus group meetings, student work, and teacher reflection forms. The implementation debriefs were conducted in focus groups with smaller groups of the entire teacher designers which allowed us to invite individual comments while also situating those comments in context of the group that worked together during the design process (Morgan, 2011). Based on the data analysis from this focus group debriefs, we selected six teacher designers to conduct one on one interviews. The research team used open coding first individually, keeping analytical memos which provided preliminary analysis allowing “processes of discovery in the material” (Morgan, 2011, p.14). Next, the research team employed Knodel’s (1993) grid analysis to ensure researcher fidelity to the transcripts during subsequent analysis. Grid analysis allowed the research team to review transcript segments associated with each subtopic and calibrate the codes and categories to ultimately identify recurring themes.

Overarching Research Questions

Our design based implementation research questions included:

RQ1) How do teacher designers use the Mathematics LT-based Curricular Modules during their implementation cycles?

RQ2a) How does involvement in this design project influence teacher designers’ future work? b) In what ways did teacher designers’ deep dive into LTs translate into their use of LTBI in coaching or leading school districts? c) How does the focus on strengths-based instruction influence teacher designers’ approach to their instruction or work with teachers?

Results

In addressing the first research question, how do teachers use the Mathematics LT Framework/LT-based Curricular modules during their implementation cycles, our findings revealed two themes. First, teacher designers used their professional judgment and knowledge of LTs to assess the quality and appropriateness of curricular resources for supporting students in meeting specified learning goals. Secondly, curricular materials designed using the LT framework supported teacher designers’ understanding of students’ learning and informed their instructional decision making.

Teacher designers' demonstrated their professional judgment by assessing the quality and appropriateness of the curricular materials. Teacher designers implemented formative assessments and bridging activities to assess the quality and requirement criteria of each teaching resource. For example, through implementation and assessment of a teaching resource, Kara determined that it did not meet the requirement criteria of a rich task and recommended it be used instead as a formative assessment. Kara stated that "a lot of those tasks, they feel like worksheets. It was basically just a list of questions. …That feels like a quick check. No richer. It didn't feel like anything too different than a quiz-like question." Kara questioned the "richness" of the teaching resource and determined that it would not be appropriate as a "rich task" but instead could be useful in other ways. Kara's assessment was affirmed by another teacher designer.

Teacher designers also used their knowledge of their students to assess the value of teaching resources. Rebecca found it difficult to implement a computer-based game with her first grade class due to the technological expertise needed to play it. Although the mathematical concepts of the game were well-aligned to her students' needs, they struggled with the website. Rebecca adapted the game to a paper-based format which was more accessible to her students. Mia used her knowledge of her students in a slightly different way. The substantial changes she witnessed in her students' mathematical confidence helped her realize the "richness" of the teaching resource. She reflected on how the high-quality teaching resources changed the ways students engaged in their mathematics learning, stating that "it was a huge difference just within a week's time. They felt more confident. That was the biggest thing I took away, the kids were not afraid of being wrong anymore, and they were very comfortable with being able to manipulate and do the work."

Additionally, the teacher designers critiqued teaching resources according to their alignment along the LT. After playing the game "Race to 100" with her second grade class, Kara determined that the game was a strong teaching resource for moving her students along the place value LT. Other teacher designers noted that while some games did not align well to a bridging standard, other games could be used for several bridging standards.

Teacher designers' reflections on their students' learning in response to the LT-based curricular modules revealed a second theme and provided a lens for teacher designers to notice their students' understanding and make instructional decisions. Jana, an instructional coach, discussed how the resources helped teachers in her school identify and address unfinished learning from previous grades. Because the curricular design used bridging standards, Kara was able to look for resources aligned to prior grades to support the prerequisite skills and knowledge her students needed for their current grade stating, "If you want to reteach anything, let's say I'm teaching second grade this year, so I'm going to reteach this first grade skill before I teach the second grade skill." Bridging standards were an important element of LTs for both Jana and Kara. This focus on underlying mathematical concepts allowed them to see a progression of complexity and shift along the trajectory as needed to find the appropriate teaching resources for their students.

The LT-based curricular structure supported the teacher leaders in reframing how they view student learning. Sienna, an instructional coach, found that the LT structure helped teachers see their students' learning as a progression and consider next steps rather than visualizing a gap between students' current understanding and the "final goal of the standard". Kara had a similar epiphany in her second grade classroom. She found that the LT structure allowed her to focus on conceptual understanding in her second grade students' work rather than simply quantifying the number of incorrect answers, stating "When you go to grade something or check it over, I'm not necessarily looking at 'Oh, they got 15 out of 20. They're missing a bunch.' …I'm really zoning and honing in on what patterns I can find. I feel like that's what this cycle has taught me is that there are patterns in student work." Kara's attention to patterns in her students' work allowed her to identify their position on the LT and plan targeted instruction to support their learning. Kara pinpointed her students' understanding of double-digit addition and made appropriate instructional decisions, stating "We just started teaching double digit addition. I know they know their facts, but they aren't getting regrouping. Okay, well then that's what they need. We don't need to work on the basics. It's not that they can't add… They can add single digit numbers, so how can I break that down when we go to add something more complicated than that." Likewise, Rebecca suggested that the LT approach helps lessons to be more effective because they focus on where students are and their precise needs. The teaching resources were cognitively demanding and grounded in LT research, thus equipping Kara to look beyond the number of incorrect responses, focusing instead on student understanding and instructional decisions.

Naomi found the open-ended formative assessment questions to be valuable for revealing students' prior knowledge. On a formative assessment question asking for a number less and greater than 153, Naomi observed, "that open-ended part of those two questions shows their thinking. Like who's thinking one more or one less. For what's greater than 153, one of my kids wrote 582… That gave them a way to show other numbers they know, not just one more, one less." From the formative assessment, Naomi realized that her students needed more experience with numbers beyond the typical hundreds chart and chose the Mystery Number routine to broaden their exposure. In addition, she appreciated how an open-ended task allowed her to see the edges of student thinking with students naming different magnitudes of numbers that fit the criteria for the Mystery Number.

In addressing research question 2a) "How does involvement in this design project influence teacher designers' future work?", we found that teachers noted the ease of usability as a "grab and go resource". Teachers reported an advantage that all the materials were conveniently organized on a website, saying, "It is truly a one stop shop it really, really is" and "since we were already going to teach this anyways, it's easy and convenient, it is a one stop shop." However, this also led to a disconnect between the original project goal of sourcing pedagogically rich resources and instant implementation of those resources. In several instances, teacher designers initially liked the material, but struggled with implementation. Sienna said, "I really struggled with [the task], to the point where I actually had to create my own little recording sheet." She described a conceptual hands on lesson using base ten blocks, which required monitoring and listening to students working in the moment. The recording sheet helped her keep track and assess various student strategies. While teacher designers attributed successful implementation to the convenience of the materials, that convenience led to a perception that a "one stop shop" did not require the same amount of lesson planning.

With the disrupted instruction due to COVID-19, Jana noticed "gaps" in students' understanding, but found these resources useful for understanding and redefining the specific nature of the “gaps” using strength-based language. For example, Jana states, “third graders who have first grade gaps and second grade gaps, this LT has been really important for [teachers] and really useful.” Similarly Mia transitioned from “gaps” to strength-based language by noticing that teachers were more focused on student work rather than “just number correct.” Mia also reported increased student confidence saying, “It was a huge difference just within a week's time and [the students] felt more confident. The kids were not afraid of being wrong anymore, and they were very comfortable with being able to manipulate and do the work.” Mia also reported teacher confidence saying, “The teachers were like blown away that our kids can actually do this.” This transition from “gaps” to strength-based language was particularly important as teachers implemented previous and current grade standards. Jana explained that “A lot of our teachers are trying to become experts in [prior grade] areas that they're not used to being an expert and having the LT and activities at their fingertips has been super helpful so far” because it helps teachers to “think more about the next steps that the students need.”

In addressing research question 2b) “In what ways did teacher designers’ deep dive into LTs translate into their use of LTBI in coaching or leading school districts?”, we found that mathematics specialists and school-based coaches used these resources as a type of professional development to look at LTs using student strengths. Sienna described this as, “looking at more about what is the next step, the thing that [students] need, what is it that our students do know and because of that we're thinking more about the progression of the students, rather than the end.” Mia explained that these resources were especially beneficial after the disrupted learning due to COVID-19 because they “gave me a tool, because I kind of felt as lost as they did. [sic] we've never done this before, we've never faced it… I feel like anybody I've told about it, I feel like it makes so much sense, the fact that it's [strength-based] like this is, this is what they need to come in with versus where they're going.” However, the way the coaches implemented the resources varied. Mia created classroom-ready Google Slides for a routine. “I just kind of developed these little snippets of little activities of Google slides that I would use with the students and the teachers.” Mia also explained the need for creating supplemental resources because “my teachers [sic] are stressed, they are worn out” and by “packaging” the resources, she can share them with teachers and the many long term substitute teachers in her school. Further, these resources have been accepted and distributed at multiple leadership levels from teachers, principals, and even division levels. Leaders at Jana’s school and district were also eager to distribute the modules. She stated, “Our curriculum supervisor at the division level is the one who's really pushing it out for our division [sic] and in our curriculum unit guides that we have for each of our units k-5 with the PDFs from the bridging site have been dropped in so teachers have access to the site. They know about it, they've had to go through video training on it.”

In addressing research question 2c) “How does the focus on strengths-based instruction influence teacher designers’ approach to their instruction?”, we found that teacher designers began to have a more holistic view of student knowledge and they were less overwhelmed. Making the connection to growth mindset, Sienna noted that the teachers she works with were "thinking more about the next steps that the students need rather than 'they can't get to the standard' or 'they're not doing the standard.' It's more about 'this is where they're at, this is the next step they need to know.'" For example, Mia shifted focus from percentage correct to patterns evident in student work, reporting, "there are patterns in student work, and you can often find that they're doing one thing correctly and then they're just misinterpreting whatever next step." This perspective of highlighting strengths reduced teacher stress, because "it just kind of helps it not seem as overwhelming because you can see progress in a student, even though they're not achieving the standard, if you're looking at their strengths and what they do know."

Implication of our Study

This design-based research suggests several practical applications for teachers, coaches, and curriculum developers. Firstly, this research showed that teacher designers' knowledge of LTs supported their instructional decision making. The teacher designers who participated in the professional development program were recruited for their level of experience and recognized mathematics education leadership. And yet, after participating, they felt more equipped to identify and implement rich strength-based lessons. Specifically, teacher designers knew more about LTs and how to interpret student work in order to identify their strengths on the LT.

Secondly, this research showed that teacher designers who were coaches or leaders distributed their understanding about strength-based LTBI on both a small scale, such as coach to teacher, and large scale, such as school or district settings. While the structure of the modules provided support for teachers' understanding of the LT, coaches needed to constantly refer back to the resources until teachers used consistency when implementing them. All leaders reported that the materials were organized, accessible, easy to modify, and invoked discussions about student strengths and differentiated lessons.

Finally, this design research gives insight on the important aspects to consider when designing curricula and resources. The resources in this project were sourced by a recruited group of teacher designers. Through multiple cycles, the teacher designers vetted and implemented the resources, gathered student work, and discussed the implementation to validate the choice of activities. This cycle allowed teacher designers to propose, explore, discuss, and finally edit those resources in order to make them more user-friendly and applicable to the standards. This research demonstrated significant ways that practitioners can engage with learning trajectory research to transform "post pandemic pedagogy" (Ladson-Billing, 2021), reframing the predominant conversation from "educational gaps" to student progress along the LT continuum.

ELEMENTARY MATHEMATICS TEACHERS' ASSEMBLAGE OF NUMBER TALKS: AN INQUIRY GUIDED APPROACH

Hilary R. Tanck
High Point University
htanck@highpoint.edu

Beth L. MacDonald
Illinois State University
blmacd1@ilstu.edu

This inquiry explores elementary mathematics teachers' curriculum work as they integrated a new component, Number Talks, into their existing curriculum assemblages. Number Talks are short 5-15 minute whole group discussions with specific procedures focusing on students' strategies for mental computations. Assemblage theory was used to frame how participants modified Number Talks when incorporating them into their classrooms. Participants described how they integrated Number Talks into their existing curriculum assemblages, collaborated with colleagues creating overlapping assemblages, and deterritorializing Number Talks to change their functionality. We discuss the implications of participants changes to Number Talks and the adjustments participants made to their existing curriculum assemblages.

Keywords: Curriculum, Elementary Education.

Number Talks began in the 1990's and have increased in popularity informing professional development, books, and educational blogs (https://www.mec-math.org/number-talks/). The effects of Number Talks, however, are largely under investigated (Matney et al., 2020). Number Talks are teacher facilitated discussions centered on students' mathematical strategies for solving computational tasks (Parrish & Dominick, 2016). These conversations typically last between five and 15 minutes. Number Talks follow specific procedures in which students solve a task mentally, share solutions, and describe their strategies in a whole group discussion. Due to the focus on students' ideas and strategies, Number Talks alter the role of the teacher moving from a traditional teacher-directed mathematics classroom to a more student directed classroom (Brown, Stein, & Forman, 1996) requiring significant changes to practice for most mathematics teachers (Cobb & Jackson, 2011). As teachers' professional knowledge expands and new curriculum resources are introduced teachers', curriculum work also changes (Gueudet & Trouche, 2009). This study aims to examine teachers' curriculum work as they integrated Number Talks into their mathematics classroom. *The following research question guided the inquiry: how do elementary mathematics teachers assemble Number Talks?*

Theoretical Perspective

Linear or mechanistic frameworks of curriculum are restrictive and reductive and have dominated the conceptualization of curriculum in mathematics education (Fleener, 2002). Moreover, curriculum defined as a bounded series of learning goals isolated from the learning environment is static (Doll, 1993; Grumet, 1988). While researchers (e.g., Remillard, 2005; McDuffie et al., 2018) acknowledge teachers implement curricula materials in unique ways and Cai's (2014) leveled framework considers what occurs in the classroom (i.e., intended curriculum) findings have done little to influence how curriculum is conceptualized. This study embraces the temporality, connectivity, and in process conceptualization of curriculum advocated by Grumet (1988).

Deleuze and Guattari's (1987) theorization of assemblages provided a space for teachers' curriculum work to be considered in process. Deleuze and Guattari described an assemblage as a collection of heterogenous components organized to perform some function. Assemblages are temporary and transform quantitatively and qualitatively as components are added or removed. For example, a teacher enacting a Number Talk may use Number Talks procedures, allow students to select the numbers for the mathematical task, and add a checking your solution component to conclude the discussion in which students use sticky notes on the board to verify their answer. The additions and modifications to Number Talks changes the functionality of this curriculum. Each component works together for a moment in time creating an assemblage. Moreover, an assemblage is not simply a product, but rather the coming into existence or the need to organize, reorganize, and/or construct. As the assemblage shifts or sharpens boundaries map out an assemblage's territory (i.e., territorialization). Conversely, as changes occur, or new components are introduced an assemblage blurs or fragments and deterritorializes.

Methods

Part of a larger Convergent Mixed Methods study (Creswell & Plano-Clark, 2011), this paper explains results from a qualitative analysis of teacher participant interviews, examining ways teachers planned, adapted, and assembled Number Talk curriculum with their already enacted district-driven curriculum.

Participants, Setting, Procedures, and Instruments

Seventeen elementary teachers—teaching 4^{th}, 5^{th}, and 6^{th} grade mathematics—from Duval County School District in the Western United States participated in the interview stage of the study during the fall of 2021. Four of the participants were enacting Number Talks for the second year, while 13 introduced Number Talks into their classrooms for the first time. Each participant engaged in one 15-minute semi-structured interview via Zoom. Interviews focused on teachers' planning process and how Number Talks were being implemented in their classrooms. The interview included questions, such as: (1) what role do Number Talks play in your mathematics classroom?; (2) how do you select number talks?; (3) what adjustments if any, did you make to incorporate Number Talks into your classroom? The researchers created memos in the form of written notes during and following the interviews.

Analysis

An open-coding scheme was used to analyze the memos. Codes were condensed into categories (e.g., integration of Number Talks and curriculum, number sense, and Number Talks procedures). While this process offered a level of analysis, it left the data segregated. A different method of analysis was needed to create opportunities for entanglement. Taking a writing approach to analysis Markham's (2012) bricolage-style of writing (i.e., layered text) or the bringing together of various writing piece was taken up. We initially engaged in analytic memo writing, summarizing the interviews as a collection. Then layered writing was used to bring together interview memos from each participant to create a composite piece (see Figure 1). The layered writing approach created a grass like structure as new concepts and ideas sprouted between previous text.

opportunities to justify their solutions as when they were engaged in their district provided curriculum materials. Rachel integrates her exciting curriculum and NT. The CMI is similar to NT in that the students engage in similar patterns of discourse and they often begin with student-to-student discussion (Amanda). Some teachers used their pre-existing curriculum as a jumping off point to select number talks and incorporate them into their mathematics classrooms. I don't take it from iReady [pre-existing curriculum]. I add on to what I know what to add on with – using prime factors to use factor trees. How each factor has its own fingerprint (Holly). Would be to adjust them as our curriculum changes. As we move on to fractions, we can consider operations with those fractions (Samantha). Additionally, some teachers followed the NT book and progressed through strategies based on the book. Going to the book to see what the next strategy is (Taylor).

Figure 1: Layered writing excerpt

Preliminary Findings

Through the leveled writing analysis tracings or patterns emerged. Participants described the integration of Number Talks into their existing curriculum assemblages, collaborating with colleagues creating overlapping assemblages, and deterritorializing Number Talks to change their functionality. The subsequent section explores these tracings.

Integrating Number Talks into Existing Curriculum Assemblages

Introducing a new component, Number Talks, into participants existing curriculum assemblages detteritorialized, or disrupted, their assemblages. The boundaries of their curriculum assemblages and daily schedules blurred as participants made adjustments. Participants stated one of the biggest challenges was finding time for the Number Talks. Taylor described this challenge, "I had to find time. Where was I going to find the time where it would be effective for students?" Some participants eliminated components of their existing curriculum assemblage. Madison replaced a component, a warm-up worksheet, with Number Talks, "I used to do a warm-up worksheet. I have gotten rid of the worksheets and my spiral review. This is really strange because I used to give 10 problems and now just give one problem." Other participants modified their curriculum assemblages. Amanda addressed the issue of time by changing her morning routine using the Number Talk as bell work. Lana on the other hand moved her math lesson to a different part of the day to allow for an extended math lesson. To accommodate time constraints, participants used Number Talks at varying frequencies (e.g., Jessica used Number Talks every day, Rachael tries to do them two or three times a week).

Participants' conceptualization of how Number Talks fit into their curriculum assemblages ranged from siloed events to integrated components. Participants who conceptualized Number Talks as siloed events either separated Number Talks from the mathematics lesson enacting them at a different point in the day or used Number Talks before the mathematics lessons but saw them as independent events. Stephanie took up a siloed approach, "I do it [Number Talks] first thing in the morning when the students come in. It does not tie into the math lesson." Lana also held a siloed conceptualization. Although Number Talks were taught at the same time as the mathematics lesson—immediately prior to the lesson—they were unconnected events. Kenny on the other hand conceptualized Number Talks as integral components of the mathematics lesson. Kenny used Number Talks to start class and help students get into a mathematical mindset—he described Number talks as a safe place for students to share ideas and lead into the mathematical content of the day. Some participants conceptualized Number Talks as an integrated part of the curriculum but were not yet able to match their conceptualization to their teaching practice. Integrating new components is a process and Dana said she is currently doing Number Talks unrelated to the lesson; however, she wants to eventually tie them into class.

Overlapping Assemblages

Participants' curriculum assemblages overlapped as they collaborated with colleagues and students. Many of the participants planned Number Talks with their team or other colleagues in their building. Participants noted working with colleagues when struggling to get students to try a specific strategy. For example, Alexa was unable to get her students to use a regrouping strategy. She worked with her team to change mathematical tasks like 68-13 to 63-18 to promote the use of a regrouping strategy. Participants' curriculum assemblages also overlapped when they brought student strategies from a colleague's class and used it in their own number talk to demonstrate a specific strategy.

In addition to working with colleagues to develop Number Talks, participants both explicitly and implicitly built Number Talks with their students. Participants (e.g., Marissa and Taylor) implicitly worked with students to adjust pacing based on students' responses to previous Number Talks. Amanda planed with students providing them opportunities to select the numbers for the Number Talk.

Teachers Deterritorialization of Number Talks

As participants integrated Number Talks into their classrooms, they made modifications in order for the Number Talks to function in their classroom. Participants interpreted Number Talk procedures in their own way and adjusted to match their teaching style. Some participants tried to follow the Number Talk procedures as intended. Jessica used dot talks when introducing her class to the Number Talk procedures of hand signals, giving solutions, and sharing strategies. Alexa altered students' physical space moving students to the floor to decrease distractions and ensure students were working the task in their heads instead of writing out their process. Other participants modified Number Talk procedures. Carolyn provided students with sticky notes to record their ideas. COVID-19 also presented challenges participants needed to address and pushed on participants' Number Talk assemblages. For example, Alexa created "calling bodies" or remote students assigned to in person student who communicate via phone call or zoom discussions.

Discussion and Conclusion

Findings elicit questions about how Number Talks are integrated into existing curriculum assemblages. Framing teachers' work with Number Talks using assemblage theory provided opportunities to examine participants' work as temporal and changing with their integration, overlapping components, and modifications. In efforts to accommodate a new component, Number Talks, into their existing curriculum assemblage participants added and removed elements from both their pre-existing curriculum and to Number Talks. Continued research is needed to understand teachers' curriculum work with Number Talks over time. Additionally, future research could consider how teachers' curriculum work with Number Talks impacts students' agency and number sense development.

Background

The instructional materials that mathematics teachers use impact student learning (Remillard et al., 2014; Lloyd et al., 2017). However, purchasing instructional materials are expensive, hence districts are turning to open source materials such as Illustrative Mathematics (IM). Unlike many other free online resources for instructional materials (e.g. Pinterest (Shapiro et al., 2019)), IM is a comprehensive curriculum with a scope and sequence and is aligned with Common Core content and practice standards (Ed Reports, 2022). The high school IM curriculum became available in 2019 and the elementary curriculum in 2021, so little research has been done on teacher perceptions of the curriculum. This poster aims to address this by sharing teacher perceptions of the IM curriculum using data from teacher interviews from year 1 and year 3 of their implementation of IM.

Methods

All Algebra 1 teachers throughout an urban district began using IM in 2019-2020 (year 1) and it continued to be the primary instructional resource provided by the district in 2021-2022 (year 3). We interviewed 22 Algebra 1 teachers in year 1 and 13 in year 3 about their perceptions of the IM curriculum using an interview protocol. The protocol ranged from open-ended questions, such as "What do you think about the Illustrative Mathematics curriculum?" to more specific, e.g. "How does IM support your ELL students?" The interview transcripts were read to uncover themes that emerged, common themes were grouped when appropriate, and then the interviews were reread to code for the emergent themes. Finally, we recorded how many teachers expressed an idea represented by each emergent theme.

Findings

Some themes stayed the same from year 1 to year 3. For example, over 50% of the teachers in both years noted the benefit of IM's use of real-world contexts for Algebra 1 topics. Over 50% both years also noted a challenge in not enough time for teaching everything. Other themes changed over time. In year 1, teachers appreciated having ready-to-use materials (in previous years they had to create their own teaching resources), however, in year 3, teachers were more likely say the appreciated the design of the curriculum, for example, how it spiraled the content.

Conclusion

As the districts move to open-source instructional materials such as IM it is important to understand how teachers are perceiving the curriculum so that curriculum designers, researchers, and district decision makers can use the information to better support teachers.

ANALYZING THE LEVELS OF COGNITIVE DEMAND OF TASKS IN MATHEMATICS TEXTBOOKS AND UNIVERSITY ENTRANCE EXAMS

Seyedehkhadijeh Azimi Asmaroud

Keywords: University entrance exams; Text book; Levels of cognitive demand

The University Entrance Exam (UEE), a comprehensive 4-5 hours multiple-choice exam known as Konkour, is a centralized nationwide test for high school graduates to gain admission to higher education in Iran. These UEEs have been the sole criterion for students' admission to universities for more than four decades (Salehi & Yunus, 2012). As students' performance in the UEE is a critical factor influencing their future careers, it is essential that UEEs, as assessment tools, be aligned with school curriculums.

This study was part of a larger study that compared the type of the mathematics questions in two series of high school mathematics textbooks, old-series (2016-2018) and new-series (2019 - 2021), with the type of mathematics questions used in the UEEs in the aforementioned periods. The underlying rationale for focusing on the textbooks used in these two periods was that these textbooks are used nationwide and reflect a good picture of the nature of tasks implemented by teachers to prepare students for UEEs. In this study, the result of the study about geometry questions will be discussed.

This study draws from a framework developed by Smith and Stein (1998) about the Levels of Cognitive Demands (LCD) of tasks. This framework categorizes mathematical tasks according to the level of cognitive demands in two categories: a) low-level, including Memorization (LM) and Procedures Without Connections (LP), and b) high-level, including Procedures With Connections (HP) and Doing Mathematics (HDM). Questions related to topics in ratio and proportion, angle relationships in circles, Thales theorem, similarities and its applications, polygons, and area from 10th and 11th-grade textbooks (305 tasks), and also questions related to the same topics in UEEs (34 questions) were coded based on this framework. To ensure the validity of the study, I asked a colleague (Creswell & Miller, 2000) to do coding independently for random questions from UEEs and two textbooks series, then we compared assigned codes.

The findings of the study indicate that the levels of the tasks related to geometry concepts in the old textbook series were predominantly at HP and LP levels (respectively 38% and 36%). The majority of tasks in the new textbook series were at the HP level (49%). There were more HDM tasks in the new textbook series (31 % in comparison to 18% in the old book series). There were not any questions at the LM level in UEEs in both periods. The percentage of questions in UEEs in HP level was much higher in comparison to the two textbook series (53% in 2016 - 2018 UEEs and 66% in 2019- 2021 UEEs). The percentages of questions at the HDM level were 21% in 2016 - 2018 UEEs and 17% in 2019 - 2021 UEEs (tables including more detailed information will be presented in the poster).

Research showed that throughout the classroom sessions LCD of tasks stay the same or decline (Stein, Grover, & Henningsen, 2001). Thus, considering the findings of the study that shows on average the LCD in UEEs are higher than the LCD of tasks provided in both textbook series, it seems that including more tasks in higher LCD is required in the school's curriculum.

Keywords: Assessment

Using a test for a purpose it was not intended for can promote misleading results and interpretations, potentially leading to negative consequences from testing (AERA et al., 2014). For example, a mathematics test designed for use with grade 7 students is likely inappropriate for use with grade 3 students. There may be cases when a test can be used with a population related to the intended one; however, validity evidence and claims must be examined. We explored the use of student measures with preservice teachers (PSTs) in a teacher-education context. The present study intends to spark a discussion about using some student measures with teachers. The Problem-solving Measures (PSMs) were developed for use with grades 3-8 students. They measure students' problem-solving performance within the context of the Common Core State Standards for Mathematics (CCSSI, 2010; see Bostic & Sondergeld, 2015; Bostic et al., 2017; Bostic et al., 2021). After their construction, the developers wondered: *If students were expected to engage successfully on the PSMs, then might future grades 3-8 teachers also demonstrate proficiency?*

Methods

Data came from three sources: (a) an expert panel content review, (b) Rasch (1980) modeling of PSM scores, and (c) consequences from testing data from PSTs and PSM administrators. 178 PSTs from a Midwest university completed the PSMs. They came from two teacher education programs: grades K-5 or grades 4-9. PSMs 3-8 were completed in their program's first-year and again in the fourth-year. The intended use for the PSMs was formative and for program evaluation. They were informed that results did not impact course grades. Content and consequences data were gathered from mathematics content and mathematics education instructors. Qualitative data were analyzed using thematic analysis (Miles et al., 2016). Quantitative data were analyzed with WINSTEPS© (Linacre, 2019).

Findings & Discussion

Content experts felt items were appropriate for use with PSTs and connected with content from their classes. PSMs 3-8 fit the Rasch model indicating good psychometric quality. Finally, thematic analysis of consequences data indicated that the PSMs felt no different than a unit test and offered formative data to adapt instruction. Collectively, these findings help to inform the potential uses of the PSMs, a student measure, for use with a related population, PSTs.

A CHARACTERIZATION OF COLLEGE ALGEBRA ASSESSMENT DURING THE TRANSITION TO EMERGENCY REMOTE TEACHING

Ash Demian
Texas State University
afd9@txstate.edu

Keywords: Assessment, Emergency Remote Teaching, College Algebra

Introduction and the Purpose of the Study

The COVID-19 pandemic led to a global lockdown and compelled the institutions to shift to emergency remote teaching. This transition and the lack of knowledge of using technology affected teaching practices, including assessment. Confronted with new contexts for assessment and threats to validity caused by ineffective proctoring, many instructors had to rethink how to evaluate student progress. This study investigates the common characteristics of college algebra assessment in six dimensions and determines any changes during emergency remote teaching. In addition, the analysis compares the college algebra instructors' views about the purpose of evaluation. Finally, the study tested the efficacy of a new tool that instructors can use to analyze their assessments.

Research Questions

What are the characteristics of the exams given by college algebra professors? What are the college algebra teachers' beliefs about the purpose of assessment? How did these characteristics change during ERT, and what changes persisted after returning to normal teaching? What factors determined which changes faculty chose to retain?

Study Framework

The study framework consists of six dimensions. Cognitive demand, first introduced by Bloom (1956) and revised by Tallman et al. (2016), contains seven hierarchal levels starting at *remember* at the base and *create* at the top. Three additional dimensions, item format, task representation, and solicited solution, were adapted from Tallman et al. (2016). Additionally, the framework contains two new dimensions developed for study: computational demand and verbal demand.

Methodology and Results

Data Collection

Participants of this study are 30-40 college algebra instructors from two- and four-years institutions in Texas that have taught college algebra before, during, and after the COVID-19 pandemic. The study uses three data sources: mid-term and final tests to determine the characteristics of college algebra tests, online surveys to determine the instructors' beliefs about the purpose of assessment and focus-group meetings on Zoom with a subset of instructors.

Results

The preliminary results of twenty tests showed a low level of cognitive demand where 65% of the items were level 2 (recall and apply procedures). On the other hand, a focus group meeting showed that the instructors emphasized higher levels of cognitive demand. Furthermore, 65% of the items are multiple-choice, and 80% are symbolic.

We surveyed 524 elementary teachers from 46 states about their mathematics curricular decision-making during the COVID-19 pandemic (Giorgio-Doherty et al., 2021). Building on findings from this study, we designed protocols for individual and focus group interviews with teachers from the same school to further explore the complexity of teachers' curricular use revealed in the survey. Here, we report findings from these interviews. The research questions guiding our study were: (1) How do teachers create coherence across their curricular resources? (2) How and why do teachers select or evaluate and adapt curricular materials to teach mathematics? and (3) How do teachers perceive their curricular autonomy? We found most teachers were using multiple curricular materials (some mandated and some not, ranging up to 11 different sources of materials) to plan and teach mathematics. We found teachers frequently focused on content (e.g., connections to key concepts, standards, or lesson objectives) as the key focus of creating coherence between materials for students and for lesson planning. Content coherence also seemed to drive differentiation. Most teachers reported differentiating more than usual to address larger learning gaps across students in their classes due to the pandemic. Teachers stated a preference for curricular materials (like *IXL*) which allowed them to find tasks on particular content and assign students practice problems related to that content at grade level and above/below. Teachers varied in how they responded to different solution strategies presented by different materials. Some teachers provided coherence by directing students to rewrite directions so they use the same solution strategy as in prior lessons from other materials; other teachers felt students experienced better connections to content as they made sense of different solution strategies from different materials. Several teachers used *TeachersPayTeachers* (TPT), with some reporting materials on TPT engage students better than materials from their primary curriculum, do not need modifications, or better meet their instructional preferences. We found teachers who reported high levels of enjoyment and confidence in teaching mathematics made the most adaptations to curricular materials and most often designed their own. Many teachers reported adapting curriculum to be more engaging to students. This included adding visuals or enlarging text size and creating opportunities for problem-based and hands-on learning. Some reported adapting or creating materials to make connections to the world or be more culturally relevant. Overall, teachers reported high levels of curricular autonomy for all curricular materials, including mandated materials (median score of 7 out of 10) and non-mandated or suggested materials (all scoring 10 out of 10).

DIMENSIONS OF CARE: A DIFFERENT APPROACH TO ANALYZE TEACHERS' INTERACTION WITH THE CURRICULUM

Ana-Maria Haiduc
Purdue University
ahaiduc@purdue.edu

Literature Review

Teachers' refined thinking about how students learn mathematics is visible in their curriculum decisions when planning. They make decisions influenced by many factors: the design of the materials, teachers' knowledge, skills, beliefs, goals, and context (Remillard et al., 2009). In addition to these factors, I argue that mathematical care influences teachers' decisions. The mathematical care component is conceptualized in this research as a driven factor for attending to students' cognitive processes of learning mathematics and continuously adapting the mathematical activities based on students' specific needs. These two actions align with the first two phases that characterize the notion of a caring relationship largely discussed by Noddings (2013): engrossment (receptive to the learners' needs), and motivational displacement (respond with help to the identified needs). Responding to every student's mathematical needs means making modifications, adaptations, and accommodations to the curriculum (Remillard et al., 2014; Stein et al., 2007). For example, adaptations of the mathematical activities in relation to students' mathematical needs could be in the form of incremental challenges for the students who gave up learning mathematics (cultivating a growth mindset set (Dweck, (2008)) or higher cognitive demanding tasks for students with an increased interest in mathematics (Benbow, et al. 1992), warm-up activities to supply motivation (Williams, 1984) or providing a visual context for English learners (Slavit & Ernst-Slavit, 2007). According to Noddings (2013), students' responses to these actions represent the third component that completes a caring relationship: recognition. When teachers "act with special regard for the particular person in a concrete situation" (Noddings, 2013, p. 24) they demonstrate care for students. Students who enter into a mathematical caring relation "have a sense of being seen by the teacher" (Hackenberg, 2005, p.47), and that is a feeling of being listened to, with ideas valued, and, perhaps, understood.

Methodology

The paper's contribution lies in exploring teachers' rationale when making decisions regarding the mathematical activities they select and the changes they make. For example, designing tasks in relation to students' ways of operating mathematically (Hackenberg, 2005) or accommodations for the students with learning disabilities that do not reduce the level of engagement (Barr et al., 2021) represent dimensions of care related to the students' cognition. Providing recreational problems to show the fun side of mathematics (Cooney, 1985) represents a dimension of care for getting students excited when doing mathematics. Selecting tasks that give students opportunities to show their intelligence in various ways while the teacher is positioning students as competent by coding a variety of skills, mathematical and non-mathematical, disrupting the hierarchy of intellect and giving voice to all students (Louie, 2017), represents a dimension of care for equity. Thus, this research constructs dimensions of care by analyzing episodes from literature that link needs, decisions, and feelings.

Research Question

The research question is how mathematical care can be conceptualized as a factor that influences teachers' curricular decisions?

EXAMINING ALGEBRA TEACHERS' UNIT PLANNING PROCESSES

Jaepil Han
University of Missouri
jaepilhan@mail.missouri.edu

Keywords: Curriculum, High School Education, Instructional Activities and Practices

There is growing agreement that effective mathematics instruction starts from teachers' careful and purposeful planning (NCTM, 2014). However, teachers' planning often only includes teachers' decision making *before* instruction or it only consists of *selecting* tasks and *organizing* the ways they will enact the tasks with students (Kilpatrick et al., 2001). Because planning individual lessons typically comes after teachers have already established a larger sequence of lessons, it is important to examine how teachers plan at the larger curriculum level. Despite the existence of different curriculum level planning, little attention has been given to teacher planning on larger curriculum levels (e.g., unit planning, course planning). To this end, the purpose of this study was to answer the question: How are the processes of experienced Algebra I teachers' unit planning similar with and/or different from one another?

As part of a larger dissertation study on experienced algebra teachers' unit planning, I analyzed the processes (e.g., practices, sequences) of 5 experienced Algebra I teachers from school districts of varying sizes across the nation, who actively designing curriculum units came. By adapting Roche et al.'s (2014) *teacher planning framework*, I identified the teaching practices that the teachers enacted in unit planning. I then created diagrams of the teachers' unit planning processes (e.g., unit planning timings and sequences) using *logic models* (Yin, 2014).

The experienced teachers engaged with a set of seven unit planning practices and the sequencing of these practices followed a general sequence across the teachers—a) *checking and examining curriculum documents*, b) *setting learning goals*, c) *mapping out lessons and assessments*, d) *planning lessons*, e) *planning assessments*, f) *modifying lessons and assessments*, and g) *evaluating implemented unit plans*. To plan units, the teachers engaged with the practices not only before units but also *during* and even *after* units. Although they enacted the majority of the unit planning practices before unit, they continued their unit planning during unit as they modified the unit pacing or assessments based on what they actually taught and students' progress towards the unit-end goals. After every unit, the teachers evaluated their implemented unit plans through self-reflection or student feedback regarding the unit pacing and difficulty. Thus, the experienced teachers' unit planning consisted of the teaching practices for *planning*, *implementing*, and *reflecting* unit plans.

The present study expanded the traditional conception of teacher's unit planning to that including not only planning but also enacting and reflecting. This expanded conception aligns with Sherin and Drake's (2009) conception of teachers' curriculum use before, during, and after instruction. Thus, this finding noted teachers' continuous engagement with planning and the reflective aspects of planning, which two were often missing from the body of literature on teacher planning. The findings shed light on experienced algebra teachers' planning processes of larger curriculum units. In addition, it provides a better understanding of the nature of teachers' unit planning and a snapshot of how teachers aim to help students learn outside of the classroom environment, which potentially inform us of supports that we may offer teachers to promote alternative approaches to or sequences of the unit planning practices.

FEATURES OF HIGH-QUALITY MATHEMATICS MATERIALS: VARIATIONS IN APPROPRIATENESS FOR DIFFERENT GROUPS OF STUDENTS

Erica N. Mason
University of Illinois, Urbana-Champaign
enmason@illinois.edu

Camille Griffin
University of Illinois, Urbana-Champaign
cgriffi5@illinois.edu

Keywords: curriculum, teacher beliefs, students with disabilities

The instructional materials available to teachers relate to the types of learning opportunities afforded to students (Hiebert & Grouws, 2007). As school districts undergo ambitious mathematics reform, various stakeholders are brought together to make key decisions related to the instructional materials provided and endorsed by the district. The various stakeholders that constitute a district's curriculum committee likely bring various perspectives about the form and function of features of instructional materials they consider high-quality (e.g., Saxe et al., 1999). Further, stakeholders likely also hold varying views about for whom those high-quality forms are "appropriate" (e.g., Jackson et al., 2017). The purpose of this project was to gain insight about the features of instructional materials committee members viewed as "high-quality," specifically (1) the degree to which there was coherence in the form and function of those features across committee members and (2) committee members' views about students' mathematical capabilities in relation to those features.

This work was conducted across a year-long research-practice partnership between a group of special education researchers and one school district. The district was undergoing ambitious mathematics reform in light of persistent course failure at the high school, thus prompting district leaders to make strides toward vertical alignment. A mathematics curriculum committee ($N = 25$) was formed and consisted of district-level coordinators, building-level administrators, instructional coaches, general education teachers, special education teachers, early childhood teachers, dual-language program teachers, all of whom served students across early childhood and through Grade 12. All committee members were invited to participate in two interviews about their experiences being on the committee and their views about what constituted high-quality instructional materials. Thirteen (52%) of the committee members consented to participate in the first round of interviews, which were conducted in November and December 2021. The majority of interviews were conducted via Zoom (n =10), although a few committee members preferred to meet in person. We used a semi-structured interview protocol, and all interviews were audio recorded and later transcribed.

To address the second articulated purpose, preliminary findings suggest members of the curriculum committee viewed some features as appropriate for all students (e.g., "[enrichment activities] can work for everyone."), some features as specifically not appropriate for some students (e.g., "[materials that allow for multiple ways of solving] can be difficult and challenging [for] students who, maybe their brains process in a different way, or they process at a different rate."), and some features that were both appropriate and not appropriate for particular groups. A second round of interviews will be conducted in April and May 2022. Practically, results from this study could be used to inform the ongoing work of this committee as the district moves into the piloting phase of their reform effort. Beyond this school district, findings from this work could reveal critical, but perhaps overlooked, components of ambitious reform, including the need to uncover committee members' views about students' capabilities and consider the relation of such views to decisions about instructional materials.

Keywords: Standards, Curriculum, Policy, Comparative.

Over the past two decades, increasing demand for quality education has been the focus of many educators in the United States who have introduced the standards-based education movement (Ravitch, 1995). Countries worldwide present standards as national curricula (Schmidt et al., 1997). Regardless of their title, such curriculum or standards define the vision for what is important for the nation's children to learn in their schooling. Research shows that there is a connection between mathematics standards and the mathematics performance of the students (Akkoc, 2008). Furthermore, research on students' achievement in mathematics attributes achievement disparities to the curriculum and argues that different curriculum standards may produce different results (Cai, 2004). This comparative standards analysis of mathematics standards addresses one secondary mathematics topic, trigonometry of four countries as we investigated similarities and differences in learning expectations for students from Ghana, South Africa, the United States' proxy Common Core State Standards for Mathematics (CCSSM), and Zambia. Stigler and Perry (2014) emphasized that better understanding of one's own culture gained through comparative studies leads researchers and educators to a more explicit understanding of their own implicit theories about how children learn mathematics. Without comparison, we tend not to question our own traditional teaching practices, and we may not even be aware of the choices we have made in constructing the educational process. We employed Webb's (2007) Depth of Knowledge (DOK) to analyze cognitive expectations to draw similarities and differences. Analyzing curriculum standards offers insight into the recommended level at which trigonometry should be taught.

Preliminary findings show the CCSSM has more strands compared to Ghana, South Africa, and Zambia. Findings suggest that all the four countries' standards have similar trigonometric concepts although the standards vary across DOK levels. For example, all four countries have standards related to drawing trigonometric functions. However, as seen in Table 2, Ghana and Zambia's standards contain a lower-level verb (e.g., to draw) while the CCSSM's and South Africa's standards emphasize a higher-level verb (e.g., to model). We noted that the CCSSM and South Africa did not have any standards at level 1 (e.g., recall and reproduction) while Zambia had 3 and Ghana had 1. Likewise, compared with Ghana and Zambia, the CCSSM was more likely to emphasize higher-order thinking skills at level 3 and level 4 with 11 standards out of 14, while South Africa had 9 standards at higher levels (i.e., level 3, level 4) out of 14. Ghana had 2 standards at levels 3 and 4 out of 8 total standards, while Zambia had 5 standards at levels 3 and 4 out of 14 total standards. Our qualitative analysis showed that all four countries study trigonometric ratios in right-angled triangles and use right-angled triangles to solve problems. The CCSSM were not written to a particular order of grade while the South Africa, Ghana, and Zambia syllabuses are tailored to grade levels, for example, the South African syllabus has trigonometry run throughout the senior secondary level from grade 10 through to grade 12 while the Zambian syllabus has trigonometry taught only in grade 11. Future studies could extend this study by analyzing additional curriculum resources such as textbooks.

AN ANALYSIS OF TOPICS INCLUDED IN INTRODUCTORY COLLEGE MATHEMATICS COURSES

Josh Naddor
North Carolina State University
jnaddor@ncsu.edu

Keywords: Curriculum, Undergraduate Education

Introduction

Numerous organizations have provided recommendations for what mathematics K-12 students should learn (National Council of Teachers of Mathematics, National Governors Association Center for Best Practices & Council of Chief State School Officers) and for what preservice mathematics teachers and current mathematics majors should learn (AMTE, 2017; CBMS, 2012; Saxe & Braddy, 2015). There are also recommendations for what the mathematics students should study prior to calculus (Cohen, 1995). Cohen (1995) made recommendations for what mathematics content students should study prior to calculus, which included number sense, symbolism and algebra, geometry, function, discrete mathematics, probability, and statistics, as well as mathematical proof. In a more recent publication, Saxe & Braddy (2015) recommend updating curricula to also address real world connections and affective dimensions of students' learning of mathematics. The purpose of the current study is to examine the content included in college mathematics courses taken prior to calculus in order to better understand how universities are implementing the recommendations about which content to include. Examples of such courses include college algebra, trigonometry, and quantitative reasoning.

Data for this study were 76 course syllabi from 50 public research-intensive universities in the southeastern United States. Each syllabus was analyzed to note the topics covered. These topics were then grouped into categories and tallied using a frequency table. The number of unique courses that contain content related to a specific topic are shown in Table 1.

Table 1. Frequencies of mathematical topics in course syllabi

Financial Mathematics	**40**	**Logic**	**26**	**Set Theory**	**19**
Probability	**39**	**Statistics**	**34**	**Math in the Real World**	**40**
Graph Theory	**18**	**Voting Theory**	**15**	**Combinatorics**	**16**
Algebra	**25**	**Operations Research**	**24**	**Game Theory**	**10**
Number Theory	**14**	**Geometry/Topology**	**16**	**Linear Algebra**	**10**

The topics with the most occurrences were Financial Mathematics (40), Math in the Real World (40), Probability (39), and Statistics (34). Conversely, the subjects with the fewest occurrences were Number Theory (14), Game Theory (10), and Linear Algebra (10). The average number of unique topics was approximately 4.645 topics per class. Several classes contained only one topic while others contained up to eleven unique topics. The topics that occurred most frequently seem to have real-world connections, as recommended by Saxe & Braddy (2015) and Cohen (1995). Additional data need to be collected to better understand affective dimensions related to learning mathematics and how these courses prepare students to appreciate the beauty of mathematics, use technology efficiently, and communicate effectively.

FACILITATING MULTILINGUAL LEARNERS' FRACTION DIVISION PROBLEM SOLVING: IMPACT STUDY FINDINGS

Johannah Nikula	Jill Neumayer DePiper	David Bamat
Education Development Center	WestEd	Research for Action
jnikula@edc.org	jdepiper@wested.org	davidbamat@gmail.com

Keywords: Middle School Education; Problem Solving; Equity, Inclusion, and Diversity

Purpose and Theoretical Framework

This study examines whether a focus on diagramming and language can facilitate mathematical problem solving for multilingual learners (MLs)—i.e., those identified as English learners. To meet MLs' strengths and needs in mathematics, we posit that three interdependent focus areas must be integrated: an asset-based approach towards MLs (e.g., NASEM, 2018; de Araujo et al., 2018; Moschkovich, 2002); student engagement with rigorous mathematics (e.g., Moschkovich, 2013) facilitated by the use of mathematical diagrams (e.g., Stylianou & Silver, 2004; Woodward et al., 2012; Driscoll et al., 2012); and language-focused instructional strategies (Celedón-Pattichis & Ramirez, 2012; Lee et al., 2013; Driscoll et al., 2016; Baker et al., 2014).

Methods

We designed and studied a grade 6 fraction division unit with supports for MLs such as language strategies (e.g., the 3 Reads, structured pairs work, sentence starters) and student use of diagrams (e.g., number lines, area models). We conducted a cluster randomized trial; this poster focuses on: *How did participation in these lessons impact students' diagramming in their fraction division problem solving?* Teachers were randomly assigned to use "business-as-usual" fraction division units (control) or our fraction division unit (treatment). Students completed a pre/post fraction division assessment, which was scored for *Diagramming* based on their representations of quantities and relationships for each item. The analytic sample included data from 246 treatment students (12 teachers) and 229 control students (11 teachers). We estimated the treatment effect of our unit on students' Diagramming scores and modeled the relationship between treatment and the Diagramming outcome through a series of multilevel regression models with students nested within teachers.

Results and Implications

When analyzing Diagramming scores, the best fitting model, controlling for prior diagramming ability and fraction understanding, ML status, and attendance, indicated a statistically significant adjusted mean difference, representing a medium-to-large effect ($b = .571$, $p < .01$). Evidence of a positive treatment effect, and no statistically significant interaction between ML status and condition, suggests that MLs made similar growth as their monolingual peers. By providing empirical evidence about lessons that foster MLs' use of diagrams in problem solving, this study responds to the lack of empirical research with attention to MLs' strengths (de Araujo et al., 2018) and has implications for instruction. This was an initial phase of a larger project; continued work will investigate MLs' perspectives on lesson components.

SPATIALIZING THE EARLY MATHEMATICS CURRICULUM

Robyn K. Pinilla
Southern Methodist University
rpinilla@smu.edu

Keywords: Geometry and Spatial Reasoning, Early Childhood Education, Instructional Activities and Practices, Curriculum

Children develop early spatial reasoning skills, including geometry and measurement, through play from a young age (Huinker et al., 2020), yet early childhood and lower elementary math curricula and teaching aim primarily at numeracy (Bruce et al., 2012). While spatial reasoning supports learning in other mathematical domains (Drefs & D'Amour, 2014; Farmer et al., 2013), early childhood teachers are more prepared to teach numeracy and generally dedicate little instructional time to spatial reasoning (Clements & Sarama, 2011; Moss et al., 2015). Davis and colleagues (2015) called for the radical spatialization of mathematics curricula as a potential solution, with spatial reasoning explicitly taught to support better mathematical reasoning.

The development and malleability of children's spatial reasoning skills are well researched (Sarama & Clements, 2009; Uttal et al., 2013), but few studies investigate what can support teachers of young children enacting spatial reasoning instruction in the classroom (Moss et al., 2015; Woolcott et al., 2020). This study aims to answer the following research question: How can curriculum and related professional development support early childhood teachers to enact spatial reasoning instructional practices?

Drawing on situated learning theory (Lave & Wenger, 1991) and a sociocultural approach to mathematics teacher learning (Horn & Garner, 2022), I respond to Davis and colleagues' (2015) call through a more incremental spatialization of the curriculum (National Research Council, 2006) at a research-practice partnership school.

Methods

This in-progress design research study (Cobb et al., 2003) occurs within a neighborhood STEM school at which the pre-k through 1st grades will open initially in fall 2022. By working with kindergarten and 1st grade teachers, I aim to illustrate the iterative design of a spatialization framework and innovative instructional practices. The school's inquiry learning framework and open-source curriculum use present an opportunity to develop standards-aligned spatializations with incoming teachers. The initial framework to spatialize instructional routines will be reviewed based on teachers' feedback, as elicited through ongoing professional development and observed teaching enactments. These processes support the iterative design of principles to support early childhood teachers' incorporation of spatial reasoning into their teaching practices. Data collected will include researcher-generated artifacts, observation records, and curriculum documents. Data collection and analysis will occur concurrently, with multiple data sources used to triangulate findings for enhanced trustworthiness (Merriam, 1998) and transferability (Lincoln & Guba, 1985) of emergent principles.

Results and Implications

Results of this design research will include information about the tools developed, their curricular alignment, and the iterative steps to articulating a framework to support early childhood teachers in enacting spatial reasoning teaching. This study serves as the first step toward a radical spatialization (Davis et al., 2015) of mathematics curricula by illustrating ways to integrate spatial reasoning instruction in early childhood classrooms.

NOTICING STUDENTS' MATHEMATICAL STRENGTHS IN WRITTEN WORK AND VERBAL EXPLANATIONS

Lisa Skultety
University of Central Arkansas
lskultety@uca.edu

Keywords: Preservice Teacher Education, Teacher Noticing, Instructional Activities and Practices, Assessment

For teachers to successfully enact responsive teaching (Richards & Robertson, 2016) and incorporate students' thinking into their instructional choices, they must first attend to and interpret students' mathematical thinking in their classrooms (Jacobs, Lamb, & Pilipp, 2010). This set of skills, referred to as *noticing students' mathematical thinking*, is particularly challenging for novice teachers (Star, Lynch, & Perova, 2011). While research has highlighted the importance of noticing students' mathematical thinking in math instruction, the discussion often fails to contextualize their noticing in light of equity and power in the classroom. It is necessary to consider that teachers' instructional choices are not solely based on the mathematics that a teacher notices in students' thinking, but also how teachers view students' thinking as valid (Louie, 2018). This can be particularly problematic since teachers, especially novice teachers, have difficulty valuing students' thinking that differs from their approach or solution to a problem and commonly only assign competence to students' strategies that match their own (Bannister et al., 2018). Jilk (2016) argues that the culture of education often trains teachers to notice students' thinking in light of whether their solution is correct or incorrect. This often results in a deficit view of students' thinking where teachers are continually noticing how students' thinking is "wrong." While identifying errors is not necessarily problematic in and of itself and is indeed a necessary component of noticing students' thinking, when a teacher can only see a student's mistakes, the teacher can easily miss valid mathematical thinking.

In this poster, I present my findings to the question, *what mathematical strengths do elementary preservice teachers notice in students' written work and verbal explanations?* I chose to focus on verbal and written work because students' mathematical understanding is most often assessed in these modes. Sixty-two elementary preservice teachers responded to ten activities of students' thinking in a mathematics content course. Five of the activities showcased students' written work and the remaining five activities were videos of students verbally explaining their mathematical thinking. Participants were asked to name what they thought was smart in each student's work and why. I coded participants' responses to questions referencing students' mathematical strengths according to the depth of their analysis and their justification of the strength. Findings demonstrated that overall, preservice teachers were able to name strengths in students' mathematical thinking more frequently in the video verbal explanations, and that those strengths were of deeper substance than analyses of students' written work. Furthermore, in the activities, all of the students with written work arrived at the correct solutions, but the preservice teachers were frequently unable to recognize the novel strategy as correct. These findings highlight the challenge of classroom assessments that are based entirely on students' written work, as preservice and novice teachers may not be able to move beyond "correct" or "incorrect" views of assessment, might not notice correct strategies that deviate from their own thinking, or be able to recognize strengths in all students' mathematical work.

Chapter 3:

Early Algebra, Algebraic Thinking, and Function

ELEMENTARY TEACHERS' SHIFT FROM ARITHMETIC TO FUNCTIONAL THINKING THROUGH PROFESSIONAL DEVELOPMENT

Alysia Goyer

sgil2013@gmail.com

Teruni Lamberg
University of Nevada, Reno
Terunil@unr.edu

Elementary In-service teachers participated in professional development related to algebraic thinking. A pre and posttest was administered. The analysis of how teachers conceptualized and solved a problem involved functional thinking shifted from the pre and posttest. Initially teachers solved the problem using additive thinking involving arithmetic. After professional development, teachers shifted to using functional thinking to solve the same problem. Implications for teacher knowledge and professional development are described.

Keywords: Algebraic Thinking, Professional Development, Teacher Knowledge

Students learn algebraic thinking starting in elementary school where they learn to recognize patterns, understand that the equal sign represents a relationship and express their mathematical ideas through representations. As students reach middle grades, they transition to learning about expressions, and functional thinking. This means that early elementary teachers lay the foundation for later development of understanding of formal algebra (Hohesee, 2017). Most researchers have extensively studied how students think algebraically and what teachers should focus on when teaching algebraic thinking (Jacobs et al., 2007). However, research is lacking on teachers' conceptions of algebraic concepts (Demonty et al., 2017; Warren et al, 2016). Warren et al. (2016) highlights the importance of research related to teacher knowledge since it has a direct influence on teachers' ability to make decisions to support their student learning. This study documents shifts in teachers' conceptions of algebraic thinking as they participated in teacher professional development on algebraic thinking. Specifically we investigated: How did professional development shift K-8 teachers' thinking involving algebraic relationships?

Theoretical Framework

There are three strands of algebra: building generalizations of arithmetic, generalizing toward the idea of a function, and modeling (Kaput et al., 2017). The transition from arithmetic to algebraic thinking involves the ability to notice patterns and relationships among operations as opposed to simply calculating the answer. This process involves engaging in reasoning and sense making as it relates to noticing patterns and relationships (Blanton & Kaput, 2005; Swafford & Langrall, 2000). In middle school students are formally introduced to expressions, equations, and functions. Therefore, they start using variables to represent unknown quantities, changing quantities in expressions and exploring functional thinking (CCSSM, 2012). In addition, they start comparing equivalent expressions based on properties (Kieran, 2004).

Input-output relationships are key in functional thinking, exploring the relationships between variables and their patterns (Scharfenberger & Frazee, 2020) that model quantitative situations algebraically which can be generalized (Driscoll, 2001; Obara, 2019). An input-output table is a tool to represent the relationship by isolating pertinent information in a problem (Store, 2018).

Common misconceptions involve generalizing too quickly, pattern-spotting can remain trivial, and students can generalize about the wrong properties (Driscoll, 1999). Russell et al. (2011), state that to support generalization, teachers should develop routines of noticing, articulating, and investigation. In order to support functional thinking, teachers should engage in physical or conceptual activities that involve relationships between one or two of the variables, keep a record of the quantities, identify the pattern, and coordinate representations of the identified pattern relationship (Russel et al., 2017; Smith, 2017).

Schulman's (1986) work on pedagogical content knowledge (PCK) has paved the way for various branches of mathematics (Ball et al., 2008), yet PCK research is comparatively scarce with algebraic thinking (Store, 2018). There is an interdependence between professional development (PD), teachers' content knowledge and PCK which can ultimately change classroom discourse and practices around algebraic thinking (Nathan & Koellner, 2007). Therefore, this study explored teachers' conception of algebraic and functional thinking in a pre and posttest question on algebraic and functional thinking.

Methods

A PD focusing on algebraic thinking was offered to K-8 elementary teachers as part of a week-long summer institute. The teachers were from a rural school district in a western state. The summer institute focused on having teachers' model and solve similar kinds of problems, and focused on having teachers explore functional relationships and writing expressions. A pre-test (N=20) and post (N=27) was administered, with the analysis of this paper focusing on a single questions, specifically part b) of the questions that required the participants to create an expression.

Tables for a wedding are being set up outside. The seat 8 people as shown below:

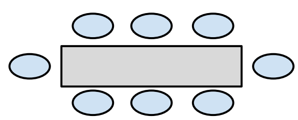

Figure 1

a) How many people will 2 tables seat if the shorter end is placed together?

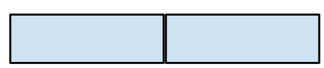

Figure 2

b) Create an expression for how many people n tables will seat.

The PD focused on teacher noticing. The teachers explored a similar problem to the one they solved on the pre-test. Teachers were asked to describe what they noticed. The teachers then expanded on their original table problem to investigate what would change if the tables were pushed together vertically as opposed to horizontally. Figure 3 shows one group of teachers' recorded strategies to generalize the patterns they noticed.

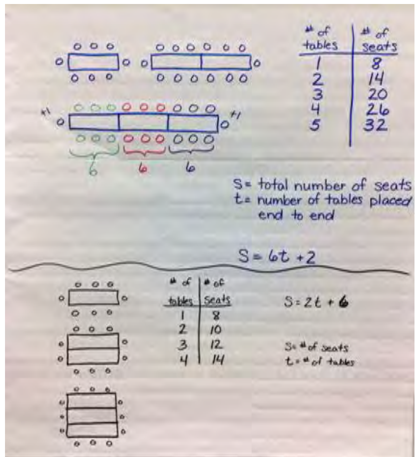

Figure 3

The PD Leader additionally probed the teachers to make sense between the differences between the *6t* and *2t* between the two problems. She asks the teachers to identify what is changing and how it is changing, and how that would be represented in a table and how it be represented graphically. She then redirected the teachers to explain how that relates back to the table model, and what is staying the same. A posttest with a similar problem was administered at the end of the week.

Data Analysis. An inductive coding scheme (Saldaña & Omasta, 2018) was created as follows (see Figure 4). We defined variation as the change between the number of seats for each table(s) added.

Interrater Reliability: Analysis coding of the pre and posttest was conducted blindly between two coders and achieved an initial intercoder reliability of 93.6% using percentage agreement outlined by Syed & Nelson (2015). However, these initial differences were discussed and resolved to achieve full agreement.

Code	Example from Pre-Tests	Description
Noticing Variation & Constant	$6n+2$	Subject was able noticed both constants and variation to generalize
Noticing Only Variation	$6n$	Subject only noticed variation to generalize
Generalized Too Quickly for Variation	$n \times 7$ or $8n$	Subject created a variation generalization that applied to only singular term
Difficulty in Identifying Independent Dependent Variables	$n = 2x - 2$ where x = # of people at one table	Subject was unable to generalize due to an incomplete understanding of independent/dependent variables
Other	$p = n-(2n)$	Other generalizations

Figure 4

Results

The pre-test demonstrates high variability in the difficulties displayed by the participants (see Figure 5). Only 40% accurately noticed both the variation and the constant, and provided a correct expression. This increases drastically in the post-test, with approximately 85% of participants noticing the variation and the constant and providing a correct expression. Additionally 7% of the post-test participants noticed only the variation, showing that there was a dramatic increase in noticing variation overall between the pre and posttests. There were no participants during the post-test that generalized too quickly with an incorrect change, dropping to 0% from 40% on the pre-test. There was one participant in both the pre-test and the post-test that had difficulty identifying independent and dependent variables.

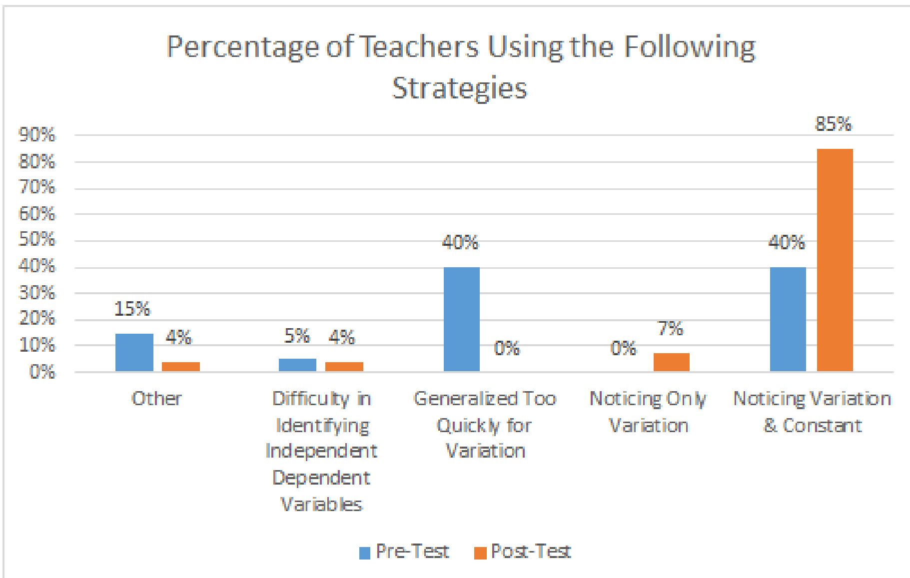

Figure 5

Discussion

The most significant change made to teachers' algebraic thinking was building in the categories of noticing both variation and the constant. This shows a shift away from arithmetic thinking to functional thinking. During the professional development teachers made connections to patterns they noticed, tabular representations, to the algebraic expressions. These connections strengthened the teachers' understanding in identifying variation and constants in their patterns and expressions. However, this illustrates that teachers, just like students, can initially fall into common generalizability pitfalls when analyzing patterns. Teachers can generalize too quickly, generalize about the wrong properties, or have difficulty in understanding the independent and dependent variables as it relates to functional relationships. PD's need to provide opportunities to identify teachers' misconceptions as well as the opportunity to practice noticing, globalizing, and extending their own algebraic generalizations. If teachers are given the opportunity to develop and refine their own algebraic habits, it will reinforce their PCK (Nathan & Koellner, 2007; Shulman, 1986) which then influences their classroom discourse which will encourage them to model and support students' thinking as they develop their own algebraic sense-making.

CONFERENCING TO SUPPORT MATHEMATICAL ARGUMENT WITH MULTILINGUAL STUDENTS

EL USO DE CONFERENCIAS PARA APOYAR ALUMNOS MULTILINGUËS CON ARGUMENTOS MATEMÁTICOS

Salvador Huitzilopochtli

jmoschko@ucsc.edu

This classroom design study sought to support multilingual, middle-school students learning mathematical argument with writing practices (leveraging audience, revising, and conferencing). The study was set in a rural, Northern California, dual-immersion school with over 96% Latinx students and over 80% low-income. We used a proof schemes (Harel & Sowder, 1998) framework to examine revisions that students made during mathematical conferences. Findings show that some students used conferencing as an opportunity to revise (or generate arguments) while other students used conferencing as an opportunity to revise procedures or their use of formal terms. Findings support the notion that language should not serve as a gatekeeper that prevents multilingual students from accessing rigorous mathematics.

Keywords: Reasoning and Proof, Culturally Relevant Pedagogy, Middle School Education

Mathematical arguments and proof are difficult for students of mathematics to learn (Healy & Hoyles, 2000). Part of the difficulty is found in the need for students to learn a new *basis of belief* that is neither "natural" (ECEMS, 2011) nor appropriate in settings outside of mathematical activity. Hence, most students arrive to the mathematics classroom and approach mathematical argument with little more than a few examples as "proof" of mathematical claims (Knuth, Choppin, & Bieda, 2009; Harel & Sowder, 1998).

This research presents preliminary findings from a larger dissertation study that sought to support multilingual students' development of mathematical arguments by conferencing on their written responses when asked to justify mathematical claims. This brief research report elaborates findings from the use of mathematical conferences to support students to revise their arguments and was guided by the following question: How did the practice of conferencing support students to revise mathematical arguments?

Conceptual Framework

This research is framed by several overarching concepts. First, we used a sociocultural view of mathematics learning and mathematical writing (Moschkovich 2002). We assumed these activities to be discursive and framed by knowledge and practices where meaning is situated and negotiated (Moschkovich, 2015). We focused on the practice of *justifying,* which involves students using informal mathematical arguments to construct mathematical certainty about generalizations (Smith, 2008; Stephens et al., 2017). We used the *proof schemes* framework (Harel & Sowder, 1998) to analyze arguments created by students. In this framework, students could make use of three classes of proof schemes: external conviction, empirical, and analytical. External conviction proof schemes rely on ritual, authoritarian, or symbolic arguments to determine what is true. Empirical proof schemes rely on facts or the senses to construct certainty. Analytic proof schemes seek to settle a claim in general and rely on the structure of mathematical knowledge and logic to convince.

Methods

This research represents a part of a larger classroom design study that used audience and conferencing to support students learning mathematical argument. The study was set in “Esperanza Elementary School” (pseudonym); a rural, Northern California, dual immersion school with 96% Latinx students (over 80% of which are low-income). The study involved a unit of instruction on mathematical argument with three lessons that featured a Convince Form and two rounds of conferences. The Convince Form was designed to leverage audience as it supported the process of justifying by prompting students to ‘convince themselves’, ‘convince a friend’, and then ‘convince a skeptic’ of their mathematical claim. This research brief focuses on two tasks: 1) the *Happy Numbers* task (Dietiker, Baldinger, Kassarjian, & Shreve, 2013), and 2) the *Consecutive Sums* task (MARS, 2015). ‘Happy’ numbers are found by separating the digits of a number, squaring each digit, and then adding the resulting products. If the resulting sum is ‘1’, then the number is ‘Happy’. If the sum is not ‘1’, then the process repeats until it results in a sum of ‘1’ or a sum repeats (in which case, the number is ‘not Happy’). See Figure 1 for prompts related to Task 1. Task 2 involved the Consecutive Sums task. Students were prompted to qualify each of six mathematical conjectures as “Always”, “Sometimes”, or “Never” true and then justify their choice (see Figure 2). Each task was modified to accommodate remote data collection during the ongoing COVID-19 pandemic. We used case studies of a few representative students to illustrate patterns in the data. Author 1 (Huitzilopochtli) conducted the interviews.

A. There are 17 Happy Numbers (from 1 – 99). Find as many as you can.
B. Find five 3-digit happy numbers.
C. Eva found out that 478 is a happy number.
   i. What other numbers *must* be happy numbers?
   ii. How do you know?
   iii. Find at least 10 new happy numbers.

Figure 1: Task 1—Happy Numbers (Dietiker, et al., 2013)

Figure 2: Task 2—Consecutive Sums (MARS, 2015)

Results

Some students used conferencing as an opportunity to revise (or generate) arguments while other students also used conferencing as an opportunity to revise procedures and formal terms.

Revising Arguments

Eight of the 12 conferences involved students revising arguments: three fifths of the students on Task 1 and five sevenths of the students on Task 2. We review the case of "Nina" to illustrate revisions made for Tasks 1.

Prior to the conference, Nina submitted a list of examples in response to Task 1, Part A. Nina did not respond to Parts B or C. During the conference, I prompted Nina to look for patterns in her list of examples. She noticed that some of the 'happy' numbers had the same digits (e.g., 68 and 86). When I asked how that worked, Nina replied, "Because you're… square the individual numbers and… yeah… so, you're gonna get the same, like, sequence for the… yeah." (Transcript turn 19 – 22). Afterwards, I asked Nina to use her idea to find three-digit 'happy' numbers (Part B). Nina said that "you can get the same digits but put a zero in between or at the end" (Transcript turn 28). I asked her why it works, and Nina said, "Because when you square zero, you 're gonna get zero, so it doesn't make any change in the final answer" (Transcript turn 34). At that point, I asked Nina to use her ideas to find which numbers *must* be happy numbers if 478 is a 'happy' number (Part C). Nina correctly determined 4,780, 4,078, and 8,740 were all 'happy' without the need for calculation (Transcript turns 40 – 42). This example shows how Nina used examples to develop the claim that you can use a zero digit to generate novel 'happy' numbers. While her use of the identity property of addition (i.e., $a + 0 = a$) is implicit, Nina is poised to make a general claim and justify it with data (in the form of examples) and warrants (in the form of mathematical properties). Nina began the interview with a list of examples but no claim about how to generate more 'happy' numbers. Then, she engaged in some inductive reasoning as she generated an empirical argument that a zero digit can be used to make novel 'happy' numbers.

Revising Procedures and Formal Terms

Six of the twelve conferences involved students revising either procedures or formal terms; four students revised procedures and five clarified formal terms (three of which revised both). We will review the case of "Yolanda" who revised both.

In response to Task 2, Yolanda qualified all of the claims by placing cards but did not justify any of the choices. During the conference, Yolanda chose to discuss how she qualified the claim that "To find the sum of consecutive whole numbers, find the middle number and then multiply it by how many numbers there are" (Conjecture C; see Figure 3). Yolanda benefitted from support with the procedures for testing the conjecture using examples and using the term "consecutive" with the intended meaning.

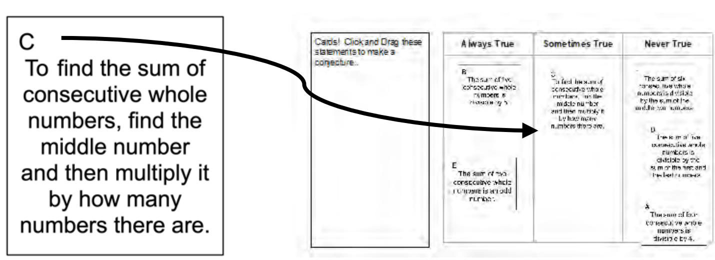

Figure 3: Yolanda's claim is Conjecture C is sometimes true.

I then asked her if she can test the claim, to which she responded, "I don't know" (Transcript turn 42). I picked an example for her to test, 3 + 4 + 5, and she responded by simply adding them to get 12 (Transcript turn 44). I supported her to test the conjecture by walking her through the steps to determine whether multiplying the middle number by the number of addends equals the sum (turns 49 – 58). Then I asked her to come up with her own example to test and she suggested "2 + 4 + 6" (turn 64). Yolanda refined her working definition of what "consecutive" means. Her initial suggestion to test "2 + 4 + 6" (turn 64) used consecutive *even* numbers (i.e., not consecutive whole numbers). My clarification supported her work on the task, and Yolanda later used the intended meaning for 'consecutive' on her own. I asked Yolanda to test her own example and she suggested '9 + 10 + 11 + 12'. Then, she made the following observation:

> Because it's four and if you—you could put four in a group so then it would be two and two. But then, there wouldn't be a middle number. Or, at least, there can't be. And the middle numbers could be 10 and 11, but it would have to be one. (Transcript turn 138)

Yolanda suggested that there is no whole number in the "middle" of a set of four numbers. Before the end of the conference, I invited Yolanda to "say more" about when the conjecture does and does not work. Yolanda responded, "Because if you do 4, I don't think it'll be able to work but if you do more, it could possibly work. Or if you do less" (turn 160). I asked if "3 + 4" worked and Yolanda said, "That can't work" (turn 162) because "it's only two and there would at least have to be three" (turn 164). To conclude, we reviewed what we had done, and I asked her to summarize when she thought the conjecture worked. In the chat, she responded, "it works when there is [sic] 3 and 5+ numbers but it won't work if it's 4 or 2 numbers" (chat file 12/7/2020). With support, Yolanda revised the procedures to test whether an example satisfied the conjecture and her use of the word "consecutive". She began the conference without a justifying scheme and with support is reasoning empirically. Moreover, Yolanda is positioned to further define cases when Conjecture C is true and when it is not.

Discussion and Conclusion

The purpose of this study was to use writing-related practices (leveraging audience, revising, and conferencing) to support multilingual middle school students learning mathematical argument. We found that students used the conferences to revise (or generate) arguments, procedures, and their use of formal terms (such as "consecutive"). These findings suggest that conferencing has potential as a practice to support all students learning mathematical argument, but especially multilingual students to ensure that they understand feedback and receive support to revise their arguments and use of formal terms. An implication of this study is that an iterative approach to justifying might support students to generate more general arguments. The implications of this study extend more broadly because formal terms, such as those common in 'academic language', are often seen as a gatekeeper for multilingual students (NASEM, 2018) and can function as a 'symbolic border' (Faltis & Valdés, 2016). Conferencing might support access to more rigorous mathematics for multilingual students.

Acknowledgments

We would like to acknowledge the students of Esperanza Elementary School and "Ms. Garcia" for their participation. We would also like to thank [funding source] for their support.

QUANTITATIVE REASONING, DEDUCTIVE REASONING, AND OPERATING WITH ALGEBRAIC SYMBOLS: A NOVEL FRAMEWORK

Teo Paoletti

Allison Gantt
University of Delaware
agantt@udel.edu

In algebra, operating with symbols meaningfully depends upon a student's quantitative and deductive reasoning. Students can engage in these types of reasoning in different combinations, which has not yet been well conceptualized by mathematics education research. In this report, we present a framework that describes different combinations of how students use quantitative reasoning, deductive reasoning, and/or operating with algebraic symbols. We describe and illustrate each combination using examples from extant literature.

Keywords: Algebra and Algebraic Thinking, Quantitative Reasoning, Deductive Reasoning

Although the subject of algebra involves a wide array of reasoning and skills, one common feature (and source of difficulty) involves operation with algebraic symbols (i.e., variables, expressions, equations, and inequalities) to solve problems (Kaput, 2008; Kieran, 2004; Steffe & Izsák, 2002; Stephens et al., 2017). Previous research has found that even when students can operate with algebraic symbols efficiently, they may not maintain meanings that support them in deductively understanding why they can manipulate algebraic symbols or how symbols are applicable to quantitative situations (e.g., Blanco & Garrote, 2007; Didiş et al., 2011; Hohensee, 2017). We present a framework to support researchers to make sense of students' activity on tasks that may involve intersections of their quantitative reasoning, deductive reasoning, and operating with symbols. Our framework characterizes ways students may employ quantitative and/or deductive reasoning with or without operating with algebraic symbols. We use examples from the extant literature to describe each type of reasoning.

Quantitative Reasoning and Deductive Reasoning

Smith and Thompson (2008) define quantitative reasoning as when individuals conceive of and reason about the relationships between quantities. Quantitative and algebraic reasoning are closely intertwined. For example, Steffe and Izsák (2002) contended that algebraic reasoning entails "quantitative reasoning about constant and varying unknowns" (p. 1164). Similarly, Smith and Thompson (2008) argued that "quantitative reasoning provides conceptual content for powerful forms of representation and manipulation in algebra" (p. 100). However, they also note that, for many students, algebra is reduced "to a set of rituals involving strings of symbols and rules for rewriting them" (ibid, p. 96). Researchers (e.g., Thompson & Thompson, 1995) have conjectured that such an understanding of algebra may stem from a lack of opportunities to construct and reason about relationships between quantities.

By comparing several definitions of deductive reasoning (e.g., Ayalon & Even, 2008; Morris, 1995; Rivera & Becker, 2007; Stylianides & Stylianides, 2008), we synthesized features of deductive reasoning. First, such reasoning starts with given information students must presume is true. Then, students must use this information to reach conclusions they understand are logically true (e.g., do not require empirical verification). Addressing the relationship between deductive reasoning and algebra, Morris (1995) characterized *algebraic deductive reasoning* as applying "rules of transformation [which] include . . . operations specific to algebraic reasoning such as the ability to manipulate algebraic symbols" (p. 9). For our purposes, algebraic deductive reasoning entails manipulating symbols and applying rules in ways the reasoner understands lead to "logically necessary" conclusions (Stylianides & Stylianides, 2008, p. 865).

A Framework to Characterize Students' Quantitative and Deductive Reasoning in Algebra

In Figure 1, we present six regions representing different ways students may leverage quantitative and/or deductive reasoning with or without operating with symbols in algebra. Because our focus is the domain of algebra, we did not include a region entailing deductive reasoning that is absent of quantitative reasoning and operating with symbols.

We do not intend for our framework to categorize students but rather, students' reasoning on particular tasks around specific mathematical content. Further, depending on the context, a student may not *need* to reason in certain ways. Hence, when we say a student does not provide evidence of certain reasoning in a particular context, we are not implying the student cannot reason in those ways. We acknowledge the student may just not have perceived a need to engage in such reasoning. Relatedly, our goal was for the framework to characterize reasoning, not correctness.

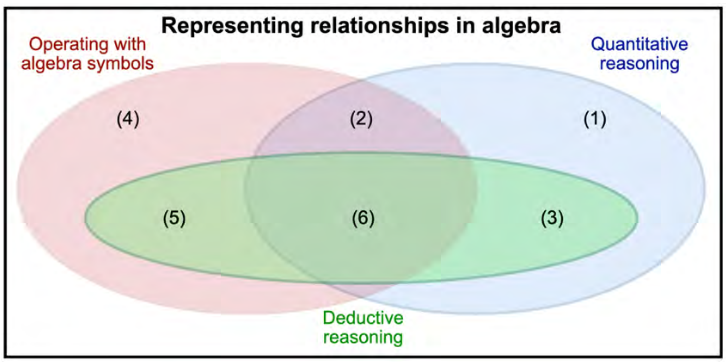

Figure 1: A framework characterizing students' reasoning.

Region 1: Reasoning Quantitatively without Reasoning Deductively or with Symbols

Region 1 reasoning consists of reasoning quantitatively in ways that do not entail reasoning deductively or algebra symbols. In fact, when students first make sense of a novel situation, their initial reasoning may be solely quantitative. For example, Ellis et al. (accepted) described how a 4-year-old student, Mario, addressed the *Faucet Task*. The task prompted students to engage with two quantities: the amount and the temperature of water coming out of a faucet. Mario was also encouraged to consider how these two quantities varied as the cold and hot knobs were turned on or off. With both knobs halfway on, Mario predicted that if the cold knob was turned all the way on, there would be "less water and colder." He then tested his prediction to determine that although the water was colder, there was more water. As he engaged in several scenarios, he began to coordinate changes in water temperature and amount of water as each knob was turned. Critically for our purposes, Mario reasoned about the relationship between turning knobs and the amounts of the quantities *without* the use of symbols to represent his thinking. Further, his reasoning was inductive, relying on testing conjectures, rather than deductive. Therefore, we interpret his reasoning as in Region 1 (i.e., quantitative reasoning only).

Region 2: Reasoning Quantitatively with Symbols without Reasoning Deductively

Region 2 reasoning entails reasoning quantitatively and representing quantitative relationships with algebraic symbols but without reasoning deductively. There are numerous examples of such reasoning in the extant literature (e.g., Dougherty, 2008; Izsák, 2003; Stevens, 2020, in press). For example, Paoletti et al. (2021) described how middle school students used algebraic inequality and equality statements to represent when one quantity was greater than, less than, or equal to a second quantity (e.g., by writing $P < T$, $P > T$, and $P = T$ to represent a moving car's distance from Philadelphia as being less than, greater than, or equal to its distance from Trenton). The students reasoned quantitatively to represent the relationships with algebraic symbols but relied on empirical verification throughout by observing locations in the situation, thereby providing no evidence of deductive reasoning. For this reason, we interpret this as an example of reasoning in Region 2 (i.e., quantitative and with symbols, but not deductive).

Region 3: Reasoning Deductively and Quantitatively but without Algebra Symbols

Region 3 reasoning entails reasoning deductively and quantitatively but without employing algebraic symbols. Hackenberg (2010) exemplifies such reasoning. In this paper, a student, Deborah, reasons about the following problem: "The Lizards' car travels 1/2 of a meter. That's 3/4 the distance the Cobras' car went. Can you make how far the Cobras' car went [in the digital environment] and tell how far it went?" Describing Deborah's activity, Hackenberg stated:

> Deborah immediately copied the unit meter she had made, partitioned it into two equal parts, and partitioned the first part into three equal parts. She pulled out one of those parts and repeated it to make a 4-part bar, which she called four-sixths of a meter. (p. 417)

We note that, Deborah was reasoning quantitatively about the situation as she represented and related the various distances. Further, Deborah relied on the diagram to reason deductively about the relationships involved in the situation. Specifically, her activity suggested she assumed the givens (i.e., that Lizards' car travels 1/2 m and that this is 3/4ths the distance Cobras' car travels); she reasoned that 3/4ths the distance Cobras' car travels is 3/6 m; and she came to the logical conclusion that the total distance Cobras' car travels was 4/6 m. Finally, notice that Deborah did not use algebraic symbols. Thus, we categorize such reasoning as in Region 3.

Regions 4 and 5: Operating with Symbols Non-Quantitatively with or without Reasoning Deductively

Regions 4 and 5 both entail operating with symbols without explicit focus on measurable attributes of objects (i.e., non-quantitative). The difference between Regions 4 and 5 is whether the reasoning is deductive or not. Because students' normatively correct algebraic work could reflect reasoning in either region, using non-normative examples can help differentiate between students' reasoning in the two regions. To highlight this, we describe Regions 4 and 5 in tandem.

Didiş et al. (2011) explored students' reasoning about quadratic equations in ways that highlight the distinction between Regions 4 and 5. Although most students could provide solutions to equations of the form $(x - a)(x - b) = 0$, their evaluations of hypothetical student work suggested that only some were engaging in what we identify as deductive reasoning. The hypothetical work showed a quadratic equation (i.e. $x^2 - 14x + 24 = 3$ where both the quadratic expression and constant had been factored (i.e. $x^2 - 14x + 24 = (x - 12)(x - 2)$ and $3 = 3 \cdot 1$). The hypothetical work arrived at a solution by setting one factor of each expression equal to a factor of the other (i.e., $x - 12 = 3$ and $x - 2 = 1$). Students who argued that the solution was correct may not have maintained meanings for their process based on the zero-product property, which provides the logical underpinnings of this solution (i.e., Region 4). In contrast, we conjecture a student who argued the hypothetical solution is incorrect had assessed that the hypothetical solution did not lead to "logically necessary" conclusions (i.e., Region 5).

As the students made no references to quantities (which is unsurprising given the prompt's abstract context) and they were operating with algebraic symbols, we infer the reasoning is indicative of Regions 4 and 5. These examples highlight how it can often be unclear if a student's procedures entail deductive reasoning when examining normatively correct solutions (e.g., correct solutions to $(x - a)(x - b) = 0$). By responding to unconventional hypothetical student work, we are able to observe potential differences in students' processes as entailing deductive reasoning (Region 5) or not entailing deductive reasoning (Region 4)

Region 6: Reasoning Quantitatively and Deductively while Operating with Symbols

Region 6 reasoning requires both deductive and quantitative reasoning while operating with algebraic symbols. Hall et al. (1989) provided an example of a student engaging in such reasoning on the following problem: "George rode out of town on the bus at an average speed of 24 miles per hour and walked back at an average speed of 3 miles per hour. How far did he go if he was gone for six hours?" (p. 249). Reflective of reasoning quantitatively, the student created several equations which had an explicit focus on measurable attributes (e.g., "walking distance = (3 miles/hr)($6 - x$ hours)") and relationships between measurable attributes (e.g., "bus distance = walking distance"). Further, the student used equations to relate two equivalent distances (e.g., $24x = 18 - 3x$), then reasoned deductively to determine the time, in hours, the bus traveled ("bus distance = 16 miles"). The student then used this value to eventually determine a solution to the problem. Therefore, we classified this reasoning as in Region 6.

Discussion

Our goal in this paper is to present a novel framework that allows researchers to engage in a nuanced analysis of the intersections between students' quantitative reasoning, deductive reasoning, and their operating with algebraic symbols in a particular task or context. Specifically, we theorize that students' reasoning can fit within (at least) six regions when reasoning quantitative and/or deductively while operating or not operating with algebra symbols. The fact that we located examples in the literature of reasoning that align with each region highlights the potential efficacy of this framework to characterize students' reasoning.

Based on our personal experiences and extant research (e.g., Hohensee, 2017), we conjecture most students leave K-12 with ways to operate with symbols but with insufficient understanding about how deductive logic justifies their operations on symbols or how their procedures connect to quantities (Regions 4 and 5). Also, when students are encouraged to reason about quantities, we conjecture quantities are often only considered when setting up equations (Region 2) but then their work with the equations largely ignores the quantities under consideration (moving to Regions 4 or 5) as in the example in Figure 4.

Hence, there is a need to design and research instructional activities that support students in developing meanings that enable them to reason in ways that would fit within Region 6. There are indications that connecting pictorial and algebraic representations can be particularly productive for students (e.g., Bartel et al., 2021; Chu et al., 2017). Research exploring these activities has the potential to address the need to better understand and improve students' algebraic thinking and learning.

We explore early algebra moments, that is, the opportunities that arise during the course of classroom instruction that a teacher could potentially capitalize upon to address important early algebra ideas or practices. We categorize early algebra moments as anticipated (based on the intended lesson) or spontaneous (not anticipated and arise "in the moment"). In this paper, we report on the analysis of sixteen video-taped observations of Grade 5 teachers' implementation of the same early algebra lesson and illustrate the results with contrasting exemplars of the two types of moments. In addition, we also highlight an episode of a spontaneous moment that capitalizes on collective argumentation. Finally, we discuss implications for future research, professional development, and student learning associated with the early algebra moments.

Keywords: Algebra and algebraic thinking, elementary school education, teacher noticing, classroom discourse

Blanton and Kaput (2003) described elementary teachers' algebra "eyes and ears" in terms of their ability "to spot opportunities for algebraic thinking" (p. 76). In this paper, we expand on this idea and explore what we call *early algebra moments*, that is, the opportunities that arise during the course of classroom instruction that a teacher could potentially capitalize upon to address important early algebra ideas or practices. We categorize early algebra moments as anticipated or spontaneous moments; in the former case, these are moments that are reasonable to expect based on the intended lesson (and that are also further delineated as taken up or as not taken up by the teacher), and in the latter case, these are moments that were not anticipated and that arise "in the moment."

Background of work

The larger project, from which this study draws, examined the impact of an early algebra intervention for Grades 3-5. The intervention consisted of 18 one-hour lessons for each grade level, and was developed using a learning progressions approach (Authors, 2018). The lessons were taught over the course of the school year for each grade level. The aim of the lessons was to develop students' abilities to generalize, represent, justify, and reason with mathematical structure and relationships across a variety of mathematical contexts. The lessons focused on several big ideas of early algebra: (a) mathematical equivalence; (b) generalized arithmetic; (c) functional thinking; and (d) variable (Kaput, 2008). This study draws from and expands upon a series of studies that examined the impact of this intervention in Grades 3-5 (Author, 2015) comparing the performance of students who participated in the intervention with the performance of students who received their district's regularly-planned curriculum (Author et al., 2015; Author et al., 2017; Author et al., 2018).

Conceptualizing Early Algebra Moments and Their Enactment

We value teachers as co-producers of knowledge, experts, and informants to research (Bromme, 2014; Kieran, Krainer, & Shaughnessy, 2012; Sowder et al., 2005). The relationship between research and practice is bidirectional; research and practice communities have much to contribute to each other's work (Arbaugh, et al., 2010). The professional knowledge of teachers can be characterized as a complex cognitive set of skills honed through formal training and years of practical experiences. This expertise shapes the ability to notice, interpret, and respond to students often within a series of complex classroom events requiring immediate, improvisational teacher reactions (Borko & Livingston, 1989; Shulman, 1987). We ask, "What are examples of teachers' improvisational implementation of early algebra lessons?" Through our examination of teachers' implementation of early algebra lessons, we seek to learn not only about the ways in which they engage (or not) with anticipated early algebra moments, but also the ways in which spontaneous (or unanticipated) moments arise during their enactment of these lessons. This latter case, in particular, serves to highlight the unexpected and often creative ways in which teachers implemented the lessons, and as such, also serves to inform and refine research and professional development in early algebra—a domain of importance to students' future mathematics learning as well as a domain that presents instructional challenges for elementary school teachers (Hohensee, 2015).

Researchers have documented critical moments within a mathematics lesson that afford teachers an opportunity to notice and act in order to further student reasoning and understanding (e.g., Fennema et al., 1996; Leatham et al., 2015; Stockero & Van Zoest, 2013). The specific language used to describe these moments during instruction varies among researchers: "teachable moments", "mathematically significant pedagogical opportunities", "crucial mathematic hinge moments", and "pivotal teaching moments". A commonality of such moments is that they are largely unplanned or unanticipated and thus require teachers to notice them in the moment. Specifically, within early algebra, teachers can capitalize on such moments to draw connections to algebraic thinking and foster practices that promote algebraic thinking (Blanton & Kaput, 2003). Blanton and Kaput argued that these moments are incorporated into classroom teaching on a regular basis and often spontaneously. To illustrate the categories of early algebra moments, consider the following task presented to Grade 3 students: Is the number sentence, 34+10=44+9, true or false? In this case, we expected *anticipated moments* associated with an operational view of the equal sign (i.e., the number sentence is true since 34+10=44) and a computational view (i.e., find the sum of both sides and compare). We also identified a *spontaneous moment* when the teacher drew, and then referred to, separate rectangles around the expressions on each side of the number sentence as a means to visually highlight a relational view of the equal sign (i.e., an equivalence relation between two quantities).

While moments in which teachers note "interesting student algebraic thinking" in video-taped observations of secondary algebra classrooms have been studied (Walkoe, 2015), there is a dearth of such work for the domain of early algebra. We hope to add to the body of early algebra research by detailing these critical moments that afford opportunities to foster students' algebraic thinking. Furthermore, there is a lack of empirical analysis of observations of multiple teachers teaching the same early algebra lesson. Our corpus of data provides a unique opportunity to document and analyze the ways in which teachers capitalized, or did not capitalize, on opportunities to engage students in algebraic thinking.

Methods

In the following section we first describe the data used in the study and the data analysis process. In particular, we describe our coding method and illustrate the coding with representative algebra moments from the focus lesson.

Setting and Participants

This study involved 16 Grade 5 teachers in three school districts located in a southeastern US state. The teachers varied in their years of teaching experience from relatively new teachers to veteran teachers. The districts were diverse in terms of race and socioeconomic status, as well as location (rural, suburban, and urban).

Lesson

Students were taught the early algebra intervention by their classroom teachers as part of regular mathematics instruction. This study focuses on one of the lessons, roughly one hour in duration, implemented by each of the sixteen Grade 5 teachers. There were three parts to the lesson: a warm-up, a main activity, and a concluding discussion that focused on reviewing the main activity's key concepts. For the warm-up of this lesson, students were asked to construct a graph to model the relationship of selling twice as many strawberry ice cream bars as chocolate ice cream bars. The main activity of the lesson focused on the distributive property, and students expressed the shaded, white, and total areas of the rectangular figure (see Figure 1) using variables with expressions, equations, and inequalities. The goal of the main

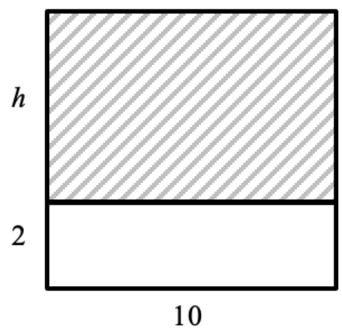

Figure 1: A rectangular model of the distributive property.

activity was to build students' experiences with the distributive property through writing expressions, equations, and inequalities. Students were asked to consider the various rectangular areas to write an inequality that relates the grey rectangular area to the white rectangular area. They were then tasked to write an expression for the total area (i.e., $10(h+2)$ or $10h + 20$). Lastly, students were asked to solve for h if the total area of the composite figure was 100 square units. The concluding activity for the lesson centered on the students determining the difference in area for a rectangle that is $7h$ square units and a rectangle that is $3h$ square units, as well as on the different roles variables play in equations and expressions.

Data Analysis

In order to identify and characterize algebra moments in the observations of the lesson, our coding had two phases. First, prior to viewing the video observations, the research team reviewed the intended lesson, both student and teacher facing materials, and identified a set of 13 anticipated moments for the lesson. An *anticipated moment* is defined as an expected response based on the intended lesson that supports students' understanding of an algebraic concept or fosters an algebraic practice. To illustrate an example of an anticipated moment, the first part of the main lesson prompts students to represent the areas of a rectangle partitioned into two parts, both with length 10 units and widths h and 2 units (see Figure 1). The anticipated moment for this part of the lesson is "variable expressions are written and shared such as $10h$".

Through the course of our viewing of the video observations, in contrast to anticipated moments, we identified *spontaneous moments*. We define spontaneous moments as moments that were not anticipated based on the intended lesson, and that arise "in the moment" to support students' understanding of an algebraic concept or foster an algebraic practice. To illustrate an example of a spontaneous moment, in response to the aforementioned prompt to represent the areas of a partitioned rectangle into two parts (see Figure 1), a spontaneous moment was coded as such when a student objected to the lesson prompt stating "We can't represent the area of the grey rectangle since we don't know what that variable (h) is equal to." A teacher's response to the student was "Do we have to know what the answer is? What h is? …Or can I just leave it as h?" While the printed lesson material for teachers addresses common student misconceptions and details potential student responses, the student's discomfort or resistance to the lack of closure with the variable expression ($10h$) of the area (*cf.* Arcavi, 2005) was not an intended (or anticipated) part of the lesson.

We further delineated each moment as either *taken up* or as *not taken up* by the teacher. A moment taken up requires the teacher to notice and capitalize on the opportunity in a way that supports students' understanding of an algebraic concept or fosters an algebraic practice. In contrast, a moment not taken up is when a teacher does not address an algebra moment (whether intentionally or not). Note that an opportunity not taken up could also occur for algebra moments that, if taken up, would have been coded as spontaneous. In this case, such *not taken up* spontaneous moments were identified by the research team when observing an unanticipated opportunity that arose in the course of instruction but was not addressed by the teacher. For example, in response to writing an expression for the area of the rectangle, a student claims that h must be equal to 8 since h is the eighth letter of the alphabet. The teacher acknowledges "that works out, huh?" but does not address this variable misconception.

The coding process began with the coding of four observations by our team of six coders. After successively meeting after each coded observation to refine our anticipated moments and what constitutes spontaneous moments, we then coded the remaining twelve observations as two teams of three coders. We coded individually and then met to compare and discussed our codes. The intercoder reliability was high for both anticipated moments (approximately 95%) and spontaneous moments (approximately 92%).

Results

The lesson had 13 opportunities for anticipated early algebra moments, and across the 16 teachers' enactment of the lesson, there were 208 total opportunities. Of those, there were 145 instances (70%) in which anticipated moments were taken up, and 63 instances (30%) in which anticipated moments were not taken up. In the former case, we are not making distinctions here with regard to the "quality" with which a teacher took up a particular moment (we illustrate such distinctions below), only that they attended to the algebra moment. In this latter case, the moments that were not taken up most often were a result of teachers not addressing those parts of the lesson (for example, a teacher pressed for time may have skipped parts of the lesson). For spontaneous moments, there were 56 moments identified with 43 of those moments (77%) taken up and 13 of those moments (23%) not taken up. See Figure 2 for a summary of algebra moments counts across the 16 teachers. Of the thirteen possible anticipated moments for each lesson, the average number of anticipated moments taken by each teacher is about 9 while the average number of anticipated moments not taken up is about 4. There was an average of 2.7 spontaneous moments taken by each teacher, and an average of 0.8 spontaneous moments were not taken up by teachers.

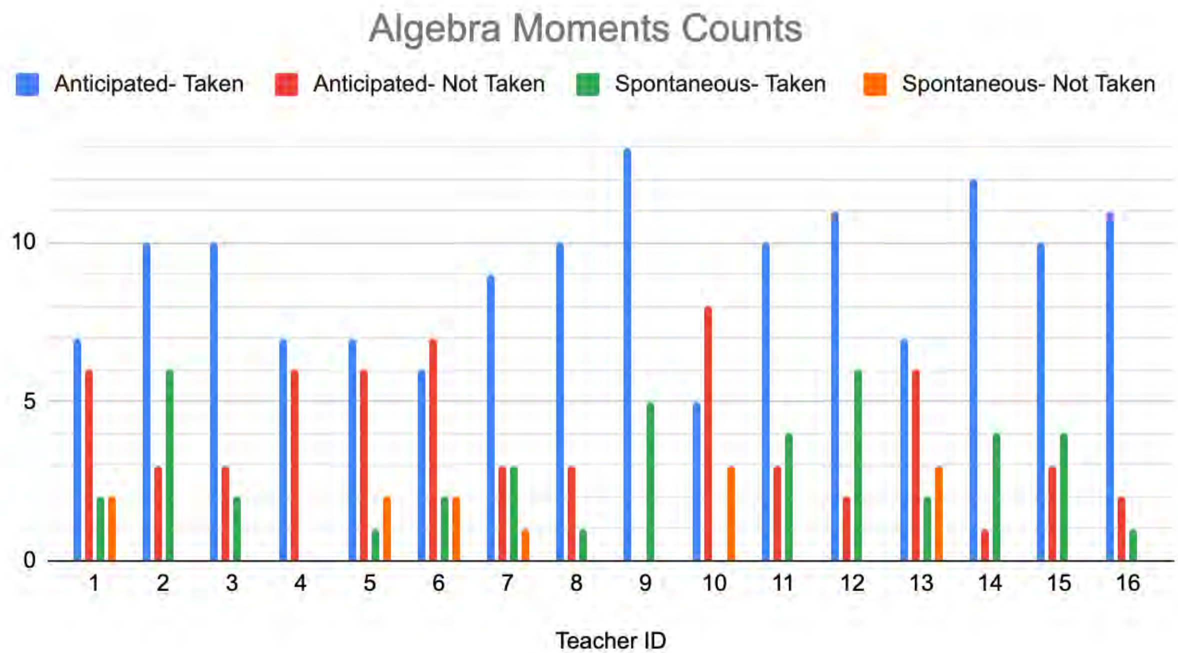

Figure 2: Counts of Anticipated and Spontaneous Moments, Missed and Taken, Across 16 teachers

Taking a closer look at the early algebra moments, we now present several excerpts to illustrate the variety of ways in which the teachers engaged with anticipated and spontaneous moments. The excerpts also serve to highlight qualitative differences in the nature of teachers' enactment around these algebra moments. The following excerpt is representative of teachers' enactment of the anticipated moment associated with describing an inequality that relates the grey rectangular area to the white rectangular area in Figure 1 (i.e., $10h > 20$).

Episode 1: Anticipated Moment, Taken Up, Teacher 11

A student stands at the front of the classroom after writing "$10 \cdot h > 10 \cdot 2$" on the white board.

Teacher: Alright, tell us what you wrote.

Student: Ten times h is greater than 10 times 2.

Teacher: (*to the class*) Does everybody see how that is correct? If you look on your picture, you see that the area of the grey rectangle is larger than the white one. Does that make sense?

Of the 16 observed classrooms, every teacher addressed this anticipated moment. However, we also identified a number of spontaneous moments that arose as students engaged with this task. The following spontaneous moment example occurred when a teacher took up her students' claims that h could represent different values, which would then result in different inequalities.

Although one might expect this to be part of the lesson, the lesson as intended did not suggest that teachers address this point.

Episode 2: Spontaneous Moment, Taken Up, Teacher 2

Teacher	I hear some people…some really good conversations. Leah, can you finish what you were saying about the areas of the white and the grey?
Leah	So, we said that the white part represents the 10×2 …equals 20. And we think that one is greater because …Well, you don't know what *h* represents.
Teacher	Absolutely. Can I get some agreement, disagreement? Maybe someone who agrees that the white (area) is greater? Someone who disagrees, okay? What do you say Aliyah and Sydney?
Aliyah	We agree because 10 times 2 is 20, and 10 times *h* is…um, unknown.
Other students	Wait!…(*inaudible classroom discussion*)
Teacher	All right so 20 is greater than… we don't know (*teacher writes "$20 > 10\times h$" on the board*). Charlene?
Charlene	I kinda agree but I kinda disagree because we don't know what $10 \times h$ is …we don't know what *h* is— maybe it's a 100, but maybe it's 15, so it could go both ways. We don't really know which one is bigger.
Eric	*h* can be any number. It's a variable.
Unknown student	But you don't have *h* right now!
Teacher	Okay. Vincent, what are you thinking?
Vincent	Because in the graph (*picture, Figure 1*) the *h* is more bigger than the 2.
Teacher	In this specific picture? The *h* is bigger than the 2? (*gesturing to a projected Figure 1)* …Based on the picture, we could make an assumption…so then $20 < 10h$?
Unknown student	Well, you didn't say that— you didn't say "based on the picture".
Teacher	Right, right… Well, what number could *h* be that would make it smaller than 20?
Students	(*overlapping talk*) One… Zero!
Teacher	So, if it's zero, it (*gesturing to* $10 \times h$ *in "$20 > 10\times h$"*) would be zero.
Unknown student	Also, one.
Teacher	Yep, I heard a couple of people say "one". If it's one, then it would be 10.
Leah	So, which is right?

Unknown student	We don't know yet.
Teacher	I think it's really cool— it depends on your argument.

In this excerpt, the teacher skillfully takes up a student's claim that relies on the meaning of a variable as an unspecified quantity. The teacher revoiced the claim to the whole class and solicited the reasoning of others. A lively class-wide discussion ensues with students engaged collaboratively as they made and justified other claims using algebraic reasoning about the cases of the variable. The teacher noticed and made productive improvisational decisions to elicit student thinking about an important algebraic idea (i.e., that value of the variable, in this case h, is unknown).

A commonly taken up spontaneous moment that surfaced across the observations during the main activity as well as during the concluding summary activity of the lesson involved the use of substitution to evaluate the equality between two expressions (not suggested as potential student approach in the teacher-facing lesson materials). In the former case, students suggested substituting $h = 8$ into $10(h + 2)$ and $10h + 20$ to determine if the two ways to express the area of the larger rectangle were equivalent. While in the latter case, students' explanations regarding the difference in the areas between two rectangles, one with area $7h$ and the other with area $4h$, involved substituting a numerical value into the equation $7h – 3h = 4h$ to evaluate the truth value of the equation. In both cases, the teachers took up students' suggestions by either performing the substitution on the board or having a student perform and evaluate the substitution.

There were also a significant proportion (23%) of spontaneous early algebra moments (as identified by the research team) that were not taken up by teachers. For example, several teachers did not take up opportunities to engage students in discussion about their desire to assign a specific value to the variable h before an expression for the total area of the two rectangular areas could be determined. In one teacher's classroom, several students expressed a need to physically measure with a ruler or an improvised ruler (e.g., repeated measurement with the width of their finger, tick marks on a paper) to determine a numeric value for h. One student, using a pencil as a ruler, insisted that the length of h was half of 10 (based on the figure itself) and thus thought that $h = 5$. The teacher's response was "okay, then plug that in for your h". Here the teacher did not address the meaning associated with using a variable in the area expression, and the lesson materials did not anticipate that students might express the need to assign a specific value to h in order to write an expression for the areas of the rectangles.

Discussion

Algebra moments that surface in the implementation of early algebra lessons that the research team anticipated, indeed occurred, and were addressed by the majority of teachers (not a surprising result if teachers simply followed the lesson). Similarly, those spontaneous algebra moments that the research team did not anticipate, were also addressed by the majority of teachers. These latter findings are both somewhat surprising given often negative characterizations of elementary school teachers' mathematics knowledge, and promising with respect to teachers' abilities to engage their students with early algebra ideas and practices. In short, at least for these sixteen teachers, their early algebra "eyes and ears" were relatively well developed. Yet, for those early algebra moments not taken up—both anticipated and spontaneous—the current study offers little insight into why these moments were not taken up or missed. In some cases, there may certainly be reasonable professional explanations supporting a teacher's decision to not take up a moment including practical limitations such as time and classroom interruptions. In other cases, it may be that the moment was indeed missed, that is, a teacher did not notice the opportunity as it arose during the course of instruction—cases that speak to the need for professional development if teachers are expected to meaningfully engage their students in early algebra.

There are also important characteristics of algebraic moments that, although not reported on here, are a part of our ongoing study, namely, the quality of teachers' instructional practice around early algebra moments. It is clear as we view the lesson observations that not every algebra moment is addressed in exactly the same way, and that there are differences in the ways in which teachers address these moments as well as in what students may learn as a result. For example, the warm up for this lesson prompted students to create a coordinate graph to represent the relationship between two co-varying quantities—one which was increasing at a rate twice that of the other quantity. One teacher facilitated a classroom discussion with her students in which they first predicted what such a graphical representation would look like prior to students generating graphs themselves, and then shared and compared the student-generated graphs. In contrast, another teacher led a teacher-centered episode in which she generated a table of the two co-varying quantities for students to copy, and subsequently led the creation of the coordinate graphical representation of the relationship with little to no student input.

Conclusion

In this paper we introduced the idea of early algebra moments, both those moments that arise as anticipated from an examination of a lesson and those moments that arise spontaneously in the course of instruction. By examining the same lesson implemented by sixteen teachers, we are able to see the variety of ways in which teachers engage with these moments (or, in some cases, do not engage), highlighting not only the diversity of approaches, but also the quality of instruction around these moments. Given the space constraints, we primarily focused on illustrating several examples of anticipated and spontaneous moments, These results offer promise with respect to teachers' implementation of early algebra in the elementary classroom as well as highlight the need to support teachers' efforts to develop their early algebra eyes and ears. Moreover, the results offer insights for understanding how the early algebra curricular materials support teachers in anticipating students' algebraic thinking and how teachers' spontaneous responses to moments can further students algebraic thinking. By studying and spotlighting teachers' facilitation of these moments we hope to amplify high quality teaching of early algebra. Additionally, understanding algebraic moments that were not taken up in classrooms could serve to hone professional development around noticing and attending to students' algebraic thinking.

Understanding how young learners come to construct viable mathematical arguments about general claims is a critical objective in early algebra research. The study reported here characterizes empirically developed progressions in Grades K–1 students' thinking about arguments concerning sums of evens and odds. Data are drawn from classroom lessons of an early algebra instructional sequence and interviews conducted at four timepoints during the implementation of the sequence. Overall, students transitioned from unfamiliarity with the concepts of even or odd prior to instruction in Kindergarten to making valid parity arguments at the conclusion of instruction in Grade 1. Results of this study align with other research that shows young learners can develop viable arguments to justify mathematical generalizations.

Keywords: Reasoning and proof; algebra and algebraic thinking; learning trajectories and progressions; early childhood education

Purpose of the Study

Research increasingly supports that engaging in proving in developmentally appropriate ways in the elementary grades can deepen students' conceptual understanding of mathematics as a sense-making activity (Carpenter et al., 2003; Stylianides & Ball, 2008; Van Ness & Maher, 2019). Moreover, when elementary students are supported through instruction, they can learn to use deductive—rather than empirical—reasoning to build mathematical arguments (Stylianides & Stylianides, 2008). However, intervention studies are needed to develop a "fine-grained conceptualization" (Stylianides, 2007b, p. 18) of appropriate forms of proving in early grades and to understand how curriculum can support students' construction of viable arguments.

The study reported here responds to this call by identifying learning progressions (Clements & Sarama, 2004) in how children construct mathematical arguments as they are taught an early algebra instructional sequence in Kindergarten (hereafter, Grade K) and Grade 1. The study focuses on the following question: *What levels of thinking do Grades K–1 students exhibit in their understanding of arguments about sums of evens and odds as they advance through an early algebra instructional sequence?*

Perspective

The study reported here is part of a suite of projects in which we use a learning progressions approach (Clements & Sarama, 2004) to build an effective early algebra intervention across Grades K–5 and to identify progressions in students' thinking as they advance through the instructional sequence that forms the intervention. We organize early algebra around the practices of generalizing, representing, justifying, and reasoning with mathematical structure and relationships (Blanton et al., 2018). The focus on children's mathematical arguments here is a natural part of our early algebra research. In particular, in this study we are interested in justifying as a practice of building arguments for claims about general relationships, which can elevate the role of argumentation in the elementary grades.

Methods

Our research design involved the use of classroom teaching experiments (CTEs) with individual interviews (Cobb & Steffe, 1983) to identify progressions in children's thinking. Because CTEs incorporate instructional design with the ongoing analysis of classroom data, they serve as an important mechanism for developing empirically based conjectures about progressions in thinking as students advance through an instructional sequence (Clements et al., 2007; Lesh & Lehrer, 2000).

The K–1 early algebra instructional sequence in the study reported here consisted of eighteen 30-minute lessons for each grade. A subset of lessons within the instructional sequence (3 in Grade K, 2 in Grade 1) addressed the development of parity arguments. Lessons initially focused on preliminary concepts such as "pair," "even number," and "odd number," then transitioned to the development of representation-based arguments (Schifter, 2009) about the parity of the sum of two even numbers, two odd numbers, and then an even and an odd number. Additional lessons (8 in Grade K, 3 in Grade 1) reviewed parity concepts in lesson warm-ups.

Participants

Two Grade K classrooms (Year 1) and two Grade 1 classrooms (Year 2) in one school in the Northeastern US participated in the study. Effort was made to keep the initial Grade K cohort intact in Grade 1. Table 1 shows the number of participants by grade level. The school district's demographics consisted of 10% students of color and 16% students categorized as low SES.

Table 1. Participants by Grade Level

Grade	Total No. of Participants	Participated in Grade K only	Participated in Grade 1 only	Participated in Grades K–1
K	48	22		26
1	48		22	26

Data Collection

Grade-level early algebra lessons were taught approximately once per week during each school year by a member of the research team. All lessons were videotaped, and lessons or portions of lessons (e.g., lesson warm-ups) related to even and odd concepts were identified for analysis. A subset of students was selected at each grade for semi-structured, 30-minute, individual pre/post interviews. Classroom teachers helped identify students who fit a diverse academic range. An early math diagnostic assessment (EMDA™) was administered to students at the beginning of Grade K to further ensure academic diversity. In all, 17 students in Grades K–1 participated in video-taped interviews about parity concepts. Twenty-four full or partial classroom lessons and 40 interviews were analyzed.

Data Analysis

We used a grounded theory approach (Strauss & Corbin, 1990) that focused on the identification of progressions in students' thinking around the concepts of pair, parity of numbers, and arguments about parity of sums. Interview data were analyzed independently by three team members to identify preliminary codes (levels of thinking) for our core concepts. Theoretical memos (Glaser, 1998) were constructed to provide supporting evidence for the codes, or levels. Agreement among coders was determined by comparing coding decisions and negotiating any discrepancies around early codes/levels. New codes were identified as warranted and data were re-analyzed until subsequent coding did not change our emerging models. Video of classroom data were then analyzed for confirming or disconfirming evidence of emerging codes (levels). The levels-as-coding schemes were then organized based on our empirical findings vis-à-vis canonical understandings of the mathematics attempted (Battista, 2004).

Results

In Table 2, we report our findings on levels in students' thinking about the most complex interview task—parity arguments about the sum of arbitrary even and/or odd numbers. We then share some observations from our study.

Table 2. Parity Arguments for the Sum of Two Arbitrary Even/Odd Numbers

	Non-Structural Reasoning	
Level 1 *Empirical*	Students suggest a strategy that uses or implies the use of testing cases to determine parity for an arbitrary sum.	Student provides an argument based on empirical experience (counting): "If you add even and odd it's usually even because every time I count that, it's usually even. One time it wasn't."
	Structural Reasoning	
Level 2 *Generic Number*	Students use a pairs strategy applied to generic numbers to reason about parity of the sum. A pairs strategy involved finding if a number represented through cubes (for example) could be separated into pairs without a cube left over.	When asked if the sum of "a really big odd number" and a "really big even number" is even or odd, a student gave the following response: "Odd, because let's say you did it with [12 and 15]. Fifteen has a leftover and 12 doesn't have a leftover, so it can't combine." He indicates that by "can't combine" he means there would still be a leftover.
Level 3 *Arbitrary Number*	Without referencing any numbers, students use a pairs strategy to reason about parity of the sum.	When asked to explain why any even plus any odd is odd, a student argues, "Because an odd number has a leftover and an even number doesn't have a leftover and if you combine an odd number with an even number, it equals an odd number," confirming that there would still be a leftover.

There are important similarities between the levels of thinking students exhibited and taxonomies reported elsewhere. Empirical reasoning (Level 1), by which students examined randomly chosen cases to establish a conjecture's truth, reflects *naïve empiricism* (Balacheff, 1988) or an *empirical (inductive) proof scheme* (Harel & Sowder, 2007). In the example provided, the student reflects on prior experiences in "counting" (adding) particular even and odd numbers as the basis of her argument. Schifter (2009) similarly characterizes this type of argument as *inference from instances* in her analysis of Grade 3 students' parity arguments. We see Level 2 as consistent with the notion of *generic example* (Balacheff, 1988) or *deductive (transformational) proof scheme* (Harel & Sowder, 1998) because of the use of a specific number as a generic placeholder for a general number in students' arguments. Schifter (2009) refers to this form of argument as *reasoning from representation or story context*. Finally, Level

3 reflects the construct of *thought experiment* (Balacheff, 1988), where actions are dissociated from specific examples. With young children, these actions are based on "the language of the everyday (Balacheff, 1988, p. 228)" and not the transformation of formal symbolic expressions. Level 3 thinking seems to also reflect the emergence of *structure in thought* (Harel & Soto, 2017) in that students were able to present a sequence of arguments without the need to manipulate physical, visual, or symbolic representations. Our work extends that reported elsewhere in that our focus is on the genesis of these ideas at the start of formal schooling (Grades K–1). Identifying similarities in students' thinking across K–16 grade domains can help us better understand how to structure curriculum that connects and builds ideas over time.

We found students' ability to develop representation-based parity arguments (rather than empirical arguments) to be surprisingly robust. For example, at pre-interview Grade K students were unfamiliar with the concepts of pair and even and odd numbers, but by Grade K post-interview all students were able to define even and odd using a pairs strategy and many students routinely used a pairs strategy to reason about the parity of numbers represented in concrete, visual, and abstract forms. Moreover, although Grade K students were not asked to build representation-based parity arguments at pre-interview (given that they were unfamiliar with the concepts "even" and "odd"), by Grade 1 pre-interview no students used an empirical argument to justify why the sum of an even and an odd would be odd. Six out of 10 students were able to correctly use a structural argument involving a pairs strategy (three students could not build either type of argument; one student was not asked this question).

Although these students were capable of producing structural arguments (Levels 2–3), we do not claim that they yet appreciated the power of the generality of their arguments, nor did they yet understand the logical proof structure underlying their arguments. In truth, older students struggle with this as well (Stylianou et al., 2015). At this early, pre-symbolic point in their understanding, students' thinking was more intuitive than anticipatory or intentional. However, a goal of early algebra is to help students build on these intuitive ways of thinking so that their understanding can deepen over time. For young children to engage in Level 3 thinking, even in informal, non-symbolic ways, is a critical starting point.

Conclusion

The *Common Core State Standards* (NGA Center & CCSSO, 2010) maintains that elementary students should be able to "construct viable arguments and critique the reasoning of others." There is a vital need, however, for research-based, curricular pathways by which this goal can be met (Bieda et al., 2014), as well as studies that detail how young learners' argumentation progresses as they advance through such pathways (Stylianides, 2007a). The study reported here is intended to help address this by characterizing the emergence of students' understanding of viable parity arguments from an early algebra instructional sequence Understanding how young leaners develop robust ways of thinking and arguing mathematically can not only help avoid situations where students develop "a conception of proof in the elementary school that has to be undone or unlearned in high school (p. 4, Stylianides, 2007b)," but can also help realize the ambitious learning standards advocated in current reforms.

AN EXPLORATION OF HOW COLLEGE STUDENTS THINK ABOUT PARENTHESES IN THE CONTEXT OF ALGEBRAIC SYNTAX

Claire Wladis

In this paper we explore how college students across different courses appeared to interpret the meaning of parentheses or brackets in the context of algebraic syntax. This work was influenced by theories of computational vs structural thinking, and also considered the extent to which students' definitions, computational work, and explanations appeared to be consistent with specific normative definitions of parentheses. In analyzing student work, several categories of students' conceptions emerged, which may be helpful in diagnosing which conceptions may be more productive or problematic as students progress through algebra. For students who appear to conceptualize parentheses as a cue to non-normative procedures, several categories of procedures were found, which could have implications for instruction.

Keywords: algebra and algebraic thinking; cognition

Parentheses, or brackets, play a critical role in symbolic mathematics. However, how students think about parentheses in various mathematical contexts is significantly understudied. While some studies examine how parentheses may or may not cue the correct order of operations during arithmetic tasks in primary school or whether adding extra parentheses helps students to better "see" algebraic structure (e.g., Gunnarsson et al., 2016), there appears to be no systematic research which explores which kinds of meanings students have for brackets or parentheses, particularly in a wider array of content domains which include substantial symbolic algebra. In this paper we aim to address this gap. Though extensive data collection with college students in a wide range of classes, we explore students' meanings for parentheses and generate several common categories of conceptions which students may hold.

Literature Review

Research into student's use of parentheses in algebra has been limited, and what does exist has focused primarily on what students do with parentheses when calculating rather than how students conceptualize parentheses. In the context of structure sense, Hoch and Dreyfus (2004) found that secondary students tend to use structural approaches to solve algebraic equations more when an equation uses more parentheses than when less parentheses are present. In interviews, students' use of parentheses were mixed, where some students approached problems by first 'opening' parentheses, while others preferred maintaining parentheses, finding the symbol helpful and saying "with parentheses, it's easier to see" (p.3-54). Similar findings have been reported with middle school students as well (e.g., Linchevski & Livneh, 1999), where some students at times operated on parentheses within expressions as if they are not present (Gunnarsson et al., 2016), while others operated in markedly different ways when working with expressions within parentheses (Banerjee & Subramaniam, 2005). Given that the presence of parentheses may change one's view of a mathematical expression, we think it is worthwhile to explore students' meanings of parentheses.

Theoretical Framework

Tall and Vinner (1981) describe an individual's understanding of a concept in terms of their concept image, or the "total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (p. 152). Within this structure, they describe one's *personal* concept definition as the "form of words that a learner uses for [their] own explanation of [their] (evoked) concept image" (p. 152). One's personal concept definition is idiosyncratic to the learner, and is contrasted with the *formal* concept definition, which is "a concept definition which is accepted by the mathematical community at large" (p.152). In the examples that follow, when we refer to a student's definition, we are referring to their personal concept definition, although our model is a second order model, as we do not have direct access to student's personal concept images or definitions.

In the context of this paper, we consider the role that parentheses play in the syntax of algebraic expressions and equations in which the symbols are used to indicate an operation which is prioritized over other adjacent operations; we call this the ***grouping role*** of parentheses. This role of parentheses is pervasive throughout symbolic representations across domains, but we focus on algebra examples in this paper. We note that this grouping role is distinct from other roles which parentheses may play, such as denoting intervals, ordered pairs, sets, etc.

Students may conceptualize parentheses from either a computational or a structural view, just as they may conceptualize algebraic syntax more generally as computational[1] or structural (Sfard, 1995). In a ***computational view***, students conceptualize parentheses as cuing a particular calculation or procedure, which may be normative or non-normative. In a ***structural view***, students conceptualize parentheses as demarcating a particular unified sub-expression which can be treated as an object in and of itself. For example, a student with a computational view may normatively "see" the expression $2(5+3)$ as indicating that one should first add $5+3$ and then multiply 2 by the result. A student with a structural view is able to "see" this also as 2 times whatever the result of $5+3$ might be, without actually performing the addition of $5+3$ and replacing it with the single number 8 first; instead the substring $(5+3)$ can be seen as an object itself. In an arithmetic example such as this one, the structural view appears less important, but in an algebraic expression like $2(x+3)$, the affordances of a structural view suddenly becomes more apparent and, at times, necessary, for example, for many cases of u-substitution in upper level classes where one must have a structural view of certain substrings as objects.

Edwards and Ward (2004) distinguished between two sorts of definitions: those that are created through experiences with the term (an *extracted* definition), and those that are expressed in an explicit well-defined way (a *stipulated* definition). When students have a computational view of parentheses, this may be stipulated and normative or non-normative (which may have been extracted from their experiences with common types of tasks in which parentheses occur, rather than taken from stipulated normative definitions). For some students, parentheses may only cue the normative set of procedures stipulated by the order of operations, while for others, parentheses may cue a particular procedure, regardless of whether that procedure is appropriate (e.g., taking whatever is outside the parentheses and multiplying it by each "thing" inside the parentheses, even when the structure of the algebraic expression with which they are working is not in line with the distributive property). We summarize this in the Figure 1, where we see learners' conceptions varying along a continuum, where conceptions to the right are more generalizable and transferable to a wider range of problems than those to the left. We note that an individual's conceptions of parentheses are not fixed and can further vary back and forth along

1 Sfard (1995) refers to 'operational' views, but we use the term computational here.

this continuum, even within a single problem.

Extracted computational view: Learners conceptualize brackets as a cue to a procedure, but that procedure is not consistent in all contexts with the stipulated order of operations and other symbolic conventions (e.g., to multiply regardless of actual operations).	Stipulated normative computational view: Learners are able to conceptualize brackets as a cue to follow the stipulated order of operations (i.e., simplify what is inside the innermost brackets first).	Structural view: Learners are able to conceptualize brackets as demarcating a unified sub-expression within a larger expression or equation, which can be thought of as an object in and of itself. This may be the reification of the process of the stipulated order of operations.

Figure 1: Types of Conceptions of Parentheses

Methods

Data for this study includes students' written responses to open-ended questions and transcripts from stimulated recall interviews about similar multiple-choice questions. Open-ended responses were collected from 124 students at an urban community college in 18 different courses, from developmental elementary algebra (similar to Algebra I in high school) to linear algebra. Open-ended questions were about what parentheses means to the students (both in and out of context), as well as algebra problems where students were asked to simplify expressions that included parentheses. Students' open-ended responses were analyzed using thematic analysis (Braun & Clarke, 2006). This analysis was influenced by an initial theoretical stance which was particularly attuned to noticing similarities in patterns of students' responses with theory on extracted and stipulated definitions (Edwards & Ward, 2004) and computational and structural (Sfard, 1995) conceptions. Analysis of students' work led to a more nuanced emergent coding scheme of students' responses for definitions of parentheses. We select students' work to illustrate the resulting coding scheme in this work and draw on interview transcripts to further expound on these patterns.

Results

In this section we present several vignettes to illustrate the different ways in which students appeared to be conceptualizing parentheses in the context of algebra expressions and equations. We note that categorizations of student work here are second order models: we cannot actually know what a student is thinking—we only categorize what they conveyed through their work.

Different non-normative computational conceptions of parentheses

It was common for parentheses to cue various non-normative procedures, though they tended to fall mostly into one of three categories: "Multiplication", "do first", and "ease of reading".

"Multiplication" conception of parentheses. The most common response among students at all levels when asked what parentheses mean in mathematics was "multiplication". We note that technically parentheses do not indicate multiplication; they simply co-occur often with concatenation, which actually indicates multiplication. However, during data collection in both interviews and open-ended questions, we found that students rarely recognized this distinction. This may be an extracted definition taken from their many experiences with tasks in which parentheses and multiplication co-occur, or it may even sometimes be inaccurately stipulated by instructors (we have observed instructors in classrooms using phrases like "parentheses mean to multiply"). So while not technically mathematically normative, this view can be a very rational reaction to existing instructional practices. However, this conception may lead to incorrect computational results when the operation next to the parentheses is not multiplication, as well as a fundamental misunderstanding of the role that parentheses are intended to play in algebraic expressions and equations. Consider, for example, the work from Alpha (see Figure 2) who was enrolled in an elementary algebra course (a non-credit course similar in content to Algebra I).

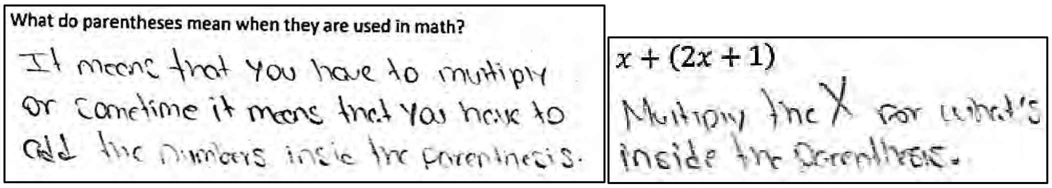

Figure 2. Alpha's Parentheses Definition and Evoked Interpretation in Computation

Alpha's definition of parentheses (Figure 2, left) shows two meanings. Firstly, they tell us that parentheses tell us to multiply; but they also say that parentheses tell us that we have to add the numbers inside the parentheses, which we understand to be a kind of "do first" interpretation of parentheses (see next section). Alpha further provides an example of how the interpretation of parentheses as multiplication can be problematic during computation on the right in Figure 2, where they multiply even though addition is the operation between x and $(2x + 1)$.

"Do first" conception of parentheses. The second meaning Alpha's definition (Figure 2, left) may be referring to is a potentially normative definition of parentheses-- it is not completely clear from their wording, but they may be referring to the precedence of parentheses in the order of operations. We describe this thinking more in the next section, but focus now on some ways in which students applied this definition non-normatively. We begin by considering the work of a student whom we will call Gamma, who was enrolled in a course for students training to be elementary school teachers (prerequisites for this course include elementary and intermediate algebra, but not precalculus). In this excerpt, Gamma is attempting to simplify $3 - 2 \cdot (8 - 3^2)$.

> So, I try in my head, so they break it down, PEMDAS, so parentheses first, so I did like eight minus three is five and I know that's going to leave me with five squared. So, I just left that as it is and looked over here and seen what has five to the second exponent. And realized, you know, okay that's the same because that would be my next step is to solve the parentheses…. Because PEMDAS I solved what's in the parentheses first and then looked at the exponents and then that's pretty much how I saw it.

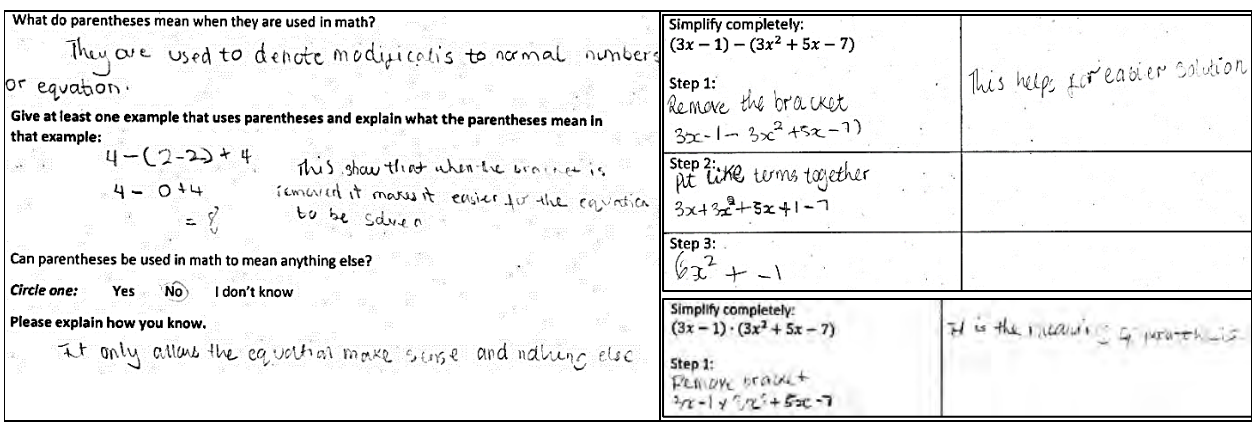
Gamma appears to be thinking of the parentheses as something which cues work inside them to be done first, and because exponents come after parentheses, they do $8 - 3$ first. We classify this as an extracted view, because their notion of "doing the parentheses first" is cuing an incorrect extracted definition of the order of operations, in which things inside the parentheses are combined together in order to "get rid of" the parentheses before doing the exponent that is inside the parentheses itself. Here Gamma appears to be interpreting the parentheses as a cue to a particular (incorrect) computational action.

In other work, Gamma is able to use this conception of parentheses to simplify an algebraic expression correctly, although they still use a computational approach. In the next excerpt, they were asked about what was being multiplied by 2 in the expression $2 \cdot (3x - 5)$. We note that even though the question was intended to prompt an object approach (by thinking of $(3x - 5)$ as the object being multiplied by 2), Gamma still gives a computational explanation focused on "solving", even though that is not what has been asked.

When I think of parentheses it's something that has to be done first. In this particular problem, I feel like you have to distribute because you have x there. So, it's like you can't solve $3x$ minus five. I don't think you could just like get an answer from that. You have to solve what's inside of the parentheses. So, what's in the parentheses is $3x$ minus five. So, in order for me to solve that I must distribute the two that's outside into that equation. I just think of PEMDAS, you have got to do parentheses first, and then exponents, and down the line. So, I just look at a question, I know I have to do something with the parentheses first.

Gamma's notion of parentheses here appears to be a "do first" conception—they appear to be correctly connecting their notion of the meaning of the parentheses to the stipulated order of operations. However, it is not completely clear whether this "do first" notion is fully well-defined and in line with stipulated definitions. Would Gamma distribute in other problems inappropriately, for example if the two were an exponent of the parentheses instead of a coefficient? We cannot be sure since Gamma was not interviewed about such questions. During data collection, we saw many students who seemed to convey a "do first" definition of brackets/parentheses, but who performed computational work that violated the order of operations in some cases and not in others. This suggests that we may want to be more attentive to how students interpret the "do first" conceptualization of parentheses as they move from arithmetic expressions (in which what is inside the parentheses can be simplified) to algebra (where what is inside the parentheses may not be able to be simplified).

"Ease of reading" conception of parentheses. Now we consider some examples in which students appear to have interpreted parentheses as unnecessary symbols which can be removed; sometimes they justify this by explaining that parentheses are just there to make expressions or equations "easier to read". We note that this is related to the "bracket ignoring" procedure identified by Gunnarsson, et al. (2016) with middle school students. First we consider work from an elementary algebra student whom we call Tau (Figure 3).



What do parentheses mean when they are used in math?

They are used to denote modificatis to normal numbers or equation.

Give at least one example that uses parentheses and explain what the parentheses mean in that example:

$4-(2-2)+4$
$4-0+4$
$=8$

This show that when the bracket is removed it makes it easier for the equation to be solved

Can parentheses be used in math to mean anything else?

Circle one: Yes No I don't know

Please explain how you know.

It only allows the equation make sense and nothing else

Simplify completely:
$(3x-1)-(3x^2+5x-7)$

Step 1:
Remove the bracket
$3x-1-3x^2+5x-7)$

This helps for easier solution

Step 2:
Put like terms together
$3x+3x^2+5x+1-7$

Step 3:
$6x^2+-1$

Simplify completely:
$(3x-1)\cdot(3x^2+5x-7)$

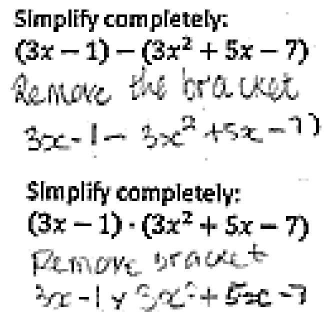
Step 1:
Remove bracket
$3x-1 \times 3x^2+5x-7$

It is the meaning of parenthesis

Figure 3. Tau's Definition of Parentheses and Computational work

Tau appears to conceptualize parentheses as something that makes it "easier for the equation to be solved" or "allows the equation to make sense". It is not entirely clear what they mean in this case—for example, in the arithmetic example that they give in Figure 3, their calculations appear to be correct. They "remove" the parentheses in that case by simplifying what is inside them first. However, this seems not to generalize in the same way to algebra cases. When we look at how they dealt with parentheses in practice when solving standard algebra tasks, we see that their first step was often to remove the parentheses before proceeding (see right of Figure 3), similarly to erasing the parenthetical symbols. Tau even justify their work by writing "Remove the bracket. This helps with easier solution" and "Remove bracket…It is the meaning of parentheses." We suspect that Tau has extracted from their prior mathematical experiences that it is desirable to find valid mathematical ways to "get rid of the bracket", this process involves simply removing the bracket, and parentheses are superfluous.

This may also be related to the "do first" conception of parentheses, as students may feel that they must remove the parentheses in order to do any computation with what is inside. Some students may remove the parentheses using a valid transformation (e.g., the distributive property, or expanding multiplication of two polynomials) and other students may remove the parentheses using an invalid transformation, like Tau. This approach was not limited only to elementary algebra students. In Figure 4, we see similar work from a Calculus I student, Zeta.



Simplify completely:
$(3x-1)-(3x^2+5x-7)$
Remove the bracket
$3x-1-3x^2+5x-7)$
Simplify completely:
$(3x-1)\cdot(3x^2+5x-7)$
Remove bracket
$3x-1 \times 3x^2+5x-7$

Figure 4. Zeta's Work in which They Remove Parentheses Arbitrarily

Combinations of different extracted and stipulated computational views.

So far we have seen some examples of different types of non-normative extracted conceptions of parentheses, but there were also students who showed a mix of normative and non-normative meanings for parentheses. One such example comes from a student, Epsilon, enrolled in the second semester of a one-year math course for future elementary school teachers (the prerequisites for the first semester of the course were elementary and intermediate algebra, but not precalculus). In an interview, Epsilon was asked which part was being subtracted, or taken away, in the expression $3x^2 - 2(x^2 + 1)$:

Interviewer:	What do the parentheses mean here in this expression?
Epsilon:	Multiplication.
Interviewer:	Do you know what the order of operations is?
Epsilon:	PEMDAS.
Interviewer:	How does the order of operations help you to understand what is being subtracted in this expression?
Epsilon:	So first, you have to deal with the parentheses. So, then that means that everything with the parentheses is like together in a box.

Epsilon, like many students, thinks of multiplication first when they are asked what parentheses mean. When asked directly about how the order of operations relates to what they are doing in the problem, they exhibit the "do first" notion of parentheses (we can't tell from this context whether it is normative or not), pointing out that "first, you have to deal with the parentheses". But they immediately follow that up with a structural grouping interpretation of parentheses, saying "that everything with the parentheses is like together in a box". It is unclear to us how Epsilon is interpreting parentheses to mean multiplication here, but when they cite a "do first" conception of parentheses they immediately link it to a grouping conception, where the "do first" conception is a justification ("then that means") for the grouping conception. While we cannot be certain, we suspect that Epsilon has reified the order-of-operations process into the grouping object, which would explain how their "do first" and grouping conceptions are linked.

Some students may use the language "parentheses mean multiplication", but then go on to only describe a correct alternative meaning, at least in the context of Algebra I course content; this may be a case in which they are incorrectly describing the meaning of the parentheses symbol, but are correctly performing computation with parentheses, so while logically incorrect, this imprecision of language may be less problematic in this case. For example, consider the next excerpt from Epsilon, in which they discuss their meanings of parentheses when asked whether $\sqrt{(3xy)^2}$ and $\left(\sqrt{3xy}\right)^2$ represent the same operations on the same things in the same order:

> [Parentheses] don't really mean like multiplication per say in this instance. So, in the first one the parentheses is the expression of $3xy$ to the second power. So, it's distributing the- Well, in both instance it's distributing the second power, but it's just where it's placed. I'm sorry, I don't know if I'm making any sense, but because of where the parentheses are placed it just changes the meaning.
>
> So, here [pointing to first expression] you have to deal with the parentheses first. So, in the first equation, you have to distribute the second power to the $3xy$ and then take the square root. And then in the second equation, you have to take the square root first of $3xy$ and then square it and those would result in different answers probably.

In this explanation, Epsilon says that parentheses mean multiplication, but then they say that this is not necessarily the correct interpretation in this case. Here instead they treat the parentheses as a cue to distribute the exponent. Their work is correct, but it is unclear if this notion of parentheses cuing distributing might lead them to distribute the exponent inappropriately in other cases (e.g., if instead of $3xy$ in the parentheses, there were a multi-term expression). As with Gamma, we had no questions on the set of questions on which Epsilon was interviewed which would allow us to see if Epsilon might distribute incorrectly in other cases. So while Epsilon's work here appears to be based on stipulated definitions, and on the surface appears to be less extracted and less problematic than Alpha's multiplication conception in terms of how it may impact their computational work, we cannot be sure whether it is actually completely grounded in standard stipulated definitions or whether their approach here might prove more problematic on other questions. Compared to Alpha, Epsilon at least recognizes that parentheses do not always "mean" multiplication, and therefore Epsilon may be more receptive to rethinking their initial statement that parentheses themselves "mean" multiplication. However, more detailed analysis of Epsilon's thinking is necessary if we are to understand whether it aligns with normative meanings for parentheses and is just being expressed in an ill-defined way, or if it actually conflicts with normative meanings.

We note also that Epsilon's explanations in this excerpt are entirely computational: e.g., they describe the process of "distributing" the square to $3xy$. This is a common pattern where students appear to rely on the notion of distributing rather than thinking of the whole $3xy$ as a single object being squared. There is not necessarily anything wrong with the way that Epsilon has explained this; however, being able to conceptualize $(3xy)$ as an object itself might be essential in other contexts, so it might be important to further assess the extent to which Epsilon is able to do this when needed. For example, we note that Epsilon struggles to explain their thinking here; it is possible that if they were able to describe this using a structural view (e.g., "in the first expression only $3xy$ is being squared, but in the second expression $\sqrt{3xy}$ is being squared"), it might be easier for them to provide a justification for their thinking.

Grouping view of parentheses

We now consider one more example in which a student appears to be conceptualizing parentheses structurally as a grouping mechanism. The following excerpt is a Calculus I student Theta's response after being asked what the result would be of substituting $2y$ in for x into the expression $2x^2 - 7x + 3$.

> If you're putting something in for something else, I always usually keep parentheses around it to make sure that I maintain whatever structure the original function had... especially in this one [the first term] because x is being multiplied, and squared, the parentheses really make a difference because if we don't have them, we could get a different, the wrong answer…. you don't need [the parentheses in $-7(2y)$] as long as you make sure you multiply the -7 by 2.

Theta mentions structure explicitly and explains how removing the parentheses gives the expression a different syntactic meaning, which in the case of $2(2y)^2$ will result in a "different result" but in the case of $7(2y)$ will not yield a different result, seemingly because of the order of operations (although they do not use the word "order of operations" explicitly). Theta's explanation shows how they appear to have linked their structural view of the parentheses to their conception of the order of operations, suggesting that it is a reification of this process.

Implications and Conclusion

This paper is an initial exploration of how students may conceptualize brackets and parentheses and adds to the literature by providing hypothetical models of what students may attribute to parentheses or brackets. We make no recommendations about how students should be taught about parentheses, however we think that these students' responses do suggest that they extract many non-normative meanings of parentheses in algebraic syntax and this may impact students' computational work. This suggests that it may be important for instructors and curricula writers to think carefully about whether their language or examples may be encouraging students to think of parentheses as "meaning multiplication", as an instruction to "do something" (where what should be done and why may be ill-defined or non-normative), or as something that is always superfluous. We suspect that simple phrases like "do the parentheses first" are being interpreted by students in a number of ways and may need to be articulated more clearly to students. It may be helpful to provide a variety of examples where parentheses are and are not extraneous to support students in coming to more normative understanding of the role that parentheses are intended to play in algebraic expressions and equations. In addition, it may be important for future research to explore in more detail how a learner comes to reify the normative "do first" view of parentheses into a grouping conception of parentheses, in which they are able to "see" the substring inside the parentheses as a unified subexpression. Thus, further research which explores the prevalence of these various views among different student groups as well as its relationship to computational work could help to improve instruction.

USES OF THE EQUAL SIGN AND EQUATION TYPES IN MIDDLE SCHOOL MATHEMATICS TEXTBOOKS

Daniel K. Siebert
Brigham Young University
dsiebert@mathed.byu.edu

Chelsea Dickson
Brigham Young University
chelsea.toler@gmail.com

Research suggests that students' difficulties in studying algebraic topics in middle school can be remedied at least in part by teaching students to use a relational meaning for the equal sign to reason about equations. However, little empirical research has been done to investigate what meanings for the equal sign and equation types are common in middle school mathematics. This study examines two series of 7th and 8th grade mathematics textbooks to identify what equal sign meanings and equation types are being used in middle school mathematics. Three meanings for the equal sign were used in all four textbooks, and each equation type was typically associated with only one meaning of the equal sign. The results imply that students need to develop three different meanings for the equal sign to succeed in middle school mathematics, and that recognizing equation types can help indicate which meaning of the equal sign is being used.

Keywords: Algebra and Algebraic Thinking, Middle School Education

One of the challenges that students face as they transition from elementary to middle school and begin studying topics in algebra is that they must learn to interpret the equal sign differently from its typical use in arithmetic. From an early age, children's predominant meaning for the equal sign is *operational*—they see the equal sign as an indicator that they should "do something" (Blanton et al., 2018; Kieran, 1981). Blanton et al. (2018) found that kindergarten students typically have this operational meaning for the equal sign even before they have received formal mathematics instruction. Furthermore, the kindergarteners in their study continued to use the operational meaning even after eight weeks of instruction designed to help them develop the relational meaning of the equal sign, namely that the equal sign indicates equivalence. Researchers have shown that the operational meaning for the equal sign persists through elementary school and is still prevalent among middle school students (Knuth et al., 2008; Knuth et al., 2005). Because the operational meaning leads to errors in reasoning about equations and other middle school topics (Kieran, 1981; Knuth et al., 2005; Matz, 1982), students' success in learning middle school mathematics is dependent upon them developing the relational meaning of the equal sign.

While the literature clearly demonstrates the importance of a relational meaning for the equal sign, research has been less clear concerning what constitutes a complete or expert understanding of the equal sign. Research on K-12 students' understanding of the equal sign suggests that students need to replace the operational meaning with the relational meaning (Blanton et al., 2018; Carpenter et al., 2003; Knuth et al., 2008), inadvertently implying that the relational meaning of the equal sign is sufficient by itself. In contrast, scholars who have studied or discussed advanced understandings of the equal sign do not treat the operational meaning pejoratively; rather, the operational and relational meanings are considered to be but two of the multiple, legitimate ways to interpret the equal sign (Jones & Pratt, 2011; Prediger, 2010). Seo and Ginsburg (2003) go as far as to note that when children read an equation in the form of $a + b = \square$ using an operational meaning, their interpretation is correct. Little empirical research exists regarding which of the multiple meanings of the equal sign are commonly used in middle school mathematics, where students begin to study algebraic topics in depth. Also, scholars have yet to examine how students know when to use which meanings. The purpose of this research study is to examine the meanings of the equal sign that are used in 7^{th} and 8^{th} grade mathematics textbooks to understand which meanings are commonly used and to examine the contexts in which they are used for characteristics that indicate which meaning of the equal sign is appropriate.

Background

Meanings for the Equal Sign

The research literature suggests that there are three unique meanings for the equal sign: operational, relational, and assignment. The *operational* meaning (Carpenter et al., 2003; Kieran, 1981; Prediger, 2010) is used to signify that an operation has been performed on one side of the equal sign (typically the left) and that the other side contains the result of that operation. For example, when the equal sign is given the operational meaning, the equation $2 + 4 = 6$ means that 4 was added to 2 and that 6 is the result of this addition. The *relational* meaning (Carpenter et al., 2003; Kieran, 1981; Prediger, 2010) indicates a claim that the expressions on either side of the equal sign are equivalent. For example, when the equal sign is given the relational meaning, the equation $2 + 4 = 6$ means that $2 + 4$ and 6 are equivalent, i.e., have the same numeric value. The *assignment* meaning (referred to as *specification* by Prediger, 2010) is used to assign a number or algebraic expression as the value or rule for a symbol or function. For example, when the equal sign is given the assignment meaning, the equation $r = 5$ is interpreted as indicating that r is assigned the value of 5 in equations or expressions containing r, such as the equation $P = 2\pi r$. Similarly, the equal sign in the equation $f(x) = x + 2$ is interpretated as f being assigned the rule, "add 2 to the input." Jones and Pratt (2011) have suggested a fourth meaning for the equal sign, namely *substitution*, which they define as indicating that the expression on one side of an equation can be replaced by the expression on the other side in other equations that contain the first expression. However, we interpret substitution as an equation operator, not a new meaning of the equal sign, and believe that both the relational and assignment meanings can indicate that substitution is a valid equation operation.

Research that has studied students' understanding of the equal sign has largely focused on the operational and relational meanings, often with the intent to explore how students can change their operational conception of the equal sign to a relational conceptualization (Blanton et al., 2018; Carpenter et al., 2003; Knuth et al., 2005). While we acknowledge the importance of helping students develop a relational meaning, we believe this research focus has caused scholars to overlook the crucial role that all three meanings play in secondary school mathematics. In particular, research is needed to understand how the three different meanings for the equal sign are used in middle school mathematics, where students are first required to regularly switch between meanings as they engage in algebraic activity. Equally important is research that identifies contextual clues that students can use to decipher which meanings of the equal sign are appropriate in different contexts.

Equation Types

Given that it is likely that multiple meanings of the equal sign are used in middle school mathematics, then it is important to understand the conditions under which each meaning should be used. These conditions likely involve the type of equation that is being used. Past researchers have sorted algebraic equations based on the quantities for which they are true and to what purposes the equations serve. Drawing across the literature, equations can be separated into three classes: tautologies, constraint equations, and specifications (Kieran, 1981; Matz, 1982; Prediger, 2010). *Tautologies* are equations that are true for large sets of numbers. They include transformations that show algebraic or arithmetic manipulations (e.g., $2(3x - 1) = 6x - 2$) and identities that illustrate properties of real numbers (e.g., $a + b = b + a$). *Constraint equations* are equations for which the expressions on each side of the equal sign are not equal for all numbers, such as $6x = 4x + 2$. *Specifications* are equations that are used to define the value of a variable or the rule for a function, such as $x = 3$ and $f(x) = -x + 7$.

The research on equation types is limited. Most of the research has focused on constraint equations, and researchers have found that many students erroneously use an operational meaning for the equal sign when first exposed to constraint equations (Knuth et al., 2008; Stephens et al., 2013). Students' understanding of tautologies and specifications have received little attention, and no empirical studies have examined which meanings of the equal sign are used when making sense of the various equation types. Research is also missing regarding which equation types are common in middle school mathematics.

To address the lack of empirical research on equal sign meanings and equation types in middle school mathematics, we conducted an analysis of two 7th and 8th grade mathematics textbook series to answer the following research questions:

1. Which meanings for the equal sign and equation types are used in middle grades mathematics textbooks?
2. Which meanings of the equal sign are used for each equation type in middle grades mathematics textbooks?

Method

Textbooks

Two curricula were chosen for this study: *Connected Mathematics 3* (CMP3, Lappan et al., 2014) and *Eureka Math* (2015). CMP3 is the most recent edition of a middle school mathematics curriculum created by mathematics education faculty at Michigan State University and funded by NSF. Eureka Math is a K-12 mathematics curriculum developed through collaboration between teachers and mathematics experts and is available for free through EngageNY.org. According to a recent Rand report (Opfer et al., 2016), both curricula are widely used; of teachers surveyed in states that have adopted the Common Core State Standards for Mathematics (CCSSM, NGA & CCSSO, 2010), 34% of the teachers reported using CMP3 and 34% reported using Eureka Math. Of the curricula surveyed in the report, Eureka Math was judged to be most closely aligned with the CCSSM, and CMP3 was judged to be the second most closely aligned. Both curricula take an integrated approach to mathematics topics and use a task-based instructional approach.

To sample the two different curricula, both teacher and student editions of grade 7 and 8 mathematics were considered. The student editions of these textbooks included only the in-class tasks for the instruction, brief summary sections about the mathematics targeted by the tasks, and problem sets for homework. In contrast, the teacher editions contained more detailed explanations of the mathematics being taught and solutions to the tasks, as well as all of the content included in the student edition. In order to explore a wide range of uses of the equal sign, we chose to analyze the sections in the grade 7 textbooks that were aligned with the CCSSM standards clusters *ratios and proportions* (7.RP), *expressions and equations* (7.EE), and *geometry* (7.G), and the sections in the grade 8 textbooks that were aligned with the standards clusters *expressions and equations* (8.EE), *functions* (8.F), and *geometry* (8.G). Homework problems were not considered in the analysis, as we anticipated that the types of uses of the equal sign that would appear in the homework problem sets would likely be well represented in the instructional parts of each topic section.

Analysis

We began our analysis by creating descriptions for a list of equation types and subtypes that we encountered in the literature. We then individually coded a few sections from both curricula, compared our coding, identified and resolved differences, and updated our codes and descriptions, sometimes adding new codes to our list or combining multiple codes into a single code. Each time we coded, we would first go through the materials and identify all the equations, and then go back and code each equation for meaning of the equal sign and equation type. We repeated this process of coding a small set of new material and comparing our codes multiple times, each time returning to previously coded data and updating our coding to reflect the most recent changes in our codes and descriptions. After 4 iterations, we reached a level of 93% interrater reliability with the Eureka curriculum. It took us 5 iterations to reach an 88% interrater reliability for the CMP3 curriculum. After achieving these high levels of interrater reliability, we continued to code separately and compare coding, analyzing approximately 90% of the data this way. The remaining 10% of the data was coded by the second author only.

We depended on our extensive experience in mathematics and our experiences using textbooks as students and teachers to make decisions about which meanings for the equal sign were being used. Some equations could be read with multiple meanings, but we coded only the meaning that best fit the context. For example, the equation $2(3x + 2) = 6x + 4$ that appeared in a problem solution (Eureka Math 8, Module 4, p. 45) could potentially be interpreted from both an operational and relational meaning. However, because the purpose of the equation was to find the result of distributing the 2 across the $3x$ and 2, and not to justify that $2(3x + 2)$ was equivalent to $6x + 4$, we coded this equation as operational. We found that each equation from the data could be coded as a single equation type and involving a single meaning of the equal sign, and that this coding maintained the integrity of the data.

After coding all of the data, we looked across our coded data for patterns between meanings for the equal sign and equation types. We also looked for variations in the equations coded for each equation type to create even clearer, more robust descriptions. We present our results next.

Results

In our analysis of equal sign meanings, we coded 11,149 equations. Overall, the relational, operational, and assignments meanings were used in 79.3%, 14.0%, and 6.7% of the equations, respectively. The frequencies for the three meanings of the equal sign separated by curriculum, year, and edition are reported in Table 1. The most common meaning for the equal sign was the relational meaning, which was used for over 80% of the equations in CMP3 7 and 8 and in Eureka Math 8. The only textbook data for which the relational meaning was not the most common was the Eureka Math 7 Student Edition; because of the heavy use of specification equations in the geometry unit, the assignment meaning was the most common meaning for the equal sign in the data from this textbook. The second most used meaning varied across curriculum, year, and edition. Teacher editions tended to use the operational meaning more than student editions. This was largely due to task solutions being included in teacher editions but not student editions. While there were large variations in the frequencies for the three meanings across textbooks, all three meanings appeared in each textbook. While we looked for additional meanings for the equal sign beside the three meanings described in the literature, no other meanings for the equal sign were encountered in the data.

Although we found all three meanings for the equal sign in every textbook, we did not find an explicit discussion in either curriculum concerning the multiple meanings for the equal sign.

Rather, changes in the meaning of the equal sign across problems, tasks, lessons, and units were not explicitly acknowledged nor identified as being a potential source of difficulty for students.

Table 1: Frequencies of Equal Sign Meanings

Meaning of the Equal Sign	Eureka Math 7 Combined	Eureka Math 7 Teacher	Eureka Math 7 Student	CMP3-7 Combined	CMP3-7 Teacher	CMP3-7 Student
Relational	65.7%	68.2%	40.3%	83.2%	81.1%	92.7%
Operational	26.8%	28.9%	5.2%	8.2%	9.6%	2.0%
Assignment	7.5%	2.9%	54.5%	8.6%	9.3%	5.3%

Meaning of the Equal Sign	Eureka Math 8 Combined	Eureka Math 8 Teacher	Eureka Math 8 Student	CMP3-8 Combined	CMP3-8 Teacher	CMP3-8 Student
Relational	83.8%	83.6%	85.3%	82.5%	80.6%	90.5%
Operational	11.2%	12.3%	2.5%	8.4%	9.1%	5.6%
Assignment	5.0%	4.1%	12.2%	9.1%	10.3%	3.9%

In our analysis of the relationship between meanings for the equal sign and equation types, we found clear patterns in our data. See Table 2 for the equation types we found in the data and their associated meanings for the equal sign. Except for the equation type *transformation*, each equation type was exclusively associated with a single meaning of the equal sign. Recall that transformations are equations that show a numeric or algebraic manipulation has been performed. Transformations were used two ways in the textbooks: to record a series of operations and their results, and to justify the equivalence of two expressions. These two purposes are associated with the operational and relational meanings, respectively. While the transformation equations themselves did not provide cues as to which meaning of the equal sign was to be used, the contexts in which the transformation equations were used did; in particular, the textbook authors used words like "because" or "since" to mark transformation equations that were meant to be read with the relational meaning of the equal sign and serve as evidence in support of an argument.

Our analysis of equations led to the creation of subclasses of equations that seem to be missing from the literature. An important distinction made during our analysis was to separate constraint equations into three subclasses: *constraint equations with parameters* (CEP), used to describe the general form of a family of functions or relations (e.g., $y = kx$, Eureka Math 7, Module 1, p. 81); *constraint equations with variables* (CEV), used to represent functions or relations between covarying quantities (e.g., $2x + 3y = 9$, Eureka Math 8, Module 4, p. 308); and *constraint equations with an unknown* (CEU), used to find or test solutions for an unknown value (e.g., $x + 5 + 7x + 5 = 98$, Eureka Math 7, Module 3, p. 135). The distinction between constraint equation subtypes is helpful not only because each subtype serves different purposes, but also because subtypes were frequently transformed into other subtypes during mathematical activity. For example, we noted that the authors often converted CEPs to CEVs by replacing parameters with numeric values, converted CEVs into CEUs by substituting in a value for one of the covarying quantities, and converted CEUs into numeric identities and non-identities (i.e., numeric equations that are either correct or incorrect, respectively) by substituting values for the unknowns to test if those values were solutions. For students to follow the ongoing mathematical activity, they must perceive that the change from one equation subtype to the another retains some of the key characteristics of the original equation, and thus preserves some form of equivalence between the two equations.

Table 2: Equation Types Arranged According to Associated Meaning of the Equal Sign

Meaning of Equal Sign	Equation Types	Purpose
Operational	• Transformation Equations	to perform an operation and record the result
Assignment	• Specification Equations	to assign a value or expression to a variable with intent to substitute
	• Restriction Specification Equations	to restrict the values that can be assigned to a variable
Relational	• Constraint Equations with Parameters	to provide a template for a family of functions or relations
	• Constraint Equations with Variables	to specify the relationship between two covarying quantities so that specific, paired values for the two quantities can be found
	• Constraint Equations with One Unknown	to specify constraints that determine which values an unknown can have
	• Formal Identity	to express a general mathematical property or principle
	• Contextual Identity	to specify the relationship between quantities in a specific context
	• Numeric Identity	to justify that a result is correct
	• Numeric Non-identity	to justify that a number was in fact *not* a solution
	• Transformation Equations	to justify the equivalence of two expressions
	• Unit Identity	to specify the relationship between two units
	• Result Equations	to declare a resulting value or solution that has been found by completing a computation or measurement

Another subclass of equations encountered in our analysis was the *result equation*. A result equation has the form *variable* = *numeric value*, with the purpose of presenting the result of computation or measurement performed somewhere else in the lesson. For example, "p = 90" was used to report the result of having added up the lengths of the sides of a rectangle to find the perimeter, and "$AB = 4$" was used to report the result of having counted the squares on a grid to measure the length of $\overline{AB}$. Because result equations report the result of a computation or measurement, they involve a relational meaning rather than an assignment meaning for the equal sign. Thus, result equations differ from specification equations in that the value of the variable in a result equation is derived from mathematical activity, while the value of the variable in a specification equation is an assigned value that is to be used for substitution later in the problem.

Discussion

Our study confirms that the three meanings for the equal sign documented in the literature appear in middle school mathematics curricula. This result is important because it suggests that for students to be successful in middle school mathematics, they must develop fluency with multiple meanings of the equal sign. Rather than helping students replace their operational meaning for the equal sign with a relational meaning, teachers instead need to help students develop an understanding of all three meanings and the contexts in which they should be used. Based on the curricula we analyzed, an explicit discussion of the different meanings of the equal sign may largely be missing from middle school mathematics textbooks. By explicitly teaching the three meanings of the equal sign and modeling expert reasoning with the equal sign, teachers can help students recognize crucial ways of reasoning in middle school mathematics.

We anticipate that some researchers might object to legitimizing the use of the operational meaning, since a reliance solely on the operational meaning has been linked with errors in solving equations of the form $a + b = \_\_ + d$ (Carpenter et al., 2003) and algebraic constraint equations (Knuth et al., 2006). After all, any equation that is interpreted with an operational meaning can be meaningfully reinterpreted with a relational meaning. However, we noticed that while reading equations in our study that we did in fact read some of them using only an operational meaning, and while we could reinterpret those equations using a relational meaning, it required extra cognitive work. We anticipate that the use of the operational meaning in algebra not only makes clearer the purpose of some equations, but also allows readers to reduce cognitive load as they construct meanings for those equations. For example, if someone writes $2(3x + 2) = 6x + 4$ to show that she performed the distributive property, reading the equation operationally to identify which operation has been formed and whether it was performed correctly matches the intent of the author. To also require the reader to add a relational meaning, interpreting the equal sign to indicate that "$2(3x + 2)$ and $6x + 4$ will yield the same value for all values of x," requires extra cognitive work. For experienced readers, identifying the operation that was performed and checking that it was performed correctly is sufficient, because this correctness *implies* a relational meaning. Such an implications does not mean that the reader must stop to construct the relational meaning; rather, the reader knows that a relational meaning *could be* constructed because a legitimate operation was performed correctly. This allows the reader to interpret the equation meaningfully while engaging in less cognitive work.

In addition to explicit instruction on the three meanings of the equal sign, we also think that students can benefit from the explicit teaching of equation types. An important result of the study is that equation types are largely associated with a single meaning of the equal sign. This close association between meanings and equation types suggests that recognizing equation types can help students determine when a particular meaning for the equal sign should be used. However, students will likely have to learn to attend to additional cues from the contexts in which equations are used, particularly when reasoning about transformation equations, because transformation equations can be read using either an operational or relational meaning for the equal sign.

Because all three meanings for the equal sign are present in middle school mathematics, research on students' understanding of the equal sign may benefit from adopting a new perspective. Currently, students' difficulties with the equal sign are often attributed to the need for students to replace their arithmetic, operational meaning of the equal sign with an algebraic, relational meaning (Carpenter et al., 2003; Kieran, 1981; Knuth et al., 2008). However, a more accurate formulation of the problem may be that students' difficulties are caused by their need to acquire new meanings for the equal sign and relate those meanings to their existing operational understanding. This reformulation of the problem suggests new directions for research, such as how students learn to reason with the assignment meaning or extend their operational meaning from numeric to algebraic equations. Research efforts that focus on understanding how students develop multiple meanings for the equal sign and coordinate those meanings when reasoning with equations is essential if the field is to make progress in helping students develop a rich, flexible understanding of the equal sign.

This research reports on the teacher language and gesture that contributed to shifts in thinking about the equal sign and equations observed in twenty kindergarteners who took part in an early algebra intervention. Our analysis revealed ways in which the teacher used language and gesture to support students in moving from describing and working with the equal sign operationally (i.e., as a signal to compute) to describing the symbol as indicating the equivalence of two amounts and successfully working with equations of various forms. We detail four kinds of language and two kinds of gesture specifically related to mathematical equivalence that we believe contributed to students' growth.

Keywords: early algebraic thinking; mathematical content early years (Grades K-2); teaching and classroom practice

Understanding the equivalence relationship denoted by the equal sign is foundational to algebraic thinking (e.g., Baroody & Ginsburg, 1983; Carpenter et al., 2003; Kieran, 1981; NCTM, 2000; National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA & CCSSO], 2010). Unfortunately, many students struggle to understand the equal sign as a relational symbol indicating the "sameness" or interchangeability of the two sides of an equation. Such students often hold instead an operational view of the equal sign as a stimulus to compute. This operational view manifests itself in students' struggles to make sense of equations in forms other than $a + b = c$. This view is problematic, as students with an operational view of the equal sign experience more difficulty solving equations when they reach middle school than those with a relational view (Knuth et al., 2006).

In Sung et al. (2021), we reported shifts in equal sign understanding observed in 20 kindergarten students who participated in an early algebra intervention focused in part on developing students' understanding of equivalence. For example, we found that students grew in their ability to provide a relational definition of the equal sign (from one student prior to the intervention to nine students post-intervention). We also observed growth in the kinds of equations that students accepted as valid. For example, prior to the intervention, only nine students accepted 5 = 2 + 3 as a valid equation, only three accepted 2 = 2, and only six accepted 4 + 2 = 3 + 3. At the conclusion of the intervention, these numbers grew to 20, 17, and 13, respectively. For more detail about the measures used and results from the study of student growth in understanding, see Sung et al. (2021).

Future studies will be needed to tease apart the influence of the particular tasks with which students were asked to engage and other aspects of their classroom experiences on their growth in understanding. In this paper, we focus on features of the teacher's practice–in particular, her use of language and gesture around mathematical equivalence–that we believe may have contributed to the shifts we observed in students' understanding of the equal sign. We first review literature on teaching practices—particularly, concerning language and gesture—that have been shown to support students' learning about mathematical equivalence and that informed our analysis of classroom observations. We next describe our research methods including the intervention in which students participated. Finally, we describe the teacher language and gesture observed in the intervention classroom that we believe contributed to students' growth.

Teacher Moves that Support Student Understanding of Mathematical Equivalence

While the selection of appropriate tasks and tools is critical to developing students' mathematical understandings and has been the focus of much of our prior work (e.g., Stephens et al., 2013; Stephens et al., 2020), the ways in which teachers implement instruction is equally critical. For example, teachers should establish a classroom culture in which students' strategies (rather than merely correct answers) are valued (e.g., Carpenter et al., 2015; Hiebert et al., 1997), engage students in meaningful classroom discussion (e.g., Ghousseini, 2015), and ensure that every student is a valued and contributing member of the classroom community (e.g., Skinner et al., 2019). There are many possible foci when observing the practice of a mathematics teacher. We focus here on practices that might be particularly significant in developing students' understandings of mathematical equivalence. Specifically, we analyze classroom data using language and gesture as our conceptual frames, investigating how teachers' precise use of language and gesture can support students' understanding of equivalence.

Language

The quantity and quality of the mathematics language to which students are exposed during instruction has implications for their mathematics learning as early as preschool (Klibanoff et al., 2006). The Common Core's Standards for Mathematical Practice (NGA & CCSSO, 2010) state that mathematically proficient students "use clear definitions in discussion with others and in their own reasoning. They state the meaning of the symbols they choose, including using the equal sign consistently and appropriately." Also important are the ways in which this symbol is used and described by teachers.

Hill et al. (2008) identified teachers' use of language as a critical factor in the quality of mathematics instruction. They focused in particular on "the density of accurate mathematical language in instruction, the use of language to clearly convey mathematical ideas, [and] any explicit discussion of the use of mathematical language" (Hill et al., 2008, p. 437). Included in this focus on mathematical language in Hill et al.'s coding of classroom instruction is the use of "general language including analogies, metaphors, and stories used to convey mathematical concepts" (p. 510) and teachers' explicit attention to defining terms, showing how to use them, and pointing out specific labels or names.

Gesture

It has been shown across multiple disciplines and age groups that students learn better when spoken instruction is accompanied by gesture (Goldin-Meadow & Singer, 2003; Macedonia et al., 2011; Ping & Goldin-Meadow, 2008; Singer & Goldin-Meadow, 2005; Valenzeno et al., 2003). Alibali and Nathan (2007) identified three broad categories of gesture that they found supported sixth-grade students' learning about modeling with algebraic equations. *Pointing* *gestures* were defined as gestures used to indicate objects, locations, inscriptions, or students, most often produced with fingers or hands. *Representational gestures* were those involving a handshape or motion of the hand or arm representing an object, action, concept or relation. Finally, *writing gestures* were defined as writing that the teacher produced while speaking. For example, a writing gesture might occur when a teacher underlines a mathematical inscription on the board while describing it with speech. Alibali and Nathan describe gestures as "essential to teachers' ability to conduct their practice" (p. 362).

Congdon et al. (2017) argue for the importance of students experiencing language and gesture at the same time when learning mathematical concepts. The third-grade students in their study were more successful learning to solve mathematical equivalence problems such as 7 + 8 + 5 = ___ + 5 when they experienced lessons involving simultaneous as opposed to sequential language and gesture. Congdon et al. (2017) argue that "gesture capitalizes on its synchrony with speech to promote learning that lasts and can be generalized" (p. 65). Wakefield et al. (2018) argue that the benefits of gesture go beyond directing attention to include its ability to add content to speech. In the case of algebraic equations, this can include using gestures to foster students' ability to see underlying structure in equations (Goldin-Meadow et al., 2009).

While acknowledging that the use of particular tasks and tools coupled with "good teaching" assisted students in making the shifts in equal sign understanding we observed in Sung et al. (2021), here we specifically investigate the teacher's use of language and gesture related to mathematical equivalence to consider how these practices may have contributed to the growth we observed. Our research question is: *How does the teacher use language and gesture to emphasize the relational meaning of the equal sign and encourage acceptance of various equation forms?*

Method

Participants

This study included two classrooms of kindergarten students in the Northeastern U.S. (n = 45) who took part in an early algebra intervention.

The Intervention

The early algebra intervention consisted of 18 lessons of approximately 30 minutes each. This intervention built on a previously implemented early algebra intervention that was found to be effective for developing students' algebraic thinking in Grades 3–5 (Blanton et al., 2019). Of the eighteen lessons, seven focused specifically on developing students' understandings of mathematical equivalence and fluency with equations (Lessons 7, 8, 9, 10, 11, 13, and 14; see Table 1). These lessons engaged students in tasks that have been found to be supportive of developing a relational view of the equal sign (e.g., true/false and missing value equations). Many of these lessons also included activities with balance scales and Unifix® cubes, which provide critical links between concrete and abstract representations of equations and have been found to mediate students' relational understandings of the equal sign (e.g., Alibali, 1999; Araya et al., 2010; Fyfe et al., 2015; Linchevski & Herscovics, 1996; Stephens et al., 2020).

We began this series of seven lessons by having students compare quantities of objects on a pan balance to develop the meaning of balance, introducing the equal sign, and modeling the state of the concrete scales with equations of the form $a = a$ (Lesson 7). Number balances were introduced to students in Lesson 8 and were used to represent equations with no operations (for example, 4 = 4), then equations with operations only to the right of the equal sign (for example, 7 = 3 + 4). These activities were designed to encourage students to work with equations in a variety of forms. In subsequent lessons, students explored decompositions of numbers and ways to represent these with equations (Lesson 9 and 10; as in Blanton et al., 2018) as well as true-false and missing value equations of the forms $a = a$ and $c = a + b$ (Lessons 11, 13, and 14). See Table 1 for a summary of the seven lessons.

Table 1: Summary of Seven Lessons Focused on Mathematical Equivalence

7. Is it Balanced? (Part 1) • Use a pan balance to explore equivalence and inequality • Write inequality statements of the form $a < b$ and equations of the form $a = a$ to represent the relationship shown on a pan balance • Generalize based on experiences with the pan balance (e.g., “To balance the scale, you have to have the same number of cubes on both sides.”)
8. Is it Balanced? (Part 2) • Use a number balance to explore equivalence • Write equations of the form $a = a$ and $c = a + b$ to represent the relationship shown on a number balance
9. Decomposing Numbers • Decompose a set of cubes into two groups in multiple ways and represent with pictures (e.g., show 8 as two groups of 4; 5 and 3; 6 and 2; 7 and 1; 8 and 0)
10. Modeling Decomposition with Equations • Represent the decompositions from Lesson 9 with equations of the form $c = a + b$ (e.g., express “8 is the same as 3 and 5” as “8 = 3 + 5”)
11. Is this True? • Evaluate equations of the form $a = a$ *and* $c = a + b$ as true or false
13. What’s the Missing Number? • Solve missing value equations of the forms $a + b = c$, $a = a$, and $c = a + b$
14. Adding Zero • Write an equation to represent a situation exemplifying the Additive Identity • Identify as true or false and find the missing value in equations exemplifying the Additive Identity (e.g., 2 = 2 + 0, 3 + __ = 3) • Express the Additive Identity in words and with a variable equation

Data Collection and Analysis

Classroom video data were collected during all lessons. We focused our analysis on one of the two classrooms and within this classroom on the seven lessons that addressed mathematical equivalence. These seven lessons were transcribed. Three team members individually watched one lesson per week while highlighting and annotating the transcript with anything they felt was worthy of further discussion. Weekly meetings initially involved the sharing of different perspectives as we worked toward the goal of more specific questions to guide our viewings of the classroom video and eventually a stable coding scheme. We ultimately settled on a coding scheme that focused on the teacher’s use of language around equations and the meaning of the equal sign during whole-group discussion. Repeated viewings led us to notice the use of gesture around two important aspects of equations—the idea of balance, and the notion of the sides of an equation—that were also integrated into our initial coding scheme.

Once an initial coding scheme was in place, three team members individually coded one classroom video and then compared results, discussed challenges, and refined the scheme for content and clarity. The project team continued this process with subsequent lesson videos, using an approach consistent with Syed and Nelson's (2015) recommendations for establishing reliability in qualitative research in ways that emphasize rigorous iterative and collaborative coding scheme development and group consensus. The final coding scheme, describing the language and gesture used by the teacher to refer to features of equations or the meaning of the equal sign during whole-class discussion, is shown in Figure 1.

Language Codes

ISA ("Is the same as"): Teacher verbally links "=" with "is the same as." Often happens when writing or speaking an equation and replacing "=" with "is the same as" or "is the same amount as" or "is the same number as" (e.g., "5 is the same as 2 + 3" while writing 5 = 2 + 3).
DEF (Definition): Teacher explicitly states or uses the definition of the equal sign, often stating that the equal sign means the two sides of the equation are the same number or the same amount (e.g., "This equation is true because the equal sign means the two sides are the same amount"; "We can use an equal sign because the amounts are the same"; "We can't use the equal sign because we don't have the same amount on both sides").
BAL (Balance): Teacher speaks of equations as being "balanced" or not balanced or links the idea of a balanced (or not balanced) scale to an equation (e.g., "This equation is true because the equation is balanced"; "What number will balance this equation?").
FORM (Equation form): Teacher explicitly addresses the form of an equation (e.g., "Is it ok to write equations like this?"; "This equation is not backwards"; "Equations don't need a plus sign").

Gesture codes

GBAL (Balance gesture): Teacher uses hands or arms to make a balance gesture when discussing the equal sign or a particular equation (e.g., holding arms out and saying "it balances" when discussing why an equation is true). Often gets coded along with BAL.
GSIDES (Equation sides gesture): Teacher emphasizes the sides of equations by pointing to the sides, waving her hand over the sides, or writing "V" underneath the side(s) to indicate grouping while talking about "sides." Can apply even when only two numbers/expressions are written and not (yet) the equal sign. Can also apply if "sides" are mentioned *while* the teacher is writing one or more equation sides on the board.

Figure 1: Teacher Language and Gesture Concerning Mathematical Equivalence

Results

Table 2 shows the frequency of the teacher's use of language and gesture related to mathematical equivalence across the seven lessons focused in this area. In what follows, we discuss each of the lessons and provide an overview of the language and gesture we observed in that lesson. We also provide examples of each language and gesture code.

Table 2: Frequency of the Teacher's Use of Language and Gesture Related to Mathematical Equivalence by Lesson

Lessons	7	8	9	10	11	13	14	Total
Language Codes								
ISA ("Is the same as")	0	15	0	11	2	0	0	28
DEF (Definition)	1	6	0	4	4	2	0	17
BAL (Balance)	0	1	0	0	6	8	11	26
FORM (Equation form)	0	1	0	3	2	0	0	6
Gesture Codes								
GBAL (Balance gesture)	0	0	0	2	4	4	1	11
GSIDES (Equation sides gesture)	0	13	0	9	6	3	7	38

Recall that in Lesson 7, students chose among the symbols <, >, and = to describe relationships shown on a balance scale. It was in this context that the teacher first stated, "The equal sign means [the two numbers are] the same" (DEF). In Lesson 8, as students spent more time writing equations to represent relationships shown on balance scales, the use of the equal sign increased, as did language around its meaning. In fact, the number of times the teacher explicitly stated or used the definition of the equal sign (DEF), replaced the "=" with "is the same as" (ISA), and explicitly gestured to the sides of an equation (GSIDES) were greatest in this lesson. For example, as she wrote "11 + 3 = 14" on the board, the teacher said, "11 plus 3 is the same as 14." Another time, when the teacher pointed to each side of the equation 3 = 3 on the board, she said, "I have 3 on this side [pointing to left "3"], I have 3 on that side [pointing to right "3"]." Lesson 8 also provided the teacher an opportunity to address with students the various forms an equation can take (FORM). At the conclusion of the lesson, she stated:

> Check out all the different equations we wrote today. We wrote… 3 + 1 = 1 + 3, with two digits on both sides [pointing to the equation as a whole]. We wrote 7 = 7, one digit on both sides [pointing to the equation as a whole]. We wrote 7 = 5 + 2, one digit on one side [pointing to the left side of the equation], two digits on the other [pointing to the right side of the equation] .... We can write equations in all sorts of different ways. All sorts of forms.

In Lesson 9, students used Unifix® cubes to represent different ways to decompose the number 8 but did not work with equations or the equal sign. Lesson 10 started with the teacher asking students for examples of equations. Multiple students offered examples in the form $a + b = c$. In an effort to emphasize the meaning of the equal sign and eventually encourage students to rely on this meaning to propose other equation forms, the teacher returned to the "is the same as" language used frequently in Lesson 8 to replace "=" as well as gesture to emphasize the distinct sides of equations written on the board. This use of "is the same as" language and gesturing to sides of equations again often happened together. At one point, the teacher discussed the student-proposed equation 5 + 5 = 10 written on the board as follows:

> So, let's check this out. 5 plus 5 is the same as 10 [pointing to each element of equation while reading and replacing "=" with "is the same as"] because I have 10 on this side [using "^" notation and writing "10" above "5 + 5" on left side] and I have 10 on this side [pointing to "10" on right side].

The teacher later proposed the equation 5 = 4 + 1 for discussion. A student expressed some discomfort with this equation, saying she would rather it look more like the previously discussed 5 + 5 = 10. The teacher responded by addressing the class:

> I think it [pointing to 5 = 4 + 1 on the board] fits all the rules of the equation. Let's check it out. It has an equal sign, right? So, that is good [makes a thumbs up gesture]. We have five on this side [pointing to "5" on the right side], right? Do we have five on this side [pointing to "4 + 1" on the right side and drawing "v" shape and "5" below "4 + 1"]?

The teacher explicitly discussed the forms an equation can take, with the goal of expanding the range of equations students would accept as valid by emphasizing the meaning of the equal sign.

Lessons 11, 13, and 14 engaged students in evaluating equations as true or false and solving equations. Throughout these lessons, the teacher referred to equations as "balanced" or not balanced. Sometimes she linked the idea of a balanced (or not balanced) scale to an equation (BAL). She also used representational gestures (Alibali & Nathan, 2007) to represent the idea of balance (GBAL). For example, in Lesson 11 the teacher referred to the equation 3 = 1 + 2 as balanced while simultaneously holding her hands out and gesturing like a balance.

The focus of each lesson seemed to influence the type of language or gesture that was implemented. For example, early lessons focused on introducing the meaning of the equal sign included frequent use of "is the same as" (ISA) and explicit definitions (DEF). As the focus of the lessons shifted towards using these concepts to evaluate and solve equations, we saw an increase in the teacher's discussion of equations as "balanced" (BAL) and her use of a balance gesture when discussing equations (GBAL). Across the seven lessons that addressed mathematical equivalence, we observed 26 instances of the BAL code, 17 instances of the DEF code, 6 instances of the FORM code, 28 instances of the ISA code, 11 instances of the GBAL code and 38 instances of the GSIDES code (see Table 2).

Discussion

Our teacher-researcher used language and gesture to focus students' attention on the meaning of the equal sign and, relatedly, to encourage them to expand the range of equation forms they would accept. As we reflect on our findings, three points come to the fore.

First, when we consider the teacher's use of language related to the equal sign, we find that this language is varied and serves varied purposes. Early in the series of lessons (in particular, Lesson 8, when students were writing equations to represent balanced scales), the teacher frequently defined the equal sign (DEF) and reiterated its meaning by replacing "=" with "is the same as" (ISA) in speech. This very precise use of language reflected the teacher's explicit attention to pointing out critical meanings for students and clearly conveying mathematical ideas (Hill et al., 2008). This "is the same as" language resurfaced in Lesson 10, when students were again writing equations, this time to model decompositions, and the teacher spoke these equations aloud. In later lessons (in particular, Lessons 11, 13, and 14), when students were evaluating equations as true or false and solving missing value equations, the teacher spoke of equations as being "balanced" (BAL) to help students develop a relational view of equivalence.

This use of “balance” reflects Hill et al.’s (2008) attention to the use of analogies and metaphors to help students construct mathematical meaning. Finally, while it occurred less frequently than the other language codes, the teacher at times explicitly referred to the forms of equations (FORM), highlighting that those equations do not have to follow the familiar $a + b = c$ form.

Second, we found two main gestures used by the teacher that promoted students’ understanding of mathematical equivalence. The first was a representational gesture (Alibali & Nathan, 2007) in which the teacher extended her hands or her entire arms to mimic a balancing scale (GBAL). This occurred most frequently in lessons 11 and 13, when students were evaluating or solving equations. The teacher’s balance gestures served to remind students of the link between a balancing scale and a balancing equation. The second gesture we observed very often was a pointing gesture (Alibali & Nathan, 2007) indicating the sides of an equation (GSIDES). Indeed, this was the most prevalent language or gesture code, occurring 38 times across the seven lessons. It might be assumed that it is obvious what the “sides” of an equation are. However, Rittle-Johnson and Alibali (1999) found that fewer than one third of the fourth- and fifth-grade students in their study of procedural and conceptual knowledge correctly identified the “sides” of a given equation, suggesting that gestural emphasis is in fact needed. It may be that emphasizing “sides” of equations helps students see the equal sign as the “center” or balance point of the equation.

Third, we found a particular language-gesture combination—ISA + GSIDES—occurred rather frequently in Lessons 8 and 10. Recall that these were lessons in which students wrote equations to represent balanced scales (Lesson 8) or decompositions of numbers (Lesson 10). This combination occurred when the teacher “talked through” an equation by pointing to and speaking of the equation’s sides while replacing “=” with “is the same as.” This simultaneous use of speech and gesture supports Congdon et al.’s (2017) assertion regarding the power of synchronizing these two modalities in instruction. The teacher used this language-gesture combination when discussing equations of the form $a + b = c$, $a = a$, and $c = a + b$. This combination of language and gesture explicitly emphasized the relational meaning of the equal sign and the fact that, because the equal sign indicates sameness, multiple equation forms are possible.

Conclusion

Early algebra is crucial to bridging students’ informal intuitions about structure and relationships to more formal ways of reasoning and representing mathematical ideas. Our findings shed light on teacher language and gestures that may support students in developing a relational understanding of the equal sign, a crucial aspect of algebraic thinking. Our work also strengthens the argument that the synchronous use of speech and gesture can promote learning.

DEVELOPING MEANINGS FOR GRAPHS FROM NUMBER LINES: THE CASE OF MIKE

Halil I. Tasova
California State University San Bernardino
halil.tasova@csusb.edu

In this study, I report on developmental shifts of a middle school student's (Mike) graphing activity as I implement an instructional sequence that emphasizes quantitative and covariational reasoning. The results suggest that representing quantities' magnitudes as varying length of directed bars on two parallel lines, forming a new space by making those lines orthogonal, and generating a point by joining those bars were an integral part of Mike developing productive meanings for graphing quantities in a Cartesian plane.

Keywords: Algebra and Algebraic Thinking, Cognition, Mathematical Representations

Constructing and interpreting graphs is a middle school mathematics topic that provides an opportunity to foster powerful learning (Leinhardt et al., 1990). Students, however, experience a number of challenges (e.g., conceiving graphs as picture of situation, event phenomena, or the literal motion of an object; see Johnson et al., 2020, for a summary of challenges) in interpreting and making sense of graphs that ultimately affect their learning of many topics in algebra and calculus (e.g., Clement, 1989; Hattikudur et al., 2012; Moore & Thompson, 2015). In particular, middle school students encounter many challenges when transitioning from discrete graphs to continuous graphs as they are influenced by their past experience with bar graphs and line plots introduced in K–5 education (Boote & Boote, 2017). A promising way to support students in developing productive meanings for graphs is to emphasize a graph as an emergent trace of how two quantities vary simultaneously (i.e., emergent shape thinking; Moore, 2021). Numerous researchers have investigated students' ability of graphing coordinates (e.g., Ponte, 1984; Shaw et al., 1983), formulas (e.g., Hattikudur et al., 2012), and motion (e.g., Botzer & Yerushalmy, 2008; Radford et al., 2009; Nemirovsky et al., 1998), but far fewer researchers have focused on investigating how students construct graphs as emergent traces of quantities' covariation (e.g., Frank, 2016; 2017; Tasova, 2021). Even fewer researchers have investigated the sources of students' capacities to create a point as a simultaneous representation of two quantities' values so that they can construct a graph as an emergent trace of those values' covariation (e.g., Tasova & Moore, 2020; Thompson et al., 2017). Thus, I investigate the following questions: What ways of thinking do students engage in graphing activities intended to emphasize quantitative reasoning? What ways of reasoning are involved in students developing productive meanings for graphs?

Theoretical Framework: Quantitative and Covariational Reasoning

This study focuses on students' graphing activities involved in reasoning with relationships between quantities in real-world situations. I use *quantity* to refer to a conceptual entity an individual constructs as a measurable attribute of an object (Thompson, 2011). When engaging in dynamic contexts, students can use *covariational reasoning*, which entails attending to how one quantity varies in relation to the other (Thompson & Carlson, 2017). In this study, I demonstrate ways in which students make sense of quantitative relationships in dynamic events and in graphs by reasoning with quantities' *magnitudes* (i.e., the quantitative size of an object's measurable attribute) independent of numerical values (i.e., the result of measuring that attribute). Researchers have argued for the powerful role of reasoning with magnitudes in supporting students understanding of quantitative relationships (e.g., Thompson et al., 2014).

A relationship between two quantities is often represented in a Cartesian plane formed by two perpendicular number lines creating a two-dimensional (2D) space. The idea of representing quantities' values or magnitudes on number lines is often taken for granted by researchers when discussing students' construction of coordinate graphs (Lee et al., 2018). This is not surprising given that the focus of instruction is given to bar graphs and pointwise readings in elementary and secondary education. The researchers (Earnest, 2015; Schliemann et al., 2013) who have studied the relationship between the conception of number lines and coordinate systems have focused on individual points on the number lines and the intervals between them. Their focus did not give attention to representing quantities' magnitudes and continuously changing quantities. Thus, in this study, I extend this previous work by investigating the nature and extend of students' ability to represent varying quantities' magnitudes on number lines, and how those abilities influence their meanings of graphs.

Methods

Participants

This study is situated within a larger study that examined two sixth-grade students' (Mike and Naya) and four seventh-grade students' (Ella, Dave, Marc, and Zane) graphing activities in a teaching experiment (Steffe & Thompson, 2000) that occurred at a public middle school in the southeast United States. This study focuses on Mike's meanings for graphs and his developmental shift of those meanings over the teaching experiment.

Data Sources and Analysis

Mike participated in 14 teaching sessions each of which last for approximately one hour. Data sources included video and transcripts that captured the participants' exact words, gestures, and drawings. Students' written work, screen recordings from a tablet device, and notes taken by research members who participated in the sessions were also collected as data sources. I conducted a conceptual analysis in order to understand students' verbal explanations and actions and develop viable models of their mathematics (Steffe & Thompson, 2000). My analysis relied on the generative and axial methods (Corbin & Strauss, 2008), and it was guided by an attempt to develop working models of Mike's thinking based on his observable and audible behaviors.

Tasks

Before conducting the teaching experiment, I developed an initial sequence of tasks with a dynamic geometry software and displayed on a tablet device (for digital versions of all the tasks, go to https://www.geogebra.org/m/szscxzd8). In Downtown Athens Bike Task (DABT), I present the students with a map of Downtown Athens highlighting a straight road, two places located near the road (i.e., the Arch and Canon; see Figure 1a), and a bike on this road. I asked students to graph the relationship between the bike's distance from Arch (DfA) and distance from Cannon (DfC) as the bike moves at a constant speed back and forth along the road.

In the Crow Task (CT), I present with the same map in addition to a movable crow (see Figure 3). I also presented a Cartesian plane with the horizontal axis labeled as DfC and vertical axis labeled as DfA. Students can move the crow freely while observing how the corresponding black point in the plane moves (see https://youtu.be/5JgrPAuG15Y).

In Matching Game Task (MGT; Figure 2a), I present the students with the same map highlighting a straight road (i.e., College Avenue). Arch and Cannon are located on the road, and a bike rides along this road. I also present a dynamic tool where students engage with quantities' magnitudes represented by directed bars placed on empty number lines (also called magnitude lines). The directed bars can be varied in length (see https://youtu.be/knrN7XCbyOY). In this part of the task, the bars and the bike in the situation are not synced, and I ask students to adjust the length of the bars on the magnitude lines to match with various bike positions in the map. I aim to help students understand that the length of both bars should be constrained in a way that they simultaneously represent the bike's DfA and DfC. I asked students to place tick marks as a way to *record* those lengths on the magnitude lines before I change the bike's location to another state. I conjectured that this tool might help students when they move to 2D space to represent two quantities by a single point in a coordinate plane.

Results

Mike's Graph in Downtown Athens Bike Task

I asked Mike to sketch a graph to represent the relationship between the bike's DfA and DfC. The reader can see Mike's graph in Figure 1b, which consisted of a line upward from left to right. Mike first conceived the *entire* vertical and horizontal axes of the plane as the psychical Cannon and Arch, respectively. The axes did not represent magnitude or number lines, but instead were referents to the objects themselves. Mike then drew a line upward from left to right to represent "where the bike travels." He added tick marks and dots on his line graph "to represent like where the bike could be." For example, when the bike is at a location 1 in the map (i.e., DfA and DfC are each at their minimum), he said "it [the bike] would go right here [*pointing to the tick mark on his graph near 1 in Figure 1b*]."

Figure 1: (a) DABT and (b) Mike's graph (numbered labels are added for the reader)

Mike also imagined moving the bike on the plane according to the variation of its DfA and DfC. He conceived DfC and DfA as being represented by vertical and horizontal segments drawn on the plane, respectively. He said "this distance [*moving his finger up and down over the vertical line segment that he drew on the plane*] is the distance from the Cannon and this distance [*moving his finger over the horizontal line segment that he drew on the plane*] is the distance from the Arch." The vertical segments on the plane represented the bike's DfC because Mike assimilated the horizontal axis as a reference ray that he measured bike's DfC from. Similarly, the horizontal segments on the plane represented the bike's DfA because he assimilated the vertical axis as a refence ray he measured the bike's DfA from. Increasing length of the horizontal and vertical segments on the plane indicated an increase in the bike's DfA and DfC. Moreover, Mike understood that the length of horizontal segment is shorter than the length of the vertical segment for each point on the graph as the bike's DfA is always less than the bike's DfC on the map. Thus, although Mike assimilated his graph as "where the bike travels," Mike's graph was not the bike's path *as it is* seen in the map; it was not an iconic translation. Mike's meaning of the points included determining quantitative features of the bike in the situation (i.e., its DfA and its DfC) and he ensured they preserved those quantitative properties on the plane.

I consider Mike's graphing activity as a different way of graphing relationships because he engaged in quantitative operations to make sense of the results of his activity and produce a graph to his satisfaction. Specifically, he represented the quantities' magnitudes in the space by committing to two frames of reference (i.e., the axes), and then placing a point where those magnitudes meet on the path he produced. Tasova and Moore (2020) termed this meaning of points as a *spatial-quantitative multiplicative object*, which involves an individual envisioning point on the plane as a *location/object* that also entails *quantitative* properties. This meaning of points on the space is different than representing quantities' magnitudes *on* the axis and creating a point by taking two orthogonal magnitudes along the axis and creating projections. In the next activity, I provided an opportunity for Mike to develop such a meaning of a point.

Mike's Activity in Matching Game Task

I designed MGT (Figure 2a) in order to engage Mike to (i) represent two quantities' magnitudes on parallel magnitude lines and then transition to (ii) representing two quantities' magnitudes as *a single point* by making the magnitude lines orthogonal and projecting the magnitudes on the plane. I conjectured that Mike's engagement with MGT could promote an understanding of points for Mike as an abstract object in relation to representing two quantities' magnitudes rather than representing a physical object that moves on the plane. I let Mike to change the bike's location on the path and observe how the bars were moving on the magnitude lines (see https://youtu.be/6Q3pSDhXEMs). I asked Mike what the red and blue bars might represent. He responded that the blue bar represents the bike's DfA, and the red bar represents the bike's DfC. When asked to show how he knew, he located the bike near Cannon on the map and said "well, the bike's distance from Arch right now [*measuring the length of the blue bar on the magnitude line with his fingers*] is this much [*translating his fingers—by keeping the same distance between them—and placing it on the map*]". He also added "it [*pointing to the bike on the map*] is right by the Cannon, so, it [the red bar] is not there [*pointing to the zero point on the magnitude line labeled 'Distance from Cannon'*]."

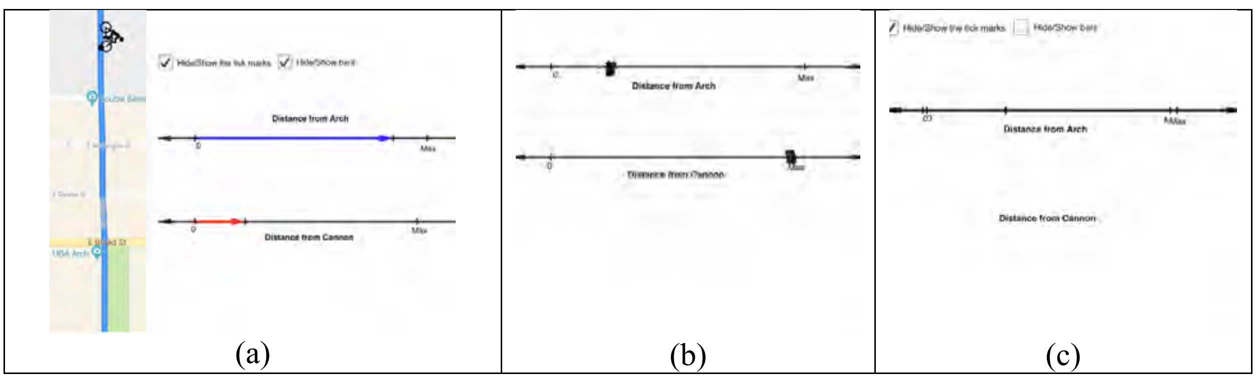

Figure 2: (a) MGT (b) Mike's tick marks on the magnitude lines representing the bike's DfA and DfC, and (c) Mike's activity seeking to create a single point

I also hid the red and blue bars on the magnitude lines. Then, I asked Mike to place tick marks on the magnitude lines to show where the head of each bar would be on the magnitude lines for different locations of the bike on the map. For example, I located the bike at the bottom of the map and Mike successfully placed tick marks on each magnitude line accordingly (see Figure 2b). When placing the tick mark for the bike's DfA, he engaged in the same measurement activity with his fingers—measuring the distances with his fingers on the map and translating his fingers onto the magnitude lines by keeping the same distance between them. Moreover, he stated that "tick marks show where the end of the bars would be." I conjectured that this meaning of tick marks might help Mike to *record* the variation of the bar on the magnitude line since the varying bars do not leave trace or a mark as they move on the magnitude lines. In turn, I conjecture that this activity might help Mike when we move to 2D space to record the relationship between two varying quantities on each axis of the plane.

With Mike doing so successfully and indicating that he conceived of the tick marks in relation to quantities' magnitudes, I decided to transition to the next part of MGT where I asked Mike if he knew a way to represent the bike's DfA and DfC by *a single point* instead of the two tick marks that he placed on two parallel magnitude lines. I also informed him that he can move and rotate those lines freely on the tablet screen. Mike was not able to create a single point to represent two quantities' magnitudes, except for one case where the bike's DfA and DfC had the same length (see Figure 2c). He moved the magnitude lines on top of each other by matching the zero and max points. He then located the bike in the middle between Arch and Cannon on the map and pointed out that the tick marks representing the bike's DfA and DfC were matched on the magnitude lines. Referring to the tick mark, he said "it represents both the distance from Arch and the Cannon because when the bike is right there [*pointing to the bike located in between Arch and Cannon*], they are both the same distance from the Cannon and the Arch."

He could not find a way to create a single point that simultaneously represented other states of the bike's DfA and DfC. He needed to construct a new space that was different than the one-dimensional (1D) space in a way that he could satisfy the simultaneity for all states of the bike's DfA and DfC. This was a need, from my perspective, why we need a 2D space. I didn't have evidence that Mike perceived such a need at the moment as he was satisfied with his activity for one occasion of the bike. This suggested that I should provide other opportunities for Mike that could afford him to structure the space in a way that he could see additional features that is not available in 1D space. Thus, I decided to move to CT where I provided him a coordinate system as a given space. My goal was to provide Mike with additional figurative material that might afford him to structure the space in a way that is compatible with Cartesian plane.

Mike's Activity in Crow Task

Mike was able to move the crow freely while observing how the corresponding black point on the plane moved (see https://youtu.be/mIpOiSuq0mE). When asked to explain what the black point might represent on the plane, he conceived the dot as the crow. However, he was not sure how the black dot moved according to how the crow flied on the map. He said, "I guess [the dot is] the crow, but I still don't understand this" meaning that he did not know how the black dot moved on the plane as the crow moved on the map. Since I knew he was able to reason with quantities, I wanted to draw his attention to the crow's DfA and DfC in the situation when the crow was not flying (i.e., static moment). I asked Mike to show how he imagined the crow's DfA and DfC on the map when the crow was located next to Georgia Theatre (see Figure 3a, left). He drew two segments to show the crow's DfA and DfC on the map (Figure 3a, left). I then asked him to place tick marks on the axis of the plane to represent the crow's DfA and DfC. Recall that, in MGT, Mike was able to transform (i.e., dis-embed and represent) the magnitude of the bike's DfA and DfC from situation to the parallel magnitude lines by ensuring to preserve their length by using his fingers. He successfully placed tick marks on each magnitude line to represent the bike's DfA and DfC (see Figure 2b). Since he never assimilated what I perceive to be the axes of the coordinate plane as the magnitude lines, I did not expect him to insert tick marks on each axis normatively in his first attempt. However, I still desired to ask this question because this could draw his attention to the axes of the plane in later attempts. My goal was to help him to make connection between his activity of inserting tick marks on two parallel magnitude lines and inserting tick marks on the axis of the coordinate system.

He first assimilated the black dot on the plane as the crow stating “so, um, and this is where the crow is.” Mike then plotted two tick marks on each axis where he thought where the physical Arch and Cannon were on the axes (Figure 3a, right). He said “these tick marks are where the Cannon and Arch is, I think.” Mike then represented the crow’s DfA as the distance from the Arch on the axis and the crow’s DfC as distance from the Cannon on the other axis. He drew segments from these marks to the black dot on the plane explaining “these [s*liding his index finger over the segments he drew on the plane*] are the two distances. I mean, I don’t know” (see Figure 3a, right; the computer-generated tick marks on each axis were not available at the moment). This suggested that his meaning of the point at the moment included envisioning the point as a location/object by coordinating quantitative features of the object on the plane, which is the same meaning that Mike had in his previous graphing activity in DABT (see Figure 1).

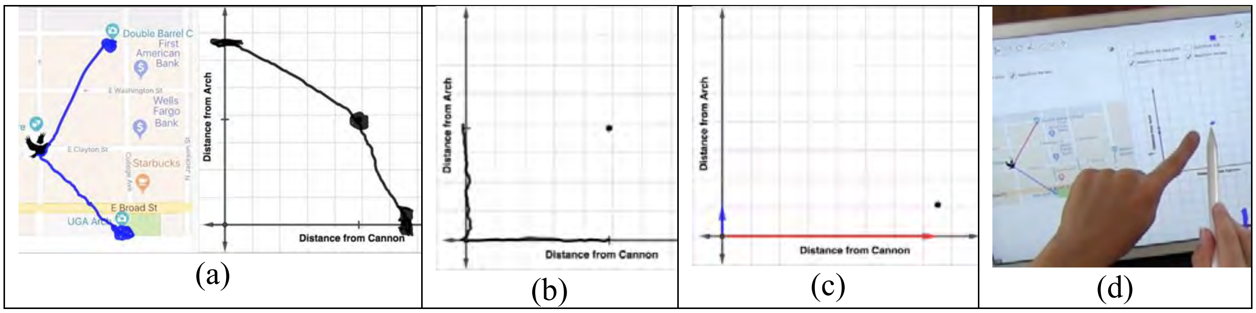

Figure 3: (a) Mike’s activity in CT, (b) Mike’s segments on each axis, (c) Bars in CT, and (d) Mike’s physical action of joining the projection of the two magnitudes on the plane

Then, I showed the computer-generated tick marks on each axis of the coordinate plane (see the additional tick marks on each axis in Figure 3a, right). My goal was to provide additional figurative material for Mike that could afford him to conceive the axis as the magnitude lines. Mike immediately surprised by the locations of the tick marks on the axes. He questioned “why are they there” and he could not resolve this perturbation at the moment. Since I knew Mike had a meaning for tick marks on the parallel magnitude lines in relation to quantities’ magnitudes in MGT, I decided to ask Mike to reflect on his previous activity where he placed tick marks on the magnitude lines in MGT. I asked Mike what the tick marks meant to him in the previous activity. He said, “end of the bar, like where the bar ended.” I then asked him where these bars might be on the plane in CT. He began erasing his work on the plane in Figure 3a (right). He stated that “based on, um, the little tick marks, um, like maybe there is two bars, maybe like there is two lengths from the origin that go to these two [*referring to the tick marks*].” He then drew the horizontal and vertical bars on axes (see Figure 3b). When asked to describe what these bars represented, he responded “the distances from the Cannon and Arch.”

In order to get more insights into his meaning of bars on the axis, I showed the blue and red bars on the map and on the axes (see https://youtu.be/oFGjq9UgQNA?t=11). I asked Mike to move the crow on the map and observe what was going on with the bars on each axis of the plane. As he moved the crow on the map, Mike determined that the bars on the axes and the bars on the map “are the same.” He elaborated by saying “lines are getting longer and shorter, like the lines here [*pointing to the bars in the map*] or the bars are equal to the bars like [inaudible].” For example, he moved the crow right next to the Arch on the map and determined the length of the blue bar was too small (see Figure 3c). He said “it [the crow] is right next to the Arch [on the map] and the blue bar is really small.” This activity provided evidence that Mike conceived the bars on the axes of the plane in relation to the quantities’ magnitudes. Thus, I decided to investigate his meaning of a point on the plane to see if and how Mike could join two magnitudes and generate a point that represented both. Then, I hid the black dot on the plane keeping the blue and red bar on each axis visually available and asked Mike where the black dot would be on the plane. Mike plotted a point on the plane by intersecting the projections of the quantities' magnitudes that were represented on each axis of the plane (see his joining gesture in Figure 3d) and his meaning of the point included "the crow's distance from Cannon and Arch."

Mike's Activity in Matching Game Task (Second Attempt)

I next directed Mike to the previous task (i.e., MGT) and asked that he create a single point to represent the bike's DfA and DfC simultaneously given two parallel magnitude lines (see Figure 2a). I asked Mike if this task and CT are related. Mike said "maybe, if we make this [*pointing to the parallel magnitude lines*] a *x* and *y*-axis thing." Then, Mike rotated one of the magnitude lines and placed it perpendicular to the other magnitude line by matching the zero points in both lines (see Figure 4a). He then plotted a point where the projection of the red and blue bars intersected on the plane. I asked him how he knew this point showed both the bike's DfA and DfC, he drew the vertical and horizontal segments (see Figure 4b) and said "it [*referring to the vertical segment*] is the bike's distance from the Arch and it [*referring to the horizontal segment*] is the bike's distance from the Arch." Mike also successfully created a single point to represent the bike's DfA and DfC for another location of the bike (see Figure 4c).

Mike's Final Graph in Downtown Athens Bike Task

In DABT, I played the bike animation (see Figure 1a) and asked Mike to draw a representation showing how the bike's DfA and DfC varied. Mike began his graphing activity by drawing a straight line upward from left to right on the tablet screen (Figure 5a). Mike also drew his graph on paper as a dotted and dashed straight line upward from left to right (see Figure 5c, the additional horizontal and vertical segments were not drawn yet). When asked to illustrate how his graph showed the relationship between DfA and DfC, he moved his right index finger horizontally back and forth in the air and moved his left index finger up and down vertically in the air (see the red arrows an indication of the path for his fingers in Figure 5b). His movement of the fingers suggested that he might be imagining the varying bars in relation to his graph on the plane. I asked him to elaborate on his finger movements. He explained,

> When we moved them, we moved them like [*making the same gestures in Figure 5b over the vertical and horizontal axis of the plane*], the two lines go like [*joining his fingers on the graph*] and it crosses these little tick marks [*pointing to the tick marks on his graph by sliding his finger on his graph from left to right*].

From his activity, I infer that Mike imagined the projection of quantities' magnitudes on the axes meeting on the plane along with the variation of these bars creating the graph. In order to get more insights into his meaning of the graph on paper, I asked Mike to show how his graph on paper showed the bike's DfA and DfC for certain states of the bike in the situation. For example, I asked Mike how his graph showed the moment where the bike was located at the right side and at the middle of the path on the map. Mike drew horizontal and vertical segments on the plane representing the bike's DfA and DfC to show these two moments (see Figure 5c). The horizontal segment represented the bike's DfC because it was the projection of the red bar on the horizontal axis. Similarly, the vertical segment on the plane represented the bike's DfA because it was the projection of the blue bar on the vertical axis. I infer that the way he represented quantities' magnitudes was now compatible with representing a point in a canonical Cartesian plane.

Discussion

In this study, I illustrated Mike's meanings for graphs and the development of those meanings from the teaching experiment as I implemented an instructional sequence that I developed in order to support him in developing emergent shape thinking—a productive and covariational meaning for graphs from quantitative reasoning perspective (Moore, 2021). In particular, I aimed at promoting meanings of (i) representing quantities' magnitudes as varying, directed bars on parallel magnitude lines, (ii) coordinate system as a two-dimensional space constituted by two orthogonal magnitude lines, (iii) points in coordinate systems as a simultaneous representation of two quantities' magnitudes, and (iv) graphs as an emergent trace of that point representing the quantities' covariation.

Mike initially assimilated the points in the plane in relation to the physical objects that appear in the situation, and his meanings for points were based in quantitative properties. I consider Mike's initial representational activity as illustrating an alternative meaning of a coordinate system and coordinate points. I found that being able to represent the quantities magnitudes as varying bars on the magnitude lines was a critical development in the teaching experiment as it laid a foundation for students to re-organize the space and construct a Cartesian coordinate system. In his subsequent activity in MGT after his engagement in CT, Mike successfully manipulated the parallel magnitude lines to create a single point on a Cartesian plane. This re-organization of the space was an important moment for him to be able to use the plane in order to create a single point that simultaneously represented two quantities magnitudes. Furthermore, representing quantities on magnitude lines played a significant role in his development as he subsequently and frequently referred to the variation of quantities' magnitudes represented *on the axes* when explaining how his graphs showed certain covariational relationship on the plane.

STUDENT REASONING IN DYNAMIC SITUATIONS: SPATIAL PROXIMITY REASONING

Halil I. Tasova
California State University San Bernardino
halil.tasova@csusb.edu

In this paper, I introduce a mode of reasoning, which I call spatial proximity reasoning, that entails coordinating the (co)variation of an object's degree of proximity (i.e., closeness or nearness) to other objects (i.e., reference objects) in a dynamic real-world situation. I compare and contrast spatial proximity reasoning with quantitative (co)variational reasoning. I also present the implications of spatial proximity reasoning on students' graphing activities in one- and two-dimensional spaces.

Keywords: Algebra and Algebraic Thinking, Cognition, Mathematical Representations.

This paper reports on a study addressing the following research questions: (a) How does spatial proximity reasoning differ from quantitative covariational reasoning? (b) What are the implications of spatial proximity reasoning for students' graphing activities? In the findings below, I illustrate that Zane who engaged in spatial proximity reasoning assimilated what I perceived to be the representation of a quantity's magnitude on a number line in a certain way that was different from Ella who engaged in quantitative covariation. Zane imagined the physical objects on the number line whereas Ella represented the quantity's magnitude on the number line isolated and decomposed from its physical context. In turn, their representational activity in two-dimensional space differed as an implication of their reasoning.

Background

This study focuses on students' reasoning when they engage in dynamic real-world situations that involve quantities varying (from my perspective). I use *quantity* to refer to a conceptual entity an individual constructs as a measurable attribute of an object (Thompson, 2011). When engaging in dynamic contexts, students can use *covariational reasoning*, which entails attending to how one quantity varies in relation to the other (Carlson et al., 2002; Saldanha & Thompson, 1998; Thompson & Carlson, 2017). Different from students' quantitative covariational reasoning, I identified a new mode of reasoning, which I call spatial proximity reasoning. I define students' spatial proximity reasoning as coordinating the (co)variation of an object's degree of proximity (i.e., closeness or nearness) to other objects (i.e., reference objects) in a dynamic situation (e.g., the bike is getting closer to or farther from Arch). Note that students do not engage in coordinating the magnitudes or values of quantities, instead they coordinate the *nearness* between two objects without attending to the measurable attributes of these objects. For example, I observed students conceiving "the bike's distance from Arch" not as a measurable attribute of the bike, instead as the bike's degree of proximity to Arch. Indication of this type of reasoning might include having students using the linguistic adverbs "closer", "farther" when there is no evidence of students imagining quantified attributes of an object (e.g., the values or magnitudes of the bike's distance form Arch getting increase or decrease). I have often observed that student's image of variation regarding the bike's proximity to Arch included two separate objects that were getting close to or farther from each other, rather than including a varying length of a segment. Based on the analysis of my teaching experiments, I present evidence of spatial proximity reasoning and identify implications for students' representational activities (e.g., imagining the physical objects on the number line or on the coordinate plane).

Methods

This study is situated within a larger study that examined two sixth-grade and four seventh-grade students' graphing activities in a teaching experiment (Steffe & Thompson, 2000) that occurred at a public middle school in the southeast United States. In this study, I focus on two students' data, Ella and Zane (seventh-graders) because their reasoning and graphing activities were distinct, and worth documenting and contrasting. Ella and Zane (as a pair) participated in 6 teaching sessions each of which last for approximately one-hour.

Data sources included video and transcripts of each session that captured their exact words, gestures, and drawings. I conducted a conceptual analysis in order to understand their verbal explanations and actions and develop viable models of their mathematics (Steffe & Thompson, 2000). My analysis relied on generative and axial methods (Corbin & Strauss, 2008), and it was guided by an attempt to develop working models of their thinking.

Before conducting the teaching experiment, I developed an initial sequence of tasks each of which was designed with a dynamic geometry software and displayed on a tablet device (see https://www.geogebra.org/m/uyy2kxz8 for digital versions of the tasks presented in this paper). In *Downtown Athens Bike Task* (DABT), I present the students with a map of Downtown Athens highlighting a straight road (i.e., Clayton St.; Figure 1a, left). I asked students to graph the relationship between the bike's distance from Arch (DfA) and distance from Cannon (DfC) as the bike moves at a constant speed back and forth along the road. I also designed numerous tasks where students engage with quantities' magnitudes represented by varying length of directed bars placed on empty number lines (also called *magnitude lines*, see Figure 1a, right). The length of directed bars on the magnitude lines vary according to the bike's movement in the map. Note that I call the line "empty number line" in order to emphasize magnitude reasoning as opposed to numerical or value reasoning.

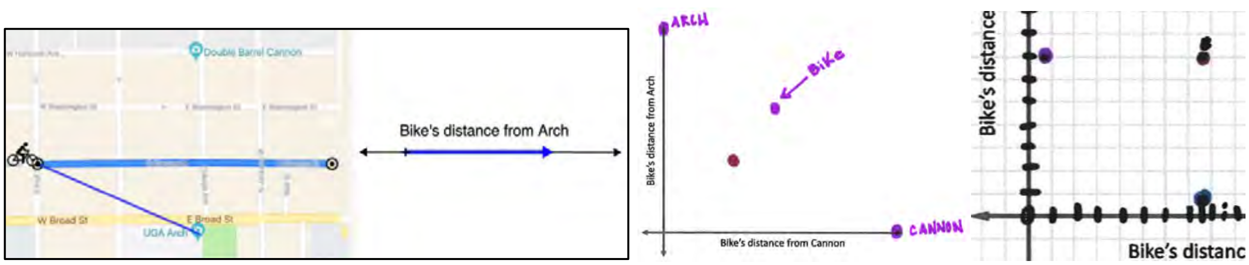
Results

In this section, I illustrate and contrast Ella and Zane's activity where they were asked to interpret the varying bar on a magnitude line (see Figure 1a, or https://youtu.be/xMa9sNMxRIo). While moving the bike to the right from its position seen in Figure 1a, I drew students' attention to the fact that the right end side of blue bar on the magnitude line was moving to the left (indicating the bike's DfA was decreasing). Then, I asked Zane and Ella to explain why that was happening. Referring to the map, Zane claimed, "the bike is getting closer to Arch," which was compatible with how he described the variation of the bike's DfA in the previous activities using the linguistic adverbs "closer to" and "farther from." I did not have any evidence that Zane coordinated the bike's DfA as the bike's measurable attributes. When I explicitly asked him to visually show how he saw bike's DfA on the map, he wrote "Far" at each end side of the bike's path on the map where the bike was far from Arch. This suggested that Zane's image of variation included coordinating the variation of the bike's proximity to Arch.

Then, by pointing to the blue bar on the magnitude line (Figure 1a, right) and tracing the pen over the line from right to left, he added it "is gonna get closer to right here [*pointing to the zero point on the magnitude line*], which is Arch." Zane conceived Arch and bike as physically placed on the left and right end side of the blue bar, respectively, and he thus perceived blue bar's change to be compatible with his spatial proximity reasoning because the bike moved closer to the Arch *along* the line, with Arch playing the role of reference object. Zane abstracted the two objects (Arch and bike) and their proximity when engaging in the situation. Thus, he imagined these physical objects in his representational activity too.

Differing from Zane, Ella determined that the bike's DfA is decreasing while moving the bike to the right in the map. She explained "it [*pointing to the blue bar*] is gonna get smaller because distance is smaller on the number line too." Moreover, Ella labeled the starting point as "zero", whereas Zane conceived the same point on the magnitude line as "Arch." Her activity suggested that Ella conceived the length of the blue bar on the map and on the magnitude line as a representation of the bike's DfA. I conjecture that Ella's activity was an implication of her quantitative variational reasoning (i.e., the bike's DfA is decreasing) whereas Zane's activity was an implication of his spatial proximity reasoning (i.e., the bike is getting closer to Arch).

In order to understand how Zane understood Ella's response and focus on "distance", I asked Zane to re-voice Ella. Zane's explanation included his original reasoning (i.e., imagining the Arch and the bike physically on the line getting closer and farther). Thus, Zane assimilated Ella's answer to his meaning because they were compatible with respect to the behavior of figurative material. Since Zane's meaning included spatial proximity (i.e., nearness) between two places, it made sense to imagine Arch in place of the origin in one-dimension because the value of the bike's DfA was zero at that point. However, their meanings and reasoning have different implications when we move to two-dimensional systems, which I illustrate as follows.



(a) (b) (c)

Figure 1: (a) Representing the bike's DfA on the map and on the magnitude line, (b) Zane's graph, and (c) Ella's graph

In DABT, I asked them to represent the relationship between the bike's DfA and DfC on a given paper with a coordinate plane. By the time I asked this question, the picture of the situation and the parallel magnitude lines on the tablet screen was visually available to them. Recall that Zane conceived the objects from the situation (i.e., Arch and the bike) on the magnitude line, and he thus conceived the varying bar as illustrating the bike was getting closer to Arch. In two-dimensional space, and via conceiving Arch and Cannon on the axes implied by the labels, Zane attended to the spatial proximity between objects by coordinating the bike's location in the plane (see his graph in DABT in Figure 1b). To justify his graph, he rotated the plane counterclockwise in order to match with perceptual feature of the map. That is, he rotated the plane in a way that Cannon and Arch are at the top and bottom of the plane, respectively, and the bike moved horizontally in the plane, just like it did on the map.

Although Zane's form of reasoning is productive in terms of completing the goal of the activity as he perceived it (i.e., showing where the bike is in the plane), this creates a problem in the normative Cartesian that is based on two directed distances (i.e., horizontal and vertical). On the other hand, Ella conceived the length of the bar on the magnitude line as a proxy for the quantity that she conceived in the situation (i.e., the bike's DfA). In doing so, she conceived a constrain regarding how to represent the variation of a quantity on a magnitude line (e.g., only left and right on a horizontal line). Thus, she organized the space accordingly in later activities when considering two-dimensional space (see her graph in DABT in Figure 1c). Ella referred to the axes of the plane as "number line" and plotted tick marks on each axis in conjunction with tick marks plotted on the magnitude lines on the tablet screen. She added dots near certain tick marks on each axis (see the dots in Figure 1c) to represent a certain state of bike's DfA and DfC. Then, she plotted a point in the plane "where those two [*tracing the pen in the air from the dots on each axis to the dot on the plane horizontally and vertically, respectively*] would meet up if they have like a little line." This provided evidence that Ella was able to assimilate the axes of the plane in relation to the magnitude lines and, in turn, she was able to imagine the magnitudes varying on the axes of the coordinate plane. Since it has a significant impact on students' graphing activity, we, as a researcher or teacher, should pay attention to the types of reasoning students might demonstrate when they graph in dynamic situations.

Discussion

In this study, I illustrated various ways in which students reasoned in dynamic situations (i.e., quantitative covariational reasoning and spatial proximity reasoning). These different ways of conceiving dynamic situations suggest that it is really important for us, as researchers and teachers, to understand how students conceptualize the objects' varying attributes in the situation. We should not assume that the variation that students might conceive is the same as *given* in the dynamic situation. Thompson and Carlson (2017) pointed out that researchers might conceive the varying quantities in a situation; however, it might not be the case for students. In their extensive literature review, Leinhardt et al. (1990) reported that researchers often thought that variation has something to do with the situation only as opposed to acknowledging the importance of conceptualizing the variation in students' mind. Thus, merely offering dynamic situations to students does not imply that students will engage in quantitative covariational reasoning. We need to understand how students might conceive dynamic situations and how they might imagine and represent the quantities' magnitudes vary.

I believe the distinction I made in this study could provide a lens for researchers to investigate students' graphing activity especially in contexts in which a *motion* occurs. Since many embodied activities often involve graphing with a motion sensor technology, students could either coordinate an object's distance from the motion detector or coordinate the object's proximity to the motion detector when creating or interpreting a graph. Researchers (e.g., Hobson, 2017; Nemirovsky et al., 1998) reported that students could produce a normative graph (or interpret a graph normatively) as a representation of the motion although they don't attend to the quantities in the situation, such as distance between the object and the reference point (e.g., motion detector). For example, when engaging in creating graphs generated by a motion detector representing how a handheld button's distance from the detector varied over time, Nemirovsky et al. (1998) reported that students determined "the line on the screen becomes higher when one moves the button away from the tower and lower when one moves the button toward it" (p. 122). Nemirovsky et al. interpreted that, for the students in their study, distance between the button and the tower (i.e., motion detector) was not related to meters, instead it "concerned the possibility and impossibility of creating certain graphical responses" (p. 164), which is related to spatial proximity reasoning. They noted that distance "is about the impossibility of certain actions that would be possible if the objects were nearby, not a matter of meters" (p. 164). Therefore, I believe the construct, spatial proximity reasoning, can be used as an additional lens when investigating students' representation of motion as a graph (e.g., distance-time graphs).

Keywords: Algebra and Algebraic Reasoning, Middle School Education, Mathematical Representations

One of the main practices that separates arithmetic and algebraic reasoning is the use of variables (i.e., literal symbols). Drawing upon decades of research, Lucariello et al. (2014) noted that secondary school students struggle to make sense of and use variables correctly, making errors like ignoring variables in algebraic expressions, treating variables as labels for objects, or assuming all variables refer to specific unknowns. At least part of students' confusion regarding variables is caused by the multiple meanings associated with variables in algebra (Blanton et al., 2011; Philipp, 1992; Usiskin, 1988). We refer to the meanings and accompanying uses for variables as *variable types*. Examples of variable types include *generalized number* (for expressing properties), *unknown number* (for solving an equations), and *parameter* (for describing a family of functions or problem types). Usiskin (1988) highlighted the complexity of deciphering variable type by not only identifying many variable types, but also by showing that the variable type associated with a literal symbol can change during algebraic activity, even within a single problem. While scholars have identified and described many variable types, little empirical research has been conducted to determine which variable types students encounter in secondary school mathematics, particularly in middle school where the frequent use of variables is first encountered.

In this study, we investigated the variable types used in three popular US 7-8 grades mathematics curricula: *Eureka Math* (2015), *Connected Mathematics 3* (Lappan et al., 2014), and *Glencoe Math* (2015). We sampled 3 units from each grade of each textbook series. For each textbook, we selected 2 units related to the expression and equations strand and 1 unit related to the geometry strand of the Common Core State Standards for Mathematics (NGA & CCSSO, 2010). We started our textbook analysis using a coding scheme consisting of the variable types described by Usiskin (1988) and Blanton et al. (2011). We both participated in coding all 3 textbook series, and began coding individually when interrater reliability exceeded 90% on each textbook series. Original codes were modified and new codes added as needed to fit the data.

Our analysis led to the identification of 8 main variable types. All 8 types were observed in both grades of all 3 of the textbook series. The most widely used variable types were *unknowns*, *placeholders*, and *objects*. All lessons used at least 2 variable types, and some involved as many as 5 types. Adding to the complexity of variable use was the frequent need to reinterpret a literal symbol without explicit acknowledgement by textbook authors that the type had changed. For example, the textbook authors would use variables as *placeholders* to represent relationships between quantities in a story problem, reinterpret them as *unknowns* at the start of the equation solving process, treat them as *objects* when performing symbolic manipulation, and then rethink of them as *knowns* to check the answer. Our results indicate that a sophisticated understanding of variable types and their accompanying uses is necessary to make sense of algebraic expressions and equations even in the early weeks of a 7^{th} grade course. These findings suggest a strong need for explicit instruction on variable type and use to enable students to meaningfully create, make sense of, and operate on variables in algebra.

This theoretical paper describes how Community-based Mathematical Modeling can advance equity and cultivate civic empathy in elementary school settings. We provide a framework for community-based mathematical modeling instruction consisting of five goals: facilitating connections, fostering engagement, promoting rigor, cultivating civic empathy, and elevating justice. We illustrate how these goals work together to advance equity and cultivate civic empathy through classroom vignettes of community-based modeling lessons. Through this theoretical synthesis, implications for community-based mathematical modeling instruction will be discussed.

Mathematical Modeling as an Equity and Empathy Lever

Mathematical modeling (MM) is an iterative cyclical process that uses mathematics to make-sense of and analyze real-world situations. MM includes posing the real-world problem, identifying important quantities and making assumptions to define variables, which then leads to developing a mathematical model, analyzing and assessing the solution, and refining the model (Garfunkel & Montgomery, 2019). MM nurtures 21st century skills of creativity, critical thinking, communication, and collaboration (Suh & Seshaiyer, 2013). It is an area of mathematics that offers children opportunities to grow mathematically and connect mathematics to their lived experiences, families, and communities. There has been a well-established literature on mathematical modeling. However, the centering of equity and empathy remains underemphasized (see Anhalt et al., 2018; Aguirre et al, 2019; Suh et al, 2018; Turner et al, 2022; Cirillo et al., 2016; for notable exceptions). We argue that MM is a humanizing endeavor that authentically connects to the real world, starting with ill-defined, often messy community-based problems and providing opportunities for students to develop empathy and compassion toward other people, living things and our planet (Lee et al., 2021). By showcasing children's diverse perspectives, curiosities, and mathematical and experiential strengths as resources for learning, mathematical modeling is a powerful *lever for equity and civic empathy* in the elementary mathematics classroom.

In our work, equity means that: All students **in light of their humanity** – personal experiences, backgrounds, histories, languages, physical and emotional well-being – must have the opportunity and support to learn rich mathematics that fosters meaning-making, empowers decision-making, critiques, challenges, and transforms inequities/injustices. It promotes equitable access, attainment, and advancement for all students (Aguirre, 2009; Aguirre et al, 2013).

In terms of empathy, we draw on the foundational work of Freire (1970) on critical consciousness and recent report from the National Academy of Education (Lee et al., 2021) for civic reasoning and discourse to deepen children's empathy with others who may have different perspectives. Civic empathy- "working to see the world from another person's perspective—can help us to overcome some of the impediments to listening and can improve our ability to relate to each other civically" (Lee et al., 2021, p. 39). Mirra's (2018) concept of *critical* civic empathy is useful because she differentiates individual empathy, or simply seeing another's perspective, from critical civic empathy, which includes seeing another's perspective while also engaging in structural analysis of power and privilege to take civic action for social transformation. We lean on this concept of critical civic empathy as we focus on community-based mathematical modeling. There is growing consensus that elementary grade students can engage in community-based mathematical modeling. Researchers specifically highlight how students draw on their lived experiences to support mathematizing activity (Albarracín & Gorgorió, 2020). Turner et al (2011) found that when children mathematized situations rooted in their communities, what the authors referred to as *community mathematization*, children considered the real-world implications of their decisions and models.

Recent research confirms how teachers foster this connection through *community-based* MM tasks and routines (CMM). Turner et al (2022) document how elementary teachers designed community-based modeling tasks centering social and environmental justice such as helping a community-center order food supplies to feed unsheltered families and determining plastic waste generated from the school cafeteria. Aguirre et al (under review) designed an instructional routine called Mathematizing-the-World routines (MWR) that leverages community mathematization. The MWR focuses on three prompts that are similar to those in the introductory act of Three Act Tasks (Lomax et al., 2017). The first question, "What do you notice?" strengthens students' observation skills. The second question, "What do you wonder?," builds on students' curiosities and strengthens problem-posing skills. The third question, "What questions can be solved using mathematics?" draws students' attention to problem-posing with mathematics. To foster empathy and connection while mathematical problem-posing, the teacher offers additional prompts including: Why is this question/issue important? "Why should we care about this question/issue?" "Who else might care about this question/issue?" "Why might it be important to them?" (Arnold et al, 2022). For each prompt, teachers record student responses on a class chart. In some cases, the class identifies a specific mathematical question to investigate further. The teacher may also use this routine to launch a CMM task.

This theoretical paper describes how CMM can advance equity and cultivate civic empathy in elementary school settings. We continue to push the field of MM and teacher education to center on equity, empathy, and justice; opening up space for young children to be critical decision makers and community change agents (Aguirre et al, 2019; Anhalt et al., 2018; Cirillo et al., 2016). We draw on current and past MM projects that advance equity and strengthen teaching in elementary settings. Through this work we identified 5 instructional goals that frame how CMM leverages equity and civic empathy: *facilitating connections, fostering engagement, promoting rigor, cultivating civic empathy, and elevating justice.* To illustrate these goals in action we present two elementary classroom vignettes: a MWR on analyzing racial representation in school libraries and an environmental justice modeling task on water quality. To ground our work, we propose a theoretical framework to leverage equity and empathy with CMM.

Theoretical Framework to Leverage Equity and Empathy in Modeling

Below, we identify five instructional goals in CMM instruction that advances equity and empathy in elementary classrooms: ***facilitating connections, fostering engagement, promoting rigor, cultivating civic empathy and elevating justice*** (see Figure 1). Each goal is grounded in the literature and preliminary findings from our projects.

Goal 1: Facilitate Connections

Through CMM children can connect mathematics to themselves, their peers, families, communities, and to the world. CMM acts as a mirror and a lens for students and their teachers. The emphasis on deliberately connecting to children's lived experiences promotes multiple opportunities for children to see themselves in the mathematics (mirror) and use mathematics to analyze the world around them (lens). CMM connects children with each other in order to share ideas and experiences. By building multiple connections to self, family, community, other subjects, and the world, CMM humanizes mathematics teaching and learning (Suh et al, 2018; Gutierrez, 2018).

Goal 2: Foster Equitable Engagement

CMM activities open up access to meaningful complex problem solving for children with varied mathematical, cultural, and linguistic backgrounds. Modeling lessons incorporate a variety of participation structures to elicit diverse contributions, support peer collaboration, and minimize status issues in the classroom (Featherstone et al., 2011). CMM tasks are also group-worthy tasks that have multiple entry points and solution paths for students with varied mathematical strengths to work collectively and solve (Horn, 2006). We have also seen that modeling activities build math stamina and perseverance. In our project, teachers reported more children engage in mathematics for longer periods of time with modeling activities (Turner et al, 2021).

Goal 3: Promote Rigor

CMM activities are high cognitive demand activities that emphasize observation, analysis, argumentation, and critique (Smith & Stein, 1998). All strands of mathematical proficiency can be accessed through modeling activities: conceptual understanding, procedural fluency, strategic competence, adaptive reasoning, and productive dispositions (National Research Council, 2001). Historically, one way children have been marginalized in mathematics is by denying them access to rich and rigorous mathematics. Through racist tracking practices, challenging enrichment opportunities are often reserved for children with a specific label like "gifted" or "highly capable". However, denying access to rich complex tasks that foster curiosity and problem posing is a form of dehumanization (Aguirre, 2009; Freire, 1970). CMM opens up new avenues to engage more children in high cognitive demand (rigorous) activities.

Goal 4: Cultivate Civic Empathy

Learning for Justice (https://www.learningforjustice.org/) provides educators with a set of social justice standards (Learning for Justice, n.d.) as a road map for anti-bias education with four critical domains—identity, diversity, justice and action. In the diversity domain, one anchor standard states-*Students will respond to diversity by building empathy, respect, understanding and connection.* To unpack what building empathy means, we lean on Mirra's (2018) work on critical civic empathy–moving beyond oneself and into the perspective of another person and then to take civic action. Mirra (2021) challenges educators to consider the power of empathy- "If my experience of seeking to empathize with another person's challenges does not encourage me to heal the roots of those challenges–through community action, voting, protesting—then what good is that empathy, right?" (p. 12). CMM has the transformative potential (Jemal, 2017) to develop a level of critical civic empathy that leads to action to transform contextual factors that may be perpetuating inequitable conditions and that are necessary for change.

Goal 5: Elevate Justice

CMM provides opportunities to examine issues of fairness, access, power, and civic engagement in our homes, communities, and schools. CMM and teaching mathematics for social justice share three important features: both engage students in ill-defined (messy) problems for which there can be multiple and equally valid approaches; both leverage real-world knowledge that students bring to the classroom; both raise students' interest in mathematics by supporting them to better understand their world (Cirillo et al., 2016). Children have questions about the world; they have ideas about what it means for a situation to be fair. They have heard adults talk about societal topics such as healthcare, government sanctioned violence, racism, as well as food, water, and air quality. Some experience economic hardship while others look for ways to relieve it. Some experience natural disasters such as hurricanes, earthquakes, and fires. And most recently, we have all been touched by the COVID19 pandemic. CMM can provide a space for students and their teachers to engage in these justice-focused discussions.

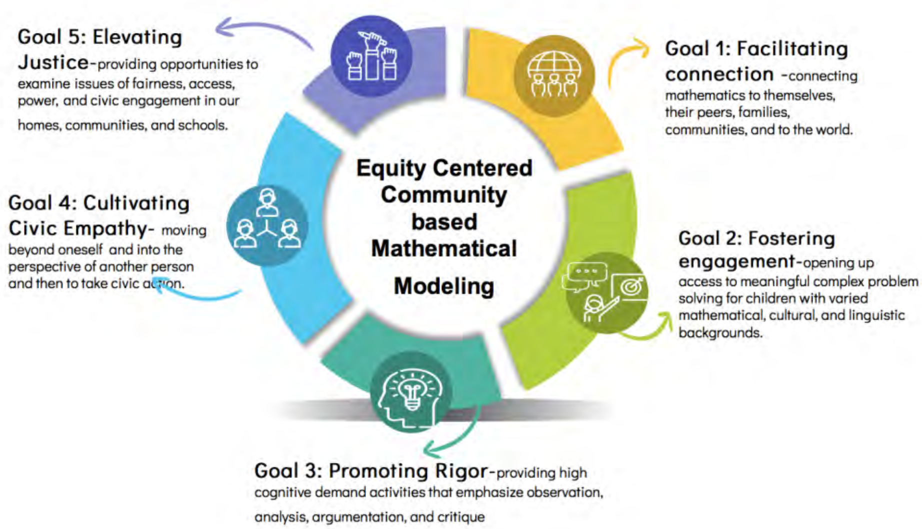

Figure 1: Theoretical Framework to Leverage Equity and Empathy in Modeling

Community-based Mathematical Modeling Case Vignettes

Vignette #1 MWR - Exploring representation of class/school libraries

The first vignette provides a picture of practice from a team of elementary teachers who wanted to integrate MM to prompt deep conversation around the important social issues of ethnic representation in library collections and to learn about race as a part of identity. They launched the unit with a MWR, where a picture prompts (see Figure 2) students to notice and wonder about a phenomenon. In order to mathematize representation of race in classroom libraries, students examined a numberless graphical representation. As students noticed and wondered about the real-world statistics the mathematician was communicating, their conversation suggested awareness of injustice. Students perceived this as an issue of fairness, connecting the availability of main character representation to the disparate number of mirrors for different races and the characters' facial expressions. Empathetic comments emerged such as, "The kids are frowning because there’s a lot of books about White people and not a lot about Brown people,” and “The Latinx girl is shocked, the mirror is broken. This is not fair.”

What do you notice?	What do you wonder?
-The kids are frowning because there's a lot of books about White people and not a lot about Brown people -Back then, they said White people were better so they didn't write as many books about other people. -The LatinX girl is shocked. -The mirror is broken. -It's not fair.	-[POC] are probably wondering why there aren't more books about them. -Why isn't it fair? -Why are they not getting the same attention as the White boy? -Why is the bear's mirror bigger than the people?

(Data on books by and about Black, Indigenous and People of Color published for children and teens compiled by the Cooperative Children’s Book Center, School of Education, University of Wisconsin-Madison)

Figure 2: Numberless Graph Depicting Characters From Diverse Backgrounds Used in Data Talk

This data talk compelled third graders to take inventory of their classroom libraries, framing an investigation to see if their personal race was represented in the main character of books (mirror of representation) as well as if they could see another's racial representation among the books (window to representation of others) (Sim-Bishop, 1990). The analysis of their classroom library involved collective decisions from the students about how to sort the books, what racial categories to use, and how to determine the race of the main character. The inventory revealed the underrepresentation of diverse main characters and led to a powerful modeling task to make their library more fairly represent their classroom demographics. The class created a model that determined how many books of diverse characters should be purchased and wrote a letter to the principal asking for funds to make their library collection more representative of the class. This vignette showcases how the CMM had a transformative potential (Jemal, 2017) to develop a level of consciousness around race representations in their library that led to action to get more books for their library.

The absence of a child’s culture and race from classroom libraries is problematic as they receive a message that their school does not think their culture is important enough to feature in the library. This library representation modeling task **facilitated connections** by giving students ownership in how they would solve the problem of underrepresentation. Having students identify books that reflected their culture and race provided an opportunity for students to make connections to their identities. It **fostered engagement** through a group-worthy task with multiple entry points for students to participate in mathematical and democratic decision making. Grade appropriate **rigor was promoted** through important data analysis, representation, and mathematical decision-making for justice. It also **cultivated civic empathy**, first with feelings of sadness and outrage at the realization of injustice, then through community pride and healing in taking action to purchase books that affirmed their own representation as well as their peers'. Taking action **elevated students’ sense of justice**, and reinforced how they can use mathematics to address inequities and transform their community into a better place.

Vignette #2 Safe Water for Schools

This vignette focuses on students learning about the importance of access to clean water through studying the Flint water crisis and engaging in a math modeling task about safe water for their school community. To **facilitate connections**, teachers launched the CMM task by building context about the water crisis in Flint, Michigan. Students read short articles and viewed images of corroded pipes and brown water in bottles. Teachers shared information about how lead is toxic to the human body, especially for children's brains. Next, teachers engaged in an MWR routine with images of water fountains covered with plastic and signs that said "do not drink" and an image of two elementary students taking a large five-gallon jug of water from a supply room. The MWR provided space to **foster engagement** as different students voiced their noticings, wonderings, and personal connections and emotions about the situation. Figure 3 depicts the wonderings from a 5th grade class. The starred questions are questions that could be answered with math. Students then pursued a modeling task that asked them to imagine themselves in this situation, **cultivating civic empathy** as they determined how many large jugs of water they would need for their class for one day, week or month.

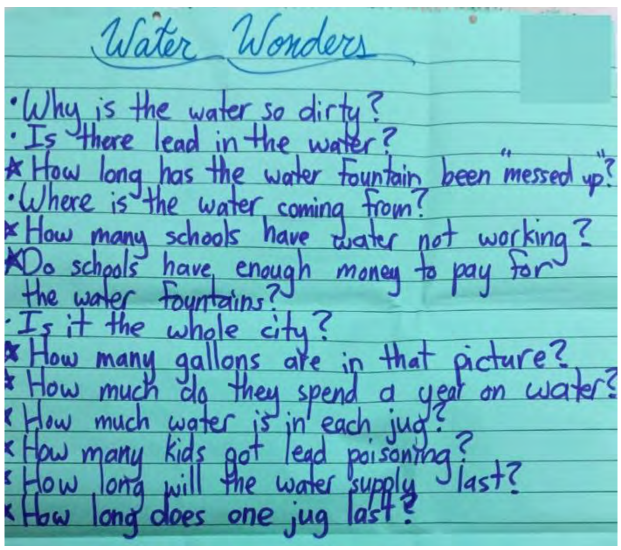

Figure 3: MWR Chart

In Ms. G's 4th grade class, students were living this reality. Their classroom sink/water fountain had recently been shut off due to lead found in the water. They had dispensers with large jugs of water in the hallway shared with other classes. Students identified two important quantities to take into consideration. They needed to figure out how many people would be drinking and how much they would drink per day. Students wrestled with who to include, for example just students; students and teacher; absent students or guests. To help students make decisions about the amount of water to drink, teachers provided a data table that gave ranges of daily water needs (in cups or ounces) by age and grade level. Teachers also shared that the large jugs were 5 gallons and there are 16 cups in 1 gallon. Students worked together in groups to make decisions that took into consideration how long they spent at school, and if people brought their own water bottles. Students' solutions varied with some groups deciding they would need 2 large jugs, 3 large jugs or 4 large jugs. After several students shared their solutions, Ms. G invited students to think about how other students could use their models if a similar situation arose in their school. In other words, to generalize.

Ms. G: So, we've all done our presentations, but we didn't get a chance to talk about what directions would you give another kid. If you were telling a kid in another class how to make a plan for how much water to order, what are some things we could say we could generalize? We can say, that is generally true, that is consistent? So, if another kid from another class wanted to make that plan for the water, what are some things we would tell them that they could do? Max?

Max: I would probably say first start off to find how many kids are in your class. And how often do they drink water? And, ask for their age and just go from there.

Ms. G: Okay so knowing their age. Does it matter that one team said 7 cups because their age was young on the chart and another team said 10 cups? Does it matter or is that okay to make a decision like that?

Many Students: Yeah - Make a decision

Ms. G: So, you make your decision and then you go with it to do the math. What else can we generalize?...

Max: One thing is to define, like, how long are you going to do it. Are you going to do it for a day, or are you going to do it for a week?

Ms. G: Ok. Amari, you have a thought?

Amari: Yeah, how do you know if all the kids are going to show up for school?

Ms. G: Yes, some kids could be absent. Those are other things. So, when you plan how many students, you might assume that somebody is going to be absent.

Ms. G. **promoted rigor** by asking students to generalize, as this communicates that students are capable of complex mathematical work. Ms. G supported students in this rigorous practice by reminding students of the components of their own models, and by revoicing the ideas that students shared. The CMM lesson **facilitated connections** as it was relevant to Ms. G's students; they found lead in the water at their school, and students were genuinely concerned about access to safe water. Finally, Ms. G **advanced equity and civic empathy** by inviting students to connect the specific situation of the task to broader issues of social and environmental justice. By generalizing their solutions, students had opportunities to cultivate empathy, and elevate justice for their own and other's communities.

Theory Synthesis and Implications for Teaching CMM for Equity and Empathy

These two vignettes illustrated how community-based mathematical modeling promotes **five equity goals** for mathematical modeling instruction in elementary settings (*facilitate connections, foster engagement, promote rigor, cultivate empathy and elevate justice*). Next, we discuss these theoretical perspectives on mathematical modeling as a lever for equity and civic empathy in relation to the phases of the mathematical modeling process.

In the first phase, *Making Sense of the Problem*, CMM affords opportunities for teachers to select meaningful contexts that connect to student experiences and issues of fairness, access, representation and justice. In both of our vignettes, elementary students were engaged in *local* community-based problems -- issues of equitable representations of classroom library collections and access to clean water - that also align with broader initiatives to reduce inequity and improve the health and lives of global citizens(https://sdgs.un.org/goals). We make these parallels to global issues to demonstrate how community-based math modeling has transformative potential (Jemal, 2017) for even young mathematical modelers to bring awareness of inequities, and to experience critical civic empathy to take action in powerful ways in their community. By providing images, videos, realia, and graphs to support students' engagement in discussion, we can position students' funds of knowledge and experiences as resources to pose problems.

In the second phase, *Identify Important Quantities*, CMM afforded opportunities to listen to students' ideas and experiences with a sense of curiosity. Modelers make assumptions and decisions when defining variables and determine what they consider to be important which impact the models they create. This is also where data can present evidence of inequities as the library representation modeling task revealed a disproportionate number of books in one racial category, as compared to the others. Older students might examine inequities in COVID 19 pandemic data such as the disproportionate mortality rate for African American and Latinx communities. These important quantities drive the need to better understand underlying issues.

In the third phase, *Build and Operate on a Model*, CMM affords students opportunities to use diverse tools, strategies and representations to build and operate on models and to recognize the strengths in other students' strategies. Teachers honor the ways that students draw on mathematical understandings and funds of knowledge in their model building work. This phase is what inquiry-based learning and "doing mathematics" looks like in terms of promoting rigor and engagement in a cognitively demanding task (Smith & Stein, 1998). This type of learning disrupts the misguided belief that children need to master the basics before engaging in rich and complex math which often happens in schools with historically marginalized student groups causing harm and differential learning experiences (NCTM, 2020).

In the fourth phase, *Analyze and Interpret Models*, CMM affords opportunities for students to collaborate, refine, and consider multiple models by comparing and contrasting strategies and to identify how decisions and assumptions impact solutions. This is a crucial component of perspective taking that is highlighted in the social justice standards (Learning for Justice, n.d.) and in the civic reasoning and discourse literature (Lee et al., 2021). Encouraging students to revise and refine models *foster engagement.*

In the final phase, *Validate and Generalize Models*, CMM encourages students to consider how the components of their own models would work or need to change in a new situation. The Safe Water task enabled students to consider situations similar to the Flint Water Crisis. And, in fact, one classroom recently had their water shut off because lead was found. Inviting students to generalize models to help others in similar situations cultivates civic empathy and empowers action to change the inequities discovered through mathematical analysis in the CMM task.

We situate this work in the midst of the 'double pandemic' (Brennan, 2020) which refers to the COVID-19 interruptions as well as the heightened awareness of systemic racism. Aligned to the PMENA 44's theme, *Critical Dissonance and Resonant Harmony*, we share this theoretical paper to engage in conversation to move beyond the "dissonance" and inequities in our world and consider how Community-based Mathematical Modeling can be a "post pandemic pedagogy" (Ladson-Billings, 2021) to advance equity and cultivate civic empathy in school mathematics. Our hope is that the framework offers a pathway for harmony and humanizing children's learning experiences in the elementary mathematics classroom.

Acknowledgments

The work reported here is supported by a grant from the National Science Foundation (Grants 2010269, 2008997, 2010202, 2010178). We would like to thank all the courageous educators, children and families who continue to impress upon us the importance of making our world a more just and humanizing place.

DISCOURSES OF JUSTICE: CONNECTING VISIONS AND PRACTICES TO IDENTIFY AREAS FOR FUTURE RESEARCH AND TEACHING

Megan Brunner
Oregon State University
brunnerm@oregonstate.edu

This systematic review aims to identify the Discourses (Gee, 2000) invoked regarding justice in PK-12 mathematics education literature, linking visions and practice. The three Discourses of Justice presented in this manuscript draw upon different visions of justice, where the differences arise through the proposed locus of change – the individual (Empowerment), the institution (Transformation), and ideologies around purposes of education (Democracy). However, the Discourses also share similarities across the associated teaching practices for each. There are differences in usage of these Discourses across the literature, which present opportunities for innovations in future research and teaching toward a more just math education system.

Keywords: Social justice; systemic change; instructional vision

Social justice in mathematics education has been a long-standing and evolving conversation among researchers (Gutierrez, 2002, 2013; Ladson-Billings, 1995, 2021; Martin, 2019; Secada, 1994), teacher educators (Aguirre, et al., 2019; Bartell, 2013; Felton-Koestler, 2019; Wager & Stinson, 2012), and teachers and administrators (Gutstein, 2006, 2013; NCSM & TODOS, 2016). Each of these groups of stakeholders has wondered, what does it mean to do social justice work in mathematics education? How does one teach mathematics, prepare teachers, or conduct research in a way that serves social justice goals?

In response, many have raised the need for identifying classroom practices that can support more just mathematics teaching (Aguirre & Zavala, 2013, Bartell, et al., 2017, Garii & Rule, 2009). Others have talked about the need for teachers to develop critical consciousness and reflective capacity to better attune to the dynamics of power and privilege in their classrooms (Esmonde, 2014, Gutstein, 2006, Harper, 2019, Kokka, 2019, Ladson Billings, 2021, Stinson, 2014). As the field engages in these conversations, a variety of terminology is invoked to problematize the state of mathematics education and identify focal points for change. These differing perspectives can lead to challenges in understanding the outcomes of possible instructional innovations; across the literature, different implications for practice may be aligned to a variety of perceptions of what justice entails (Chubbuck & Zembylas, 2008) Researchers, teacher educators, and teachers look to the literature for insight and inspiration on next steps towards justice. Thus, it is important to be able to parse what members of the field perceive as justice and the connected actions they suggest to make progress towards those aims.

Parsing perceptions of justice and their associated practices can occur by examining the framings researchers link together when discussing justice in mathematics education. Some mathematics education researchers have called out the ways different framings operate to communicate the values, beliefs, and perspectives one might hold and how these perceptions shape their actions, such as Louie's (2017) exploration of a culture of exclusion in a mathematics department. In this study, I use the term "vision" to describe the multifaceted set of values, beliefs, goals, and priorities that guide one's exploration of justice. Many researchers claim that teachers' classroom practice is entangled with their visions of justice (Adiredja & Louie, 2020; Chubbuck & Zembylas, 2008; Gutierrez, 2002; Horn, 2007). Consider that the problem perceived by a researcher influences the focus of their study, the data they collect, and the ways they interpret that data; the problem articulated by a teacher educator shapes the conversations they facilitate and the facets of instruction they focus on in their teaching; the purpose teachers perceive for shifting their instruction influences the practices they enact and the ways they interact with other members of their institutions. Making visions of justice and the connected practices and actions explicit provides a foundation to unpack the ways researchers, teacher educators, and teachers work towards the goal of a more just mathematics education. Explicitly articulating a vision of justice is challenging, yet without the acknowledgment of problems of injustice one perceives, the instructional choices one makes can become confused or misaligned with their goals toward justice.

This study is a systematic literature review of K-12 mathematics education research regarding justice. First, I overview foundational literature on justice in K-12 mathematics education. Then, I articulate the theoretical underpinnings of Discourses as a way to connect visions of justice and the actions taken to achieve that vision (Gee, 2000, 2008). I discuss my methods for selecting relevant literature and the coding process I applied, through which I found three different Discourses of Justice in K-12 mathematics education research. I present each Discourse of Justice and detail the ways it is invoked across the research base. Finally, I propose implications for research and teaching based on the current status of Discourses of Justice in the field.

Theoretical Background

The ways that people use language and other forms of communication build on those that come before them, which serves to construct sets of meaning or interpretation. Gee (2000, 2008) identifies these sets of meaning as Discourses, where invoking a Discourse can identify one as a certain type of person. Invoking a Discourse involves not just language (written or spoken) but also "…language, other symbolic expressions, and 'artifacts', of thinking, feeling, believing, valuing, and acting" (Gee, 1996, p. 131). These features are considered discourses, or "stretches of language in action" (Gee, 1996). Regarding the research literature, discourses are the ideas and practices captured in stretches of writing. The ways these discourses are used to make an argument across a manuscript draws upon (and simultaneously adds to) particular sets of meaning or framing (Discourses). Invoking a certain Discourse can help position the researcher towards a certain audience or align their work with other researchers in the field.

Visions of and Practices Towards Justice

Discourses can be recognized through the beliefs, values, and goals one insinuates, and the actions, or practices, one engages in towards those goals (Gee, 2000, 2008). In this study, I consider the beliefs, values, and goals one holds about the future of a more just mathematics education as their "vision of justice" (Hytten & Bettez, 2011; Picower, 2012). A vision of justice can encompass the reasons justice is needed (i.e., the injustice being addressed), the things justice should provide or lead to, and the key features of justice that are seen as necessary and important. Visions of justice refer to the overarching perspectives one holds for what education should look like in a more just world. Visions of justice include macro-level considerations about value systems and perspectives that one considers regarding mathematics education. These values and beliefs are communicated through micro-level interactions as one takes action to achieve their goals (Ryve, 2011). The other component of Discourses is the practices that align with certain beliefs, values, and goals. Practices include the habitual actions of instruction and the pedagogical strategies one might engage in to achieve a teaching goal (Lampert, 2010). Practices may be of a variety of grain sizes, but they are action-oriented and implementable in contextually situated ways. Practices may not be aligned with any one vision of justice. The combination of visions of justice and the practices one sees as serving that vision are what constitutes a Discourse.

Conveying Meaning via D/discourses

D/discourses (Gee, 1996, 2000) coordinate the ways language is used to construct and negotiate meaning, where language involves not just speech and text but also actions, practices, and ways of interacting. Discourses are sustained through the cultural, political, and institutional recognition that happens within interactions as a result of the ways individuals portray and perceive themselves and others (Gee, 2000). That is, as individuals interact with others, they invoke parts of Discourses that give insight into the meanings they are conveying and the ways they want to be perceived.

Discourses may be invoked in a few ways. First, we can *revoice* language stretches associated with a particular Discourse. Revoicing serves to align intended meanings with the histories and prior uses of that phrasing (Bakhtin, 1981). In research, revoicing occurs through citations or quotations to support an argument; in teaching, revoicing may come through discussing certain pedagogical resources or goals an educator holds for a lesson or task. Framing one's work alongside others who use similar language in their research and teaching raises a set of meanings from which to interpret their current argument. Another way Discourses might be invoked is through similar cues of meaning explicated through new stretches of language (e.g., talk and action), otherwise thought of as *refracting* (Volosinov, 1973). Refracting is the reauthoring of a Discourse into a new context. The power of refracting is important to acknowledge, as discourses are enacted within interactions; individuals need to act in a way that draws upon available Discourses but fits the context in a given moment.

Discourses are macro-level frames for sense-making that get recognized in interaction through combinations of practices, behaviors, values, and tools, among other features. Drawing upon certain Discourses can support utilizing specific tools or practices to achieve objectives. Discourses link perceptions of situations to the actions one may take toward an objective; in pursuing a goal of a more just mathematics education system, the Discourses available to an actor will shape the perceptions of justice they hold and the actions they see as necessary to achieve it. Likewise, holding a certain vision of justice may influence the practices that one sees as accessible at a given moment. This study argues that connecting visions of justice and the practices that achieve those visions will help researchers, teacher educators, and teachers more clearly communicate their goals for education regarding justice.

Research Questions

Identifying the Discourses that are available across the field of K-12 mathematics education research and teaching can be challenging - Discourses are culturally recognized and acknowledged, so they can operate implicitly as well as explicitly in one's actions. However, knowing how researchers, teacher educators, and teachers are invoking Discourses to situate their work of transforming the mathematics education system is necessary to understand their scope and intentions. Further, recognizing different framings of justice (against the perception of injustices currently existing in the mathematics education system) is necessary to continue aligning, innovating, and imagining the actions that are possible to take in creating change and a more just system. Thus, this study explores the questions:

1. What are the Discourses of Justice that exist in the literature on justice in PK-12 mathematics education?

2. How does the literature on justice in PK-12 mathematics education invoke Discourses of Justice? What implications does this have for future research and teaching?

Methodology

Systematic literature reviews provide a synthesis of the research base on a topic, to present arguments for new perspectives or provide insight for future research (Petticrew & Roberts, 2008). This systematic literature review serves to synthesize research on justice in K-12 mathematics education and to present an argument for using Discourses of Justice as an organizational and analytical lens in future research and practice.

Data Collection: Identification of Literature

To identify literature relevant to the construction of Discourses of Justice, I set a series of selection criteria. I searched the Education Resources Information Center (ERIC) and Google Scholar to look across general education and mathematics databases for manuscripts published after 2000 regarding "mathematics" AND "justice" to yield 409 and 420 initial results, respectively. Subsequent rounds of criteria were applied to the initial results to narrow the focus and applicability of selected papers to answer the research question (Petticrew & Roberts, 2008; Yolcu, 2019). Manuscripts that did not explicitly discuss mathematics *and* justice in these three areas were excluded. Then, I skimmed the entire body of the remaining manuscripts for definitions of justice and explicit focus on teaching mathematics in grades PK-12. Texts that did not make an explicit theorization or definition of justice were excluded. In this stage, I also excluded manuscripts that did not explicitly connect to PK-12 mathematics education in terms of research focus or participants. Finally, I read each of the remaining manuscripts in full, excluding papers from the same author or group of authors which leveraged the same articulation of justice. In my reading of the data set, I kept notes on additional texts that were regularly cited about social justice research but had not been identified in my original search results; I reviewed each of these texts using the exclusion criteria laid out above, and 5 additional manuscripts passed each stage and were added to the data set. Thus, the data set for this study consisted of 70 total manuscripts focused on PK-12 mathematics education and justice.

Data Analysis: Segmenting and Coding for Discourses of Justice

Once demographic information was identified for all manuscripts in the data set, I segmented each text into sections. Segmenting the manuscripts provides a narrower focus for coding and allows for patterns to arise around how Discourses are invoked throughout manuscripts in the field. The three-section descriptions I used to chunk each manuscript were *Problem Setting*, *Theoretical Framing*, and *Findings & Discussion*. While these sections are aligned with some headers of manuscripts, every paper uses a unique organization for its argument. I only coded the sections of the manuscript that were specific to justice and mathematics education.

I read each manuscript section multiple times and highlighted phrases or sentences that provided answers to each of the analytic questions, color coding for each (Table 1).

Table 1: Analytic Questions for Eliciting Discourses

Analytic Questions	Contribution to Eliciting Discourses
Q1. Why is "justice" important?	articulates the problem needing to be solved
Q2. What will "justice" provide?	evidence of the action that should occur
Q3. Who decides what "justice" is?	identifies the stakeholders and responsible actors

Q4. What are the key elements of "justice"?	clarifies the focus and values of the Discourse
Q5. How is "justice" assessed or achieved?	explains what tools and practices will get utilized
Q6. What implications for "justice" are reported?	reports challenges and insights for tools and practices

Adapted from Churchward & Willis (2019)

As this open coding process was completed for each manuscript, I kept memos to track common themes and patterns I noticed in the ways authors discussed justice (Auerbach & Silverstein, 2006). I regularly re-read all the excerpted text across all coded manuscripts for each analytic question to identify new themes in the data or notice outliers in the framing of justice used across manuscripts. Once all 70 manuscripts were coded and entered into the spreadsheet, I created themes of the Discourses of Justice out of my memo-ed patterns. I then re-read the manuscripts and coded the manuscript sections with the Discourse of Justice descriptions. Instances where the text excerpts from coding did not align with the descriptions of the Discourses led to revision across the themes, until all Discourses were able to be applied to the coded data without outliers (Auerbach & Silverstein, 2006).

The resulting three themes, or Discourses, represent sets of meaning that encompassed answers to all six analytic questions. These Discourses stand apart from one another due to the focus placed on what needs to occur to achieve justice in mathematics education. The Discourse of Justice as Empowerment centers on the empowerment of individuals in pursuing justice; the Discourse of Justice as Transformation focuses on taking action to challenge systems, structures, and policies at an institutional level; and the Discourse of Justice as Democracy identifies a need for ideological change to truly achieve justice in mathematics education.

Findings: Three Discourses of Justice

The three Discourses of Justice (DoJ) presented in this manuscript draw upon different visions of justice, where the differences arise through the proposed locus of change. However, the Discourses also share similarities across the associated teaching practices for each. I discuss trends for how each DoJ is invoked throughout arguments in manuscripts in K-12 mathematics education. I connect each trend to potential reasons for their existence and propose future areas of exploration and innovation for research and teaching.

A Discourse of Justice as Empowerment

The Discourse of Justice as Empowerment (DoJ-E) gains its name based on its focus on the empowerment of individuals via mathematics education. In this frame, justice is achieved through individuals becoming more empowered. this occurs through developing students' (a) mathematical power (e.g. Gutstein, 2003; Frankenstein, 2013; Nicol et al., 2019; Voss & Rickards, 2016); (b) participation, agency, and identity (e.g. Aguirre, et al., 2013; Hand, 2012; Planas & Civil, 2009), (c) humanity and ethical awareness, (e.g. Atweh & Brady, 2009; Boylan, 2009; Nava et al., 2019; Register, et al., 2020) and (4) awareness of the power and role of mathematics in structuring the world (e.g. Brelias, 2015; Felton-Koestler, 2017; Gutstein, 2016).

Patterns of Empowerment. The DoJ-E centers on the improvement of individual learning opportunities and personal growth in awareness and agency. This Discourse was the most commonly invoked of the three, with 100 percent of analyzed papers containing at least one section that referenced this Discourse (Table 2). Only 13 papers did not cite a notion of justice based on the DoJ-E in the problem setting section. Almost every single manuscript analyzed in this study leveraged a theoretical background (64 of 70) or presented findings or implications (68 of 70) that invoked a DoJ-E. Further, this Discourse was consistently invoked throughout manuscripts, with 56 out of 70 papers drawing upon a DoJ-E in every section. This implies that many researchers in mathematics education are envisioning justice as empowerment from their initial conceptualizations of problems for study, through their articulation of justice and the theories that guide their study and return to notions of empowerment in their presentation and interpretations of findings.

Table 2: Discourse of Justice Across Manuscript Sections[1]

	Problem Setting	Theoretical Framing	Findings & Discussion	At Least One Section[2]	All Sections[3]
Empowerment	57	64	68	70	56
Transformation	31	43	32	51	17
Democracy	19	14	17	28	7

[1]n=70 total manuscripts reviewed
[2]number of papers that invoked the Discourse of Justice in at least one section of the manuscript
[3]number of papers that invoked the Discourse of Justice in every section of the manuscript

This focus on individual empowerment draws from the research base, which has a strong focus on identity, participation, and practices as evidence of learning. In 2000, Lerman invited the sociocultural turn in mathematics education, followed by Gutiérrez's (2013) call to take up sociopolitical perspectives in teaching and research. Research from these perspectives regarding teaching practice and social justice naturally involves some focus on impacting individuals. Researchers, teacher educators, and teachers alike must focus on supporting all students' growth as mathematicians and as people in the pursuit of justice. True systemic justice cannot happen without individual empowerment and changes within interpersonal interactions (Gutiérrez, 2009). It is challenging to do social justice work (Gregson, 2013; Gutstein, 2003) and discussing specific practices and principles that impact learning and classroom interactions can seem more manageable (Bartell, et al., 2017), as well as provide more opportunities for evidence of change. However, researchers and practitioners must be able to connect practice to the broader visions for justice and the mechanisms for change they are working through; without this explication, the impact of these practices may not address structural issues past those at the micro-level of classroom interactions.

A Discourse of Justice as Transformation

The Discourse of Justice as Transformation (DoJ-T) resonates closely with ideas from foundational critical theorists and mathematics educators who discuss justice such as Freire (1993) and Gutstein (2003, 2006). Researchers who discuss notions of justice using the DoJ-T focus on taking action to challenge and transform unjust systems, structures, and policies. These researchers move past building awareness of inequities or providing access for success within inequitable systems to discuss actions to shift the systems themselves. This Discourse is invoked as researchers frame goals of social justice teaching towards transforming (a) the norms and practices of the discipline of mathematics (e.g., Felton-Koestler, 2019; Hughes & Laura, 2018; Povey, 2002, (b) structures and policies in schools (e.g., Kokka, 2015; Raygoza, 2020; Rands, 2013), and (c) societal organization and systems (e.g., Gutstein, 2013; Leonard & Moore, 2014; Martin et al., 2010).

Patterns of Transformation. The DoJ-T was regularly evoked across literature on justice in K-12 mathematics education. This Discourse encompassed conceptions of justice that focus on the disruption of unjust systems, structures, and policies – and acting to right those wrongs. Fifty-one manuscripts cited a DoJ-T at least once across possible sections (Table 2). Of these instances, 43 manuscripts invoked a DoJ-T in the Theoretical Framing sections (84%). Some of these manuscripts elaborated a DoJ-T from their initial conceptualization of a problem through to their results or implications (n=17). Of those 43, 10 manuscripts invoke a DoJ-T only in their theoretical framework, and not in any other section of their argument. This pattern shows that DoJ-T is most commonly referenced through explication of theoretical foundations and is less likely to be drawn upon in setting up studies or interpreting findings.

The predominance of DoJ-T in the Theoretical Framework sections of manuscripts, whether in conjunction with other DoJs or on its own, speaks to the power of envisioning structural change in mathematics education. Much of the foundation for this power can be traced back to critical theorists in mathematics education, such as Freire (1993), Frankenstein (1983, 1990), and Gutstein (2003, 2006). These theorists all identify some component of transforming society and schooling in their conceptions of justice. As researchers, teacher educators, and teachers build on these foundational ideas of justice in math education, they are revoicing notions of transformation. The revoicing of DoJ-T consists of the vision of justice and fair systems, as well as the call to action. Less common in this revoicing is a variety of practices and implications of what this call to action might entail. The literature emphasizes the use of real-world, open-ended tasks within which students construct alternative solutions that rectify inequities, which are still challenging to incorporate effectively (Bartell, 2013; Gregson, 2013; Gutstein, 2003, 2016; Harrison, 2015). However, because of the hesitation to turn “justice” into a set of teaching practices – instead choosing to talk about justice as a sliding signifier (Larnell, et al., 2016; Stinson & Wager, 2012) – it is challenging to communicate how to act towards transformation in their environments. Transformation is a lofty vision, and the steps to achieve it are not clearly defined. Future research should support the linkages between micro-level interactions and structural transformations necessary for achieving system-wide justice.

A Discourse of Justice as Democracy

The Discourse of Justice as Democracy (DoJ-D) attends to a broader ideological motivation for pursuing justice. The ideological purpose of general education discussed concerning social justice work is to prepare well-developed and successful persons to sustain society. This vision of justice entails pursuing democratic societies constructed and maintained by civically engaged persons (Apple, 1992). Achieving justice involves the organization of teaching and learning to serve these democratic ideals. In mathematics education scholarship, researchers who discuss justice through a DoJ-D identify ideals of preparing members of society who take up (a) democratic participation and environments (e.g., Frankenstein, 1990; Panthi, et al., 2018; Reagan, et al., 2011) and (b) citizenship and civic engagement (e.g., Bond & Chernoff, 2015; Kokka, 2019; Ndlovu, 2011; Tanase & Lucey, 2017).

Patterns of Democracy. The DoJ-D was the least likely of the three Discourses to be invoked across the research base. The DoJ-D was found in 28 unique manuscripts (Table 2). Papers often leveraged notions of justice as democracy when constructing their problems for research (n=19) or in discussing implications of their arguments (n=17). A further 14 papers mentioned democracy in their theorization of justice. However, only 7 papers invoked a DoJ-D across every section, which implies that 13 of the 28 total articles referencing democracy only utilized a DoJ-D in one section and did not carry this thread consistently across their argument. I see this trend of DoJ-D as evidence that phrases like “democracy,” “citizenship,” or “civic/political engagement” are connected to broader ideologies around the role of education in preparing students to be meaningful participants in society. This ideology is useful to justify the attention to social justice in mathematics, but there is a lack of connection to clear theorizations and aligned practices to achieve it.

The role of democracy and citizenship as central principles of teachers' pedagogy requires critical thinking and analysis, not just the incorporation of specific teaching practices into classrooms. The DoJ-D lacks consistent refraction in manuscripts such that it is challenging to understand how one should work toward goals of democratic justice. Many manuscripts do not as clearly link instructional practices to visions of justice through the lens of DoJ-D (e.g., Turhan Turkkan & Karakus, 2018), or they identify instructional practices that overlap with those suggested in other DoJs. Ladson-Billings (1995) notes that citizenship can be achieved best by the practice of critically analyzing societal injustices, which connects DoJ-D to Transformation. Other researchers echo this call, articulating that TMfSJ practices, which emphasize transformation, are essential to creating a democratic society (e.g., Gutstein, 2003; Reagan, et al., 2011). Register and colleagues (2020) theorize about the role of mathematics literacy in public policy and decision-making for the democratic preservation of society; however, when discussing implications for teaching, these authors recommend practices around identity work and participation, rigorous mathematics, and other forms of empowerment. Other manuscripts simplify their calls for democracy by building democratic participation through group work and complex tasks (Kokka, 2015) or equitable turns of talk (Hung, 2015), similar to strategies aligning with the DoJ-E. Researchers need to explicate connections they see between the DoJs or provide more context to facilitate discussion on how teaching practices might be different in action when attending to different visions of justice.

Conclusion: A Call to Action

This study is a systematic literature view of the ways justice is discussed in research on K-12 mathematics education. It provides a theoretical lens of Discourses (Gee, 2000, 2008) to connect visions of what justice provides with the actions necessary to achieve it. The three DoJs that arose from the analysis of the literature represent different articulations of justice around different mechanisms of change (the individual, the institution, and ideologies, respectively). This manuscript posits that these DoJs are invoked inconsistently across research arguments, with some Discourses more fully connected and articulated than others. The patterns of use led to the identification of areas for future scholarship and exploration. The purpose of establishing this lens is not to prioritize one DoJ over another, nor is it to critique the existing research's current innovations towards constructing a more just mathematics education system. Rather, this perspective provides an opportunity for intentional reflection in scholarship on justice in mathematics education and identifies areas for further exploration and clarification of how to move, together, towards a more just system.

Acknowledgments

Many thanks are extended to Dr. Rebekah Elliott for their ongoing support around the ideas expressed in this paper.

EQUITABLE TEACHING PRACTICES: DEVELOPING EMERGENT BILINGUALS' POSITIVE MATHEMATICAL IDENTITIES

PRÁCTICAS EQUITATIVAS DE ENSEÑANZA: DESARROLLANDO IDENTIDADES MATEMÁTICAS POSITIVAS EN LOS BILINGÜES EMERGENTES

This paper focuses on Emergent bilinguals (EBs) who traditionally face unequal opportunities to learn mathematics, harming their identities. The purpose of this paper is to illustrate how a fifth-grade teacher cultivated the development of her EBs' mathematical identities by giving them opportunities to participate in cognitively demanding activities. Drawing on a conception of mathematical identity as something that changes in response to different situations, we illustrate how a fifth-grade teacher positively impacted her students' mathematical identities. The results reveal that when teachers use instructional strategies such as distributing mathematical authority, positioning students as mathematically capable, and incorporating students' languages as a resource for instruction, their EBs have multiple opportunities to build positive mathematical identities.

Keywords: Equity, Inclusion, and Diversity, Instructional Activities and Practices, Problem Solving.

Most teachers in the United States have or will have Emergent Bilinguals (EBs) in their classrooms, and few are well prepared to teach them (Samson & Collins, 2012). In this paper, the term EBs is used as equivalent of the term English Language Learners (ELs) because it has a more positive connotation of students language abilities; It acknowledges students proficiency in one language who are becoming proficiency in another language (de Araujo et al., 2018). EBs face unequal opportunities to learn mathematics, reflected in their limited access to advanced mathematical courses and experienced and qualified teachers (Flores, 2007; Samson & Collins, 2012). One approach to address the opportunity gap is to provide EBs with meaningful opportunities to learn mathematics (Moschkovich, 2013). Providing equitable opportunities to learn mathematics for EBs entails increasing their access to teachers who focus on developing their reasoning and use language as a means to enhance instruction (Moschkovich, 2013). An outcome of such instruction is positive mathematical identities for EBs (Bartell et al., 2017).

This paper explores how "Ms. Wilson" implemented equitable teaching practices to support students to develop positive mathematical identities. Equitable teaching practices allow teachers to provide all students with opportunities to participate in cognitively demanding activities that enhance their mathematical identities (Moschkovich, 2013). The equitable teaching practices portrayed in this study were implemented to support every student, particularly those historically marginalized by race, class, ethnicity, culture, and language. The research question we explore here is: How do the opportunities provided to EBs during the implementation of equitable teaching practices help students develop positive mathematical identities?

Equitable Mathematics Teaching Practices

Equitable teaching practices in mathematics are defined as teachers providing all students with opportunities to participate in high cognitively demanding activities that respond to students' needs and enhance their mathematical identities (Moschkovich, 2013). Equitable mathematics teaching practices develop students' conceptual understanding, mathematical reasoning, and mathematical identities through discourse by integrating students' previous knowledge, cultures, and languages (Moschkovich, 2013). Bartell et al. (2017) identified nine equitable mathematics teaching practices: Draw on students' funds of knowledge, establish classroom norms for participation, position students as capable, monitor how students position each other, attend explicitly to race and culture, recognize multiple forms of discourse and language as a resource, press for academic success, attend to students' mathematical thinking, and support the development of a sociopolitical disposition. In this study, we highlight three of these practices as characteristics of Ms. Wilsons' classroom that positively impacted her students' mathematical identities: (1) Positioning students as capable, (2) Recognizing multiple forms of discourse and language as a resource, and (3) Establishing classroom norms for participation.

Teachers' instructional practices determine the degree to which students develop confidence in themselves and see them as mathematical doers (Aguirre et al., 2013). Teachers can support students' development of positive mathematical identities by believing in their students' capabilities, allowing students to use diverse strategies and forms of communication, giving students a voice, and monitoring students' identities development (Allen & Schnell, 2016). Students' positive mathematical identities are developed when their peers or teachers recognize their mathematical contributions (Wood et al., 2019). Unfortunately, EBs are more likely to face low expectations and be stereotyped, harming their mathematical identities (Flores, 2007). Positioning students as mathematical capable is promoted when teachers move away from stereotyping students based on their cultural backgrounds, select challenging curricula, and share mathematical authority with students (Bartell et al., 2017). Classrooms in which teachers hold high expectations for their students result in students having more opportunities to learn challenging mathematics (Flores, 2007). Teachers provide students with opportunities to communicate their ideas, justify their reasoning, make sense of others' ideas, and transfer their knowledge to other contexts and concepts (Banes et al., 2018; Moschkovich, 2013). Moreover, teachers consider students' cultural and linguistic differences as strengths (Bartell et al., 2017).

As part of their instruction, teachers should choose high cognitively demanding tasks and maintain or enhance that demand during classroom implementation. Cognitively demanding tasks have the potential to develop students' conceptual understanding through oral and written explanations that involve pictures, gestures, diagrams, and formal and informal language (Wood et al., 2019). In a classroom where promoting mathematical reasoning is the goal, tasks must provide opportunities for all students to engage in thinking, make comparisons, establish relationships, make conjectures, validate, and justify their thinking (Vale et al., 2017). Teachers of EBs must provide mathematically and linguistic rich tasks that allow all students to collaborate, interact, think, talk, reason, and use their first language (McGraw & Rubinstein-Ávila, 2009). Instruction of EBs needs to incorporate processes such as explaining, comparing, conjecturing, generalizing, justifying, and exemplifying, referred to as the language of reasoning (Bragg et al., 2016). Teachers should use questions, sentence frames, and prompts to support students in communicating their reasoning (Coleman & Goldenberg, 2009). Tasks serve as resources for positioning students as mathematic doers and consequently enhance their mathematical identities.

Equitable teaching practices for EBs support developing mathematical reasoning by implementing mathematical activities that allow students to use multiple resources to understand, solve, and communicate their mathematical ideas (Moschkovich, 2013). Teachers of EBs need to emphasize the development of everyday and academic English language and focus on culturally diverse and inclusive practices (Samson & Collins, 2012). Incorporating students' first language and cultures creates a school philosophy where home and community are integrated, facilitating access to the curriculum, reducing stress, and maintaining self-esteem (Necochea & Cline, 2000). Teachers are encouraged to use students' first languages for support when possible. For example, prior to a lesson, teachers might preview the content for the students in their primary language and identify vocabulary and different representations that may help students in the communication process (Coleman & Goldenberg, 2009). Additionally, translanguaging, identification of cognates (e.g., equation and ecuación), and use of words in context are strategies teachers can use to help students make meaning of new languages (Coleman & Goldenberg, 2009). Translanguating goes beyond language switching and includes all the linguistic resources to communicate based on social and cultural practices (García & Wei, 2014).

In general, students benefit from teachers establishing sociomathematical norms for participation as an equitable teaching practice (Bartell et al., 2017). Sociomathematical norms go beyond regular classroom norms and are specific norms in mathematics that regulate discussion, encourage students to justify their mathematical ideas, make their reasoning clear, and improve their reasoning skills (Yackel & Cobb, 1996). Sociomathematical norms influence the effectiveness of instruction by providing an adequate environment to support student engagement. In particular, establishing sociomathematical norms helps build a community by setting up and guiding discussions so that all students have a voice and their participation is valued (Bartell et al., 2017). As students become familiar with the accepted norms, they understand their role and the role of others in the classroom (Yackel & Cobb, 1996). In equitable classrooms, students have consistent opportunities to share their reasoning and to assess the reasoning of others; they become a mathematical authority in the classroom (Cobb et al., 2009).

Mathematical Identity

Research on mathematical identity considers students' persistence and interest in mathematics, their motivation to learn mathematics (Cobb et al., 2009), and the relationship between learning and cultural and social issues that influence the learning environment (Cobb & Hodge, 2007). Teachers' instructional choices determine the impact that instruction will have on students and the degree to which they develop positive mathematical identities (Aguirre et al., 2013). As part of instruction, teachers should support students to develop confidence and see themselves as powerful doers of mathematics. Teachers can accomplish this goal by grouping students to work collaboratively, establishing high expectations for students, and creating environments where teachers are facilitators of classroom activities (Bartell et al., 2017). Allen and Schnell (2016) share some strategies that teachers can use to support students' development of positive mathematical identities. These strategies include knowing and believing in the students, reconceptualizing mathematical success (e.g., giving value to the use of different solution strategies instead of already defined procedures), prioritizing students' voices, and monitoring identity formation. Teachers should know and believe in their students' capabilities. In short, "viewing student attributes as assets rather than deficits" (Allen & Schnell, 2016, p. 401). When students believe in one another as problem solvers, they are able to value the positive contributions of their peers.

Meanwhile, teachers can use instructional strategies such as representing new ideas in diverse ways, asking purposeful questions, listening to others, revoicing and paraphrasing students' reasoning, discussing an idea before writing it down, establishing connections, and communicating mathematics ideas using different forms of communication (Moschkovich, 2013). Teachers can prioritize student voice by giving students opportunities to discuss their ideas in small groups and then in the whole class. The incorporation of formative assessments can support teachers to assess student's readiness and understanding of the language and the content of the lesson, as well as tools to monitor identity formation (Allen & Schnell, 2016; Hakuta, 2014).

Beyond these strategies, distributing classroom authority and incorporating students' languages and cultures as resources during instruction are equitable teaching practices (Moschkovich, 2015) that support students' burgeoning mathematical identities. Using language as a resource allows EBs to discuss and share their mathematical reasoning and understand mathematics. An important part of such instruction involves teachers creating a learning environment where students' roles and norms for participation are well defined; specifically, students understand that their ideas are important and need to be publicly shared (Yackel & Cobb, 1996). Additionally, teachers need to promote respectful relationships among students and position them as mathematically capable (Bartell et al., 2017).

Theoretical Framework

The theoretical framework for this study is socio-constructivism, which integrates cognitive, constructivist, and socio-cultural theories to make sense of the different teaching practices and examine students' mathematical reasoning, languages, and identities (Shepard, 2000). Cognitive theories provide the means to look at students' thinking structures as they develop their solutions and specific forms of reasoning (in this case, algebraic reasoning). Constructivist theories guide our analysis of social constructions of knowledge through discourse by looking at classroom interactions. Finally, socio-cultural theories inform our interpretation of students' prior knowledge, experiences, and languages in developing their mathematical identities (Cobb & Hodge, 2007).

Research Methodology

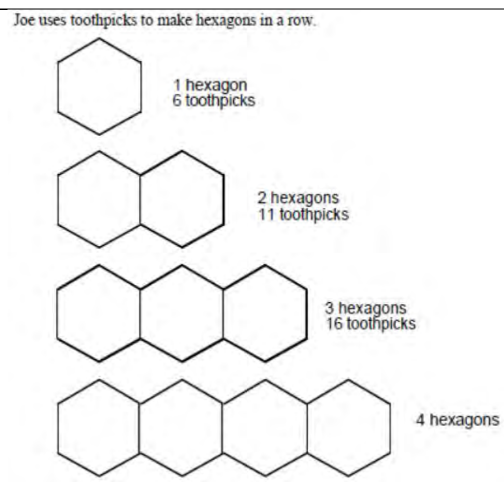
During the 2019-2020 academic year, we gathered detailed evidence of a teacher's and students' experiences during problem-solving lessons (Creswell & Poth, 2018). An explorative case study helped us identify the research question and the procedures to refine our intervention (Yin, 2014). A fifth-grade teacher, "Ms. Wilson" who worked in an urban elementary school, and our research team, collaborated three times to develop the "Discursive Mathematics Protocol," an instructional protocol designed to support the development of students' mathematical reasoning and language competencies (see Kitchen et al., 2020, for additional information about the DMP). The DMP builds on Pólya's (1945/1986) iconic problem-solving heuristic and incorporates research-based "language practices" and essential teaching practices borrowed from the *Principles to actions: Ensuring mathematical success for all* (NCTM, 2014).

This paper examines how Ms. Wilson's implementation of the equitable teaching practices with the aid of the DMP contributed to developing her students' mathematical identities. Ms. Wilson is a bilingual (English-Spanish) White woman certified as an English as a Second Language (ESL) teacher. When this study was undertaken, Ms. Wilson had taught for five years, attending a significant number of EBs because of her ESL expertise. For each problem-solving lesson, the research team engaged Ms. Wilson in a planning session conducted via Zoom prior to the lesson and in a debriefing session after the lesson. The focus of the planning lessons was on the language and cognitive demand of the task, possible strategies and challenges, and the formulation of questions to elicit students' thinking and participation. The debriefing sessions serve as a space for reflection and improvement. The teacher and the team discuss what went well in the class and what can be improved to support students' participation and development of mathematical reasoning and language. During the problem-solving lessons, the three research team members and Ms. Wilson followed a co-teaching approach (Cook & Friend, 1995) to teach the lesson (roles and amount of teaching vary across lessons). Team teaching served as a strategy to directly support Ms. Wilson to plan, deliver, and reflect on the problem-solving lessons.

We gathered information to gain insights about the equitable teaching practices and how the different opportunities provided to EBs supported them to develop positive mathematical identities. We collected data from two problem-solving lessons that included students' work, videotapes of interactions among students and Ms. Wilson and just the students, and videotapes of Ms. Wilson carrying out each lesson. In addition, we interviewed Ms. Wilson to learn directly from her about the teaching practices she implemented to support EBs in developing positive mathematical identities.

We interpreted videotapes, student work samples, and the interview conducted with Ms. Wilson using interpretative methods (Creswell & Poth, 2018). The emergent themes summarize Ms. Wilson's beliefs and teaching practices during problem-solving lessons that supported students' development of positive mathematical identities. In the findings, we discuss each indicator by examining Ms. Wilson's narratives, her teaching practices, and her students' work.

For the problem-solving lessons illustrated here, the "Hexagons in a Row" task (See Figure 1) was implemented. In the first, second, and fourth questions, students start by finding near generalizations (patterns that can be found by drawing or making a short table) and then directly apply the derived functional relationship to find a far generalization (patterns that require to find arithmetic or algebraic expressions) (Callejo & Zapatera, 2017). In questions 3 and 5, students apply the inverse of the functional relationship derived (reverse thinking) (Callejo & Zapatera, 2017) to find the number of hexagons made with a given number of toothpicks.



1. How many toothpicks does Joe need to make 5 hexagons? Explain how you figured it out.
2. How many toothpicks does Joe need to make 12 hexagons? Explain how you figured it out.
3. Joe has 76 toothpicks. How many hexagons in a row can he make? Explain how you figured it out.

Extension questions

4. How many toothpicks does Joe need to make 100 hexagons? Explain how you figured it out.
5. Joe has 1001 toothpicks. How many hexagons in a row can he make? Explain how you figured it out.

Figure 1: Hexagons in a Row task

Research Findings

We identified three major themes related to equitable teaching practices enacted in Ms. Wilson's classroom during the mathematics lesson to support EBs' development of positive mathematical identities: Sharing mathematical authority, positioning students as mathematically capable, and incorporating students' languages as resources for instruction. Table 1 summarizes the different indicators we identified in the data. All the vignettes are instances of EBs' oral participation in the class or written work.

Table 1: Themes Derived for Mathematical Identity

Theme/	Indicator	Practice code
Sharing mathematical authority	Students had consistent opportunities to develop and articulate their solutions to tasks and assess the solutions of others (Cobb et al., 2009)	Exchange and assessment of ideas
	Students acknowledge the importance of making their ideas public shared (Bartell et al., 2017).	Making ideas public
Positioning Students as mathematically capable	Teachers believe their students are mathematically capable (Bartell et al., 2017).	Teacher's beliefs
	Choose and implement high cognitive demand tasks.	Tasks
Incorporating students' languages as resources	Incorporate of students' languages as resources during instruction (Moschkovich, 2015)	Language
	Review vocabulary and develop mathematical language (Banes et al., 2018).	Vocabulary
	Engage students in mathematical discourse (Banes et al., 2018).	Discourse

Ms. Wilson Shared her Mathematical Authority. She distributed the authority in the classroom, letting students share their ideas and assess the ideas of others. She engaged students in productive discussions that included asking purposeful questions, using and connecting multiple representations, interpreting diagrams, and discussing ideas in small groups and whole-class discussions. Throughout, Ms. Wilson encouraged students to build arguments and to reject or accept the strategies or solutions presented in the class. For example, three students shared the expressions they use to calculate the number of toothpicks to make 12 hexagons. Students discussed the similarities, differences, and validity of those expressions to answer the problem. Most of the students could indicate what each number in the expressions represented (number of hexagons, number of toothpicks to make one hexagon, and number of touching sides) and applied those expressions to respond to questions in the task. Laura described the three different expressions provided for her classmates giving the arguments for their validation (expression 1: 12 x 5 + 1, expression 2: 6 x 12 -11, expression 3: 5 x 11 + 6)

> Me and Sandra said that for the first one, 12 times five plus one; Ryan was looking at it like they were all five [the number of sides in a hexagon]. And then he saw that one of them has six sides while the others have five, so he had to add that one to show that one is six [has six sides]. The second one, six times 12 minus 11, shows that it was easier for them to think of them [the sides] as all six and then because only one of them was six and there was 12 hexagons, they needed to subtract 11 because one still has six [sides]. [For] five times 11 plus six; we thought of it as the two different groups, the groups of the fives and the one six, and so it just depends on how you group them.

Laura's explanation showed a clear understanding of the different strategies. She acknowledged her peers' ideas and tried to make sense of those ideas. Students presented their solutions, while

Ms. Wilson asked them to indicate the meaning of each term in their expressions. We can see that through this exchange, Laura was able to summarize the different strategies indicating how many sides were counted, how the hexagons were grouped, and why some expressions included addition and others subtraction. Laura was able to connect multiple ideas and restate others' thinking. In Ms. Wilson's class, students were constantly asked to make their ideas public and assess others' ideas to engage them in learning mathematics and as a means to demonstrate that their ideas were important contributions. Students in Ms. Wilson's classroom valued all the mathematical ideas presented to solve the task. Ms. Wilson let students decide when a strategy or solution was wrong.

Positioning Students as Mathematically Capable. Ms. Wilson's high expectations were reflected in her students' positive attitudes and participation in the class. She believed in students' capacities to solve challenging tasks. In the following excerpt, Ms. Wilson talked about the hexagons in a row task and the possibilities it offers to the students.

> … when I was thinking about [choosing a task] I was trying to think more in line with the content that I was doing, but I think this one was broader, and so it allowed for more thinking and problem-solving, which is something I would like to be focusing on more…how does this [content of the task] connect to a bigger mathematical idea or what can you take away from this and use later because I feel like there's so much good in math and the hexagons task that maybe some of them [the students] will say I can look for these different patterns next time.

When implementing cognitively demanding tasks, Ms. Wilson was challenged by some of her students who had negative attitudes toward mathematics or lower expectations for themselves. Some of her EBs were not confident about their abilities. We asked her how she dealt with EBs when they did not participate in the class and how she helped them realize that they could solve the task.

> Students like Samuel [an EB student], he definitely wants teacher direction first, even if he does understand. He wants to like to clarify everything with me. So I'm working on it with him of like, we can talk through it, but I'm not going to tell you what to do. And same with today, he really likes to just know that he's doing the right thing. And so, for them, it's just like building confidence.

Building students' confidence increased their participation and helped them develop positive mathematical identities. Ms. Wilson created a learning environment that empowered her EBs. She constantly compared their work to the work of mathematicians. At the conclusion of the problem-solving lesson, she stated the following to the whole class:

> What does complete [a task] look like? It is having an answer for each question, showing your work for each question, and then explaining your thinking. Each place [questions in the task] has explain how you figure it out. You will not be able to communicate with them [the researchers] after this task is over, right? So, you have to put it in writing. Great mathematicians put their ideas into writing.

Ms. Wilson had high expectations for her students and prioritized their voices. Students talked about mathematics, compared their solutions, tried other strategies, and assessed their thinking and other students' thinking.

Incorporating Students' Languages as Resources in Instruction. Ms. Wilson recognized and valued students' backgrounds as a resource to learn mathematics (Aguirre et al., 2013). Her acknowledgment of students' languages helped her EBs develop positive mathematical identities. As a whole class, they discussed the meaning of some words, used the words in context, and put the problem in their own words. Mathematical discourse played an important role in supporting students to understand the task and share their ideas using multiple forms of communication. Students in Ms. Wilson's class mainly increased their vocabulary by talking. Gestures were widely used to describe mathematical patterns during which students pointed at different parts of the diagram or showed how to count the toothpicks and the shared sides. Gestures combined with speech helped students assess their thinking by noticing disagreement between the description provided and the elements pointed to in the figure. One EB, Samuel, explained that there were four shared sides in four hexagons in a row. He used the diagram as an aid to explain his understanding of the task. When counting and pointing to the shared sides, Samuel realized that there were just three of them. The use of gestures supported him and other students to communicate their ideas. Ana, another EB, used her pencil and the figure representing four hexagons to explain how she found the number of toothpicks needed to make five hexagons:

> What I did was I got 6 as like a whole, so there is 6 right there [circle the first hexagon and write down 6], and then there's 1, 2, 3, 4, 5 [she outlined the second hexagon using the pencil] and then there's 5 [counting the third hexagon], and then there's 5 here and then is 5, 5, 5, and since there are five hexagons is another hexagon right there [sketching the fifth hexagon] so then 5 times 4, because is 4 right then plus 6 because is the hexagon here [She pointed out the first hexagon in figure 4] and then 26 which is the answer.

Consistently communicating her ideas and combining linguistic resources (gestures, diagrams, language) helped Ana and other students to assess their solutions and become more confident about their ideas.

Discussions and implications

In this study, we explored how the implementation of equitable teaching practices provided EBs with opportunities to develop positive mathematical identities. Ms. Wilson's implementation of equitable teaching practices, such as opportunities to solve cognitively demanding tasks, use multiple forms of discourse and language, position students as mathematically capable, and share mathematical authority, helped her students develop positive mathematical identities. She valued the ideas of her students and held high expectations. The excerpts show that representations, discourse, gestures, and language served as resources for students to communicate their reasoning, increasing their opportunities to participate in class to share and assess their ideas (Banes et al., 2018; Cobb et al., 2009). Students like Laura recognized multiple solution strategies and were able to justify the validity, similarities, and differences between them. Students in Ms. Wilson's class had the authority to evaluate others' thinking and were positioned as mathematical capable. Their linguistic approaches were seen as strengths instead of deficiencies contributing to the development of positive mathematical identities (Bartell et al., 2017).

Incorporating equitable teaching practices in the mathematics classroom benefits all students, increasing participation and enhancing students' mathematical identities (Cobb et al., 2009; Yolcu, 2019). This study demonstrates that incorporating equitable teaching practices is beneficial for EBs to develop positive mathematical identities. Specifically, our analysis of equitable teaching practices shows the benefits of providing opportunities for EBs to simultaneously develop mathematical reasoning and language competencies.

This research report analyzes the process of engaging 18 youth in urban emergent communities to enact Digital Mathematics Storytelling to explore their mathematics identities. The youth, in grades 7-11, engaged in the process of crafting and sharing their digital mathematics stories within two week long summer camps. Using a Participant and (Re)design Research Methodology, the research team explored how the constructs of Digital Storytelling, Mathematics Identity, and Storytelling can help us better know how to craft experiences that connect to youth knowledge.

Keywords: Equity, Inclusion, and Diversity; Design Experiments; Informal Education; Technology

Objectives

During the COVID-19 pandemic, many urban emergent school districts[1] in the United States of America, already dealing with racial and socioeconomic segregation, were overwhelmed with how to support the health and safety of their students and communities, while also responsible for their students' academic learning. Because of this context, research projects based within school settings had to either switch to a completely remote model or completely disconnect from the school context.

Our research team delt with the dissonance of our urban emergent partner schools having to engage in a much more stressful version of teaching by enacting a community-based approach, creating our own external summer camp experiences to invite youth to work with and co-create ways to enact Digital Mathematics Storytelling together with us without having to burden school and teaching partners. In particular, our summer camps hoped to create community-oriented spaces for thriving mathematics conversations, particularly for youth from urban emergent communities, after a year of remote learning that isolated many young people from their school communities. While our other work focuses on the actual stories and learning that young people enacted when engaging in Digital Mathematics Storytelling, this paper focuses on the ways our research team were able to plan, augment, and enact two week-long summer camps to best serve and learn from 18 youth, aged 12-17, in the wake of the COVID-19 pandemic. The objectives of this research study involved: (1) developing a protocol for Digital Mathematics Storytelling through Participatory (Re)design Research and (2) understanding how youth might see the construct of storytelling as connected to their own mathematics identities.

[1] The term urban emergent signifies communities in large cities, but not as large as metropolitan areas such as New York or Los Angeles. These urban emergent communities, however, encounter the same scarcity of resources and historical issues of segregation (Milner, 2012).

Theoretical Perspectives

Non-white children in urban emergent communities are often positioned in ways that do not allow them to craft their own mathematics identity. In particular, while students in urban emergent communities live mathematically rich lives, they are provided few opportunities to connect their out-of-school mathematical knowledge to in-school mathematics tasks that are often based on white, middle-class lifestyles they cannot relate to (Civil, 2009; Nasir & de Royston, 2013). For instance, when a student shares about the intricate proportional reasoning she witnesses in the kitchen as her mother and aunts prepare multiple dishes in unison, she positions them not only as holders of culinary knowledge, but also of mathematics knowledge. However, scaling up this approach of connecting out-of-school mathematics knowledge to in-school mathematics learning has been difficult because (1) family and community mathematics often operates socially, involving storytelling and group problem solving, while school mathematics is often positioned as internal knowledge measured individually (D'Ambrosio, 1985; González et al., 2001; Powell & Frankenstein, 1997), and (2) exploring students' home and community mathematics knowledges asks for even more labor from already overworked teachers.

Community Funds of Knowledge

One approach to address this issue of connecting out-of-school mathematics to in-school mathematics is through *funds of knowledge*, which honors families, communities, and the knowledge they bring to classroom mathematics. This community-based approach to mathematics teaching recognizes that "the historically accumulated and culturally developed bodies of knowledge and skills essential for household or individual's functioning and well-being" are mathematically rich resources (Moll et al., 1992, p. 133). A child's motivation to learn mathematics, thereby increases based on the increase in connections they make between two types of mathematics: (1) the mathematics they see in their families and communities and (2) the mathematics they experience in the classroom (Aguirre et al., 2013; Civil, 2016; González et al., 2001).

Within most urban and urban emergent communities, mathematics knowledge exists within social discourses such as storytelling (Turner et al., 2009). However, in the mathematics classroom, mathematics is treated and assessed as individual knowledge with little social interaction (González et al., 2001). For instance, Turner et al. (2012) detailed how well-meaning elementary teachers who were not from a Latinx community created a contrived mathematics activity around buying and selling *raspados* (shaved ices) at a community stand, but they did not ask children nor community members to share how mathematics conversations actually take place at the *raspado* stand. Surface-level attempts like this create harm by tokenizing children's cultures and imposing foreign values. In this case, the teachers imposed a value of capitalistic efficiency–getting the most *raspados* for your money, rather than connecting to community values (Bright, 2016).

To be successful, a community funds of knowledge approach to mathematics teaching must invite family and community members into the learning experience (Moll et al., 1992). These experiences help mathematics educators become part of the communities they serve, helping them understand how mathematics knowledge exists outside of Eurocentric ways of knowing (D'Ambrosio, 1985; Powell & Frankenstein, 1997), how mathematical thinking is situated within local contexts (Lave, 1988), and how to merge the classroom and community spaces to form a third space that honors all practices, knowledges, and beliefs (Gutiérrez et al., 1999). However, reaching this level of awareness is particularly difficult as it essentially asks teachers to become ethnographic researchers (Oughton, 2010). This approach also has a tendency to prioritize teachers' cultural capital, since the teacher is often involved in translating the community knowledge for the classroom (Oughton, 2010; Turner & Drake, 2016).

Digital Storytelling

Another approach to connecting out-of-school mathematics to in-school mathematics involves the ancient art of storytelling. When students in urban emergent communities tell narratives about their out-of-school mathematical experiences, they position themselves and their communities as mathematical. They tap into the power of authorship to counter stigmas that discourage them from engaging in mathematics (Aguirre et al., 2013; Love, 2014; Özpinar et al., 2017). In a world where video and image-sharing platforms, such as Instagram and TikTok allow for routine sharing of personal stories (Rideout, 2017; The Associated Press-NORC Center for Public Affairs Research, 2017), a strong case exists for utilizing these emerging digital literacies. Therefore, this study's aim involved developing and exploring how Digital Mathematics Storytelling, a mechanism in which students use videos, photographs, and audio to craft and share mathematically-rich narratives from their families and communities, might help connect out-of-school mathematics to in-school mathematics in a non-school-based setting.

Digital storytelling involves using images, voice, and music to tell a story in the form of a short one to five-minute videos (Lambert, 2013). Storytelling is the primary mechanism for sharing important knowledge between generations in nearly all cultures–the very act of storytelling can define a community, a history, and a shared knowledge base (Prusak et al., 2012). Furthermore, children from marginalized communities often tell counter-stories that push against deficit-focused stereotypes, using these stories to explore and strengthen their identities and connect more deeply to their communities (Delgado, 1989; Duncan, 2006; Matias & Grosland, 2016).

The transformative moment in a digital storytelling cycle happens within the listening-focused small group space called the *storycircle*, when storytellers share their stories-in-progress to each other (Lambert, 2013). This storycircle forges a collaborative learning space where participants see the value of their cultural and community identity (de Jager et al., 2017). It is within the sharing of and retelling of stories that mathematics identities are formed as children begin to see themselves as part of their mathematics narrative (Aguirre et al., 2013; Chao, 2014; Langer-Osuna, 2015; Sfard & Prusak, 2005). Often, structured story prompts or visual organizers can help children manage the complexity in their stories (Ohler, 2006), so that children do not simply document what is happening, but craft a narrative that involves conflict, growth, and change in order to strengthen their ties to the community. Simply put, Digital Mathematics Storytelling is not just documenting what one sees, but involves crafting a narrative that centers one's humanity, growth, conflict, and soul.

Figure 1 shows our initial framework of a digital mathematics storytelling experience, which features *two* storycircles, the first involving self-reflection and the second involving sharing drafts for feedback from peers and adults. In this example, a 4th-grade child initially wants to tell a story about how she uses mathematics in the kitchen, a classic connection to home mathematics. In her first storycircle, as she thinks about how to tell her story and realizes that she does not see much measuring and adherence to recipes at home, but rather sees her mother and aunt cooking through approximation and tasting. In her second storycircle, she shares her emerging narrative with peers and uses their feedback to assemble video and audio clips to create a finished video to share at a culminating community screening. This research paper troubles our initial Digital Mathematics Storytelling framework by exploring the research question: *During* *the COVID-19 pandemic, when engaging in classroom-based research became too burdensome for teachers in urban emergent communities, what happens when enacting and building a Digital Mathematics Storytelling workshop for youth, particularly in connection to the construct of mathematics identity?*

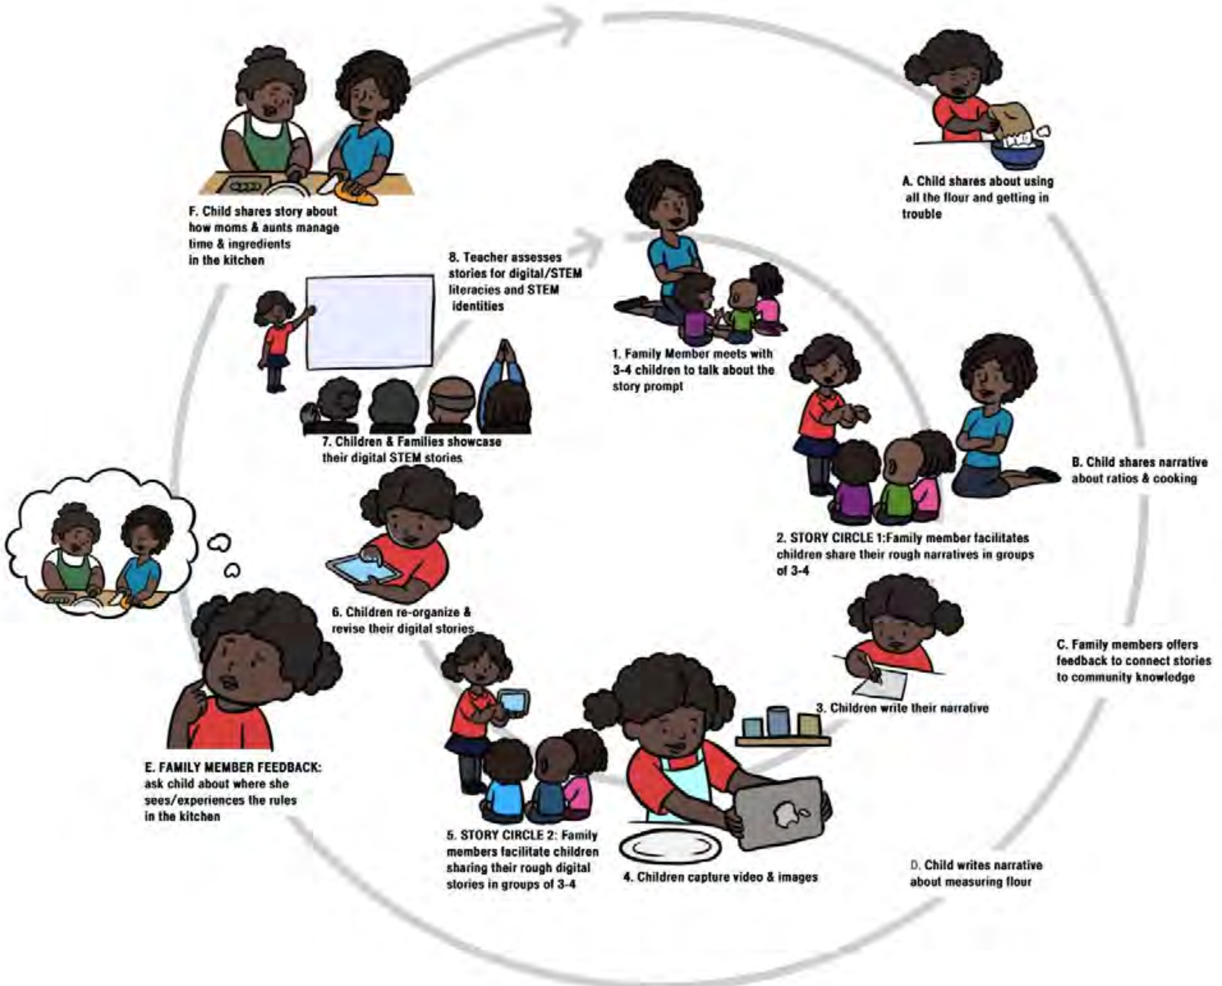

Figure 1. The Initial Storycircle Framework, which shows how a child's mathematics story evolves through two storycircles of reflection, sharing, and revision.

Research Design and Methodology

The research team enacted two week-long digital mathematics storytelling camps involving 18 students, aged 12-17, in grades 7-11. The students came from a variety of school districts and ethnic backgrounds and were recruited heavily from the researchers' own networks. The camps were hosted at a university-owned community innovation and outreach center in the Midwestern region of the United States of America. Because the camp was hosted in a facility operated by this university, all participants had to show proof of COVID-19 vaccination, which potentially influenced the pool of recruited participants.

Participatory and (Re)design Research

Researching technology that values participants' voices invites a Participatory Design Research methodology, which builds upon design-based research, but positions all participants as integral to designing the research goals and aims (Bang & Vossoughi, 2016). One of the main critiques, however, of design-based research (Cobb et al., 2003; The Design-Based Research Collective, 2003) is that, while very suitable for technology-driven educational research, the researchers still hold the authority to make research decisions (Engeström, 2011). Therefore, we attempted to enact a modified (Re)design Research method, to allow participants to not just engage in the enactment, but also help us with the very design of the Digital Mathematics Storytelling research framework itself.

By utilizing feedback from students who participate in the Digital Mathematics Storytelling camp, we used this developmental study to focus on developing protocols of how to implement Digital Mathematics Storytelling for middle and high-school aged students in urban emergent communities. Additionally, we explored the ways that Digital Mathematics Storytelling impacted and allowed insight into students' evolving mathematics and storytelling identities.

Research Measures

Pre and Post-Interviews. Over the course of the first two days of the Digital Mathematics Storytelling camp, a member of the research team met with each student to talk about the student's identities around mathematics and digital storytelling in a 5-to-10-minute interview. Then, on the last day of the camp, each student engaged in a similar 5-to-10-minute post-intervention interview with a research team member. These interviews also asked students about what they would like to change about the camp, which allowed us as facilitators to alter our daily structures to respond to what the students felt could better help them become Digital Mathematics Storytellers..

Analysis of Digital Mathematics Stories. The final Digital Mathematics Stories that the students submitted as their "final project", as well as the digital artifacts (videos, images, photographs, text comments) that the students used in their process to create their stories, were also analyzed. In this paper, we focus less on the content of these stories and more on what they unveil about the ways the camp and the protocols of Digital Mathematics Storytelling engaged the students.

Reflective Analysis. Over the course of the two camps, the students engaged in the developing Digital Mathematics Story curriculum. At the beginning of the first camp, this curriculum consisted of four loose modules, each involving a combination of whole-group, small-group, and individual activities. The modules were designed to take about three hours to enact, which was the length of each day of the camp. This initial Digital Mathematics Story curriculum was created and maintained by the research team and based heavily on the existing Digital Storytelling modules created over the past 30 years by StoryCenter (Lambert, 2013). Every afternoon, after the students had left the camp, the research team met for an hour to discuss how the day went and how to alter the next day's plans, with the only caveat being that the camp should culminate in the students creating individual 3–5-minute Digital Mathematics Story videos to present on the last day of the camp. These conversations were recorded and served as an artifact of how we engaged in continual tweaking and augmentation of the daily activities to best engage the students.

Analysis

The three measures, as detailed in Table 1, show: (1) The Pre and Post-Interviews, (2) analysis of the Digital Mathematics Stories, and (3) the recordings and notes of the daily reflections to document how we changed the curriculum. First, in terms of exploring ways to enacting a Digital Mathematics Storytelling protocol, we used a Participatory (Re)design Research Framework (Bang & Vossoughi, 2016; de Jager et al., 2017; Lambert, 2013). Second, to attend to student's mathematics identities as connected to other narrative and other social identities (Aguirre et al., 2013; Langer-Osuna & Nasir, 2016; Sfard & Prusak, 2005).

Table 1: Alignment of the research objectives, data collection, and analysis methods

Research Objective	Data	Analysis
Enactment of a Digital Mathematics Storytelling Experience	Pre/Post Interviews Students' Stories Reflective Conversations	Participatory (Re)design (Bang & Vossoughi, 2016; The Design-Based Research Collective, 2003)
Mathematics & Storytelling Identitites	Pre/Post Interviews Students' Stories	Identity as Narrative (Sfard & Prusak, 2005)

Results

Evolution of the Digital Mathematics Storytelling Enactment

The initial digital mathematics storytelling modules consisted of a warmup game to start the day, two initial activities to help get students comfortable with making and editing videos, and four daily modules focusing on students making videos that explored their identities as a (1) storyteller, (2) digital storyteller, (3) mathematician, and (4) digital mathematics storyteller. Additionally, each morning started off with a community building game. Each of these modules focused on exploring activities around those identities such as learning to tell a story in three acts or how a close-up shot conveys a different tone than a wide-angle shot.

In the early feedback from the students and our own reflective conversations, we noticed that (1) students gravitated towards group tasks and wanted to engage in almost all activities in small groups as opposed to individually and (2) students who signed up to attend this camp thought that this would primarily be a mathematics camp and thereby were hoping to have more opportunities to engage in mathematics. Both early observations led to modifications to our protocol.

Community Activities

This summer camp occurred in 2021. Every single student in our camp had spent the prior year in a remote or virtual learning environment and had missed opportunities to work with other peers in a physical setting. So, we decided to augment all the modules so that they did not emphasize individual videos and contributions, and to use the majority of our camp time to focus on community and group activities and games. This was a move that seemed appreciated, as almost every one of the post-interviews mentioned that the best part of the camp was the games that students played to get to know each other and build camaraderie. In hindsight, we even realized that the end goal of having each student create their own individual digital mathematics story took away from this emphasis on community as it situated digital storytelling as an individual endeavor. In the post-interviews, all but three of the students mentioned that they had much more fun working on the group video projects as opposed to making their own individual videos. And when students were asked to create individual video stories, two students never finished their videos, but were willing contributors to the group video stories. Figure 2 shows an example of the ways the students engaged in creating videos together in small groups.

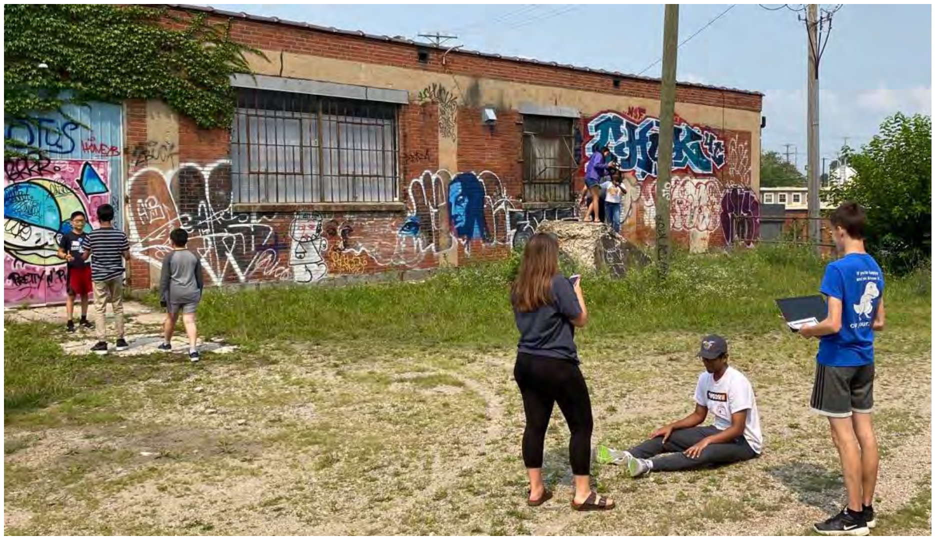

Figure 2: One finding was that students engaged much more with group video storytelling, as shown here, as opposed to making individual videos.

Mathematics Identity

Because so many of the students wanted to engage in mathematics, the research team decided to stop focusing so heavily on telling stories and actually engage the students in an augmented mathematics circle, opening up space for students to join groups to solve open-ended, challenging mathematics tasks. Figure 3 shows a group of students analyzing and discussing each other's strategy to an open-ended mathematics task. In the majority of the post-interviews, students mentioned how much fun it was to engage in this open ended, inquiry-based mathematics discussion, particularly because it was so different than the mathematics they were used to doing at school.

Figure 3: Students were surprised that this was more a video making camp and not a mathematics camp, so we gave them an opportunity to engage in group mathematics problem solving

Storytelling Identity

Additionally, students expressed to us that they found engaging in visual storytelling and learning about storytelling to be quite new and challenging. The majority of students who attended the camp shared that they had experience making videos in the past, but that these were videos for class projects or talking head videos. In our emphasis on understanding the various aspects of video filmmaking, such as exploring the differences in wide, medium, close-up, and extreme close-up shots or how to diagram a story into an exposition, rising action, climax, falling action, and conclusion, we realized that a generational divide existed between what we, as educational researchers thought storytelling was as compared to our students. We crafted our modules to explore storytelling from unpacking popular commercial films from *Pixar* or *Marvel Studios*. But what we found was that, while these pop-culture references were recognized by the students, our students' funds of knowledge around videomaking and storytelling revolved more around a new style of visual communication: *the YouTube video*. Again and again, our students wanted to make videos where they spoke directly to the camera, use graphics and editing features that drew visual emphasis onto particular objects or close-ups, and contemplate how to engage the viewer *after* their video was viewed.

Discussion

Overall, our digital mathematics storytelling camps opened a space for us to learn directly from our participants about how to enact and support the process of digital mathematics storytelling, as connected to emerging mathematics and storytelling identities. As with all (re)design research, what we sought was not a solution to a problem, but to better understand a process, the process of connecting storytelling to mathematics using digital video technology. First, we found that our students in urban emergent communities craved opportunities to engage with each other, both as mathematicians and storytellers. We interpret this to mean that as a field, the mathematics experiences our students encounter are too heavily based in individual accomplishment and competition. Second, we learned that our own interpretation of digital storytelling needs to be updated for the modern world, in which our own students' savviness with the language of *TikTok* and *YouTube* enabled them to revise what digital storytelling is and looks like. And finally, we all struggled in connecting storytelling to mathematics. A week-long camp is not enough time to do away with the years of focusing on mathematics as solving short, single-answer problems and seeing and understanding the ways narrative structures can be used to explore mathematical thinking. Our work is ambitious. But through this experience, we found a glimmer of hope that a digital mathematics storytelling experience can start re-orientating a student as to what mathematics is, how it connects to personal experiences, and how it is the product of one's own narrative.

Acknowledgments

We are thankful to our participants and their families for sharing their time, their communities, and their very personal stories and experiences during these Digital Mathematics Storytelling camps. This work is supported by NSF, Project #1943208.

WHITENESS IN FEARMONGERING TOWARDS MATHEMATICS EDUCATION REFORM

Eric Cordero-Siy	Michael Lolkus	Frances K. Harper
University of Wisconsin-Madison	Purdue University-West Lafayette	University of Tennessee-Knoxville
epsiy@wisc.edu	mlolkus@purdue.edu	francesharper@utk.edu

In this paper, we analyze a widely shared article from a prominent conservative media outlet that positions current mathematics education reform as something to be feared. We characterize how the text upholds whiteness and positions actors attempting to accomplish reform as bad actors. This work has implications in how mathematics education researchers can understand, approach, and respond to the current backlash towards reform and beyond.

Keywords: Social Justice; Equity, Inclusion, and Diversity; Policy

Recent reform efforts to center issues of equity and social justice in mathematics classrooms have been under fire from the loudest sectors of right-wing media. In its current form, reform efforts have centered around the inclusion of social justice discussions in mathematics classrooms or as some policy-makers frame it, "critical race theory" with some states explicitly banning the topic and setting up "tip lines" to report teachers who teach anything that could be misconstrued as teaching "critical race theory." The hysteria around incorporating social justice issues in mathematics classrooms has been increasing alongside recent attacks on mathematics education researchers. For instance, critics of the proposed new California mathematics framework argued that integrating issues of racial justice in mathematics will water down rigorous mathematics and harm society because "with fewer people who know math well, how are we going to build bridges, launch rockets or advance technologically?" (Evers, 2021). Even though the number of vocal critics of the current mathematics education reform (MER) are increasing, there has been little work to understand the nature of the backlash and how it is growing. It is essential to understand the machinations of the backlash because it is through understanding the tools of backlash, we can contextualize meanings and diffuse their potency (Rubel & McCloskey, 2019). In this paper, we ask, "How is the current MER movement towards racial and social justice framed in conservative media?" Using critical discourse analysis (CDA) and theories of whiteness, we examine a National Review (NR) article on the current MER. We demonstrate how this text upholds whiteness by the ways it constructs MER and its actors.

Theoretical Framework

We examine the resistance to current MER efforts toward racial and social justice in mathematics education through the lens of whiteness. Whiteness, "the ideology that maintains White supremacy, valuing one racial group over others" (Battey & Leyva, 2016, p. 50), operates in mathematical spaces to maintain the status quo, across three dimensions of *institutional*, *labor*, and *identity*. Here, *institutional* refers to neutral approaches to teaching mathematics, privileging of some voices and histories, and recognizing who has power in mathematical spaces; *labor* recognizes the ways in which emotional, behavioral, and cognitive contributions of marginalized individuals are undervalued; *identity* recognizes ways in which people who identify as white or with white ideals are granted unearned privilege and unquestioned validity. Furthermore, in (mathematics) education, "those who benefit from whiteness hoard real property to gain intellectual property" (Bullock, 2017, p. 633).

We also adopted Okun's (2021) lens of white supremacy culture to consider ways in which power is maintained. We are interested in four of the 18 elements: *fear*, *one right way*, *either-or and the binary*, and *power hoarding*. Okun shares *fear* is the primary strategy for sustaining white supremacy culture by undergirding all other elements, and "promised safety is false because it is always based on the abuse and misuse of power" (p. 7). *One right way* adheres to the belief that there is one right way to do things, and those who do not conform must have something wrong with them. An *either-or and binary* perspective limits the recognizing possibilities of both/and, and attempts to simplify complexity. Finally, *power hoarding* is used in white supremacy to instill the belief that there is limited power to go around.

Data, Methods, and Analysis

We use CDA to "explore connections between educational practices and social contexts" (Mullet, 2018, p. 117) and how power structures are maintained (Oughton, 2007). We explored one text from the NR entitled "The Folly of 'Woke Math'" (Spivak, 2021). To analyze the text, we used Mullet's (2018) CDA framework. Mullet outlines CDA in stages, yet allowing for flexibility to "best fit the scope and goals of the research problem.... [and] textual analysis is also left to the analyst." In this case, we use whiteness constructs to interpret the data. Moreover, Mullet cautions analysis may "further the researcher's own ideological agenda, rather than the agenda of the disempowered" (p. 123). To this end, we are mathematics education researchers and teacher educators (two of whom are white) with a commitment to racial and social justice.

Based on the framework, we selected a discourse to examine (i.e., the backlash to decenter social and racial justice in MER), selected and explored the background of a text, identified overarching themes, analyzed external (i.e., Discourses, ideologies) and internal (i.e., power, positionalities) relations, and interpreted the themes as manifestations of whiteness. Although literature on whiteness helped sensitize us to code for themes, concepts from the literature on whiteness were used to interpret the themes rather than dictate the themes.

We selected the NR text because the backlash against current MER is fueled by accessible, widely shared articles such as this text. NR is credited for defining conservatism in the modern American era (Hart, 2006; Sivek, 2008; Bogus, 2011) with many conservatives crediting NR as formative in their understanding of politics (Del Visco, 2019). In their 2021 media kit, NR received 25 million page views, produced 75,000 units for print, and communicated with 788,000 newsletter registrants and 1.4 million followers on social media. They also identify their audience as 86% male, 14% female, and a household income of $187,000 (they do not specify the measure of central tendency). Of their readers, 84% "took action as a result of reading NR." The text we analyzed (i.e., Spivak, 2021), has been shared on social media 1,678 times according to sharescore.com. By examining sources with a strong ideological identity, we show the constructed identities and how they operate within an ideological bound (Del Visco, 2019).

Results & Discussion

In Spivak's (2021) article, NR constructs mathematics in ways aligning with how researchers have operationalized whiteness in mathematics education. They also construct and position current MER as internally inconsistent, dangerous, and growing. This results in a fear-based image of the current MER. In our elaboration, we use quotations for direct lifts from the text.

Naming the Paradigm: Backlash to a Threat to whiteness

Throughout the text, the author elaborates on "woke math," which we call *the paradigm*—white supremacy culture is upheld by long-standing conceptions of mathematics (e.g., focus on answers, using correct methods). In opposition, the author positions mathematics as objective:

> It is an undeniable truth that there are correct and incorrect answers in basic math. There is no white math, or black math. There is only math. Americans, particularly our black and Hispanic students, are falling behind because, instead of finding better ways to teach, progressive educators debase math.

By naming mathematics as apolitical and absolute truth, as refuted by the paradigm, the author adheres to perspectives of mathematics that have been, and continue to, uphold whiteness (i.e., *institutional*; Battey & Leyva, 2016). Namely, the paradigm focuses on "getting the right answer, using the right method, or believing some students are more capable than others is white supremacy." The author's positioning of mathematics maintains white supremacy through claiming there is one right way to engage with mathematics (Okun, 2021), and using mathematics to sort and rank students based on perceived ability (TODOS, 2020).

Further, the author frames the paradigm as a threat by positioning mathematics as removed from ongoing conversations of equity and justice. For instance, the author comments on "the idiocy of having math teachers lead discussions on social justice instead of teaching black children how to do math." By upholding binaries of practice (Lolkus et al., 2022), or an *either-or* mentality (Okun, 2021), that justice-oriented teaching does not or cannot also support rigorous mathematics, the author perpetuates whiteness. The author also positions the paradigm as inconsistent because, although it supports Black and Brown children, they are "falling behind" because of a de-emphasis on better teaching and that those who espouse the paradigm "claim the mantle of protector have become the oppressors." They also argued the paradigm eliminates practices supporting "needs of black children, [thus] they do not believe black children can learn math." White supremacists used this tactic to remedy "past and current racism by asserting that the plea for justice is racist itself" (Rubel & McCloskey, 2019, p. 117).

Ultimately, the author's critique of and resistance to the paradigm demonstrates how white supremacy upholds and maintains the order and structure of the status quo (Giroux, 2021). By calling out examples of the paradigm as threatening mathematics institutional systems that have historically benefitted white folks, the backlash upholds whiteness.

Fearmongering: A Mechanism to Preserve whiteness

Fearmongering, or attempts to "use fear to divide and conquer, always in the service of profit and power for a few at the expense of the many" (Okun, 2021, p. 7) is a part of white supremacy culture. Much like attempts to create fear of the 'other' through harsh language and labels (e.g., Zimmer, 2019), the author of the text describes the paradigm as unsuitable due to being "dangerous," "fiction," "idiocy," "cringe-inducing," and "gobbledygook." Exemplars of the danger of the paradigm are laid out when the author reinforces mathematics needing nothing more than correct methods by recounting the loss of the Mars Climate Orbiter, the failure to track and intercept an Iraqi Scud missile, and deaths associated with errors in medication doses.

Aligned with safety, the author instills fear by illustrating what happens when the othered (i.e., minoritized) students are included. They argued ending standardized and proficiency exams, currently used for international competition and college admittance (i.e., *institutional*; Battey & Leyva, 2016), would "pre-select outcomes by race" and "adjust the scores for poor students." They also see tracking as "hold[ing] back gifted children" and not "permitting gifted students to take advanced courses" and limiting "better students to advance," "no one learns, [thus] outcomes are equitable." Again, they promote whiteness and preserve white supremacy by positioning some students as superior to others (i.e., *identity*; Battey & Leyva, 2016) and for Black and Brown students to learn, white students must not (i.e., *power hoarding*; Okun, 2021).

The author describes the paradigm as something to be feared by illustrating a society marred with death and "substantial property damage" with an educational system that assesses based on "skin pigmentation;" thus, positioning the paradigm as something to be avoided at all costs.

Bad actors: Orchestrating the paradigm. As an extension of the fearmongering, the author elucidates the paradigm as a growing movement with powerful orchestrators. Throughout the text, they introduce two powerful actors, "progressive" mathematics educators and their funders.

First, the author positioned a group of "progressive" mathematics education researchers (i.e., Deborah Ball and Rochelle Gutiérrez) who espouse and promote the paradigm. The author casts them as actors not to be taken seriously by using emotional verbiage when describing their actions such as "complains," "groans," "fretting," and "overstates." We take this framing to discredit their ideas, a mechanism usually directed towards female scholars (Cameron, 2022). Moreover, the emotional language is also placed upon their work. For instance, they write, "Gutiérrez worries that algebra and geometry perpetuate privilege," and "Ball complains that math is a 'harbor for whiteness.'" Thus, the author positions them and their work as not to be taken seriously because it "sound[s] like parody."

The author named powerful institutions and their initiatives as one of the driving forces behind the dissemination of the paradigm. They note the Gates Foundation's involvement as a funder of Ball's project, TeachingWorks, and positions it as "ready to profit." They identify Education Trust-West as one of the funders for the toolkit, *A Pathway to Equitable Math Instruction*. They position Education Trust-West closely to the Obama administration by identifying the organization's president, John B. King Jr., Obama's secretary of education from 2016-2017. The inclusion of both Obama and Gates positions them as the orchestrators of the paradigm. It is clear through past articles in NR how they position both Obama and Gates as the bogeymen of the left (Smith, 2021; McLaughlin, 2021) and, based on the intended audience of the text, would bring less credibility to the paradigm. Moreover, the author argued that these actors may be a reason why the paradigm is "gaining traction" and "strongly endorsed by educators, leading mathematics organizations, and policy-makers." As part of the fearmongering, the author creates an image of the paradigm not as a static curricular feature, but as a flawed and emotionally-based growing initiative backed by powerful orchestrators.

Conclusions and Implications

We demonstrated how NR constructs mathematics as steeped in whiteness and how they reject whiteness as a feature of status quo mathematics by positioning this as a paradigm to be feared. They illustrate a world where, if the paradigm is fully implemented, it would have adverse consequences to its readers' lives. They then amplify this fear by portraying the paradigm as a growing phenomenon with the help of several powerful actors and institutes.

This work has implications on understanding backlash to MER. Perhaps, whiteness is a feature of resistance to MER. In that, NR is not unique; it echoes past critics that do not call out whiteness explicitly in the way NR does. For instance, in Tom Lehrer's song New Math, he derides making sense of algorithms in favor of getting the correct answer. The critics of the late 90's MER argued reform would deteriorate the "economic and social well-being of our nation" because MER "favors weaker students, [and] the top students being shortchanged" (Wu, 1997, p. 951). Tactics have also persevered. Critics of the 90's standards positioned MER as unreliable and inconsistent because of "extremely bad" and "fuzzy" mathematics (Schoenfeld, 2004). It is through understanding the nature of the backlash that mathematics educators may see how whiteness rebuilds the status quo. In turn, educators and allies can begin to respond to the loudest voices suppressing those who fight for more inclusive and just mathematics education.

THE WORLDS THAT TRANSCRIPTS HIDE IN MATHEMATICS EDUCATION RESEARCH

Higinio Dominguez
Michigan State University
higinio@msu.edu

Sofía Abreu
Michigan State University
abreusof@msu.edu

This brief research report showcases an alternative to transcript analysis that halts the process of reducing participants' expressive worlds to an orderly regime of words. Drawing from a philosophical conversation with grade-five students on the concept of space, the paper advances a methodological/analytical perspective that recalls transcripts and reissues them as liminal spaces of possibility while interrogating the limitations of conventional approaches to transcript analyses for generating new knowledge. Several philosophies inform our contribution, including Indigenous Knowledges, Feminisms, New Materialisms, and Posthumanism. The paper describes the process of constructing a transcript and coming to see it beyond its static, linear nature. The findings suggest that the encounter of researcher with data constitutes an opportunity to re-encounter possibility, embrace generosity, and engage imagination in research.

Keywords: research methods; elementary school education; equity, inclusion and diversity.

Objectives and Research Question

Many educational research practices promote a distancing of the researcher from the participants by reducing their world of experiences to codes stamped on transcripts or transcript excerpts that interrupt the continuity and vibrancy of a human experience. Arguments supporting these practices herald the objectivity (e.g., the case of coding) or representativity (e.g., the case of excerpts) of knowledge. Good research, then, must generate knowledge that skews the redundant details that belong in the imperfect material/subjective experiences of humans.

Our motivation for writing this paper grew out of our concern for the dissonance between philosophies that openly and honestly recognize how human experience is uncertain yet alive and vibrant, and the widely accepted analytic approaches that remove both uncertainty and vibrancy from our human affairs. Our concern has slowly grown into this opportunity to provide a specific example of how we as researcher-graduate student have come to *re*cognize—to know again, but differently (Dominguez, 2014)—our encounter with data. The purpose of this short research report is to share with our mathematics education research community this specific example that illustrates (a) a methodological/analytical critique on how language territorializes methodologies and analytic approaches in mathematics education research, (b) an alternative that we see as trespassing the static lines of text on transcripts as a transgressively liberating methodology that takes the research back to worlds filled with possibility and philosophy, and (c) a theoretical perspective that looks more into the future of knowledge, the possible that has been sequestered, and a reinvigorating vision of the relationship between researchers and data, including how we encounter data in our research. Accordingly, our research question is: What possible worlds (of ideas, relationships, and resonances) emerge when researchers halt the process of reducing everything to language and instead re-enter the space between words and images as a way of reinvigorating the researcher-data encounter? What opportunities to advance the learning of mathematics can we envision from these generous researcher-data encounters?

Philosophical Perspective

Every line in a transcript and every frame in a video includes both the actual (what was realized) and the virtual (not in the sense of unreal, but in the sense of unrealized, what remained as a possibility). In Spanish, “lo que se quedó en el tintero” (what remained in the inkwell).

Figure 1: Lines of flight as reductionist process is halted

This drawing (see Figure 1), for example, expresses all at once the reductionist process of researcher-data encounter that we halted right at the space between video and transcript, where tensions produced lines of flight (vibrant dark area moving in multiple directions).

This new way of thinking about the researcher-data encounter is minoritarian when compared with more commonly accepted views (Deleuze & Guattari, 1987). As Lenz Taguchi (2012) explains, “The expression ‘becoming minoritarian’ defines the very process of escape from ‘majoritarian’ norms, subject positions, and habits of mind and practice” (p. 267). Reinvigorating the researcher-data encounter aligns well with the idea of a living theory (Whitehead, 2009), for we see images, sounds, movements, materials, bodies, and the concept of space as a living, vibrant assemblage (Bennet, 2010; Cajete, 2000). In that living time-space-matter (Barad, 2007), agentivity emerged not from individual humans—the traditional perspective from the humanities—but from the assemblage of forces, intensities, and energies coming together (Little Bear, 2000; Mikulan & Sinclair, 2017).

Our current technology for producing data is human- and language-centric, with a focus on sequentially recording the actual while neglecting the virtual. Yet, virtuality (Barad, 2012; Deleuze, 1995) is as important as what becomes actualized (Whitehead, 1978). Virtuality is not completely invisible, though, for it tends to awaken gestures (Châtelet, 2000). Returning to a neglected virtuality as our methodological/analytic approach does, “requires another kind of thinking […] using all of our bodily faculties and our imaginary” (Lenz Taguchi, 2012, p. 267).

Drawing reconnects us to virtuality, by freeing the researcher-data encounter from its linear cage to an all-over relationality of a drawing surface (Sousanis, 2015). The possibilities become endlessly rhizomatic, and the vibrant indeterminacy of spatial, temporal, and bodily boundaries become more palpable (Abreu, in press). Drawing can become a generative node of transformation where the virtual is particularly vibrant since the actual and the virtual are in intense tension as uncertainty “está en la mera punta del lápiz”—is right at the tip of the pencil. A drawing is never ‘finished’ as it continues to be an active force that transforms and is transformed by the world after the drawing encounter (de Freitas & Sinclair, 2012).

The material agentivity of drawing brings into focus the role of multiple expressivities that emerge from spaces of tension in which multiple materialities look unapologetically into the researcher’s eyes (and other senses). Barad (2007) reminds us, “Neither discursive practices nor material phenomena are ontologically or epistemologically prior. Neither can be explained in terms of the other. Neither is reducible to the other. Neither has privileged status in determining the other. Neither is articulated or articulable in the absence of the other; matter and meaning are mutually articulated” (p. 152). We therefore envision our analytic approach as “a ‘meeting place,’ where different data, each with their own trajectories, come together with the researcher to create something new” (Taylor, 2013, p. 814).

Modes of Inquiry

Consistent with the idea of possibility as emerging from uncertainty (and vice versa), our analytical approach emerged not as pre-planned but rather from conditions of uncertainty as follows. The first author had been collaborating with one teacher for about two years as part of his community engaged scholarship. One morning, he received the usual phone text from the teacher, this time asking him to help her teach how to plot ordered pairs. Rather than turning this opportunity into a procedure-oriented lesson, the first author decided to engage the grade-five students into a philosophical discussion of space. An influential idea that was brought into this discussion was that “the body does not move into space and time, it creates space and time: There is no space and time before movement” (Manning, 2007, p. xiii). With a small plane made with popsicle sticks hanging from a piece of thread and three cardboard Cartesian planes, the philosophical discussion attracted the students’ moving bodies, gestures, drawings, imagination, and language into an assemblage that was videorecorded by one graduate research assistant.

Although term “data” comes from the Latin datum = given (Brinkmann, 2014), data are never generously given to researchers; we produce data. We find this recognition helpful in terms of sensitizing us to the idea of the researcher-data encounters. One of these key encounters occurred when we watched the video followed by the transcript production and reading. We thus felt the need to have responsive and responsible encounters with data. Consequently, in our analysis we assumed that the words in the transcripts and the moving images on the video were as agentive as the participants and researchers. As such, we needed to co-respond with these data, as in the correspondence of people exchanging letters (Ingold, 2013; Roth, 2016).

Results…Or rather Possibilities

Figure 2: Panels from *Young Philosophers*

Our results, or rather possibilities, come from a comics book we produced titled, *Young Philosophers: What Can They Teach Us about the Concept of Space?* Drawings in this book emerged saturated with *possibilities*, creating a *generous* flow of ideas that harmoniously connected with other ideas, while harboring *imagination* at every trace of the pencil and use of the space on the page (see Figure 2). We allowed, neither video nor the transcript alone to influence our analytic departure, our line of flight (Deleuze, 1995); instead, we sought the energy of the tension between the two. The energy we describe here can also be understood by envisioning a zigzag movement between the words in the transcript and the moving images on the video. As an example, on the page at left, we trespass the fixity of the words "…everything is kind of living…" by illustrating this idea as shown on the bottom part of the page. These illustrations—not the words on the transcript; not the images on the video—took us back to philosophical ideas about space (e.g., Cajete, 2000; Kimmerer, 2013; Little Bear, 2000; Manning, 2007). The generosity of these possibilities is in how our analytic approach invites the virtual to be at par with the actual. We refused to further reduce words into codes; instead, we re-encounter the words with a recognition of their agentivity to revive our imagination with images that, being also agentive, mobilized ideas that had been virtual.

Although it may be tempting to see our comic book as a final result, we prefer to see *in* it a space of possibility, a living artefact whose life is sustained as it passes across diverse hands, assemblages, and imaginations. At each passing, an expansion of the space that connects the actual with the possible occurs. The following is one moment filled with possibilities. Unlike traditional expectations to generalize findings, our hope is to generalize possibilities. Is what you will read also possible in your own context? In your own research? In your own practice?

Discussion and Takeaway

Transcript analysis answers the question: What did actually happen here? In contrast, our analytic approach, with its focus on halting reductionism, addresses the question: What could have happened here? Not content with an exclusive focus on the actual, our approach brings the researchers into a reinvigorating encounter with the data by considering spaces of tension; in this case, the space between video and transcript. Attention to this space allowed us to vivify the virtual through the continuous energy and imagination of drawing. Through drawing, we were able to connect students' philosophical ideas with the ideas of other philosophers. These possibilities emerged from our analysis in the form of a line of flight (Deleuze, 1995). We see in these lines of flight a more generous reading (Spence, 2011) of the worlds that transcripts tend to reduce to the actualized. For us, an important takeaway is how generous readings can contribute to address issues of equity, diversity, and inclusivity in our research.

Our methodological/analytic approach draws on feminist new materialisms and Indigenous Knowledges. Collectively, these philosophies look more into the future and the possible (Grosz, 2010) than more traditional theories that are interested in confirming a kind of knowledge that is assumed to pre-exist, which we see as a way of disdaining the future. Our interest in the virtual is motivated by our love for the possible; analyses that are closed and deterministic exclude not only the possible but our faculty to imagine it. We wonder how many students and their ability to imagine the possible have been excluded by these kinds of ungenerous readings of their worlds.

Finally, the "wheels" of transcript analysis continue to turn, and we wonder to what extent are they turning away from complex realities and more toward what Popkewitz (2004) calls the fabricated fictions of educational research. Our analytic approach intends to halt this wheel, to redirect it, not to an objective or finished reality, but to the potentiality that is part of every reality. We see the space between video and transcript as filled with tensions that we can use as catalysts for what is possible. Video, transcript, and coding are all complicit in reducing human experience. Reducing the human experience is dehumanizing. We are concerned with humanizing researchers (Tuck & Yang, 2014) first, so we all can see the limitations of current technologies when placed vis-à-vis force such as possibility, imagination, and generosity. Given the transformative effect this methodological/analytic approach has had on the emergent career of a mathematics education graduate student, Sofía, and the mid-career of a mathematics education researcher, Higinio, we believe the approach has the potential to re-engage researchers more generally to conduct more humanizing research in mathematics education.

AN EXPLORATORY ACTION RESEARCH STUDY OF SOCIAL JUSTICE MATHEMATICS IN UNDERGRADUATE PRECALCULUS

Abigail Erskine
Syracuse University
aberskin@syr.edu

Brian Odiwuor
Syracuse University
bodiwuor@syr.edu

Nicole L. Fonger
Syracuse University
nfonger@syr.edu

In this exploratory action research study we investigated teaching mathematics for social justice in undergraduate mathematics. We asked: How if at all do undergraduate students consider the importance of local social justice issues as embedded in the context of a precalculus course assignment?; and As instructors, how might feedback from students' experiences of a social justice mathematics lab inform our future teaching and research practices? We discuss emerging findings from our initial analyses of student surveys. We also elaborate how these findings will inform our efforts to link research and practice at the intersection of supporting students' math cognition and exploring social justice issues through teaching mathematics for social justice.

Keywords: Precalculus, Problem Solving, Social Justice, Culturally Relevant Pedagogy.

Social justice is, ultimately, about understanding the macro systemic power dynamics that perpetuate the conditions in which we live. Social Justice Mathematics (SJM) educators explicitly aim to develop students' sociopolitical consciousness in addition to teaching mathematics content (Gutstein 2006; Gutiérrez 2013). This bivalent approach to justice emphasizes that both redistributive justice, or equitable distribution of fundamental resources, and recognition justice, or respect for human dignity and diversity with all groups having a voice, are necessary to achieve social justice (Basok et al 2006; Gonzalez, 2009; Bartell, 2013). SJM may also be referred to as critical mathematics orteaching math for social justice (Kokka, 2015).

The purpose of this exploratory action research study is to traverse the terrain of incorporating research on SJM teaching into our classrooms as mathematics educators at the university level. The main problem we aimed to address in this research was to move from theory to practice in employing conceptual orientations toward SJM in our own teaching and research. Our research was guided by the following questions: How if at all do undergraduate students consider the importance of local social justice issues as embedded in the context of a precalculus course assignment? As instructors, how might feedback from students' experiences of a SJM lab inform our future teaching and research practices? In this paper we discuss emerging findings from our initial analyses of students' surveys. We also elaborate how these findings will inform our future efforts to link research and practice at the intersection of supporting students' mathematical literacies and exploring social justice issues.

Conceptual and Theoretical Framework

Gutstein (2006) and Kokka (2020) posit two sets of goals in teaching mathematics for social justice. First are the *mathematics pedagogical goals* which aim to support students in gaining mathematical power to read the world, succeed academically, and conceive of mathematics as a useful tool. Second are the *social justice pedagogical goals*—reading the world with mathematics and being able to take actions to change the world. SJM involves developing positive cultural and social identities among students to coexist in the current diverse society where values from both dominant cultures and non-dominant cultures are preserved.

We draw on Freire's (1970) notion of 'praxis' to argue that students should use mathematics to investigate and challenge injustices and inequalities relating to their own lives and wider society. Praxis can be understood as "reflection and action upon the world in order to transform it" (Freire, 1970, p.36). The goal is to recognize and draw upon learners' lived experiences to emphasize the cultural relevance of mathematics (Aguirre et al., 2013) and develop a critical understanding of the nature of mathematics and its position and status within education and society. In this approach, students can play a role in providing solutions to injustices that surround us. As argued in Freire (1970) it is not enough for people to study the world only, there is also a need to act towards creating a more just world. To accomplish such a goal, students must gain a deeper understanding of the conditions of their lives and the social dynamics of their real world. To incorporate social justice issues into mathematics teaching, tasks can be designed to improve students' mathematical thinking which will help them to become aware of the social injustices that occur within society at large and in their own lives at the same time increasing their mathematical understanding.

Methods

We employed one cycle of action research (Segal, 2009) to explore the phenomena of integrating social justice issues into mathematics lessons and course assignments for undergraduate precalculus students. This cycle of action research included systematic planning, engagement with students, and reflection on our research-based teaching intervention.

Participants and Teaching Context

This research was conducted at a university in the Northeastern U.S. All students enrolled in an undergraduate precalculus course in Fall 2021 completed a problem solving lab within the first four weeks of the semester. Of this larger pool of students, 16 students chose to complete a survey about their experiences during the last 2 weeks of the semester.

The pre-calculus course is designed to prepare students for success in the study of calculus. The core focus of the course is to develop representational fluency in using functions to model relationships between quantities. Throughout the semester, students engage in applied problem solving in collaborative group settings using graphing technologies.

Authors' Statements of Researchers Positionality

As argued in D'Ambrosio et al. 's (2013) and Holmes's (2020), the researcher's positionality influences the design of research in terms of how participants are recruited, the kind of data collected, and how that data are analyzed. I (Abigail) recognize myself as an African female, a graduate student, and an advocate for educational equality. I understand what it means to be in a classroom with people from diverse backgrounds. I believe in an educational setting where every student has the right to be as inclusive as possible in the classroom. I was a lead instructor for Precalculus in the Fall of 2021 and supervised students who participated in this study. I (Brian) identify as African, a father, STEM educator, researcher, and Ph.D. student and subscribe to liberalism(Bell, 2014; Charvet, 2018) as political and moral philosophy. As a man, I recognize that there are privileges that I may have because of my gender, the same way I recognize the alienations I have experienced as a person of color residing in the United States. This has motivated me to advocate for critical consciousness or conscientização (Freire,1970) in the spaces I participate in. As a white female mathematics education researcher and faculty member (Nicole), I seek to explore both research and practice focused on SJM to advance a more meaningful understanding of mathematics for a racially diverse group of students. My interest in SJM is largely motivated by a personal journey of unlearning racism and whiteness ideologies as they intersect with my work as a mathematics educator. During Fall 2021 I was the course supervisor for all undergraduate precalculus courses that study participants completed. In this role, I set the syllabus and introduced the problem solving lab that is the focus of this research study.

Problem Solving Lab

Fonger designed the problem-solving lab by adopting a set of tasks that a high school mathematics teacher had developed over the past 4 years (Keech, Routhouska, & Fonger, in press). Erskine was among the group of instructors who gave this task to precalculus students at while they were learning about linear function and change. In general, students investigated trends in the historical population of residents in a city and the role of building a federally funded highway system that impacted population decline in that city. The mathematical focus of this lab was to model and make predictions of population data over time using linear equations. Prior to completing the mathematics tasks of the problem-solving lab, students read news articles and a zine (a mini-magazine) to inform their understanding of the social issues in this lab related to redlining, the razing of a predominantly Black neighborhood, and the impact of highways on population decline in this city. We intended to support students' understanding of how government decisions negatively impacted many Black residents of the city. Figure re 1 introduces the lab.

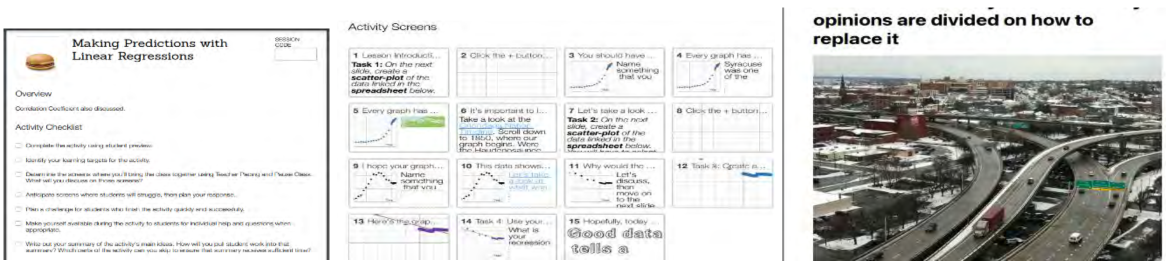

Figure 1: Screenshots of the problem solving lab, activities, and related texts.

Research Instruments and Data Collection

We used two primary instruments to collect data: students' written responses to the problem-solving lab, and a post-lab survey. We designed these instruments to obtain information about students' experiences of the mathematics lab with a focus on relating their classroom mathematical experiences to real world situations and social justice issues. The problem solving lab write up was in the form of paragraph responses designed to address both the mathematics (e.g., write the equation of your "line of best fit") and the social issues (e.g., what does the highway have to do with population decline in this city?). The survey consisted of 10 questions and students responded on a 5-point Likert-type scale asking them to (1) Strongly Agree, (2) Somewhat agree, (3) Neither agree nor disagree, (4) Somewhat disagree, or (5) Strongly Disagree.

Data Analysis

Following Morse (2009), we adopted a mixed methods approach wherein the qualitative component (collection of student problem solving lab) preceded and informed the design and delivery of a quantitative component (the survey of student experiences). At the time of this writing, our analyses are ongoing. We focus this brief report on our analysis of the survey responses. We plan to share qualitative analyses of students' lab responses when presenting this research.

Results and Discussion

Recall the two research questions that guided this study: How if at all do undergraduate students consider the importance of local social justice issues as embedded in the context of a precalculus course assignment?; As instructors, how might feedback from students' experiences of a social justice mathematics lab inform our future teaching and research practices? To the first question, we share a summary of student responses to the survey questions in Table 1.

Table 1: Students' experiences with social justice mathematics lab

	N	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree.
The Problem Solving Lab supported me to read and interpret a scatter plot relating two quantities (city population, time since 1850)	16	6%	0%	13%	50%	31%
The Problem Solving Lab supported me to model local data with a linear function and interpret the meaning of the data with respect to the context.	16	0%	6%	19%	31%	44%
l The Problem Solving Lab supported me to learn about possible reasons the city population declined after the year 1950	16	0%	0%	13%	19%	69%
The Problem Solving Lab supported me to believe that the construction of the highway is an important issue for city residents	16	0%	0%	19%	19%	63%
The Problem Solving Lab supported me to affect change on social justice issues in the city	16	0%	0%	31%	38%	31%
The Problem Solving Lab supported me to identify inequities for city residents	16	0%	0%	19%	25%	56%
The Problem Solving Lab supported me to appreciate the connection between math and problem-solving skills.	16	0%	6%	13%	25%	56%
The Problem-Solving Lab is relevant to my life experiences.	16	0%	19%	19%	38%	25%
The Problem-Solving Lab is relevant to what I learn in math class.	16	13%	13%	19%	31%	25%

From Table 1, we see that over 60% of the participants either agree or strongly agreed to the survey questions. The percentage of student who disagree or strongly disagree was 6% or 0% on 7 out of the 10 questions. We can infer that majority of the students (>70%) can relate mathematical content learnt in class to social issues that revolve around them. This analysis also shows that the social issues incorporated in the pre-calculus lab seemed to support students' awareness and consciousness of being able to identify inequities for city residents.

These data inform our response to the second question as well. It is troubling that 26% of responses disagreed with the idea that the problem solving lab is relevant to what I learned in math class. Moreover, 38% of respondents either disagree or are neutral about the relevance of this lab to their life experiences. As instructors, we had designed the problem solving where lab to connect to issues in the same city where the university classrooms are located. We have used this feedback to inform and revised iterations of the problem solving lab. For example, we have added content to the lab that explicitly connects to the *place* of the social justice issues. Given that many students on the university campus have not physically visited the site of the social injustice, we also introduced additional videos and visualizations as resources to connect to students' experiences in potentially more meaningful ways. We would also like to move toward designing opportunities for SJM that not only mathematizes the social justice issues, but pot position students to address the issues.

In future iterations of this lab, we will take greater care to help students see explicit links between the lab and course goals.

OBSCURING RACIAL INEQUITIES THROUGH GENDER-FOCUSED DISCOURSE: AN ANALYSIS OF STUDENT PARTICIPATION IN A CALCULUS CLASS

Heather Fink
University of California, Berkeley
hfink@berkeley.edu

Inequities in STEM participation for people of color and women are documented extensively, often highlighting issues of representation and/or achievement. This study adds to the literature by looking at participation inequities in a high school calculus class. Equity is conceptualized as a fair distribution of opportunities for students to engage in rich mathematical experiences. Analysis of participants' dialog revealed talk about student participation focused primarily on gender patterns, even when pertaining to only one race-gender group of students (i.e., White males). Analysis of whole-class participation showed White dominance superseded male dominance; White males had the most robust opportunities to participate followed by White females, females of color, and males of color. Findings suggest participants' gender-focused discourse obscured racial inequities in classroom participation.

Keywords: Gender; Equity, Inclusion, and Diversity; Classroom Discourse

Decades of research document inequities related to sexism and racism in STEM (science, technology, engineering, and mathematics) participation (e.g., Martin, 2009; Wang & Degol, 2017). Often participation studies focus on issues of representation (e.g., Cheryan, et. al., 2017) or achievement (e.g., Oates, 2009). In contrast, this study looked at participation inequities as they played out through interactions in a 12^{th}-grade calculus class over one distance learning semester. The focus of this study was on how classroom participants (teacher, student teacher, and students) made sense of students' participation with respect to race and/or gender and how whole-class participation patterns corresponded to race and/or gender.

Equity is defined as the fair distribution of opportunities for students to engage in rich mathematical experiences, supporting deep disciplinary understandings and positive mathematical identities (Esmonde, 2009; Schoenfeld, 2014). Students' identities are conceptualized as complex and multi-dimensional. In the words of Crenshaw (1991), "Because women of color experience racism in ways not always the same as those experienced by men of color and sexism in ways not always parallel to experiences of white women, antiracism and feminism are limited, even on their own terms" (p. 1252). Racism and sexism extend into classroom spaces where students' opportunities to participate and learn mathematics are shaped in racialized and gendered ways (Esmonde & Langer-Osuna, 2013; Gholson & Martin, 2019; Sengupta-Irving & Vossoughi, 2019).

This study aims to provide a nuanced understanding of students' varied experiences in a high school calculus class "by making visible what has been obscure and bringing to the center what has been marginalized" (Bullock, 2018, p.123). Research questions are: 1) How did participants articulate participation issues related to race and/or gender? 2) How were whole-class contributions distributed across students in the class?

Theoretical and Conceptual Framing

Teaching and learning are considered sociopolitical endeavors through which power is distributed, either perpetuating persistent inequities or challenging existing hierarchies and injustices (Gutiérrez, 2013; Philip et. al., 2017; Valero, 2018). Based on sociocultural theories, learning is defined as changes in students' participation in collective classroom practices (Lave & Wenger, 1991; Vygotsky, 1978) and is a function of students' opportunities to participate (Gresalfi, et. al., 2009). Inequities are created and perpetuated through the construction of disparate and stratified opportunities for students to engage in meaningful learning experiences (Esmonde & Langer-Osuna, 2013; Shah & Crespo, 2018). Over time, patterns of participation play out through interactions between teachers, students, and mathematical tasks (Clarke, 2004), and these interactions are racialized and gendered forms of experience (Leyva, et. al., 2021; Martin, 2006).

Methods

Data Collection

Participants. Participants included one math teacher (White female), one student teacher (Mexican male), one researcher (White female) and 12th-grade students in the teacher's 1st period (Pd.1) AB Calculus class and 2nd period (Pd.2) AB Calculus class. The public high school used distance learning during the 2020-21 school year. Due to the pandemic, students took only three courses at a time, resulting in fewer lessons per course than is typical. Race and gender identities are self-stated for participant interviewees. Racial identities included Black, Chinese, Filipino, Iranian-American, Mexican, Mixed, White, and others. Gender identities included female and male. I have selected identity groups intentionally and I acknowledge they are imperfect. Non-White identifying students are grouped as "Students of color" based on how students talked about themselves related to their peers. (Guadalupe said, "it's different with PoC girls and the White girls in class…") I have chosen to capitalize "White" to draw attention to the power this classification holds, intending to highlight the non-neutrality of this label (Ewing, 2020).

Participant Discourse Data. Table 1 displays descriptions for the four data types included in the race-gender discourse analysis: lessons, lesson debriefs, one-on-one participant interviews, and informal conversations. Table 2 shows the race and gender of participant interviewees.

Table 1: Data Used for Discourse Analysis

Source Type	With Whom?	Quantity	Total Hours
Lessons	Pd.1 class	45 observations (semester 2)	45
	Pd.2 class	47 observations (semester 2)	47
Lesson Debrief Sessions	teacher & student teacher	30 Pd.1 debrief sessions	2.0
		45 Pd.2 debrief sessions	7.7
Participant Interviews	teacher	1 teacher, 4 interviews	3.6
	student teacher	1 student teacher, 3 interviews	1.9
	Pd.1 students	9 students, 16 interviews	9.4
	Pd.2 students	8 students, 11 interviews	6.0
Informal Conversations	teacher & student teacher	8 recorded Zoom conversations	1.8
		12 email chains	n/a

Table 2: Interviewee Identities

	People of Color	White
Female	Students-5	Teacher-1 Students-4
Male	Student Teacher-1 Students-5	Students-3

All lessons, lesson debriefs, and participant interviews were video-recorded through Zoom and took place during the spring semester (Jan - June 2021). Most video-recorded informal conversations and email exchanges took place during this timeframe as well; however, several informal exchanges between the researcher and teacher occurred during the fall semester.

Student Contribution Data. This paper uses observations of whole-class discussions that occurred during 30 "regular" semester 2 Calculus lessons (Pd. 1); optional "help" lessons were excluded from the analysis (Table 3). In addition, Pd. 2 calculus lessons were excluded from this analysis due to space, though both classes are included in the race-gender discourse analysis.

Table 3: Description of Data Used for Contribution Analysis

	Pd. 1 Calculus
# of School Days (Semester 2)	48
# EQUIP Whole-Class Observations	40*
# of "Regular" Lesson Obs	**30**
# of Optional "Help" Lesson Obs	10

* 5 days - groupwork only; 2 days - testing, 1 day - researcher absence

Whole-class discussion data was collected using EQUIP (Equity QUantified In Participation) (Reinholz & Shah, 2018), an observation tool used by researchers to track user-defined discourse dimensions at the student contribution level. The discourse dimensions in EQUIP relevant to this paper are *Contribution solicitation method* (i.e., cold-called, encouraged, volunteered) and *Contribution type* (i.e., responded to a teacher question, asked a question, shared solution, responded to student question, declined to answer, offered a comment, identified mistake, read out loud, shared screen). Every time a student contributed during a whole-class discussion, the contribution was logged using EQUIP and selections were made for each discourse dimension.

Data Analysis

Participant Discourse Analysis. All explicit references to gender and/or race made by participant interviewees (from Pd. 1 & Pd. 2) during the spring semester 2021 were identified from video; several conversations between the teacher and researcher at the end of the fall semester 2020 were also included. All references were sorted into one of four topics (Table 4).

Table 4: Reference Topics with Examples

Topic	References to…	Example
Participation	how categories of students participated during class	White boys dominated class conversations
Representation	the relative number of participants in activities, locations, professions	lack of female students in advanced math courses
Beyond this Class	patterns extending to students' community or society generally	lower expectations for females of color doing math
Self-Reflection	participants' first-hand experiences	pressure to do well and prove assumptions wrong

Once sorted by general topic, references were grouped into specific observations, accounting for different wording but the same meaning. For example, the comments "I noticed the classroom is very male-dominate" and "the boys were talking too much" were both coded as the same participation issue (i.e., boys dominated class conversations). These observations were then sorted according to identity category (e.g., gender, race-gender, race-class) depending on how participants framed their observations. For example, if a participant referred to students' gender and race identities, the observation was assigned *race-gender* as the identity category. References were also coded depending on which participant made the observation.

Whole-Class Contributions. Student contributions were exported from EQUIP to excel and merged with student gender and race data (self-stated when available, otherwise teacher ascribed). Data were aggregated by lesson, student, and class. Quantities were first tabulated by gender (i.e., male, female) and then by race-gender groups (i.e., female students of color, White female students, male students of color, White male students). Only student contributions from Pd.1 (not Pd.2) were included in this paper due to space limitations.

Findings

Findings are organized according to the two research questions. The first section reports how classroom participants (the teacher, student teacher, researcher, focal students) articulated participation issues related to gender and/or race. The second section reports how whole-class contributions were distributed across gender-race groups.

Participation Issues as Articulated by Classroom Participants

To understand how participants conceived participation "issues," we take a closer look at the references related to classroom participation that were positioned by participants as less-than-ideal. Table 5 shows specific classroom participation issues by identity category, including which participant(s) made the references.

Table 5: Race and/or Gender Participation Issues by Participant

	Observations of... Classroom Participation Issues	# of References Total	By Whom?
GENDER (30)	Boys dominated class conversations	12	T-6, ST-2, S-4
	Girls did not speak up	7	T-6, S-1
	Boys did not collaborate as well as girls in small-groups	7	T-4, S-3
	Student comment-"Wednesday help sessions are for girls"	3	ST-2, S-1
	Boys were sought out as math experts more than girls	1	T-1
RACE-GENDER (6)	White boys dominated class conversations	6	T-3, ST-2, R-1
RACE (1)	Students had different opportunities to participate (White vs. students of color)	1	R-1
RACE - CLASS (2)	Affluent White kids spoke about expensive ski vacations during class	2	T-2

KEY

T	Calculus teacher
ST	Student teacher
S	Student(s) in the class
R	Researcher

Almost all observations of participation issues referenced gender in some way, either gender-alone or the intersection of gender and race (36 out of 39, 92%). The most common participation issue articulated was that boys dominated class conversations, identified by the teacher, student teacher, researcher, and four students. There were 18 references to this issue; 12 referred to boys in general and 6 referred to White boys. This issue was talked about as a gender issue (boy dominance) twice as often as a race-gender issue (White boy dominance), even though the students to whom participants were referring were all White males. The four students who mentioned this issue were students of color (3 female, 1 male) and all described the issue without mentioning race. However, it is possible students *thought* about the issue as race-related but chose to *speak* about it as gender-related. On the other hand, the adults all spoke about imbalanced participation as a race-gender issue at least once. The teacher spoke about this issue sometimes as a gender issue and sometimes as a race-gender issue, as did the student teacher. The researcher made one reference to the issue, referring to it as "White boy" dominance.

Another often-mentioned participation issue was that girls in the class did not speak up enough. The teacher mentioned this issue 6 different times, expressing frustration with the situation. During a lesson debrief, the teacher shared, "I'm really annoyed with [name 1] and [name 2] cuz they are the starlets in this class. They get everything right. They would have been in BC Calculus, but they decided not to bother. And they're not contributing to the class." The issue was also brought up once by a White female student who shared, "For the really hard problems, there are 3 girls who get it and they're the only girls in the class- or not the only girls, the only *students* in the entire class who get it, but they don't really want to speak up and explain it or talk about it, which I've found really interesting." The three students to whom the teacher and student are referring are all female students of color; however, the issue was identified as a gender issue, not a race-gender issue. The teacher and student's confusion regarding why students were not speaking up could have been connected to presumed similarities in gender identity, but they were not accounting for differences in racial identities. The White female teacher and White female student may not have known what it was like to be a female *of color* in a *White* male-dominated math class. In support of this theory, here is one example of how race shaped experiences for one female student of color in this class:

> Within calculus and the girls, I feel like we should be supporting each other more than some of us do… it's different with PoC girls and the White girls in the class… It's a little bit more hostile, [White girl] is very hostile toward me. And so, I'll be like, 'Oh, okay.' I don't want to overstep. And with [PoC girl] it's not like that… I understand the PoC girls more and so they're a bit more supportive… a lot of times [White girls] are a little bit more reserved about their work, which is fine. You don't have to help us or share your work with us, but we don't necessarily act that way towards them… it's not the same. It's just different.

There was only one reference to a participation issue related to race-only; that reference was made by the researcher. After completing a preliminary class observation at the end of the fall semester, the researcher shared with the teacher her observation that only one student of color had opportunities during the class period to participate in competent mathematical ways (e.g., answer how/why questions). The only other race-related participation issue raised was by the teacher in reference to two affluent White students talking about their ski vacations.

Student Contributions during Whole-Class Discussions

Contributions were quantified by totaling the number of contributions made by Pd. 1 students during regular lesson whole-class discussions over the entire semester. There were 28 students enrolled in this course who made a total of 767 contributions during the 30 observed lessons.

Given participants' gender-focused discourse shown in the previous section, contributions were initially examined by gender. Table 6 shows total contributions, mean contributions, and contribution solicitations broken down by gender (female / male). Values in the table are color-coded depending on how the percent of contributions compares to the percent of female and male students in the class. If the percent of contributions made by a group is more than 3% higher than the percent of population represented by that group, then table values are green. If the contribution percent is within 3% of the population percent, then values are yellow. If the contribution percent is more than 3% lower than the population percent, then values are red. The same color-coding scheme is used in all tables in this section.

Table 6: Student Contributions by Gender

	Total # of Students	Total Contributions (Semester 2)	Mean Cont. per Student	Contribution Solicitations		
				Cold-Called	Encouraged	Volunteered
ALL Students	28	767	27.4	218	44	505
Female	8	181	22.6	74	21	86
	29%	24%		34%	48%	17%
Male	20	586	29.3	144	23	419
	71%	76%		66%	52%	83%

KEY	Difference from Population %
Green	3% or more higher
Yellow	+/- 3%
Red	3% or more lower

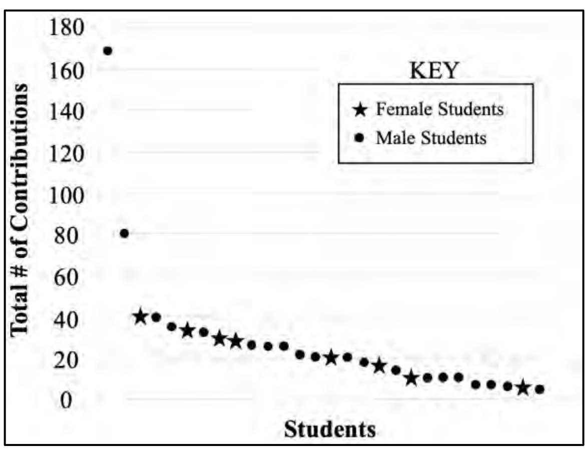
Female students made 24% of all whole-class discussion contributions averaging 22.6 contributions per student, which is 5% lower than what would be expected given perfect alignment between contributions and population representation. The difference is notable but not extreme. Looking at solicitation method highlights bigger differences in participation patterns between female and male students. Specifically, 83% of voluntary contributions were made by male students, and the teacher encouraged roughly the same number of contributions from female and male students. In addition, the teacher cold-called on male students twice as often as female students. Considering females represented 29% of students, the number of voluntary contributions was considerably lower than expected for females, whereas the numbers of cold-called and encouraged contributions were higher. Table 7 shows contributions made, again broken down by gender, by participation type (e.g., # of responses to a teacher question, # of questions asked, # of times a student declined to answer a question).

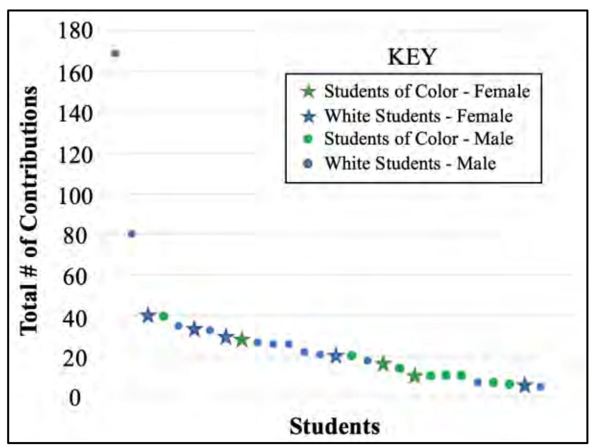
Table 7: Student Contributions by Participation Type and Gender

		Total # of Students	Responded to Teacher Q	Asked a Q	Shared Solution	Responded to Student Q	Declined to Answer	Offered a Comment	Identified Mistake	Read Out Loud	Shared Screen
ALL Students		28	482	132	45	30	29	25	12	8	4
Female		8	106	14	18	10	13	6	6	4	4
		29%	22%	11%	40%	33%	45%	24%	50%	50%	100%
Male		20	376	118	27	20	16	19	6	4	0
		71%	78%	89%	60%	67%	55%	76%	50%	50%	0%

Data indicate females (compared to males) were somewhat less likely to offer unsolicited comments or respond to teacher questions and much less likely to ask questions. They were also somewhat more likely to respond to student questions and much more likely to share problem solutions, decline to answer questions, identify mistakes, read out loud, and share their screen. There was a mix of seemingly productive and unproductive forms of participation by female students. Taken together, data suggest female students were less likely than male students to participate in academically risky ways. One explanation is that females shared problem solutions and identified peers' mistakes when they felt confident with content; in contrast, they declined to answer teacher questions and neglected to ask their own questions when they were more unsure.

To get a better sense of how contributions were distributed among individual students, total contributions per student were sorted from high to low and then plotted (Figures 1a & 1b).





Figures 1a & 1b: Contributions per Student by Gender (1a) & Race-Gender (1b)

Figure 1a shows two outlier male students (dots), one with 169 contributions and one with 80. Female students (stars) seem to be spread evenly across the class, with females taking 4 out of the top 9 contributor positions. Based on Figure 1a, one might conclude inequitable participation in this class could be attributed to the dominant males; presumably, if these two students stepped back allowing others to contribute, then all would be ok. However, adding race to the analysis tells a notably different story. Figure 1b reveals 12 out of the top 14 class contributors were White (86%), including the two dominant males. Although females seemed to be distributed evenly across the spectrum of class contributors, students of color (green symbols) were not. This finding prompted analyses of contributions by race-gender groups (Tables 8 & 9).

Table 8: Student Contributions by Participation Type and Race-Gender

	Students of Color						White Students					
	Total # of Students	Total Contributions (Semester 2)	Mean Cont. per Student	Contribution Solicitations			Total # of Students	Total Contributions (Semester 2)	Mean Cont. per Student	Contribution Solicitations		
				Cold-Called	Encouraged	Volunteered				Cold-Called	Encouraged	Volunteered
Female	3 11%	54 7%	18	21 10%	6 14%	27 5%	5 18%	127 17%	25.4	53 24%	15 34%	59 12%
Male	8 29%	117 15%	14.6	53 24%	5 11%	59 12%	12 43%	469 61%	39.1	91 42%	18 41%	360 71%

Table 9: Student Contributions by Participation Type and Race-Gender

	Total # of Students	Responded to Teacher Q	Asked a Q	Shared Solution	Responded to Student Q	Declined to Answer	Offered a Comment	Identified Mistake	Read Out Loud	Shared Screen
ALL Students	28	482	132	45	30	29	25	12	8	4
Students of Color										
Female	3 11%	25 5%	7 5%	7 16%	3 10%	4 14%	1 4%	2 17%	2 25%	3 75%
Male	8 29%	74 15%	24 18%	7 16%	3 10%	8 28%	0 0%	1 8%	0 0%	0 0%
White Students										
Female	5 18%	81 17%	7 5%	11 24%	7 23%	9 31%	5 20%	4 33%	2 25%	1 25%
Male	12 43%	302 63%	94 71%	20 44%	17 57%	8 28%	19 76%	5 42%	4 50%	0 0%

Findings from this analysis reveal that participation inequities in this class extended beyond gender groups. Male students did not dominate class contributions; *White* male students dominated. In fact, male students of color experienced the fewest opportunities to participate across all contribution categories compared to the other gender-race groups. Male students of color made 117 contributions, only half of what would be expected given their representation in the class (15% of contributions vs. 29% of population). They were the least likely group to share problem solutions, respond to student questions, or offer unsolicited comments. None of these three types of participation were required by the teacher; the teacher asked for volunteers to share homework solutions for extra credit and if no one volunteered, the teacher did it. The teacher also answered students' questions if no student volunteered to answer them, and unsolicited comments were shared without any explicit invitation and therefore not required. The only participation type for which male students of color were within the expected range was declining to answer questions. They declined to answer their fair share of questions, but this is the one contribution category for which higher is not better.

Female students of color experienced the second fewest opportunities to participate. The three group members accounted for 54 contributions (7% of total contributions vs. 11% of population) averaging 18 contributions per student, slightly higher than male students of color (14.6 per student), but lower than White females (25.4 per student) and White males (39.1 per student). Female students of color were cold-called and encouraged to contribute as expected, while White female students were cold-called and encouraged *more often* than expected. In addition, White female students responded to teacher questions and offered unsolicited comments as expected, while female students of color contributed in these ways *less often* than expected. White female students were not that different from their White male peers with most contribution frequencies falling within the expected range or above. Consistent with the initial analysis, the exceptions seem to be related to risk-averse participation and seem to be true regardless of race; specifically, females (in general) were less likely to ask questions, more likely to decline to answer, and less likely to offer voluntary contributions. With 469 total contributions (61% of total contributions vs. 43% of population) White male students dominated whole-class participation. The two outlier White male students certainly impacted the contribution numbers, but they were not the only White males contributing; nine out of the top 14 class contributors were White males. The only two participation types with lower-than-expected rates for White males were declining to answer questions and sharing screens. Four times during the semester the teacher asked, “Can someone please share the task prompt on their screen?” and all four times females responded to this request; three of those four times were female students of color.

Discussion

Participants spent much more time talking about classroom participation issues related to gender than race. Even issues that pertained only to White male students or female students of color were repeatedly framed with respect to gender alone. Differences in whole-class participation by gender did indeed exist but the analysis of gender-race groups revealed a more nuanced, and consequentially different, participation story. Findings revealed *White* dominance superseded *male* dominance; White male students had the most opportunities to participate, followed by White female students, female students of color, and finally male students of color.

Taken together, findings suggest participants’ gender-focused discourse obscured racial inequities in classroom participation. Gender-focused discourse drew attention to discrepancies in male / female participation, but differences in the participation of White students and students of color were not noticed, or at least not talked about. The only participation issue mentioned related to race (and not gender) was an issue I raised before the start of the spring semester. After doing a trial run with EQUIP, I shared with the teacher that only one student of color had been given opportunities during that class period to contribute in “mathematically competent” ways. The teacher acknowledged the importance of this observation at the time. Yet, neither one of us (both White women) referenced this (or any other) race-related participation issue again. It was not that I noticed issues and chose not to mention them; I did not see racial inequities in spring semester participation until I conducted the gender-race analysis of student contributions.

Questions remain as to how our identities as White women may have clouded our ability to talk about and notice racial inequities. However, the student teacher, a man of color, did not mention race-related participation issues either. It is very possible that students of color noticed racial inequities but chose not to talk about them. Despite the seemingly strong relationships I built with students that year, the fact remained that I was a White woman researcher asking students of color to share with me their personal observations. Students shared a lot, but I cannot assume they shared everything they noticed or experienced.

While attending to gender inequity is extremely important, attending to gender alone is not enough. Discourse focused exclusively on gender obscures the intersectional experiences of numerous other marginalized groups of students, including male students of color, transgender and queer students, and students labelled with “disabilities.” In addition, attending only to gender reifies gender as a binary, which further marginalizes students who identify as neither male nor female. Moving forward, an intersectional approach to mathematics education research is of utmost importance. Topics worth exploring further include: how racial and gender-based inequities interact with inequities related to virtual classroom spaces, how gender and race shape participants’ noticing, how classroom participation varies for groups of students across different contexts, and how the experiences of individual students within the same identity groups compare to one another.

BLACK STUDENTS' TENSIONS WHEN FREEDOM DREAMING ABOUT AN IDEAL MATHEMATICS EDUCATION IN RURAL APPALACHIA

Sean P. Freeland	Matthew P. Campbell
West Virginia University	West Virginia University
sfreelan@mix.wvu.edu	mpcampbell@mail.wvu.edu

This preliminary work is from a larger study on the experiences of Black students learning mathematics in rural Appalachia. Following previous findings, this piece analyzes a series of interviews with Black students from West Virginia who were asked to imagine their ideal mathematics education through the lens of critiquing injustices. These freedom dreams were intended to develop features of a new mathematics education; however, there were tensions present in their re-imagination. They were often constrained by dominant notions of achievement and race in mathematics education. These tensions and student voices need to be taken into consideration in reform and change in mathematics education in rural Appalachia and beyond.

Keywords: Equity, Inclusion, and Diversity; Social Justice; Systemic Change

Past movements in mathematics education have had de-humanizing effects on students, particularly Black students and other students of color. Success in mathematics education has been defined by achievement on standardized tests and a limited conception of what it means to do mathematics (Martin, 2019). Mathematics education policy has contributed to this de-humanization through standardization (Martin, 2015), including through the standards movement of the past three decades (e.g., CCSSO, 2010; NCTM, 1989, 2000). This de-humanization also sidesteps systemic racial issues in mathematics education, instead focusing on ways to "help" or remediate the "low" performance of poor or Black students (Bullock, 2019).

Recent efforts to pursue equity in mathematics education have focused on humanizing mathematics and the experiences of students engaging in school mathematics (i.e., Gutstein, 2006; Rubel et al., 2016, Su, 2020). However, much of the focus on educational equity in mathematics education attends primarily to traditional notions of achievement (i.e. grades, standardized test scores) and access to high quality mathematics. As Gutierrez (2012) states, this only partially addresses the concept of equity and the de-humanization of mathematics and students by focusing only on dominant structures while failing to emphasize critical issues of power and identity issues (Gutierrez, 2012). Current notions of equity are generally uncritical and avoid human and social issues. They maintain the status quo in mathematics education, failing to re-think the field, especially for Black students. This allows mathematics education to remain as a White institutional space into which Black students are "invited" (Bullock, 2019). A more human mathematics education is possible by re-thinking and critiquing current embedded practices and structures and by considering the voices of students, particularly Black students.

In this brief report, we highlight preliminary analyses of a series of interviews with Black students from West Virginia to re-imagine a new mathematics education, highlighting the ideas and tensions that shape their perspectives. This research contributes to efforts to humanize mathematics education and center student voices by situating the work in a context that is under-researched—rural, central Appalachia—where issues of race are traditionally backgrounded (Cabell, 1985; Hayden, 2002). Students were asked to re-imagine a mathematics education that focuses on identity, power and racial issues. This was an attempt at a "freedom dream" (Love, 2019) of what mathematics education can be through the lens of critiquing injustice and harnessing the power of Appalachians and their communities. We enter this work as White, cisgender male mathematics educators who live and work in rural Appalachia. We acknowledge our Whiteness and the benefits we receive from the status quo in mathematics education, and we believe in the power of students in Appalachia, particularly Black students, and use this work to elevate their voices in this re-imagining.

Freedom Dreaming/Black Liberatory Mathematics

In order to make mathematics education truly equitable and human, particularly for Black students, and to make it an instrument for social justice, we need to begin truly re-imagining what it can be. Freedom dreams are imaginations that are focused on challenging injustices in education and society (Love, 2019). Freedom dreams are, however, grounded in reality. They are not "whimsical, unattainable daydreams, they are critical and imaginative dreams of collective resistance" (Love, 2019, p. 101). The de-humanization of the educational system, in particular mathematics education, is so ingrained that to change it requires imaginative resistance to the oppressive structures that exist including standardized achievement tests and linear teaching based on memorization and procedures. This is especially necessary as Black students have experienced various forms of violence in their participation in mathematics education. They have long been invited to the space, but only if they apply to the norms of mainstream mathematics education (Martin, et al., 2019). Freedom dreaming can move towards a Black Liberatory Mathematics education that moves away from the notions of access, equity, and inclusion which often fall short. This is a way to re-think mathematics in a way that values Black students, their families, their communities, and their cultures (Martin et al., 2019).

Rural Appalachia as the Context of the Study

As hooks (2009) states, there are competing cultures in rural Appalachia: "the world of mainstream white supremacist capitalist power and the world of defiant anarchy that championed freedom for everyone" (p. 11). The goal of freedom dreaming is to tap into the second culture that is found in so many communities across Appalachia and to upend the first dominant culture. This can have an impact not only on Appalachian communities, but it can build mathematics communities that challenge the status quo. Rural Appalachians, and particularly Black people in the region, face health, environmental, educational, and other issues imposed on them by a White capitalistic society (Catte, 2018). A new mathematics education can work to dismantle the structures in mathematics education and society that contribute to these disparities. To begin to make progress on this vision, we pursue the following research questions: (1) What do Black students in rural Appalachia consider an ideal mathematics education when they freedom dream through the lens of critiques of injustice and community-based solutions? (2) What tensions exist for students between this re-imagination and traditional notions of success rooted in de-humanization?

Methods and Data Analysis

Data for this study come from a larger study exploring Black students' experiences learning mathematics in rural Appalachia. Participants were six high school students from across West Virginia who identify as Black and who took part in a statewide after-school mathematics and science program focused on mentoring students to enter and succeed in STEM-based degree programs. The first author was previously an assistant director of the program, which provided initial mentoring relationships with the participants. In the program, students conduct community-based research projects, thus providing experience in addressing injustice in their communities. They also are admitted to the program based on traditional academic achievement, and they must maintain a certain grade point average to remain in the program.

The first author conducted initial one-on-one and focus group interviews with the students followed by individual follow-up interviews. Each interview was approximately sixty minutes in length. Following previous findings (Freeland, 2021), this work is focused on a re-imagination of mathematics education by Black students who are subjected to de-humanizing mathematics education in the region. Students were asked multiple questions particular to this research. First, they were asked to describe their ideal mathematics education. Next, they were asked to consider how their work in communities and with community-based research could be applied to mathematics classes. Lastly, students were asked what they would want mathematics teachers to know about teaching mathematics to Black students in rural Appalachia.

Data analysis occurred over multiple phases via open coding (Miles et al., 2019). The first stage involved coding students' responses when asked to freedom dream and finding examples of a re-thinking or re-imagining of mathematics education. While the goal was to move from codes to features of a re-imagined mathematics education, what emerged were tensions present in their freedom dreams. To explore the tensions that were present, codes were further refined to include examples of humanization and de-humanization. Also, we drew on Rubel's (2017) work discussing "changing the game" and "playing the game" of mathematics education, providing another lens to explore the conflicts that students experienced when freedom dreaming. This data focuses on three students from the larger study: Letitia, Zahara, and Yara. Their freedom dreams represent a preliminary view of the complexity of re-thinking mathematics education and the tensions students feel when doing so.

Preliminary Findings

Tensions Associated with Achievement in Mathematics Education

Students' freedom dreams re-imagine the way that classroom interactions occur and re-thinks traditional classroom structures. However, these dreams always have an eye towards traditional achievement through exams, standardized testing, and high grades. For example, Letitia mentioned a way for students to work consistently with their classmates in groups of two or more. However, this found its way to a discussion of assessment as she imagined that students could complete tests together:

> We can have like two people at a table or little area. And they can work together on their stuff and be like partners for the rest of the year. Assigned partners and stuff and they help each other even when they're doing a test. Because it can be like on paper. And they're both trying to solve it.

Letitia also wants a re-imagining of grades, but she still sees the need for them. She said, "I would still keep grades, just a different type of grading based on how you understand it. But maybe not like A B C D…" However, Letitia strives greatly for high grades even though it causes her stress. She said, "I want to have good grades because I wanted to graduate with honors. I would get stressed out if I got a bad grade. I'll have like a breakdown." Similarly, Yara feels the pressure and de-humanization of grading policies while still seeing value in them. When asked if her re-imagined mathematics education would need grades, she said:

> I don't know because I like that I have good grades. Like it makes me feel good that I'm doing good and stuff. But also, I feel like I'm stress a lot about my grades. I'm always checking my grades constantly. Constantly.

In contrast to Letitia's ideas about collective learning, Zahara imagines a freer mathematics education that relies on the individual to move at their own pace in learning. She saw a video about a high school in Canada where "you learned at your own pace." She said, "There weren't really grades you just learned what you need to learn, and you just go past it whenever you learn it and just keep going." However, she also realized that teachers must prepare them for the ACT and SAT, so although they could learn whatever they could individually, the next teacher would need to "pick up where they left off." The traditional ideas of mathematics education as linear and achievement based remained strong.

Tensions Associated with Race in Rural Appalachia

The main tension for students associated with race was the feelings of wanting to be treated equally to their White peers while also having their race and Blackness recognized and honored. This is especially important in the mostly White, rural spaces these students live and learn. This is highlighted by Zahara who said, "It would be best for the teacher to treat all of them, every student, the same because if you're the only Black person you don't want to feel different more than you already do." Letitia agrees as she believes that many people doubt Black students' intelligence or mathematics abilities:

> I want them to know that you're not dumb. 'Cause people have this I guess idea that Black people aren't smart. And not really nice … or smart. I think people should just ease up on that. And treat everybody the same not any different.

This feeling of wanting to be treated exactly the same contrasts with their desire for their Blackness to be acknowledged and for people to be treated appropriately. Zahara said, "You know just treat everyone like you should be treating them in the first place." She also expressed her pride in being Black: "We didn't ask to be Black, but I'm proud to be Black. But that doesn't mean we have to be talked to or treated different like we're not as smart as other kids." Letitia sums up this tension when discussing the equal treatment of White and Black students in rural Appalachia. She said, "I think (treating everybody the same) that's different than just like saying you're the same like treatin' you White. You know, treat me the same, but you know that I'm Black and not White. And that, this is different."

Discussion and Conclusion

Black students were able to freedom dream and re-imagine a more human mathematics education. However, they were often constrained by the deeply ingrained structures including testing and grading that have defined mathematics education. They are also constrained by the Whiteness that exists in their context. Based on these students' experiences (Author, 2021), they often dislike mathematics education and view it as a series of de-humanizing series of memorizations and procedures. A re-imagining needs to occur for Black students in rural Appalachia to live in their full humanity; however, the tensions they exhibit are very real and need to be taken into consideration and honored. Their perspectives as Black students in rural Appalachia must be a part of any reform and change in mathematics classrooms.

While the students interviewed for this study seem unfulfilled in their de-humanizing mathematics education—seen as a means to an end for college or career—those same endpoints constrain the opportunities to imagine what else is possible. This provides an important starting point for future work with students and teachers to work towards a full re-imagining of a more human mathematics education focused on community, particularly in this context. These students' voices also provide an important voice now and moving forward in the discussion of mathematics education and other systems in rural Appalachia and beyond.

Principals play an important role in shaping, encouraging and supporting mathematics teachers in their daily work. They also have the responsibility for teachers and students' welfare. A survey of almost 1000 district decision-makers in the U.S, however, found that these administrators tend to make decisions about structuring students' opportunities to learn based on principles of equality rather than principles of equity (Herbel-Eisenmann, et al., 2018). Bound with, or with support of, regulating policy, principals move their school life forward day by day, being responsible for students' opportunities to learn in all subjects, including mathematics. Conversations and interviews with principals in this study focused on understanding the complexities of storylines—or grand narratives—related to organizing mathematics education for Indigenous and (rather) newly migrated students in Norwegian schools. This paper addresses the storylines about these minoritized youth, mathematics and languages.

Our research goal is to understand a range of "available" storylines (Wagner et al., 2019) to inform our longitudinal, participatory research project with teachers, administrators, community members, youth, and families. We are motivated by the fact that the opportunities that students from minoritized groups have for learning mathematics are often diminished as compared to their majority group peers due to systemic and institutional issues (Barwell et al., 2007; Civil, 2012; Le Roux, 2016; Meaney et al., 2011; Valoyes-Chávez & Martin, 2016). Over time, our partnership will develop strength-based pedagogies based on positive, asset-based storylines. In this paper, we analyze in-depth interviews with nine Norwegian principals and share some of their complex storylines about minoritized student groups, their languages and their learning of mathematics.

Positioning Theory and Storylines

The key construct we use for this paper, the idea of storylines or "lived stories for which told stories already exist" (Harré, 2012, p. 198), comes from positioning theory. As Davies and Harré (1999) point out, the multiple storylines at play "are organized through conversations around various poles, such as events, characters, and moral dilemmas. Cultural stereotypes like nurse/patient, conductor/orchestra, mother/son may be called on as a resource. It is important to remember that these cultural resources may be understood differently by different people." (p. 39). Storylines are negotiable; they are reciprocal and contingent (Wagner & Herbel-Eisenmann, 2009). Storylines also can occur at a range of scales (Herbel-Eisenmann, et al., 2015). Although positioning theory has been used in mathematics education research for over a decade, there is typically less focus on storylines than on positionings. Because storylines indicate what is expected in an interaction and can shape the potential fluid roles or positions that are made available to people, they are important to consider in relationship to mathematics teaching and learning.

Methodology

Context

This research is part of the Norwegian Research Council's FINNUT-granted project MIM: Mathematics Education in Indigenous and Migrational contexts: Storylines, Cultures and Strength-Based Pedagogies, (see https://www.usn.no/mim), a collaboration drawing on participatory approaches to investigate educational possibilities and desires, in times of societal changes and movements. Although we focus on the Norwegian context, we recognize that these kinds of societal changes and movements impact many countries throughout the world. With these changes and movements of people, language diversity may be the most obvious challenge in mathematics classrooms, but this reality also connects to cultural differences and conventional characteristics of the discipline. Indigenous communities have experienced linguistic and other challenges for decades as a result of colonization. In Norwegian contexts, several groups with a different origin than Norwegian are recognized, often with a reference to a connection to a (former) nation state. These groups are mainly seen mentioned from the 1970s and onwards when migrant workers from Pakistan, Turkey, and Morocco started to arrive in Norway. More recently immigration also comprises people from other European countries and from conflict areas in, for example, Asia and Africa (Reisel, Hermansen & Kindt, 2019). In addition to these, there are peoples/nations of Norway (without their own nation state) that appear in the contexts we are interested in; the Kven and Sami peoples belonging to the northern part of Norway. The schools in which we have partnerships are in both the northern and southern parts of Norway. Principals in northern Norway are expected to provide mathematics education in Sami, and sometimes in endangered languages such as Kven. In some of the further north communities, and in the principals' schools in the south, there are a high number of migrated youth who have arrived in the last decade and hence are not (yet) proficient in the main language of instruction, Norwegian.

Methods

Between August 2021 and now, we have been working together with people in five schools. As part of this work we did In-depth interviews with nine principals in our collaborating schools in Norway. Each interview involved two people from our university-based team and one school principal and took place on Zoom. The interviews were recorded, then transcribed in Norwegian and were also translated into English. We independently read each interview multiple times and took notes on the range of ways Indigenous and (newly) migrated students, families, and teachers were positioned in the episodes and tried to identify the kinds of storylines that were at play. We then met and shared the storylines we had identified and evidence for that storyline and, after discussion, came to consensus on a set of storylines to report. As Wagner and Herbel-Eisenmann (2009) have pointed out, there is not a 'correct' way to name a storyline because each participant's perspective may be different. Thus, we drew on the context of the interview, information we knew about the school and community, and the educational, historical, and political context of the specific country to consider how to name the storylines.

Results

In the data material from conversations with principals focusing on Norwegian minoritized youth and their mathematics education, we found a number of storylines, Here we share two larger intertwining storylines, with both supporting and contradicting "smaller" storylines in the conversations. We found that the main storylines were similar from schools in different geographical and socioeconomic areas in Norway. How the principals developed and talked about the storylines, however, differed geographically, with an emphasis on the particular communities in their areas. In this section, we elaborate on the two overarching storylines: "Mother tongue teachers are important resources” and “Students don’t (yet) have the basic language skills to build their mathematics language” in separate sections while acknowledging that they intertwine and sometimes overlap each other.

Mother tongue teachers are important resources

The overarching storyline that all principals address is their concerns for giving students the best opportunities to learn mathematics. The principals talked about how they strive to find support for students who do not (yet) know the language of instruction (Norwegian) or try to ensure teachers can teach or support in the classrooms in languages other than Norwegian. Depending on the geographical area, however, the principal’s way of talking about this storyline differed.

In the Northern context, the principals are obliged to offer education in the minoritised languages, as Sami and Kven. In addition, a number of the parents from indigenous communities want to protect and revitalize their languages and hence wants these languages to be the language of instruction for their children in schools. There are also a number of parents, however, who want their children to learn and know mathematics in Norwegian because this will support the students’ further university studies. In addition, it is very difficult to find teachers who can teach mathematics in Sami and/or Kven. Teachers who are both educated in mathematics teaching, and know the Sami language are rare, if they even exist. The challenges are complex and contradictory.

In southern Norway, there are a higher number of minoritised student groups due to recent migrations. A high number of youth came to Norway as refugees, or in families who arrived in Norway for work. These students are usually offered to participate in a “mottagsklasse”, a “welcome/arrival class”, in schools where these exist. In these classes, they together get accustomed to the school, learn Norwegian and learn subjects such as mathematics even if they are of different ages and are on different learning levels in the subjects. After one year, the students are dispersed in, what is described as “ordinary” classrooms where children are in the same age groups despite knowledge levels. Principals do not talk about these “welcome/arrival classrooms” as ordinary: they are “special” classrooms, in some schools, where the students go one year.

A storyline about the latest arrived students is that it is hard for them to learn mathematics because they do not (yet) know the language of instruction, and the teachers—mainly Norwegian—do not know the students’ languages. As one principal said, “they get lost in translation and it goes both ways”. The principals talked about wanting to employ a higher number of mathematics teachers with migrational background, to teach in these classes. Another option they suggested would be to have mother tongue teachers present in the classrooms.

Students don’t (yet) have the basic language skills to build their mathematics language

This storyline is shared by principals both in the north and south of Norway, however, with different explanations. The storyline addresses minoritised students who do not have sufficient language skills either in their mother tongue language or in Norwegian. These students may be second or third generation migrants, who heard and talked Norwegian only in day care (for example kindergarten and preschool) and then during school hours only. At home, they speak a “modified”, or “adjusted” mother tongue language, mostly lost due to parents, grandparents and/or siblings not being fully exposed to this language while living in Norway over time. The principals talk about these students as having extra challenges as they do not have enough language skills to build a mathematical language in either of their languages.

In the north, the challenges with this storyline are experienced in the same vein, however, the reasons for the storyline are different. The reasons here concern either endangered languages (for example Kven) but also generations that have lost their indigenous languages due to being forced to speak Norwegian during “fornorsksningsperioden”. In other words, families have “lost their heart language” (mistat hjärtespråket sitt) (Broch Johansen, 2020). The situations are complex, and we here give two examples: If the children have been exposed to, for example, Sami, during kindergarten, pre-school and the early years, and/or at home, then they might not know the basic mathematical concepts in Norwegian when they move to secondary school where they switch language to Norwegian as language of instruction. Or, conversely, a student may have attended an early education in Norwegian, and then moved to a secondary school where they may learn mathematics in Sami. Or they were exposed to the indigenous languages in the early years of schooling, but at home they speak Norwegian only. In these cases and according to this storyline, as a minoritised youth, they get caught in the structures and do not have sufficient language skills in any language to build their mathematical language skills. For the principals, the impact and complexities of this storyline becomes an ethical dilemma.

Discussion

We are sharing here our early interpretations about the interviews with principals. In the presentation we will have translated transcripts to share, which will help us illustrate the complexities of these storylines. We recognize that some of these storylines also appear in first attempts to gather international data related to understanding school policies and principals' acknowledgement of difference and strategies that assist or deny access to schools for all children. For example, Goddard (2007) reported that “the issue of adequate funding for interpreters is present in many countries, as is the practice—albeit contested by some—of using children to interpret for their parents” (p. 4). Providing financial resources for mother tongue teachers in schools would be a systemic approach to supporting language for newly arrive immigrants and Indigenous students. Alternatively, resources could be provided that would educate a higher number of teachers with migrational backgrounds to become educators.

In Sweden, Johansson, et al. (2007) reported mixed messages from principals and teachers about the kinds of responses and attitudes to the increasing school diversity. Alongside valuing diversity for how it enriched the school community, for example, was associations with problems of “language difficulties, social programs, support programmes…[and needs of] special support” (p. 26). One of the complexities for us relates to our desire to avoid perpetuating deficit framing of students and cultures. When we identify storylines that pervade education discourse, deficit-framed storylines exist. We struggle to find ways of reporting on these storylines to research and professional education communities while making it clear that we see them as problematic. We also acknowledge that other storylines we have found have centered on individuals rather than systems or structures that need to change (Andersson, et al., 2021; Ryan, et al., 2021). An additional complexity in our work relates to the pandemic and its influence on our research plan. Although we planned to foreground the experiences of minoritized children in Norwegian mathematics classrooms, the pandemic's restrictions on face-to-face interaction forced us to talk with principals before talking with students. We consider this arrangement less than ideal for research drawing on participatory methodology that focuses on classroom opportunities.

ANALYTICAL PROCESSES FOR MEASURING EQUITABLE NOTICING IN MATHEMATICS

PROCESOS ANALÍTICOS PARA MEDIR LA MIRADA PROFESIONAL Y EQUIDAD EN MATEMÁTICAS

In this paper, we provide two analytical methods for measuring the intersecting constructs of equity and professional noticing, as defined by Jacobs et al. (2010). One is a scoring rubric utilizing Gutiérrez's (2009) four dimensions of equity to include access, achievement, identity, and power, along the dominant and critical axes. The second is a flowchart to examine asset, deficit, or neutral language in professional noticing responses about students' mathematical thinking. We discuss the affordances and limitations of both methods, along with challenges for measuring equitable noticing in meaningful ways. Preliminary findings have shown a positive increase in the dominant axis where responses elaborate upon the dimensions of access and achievement.

Keywords: Teacher Noticing; Equity, Inclusion, and Diversity; Research Methods

Perspectives

There is emerging interest in studying equity in conjunction with professional noticing (Jong, 2017; Louie et al., 2021). For example, both Kalinec-Craig (2017) and Hand (2012) have examined student positioning (and, by extension, power) in the context of professional noticing. Specifically, Hand's construction of *taking up space* does not simply "comprise [students] participation in classroom mathematical practices, but rather is about being able to contribute to the classroom community that is aligned with who one sees herself as becoming" and the extent to which teachers' in-the-moment decision-making enlarges or constrains such student contributions through manifestations of culturally dominant ideologies (p. 237). Such connections of noticing and equity are consistent with portrayals of professional noticing as contested and political space (Lefstein & Snell, 2011; Louie, 2018). Regarding the pedagogical activity that might productively influence such spaces, van Es et al. (2017) posited a number of practices (i.e., make norms explicit for doing mathematics, support students in developing mathematical identities) and associated foci for professional noticing that they describe as *noticing for equity*. Building on this work, Louie et al. (2021) recently developed a sociopolitical framework for conceptualizing anti-deficit teacher noticing, which aligns closely to the flowcharts we will present.

The aim of this brief report is to describe two analytical methods for measuring equitable noticing, which is a burgeoning area of research (Jong, et al., 2021). Several scholars have developed frameworks for equity or social justice in mathematics (Goffney et al., 2018; Gutiérrez, 2009; Stinson & Wager, 2012), which have been applied to research in mathematics education. However, limited studies have shown analytical methods that are generalizable to multiple research settings within equitable noticing. Jackson et al. (2018) describe a coding dictionary they created in the form of a matrix that uses Gutiérrez's (2009) four dimensions of equity as columns on top and three levels of noticing as rows, which mirror the components of professional noticing (Jacobs et al., 2010). They then provide sample text based on preservice teachers' responses to vignettes about equitable access to mathematics, which is helpful to understand how they operationalized the varying dimensions of equity across levels of noticing. In our project, the depth of responses to the varying dimensions of equity were also taken into consideration.

Methodology

Context of Project

The research team was awarded an NSF grant to develop modules that integrate equity and noticing for mathematics methods courses. A total of eight modules were developed and implemented in mathematics methods courses for elementary teacher candidates during fall 2020 and spring 2021. The two frameworks woven into the modules are Gutiérrez's (2009) four dimensions of equity and Jacobs, Lamb, and Philipp's (2010) professional noticing of children's mathematical thinking, including attending, interpreting, and deciding. To measure improvement in teacher candidates' professional noticing skills and deepen understanding of equitable mathematics teaching, we designed a video-based instrument that is administered pre- and post-methods course. After viewing a 74-second clip of a second-grade classroom with racially diverse students participating in a number talk to solve the open number sentence of 10 + 10 = __ + 5, teacher candidates respond to five prompts. Three prompts relate to that which they attended, interpreted, and decided about the children's mathematical thinking in the video. And, the following two additional prompts relate to equitable noticing. Q5: "Describe how equity relates to this classroom scenario in different ways." Q6: "If you were the classroom teacher, how might you strengthen equity in this classroom scenario?" Here, we focus on our analysis of the noticing equity responses which is framed by the work of Gutiérrez (2009, see figure 1).

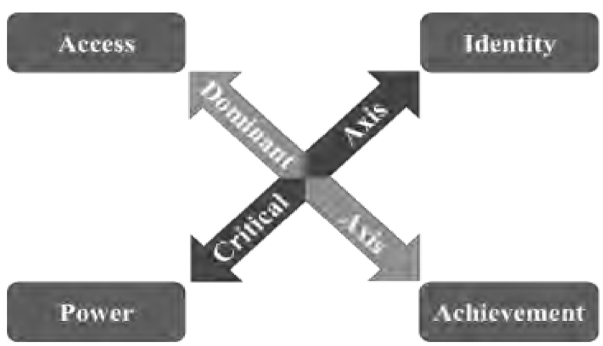

Figure 1: Four Dimensions of Equity (Gutiérrez, 2009)

Gutiérrez describes four dimensions categorized into two axes: the dominant axis (access and achievement) and critical axis (identity and power). We developed a scoring rubric ranging from 0-4 for each axis of equity (see figure 2). Alongside the scoring rubric, we created a codebook that includes codes for each dimension of equity to help us determine which dimension is mentioned and whether the response elaborates on a dimension while also grounding it in the video of the classroom scenario. While we acknowledge the limitations in this approach, we also think there is great potential for our scoring rubric to be applied to the analysis of additional mathematics classroom video clips to further research the intersection of noticing and equity. In addition, we used a flowchart developed for another equitable noticing project to code each response based on whether the framing of the language was oriented toward one of the following: asset, deficit, neutral, or both (Thomas, et al., 2020). However, in this paper we do not include results of these categories.

0	1	2	3	4
incorrect	"OR" Attend to (mention) either dimension of the axis	"AND" Attend to (mention) both dimensions of the axis	**"OR" Attend to either dimension of axis with interpretation/productive response along the axis**	**"AND" Attend to both dimensions of axis with interpretation/productive response along the axis**

***Must be connected to classroom scenario to move beyond level 2.**

Figure 2: Coding Rubric for the Dominant and Critical Axis

Each response was given a score for the dominant and critical axes. Take this attending response as an example. *"The teacher doesn't seem to call on many girls. This could be a classroom dynamic they struggle with, or a bias on the teacher's part. This relates to equity because she isn't giving each child equal access to the problem. Only certain students have the floor to give their answers, while the others sit around looking bored. It also connects to the demographics of the classroom. Which students need extra scaffolding and help while other can get the correct answer quickly."* For the dominant axis, this would score a 3 because it provided an interpretation of the access dimension by elaborating on it. For the critical axis, it would score a 4 because it elaborated on the identity dimension with gender then acknowledged power by who has a voice to share their answers (see figure 3). We created a spreadsheet with a Boolean Function to score responses depending on whether it elaborated on one of the dimensions on the axis as the "OR" (for the score of 3) or included both dimensions within the axis and elaborated one of them for the "AND" (score of 4). The spreadsheet also had a summarizing tab that highlighted discrepancies between the two scorers to discuss and negotiate.

Figure 3: Google Spreadsheet with Boolean Function for Scoring each Axis

In our scoring, we also wanted to flag any responses that discussed systemic or structural inequities and potentially score those as a 5, but none included that in the equitable deciding responses for Q6 where it was more of a possibility. In addition, we wanted to flag responses that were deficit oriented, incorrect, or unproductive. For example, the following response speaks to access, but is incorrect and unproductive: *"Students did not understand the problem and should be grouped to make sure they do."* Because of the nod to access, this response was scored a 1, but also given a negative code due to the deficit orientation. Using both scoring mechanisms (dimension and orientation) for each response assured another step toward reliability.

Results

Given our limited sample size (n=34) of matched responses from pre to post, we cannot make substantial claims based on statistically significant differences (see Table 1). However, we noticed that for Question 6 related to the dominant axis, there was an increase in responses that mention access and achievement. What is more encouraging is that post-responses appear to be more complex and include rationales. They also noticed that only boys were selected in the video and recommended in Q6 that girls should also be selected to elevate their voices, and that students should be given time to share their ideas with a partner before a whole group discussion.

Table 1: Paired T-test Results

Pre/Post Responses	Change in Mean	Std. Dev.	Std. Error Mean	t	Sig. (2-tailed)
Q5 Dominant Score	1	0.75593	0.2672	3.742	0.007
Q5 Critical Score	0.125	1.45774	0.5153	0.243	0.815
Q6 Dominant Score	0.625	0.74402	0.2630	2.376	0.049
Q6 Critical Score	0.375	0.74402	0.2630	1.426	0.197

Discussion

We are beginning to see some patterns emerge in the way preservice teachers notice equitable teaching practices in mathematics. It is encouraging that there was some growth detected in the dominant axis of equity related to decisions in Q6. However, we also acknowledge the many limitations of the implementation of the modules during the pandemic year that included a small sample size. It might also be the case that the video-based assessment and analytical process did not allow for more variation in the dimensions of equity to be fully explored. In fall 2021, there were more sites that implemented the modules with over 200 preservice teachers. Thus, we aim to better examine potential changes and relationships among the dimensions of equitable noticing in this next round of coding.

Video-based measures have been widely used in noticing because they serve as an approximation of practice (Jacobs, 2017). However, the video only shows a snapshot of a classroom interaction and may not provide a full picture of the classroom environment or dynamics. Expanding the type of classroom artifacts to include vignettes, videos, and student work might capture a more valid measure on preservice teachers' equitable noticing in mathematics that could also have greater variation across dimensions of equity.

USING ANTI-BIAS PICTURE BOOKS TO ELICIT SOCIAL JUSTICE MATHEMATICS LESSONS IN EARLY CHILDHOOD TEACHER EDUCATION

Bailey Kaufman-Ridout
Fordham University
bkaufman12@fordham.edu

Alesia Mickle Moldavan
Georgia Southern University
amoldavan@georgiasouthern.edu

This study examines early childhood preservice teachers' experiences using anti-bias picture books to design mathematics lessons addressing issues of social justice during a children's literature course. With reference to the Teaching Mathematics for Social Justice framework (Gutstein, 2006) and the Learning for Justice (2016) social justice standards, preservice teachers designed lessons to address issues of identity, diversity, justice, and action. Findings indicate that the preservice teachers were more likely to target social justice pedagogical goals focused on identity and diversity over justice and action. Additionally, the preservice teachers experienced increased confidence when working with such lessons. Recommendations are made that preservice teachers in early childhood education have explicit opportunities to engage in such tasks to develop their justice-related mathematical consciousness and professional practice.

Keywords: Preservice Teacher Education, Social Justice, Early Childhood Education, Instructional Activities and Practices

Early childhood educators provide some of the first experiences for young learners to engage with mathematical thinking (National Research Council, 2009). Thus, early childhood preservice teachers (PTs) need the opportunity to engage in explicit tasks focused on mathematics in order to become well-rounded early childhood educators (National Council of Teachers of Mathematics, 2013). An increasing priority in the field of early childhood education (ECE) is creating equitable instruction that is reflective of the world outside the classroom (Alanís et al., 2021). With content only lessons, students can experience a disconnect between the skills they learn in the classroom and real-world applications. The intersection of mathematics and social justice is recognized as Teaching Mathematics for Social Justice (TMfSJ) and aims to use mathematics as a tool to confront systemic challenges within and outside the classroom (Gutstein, 2006). When establishing goals for TMfSJ lessons, teachers need to consider both mathematics and social justice standards. Learning for Justice (2016) developed social justice standards that organize anti-bias standards within four domains: Identity, Diversity, Justice, and Action (IDJA). These standards feature grade-level outcomes that are applicable to young learners and can be used in ECE to target social justice ideas.

While the current literature examining TMfSJ lessons is primarily focused on mathematical concepts found in secondary settings, mathematics in ECE settings can benefit from the goals of TMfSJ. Although the literature on TMfSJ is broad, Ward (2020) demonstrates that TMfSJ can be used in ECE to create opportunities for action targeting social justice through child-led decision-making. Current studies (e.g., Bartell, 2013; Myers, 2019) regarding PTs experiences with TMfSJ are more commonly associated with secondary education, with very few looking at the experiences and beliefs of early childhood PTs. This study examined the research question: What are PTs' experiences engaging in an anti-bias picture book task to develop their skills and confidence to design mathematics lessons targeting social justice issues?

Theoretical Framework

Rooted in Freire's (1970) concept of critical education and Frankenstein's (1983) application of the theory to mathematics, TMfSJ aims to empower students to investigate and challenge societal inequities through the development of their critical consciousness and subsequent application of mathematical skills (Berry et al., 2020). This empowerment occurs through the prioritizing of both mathematical pedagogical goals and social justice pedagogical goals (Gutstein, 2006). One noted tension of TMfSJ is how the success of students or teachers engaging with both pedagogical goals is determined (Kokka, 2015). One variable noted in contributing to success in achieving both goals is the ability to cater instructional time to both goals (Gregson, 2013; Gutstein, 2006). Learning to balance both mathematical and social justice concepts and goals is a skill that is developed in TMfSJ practices.

For purposes of this work, we consider the theoretical lens of Berry et al. (2020)'s social justice mathematics framework that incorporates six elements detailing the progression of the social and mathematical practices that lead to action and public products. We position the elements into two stages, which we deem as progression markers, to describe where PTs are on their journey of "justice-related mathematical consciousness". We note the first stage as "beginning of justice-related mathematical consciousness" to address the preliminary progress toward equitable teaching practices that consider authentic and challenging questions or concerns to generate social and mathematical understanding. The second stage described as "emergent and continuing justice-related mathematical consciousness" continues beyond those questions or concerns to create a social and mathematical investigation that requires reflection and action, resulting in a tangible outcome. We posit that students who created an action plan were more inclined to put their plan into action, thereby having success within their targeted pedagogical goals (Kokka, 2015).

Research Methods

We used a qualitative case study (Yin, 2014) across two asynchronous sections of a children's literature course at a rural, public two-year college in southwestern United States. Consenting participants included 35 PTs who self-identified as female (n=33), male (n=1), and gender fluid (n=1) seeking early childhood teaching certification. Their demographics could be further described as Hispanic/Latinx (n=20), White (n=6), Black (n=3), Asian (n=2), American Indian/Alaskan Native (n=1), Biracial (n=1), Egyptian-American (n=1), and other (n=1).

Task Design

Students worked through asynchronous, scaffolded modules to complete this task. The first module encompassed resources from DREME (2022) to explore the use of picture books to teach early mathematics as well as review of the Learning for Justice (2016) anti-bias framework and Ward's (2020) research. Next, the PTs were tasked with selecting a relevant anti-bias picture book with consideration for how the books embodied standards from one of the anti-bias IDJA domains. They also considered which early mathematics standard each book could target, such as spatial relationships, number sense, classification, measurement, and patterning (Carpenter et al., 2017). Using their selected standards, PTs then wrote an early mathematics lesson targeting social justice in reference to their anti-bias picture book. The final action required PTs to reflect on their experience incorporating social justice into a mathematics lesson.

Data Sources

A variety of data sources were collected including pre- and post-surveys, artifacts (lesson plans), and reflection responses. Before accessing course material, PTs completed a pre-survey and answered questions relating to confidence incorporating themes of social justice into lesson planning. All participants submitted lesson plans that included both the mathematics and social justice standards that informed the lesson, background information about their selected anti-bias picture book, and a step-by-step description of the lesson. After completing the lesson plan, participants answered reflection questions about their specific lesson and responded to the post-survey that addressed their confidence incorporating themes of social justice into lesson planning after having attempted this anti-bias picture book task.

Data Analysis

We initially looked at which social justice domains the participants selected standards from and if certain books were chosen for specific domains. We also noted which early mathematics skills were selected. In addition to analyzing which standards were selected, we used descriptive, in vivo, and values coding (Miles et al., 2018) to discover what themes or aspects of identity (e.g., race, gender, ethnicity, socioeconomic status) each task and respective book centered in the context of the social justice standards. We then coded for themes within the reflective responses regarding how their mathematics task and selected anti-bias picture book encourages advocacy and action, reflects diversity as an asset, and promotes social justice mathematical thinking.

Findings

Most of the PTs (n=23; 65.71%) selected Identity and Diversity standards rather than Justice and Action standards (n=8; 22.86%), with the remaining (n=4; 11.43%) not selecting a standard. Figure 1 shows the associated issue within each domain that PTs targeted using their selected texts. For example, the domains of Identity, Justice, and Action included race as a focused issue in the lessons; however, race was not a focus in the Diversity domain. While it is good practice to support Identity and Diversity within ECE, the TMfSJ framework encourages more critical thought through inclusion of standards from the Justice and Action domains (Berry et al., 2020). The most common mathematical concept selected by PTs (n=19; 54.28%) was number sense. Others included patterning (n=5; 14.29%), measurement (n=5; 14.29%), classification (n=5; 14.29%), and spatial relationships (n=1; 2.85%).

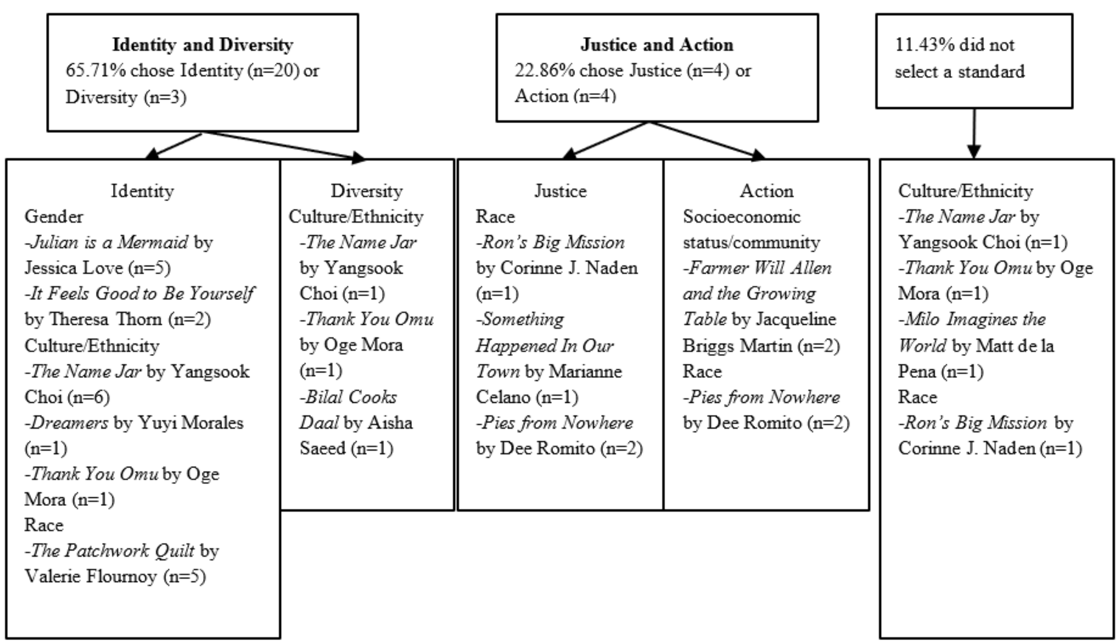

Figure 1: PT's Book Selections by Social Justice Domain

It was apparent that the PTs who selected anti-bias books within the Identity and Diversity domains created lessons that leaned heavily on the social justice goals with less focus on the mathematical goals. Findings revealed that there were fewer lessons that seemed to integrate the two pedagogical goals in a cohesive manner. One lesson plan that succeeded in balancing the pedagogical goals used an Action standard and targeted number sense. The PT used the book *Farmer Will Allen and the Growing Table* by Jacqueline Briggs Martin to explore concepts of community leaders, food deserts, and food insecurity to organize a class action plan to address food insecurity through a classroom food drive. The class demonstrated one-to-one correspondence and cardinality by counting the collected food items. A degree of mathematical consciousness was required for this PT to create a TMfSJ lesson plan that included an Action plan resulting in a tangible product for the community. When identifying a PT's stage in their journey of justice-related mathematical consciousness, it is necessary to examine the ability, or inability, that a PT has in balancing mathematical and social justice goals.

As noted in Figure 2, the PTs' mean confidence levels with social justice lessons increased after participating in the task. Furthermore, an interesting dichotomy arose in the reflective questions. For instance, two PTs commented that their text and lesson promotes social justice mathematical thinking by emphasizing how all individuals should have fair opportunities to engage. Another PT stated, "some of our peers have had the opportunity to visit some of these places and others haven't, which highlights the fact that life is easier for some people and harder for others and reasons are not always fair." These three PTs recognize that fair opportunities are needed; however, the third PT makes deliberate action plans in their lesson to critique systemic injustices, thereby demonstrating an "emergent and continuing justice-related mathematical consciousness". PTs need exposure to pedagogies that prioritize social justice, such as TMfSJ, in order to gain the confidence to create and implement these lessons into their future practice.

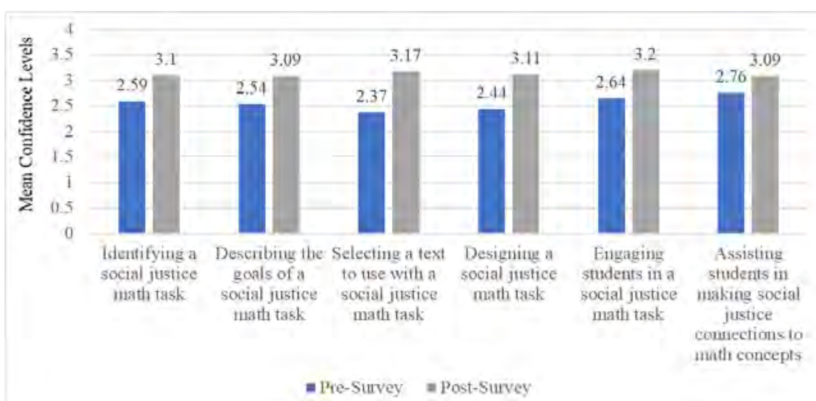

Figure 2: PT's Mean Confidence Levels with Social Justice Lessons

Conclusion

The application of TMfSJ is needed not only in the early childhood classroom but also teacher education programs. Positioning this work in generalist courses, in addition to mathematics methods courses, is important especially given how early childhood PTs lack opportunities to dive deeper into mathematical concepts and issues (Bates et al., 2013). TMfSJ gives PTs the ability to use mathematics as a tool to critically analyze the world around them, which will expand lessons past the Learning for Justice (2016) domains of Identity and Diversity and into Justice and Action (Bartell, 2013; Ward, 2020). Recognizing that PTs are at various stages of their justice-related mathematical consciousness means that scaffolded support is important for success when engaging with TMfSJ in the early childhood setting.

REDESIGNING MATHEMATICS FOR THE MARGINS: EMPATHY AS A DISRUPTOR OF DEFICIT THINKING

Rachel Lambert
University of California
Santa Barbara
rlambert@ucsb.edu

Kara Imm
Hunter College, New
York, NY
karaimm@gmail.com

A persistent problem in mathematics education has been deficit thinking by teachers about the mathematical potential of students with disabilities and students who have been marginalized in mathematics. This paper reports analysis of findings of a six-week virtual class in the summer of 2020 for 45 mathematics and special educators which integrated Universal Design for Learning (UDL) with design thinking, focusing on the teaching and learning of mathematics. Our approach grounds UDL in empathy, beginning design with developing understanding of student perspective through Empathy Interviews. In focus group conversations nine months late, participating classroom teachers reported that empathy and Empathy Interviews were the most important long-term takeaway of the course, and that empathy became a touchstone in their teaching practice. Empathy seemed to disrupt deficit thinking for these teachers.

Keywords: Equity and Diversity; Students with Disabilities; Teacher Beliefs; Affect, Emotion, Beliefs, and Attitudes.

A fundamental issue with including students with disabilities into inquiry-based mathematics is not the difficulties those students might have, but deficit thinking about the students held by teachers (Lambert, 2018). This deficit thinking is a part of the larger stigma and oppression of disabled people, but also a specific result of decades of traditional special education questioning whether of these students to profit from inquiry-based teaching (Lambert & Tan, 2020). Disrupting deficit thinking in teachers is necessary to create opportunities. But how do we as math educators and researchers disrupt deficit thinking? What kinds of practices can engage teachers in on-going development away from deficit thinking?

This brief report discusses positive findings from a professional development course for math and special educators on Universal Design for Learning through a Design Thinking lens. In our 6-session course, we explored UDL for math, as well as rethinking disability through frameworks such as disability rights and neurodiversity. Groups of educators worked together in Design Teams to identify a problem of practice around inclusion and accessibility, to learn more about the users' perspectives through empathy interviews, and to engage in a cycle of Design Thinking to develop a prototype for a new curricula, system, space or routine. Data sources for our research included class video recordings, transcripts and artifacts, as well as pre- and post-surveys.

Our course goals included empathy, specifically as an element of design thinking.

RQ1: How did participants who took our online course on UDL and Design Thinking in Mathematics take up elements of the class in their practice during the 2020-2021 school year?

RQ2: How did participants conceptualize empathy and empathy interviews? How did they operatize empathy interviews in their classrooms after the course?

Literature Review

Instead of locating disability within individual students, In UDL, disability is located in inaccessible classrooms, curriculum, and spaces (Meyer et al., 2014). The potential of UDL rests in its power to redesign these classrooms, curriculum, and systems to work better for students with disabilities. We take a critical approach of UDL through a disability studies approach (Domage 2017). We have integrated Design Thinking for Educators into our approach to UDL (Lambert et al., 2021). Design Thinking among teachers is seen as a collaborative, human-centered problem-solving approach which starts by developing empathy and understanding for the user's experiences (IDEO 2012). Empathy, as suggested by proponents of design thinking, attempts to integrate two larger ideas: perspective-taking and cultivating sense of care. Cultivating empathy for a user is to more clearly understand how that user lives in the world --- how they experience it and make sense of it. This requires a designer to put aside their own experiences, beliefs and ideas and work to view from another's point of view. Within design thinking for educators, teachers are positioned to appreciate and make sense of their students' lived experiences, so that they can later design for and with them.

In our use of Design Thinking we highlighted the importance of the empathy interview, in which the designer elicits a series of stories from the user to better understand their experiences. Empathy interviews are meant to be informal conversations between designers and users that uncover the users' experiences in a particular setting, their feelings about those experiences and ultimately, their unmet needs within that context. The goal, in a way, is to understand a person's thoughts, emotions, and motivations, so that we can design for them. When leading an interview the strategy is typically to get the user to tell stories, because stories allow designers to better make sense of how a person sees the world.

Because the empathy interview can be rich, detailed and complex, it is often the case that designers work in teams to better capture the important ideas and moments. Often the detailed notes from an interview are synthesized into a few broad categories and codified into an *empathy map*. The making of empathy maps allows the designers to move out of the empathy phase of designing and into the define phase, where two goals emerge: to develop a deep understanding of the user and develop an actionable problem statement, or point of view. Additionally, the visual aspect of an empathy map itself (not a narrative statement but a colorful retelling) reflects a common mindset of designers: showing, not telling. While not specific to mathematics education, empathy has been found to be a critical feature in teaching. Teachers' ability to empathize with their students shapes the teachers' response to problem behaviors (Wink et al. 2021). One meta-analysis of student teacher relationships found that empathy by the teacher was the strongest predictor of positive outcomes for students (Cornelius-White, 2007).

Findings from survey data (Lambert et al., 2021) indicate that the course resulted in shifts in participants' conceptualization of UDL as a set of guidelines to an active design process. Our initial survey findings also indicate that our centering of empathy became a guiding principle for participants' understanding of designing for disability. We wondered how classroom teachers who participated in the summer course would take up these ideas during a year of pandemic teaching.

Methods

We used a design research teaching experiment methodology (Cobb et al., 2003) for this study, beginning with our theory of action and using multiple, iterative methods to understand participant's learning. This paper focuses on data from a focus group of classroom teachers held in April 2021, 9 months after the completion of the course, recruited with an email sent to all course participants. The four participants in the focus group all identified as women, 3 as white, 1 as Latina, and 1 as disabled. Two were high school special educators, and two were elementary school general education teachers at a dual language school. All teachers had students with disabilities in their classes during the 2020-2021 school year, with the majority of all their students being Latinx.

Data Sources and Analysis

The focus group was semi-structured, with questions designed collectively by the research team. Two members of the research team participated in the focus group, with one facilitating and one listening for follow-up questions. The first set of questions explored experiences teaching in the 20-21 school year, then UDL and Design Thinking. After the focus group, a member of the research team transcribed the interview and wrote an initial memo on the findings, as they related to each of the research questions. All members of the research team then conducted in vivo coding of the transcript. We analyzed these codes and came to consensus on codes and themes.

Results

An important context in these results is the modality of teaching. These teachers are describing their work in the 2020-2021 school year in California, primarily in districts that were conducting school through virtual distance learning. Their students, including emergent bilingual and disabled students in elementary and high school, were taking classes over Zoom. Only one teacher, Bella, a secondary teacher, was teaching hybrid, with students in person and over Zoom each week. Learning over Zoom created (or perhaps heightened) the importance of building relationships with students (Lambert et al., 2020), particularly students with disabilities.

We found that classroom teachers described the work of the course as extremely useful for the challenging teaching of 2020-2021, particularly taking up empathy as a core aspect of their practice. When asked the general question, "What did you take away from the course," the first and all following respondents focused on the concept of empathy and the specific tool of empathy interviews. We found three themes in their understanding of empathy and its role in their teaching. First, all participants reported using empathy interviews extensively in order to design for students' actual needs and to build relationships. Second, empathy appeared to interrupt deficit thinking in designing and reflecting on mathematics activities. Finally, empathy was used as a way to understand larger themes in their work, including racial equity and inequalities around the pandemic.

Empathy Interviews

Both secondary special education math teachers described themselves as "case managers" and both did empathy interviews with all or most of the students on their caseload. Zelda, a secondary special educator who taught math, responded to our question ("What did you take away from the course, if anything") by first centering empathy as a core value in her work, "Empathy is absolutely like, just keeping that at the heart of my practice." She then described how she used Empathy Interviews with all her students. Both elementary inclusive teachers also did a version of Empathy Interviews. One interviewed all her students at the beginning and then the end of the year, over Zoom. The other elementary math teacher also did Empathy Interviews with all of her students, as well as with each family. The focus was on developing understanding of the student's perspective and experience learning mathematics, with the teacher framed as listener. The teachers discussed the importance of building relationships through these interviews, of learning more about the student's experiences. This knowledge, particularly of the student’s past experiences learning mathematics, was described as invaluable, and played a central role in the teacher’s design of their courses that year.

Shifts away from deficit thinking

Teachers described that the course effected a shift away from deficit thinking and towards more complex, strengths-based understanding of students. They reported that this shift was linked to empathy. Discussing a shift away from deficit thinking, Bella said, “I think empathy has a lot to do with that too, because once we put ourselves in the place of a child, with a disability . . . it has to change our thinking. So I think empathy is a gateway for that.” Zelda noted that the course “revealed to me some of my deficit thinking that I wasn’t aware was necessarily there.” She described a math activity with her students over Zoom that seemed to go poorly. She narrates her thought process, first how she immediately jumped to the idea that that kind of activity was too complex for her students. Then, she narratives how she interrupts that thought,

> I can catch that thought and be like, no it's not that they can't do it, it's like – what, do we need to try again? Does [the student] need more time? You know, and also asking them, like, ‘How is this going?’ So I think, for me, I feel like the course has hugely impacted my practice.

Empathy appears to be useful in helping teachers disrupt their habits of assessing students as knowing, or not knowing, or capable or not capable, and instead to see learning as a process. And to see design of instruction as necessarily co-design with students.

Larger themes related to empathy

Another application of empathy was to note when it was lacking in other teachers during the pandemic. Zelda noted that for her, as a case manager of high school students with disabilities, she brough to the math department’s attention the high number of students with disabilities who were failing math over Zoom. She reports that the math department was “rigid” and lacked empathy. She describes a feeling a “rage” towards other educators who do not seem to connect with the students.

> it's – there's been moments of rage, I'm not gonna lie …there’s such a lack of empathy, right? There's such a lack of empathy with – and rigidity. Like if there's no other time for you to like rethink your grading like – this isn't going to do it for you? What’s gonna do it? But I do think sometimes in crisis actually people like stick harder to their guns, you know they hold to their guns they're like No, this is how I do it.

Empathy seems for these educators to link the core values of social justice with relationships, and a more relational approach to the teacher student relationship.

Significance

We call attention to how a focus on empathy, coupled with analytic tools for putting empathy into practice, was important in shifting deficit thinking about students with disabilities, and shifting teachers to more flexible mathematics teaching. While empathy was an important part of our design, we did not expect it to be the primary driver of change for teachers. We certainly did not expect all four of the teachers in our focus group to have used Empathy Interviews extensively in their challenging classroom work in 2020-2021. They reported, however, how central empathy was to their work in challenging ties. In future work, we seek to better understand links for racial equity as well as disability equity. As mentioned by a participant in the course in the surveys “empathy really is like, it's like the center of the pandemic, for me, and also the racial justice work that has needed to happen and it's like cracked open in this new way.

"I WAS PLAYING INTO WHITE SUPREMACY": PRESERVICE TEACHERS' NARRATIVES POSITIONING WHITENESS, MATHEMATICS, AND THEMSELVES

Alexa W.C. Lee-Hassan
Learning Sciences Research Institute, University of Illinois at Chicago
aleeha2@uic.edu

Preservice teachers need to develop political conocimiento—experiential political knowledge—to be able to effectively advocate for their students. This includes developing a complex understanding of their own positionality with respect to race and mathematics. This brief report, part of a larger study, uses interviews of three preservice teachers describing their participation in a math content course to explore the diversity in their developing political conocimiento. Responses ranged from considering race irrelevant due to the quasi-anonymity of online instruction to drawing connections between competitiveness and White supremacy.

Keywords: Preservice Teacher Education, Social Justice, Affect, Emotion, Beliefs, and Attitudes, and Equity, Inclusion, and Diversity

In spring of 2020 Arundhati Roy described the potential for the COVID 19 pandemic to serve as a catalyst for a fundamental reorganization of our global society. The Movement for Black Lives and the so-called "racial reckoning" that followed seemed like important steps forward, but many changes were shallow, short-lived, and overwhelmed by the subsequent White-supremacist backlash (Holloway, 2021). Part of this backlash manifested as laws related to teaching, with 36 states restricting education about racism, bias, Critical Race Theory, and related topics (Stout & Wilburn, 2022). In contrast, 17 states have recently passed laws expanding requirements for teachers to address such topics. Teacher educators who work with preservice teachers (PSTs) need to acknowledge the divisive and high-stakes nature of the teaching environment into which our PSTs will graduate. We must help our PSTs develop the political understanding they will need to successfully navigate this environment and advocate for themselves and their students. Fostering the necessary learning requires addressing issues of race, justice, and equity in all aspects of teacher preparation programs (Garii & Appova, 2013; Gutiérrez, 2013; McDonald & Zeichner, 2009; Nieto, 2000; Wiedeman, 2002; Xenofontos et al., 2020), including math content courses (Lee-Hassan, 2021; Felton-Koestler, 2020). This brief report explores the developing political knowledge that PSTs in an urban education program demonstrate as they reflect on their participation in a racially diverse math content course.

Theoretical Framework

Gutiérrez (2012; 2013; 2017) describes the political knowledge that teachers need as political conocimiento for teaching mathematics (PCTM). This framework highlights the need to integrate political knowledge with mathematical content knowledge, pedagogical knowledge, and knowledge developed with students and communities. Gutiérrez draws conocimiento from the work of Anzaldúa (2002), describing a situated form of knowledge that develops through experience in community and entails the need for solidarity and praxis. Relationships and context are critical to the development of conocimiento, so PCTM is inherently context-dependent. Part of PCTM involves teachers' developing understanding of connections between mathematics, math education, and Whiteness (Gutiérrez, 2017), which can include mathematics' privileged role in society and a dominant culture of mathematics valuing hierarchies, competition, and a particular version of intelligence. In this report I propose that racially diverse, collaborative math content courses are spaces where PSTs' PCTM can manifest as they navigate and reflect on their relationships and participation. I focus on the question: How can PCTM related to race manifest through PSTs' reflections on class participation in a racially diverse math content course?

Methods

Context and Participants

The data analyzed in this report were drawn from a larger study exploring the development of PCTM in a math content course for elementary math concentrators and secondary math PSTs. The course was initially designed to develop a conceptual, function-based understanding of algebra. The larger study modified the curriculum to incorporate explorations of data from the local school district and reflections and discussions about PSTs' personal experiences to foster their developing PCTM. Tasks highlighted the relevance of race and racism in the contexts we analyzed and encouraged PSTs to share background and ideas from other courses, but connections between race, racism, White supremacy and mathematics were not explored as explicitly as might happen in an anti-racist math methods course. During the study the course used remote, synchronous instruction. There were 36 PSTs in the course with a racial distribution that approximated the university overall (no racial majority). After the course, 3 students consented to participate in the interviews analyzed in this paper. All names are pseudonyms.

- Emily: White woman pursuing her masters in secondary mathematics education
- Jessica: White woman pursuing an undergraduate degree in elementary education with a mathematics endorsement
- Anjali: South Asian woman pursuing an undergraduate degree in elementary education with mathematics and special education endorsements

The low participation rate was likely due to the sensitive nature of the course and the high-stress context of the pandemic. The analyses in this report are intended to illustrate a range of potential manifestations of PCTM, not to represent PSTs' overall experience in the course.

Positionality

I am a White, agender individual who attended suburban public schools, and whose work in urban elementary schools and universities has been grounded in critical perspectives and a focus on equity and social justice. I held a dual role as teacher/researcher for this project, so my positionality influenced all stages of the research (D'Ambrosio et al., 2013). Most relevant to the current analyses, my design and facilitation of the course included multiple prompts for PSTs to reflect on their course participation, frank discussions of race and racism, and emotional check-ins and discussions of mental health. All three participants identified the course's supportive environment as important for their comfort level, a comfort level that probably influenced their decision to engage in the interviews. Our shared race and my history of discussing race in class likely made Jessica and Emily more open in their interviews. My critical perspectives likely influenced what the PSTs felt comfortable sharing in the interviews, and certainly informed what aspects of their responses I identified as significant during my analyses.

Data Sources and Analyses

The data from this paper came from semi-structured interviews that occurred the summer after the course ended. Interviews were approximately 75 minutes long and included questions about PSTs' beliefs and experiences related to social justice, mathematics, and links between the two. This report focuses on responses to two questions about participation during the course.

1. We talked a lot at the beginning of the semester about trying to balance different people's participation in class discussions. Tell me about your thinking during those conversations.
2. Did you consider race at all when thinking about participation and class relationships?

Responses were analyzed using narrative analysis. Analyses focused on a) who/what PSTs included in their narratives and b) how PSTs positioned the individuals and entities they included with respect to each other. This paper focuses on how PSTs positioned themselves, Whiteness, and mathematics. These positionings offer preliminary insights into their developing PCTM.

Findings and Implications

All three participants described the challenges entailed in engaging in class discussion using Zoom. Both Emily and Jessica described struggling with the impulse to talk too much during class discussion, and when I asked explicitly about the role of race they both described their Whiteness as relevant to that struggle. The ways in which they narrated those struggles, however, highlighted differences in their developing PCTM.

Jessica framed her high levels of participation as a personality trait, describing herself as "a very wordy person…I bond with conversation." She described herself as wanting to engage in discussion with her peers because it's "how [she] build[s] relationships" and empathy. She highlighted that her current desire to build empathy contrasted with her experiences growing up. When asked about race, Jessica acknowledged that

> When it boils down to it I am a white woman. Um, whether or not I view myself as a white woman in every single sentence that I say, that is how I'm perceived, because that is who I am…It has an effect [laughs] on everything I say if someone knows that I'm white. Especially people of color. If they know I'm white and they're hearing me it plays into everything. It just has an effect on it. Um, and so I don't wanna overspeak in general. (Jessica)

In this quote Jessica positioned her race as a personal characteristic that is primarily relevant based on how other people—particularly people of color—perceive her. She had the declarative knowledge that her Whiteness matters, and she connected it with a concern about overspeaking, but her descriptions of why Whiteness matters were somewhat vague, alluding to other people's perceptions and a desire for everyone to have "space to speak." She did not connect her reflections about empathy with her discussion of race.

Emily, in contrast, described herself as having "a complex about being the best student"—an explicitly negative and active characteristic. When asked about race she explicitly connected that complex to "playing into white supremacy." She explained how even though she thought of herself as "hav[ing] done a lot of work on [her]self, and… done a lot of work in the world," in the context of this math class she found herself enacting toxic levels of competitiveness that she associated with Whiteness and settler colonialism. In her words:

> [S]ome of this shit is buried deep, you know? And...it can come out in—It came out in, like, ways that I was not proud of, honestly. You know? And, yeah. I think that, I think I did—I thought about it A LOT. I thought about it a lot in terms of how I was using my Whiteness, my age, my education, and all of that—all of my privilege, right? To, like, dominate a class. [laughs] It was sad when you put it that way. [half laughs] I guess what I'm trying to communicate is, like, I think I'm just doing my best, but that's what behind it, right? (Emily)

Here Emily identified a toxic characteristic of White supremacy that played a role in her behavior. She acknowledged its roots in her upbringing, but also acknowledged the ways in which it harmed her classmates and the class community and described her efforts to do better. She also reflected on the challenges of balancing participation through collective effort using a pedagogical lens that considered the relevance of mathematics in her experience.

> [S]aying, like, "Can we have a collective class?" or "Can we have a collaborative classroom." You know. So even, like, trying—even if it doesn't come out perfectly…know, because that's not a revolutionary concept in, like, you know, a seminar, right? Like, if you're in, like, a, you know, women's studies seminar or whatever [laughs] like, that's not, you know—they're probably going to try to do it like that, right? [laughs] Um...but in a math class, you know, that's, like, a whole nother—that's not something that usually is on the table. And so I think even putting it on the table was something that really made me reconsider and think deeply about,,,what does, like, an equitable class look like, you know? (Emily)

Here Emily alternated between positioning herself as a student and as a teacher. She compared the political implications of the pedagogical choices made in the course and cold-calling techniques she had been instructed to use at her current teaching job, and specified the ways in which the context of teaching mathematics influenced the pedagogical and political implications.

Anjali, in contrast, said that she did not think that race played a significant role in the dynamics of class discussions. From her perspective the fact that class was on Zoom and many students kept their videos off and mainly communicated via chat provided a degree of anonymity that "was nice because, like, nobody could judge you." She felt that overtalking was "just dependent on how the student was as a whole." She did, however, describe a lot of anxiety around how classmates or group members might be judging her class participation. In particular, she highlighted Emily's apparent competence as connected to her insecurity.

> [Emily] knew what she was doing. I was like, "Wow. I feel very dumb compared to this." And so, er, like, I tried very hard, like, that's why I would private message you questions, because I was very nervous to ask in front of people, because they're like, "Wow. She doesn't get this. Wow. Like, she should really know what's happening." And obviously I'm sure other people were in the same boat, but at that time—because I also didn't know you as well as I did nearly at the end of the semester—it was more like, just scared—being scared. (Anjali)

Here Anjali shows the other perspective of the domination that Emily described. Anjali positions herself as anxious because of the potential or perceived judgement of her classmates. It is important to note that while Anjali did not describe race as relevant to the classroom dynamics, in other parts of her interview she explicitly positioned herself as "a person of color" and described why she believed that positionality would give her better insight and help her build relationships when teaching students of color compared with White teachers.

These preliminary analyses illustrate some of the ways in which, given opportunities for reflection and discussion, PSTs' experiences in a math content course can support and illuminate their developing PCTM. As Emily explicitly noted, even though she had thought about Whiteness and competitiveness in other contexts, reflecting on her practice in an ongoing math class put things in a different perspective. The political nature of math teaching and learning (Gutiérrez, 2017) makes participation in math content courses a potentially valuable space for PST reflection as part of teacher preparation programs addressing race, equity, and justice.

Research exploring how Hispanic-Serving Institutions (HSIs) serve Latin STEM students has largely focused on features of organizational structures (e.g., support programs), but minimally examined instruction and classroom experiences. This is an important gap to fill, especially in gateway mathematics courses, where faculty relationships and quality of instruction impact Latin* students' persistence and identities in STEM. To advance such research, this report presents findings from an analysis of how perspectives from HSI mathematics faculty and students about instruction in introductory statistics converged and diverged in terms of serving Latin* populations. We present two illustrative cases of dissonant and resonant perspectives on serving Latin* students through instruction that frames mathematical ability expansively (e.g., not limited to being fast or correct). We conclude with research and practice implications.*

Keywords: Equity, Inclusion & Diversity; Undergraduate Education; Data Analysis & Statistics

Purpose of the Study

Institutions are designated as Hispanic-Serving Institutions (HSIs) if at least 25 percent of enrolled undergraduates are Latin*[1]. Despite receiving funding to increase Latin* postsecondary persistence, HSIs often lack visions of serving Latin* students and thus may not advance equitable outcomes or affirming support (Garcia, 2020). Thus, racialized and intersectional oppression among Latin* STEM students (Leyva, 2016; McGee, 2016; Rodriguez et al., 2017) are not necessarily disrupted in HSIs (Contreras Aguirre et al., 2020; Valenzuela, 2020).

Instructional quality in gateway courses, including calculus and statistics, is a major contributor to Black and Latin* attrition in STEM (Dadgar et al., 2021; Larsen et al., 2016). Although research that examines racially-equitable features of gateway mathematics instruction is emerging (Hagman, 2021; Leyva, McNeill, et al., 2021), an explicit focus on equity for Latin* students has not been adopted. Such inquiry can build a theory of racially- and culturally-affirming instruction in gateway courses to strengthen Latin* students' persistence and sense of belonging in STEM, along with enhancing HSIs' efforts to serve Latin* STEM students.

To fill this research gap, our report presents an analysis from a larger study of a HSI mathematics department's reform of instructional and organizational practices to better serve

[1] The asterisk in Latin* creates space for fluidity in gender identities among Latin American people. Latin* responds to (mis)use of Latinx, a term reserved for Latin American gender-nonconforming peoples (Salinas & Lozano, 2019).

Latin* students. We looked across faculty and student perceptions of instruction for fostering equitable opportunities of classroom participation among Latin* students in gateway courses. The following research question, aligned with the PME-NA 44 theme, is addressed: *What are forms of dissonance and resonance across faculty and student perceptions of serving Latin* students through instruction in gateway mathematics courses?* We raise implications for improving ways to serve Latin* students in mathematics departments based on our findings.

Theoretical Perspective & Relevant Literature

A guiding perspective for our analysis is *servingness*, a framework for developing culturally-enhancing experiences at HSIs for Latin* students across various dimensions, including outcomes, experiences, organizational structures, and external forces (Garcia et al., 2019). Prior research on serving Latin* STEM students in HSIs has focused on organizational features that promote academic persistence, such as course design (Chang & Chen, 2020; Meling et al., 2020), departmental policies (e.g., course placements; Burn et al., 2019), and support programs (Cruz et al., 2019). This work has importantly depicted structural interventions' advancement of equitable outcomes for course success and STEM persistence. However, these outcome-focused analyses left implicit how organizational features impacted Latin* students' racialized experiences specifically in STEM. Instruction in STEM courses was also not central in analyses. Extending this work, the present analysis uses servingness as a lens to examine HSI faculty members' and students' perceptions of instruction in gateway courses as reinforcing or disrupting racialized outcomes (e.g., grades) and experiences (e.g., cultural validation). Our analysis also considered how departmental structures (e.g., professional development) for fostering culturally-responsive learning and resisting forces of white supremacy shaped servingness in mathematics instruction.

Faculty advance servingness at HSIs through instruction and student support that disrupt racialized oppression to promote Latin* students' positive identity development and sense of belonging (Ching, 2019). However, it remains unclear the extent to which STEM faculty at HSIs leverage awareness of Latin* students' cultural backgrounds and racialized experiences to inform pedagogy. For example, in a study of HSI faculty's racial attitudes, Garcia and colleagues (2020) found that faculty held low levels of colorblind attitudes, indicating racial consciousness. However, findings also showed that STEM faculty demonstrated more colorblind attitudes than faculty in other disciplines, even when controlling for differing racial and gender demographics. Colorblind faculty attitudes in mathematics and STEM more broadly leave stereotypes of ability, inequities of access, and other racialized forces unchallenged (Bensimon et al., 2019; McCoy et al., 2015; McNeill et al., 2022), which can reinforce deficit views and thus limit instructional servingness (Chase et al., 2013; Ching, 2019). The impacts of faculty racial attitudes, including orientations to servingness through STEM instruction in HSIs as well as Latin* students' classroom experiences, have been underexplored. Our study fills this gap by triangulating faculty and student perspectives to explore the efficacy of gateway course instruction in servingness.

Methods

Study Context and Participants

Our present analysis comes from a larger study exploring the effectiveness of an ongoing, equity-oriented professional development (PD) in the mathematics department at Sonoma State University (SSU). SSU is a medium-sized, public university in California that recently received the HSI designation. In 2021, enrolled undergraduate students at SSU were approximately 45% white, 35% Latin*, 7% two or more races, 5% Asian, 2% Black or African American, and 6% some other race. Faculty PD began in summer 2021, and data collection started in fall 2021. The two-year faculty PD aims to develop culturally-responsive institutional practices, including classroom instruction and student support, to better serve Latin* students.

The research team (a collaboration between two faculty involved in the PD and educational researchers at Vanderbilt University) designed a study to look across instructors' and Latin* students' perspectives on instructional servingness in gateway courses. Twelve mathematics faculty PD participants agreed to participate in the study. Over half of faculty participants served as gateway course instructors. Latin* student participants were recruited from gateway courses by sending an e-mail message to all enrolled students with a flyer containing a URL to express interest and completing classroom visits (in-person and virtual) to provide a study overview. Instructors were not informed if any of their students served as study participants and vice versa. To the extent possible, we purposefully sampled from students who expressed interest to have multiple voices from each course section as well as to ensure variation in race-gender identities.

Data Collection

Researchers at Vanderbilt (1 faculty, 2 Ph.D. students, 1 graduate student, and 1 undergraduate student) led data collection. SSU team members also served as study participants and did not assume data collection responsibilities. Using event journaling methodology (Leyva, Quea, et al., 2021), one data source was student and faculty participants' journaling of events from instruction in gateway courses perceived as marginalizing or supportive for Latin* students. Journal entries were submitted using an online form that prompted participants for a description of events and reflection on why events were perceived in these ways. Students journaled about their course experiences as learners, and faculty journaled about their practices as instructors. Journaling was ongoing throughout the fall semester without any required number of entries.

Near the end of the semester, each participant completed a 90-minute, semi-structured individual interview on Zoom. Interviews were audiotaped and transcribed. To the extent possible, we matched interviewers and participants by race and gender as an attempt to build comfort with discussing issues of structural oppression. The first half of the interview explored what serving Latin* students meant to participants in gateway mathematics courses and in general. The second half of the interview centered around two prompts of instructional events that reflected emergent themes of servingness from journaling. Each prompt was written as a composite of journaled events. One prompt was written from a faculty perspective and addressed issues of student support. The second prompt, which is central to the analysis presented in this research report, was written from a student perspective and focused on classroom participation:

> I was asked to share my solution for a homework problem during class. I was unsure if I solved the problem correctly. I was worried about presenting an incorrect solution in front of the instructor and the rest of the class. My instructor acknowledged that my final answer was incorrect and guided me through steps for solving the problem. The instructor also mentioned that perfection was not the expectation for success and how students can learn from errors. This interaction made me feel less pressure about having to always be correct and encouraged me to more readily share my thinking during class.

For each prompt, participants were asked about the instructional event's frequency of occurrence and potential for serving Latin* students as well as recommended changes in gateway courses for more racially-equitable participation or support. All participants were prompted for specific examples from their gateway courses to support their reasoning about servingness.

Data Analysis and Positionality

Vanderbilt research team members de-identified data prior to sharing with SSU research team members for analysis. Information that explicitly or implicitly revealed participants' identities (e.g., names, students' backgrounds, faculty's professional histories) was redacted. For the present research report, we completed an analysis of data specific to participants involved in courses that contained both faculty and student participants. Our analysis looked across data for 4 faculty participants and 6 Latin* first-year student participants associated with calculus and statistics courses. In addition to journaling, we analyzed interview responses to questions about the meaning of serving Latin* students in and beyond gateway mathematics instruction, along with responses to the prompt about classroom participation presented above.

A research team member from each university coded each faculty participant's data. Two Vanderbilt team members coded each student participant's data since de-identification was still in progress. To the extent possible, at least one coder for student data identified as Latin* to have an insider perspective for data analysis. Team members independently and inductively coded data to flag instances when participants raised instructional features and departmental structures perceived as advancing or limiting servingness in gateway courses, including attention to Latin* students' social identities and cultural backgrounds. When individual coding was complete, one coder from each pair synthesized the two sets of codes for each participant's data into themes on instructional servingness. Themes were exchanged and discussed during weekly team meetings. To address our research question about dissonance and resonance across HSI faculty and student perspectives on servingness, the research team identified points of convergence and divergence in how faculty members and students in the same class perceived servingness in instruction.

Our research team approached the present analysis with critical reflexivity. The team consists of two Latino cisgender men, a Latina cisgender woman, a Black cisgender woman, a white transmasculine person, a white cisgender woman, and a white cisgender man. We brought awareness of how our varying forms of privilege and oppression influence our inquiry on instructional servingness in mathematics at HSIs. The team resisted deficit engagement with participants' reflections as mathematics learners or educators and constantly recognized how gateway mathematics instruction is situated in broader systems of social power. Interviewers and coders bracketed their lived experiences in engaging with participants' reflections to avoid analytically distorting their perspectives, all while approaching the study with a lens of criticality to interrogate structures that limit servingness in STEM contexts across HSIs. Our infusion of multiple faculty members' and Latin* students' voices in the findings captures complexities of instructional servingness in gateway mathematics and avoids portraying it in essentializing ways.

Findings

We present findings centered on an emergent theme of instructional servingness – namely, expansive framing of mathematical ability to increase Latin* students' classroom participation. This framing resists dominant views of correctness and speed as indicating innateness of ability, which do not account for educational inequalities that limit Latin* students' opportunities to develop such skills. Two cases of coupling HSI faculty and student perspectives were most illustrative of this theme. One coupling includes faculty member Dina (white woman[2]) and her students, Rosalinda (Mexican female) and Christian (Mexican male). The second pairing includes faculty member Michael (white male) and his students, Lisandra (Chicana female) and Nereyda (Salvadoran female). These couplings were specific to introductory statistics courses that enrolled exclusively first-year students and predominantly Latin* students. We organize our findings in two sections that each presents a coupling of faculty-student perspectives to highlight dissonance and resonance in reflections on instructional servingness through framing ability.

[2] Participants' identities are reported as they were self-described during interviews.

"My Teacher Likes to Tell Us That It's Okay to Ask for Help and If We Get Something Wrong, It's Not the End of the World. It Just Means That We're Actually Learning."

Serving Latin* students for faculty participant, Dina (white female), meant "need[ing] to do what it takes for all [her] students to succeed" regardless of race and other social differences, which included expanding opportunities for classroom participation. Dina perceived Latin* students' participation as often inhibited by narrow constructions of mathematical ability in K-12 education that frame being correct and quick as essential to being successful.

Interviewer:	How common do you think it is for Hispanic and Latinx students to be concerned about being incorrect or being unwilling or unable to share?
Dina:	It's very common… I would say, 'I'm afraid I have the wrong answer' is very common.... The way they're [Latin* students] prepared in math makes them feel stupid… We've been taught that math is fast.

To disrupt limited views of mathematical ability and broaden space for Latin* students' participation, Dina asks students to share prior experiences with mathematics and emphasizes that "math is really hard" to reassure them that struggle does not reflect inability. She interpreted her practice, along with the faculty behavior featured in the interview prompt, as bringing relief to Latin* students about being negatively judged when sharing their thinking. Dina approached instruction with awareness of potential linguistic barriers to classroom participation among Latin* students, especially in statistics where terms (e.g., bias) have specific meanings that differ from everyday use, "If English is not your first language, that's already a huge piece of baggage… You are at risk of having a language gap… I need to pay a lot of attention to… [students] being able to use and understand and pronounce." Dina's perspectives convey awareness of how narrow ideas of mathematical ability collide with Latin* students' experiences of educational inequities. Her awareness led to instruction that framed ability expansively and practices that clarified mathematical concepts in order to increase Latin* student participation.

Dina's view of serving Latin* students through instruction resonates with Rosalinda's reflection on her experience as a Mexican female in her class. In a journal entry, Rosalinda wrote that Dina's instruction made her "more confident in math… [and] capable in math" after having several high school mathematics teachers who undermined Latin* students' ability and dismissed her contributions. She experienced Dina's practice of framing errors as entry points for learning as reducing her fears about being wrong and encouraging her to readily participate.

Rosalinda:	Math isn't my strongest subject and… I have failed a few classes because my teachers didn't know how to serve me or other students like me. And so I like my class [with Dina]… My teacher likes to tell us that it's okay to ask for help and if we get something wrong, it's not the end of the world… It just means that we're actually learning rather than feeling bad. Because in the past, when I would get something wrong, it felt the worst.
[…]	
Interviewer:	How comfortable do you feel as a Latina student to participate?
Rosalinda:	I'm slowly getting more comfortable when it comes to going up to the board… Every time my professor, before we present, she'll be like, 'If you have any questions, even if it's a small question, feel free to ask. If we don't ask, she'll be like, 'It's okay if you get it wrong, I'll help guide you.'

Dina’s instruction served to increase Rosalinda’s access to classroom participation as a Mexican female with a history of racial oppression in K-12 mathematics, which captures resonance in faculty and student views on servingness through an expansive framing of ability.

Christian’s reflection on his classroom experience as a Mexican male student largely resonated with Dina’s view on serving Latin* students and aligns with Rosalinda’s experiences in the classroom. He likened the faculty behavior in the interview prompt to Dina’s comments during instruction for encouraging participation, “This sounds very much like my professor who has [said] things [like] ‘Mathematicians don’t always do the problems right away. They take their time’… It definitely encouraged me to not rush and take my time in math.” Christian perceived Dina’s instruction removing pressures of solving problems quickly to demonstrate his mathematical ability, which he commonly experienced prior to college. Such classroom practices brought Christian to feel like Dina “made [him] like math… [and] feel involved all the time.”

However, Christian also noted limitations on his access to participation despite Dina’s expansive framing of mathematical ability. He sometimes felt his participation was constrained by his command of the English language. Christian described “get[ting] a bit anxious sometimes for presenting [his] math solutions” out of concerns about any embarrassingly incorrect phrasing or pronunciation, “Some words, I can’t pronounce them correctly, so I struggle a bit getting my phrasing out there.” Although Christian journaled about how Dina strengthened his mathematical understanding through explanations of vocabulary, classroom participation remained less accessible to him due to risks of classmates’ negative judgment about how he communicates his ideas as an emergent bilingual. Dissonance between Dina’s and Christian’s perspectives convey how servingness through instruction that resists narrow views of mathematical ability must account for varying levels of comfort with verbal communication, especially among Latin* students developing command of the English language on top of mathematical terminology.

“When I Asked My Teacher for Help After Class and He Stayed Until I Understood the Problem, It Was A Little Bit of a Shocker For Me! I Thought I Would Be Perceived as the Stereotype That Hispanic Students are Lazy… [and] They Don't Understand Anything.”

Faculty participant, Michael (white male), reflected on growth in his development of instructional practices that foster servingness, “It's a huge part of my job right now, going through that change that's happening at our school [becoming an HSI]... Redefining my job around my students... I'm just like in preschool with the whole thing.” Michael positioned himself as constantly trying to learn more about Latin* students’ backgrounds and needs, “The way I’m trying to do it is just trying to collect more, and more, and more information, and think about how we can serve based on the information.” While Michael recognized the value of understanding Latin* students as a group, he also felt tensions about how such knowledge may shape assumptions and activate stereotypes when interacting with students, “I want to get my head around that, but I don't want to look at a student and think I know what's going on.”

Like Dina, Michael noted fear of being wrong as a barrier to Latin* student participation due to the equating of ability with correctness and speed in K-12 mathematics. He shared instructional comments about leveraging wrong answers as learning opportunities to allay such fears and frame ability expansively, “If it’s [a student’s answer] wrong, I’m going to actually be happier… You’re not the only person making a mistake, first of all, and then it’s going to give us a discussion to have.’” At the same time, Michael grappled with concerns about how his social distance from Latin* students as a white male, on top of students’ histories as K-12 mathematics learners, shaped skepticism toward his instructional messages, “They’ve [Latin* students] had dozens of teachers… And I’m just one guy they don’t know, who doesn’t look like them… So it’s hard for me to make provocative statements like this about how to approach this [mathematics learning] differently.” He reflected on the promise of connecting his students in statistics classes with former Latin* students who can “bridg[e] that culture, and race, and age gap” and disrupt current students’ distrust about his expansive views of mathematical ability.

Lisandra’s (Chicana female) reflection on her classroom experience largely exhibited dissonance and also somewhat resonated with Michael’s conceptions of servingness. Although Lisandra observed instructional practices with an expansive view of mathematical ability (e.g., attending to student struggles), she did not feel comfortable sharing incorrect thinking or exhibiting struggle with content in the statistics classroom, “It doesn't feel like, ‘Oh, we can be wrong because it's alright; we're learning.’ It doesn't feel like that. It feels like, ‘Oh, you have to be right.” Reflecting on how Latin* students are commonly worried about being wrong, she shared, “It’s been one of the many reasons why I haven’t spoken up in any class, because I’m not sure and I don’t want to embarrass myself... So I just keep to myself… I don’t want to sound dumb.” Lisandra’s concerns about being negatively judged for her intellect as a Latina student prompted her to hold back on participating in her statistics class, which resonated with Michael’s concerns about Latin* students’ skepticism toward his framing of mathematical ability.

Lisandra also described how her inhibited participation, despite Michael’s encouraging instructional behaviors, stemmed from a lack of community in the classroom. Servingness, for Lisandra, was forming part of a community that understood her as a first-generation Chicana female where she can “fully feel comfortable and safe to reach out” when needing support. The lack of community in her statistics classroom made her feel isolated and that her needs were not recognized, “I feel on my own… The teacher goes around and everything… but I feel like in the classroom, it doesn’t feel so much as a community… I don’t feel represented.” Lisandra, as a result, was often “not feeling safe in the environment enough to speak” in terms of sharing ideas and seeking help. Dissonance between Michael’s and Lisandra’s perspectives convey how servingness through instruction with an expansive framing of mathematical ability can fall short in increasing Latin* students’ access to participation. Lisandra was missing a foundation of safety and community to feel comfortable taking risks in her participation as a Chicana female.

Nereyda’s reflections as a Salvadoran female were both resonant and dissonant with her instructor Michael’s perspectives on servingness anchored in an expansive view of mathematical ability. Unlike Lisandra, Nereyda perceived her classroom experience, including Michael’s openness to student struggle and creation of a non-judgmental learning environment, as aligned with her views of servingness in mathematics. She related the faculty behavior in the interview prompt to Michael’s instruction, “He's constantly telling us that there's no need for perfection. ‘Do not worry about getting the right answer. It's just the process of learning and showing me what you have learned.’” She shared instances of seeking and receiving Michael’s support, which she perceived as especially impactful for Latin* students who often “don’t speak up because they don’t think they’re going to get the help they need” due to stereotypes of being dumb or lazy. Nereyda journaled about such support from Michael after class that disrupted stereotyping influences, which often limit Latin* students’ access to classroom participation.

> When I asked my teacher for help after class and he stayed until I understood the problem, it was a little bit of a shocker for me! I thought I would be perceived as the stereotype that Hispanic students are lazy in their study [sic] and they don't understand anything, but it made me feel heard and seen [and] that it's okay to not get things from the get-go. I now don't want to hide out.. I'm eager to go to class and keep making mistakes so I can continue getting help from my professor.

Nereyda's reflections of relief from pressures of sharing correct mathematical thinking and concealing academic struggles, thus, capture resonance with Michael's perspectives of serving Latin* students through instruction that challenges narrow constructions of ability.

Despite perceiving an overall sense of servingness through Michael's instructional practices of welcoming students' contributions and questions, Nereyda still experienced moments of discomfort with participation as a Salvadoran female due to stereotypes of ability.

> There's that stereotype that women aren't really good at math and they just don't understand. I feel like that impacts me in the classroom sometimes. I just get kind of intimidated… As well as with race, I feel like they [faculty] think that Hispanic students… need a little bit more attention… [and] can't capture the full event [referring to instruction] and it's not really like that. I journaled about it. It's the stereotype.

Nereyda particularly felt intimidated during groupwork to seek support and share her ideas. She observed a racialized pattern in self-sorted groups with "white students working together and… Latinx students just sitting out on those sidelines." When working with female and Latin* peers, either the group or Nereyda herself suppressed asking Michael for help, "In that space, I feel a little iffy or uncomfortable… He [Michael] goes around and helps people, but I feel like sometimes, some days, I can't speak up." Nereyda felt that further opening the statistics classroom space where "you share your identity with the class and when your classmates share their identity with you…creates a safe place of trust" that could alleviate racialized-gendered tensions with classroom participation. Therefore, dissonance is also evident across Michael's and Nereyda's perspectives on servingness. Michael approached instruction with commitment to resist stereotypes about Latin* students and increase participation through an expansive framing of mathematical ability. While Nereyda valued the reduced risks of seeking help and sharing her thinking, the unchallenged stereotypes of ability in her class often left participation inaccessible.

Discussion and Implications

Our findings reveal complexities of instructional servingness in gateway mathematics courses. Resonance in HSI faculty and student perspectives captured how instruction with an expansive framing of mathematical ability alleviated pressures of being quick and correct, which increased opportunities of classroom participation and support. At the same time, dissonance across faculty and student perspectives conveyed how these instructional practices were not always responsive to Latin* students' social positions (e.g., emergent bilinguals' language-based support needs, navigating racial and gender stereotypes of ability). Extending research on racial attitudes among HSI faculty (e.g., Garcia et al., 2020), our study shows how faculty consciousness of Latin* students' racialized experiences in mathematics that informed expansive framing of ability did not necessarily translate to experiences of servingness. Latin* students' perspectives suggest how instructional servingness that ensures equitable classroom participation requires explicitly confronting stereotypes of ability and building identity-affirming community.

Future work can extend our analysis by further unpacking Latin* identities to explore how within-group differences (e.g., nationality, gender and sexuality) can further inform servingness in HSI mathematics classrooms. We also call for research that explores how features of instructional servingness shift in upper-level mathematics and across other HSI contexts. In terms of practice, we call for HSI mathematics faculty to use instructional feedback from students to explore dissonance and resonance between classroom practices and Latin* students' needs. Mathematics faculty can also engage in observations of instruction with departmental colleagues and educational researchers to dissect practices that advance or constrain servingness.

Abstract. We are three mathematics teacher educators (MTEs) at a Hispanic serving institution that predominantly teach mathematics education courses for elementary and secondary teacher candidates (TCs). In this paper, we present findings from a collaborative self-study in which we used dimensions of the Rehumanizing Mathematics (RM) framework (Gutiérrez, 2018), to situate and integrate our work across mathematics content and methods courses. Our diverse cultural and academic backgrounds and lived experiences profoundly influence our professional practices, particularly our work with teacher candidates. We intentionally utilize counter storytelling as a way to describe how our respective work with TCs aligns with particular dimensions in the RM framework. Our findings indicate that our collaborative self-reflections have positively influenced our individual pedagogical practices. We have recognized through our collaborations that we have much to learn from one another to both inform and strengthen our practice as MTEs in ways that put forth a collective commitment to rehumanizing mathematics education for our students and the children they will ultimately teach.

Keywords: Culturally Relevant Pedagogy, Equity, Inclusion, and Diversity, Ethnomathematics, Systemic Change.

Introduction

Author A. As a woman of color, international scholar, a non-native English speaker, and a citizen of a formerly colonized nation, I have experienced firsthand how a conventional math curriculum, implemented in a traditional school setting has become a tool that disadvantages marginalized students, damages their self-esteem, and strips them of agency and identity. I use ethnomathematics as a tool to help learners (re) claim ownership of mathematics, acknowledge cultural funds of knowledge and establish harmony between academic mathematics and out-of-school mathematics.

Author B. I am a privileged white heterosexual female and follower of Jesus Christ and know that I hold a place of privilege and power as a mathematics teacher educator. I take ownership for my conscious and unconscious acts of racism. I realize that my position and power inherently can be a deterrent to BIPOC students unless I provide space for them to bring their whole selves to the classroom and be critical of the social and socio-mathematical norms that continue to be perpetuated in a traditional mathematics classroom.

Author C. As a former mathematics teacher of Black and brown high school students, I have witnessed how cumulative systemic inequalities in mathematics learning and teaching impact many student outcomes including affective outcomes like confidence and math identity, as well as achievement outcomes such as enrollment in advanced math courses, college, and interest in STEM majors. I have had to address their expressions of not seeing themselves in the curriculum or even feeling unseen by their own teachers.

We begin by sharing excerpts that reflect our positionality and its impact on our work as Mathematics Teacher Educators. In this paper, we describe how we disrupt the dominance of near-universal conventional mathematics (NUC) (Bishop, 1990) in mathematics content and methods courses for teacher candidates (TCs). Research reported in this paper is part of a larger project in which we engaged K-8 TCs at a Hispanic-serving Institution in experiences that potentially broadened their perceptions of and vision for mathematics education. Stimulating discussion and action is the goal around this question:

> How do we, as Mathematics Teacher Educators, attempt to rehumanize mathematics in our content and methods courses?

We intend for this collaboration and communication to result in tangible ideas that will add to the current Mathematics Teacher Educator knowledge based on promoting more humanizing practices in mathematics teacher education.

Theoretical Foundations

The philosophical questions, Mathematics for Whom? How? and What? are being repeatedly asked as it dictates what mathematics and whose mathematics is taught and how it is taught (Aguirre, Mayfield-Ingram, & Martin, 2013). Around the world, most schooling dehumanizes mathematics by claiming that mathematics is neutral, and the culture and identities students bring to the classroom should be lost to achieve academically (Paris & Alim, 2017). The research fields of situated cognition (Lave & Wenger, 1991), ethnomathematics (D'Ambrosio, 1985), culturally responsive mathematics education (Gay, 2000, 2018) and critical mathematics education (Frankenstein, 1983; Gutstein, 2006; Skovsmose, 1985) provide the theoretical foundations, research knowledge base, and practical methods to address the central research question.

Adopting these perspectives allows us, as researchers, to challenge dominant and traditionally told narratives about teaching mathematics and about learners in a mathematics classroom. From a practical standpoint, these theoretical constructs enable us to investigate meaningful pedagogical approaches that will empower and transform learners. For a truly transformative mathematics education, we must continue to engage with and support teachers and TCs who are in a position to address the philosophical questions.

As MTEs, we aspire that our instruction will prepare competent and caring teachers who will serve as an advocate for each learner. To make this a reality, we must provide seamlessly structured learning experiences that will enable our TCs to engage in a critical reflection of their beliefs about mathematics and teaching. Equally important is to identify those MTE practices that dehumanize mathematics teaching and learning. Most of the focus for rehumanizing mathematics focuses on what teachers and TCs can do in their classrooms but there has been much less on the practice of MTEs' practice for rehumanizing mathematics. Thus, from an MTE vantage point, we embrace the chosen theoretical perspectives to find commonalities in our work with TCs, creating counter spaces that refine and redefine our goals for mathematics teacher education.

Theoretical Framework

We use rehumanizing mathematics (RM) (Gutiérrez, 2018) as a lens to engage in a critical inquiry of our "selves", and to position and discuss our work. We are drawn to this framework because it provides powerful affordances for weaving funds of knowledge (Gonzalez, Moll &

Amanti, 2005), culturally responsive mathematics (Gay, 2010), ethnomathematics (D'Ambrosio, 1985), and critical mathematics education (Frankenstein, 1983; Gutstein, 2006; Skovsmose, 1985) into the fabric of our scholarship.

This framework includes eight dimensions (Gutiérrez, 2018) (See Figure 1), three of which are most relevant to the work discussed in this paper. *Cultures/ histories* glorifies ethnomathematics as a lens to counter eurocentricism, acknowledge and valorize contributions from learners' funds of knowledge, and attend to the history and evolution of mathematical ideas through non- dominant civilizations and communities. A second facet, *windows and mirrors* allows freedom of access to learners and "see themselves in the [mathematics] curriculum" (Gutiérrez, p. 5). This allows an MTE to provide a space for TCs to explore their relationship with mathematics. TCs draw on their own mathematics learning experiences to investigate their traditionally held beliefs about the teaching and learning of mathematics. *Positioning/participation*, the third feature that we highlight, enables an MTE to recognize the order of class systems in mathematics learning spaces in and out of classrooms and find ways to shift authority and share the space with learners.

Figure 1: Eight dimensions of Rehumanizing Mathematics (Gutierrez, 2018)

Methodology

We adopt a collaborative self-study (Bullock & Sater, 2017; Lovin et.al., 2012) methodology to frame and situate our work. As Loughran (2004) posits, "There is no one way, or correct way, of doing self-study. Rather, how a self-study might be 'done' depends on what is sought to be better understood" (p. 15). As we engaged in this self-study, we noted similarities in our approaches to present mathematics as a human activity and parallels in our efforts to rehumanize mathematics with our teacher candidates. We engage in a deep reflection of our roles as MTEs in relation to our "selves" and in relation to others. Table 1 provides a general overview of our teaching practices.

Table 1: Author information

Authors	Department	Courses Taught
A	Mathematics	Elementary & Secondary Math content courses
B	Teacher Education	Secondary STEM Methods course
C	Teacher Education	Elementary Math Methods course

Three characteristics define our self-study – collaborative inquiry, contextual knowledge, and a commitment for improving our practice. The traditional research methods of data collection and data analyses are a misfit in our chosen methodology. Instead, we intentionally use a counter storytelling method (Alemán, 2017) to present narratives informed by our personal and professional lived experiences. This method derives from the interpretivist tradition (Walsham, 1993) where researchers advance their work by showcasing "multiple perspectives of stories and who tells the stories," (Creswell, 2007, p. 24). The similarities that we noted in our work led to intriguing stories that we are compelled to share. Our personal and academic backgrounds and lived experiences profoundly influence our dispositions, values, habits of mind, and scholarship and we begin each story by stating our positionality. Next, we describe how our work fits along a particular dimension of the RM framework. The narratives are bound by a common commitment to providing humanizing mathematics learning experiences for our teacher candidates.

Our Stories

Author A's Narrative (cultures/histories)

I am a Mathematics Teacher Educator, and I subscribe to socio-cultural and critical theories of learning. I am also a learner enculturated in a nation subject to centuries of invasion, tyranny, and colonization. This resulted in the suppression of the rich history of Indian mathematics which distorted the philosophy of mathematics and how it is taught and learned (Raju, 2004). My lived experiences and teaching memoirs with diverse learners in K-12 settings and higher education contexts across two continents has illuminated how the near universal conventional curriculum has dominated academic mathematics, treating "mathematical knowledge as being uncontestable, objective, and disassociated from experience, history, and cultures" (Barton, 2008). Math learning experiences in such settings perpetuated among many learners, a narrow perception of and an aversion towards mathematics. Thus, I care deeply about issues of inclusion in mathematics classrooms, particularly for historically marginalized students.

My research interests primarily lie in the field of ethnomathematics which espouses connections between mathematics, culture, and society. From this perspective, I position and discuss my work along the *culture/histories* dimension of the RM framework because of its explicit acknowledgement and attention to the foundational principles of ethnomathematics. I mostly teach mathematics content courses where I have witnessed firsthand how many TCs, particularly those that are marginalized, feel disenfranchised in a math classroom that subscribes to a conventional, near universal math curriculum. Future teachers can learn how to "enhance" and "restore dignity" (D'Ambrosio, 2002) to learners in their classroom by experiencing it themselves. Thus, I deliberately anchor coursework to the principles of ethnomathematics and components of a culturally responsive mathematics education (Gay, 2000) to portray mathematics as a human activity (Bishop, 1990). These constructs also provide the necessary pedagogical reinforcements and equips me with empathy, consideration, and skills necessary to appreciate all individuals that comprise my classroom community and to see them as capable of learning and doing mathematics.

In many courses that I teach, coursework comprises practical and research components (Naresh & Kasmer, 2018). As part of the practical component, each week, TCs participate in at least one content exploration activity set in a social/cultural/historical/political context. For instance, as part of content explorations, I designed a pattern investigation activity based on the tradition of Kolam, an artform that has been practiced for many centuries by the women of the household in Tamilnadu (Ascher, 2002). By highlighting connections between mathematics and my own culture and by placing the spotlight on the mathematics of Kolam-drawing women, we develop an appreciation of the diversity and respect of cultural heritages, thus supporting the belief that all people are capable of doing mathematics. The research component requires TCs to complete a mathematics and culture project in which they partner with a community member to identify out-of-school activities that have a potential to transform into rich mathematical tasks (Naresh, Goodson-Espy & Poling, 2017). TCs use communal knowledge to frame problems that are central to their lived experiences, classical knowledge to develop mathematical competencies, and critical knowledge to gain a comprehensive understanding of the sociopolitical context for the problem (Gutstein, 2006). We adopt a socio-critical modeling approach in conjunction with Gutstein's 3-C framework that provides an "emancipatory perspective" [that] leads to a critical understanding of the surrounding world" (Kaiser & Sriraman, 2006, p. 304).

Author B's Narrative (participation/positioning)

My conscious journey to transform my instructional space to be culturally relevant (LadsonBillings, 1995) began while teaching a secondary STEM methods course about six years ago. A critical review and reflection of my own teaching revealed that I did not know the K-12 mathematics and sciences experiences and identities of the teacher candidates (Aguirre et al, 2013). During this time, I became conscious and acknowledged my privilege for identifying as a white heterosexual female and follower of Jesus Christ (DiAngelo, 2018). As a result, I hold a place of privilege and power as a mathematics teacher educator. For this reason, I chose the *participation/positioning* dimension of rehumanizing mathematics (Gutiérrez, 2018).

First, I needed to acknowledge my own upbringing in a single parent non-Christian home where I experienced both poverty and wealth. At home, my mom and maternal grandmother shared stories of our Indigenous heritage, but we have no record or connections to our Indigenous tribe. At school, I did not share my heritage but sought to fit in. My mathematical experiences were initially impeded by my dyslexia. In eighth grade was when I first recall experiencing agency in mathematics. Now I seek to support teacher candidates in giving agency and power to the students they will teach. My position and power inherently can be a deterrent to BIPOC teacher candidates unless I provide space for them to bring their whole selves to the classroom and be critical of the social and socio-mathematical norms that continue to be perpetuated in a traditional mathematics classroom. Next, are examples of activities in STEM and mathematics methods courses.

In the secondary STEM methods course, equity and diversity became a thread throughout the course rather than finite topics covered in the semester. Virtual anonymous discussions embedded in the course beginning with candidates writing their STEM autobiography and other discussion such as how their culture was an advantage and disadvantage. The anonymous post to each other gave teacher candidates a voice and space to share what they would not share with one another. In the middle grades mathematics methods course, teacher candidates chose to lead in *Number Talks* (Parrish & Dominick, 2016; Sun, Baldinger, & Humphreys, 2018) or keeping a log of what occurred in class. Everyone signed up once for a particular class for posting to the class Twitter about what they saw as worthwhile for sharing with the teacher community. My thinking was that by including Number Talks as part of our weekly routine, the position of teacher candidates would be us rather than me and them. In the elementary mathematics methods course, teacher candidates also lead Number Talks (Parrish & Dominick, 2016), but rotated in Quick Draw (Wheatley, 2007), and mathematics literacy during the semester too. Instead of Twitter, students reflect weekly through the course webpage on what was the highlight of their learning.

What I continue to find difficult is that I am ultimately seen as the person with authority/power who gives grades that account toward their progress in the teacher preparation program. Ideally, I would like the work we do together to be intrinsically motivating rather than what is needed for the 'A'. By having a component of the grading system for weekly engagement, I can capture in the moment and reflect on the participation and positioning of teacher candidates.

Author C's Narrative (mirrors/windows)

I am an Afro-Caribbean mathematics teacher educator with a positive mathematics identity that was developed largely due to the influence and encouragement of K-12 teachers who always made me feel capable in mathematics. My positionality towards my work with elementary preservice teachers stems from my converging identities as a former high school mathematics teacher at a Title I school, mother to two elementary aged Black boys, and mathematician. In my research I investigate the nuanced ways that inequity occurs in the mathematics learning of children from racially minoritized groups. Furthermore, in my work with PSTs, I am most interested in facilitating the evolution of their critical consciousness (Ladson-Billings, 1995) and investigating the varied ways that this evolution can occur. Due to systemic injustices, including racism, that have been illuminated during the global pandemic, it is especially important that preservice teachers have opportunities to be self-reflective and explore sensitive topics that may have impacted their own mathematics learning experiences and those of the children they will teach (Gay & Kirkland, 2003).

Through my research, as well as my lived experiences, I am aware of how cumulative systemic inequalities in mathematics learning and teaching impact many student outcomes including affective outcomes like confidence and math identity (Riegle-Crumb, Morton, Nguyen, & Dasgupta, 2019) as well as achievement outcomes such as enrollment in advanced math courses, college, and interest in STEM majors (Madkins & Morton, 2021). I am always striving to center the lived experiences of my TCs (especially those of Color) in my elementary math methods courses as a means to illuminate, confront and expose past traumas in mathematics learning in an attempt to interrupt reproduction of those traumas. I value my work with elementary preservice teachers. Through this work I am able to directly influence and contribute to mathematics teacher education that centers equity and antiracism in math methods courses.

Recognizing that our PSTs are the future teachers of racially minoritized children traditionally underserved and marginalized in math classrooms, children much like my own two boys, adds a certain level of urgency to my work. However, I couple this urgency with critical grace (Amidon et al, 2020) recognizing that this process should be an intentional and continuous one.

In my elementary mathematics methods course, I strive to create a space for PSTs to reflect on their own experiences learning mathematics and have explicit discussions about the common inequities that exist in mathematics learning and teaching. When delving into the dimension of *mirrors/windows*, I engage TCs in a number of activities that stem from the math autobiography assignment (Aguirre, Mayfield-Ingram, Martin, 2013) where students tell their mathematical story, recounting their in-school and out-of-school learning experiences with mathematics. As they answer several question prompts, TCs describe specific moments in their elementary mathematics learning. Following this we spend time unpacking those autobiographies through 2 in class activities: word cloud and math corners activity (Ward, 2020). The dimension *mirrors/windows* allows TCs a space for exploring their relationship with mathematics as well as "seeking to understand themselves and others in relationship" (Gutiérrez, 2018). Both activities are intended to illuminate the commonalities and differences in the TCs' mathematics learning experiences and begin to have discussions around those patterns. The RM framework allows us as MTEs to address inequitable opportunities to learn mathematics for children traditionally marginalized in math classrooms by highlighting these same inequities in the learning experiences of those who are becoming teachers themselves, teacher candidates.

Impacts of Our Collective Work on our Individual Practice

In this paper, we shared findings from a collaborative self-study that traced the collective journey of a team of MTEs. We used three dimensions of the RM framework to situate and integrate our work across mathematics content and methods courses. As MTEs, we along with our teacher candidates are the needed change to create more humanizing and socially just contexts for learning and teaching mathematics. Our collaborative self-reflections have begun to deeply influence our individual practices as mathematics teacher educators. We each have particular strengths developed through our lived experiences, both personal and professional, that we draw from in our collaborative work. For instance, while we are all mathematics teacher educators, one of us is the sole MTE faculty in the mathematics department unlike the other two MTEs who are faculty in a teacher education department. This difference presents the opportunity for conversations around the pedagogical challenges commonplace within many mathematics departments that are in direct opposition to the dehumanizing practices that undergird our work. Similarly, our identities as female mathematicians intersected with our racial/ethnic identities further inform our collective understandings around privilege, oppression, and equity in mathematics education as they relate to our own mathematics learning experiences in schools, as well as our individual work with teacher candidates. We have recognized through our collaborations that we have much to learn from one another to both inform and strengthen our practice as MTEs in ways that put forth a collective commitment to rehumanizing mathematics education for our students and the children they will ultimately teach.

Conclusion

Together, we reflect on our own math learning experiences and recall instances when we felt a sense of joy, pride, and belonging, and discover ways to re-experience those in our courses. Mathematics teacher education courses must offer a space for transformative learning experiences "not only for how students understand their abilities in mathematics but also in how they understand their relationship to others in the world" (Staats, 2006, p. 41). Our work with TCs, which we have presented using the lens of RM, has enabled us to challenge myths such as a) meaningful math cannot exist when we engage students in non-traditional math activities, b) math knowledge is mostly generated within the walls of the academy, and c) "just plain folks" are credible sources of knowledge and are able to demonstrate the use of more sophisticated mathematics. This work is rewarding and challenging at once; as a collective, we are presenting a counter-narrative to the dominant perspective that has permeated mathematics education. We believe in the potential this work holds for transforming the landscape of mathematics education and mathematics teacher education. Concomitantly, we must continue to engage in a critical inquiry of our own biases, assumptions, and teaching practices to become advocates for and to provide more empathetic mathematics learning experiences for TCs. In our future work, we intend to be critical friends (Ragoonaden & Bullock, 2016) to one another, utilizing both formal (e.g., required annual peer observations) and informal means to provide feedback to one another in ways that advance our collective agenda.

Our collaboration has resulted in an emerging Community of Practice (CoP) (Lave & Wenger, 1991) within our institution focused on providing more streamlined and humanizing learning experiences for TCs. We hope that this work will spark interest among other likeminded MTEs beyond our institutional context, broaden participation, and strengthen our CoP. In addition, from a research standpoint, it will enable us to a) investigate ways in which we can encompass additional dimensions of RM in our work, b) continue to present counter narratives to empower TCs that are marginalized in mathematics learning spaces and c) contribute to a collective repertoire of knowledge on MTE professional development centered on rehumanizing mathematics.

BEYOND THE WORLDS OF ITS DEFICIT MODELING APPROACHES: SITUATING ETHNOMATHEMATICS RESEARCH WITHIN THE SOCIAL-DESIGN EXPERIMENT INQUIRY

Emmanuel Nti-Asante
University of Massachusetts, Dartmouth
entiasante@umassd.edu

The heritage practices of many communities of color have historically been and continue to be the target of deficit approaches. In Mathematics Education, the existing solutions to this problem have focused on modeling approaches to bridge cultural ways of knowing with the institutionalized forms. This article argues that solutions to deficit approaches in cultural ways of knowing in mathematics education (ethnomathematics) are not simply about modeling bridges. We must bring together and extend these domains' various activities and practices in a forward-looking third space that occurs socially for all learners to voice, personalize, challenge, and negotiate mathematical meanings. Ethnomathematics research holds an intellectual accomplishment that results from one's ability to remediate the mathematical motives in activities done by diverse ethnic groups to include the mathematics used in formal spaces.

Keywords: Sustainability, Ethnomathematics, Culturally Relevant Pedagogies, Informal Education.

Background

As we know, our society—hence, our classrooms—are becoming increasingly diverse in terms of racial, ethnic, cultural, economic, and religious diversity (Colquitt, 2014; Mensah, 2021). However, education environments in such pluralistic societies offer students little purpose (Paris & Alim, 2017) to connect the content, pedagogical, and curricula approaches to the intellectual motives in ethnic practices of students from the non-dominant groups in the same educational environment.

Researchers like D'Ambrosio (1986) proposed ethnomathematics as one of the approaches to identifying the mathematical ideas of culturally distinct people (D'Ambrosio, 1986). The educational implications of ethnomathematics include those cited in Blikstein (2020, p. 117) by Adam et al. (2003). Ethnomathematics is a supplement for students to see mathematics as a response to human needs found in nearly every culture. A springboard for academic mathematics. As a stage in teaching and learning of mathematics that starts from the mathematical world of the child and then moves into other cultures. As support for preparing rich learning situations and activities, an approach that looks at the classroom itself as a situated cultural context and mathematical learning as part of this context.

I build on these educational implications to situate ethnomathematics as a research approach that connects the practices of today's mathematics classroom to that of ethnic practices. This includes connecting the Euclidean geometry in the classroom with the geometric practices in ethnic woodwork practices like measurement and construction in Africa. I conceptualize ethnomathematics as a third-space construct situated within the Freirian and Neo-Vygotskian approaches to intervening in educational activities (Gutiérrez, 2008). This approach allows us to bring together and extend various activities and practices of these domains' (institutionalized Mathematics and ethnomathematics) in a forward-looking third space (Paris, 2012; Guitierez,2008). This third space serves as a cross-cultural space (Nasir et al., 2010) for all learners to remediate by reorganizing and reconstructing (Gutiérrez et al., 2009) the narratives in the form of written texts of ethnic motives of mathematical practices to add to the institutionalized mathematics (Gutiérrez & Jurow, 2016).

Theoretical Framework

In 1977, the late Professor D'Ambrosio Ubiratan concluded that educators usually study the aspects of knowledge and learning in mathematics education (generation of knowledge, its social and intellectual organization, and its diffusion) in isolation from one another. Researchers identified mathematics education research with cognition, epistemology, history, sociology, and other educational disciplines but not culture. Hence, D'Ambrosio coined the term "ethnomathematics" during a presentation for the American Association for the Advancement of Science in 1977. Ethnomathematics (D'Ambrosio, 1986) became the first well-developed attempt to find curricular and theoretical combinations of institutionalized and ethnic motives of mathematics (Blikstein, 2020). Etymologically, D'Ambrosio (1990) defined ethnomathematics in the following way: the prefix "ethno" is today accepted as a broad term that refers to the social-cultural context and, therefore, includes language jargon, codes of behavior, myths, and symbols. The derivation of "mathema" is complex but means explaining, knowing, understanding, and doing activities such as ciphering, measuring, classifying, inferring, and modeling. The suffix "tics" is derived from techné and has the same root as technique. For example, Gerdes (1986) and Mukhopadyay (2008) studied implicit mathematics in basket-weaving techniques. Gilmer (1995) studied mathematics in techniques of braiding African American hairstyles.

Criticisms Against Ethnomathematics

Despite the importance of ethnomathematics, its approaches to bridging cultural ways of knowing (braiding of hair, weaving of baskets in Native American communities) with the institutionalized mathematics (like Euclidean Geometry) have been the center of critiques and, thus, its current research focus. Research in ethnomathematics uses institutional knowledge to model ethnic knowledge (Dowling, 1998; Eglash et al., 2021; Pais, 2011; Rowlands & Carson, 2002; Skovsmose & Renuka, 1997). Some researchers are known to be imposing institutionalized mathematical concepts and practices on ethnic motives of mathematics. Take, for example, an investigation of Navajo weaving by Babbitt et al. (2012, pp.1-2); they posited that:

> a common recurring angle in the weaving patterns was about 30 degrees. When asked about this particular angle, the weaver said it is created by an "up one over one" pattern (up to one weft over one warp). We could see why that would result in a 30-degree angle: because the height to width ratio of each successive stitch was about 1/3. But she then said she could make lots of other patterns (up to one over 2, up to two over 3, etc.).

In the quote above, majority ethno-mathematicians know that the native basket weaver knows not the rubrics of angles. However, the exchange above shows how sometimes we tend to research ethnic motives of mathematics by what Pais (2011) described as squeezing the natives from their otherness (Pais, 2011). This unidirectional approach deprives ethnic groups of their emic approaches to mathematics. Thus ethno mathematicians deprive the ethnic groups of their social and cultural specificity about differences that make mathematical practices unique from their point of view (Rosa & Orey, 2019). This risks reproducing etic approaches leading to colonial, primivitzing views about mathematics in ethnic practices (Dowling, 1998; Eglash et al., 2021; Powell & Frankenstein,1997). Thus, researchers build ethnic mathematical practices from an outsider's view (Rosa & Orey, 2019).

Building from the above, as cited in Lachney et al. (2016, p. 222), Rosa and Orey (2013) use the language of dialectics to describe their work on *ethnomodeling*, aiming for a bidirectional synthesis of emic and etic interpretations. Ethnomodelling, which combines ethnomathematics and mathematical modeling, is an approach that creates a firm foundation that allows for the integration of emic, etic, and dialogic approaches in exploring mathematical knowledge developed by the members of distinct cultural groups (Rosa & Orey, 2019). However, this bidirectional approach had some troubling asymmetry (Lachney et al., 2016). The bidirectional approach mainly assumes that the academic form of mathematics is outside of time and space: final, perfected, ahistorical, and universal (Lachney et al., 2016). Hence, Lachney et al. (2016) argued for a new form of modeling ethnic motives of mathematics with that of institutionalized mathematics. They believed that any new approach to bringing these two systems of knowledge together must show how Western science, mathematics, and computing are also culturally specific (Lachney et al., 2016).

Another troubling asymmetrical approach was Pias and Mesquita's (2013) Urban Boundaries Project and Tedre and Eglash's (2008) ethnocomputing. These projects have parts that failed to correspond to academic mathematics or local mathematics. This one-way approach fails students to learn to appreciate Mathematical achievements from their own and other cultures (D'Ambrosio, 1990). In the urban boundary project, Pias and Mesquita(2013) believed that our society needs to create alternative educational settings to respond to the increasing problem of exclusion faced by so-called minority populations. They think that as long as schools are structured as credit systems (Vinner, 1997), only within non-scholarized settings can a genuine ethnomathematical approach be reached. However, what is the essence of this setting if it has no linkage to the mainstream where students also go to learn? Researchers identified initiatives like the Urban Boundary Projects as a potential cause for some ethnic children's conception that doing Mathematics is as being White (Fryer & Torelli, 2005).

Mathematicians and anthropologists use computational media platforms to address these challenges from initiatives like the Urban Boundary Project (Ethnocomputing, 2017). However, a different project for using this computational media platform expanded its initial foci (Eglash, 2006). It was a rubric for the computational aspects of the computational media platform for Computer Science Education (Tedre & Eglash, 2008). The computational media platform became an amalgamation of both mathematics and computations in cultures for Mathematics and Computer Science Education research. This has resulted in the problem of striking the difference between using the platform for its ethnomathematics purpose or Computer Science Education. Lachney et al. (2016) found that adding computations in cultures to the computational platform for Computer Science Education has disempowered indigenous communities and silenced their mathematical heritage.

Lachney et al. (2016), building on their critique of Rosa and Orey's bidirectional form of modeling and that of the computation media platform, called for a recursive form of modeling. Lachney et al. (2016) concluded that there are bi-directional flows within the indigenous culture and bi-directional flows within the western culture (such as the interaction between people and machines). Hence, bringing those together results in a recursive modeling process, a nesting of flows within flows. (Lachney et al., 2016). These researchers fully fleshed out the recursive modeling in their Adinkra Computing (AC, acronym used in the original study) project. AC was a form of computations in cultures within the computational media (Eglash & Tedre, 2008) in the West African context. Hence, it is not surprising to find that it equally disempowered indigenous communities and silenced their mathematical heritage.

Also, in the recursive modeling, students only moved after computer simulations to physical renderings to repurpose STEM innovation and discovery in the service of indigenous community development (Eglash et al., 2019). This is a form of Rosa and Orey's (2013) bidirectional approach, which Lachney et al. (2016) critiqued as troubling and asymmetrical. In addition to this, recent use of recursive modeling (Eglash et al., 2021) never focused on authentic forms of cultural making (Blikstein, 2020), mathematics, and its ethnomathematics. Everything existed on the Computer. Students tend to lose the realistic pre-planning of executing any artistic pattern from diverse cultural groups. I assert that there is no reason why a mathematical model cannot include the possibility of an indigenous counterpart or conscious reflection on the part of communities who shape their own material conditions from generation to generation (Eglash, 1997).

In line with this, Barbosa (2006) and Rosa and Orey (2015) proposed socio-critical forms of modeling. This is a learning milieu where teachers invite students to take a problem from everyday or other sciences that are not pure mathematics and investigate it concerning reality via mathematics (Barbosa, 2003). However, much of everyday mathematics ignores the diverse ethnic motives of Mathematics. The question to be answered here is whose everyday? Beyond this, ethnomathematics research is more than just looking for modeling approaches; I assert that it is an encompassing and robust socio-critical literary program. Instead of researchers using everyday, I assert we use relevant ethnic mathematical practices. I will discuss this as we go forward.

What Other Options Are Available?

Ethnomathematics reflects the growing consciousness of the existence of mathematics, particularly in a certain way to (sub)cultures (Gerdes, 2001). Ethnomathematics challenge that the development of mathematics is not unilinear (Gerdes, 2001). Hence, we can use broad terms, including, in particular, counting, locating, measuring, designing, playing, and explaining (Bishop, 1988), which emphasize and analyze the influences of socio-cultural factors on the teaching, learning, and development of mathematics (Gerdes, 2001). Institutionalized mathematics is already a composition of Mathematics from the Greeks like geometry, expressions, and algorithms from the Indians, and Europeans like algebra. This characterization makes the techniques and truths of Mathematics a cultural product (Gerdes, 2001). Hence, we can revitalize ethnomathematics research to expand our understanding of the development of mathematics like geometry beyond Greeks to cultures of others like Africans, Native Americans, and many others (NCTM, 2021).

Generally, this research interest in moving "everyday life into the school" (Scribner & Cole, 1973, p. 558), in this case, "the mathematical thoughts in practices of diverse ethnic groups into schools" has a long tradition in neo-Vygotskian approaches. They help intervene in educational activities (see Gutiérrez & Jurow, 2016). This theoretical orientation and educational and social goal inspire the design of educational settings that seek to bring together cultural forms of learning and scientific practices in ways that places them on a more level playing field, that is, without reproducing inequitable hierarchical relations (Gutiérrez & Jurow, 2016). A typical neo-Vygotskian approach is the social-design experiments, leading to socio-critical literacies (Guitterez, 2008; Gutiérrez & Jurow, 2016). In what follows, I describe how I frame ethnomathematics in the social-design experiments and the consequential socio-critical literacies.

Ethnomathematics and Social Design Experiments

Social design experiments (SDEs) are an advanced approach to design research organized around a commitment to transforming the educational and social injustices faced by members of non-dominant communities to promote social equity and learning (Gutiérrez & Jurow, 2016). The injustices toward which social design experiments focus are those that are structural, systemic, and experienced as unjust by non-dominant communities. These include those discussed above. Thus, the silencing and marginalization of the mathematical practices of diverse ethnic groups by researchers in an attempt to bring them into the academic space. This also includes education environments in pluralistic societies that offer students little purpose (Paris & Alim, 2017) to connect the content, pedagogical, and curricular approaches to students' intellectual motives in ethnic practices from the non-dominant groups.

Researchers focus on SDEs is on redressing historical injustices and inequities and the developing of theories focused on the organization of equitable learning opportunities. Hence, situating ethnomathematics research in SDEs is focused on finding solutions to those mentioned above structural and systemic injustices in the pluralistic Mathematics classroom. Researchers achieved this through the SDE methodology combines traditions of design-based research (Design-Based Research Collective, 2003), namely; (a) the need to develop innovative approaches for educational improvement and (b) the need to address theoretical questions about the nature of learning in context (c) the need to study learning in the real world rather than in the laboratory (d) the need to go beyond narrow measures of learning and understand how complex learning ecologies support learning (Gutiérrez & Jurow, 2016, p.2). As well democratizing such forms of design-based inquiry. It seeks to make the design experimentation process a coconstruction between different institutional stakeholders (Cole & The Distributed Literacy Consortium,2006), which leads to social transformations (Gutiérrez & Jurow, 2016). In addition, social design experiments build on the different forms of knowledge and expertise that people develop across the multiple contexts of their lives, recognizing that even in the face of oppression, non-dominant groups have many resources for being resilient (Gutiérrez & Jurow, 2016). Hence, situating ethnomathematics research in SDEs is a means for learners from diverse ethnic backgrounds to find the pluralistic mathematical classroom as a meaningful shared space where they co-construct mathematical meanings from both the academic space and that of their diverse backgrounds. By building on ethnic motives of mathematics, the solutions and the learning that emerges through SDEs have a greater likelihood of achieving sustainability, meaning, and impact. This is contrary to the deficit approaches I outlined above.

Of significance is that SDEs' explicit focus on disrupting educational, structural, and historical inequities through the design of transformative learning activities provides openings for learning, a context of critique for resisting and challenging the conditions that create and sustain inequities, and space for generating their possible solutions (Gutiérrez & Jurow, 2016). With this perspective on equity-oriented design research in mind, SDE researchers ask and offer one solution to this central research question: How can researchers organize design interventions that intentionally leverage the diverse forms of expertise of non-dominant communities so as to create the possibility of more consequential learning opportunities for them? (Gutiérrez & Jurow, 2016, p.4). The answer proposed by Gutiérrez and Jurow (2016) is that the designs at the center of SDE strategically link practices that are valued differentially, like the ethnic motives of mathematics in society, with that of the dominant forms like academic mathematics for learners to reorganize and reconstruct. I describe designing for ethnomathematics through SDEs below.

Designing for Ethnomathematics through SDEs

Designing SDEs begins with teachers creating a repertoire of ethnomathematics testimonios. This well-developed complementary methodology enables one to uncover the mathematical motives (Pias, 2013), like measurement and designing in diverse ethnic practices like basket weaving (Gerdes, 1986). Through cognitive anthropological interviews, teachers video record the basket weaving and hair braiding techniques of Indian and African Americans, respectively. Teachers, students, or Native scholars write the audio from the video recordings into texts of the Native language, English, and many more. This written narrative is for students to use in the pluralistic mathematics classroom. They serve as mediational artifacts. Ethnomathematics testimonios are also syncretic texts, designed to exploit the existing hybridity and help to create particular social environments of development in which students begin to reimagine who they are and what they might be able to accomplish, academically and beyond (Gutiérrez et al., 2009). Developing such ethnomathematics testimonios involves conditional knowledge that involves teachers knowing when to use particular sources of ethnic motives of mathematics and how to evaluate their effectiveness concerning institutionalized mathematics. Ethnomathematics testimonio keeps to Papert's (2000) reminder. Children can learn powerful ideas about the world if we forgo those that schools have politically disempowered, teaching mathematics only through applying formulas or by proposing problems situated in "fake" contexts that fail to be meaningful for pupils.

Ethnomathematics testimonios serve as the fabric of knowledge from cultures (Nasir & Hand, 2006). They are the detailed description of cultures, including pre-planning thoughts and natural language use in cultural practices. Subsequent use of such narratives in diverse contexts might call for translations to eliminate the language barrier. This is possible through the fractionated trading zone metaphor (Collins et al., 2010). Thus, we can see that mathematical thoughts are boundary objects and interactional expertise. They adapt to the local needs and constraints of the several parties employing them (materially and linguistically) yet are robust enough to maintain a common identity across sites. This fractionated trading zone informs the definition of culture in my use of social-design experiments. Culture is both by the material culture largely in the absence of linguistic interchange. Also, culture is the interactional expertise. Students mediate by language mainly in the absence of the material culture from the ethnomathematics testimonio. The literacy in the neo-Vygotskian focus of ethnomathematics reflects that of Guitterez and Jurow (2016) and diSessa (2018). Thus, it is a form of massive intellectual accomplishment as learners go through a grand "remediation" of shifting and expanding fundamental forms of mathematics as they unfold in diverse ethnic groups and their practices to include institutionalized forms of mathematics as universally known and used. The premise for using the ethnomathematics testimonio in SDE follows that of Engeström's re-mediational design. Thus,

> Rather than giving the child just a task, ignoring her interpretation and reconstruction of the task, and observing how she manages, Vygotsky and his colleagues typically gave the child also potentially useful mediating artifacts - tools and signs. With them, the nature of the task could be radically changed. The child's potential capabilities and emerging new psychological formations might be revealed. (Engeström et al., 1986, p. 5)

As in social-design experimentation (Gutiérrez & Jurow, 2016), developing ethnomathematics through SDEs does not aim merely to contact the practices of non-dominant communities and institutions (e.g., schools). Rather, researchers organized ethnic motives of mathematics for students. Students reconstruct and reorganize to engender new forms of knowledge and expertise. This knowledge and expertise embody characteristics of the best of both sets of practices (ethnomathematics and institutionalized mathematics), albeit in new forms. At the same time, it is critical to note that the researcher designed ethnomathematics testimonios to transform the institution to embrace multiple ways of knowing, acting, and valuing. These social design experiments (Vossoughi & Gutiérrez, 2008) are organized around expansive forms of learning, powerful literacies, and hybrid language practices that result from the intercultural exchange and boundary-crossing involved in students' everyday lives like socio-critical literacies.

Socio-Critical Literacies and Ethnomathematics

Socio-critical literacies is a syncretic literacy that emphasizes the development of literacies in which researchers reframe everyday and institutional literacies into powerful literacies oriented toward critical social thought (Gutiérrez, 2008). As Gerdes (2001) characterizes ethnomathematics, socio-critical literacies focus on the cultural dimensions of learning. It takes an approach that resists home and school binaries, formal and informal learning. Instead, it focuses on what takes hold as children and youth move in and across their everyday lives' various settings and contexts (see Tuomi-Gröhn & Engeström, 2003). This approach identifies both possibility and constraint within and across contexts (Cole & Engeström, 1993). From this perspective, we can capitalize on the understanding of the cultural dimensions of learning and development that occur as "people, ideas, and practices of different communities meet, collide, and merge" (Engeström, 2005, p. 46). The socio-critical agenda of ethnomathematics does not see the original ethnic motives of mathematics as a profound source of only intervention (see Vossoughi et al., 2016). It rejects the assumptions that the computational capital of some cultures is hidden (Eglash & Bennett, 2009; Gerdes,1985) and needs a suitable environment before being made available to their owner (Eglash & Bennett, 2009).

The socio-critical forms of ethnomathematics assume that they are untapped. When tapped, they are a deep source of learning in their cultural context, which overlaps with/into other modes/mediums of learning for expansive forms of knowledge. This distinguishes the socio-critical form from most research in recursive modeling of ethnomathematics, which mostly rejects the original forms of learning. The socio-critical literacies conceptualize the notion of repertoires of practice. SDE researchers capture both vertical and horizontal forms of expertise through this repertoire of practices (Gutiérrez & Rogoff, 2003); this includes what students learn in formal learning environments such as schools and what they learn by participating in a range of practices and ethnic motives of mathematics. The socio-critical forms of ethnomathematics conceptualize the idea of a Third Space (Gutiérrez & Roggoff, 2003). This Third Space construct is more than a celebration of the local literacies of students from non-dominant groups; and certainly more than what students can do with assistance or scaffolding; and also more than ahistorical accounts of individual discrete events, literacy practices, and the social interaction within (Gutiérrez & Rogoff, 2003). Instead, it is a transformative space where the potential for an expanded form of learning and the heightening of the development of new knowledge (Gutiérrez & Rogoff, 2003).

Conclusion

The divide between many educational institutions and the students they are supposed to serve grows (Paris, 2017). Students do not feel that their identities are affirmed through the curriculum taught; it is irrelevant, very impractical, and exclusionary to their backgrounds, experiences, and lives (Paris, 2017). In Mathematics Education, a unidirectional approach has been the mode for researchers to connect the cultural ways (ethnomathematics) and institutionalized forms of learning. This seems to be very challenging. As Miller (1992, p.11) posited; how can anyone who is schooled in conventional Western mathematics “see” any form of mathematics other than that which resembles the conventional mathematics with which she is familiar? The answer to this question partially formed the focus of this write up. I assert that although these diverse forms of mathematics might be familiar, the language, terminologies, tools and many others used in one context might be different from the other. It only takes remediation in the form of reorganizing and reconstruction for one to resolve the constradictions between these two systems of knowledge for an expanded form of learning. One way to start with is to write the pre-planning thought and natural language used in ethnic motives of mathematics for learners and teachers to co-construct by adding to that of the institutionalized mathematics.

In this article, I proposed using repertoires of ethnomathematics testimonios through the neo-Vygotskian theories of intervening activities. Learners can reorganize mathematical motives in the making processes of material culture from a diverse ethnic group into institutionalized forms of Mathematics (Vygotsky, 1978). Through this, I assert that we will all become enlightened about the motives of mathematics from other cultures through the neo-Vygotskian foci of ethnomathematics research. This would help us avoid the thought that ethnomathematics research is mainly for people of color and merely turning cultural products into lessons for a white-dominant society. As a PMENA-43 reviewer who rejected my initiatives, among other reasons, stated:

> "…as a community, we need to be careful of turning cultural products into lessons for a White dominant society and be critical of who this research is to research (on Communities of Color) is out to benefit (the communities with whom we are conducting research on/with or the Mathematics classroom where mostly white middle/upper-class student benefit".

I have emphasized that institutionalized mathematics comprises cultures like Greek Geometry, Indian Algebra, American English, and symbols. Hence, mathematics education research can add that of other cultures on the grounds of Mathematics. Untapped Mathematics in other cultures might be the source of our discoveries in the form of advanced mathematical thoughts. I hypothesize that ethnomathematics as a syncretic mathematical activity is a massive intellectual accomplishment that one achieves from the grand remediation of mathematical motives in the activities done by diverse ethnic groups to include institutionalized forms of mathematics. This is a practical approach for all learners to reorganize and reconstruct non-routine Mathematical problems. One approach is designing mathematical activities that would involve all manner of learners to think with at the intersection of cultural presence, embedded knowledge, and the possibility for personal identification (Papert, 1980). Through such activities, we can answer research questions including; (a) how does ethnomathematics testimonios stimulate reflexive discussions among all learners in common cultures of Mathematics about its connectedness with the mathematical motives in other (sub)cultures? (b) How do we create a repertoire of ethnomathematics testimonios from holistic ethnomethodology which is globally accessible to all?

TRANSLANGUAGING AS A SOURCE OF MATHEMATICAL SENSE-MAKING PRACTICE DURING PROBLEM-SOLVING

Ayse Ozturk
The Ohio State University, Newark
ozturk.25@osu.edu

This study focuses on how strategic translanguaging occurs when bilingual students engage in a real-life-oriented problem-solving process and communicated their reasoning. Data for this report came from an after-school program for bilingual high school students. Action-research methodology guided data collection from classroom sessions that consisted of problem-solving with quantities. Analysis revealed that translanguaging can be a source of the sense-making process in mathematical problem-solving that leverages bilingual students' linguistic repertoire to combine everyday and mathematical registers while bridging multiple solution pathways.

Keywords: Communication, Equity, Inclusion and Diversity, Problem Solving

Research has shown that bilingual students can use a variety of tools to construct sense-making in mathematical problem-solving, such as community funds of knowledge (Gutiérrez, 2017); cultural resources (Moschkovich, 2015); everyday experience (Domínguez, 2011); and mathematical discourse, gestures, and representations (Garcia, 2017). More recent research has demonstrated that to maximize mathematical sensemaking during communication-based problem-solving, bilingual students strategically use two languages by code-switching or code-alternating (DiNapoli & Morales, Jr., 2021). This paper aims to build on prior research by studying how strategic translanguaging occurs when Turkish-American bilingual students make sense of real-life-based problem-solving processes and communicate their reasoning.

The Conceptual Framework

Drawing on Garcia's (2017) description of translanguaging as a holistic and dynamic meaning-making practice that involves coordinating linguistic and semiotic resources to make sense of concepts and contexts of mathematical problems, we adapted DiNapoli and Morales, Jr.'s (2021) framework for translanguaging mathematical practice (Figure 1) to investigate Turkish-American bilingual students' problem-solving processes:

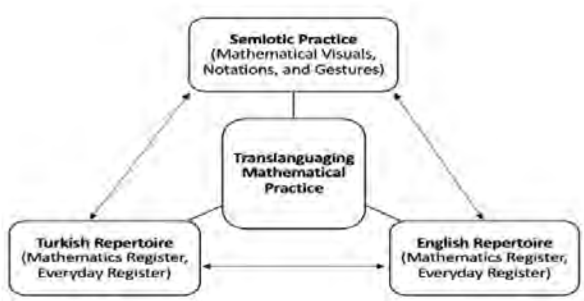

Figure 1: Framework for Translanguaging Mathematical Practice (Adapted from DiNapoli & Morales, Jr., 2021)

Within the framework, bilingual students activate their linguistic repertoire and switch between Turkish and English by utilizing mathematics and an everyday linguistic register. In order to complement mathematical discourse, bilingual students deepen their problem-solving experience with mathematical representations, including visuals, notations, and gestures. The framework guided the data analysis to reach an understanding of students' communication of their mathematical reasoning.

Research Setting and Participants

Data for this paper came from a more extensive research study conducted during a 6-week long after-school program for high school students at a public university in a Midwestern state. The class met twice a week for a total of 10 sessions, or 20 hours. The goal of the research program was to examine how bilingual secondary students call upon their mathematical experiences in real-life problem-solving contexts involving quantities (Ozturk, 2021).

The participants included six 10th-grade Turkish-American students from middle-class socioeconomic backgrounds and first-generation college dreamers. These students were all children of Turkish parents, their home language is Turkish, and their school language is English. Constant code-switching between Turkish and English is the typical way of speaking for all of them. Therefore, the study provided a flexible environment to use the two languages as they engaged in classroom activities. All participants' names given here are pseudonyms.

Methods and Data Collection

Drawing upon an action-research methodology (Mostofo & Zambo, 2015), the after-school classroom sessions consisted of real-life-based problem-solving with quantities. In each session, students solved problems in pairs, and then small groups shared strategies with others to reflect upon diverse ways of reasoning. Students were free to code-switch any time during problem-solving and group presentations, and the researcher communicated with students in two languages. All sessions were videotaped and transcribed. In addition, the students' written work was collected.

Data Analysis, Example Group Dialog, and Written Work

Data for this study consisted of video excerpts in which students were solving problems and communicating their solutions to the class. The criterion for the selection of video excerpts was that they contain students translanguaging while problem-solving. We paid attention to how students used resources such as code-switching, visual-graphic representations, or gestures while developing sense-making of quantities in the problem contexts.

Drawing from a thematic analysis (Braun & Clarke, 2012), the data analysis consisted of four steps: 1) Capturing evidence of students' translanguaging instances; 2) using a conceptual framework (Figure 1) to code student's use of English and Turkish as well as everyday and mathematical registers; 3) elaborating each translanguaging moment in which students supported their communication with non-verbal mathematical representations; 4) using the constant comparative method, we inductively created themes to describe the ways in which evidence of strategic translanguaging occupied different roles during the phases of problem-solving and collective sense-making.

Although analysis is still in process, to illustrate one theme from our data regarding the role of strategic translanguaging in the problem-solving process, we purposely selected a vignette from a group of students that worked on a problem that demonstrated students' interaction while beginning the problem and selecting appropriate mathematical units to continue their solution.

Translanguaging as an entrance of problem-solving while selecting appropriate units. In this theme, students work in pairs in the beginning phase of the problem-solving process. They brainstorm and decide how to make sense of a problem and choose methods of mathematization, abstracting a given situation and representing and manipulating it symbolically. For example, in the Traffic Jam Problem (Figure 2), students were required to perform estimation, relate quantities, and work on units in order to make sense of their interpretations of the calculation results.

> Last Sunday, an accident caused a traffic jam 15 miles long on a straight stretch of a two-lane freeway. How many people do you think were in the traffic jam?

Figure 2: Traffic Jam Problem (Adapted from Illustrative Math, 2016)

While the problem involves simple arithmetic operations, students must make reasonable assumptions about the average length of vehicles and the space between vehicles in the traffic jam. In the excerpt below, Hale and Asya were trying to imagine a 24-kilometer-long traffic jam and discussed how many cars might fit such a traffic jam. Although the other two groups chose to continue with 15 miles as a length unit, this group first converted units from the U.S. customary system to the metric system to do the rest of the calculations.

While Asya was searching for photos (from Google) to determine how long 15 miles was in kilometers and how many cars could fit in a 24 km-long road to visualize the traffic jam scenario in her mind, Hale asked her why 24 km was important to her. Asya immediately switched the code from English to Turkish and explained that it is hard to imagine the length in miles (Figure 3):

Hale:	What are you looking up?
Asya:	24 km. Kac araba sigabilir 24 km'lik trafige diye baktim.
Hale:	Hmmm—neden 24 km ki?
Asya:	Cunku 15 mili hayal edemiyorum, ama 15 mili kilometreye cevirirsek, kafamda yaklasik 24 yada 25 kilometre ne kadar biliyorum.Teyzem ve bizim evimizin arasi kadar bi uzaklik.
Hale:	Oh, I got you. Make sense.

⟷

Hale:	What are you looking up?
Asya:	24 km. I looked up how many cars might fit in 24 km traffic jam.
Hale:	Hmmm—**why 24 km?**
Asya:	Because I **cannot imagine 15 miles**. If we convert 15 miles to km, it's about 24 km. **In my mind,** I know how long **24 or 25 km is; it's like the distance from our house to my aunt's house.**
Hale:	Oh, I got you. **Make sense.**

Figure 3: Transcript and English Translation: Evidence of Translanguaging Practice (Turkish-English)

She preferred to imagine the distance in kilometers because she could relate the distance (approximately 25 km) to her everyday experience. Asya combined everyday and mathematical registers when describing 24 km (close enough to 25 km) as "it's like the distance" between her and her aunt's houses. She rethought the context of the problem, 15 miles, in the metric system because describing and representing 15 miles was not accessible at the beginning. When she explained this unit conversion (from 15 miles to 24 km), she immediately switched code into Turkish. This might have occurred because thinking in the metric system was learned in Turkish before she was introduced to the U.S. customary system; thus, working with metric units stimulated her Turkish repertoire as an intellectual resource for mathematical sense-making.

Converting units from miles to kilometers was a strategic decision because it allowed students to access mathematical ideas through their prior work—making assumptions about the length of vehicles and spaces between them in the traffic jam. Note that communication between

Hale and Asya was a valuable exchange through meaning-making in the problem-solving process. Hale's affirmative comments ("Make sense" and "I got you") about Asya's unit conversion description showed a sign that this group persevered in problem-solving steps as long as both students met at a shared understanding built on collaborative meaning-making efforts.

After Hale's confirmation, Asya started drawing the two-lane freeway and wrote down 15 miles as 24 kilometers using the sign "≈" of approximation (see Figure 4). Their first assumption about an average car length was 4.5 meters. They converted 24 kilometers to meters to more easily divide that into cars 4.5 meters long. In this way, they estimated how many cars would fit in one lane, and multiplying by 2 resulted in approximately 10,600 cars in the traffic jam. Another assumption was that the average number of people in a car during a traffic jam was 2. Students multiplied 2 with 10,600 cars and reached the result of approximately 21, 200 people would be in the traffic jam. Figure 4 illustrates students' first attempt to solve this problem:

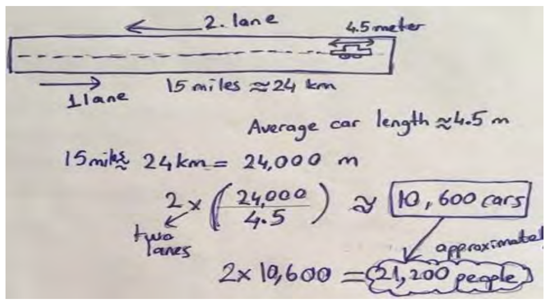

Figure 4: Example Solution for Traffic Jam Problem

When Hale and Asya presented their results to the whole class, other groups asked questions, such as why they made the assumption of 2 people in a car or why they assumed there would be only cars in the traffic. Hale and Asya also realized they had not considered the gaps between the cars, and they assumed the cars were lined up back-to-back. Hale said that even in a traffic jam, there should be a gap between cars. Students made recalculations by considering different scenarios, such as what if there were trucks and motorcycles in the traffic, and how changing vehicle numbers could impact the total number of people. Later, the class focused on how to come up with minimum and maximum numbers of people in the traffic jam if they reconsidered the important factors that could change the results (vehicle types, the length of gaps, etc.)

Preliminary Results and Conclusion

The study focused on understanding how strategic translanguaging occurs when Turkish-American bilingual students make sense of real-life-based problem-solving processes. The preliminary results showed that translanguaging occupied different roles during the phases of problem-solving and collective sense-making. The results revealed that students used translanguaging as an entrance to problem-solving while strategically selecting units that were more accessible to them.

These findings resonate with previous studies (e.g., Garcia, 2017) suggesting that positioning translanguaging as a source for sense-making practice encourages bilingual students to leverage their full linguistic repertoire as well as to combine everyday and mathematical registers. The results also show that strategically selecting appropriate quantities and their units became tools to justify mathematical reasoning and shared understanding among bilingual students. Therefore, strategic translanguaging is a powerful tool for bilingual students to bridge multiple pathways while engaging in problem-solving.

THE COMPETING EXPECTATIONS OF MOTHERHOOD AND MATHEMATICS: INTERNALIZED GENDERED AND RACIALIZED NARRATIVES WITHIN

Sam Prough
University of Delaware
sprough@udel.edu

I draw attention to the tensions between the expectations of mathematics and motherhood to highlight how mothers positively engage with their children in mathematics, even when that activity is not recognized or granted legitimacy. I ask: what do mothers' experiences in mathematics and with their children say about U.S. society's expectations of mathematics and motherhood? I highlight the experiences of five participants as they reflect on their mathematical experiences and interactions with their children. The findings demonstrate the pervasive nature of gendered binaries and privileged whiteness in the expectations of mothers in both motherhood and mathematics. The constraining expectations of what it means to mother and be involved in mathematics shows the need to shift perspectives of what counts as mothering, as parenting, and what counts as mathematics.

Keywords: gender; equity, inclusion, and diversity

The images of motherhood and mathematics in Western society have long perpetuated expectations that privilege the experiences of certain people, but not others. Expectations surrounding parenting in the U.S. are deeply rooted in gendered binaries and the norms of white, middle-class families (Dillaway & Pare, 2008). Mathematics is framed as a field for white, middle-class men aligning to the norms of masculinity and limiting who can be viewed as mathematical (Hottinger, 2016). Mothers, however, are often expected to support the early education of their children, which can include mathematics (Odenweller & Rittenour, 2017). Although some may argue that early mathematical work is not subjected to similar framing of masculinization the issue lies in the erasure of early mathematical practices as mathematics. Skills such as counting and early numeracy are described as separate from and less rigorous than mathematics (Hacker, 2016), which can further emphasize a divide in what and who counts as doing mathematical work. When a masculine mathematics intersects with the expectations of teaching in motherhood, tensions come to the forefront. A dissonance is clear between the expectations of who can do mathematics and mothers raising children that questions what it means for women who are mothers to support children in mathematical learning. Bringing attention to such dissonance, highlighting the specific tensions in the gendered and racialized components of motherhood and mathematical participation, has the ability to shift societal perspectives of what counts as mothering and what counts as mathematics.

I draw attention to the tensions between the expectations of mathematics and motherhood to highlight the challenges of parents helping their young children learn. I respond to the following research question: What do mothers' experiences in mathematics and with their children say about U.S. society's expectations of both mathematics and motherhood? Weaving together the narratives of five mothers, the findings show persistent challenges with assumptions of whiteness and upheld gender binaries in the roles of motherhood and mathematics. The reflections from the five mothers show the pervasiveness of such expectations from their time in school and its current impact on their activity now with their own children. Connecting the experiences of the participants to the literature on parents' experience in mathematics and the role of motherhood offers opportunities to disrupt notions of what mothers must do in children's early mathematical learning by considering the possibilities for what motherhood and mathematics can look like in different contexts.

Perspectives on Motherhood and Mathematics Expectations

This study expands on the literature that addresses the experiences of mothers in mathematics *and* their resultant interactions with children by considering the interactions between the two bodies of work. Some literature considers the experience of mothers as mathematics learners (Chase, 2018), some considers mothers' beliefs or impact on their children's mathematical performance (e.g., Cannon & Ginsburg, 2008; Tomasetto et al., 2011), and others have considered mothers' mathematical interactions with their children (e.g., Anderson & Anderson, 2018). It is necessary to put the experiences of mothers and their interactions with children in conversation, to understand the complex relationship of expectations put on them in their roles of motherhood and early mathematics teachers for their children. In this section, I describe the literature on the Western expectations of both motherhood and (school) mathematics. Then I consider the tensions between those expectations on a parent being upheld to the expectations of both.

Expectations of Motherhood

Previous literature has shown a continued connection between womanhood and motherhood (e.g., Arendell, 2000; Collins, 2000; Roberts, 1993). In this way, the term 'woman' is often seen as synonymous to 'mother' (Mora, 2006). Historical images and expectations of motherhood often focused on mothers' labor centered at home and fathers' labor out of the home, with clear divides in what mothers and fathers were expected to do for their family. This division of labor and familial expectations for mothers has evolved into present day to include additional responsibilities, such as working to provide other resources to the family while still being the primary parent to raise children (e.g., Duxbury & Higgins, 1991; Rothausen-Vange, 2004). Zhao and colleagues (2011) argued that "traditional thinking assumes that women should do a greater share of household labor and childcare, and mothers may be particularly overloaded compared to fathers and women without children" (p. 725). This traditional thinking persists in ways today that may not look like an expectation that mothers stay at home or homeschool their children, but still supports notions of mothers taking on the greater share of childcare.

Some of the pervasive expectations surrounding motherhood in Western society include a focus on (1) mothers being the exclusive or primary caregiver for their children (Dillaway & Pare, 2008), (2) mothering being a sacrifice of other aspects of a mothers' life (Maher & Saugeres, 2007), and (3) good mothers being recognized by the well-behaved nature of their children (Austin & Carpenter, 2008). Unfortunately, these three pervasive expectations for motherhood do not consider the complexities of what mothers do and how they do it to support their children. For example, families may be in situations where it is not possible for a mother to be the exclusive or primary caregiver, but this should not imply such a person is a bad mother because of that. Analysis of mothers' actions, context, and intentions with their children can illuminate other ways of doing motherhood.

Expectations of (School) Mathematics

What is typically expected in mathematics in school environments centers on students getting the correct answer to a problem and working quickly, where a teacher has the authority to define what student actions and answers count as appropriately mathematical or not (Esmonde et al., 2013). School mathematics is often about memorization and algorithms, even when it aspires to be about understanding. Marta Civil (2002) characterizes the traditional norms of school mathematics as "an overreliance on paper-and-pencil computations with little meaning, clearly formulated problems following prescribed algorithms, and a focus on symbolic manipulation deprived of meaning" (p. 41). Additionally, what is determined as appropriately mathematical or who mathematics is for is based in systems that privilege the norms of white and middle-class men (Rousseau Anderson & Tate, 2016). In the minds of many, the framing of mathematics in school is privileged over other types and styles of mathematical learning, such as what might happen at home (Takeuchi, 2018). Given the images and expectations of what mathematics is, students can develop ideas about themselves and their mathematical ability, taking these understandings beyond school. The expectation of mathematics as a masculine subject, intended for men but not women, has persisted (Hottinger, 2016). Such narratives about a white-centered and masculine mathematics continue to shape students' perspectives of themselves as mathematical as they grow up and become parents.

Dissonance in Expectations for Women and Mothers in Mathematics

The specific masculinization of mathematics provides context for the impact gendered expectations of mathematics has on mothers' experiences in the subject. Past understanding of mathematics and who is capable of mathematical work assumed that women do not or should not be learning and doing mathematics (Hottinger, 2016). Mathematics is a subject associated with masculine characteristics such as working independently and thinking with logic and rationality (Ernest, 2018; Solomon, 2012), but at the same time distancing these characteristics from women and their potential association with mathematics (e.g., Connell, 2010; L.A. Leyva, 2017). In the same way that mathematics highlights a separation between men and masculinity from women and femininity, the roles of parents (mother and father) have also been divided to correspond to what is considered 'appropriate' gender roles. Fathers, who are assumed more aligned to the masculine, are associated with mathematics, working, providing for their family outside of the home (Rothausen-Vange, 2004). Mothers, who are assumed more aligned to the feminine and not expected to do or understand mathematics, with a focus on domestic work that includes raising and teaching young children (Zhao et al., 2011). But the expectations of mothers to support children's early learning as part of domestic work is in tension with the expectation of women's inability to be mathematical. Past studies on mothers' involvement in children's early mathematical learning have not addressed the dissonance in expectations of mothers' roles as early teachers and a masculine mathematics.

Theoretical Framing

While the tension in expectations for mothers and mathematics stems from gender binaries for the actions and images of men and women, I want to consider the multi-layered influence of both gender and race in expectations for being a mother and doing mathematics. I use Collins' (2000) concept of matrices of domination as an analytical tool to critique the influence of expectations in mathematics and motherhood surrounding gender and race. Collins defines a matrix of domination as the organization of intersection oppressions. For example, the tension a mother feels when engaging in mathematics with children is influenced by the expectations of doing mathematics and being a mother that privileges gendered family roles, white and middle-class norms. As Collins (2000) argues, "regardless of the particular intersections involved, structural, disciplinary, hegemonic, and interpersonal domains of power reappear across quite different forms of oppression" (p. 21). The organization of expectations and domains of power of gendered binaries reappear in both motherhood and mathematics. Similarly, the privileging of whiteness reappears in both expectations of being a mother and doing mathematics.

Methods and Modes of Inquiry

I focus the findings for this paper on the experiences of five participants from a larger study about the impact of past experience on mothers' current mathematical interactions with children. The smaller set of participants is intended to give space to their narratives in the context of existing literature on the expectations of mathematics and motherhood but does not represent a generalization for all mothers' (or parents') experiences with parenting or mathematics. The larger study used a narrative inquiry approach to frame the narratives of the mothers to understand parts of their lives and make connections to the narratives of others (Clandinin & Connelly, 2000). Due to limited space, I focus only on short excerpts from their shared stories to draw attention to their discussion of motherhood and mathematics expectations. The study consisted of three interviews, two observations with debriefs, and collected artifacts to support shared stories with each participant. The elements of the study intended to capture participants' past experiences, current stories of mathematical activity, what that activity looked like and confirmation of those stories. I focus on the experiences of five participants: Amanda, Brittany, Courtney, Elizabeth, and Tara[1]. These mothers ranged in age from their late 20s to late 30s, living in rural to urban locations. Table 1 shows more detail about each of the participants.

Table 1: Name and Basic Demographics of Participants

Participant	Children (+Age)	Race	Occupation
Amanda	Grant (2)	Native American	Graduate student
Brittany	Rosie (2), Bobby (4)	White	Part-time music teacher
Courtney	Eva (3)	Black	Teacher
Elizabeth	Talia (2), Luna (7)	White	Stay-at-home parent
Tara	Sasha (1.5), Peter (3.5)	White	Part-time grocery worker

Transcripts from the three interviews and debriefs, as well as field notes from the two observations, were used as data for the study. Analysis focused on the context of participants' stories in response to the literature's expectations of motherhood and mathematics. An initial coding scheme looked for moments in their stories that described (a) emotions in mathematics, (b) positive mathematics engagement, (c) past experience influencing current mathematical interaction, (d) gendered experiences in mathematics and mothering, and (e) racialized experiences in mathematics and mothering. The details from codes a, d, and e informed the deeper analysis for this paper. Nuance in the mothers' feelings, words, and self-definitions received careful attention in coding for moments of mathematical engagement and motherhood activity. This specific attention to detail is meant to parallel the ideas of the work of the feminist narrative inquirer Madison (1993). As such, the transcription and analysis involved careful attention to deeper detail such as when the participants laughed, paused, sighed, or used filler words in sharing their stories.

Findings

What shaped the mothers' interpretations of themselves in their interaction with mathematics as well as motherhood identity was shaped by larger societal narratives of what it meant to do mathematics and be mothers. The mothers noted what counted as mothering or doing mathematics in implicit and explicit ways that highlighted gender binaries and the privileging of

[1] All participant names and the names of their children are pseudonyms.

white norms. The layers of expectations in gender and race, appearing in both conceptions of motherhood and mathematics, aligns with Collins' (2000) matrices of domination, as the organization of intersecting oppressions. In this section, I highlight aspects of the participants' stories around motherhood and mathematics that show common expectations in those areas that privilege gender binaries and white norms as described in previous literature. Although the audience for this work is centered in mathematics education, I specifically foreground the motherhood connections in relation to mathematics as the role of mothering in mathematics education is often ignored or devalued (Jackson & Remillard, 2005).

Motherhood Narratives

All but one participant shared how their mother did all or most of the work in raising them, including supporting their early learning, which shaped an expectation of what they saw was important to do for their children. Across all five mothers was a general expectation to be the primary caregiver for their children. Several participants also closely aligned their identities with that of being first and foremost a mother, reflected in the literature as a sacrifice of self for the sake of motherhood (Garey, 1995; Maher & Saugeres, 2007). Brittany, for example, talked about how she saw and defined herself in the past and now, sharing "the things that I feel like really define, in the past musical theater really defined a lot of my life and now it's mostly, my kids and my family. So sometimes that has been kind of a hard transition" (Interview 3). Brittany explained how she felt she needed to see her children and family as her primary focus, centering her role as mother above other aspects of herself, which used to center music and musical theater. The domestic work of participants' mothers as well as their frequent identification with the role themselves shaped how they interpreted their activity, as a necessity to being identified as mothers first and being the primary caregiver over other partners.

The influence of race on expectations of motherhood were more explicit in the stories of the mothers who identified as mothers of color or who had children of color. As Western society has privileged white norms in motherhood (Dillaway & Pare, 2008), reflections of fitting into such norms or helping their children fit into a world that does not privilege their experiences outside of whiteness. Due to limited space, I highlight the experiences of Elizabeth and Tara in the remainder of this section, both mothers who identified as white but currently parent children of color. In both cases, how they spoke about race related only to the experiences of parenting their children of color, not in the stories of their experiences growing up or how their actions as white mothers would be perceived. Elizabeth saw the challenges of appropriate representation in children's books, with many characters in popular and classic literature reflecting white faces. She saw this as a disservice to her daughter, Talia, who was Hispanic, sharing that she

> was really disappointed at how many books were like white kids in the books…And so, I set all those aside and I'm, we're giving those away [laughs] cause I, I think more and more how important it is for when {Talia} to open a book to see people like her reflected in that book. (Interview 3)

Elizabeth's statements reflect an expectation in motherhood (to help her daughter learn about herself through reading) and the challenges to meet that expectation given the books she has available. The activity of motherhood has an embedded association with whiteness in Western society (Morgan, 2018). In Elizabeth's story, this is reflected in the characters in children's books where there are white characters meant for white mothers to read to their white children. But those characters and expectations do not align to the experiences Elizabeth sees as important for her daughter, Talia.

Tara considered the impact of assumed whiteness for her children's future and what she needed to consider as a parent, raising children in a world that privileges whiteness. In talking about what she hopes for her children as they grow up, Tara shared the following story about potential racial prejudice they may encounter:

> Yeah I'm worried about my kids. Um, because right now they're in the super cute adorable Korean, half Korean/half white stage and they're just angelic and everyone loves them but then when they become teenagers they'll be little shits and then you know they won't have that you know, that draw anymore, and I just hope that they can just be respectful. (Interview 3)

Tara's worries for her two young children reflect how they will be perceived by others. Within her worries are particular actions as a mother she feels she needs to prepare them for such a future with actions and behaviors that fit into a world that privileges whiteness.

In the stories of these participants, the influence of gendered binaries and privileged whiteness informs their actions and thoughts about motherhood. Mothers like Brittany feel a personal responsibility to be the primary caregiver of their children, centering an identity of mother before other options, because of the expectations of women as mothers, nurturers (Austin & Carpenter, 2008). Mothers like Elizabeth and Tara consider what it means to raise children of color in a world that privileges the norms of white children and how to best support them. The next section highlights stories within the experiences of mathematics where assumptions of gendered binaries and whiteness reappear to assert particular expectations on the participants.

Mathematical Narratives

When talking about their experiences with mathematics, the participants highlighted several expectations in alignment with what happens in school mathematics, such as mathematics being a quick mental task, working on problems is done independently, and that such problems have one correct method and solution. Several of the mothers (Amanda, Elizabeth, and Brittany) shared how these characteristics of mathematics did not work for them and drew connections between a lack of mathematical ability to it being a subject meant more for men. Elizabeth, Brittany, and Tara also highlighted how they assumed their partners (identified as men) were just better at mathematics than they were, even though Elizabeth and Tara had extensive experience in the subject. Amanda explicitly identified the gendered expectation of who could or could not do mathematics from her schooling experience and how that shaped her perspective of herself, sharing that:

> I feel like it was very gendered when I was a kid. Like I always assumed there were the smart boys in class. And they were just better at math and that maybe it had something to do with me being a girl that I wasn't good at math. My mom would openly talk about how she wasn't good at math either. And then I felt like all the kids who were the best in my mind at doing math, that they could, like in elementary school they could do the timed tests and get the most answers down on the paper. And um, they didn't seem to have a problem doing algebra, were like, I can think of 1 or 2 guys specifically that I was always in the same classes with and they were always like the good at math guys. (Interview 1)

Amanda relates to expectations of school mathematics as well as the influence of her mother to shape a perspective that she must not be good in mathematics. Mendick (2006) highlights the challenges of identifying with mathematics when the subject is associated with the masculine and gendered binaries position men and fathers as masculine but women and mothers as feminine.

How people are perceived in school and in the mathematics classroom also includes racial representation, where the norms of whiteness are privileged along with characteristics of masculinity in mathematics (Hottinger, 2016). Courtney, who was an excellent student and particularly skilled in mathematics, shared stories of a teacher who constantly doubted her ability to answer questions and know the content, reflecting a similar bias in all his students of color. The assumption of whiteness in being able to learn or do well in school shaped how Courtney thought about her daughter, Eva and what she needed to be successful in school.

> I always think that I have to include the fact that yes you may not look like all of your classmates and that's ok. Um but how can we use that to teach, to teach them more about you? Or more about African Americans or like try to use that as a learning opportunity and allow her to find her own voice … I mean she's still capable of doing almost whatever, she wants or whatever she puts her mind to at least. So I think it will definitely come into play, it's come into play a little bit but, yeah, I think, I, I'm definitely I wanna be more conscious of it because I wasn't when I was a kid and I wish that I had been. (Interview 3)

What Courtney shares reflects the assumed whiteness in both school and mathematics. Her daughter Eva may need to learn to stand up for who she is and how she learns, which Courtney pulls from her own experiences in school as a Black girl.

The experiences of the mothers in mathematics show concerns about the perceptions of who can do mathematics that centers white norms and masculinity. Amanda talks about how she thought of herself as less capable in mathematics because she identified as a girl, enforced by perspectives of her own mother and the actions of students in her class. Amanda later returned to this perspective and considered what this would mean for her soon-to-be-born daughter and not wanting her to get the impression that mathematics also is not for her. Similarly, Courtney connected her own experiences with mathematics and the challenges with being perceived as a good mathematics student as a Black woman and what she felt was important to support her own daughter.

Discussion and Action

The experiences described by the mothers in both their past interactions with mathematics and how they engaged in the present with their children in the subject were influenced by the expectations of what it means to be a mother and to do mathematics in U.S. society. The gendered binaries shaping U.S. society uphold a divide in the roles of mothers and women vs. fathers and men that continue to define rigid expectations for mathematics and motherhood. Mathematics is often aligned with men and masculinity (Hottinger, 2016) and mothering is assumed to be the work of women, aligned with femininity (Odenweller & Rittenour, 2017). In mothering, the participants highlighted the expectation that they (as mothers) should be in charge of raising their children and teaching them. However, in mathematics many participants highlighted assumptions about the subject being more for boys and their perceived lack of ability in comparison to others, particularly their partners. Both instances point to the dissonance in expectations for mothers and doing mathematics; that mothers should help their young children learn but that mothers (often aligned with the identity of women) are lacking in mathematical skill. How are mothers expected to support most or all of children's early learning, which includes mathematics, while simultaneously being viewed as less capable in the subject? The response to such tensions cannot be an acceptance that mothers simply cannot well support early mathematics development.

The tensions in expectations of mathematics and motherhood extends beyond gendered binaries. The privileging and assumptions of whiteness are also a major part of U.S. society's interpretation of what counts as both motherhood and mathematics. Literature has documented the embedded racial expectations in policy and practice, as Marx (2006) states "the privileges attached to Whiteness have been, and continue to be, perpetuated in subtle ways through American institutions and popular culture" (p. 52). In mothering, the participants draw attention to what is available to support children that assumes whiteness (such as Elizabeth's recognition of primarily white characters in children's books). But in mathematics, participants reflected on how white students are assumed more capable and what it might take to support themselves and their children of color to recognize their own ability. Douglas and Attewell (2017) summarize the challenge of viewing some children as more capable than others, stating "the belief that mathematics requires innate talent is widespread in our culture…it rationalizes the notion that only some students will be able to learn school mathematics successfully" (p. 651). These perspectives of whiteness show the expectations of motherhood that support white mothers and their white children. At the same time, the expectations within mathematics make assumptions about who can and cannot do mathematics based on their race. Before any mathematical activity begins, mothers of color and mothers with children of color are already positioned as less capable and with fewer resources that support their experiences as not white.

How the mothers of this study experienced school and reflected on their experiences interacting with children as parents were shaped by gendered binaries of roles for mothers as well as expectations of whiteness in their parenting and participation in mathematics. The structures of expectations in both motherhood and mathematics have maintained activities and beliefs that uphold gendered roles for parents and their activity and privilege the norms of white families. The relationship between the expectations of motherhood and mathematics is more complex than a list of tensions or challenges experienced by individuals who are mothers and also support early mathematical learning. Take, for example, the context and experience of Elizabeth. As a white woman parenting a daughter of color, Elizabeth was concerned for the images and role models her daughter had that looked like her, with many media representations for children were white characters. However, the influence of race did not yet extend to Elizabeth's own experiences growing up.

Future work on mathematics experience and identity for mothers, particularly related to parents, requires a broader perspective on what it means to raise children and what it means to do mathematics. The limited images of what is expected for mothers and what is expected to be successful in mathematics contribute to the participants' narratives of this study; the mothers frame themselves as less mathematically capable while worrying about how their children will take up mathematics or be perceived by others. More can be seen with a similar analysis of a wider array of parents supporting early mathematical learning, such as different family dynamics and different associations with the role of 'motherhood'. Creating broader perspectives of both parenting and mathematics involves parent-centered research, considering both the actions, intent and context of how parents engage with their children in mathematics. Centering and listening closely to the experiences and actions of parents creates an opportunity for mathematics education researchers to understand new ways of mathematical engagement and new possibilities for connecting to children's mathematical learning.

THE INTEGRATION OF MATHEMATICAL AND SOCIAL CONTENT IN SECONDARY LESSONS FOR SOCIAL JUSTICE

In recent years, mathematics lessons addressing social justice have been increasingly published and taught, but little is known about how mathematical and social content unfolds within them. In this study, we interpret five secondary social justice mathematics lessons (SJMLs) as stories and analyze the questions that arise within them. We found that most of these lessons began and ended with a focus on social matters, while shorter mathematical questions arose in the middle of the lessons. However, the lessons varied in terms of what proportion of the questions overall were focused on social or mathematical thinking. Finally, we found that narrative devices were used in several lessons when the focus transitioned from social issues to mathematics, or vice versa. This way of thinking about lessons could enable the design of SJMLs that meaningfully integrate social and mathematical thinking.

Keywords: Social Justice, High School Education, Curriculum

To confront social inequity and systems of oppression, secondary mathematics teachers are increasingly seeking to integrate social justice themes within their lessons. Expanding opportunities for students to engage in a thoughtful analysis of social injustice and its consequences may enable students to become informed citizens (Gutstein, 2006). Moreover, it can enable students to recognize mathematics as a useful tool in better understanding the world, which in turn increases the relevance of mathematics and the motivation for its study (e.g., Darby-Hobbs, 2013). Finally, integrating social justice issues within mathematics lessons can provide an opportunity to (re)position mathematics as a human endeavor as opposed to a set of a priori truths (Ernest, 1998), created in part to solve worldly problems with which students can personally identify (Berry III et al., 2020).

Yet, incorporating social justice topics while teaching mathematical content is a complex goal, which therefore benefits from curricular support. Since most secondary mathematics teachers base instruction on published materials (Banilower et al., 2013, 2018), those who want to include social justice content will likely rely on existing materials. To address this need, a growing collection of social justice mathematics lessons ("SJMLs") has been published. Using published SJMLs enables teachers to explore the benefits of these lessons while developing critical new teaching practices (e.g., managing challenging discussions).

However, there is a potential for none of these benefits to come about, and maybe even for harm to be done, if SJMLs are not well-designed. In particular, SJMLs may poorly balance mathematical and social justice content. A lesson may give students the opportunity to engage deeply in a social justice issue, but treat mathematical content superficially, offering few opportunities for mathematical learning. On the other extreme, a lesson may give students the opportunity to engage deeply in mathematical thinking, but treat social justice content superficially. Such a lesson could limit insight into the world or into recognizing ways to take action and promote justice. We propose that to be beneficial and successful, SJMLs must interweave mathematical and social justice content so that they mutually benefit one another and advance what students know about both (what we refer to as *integration*).

Previous work has demonstrated how a narrative framework can enable different structures of content in lessons to become visible (e.g., Dietiker & Richman, 2021; Richman et al., 2018). This approach draws from literary theory, approaching unfolding mathematical content within a lesson as a story. Similar to a literary story, a *mathematical story* is the ordered sequence of events (such as tasks or discussions) that connect the beginning with its end (Dietiker, 2013, 2015). This conceptual metaphor provides the basis for studying how an unfolding story supports student inquiry, such as how withholding information can stimulate a reader to ask a question or how incremental revelations can enable a reader to piece together information. Thus, with mathematical stories come analytic tools that highlight what questions are raised and how these questions are addressed over the course of the lesson (i.e., analyzing the plot of the unfolding story).

By adapting the framework to include content related to social justice, we can learn whether and how social justice and mathematical content can mutually develop, potentially enabling us to identify lessons that span the spectrum as described earlier. Thus, this study explores how mathematical and social justice content is integrated (or not) in existing high school SJMLs. We begin to address the questions: *When viewed as narrative, what is the nature of SJMLs? Specifically, how is the mathematical and social content integrated?*

Theoretical Framework

Literary theory suggests that the "same story" (e.g., *Wizard of Oz* by L. Frank Baum) can be told in different ways (e.g., a reader learning that Dorothy is asleep the entire time from the start vs. learning this at the end). This difference is attributed to a story's *plot*, which describes how a story enables or constrains what a reader knows at different points of the story. Thus, a *plot*[1] can be described by examining the opportunities a story offers as it unfolds for a reader to recognize they don't know something that they want to know (i.e., ask or adopt a question) and to make progress in learning what they do not yet know (i.e., deducing part of a question). For example, plots that contain questions that span multiple parts of a story (e.g., How will Dorothy get home?) can enable a reader to make connections and anticipate what is to come (Nodelman & Reimer, 2003). As the number of questions a reader engages with increases (e.g., Who is the wizard?), the plot "thickens," creating a potentially interconnected web of questions with which the reader is parsing information and seeking answers. At the same time, in order to maintain a reader's interest, a story needs to regularly enable a reader to make progress on enduring questions and answer some questions relatively quickly. When a story only offers questions that are not answered nor even partially addressed for large portions of a story, a reader may not sense progress and may even forget some of the questions that remain unanswered (Nodelman & Reimer, 2003). Finally, in a plot with many open questions, learning new information may impact what is known by a reader about multiple questions at the same time. For example, when a reader learns that the wizard is not magical, this also reveals that the Tin Man always had a heart and that there may not be a way for Dorothy to return home. Therefore, within a learning context, a *SMJ plot* is a description of the dynamically changing tension between what is known and unknown for a student experiencing a *SMJ story*.

[1] Although the word "plot" has specialized mathematical meaning regarding the graphical representation of data, in this study, we use the term in a literary sense.

Story Arcs within a Lesson Plot

Central to a lesson plot is how questions emerge and are addressed for a student. Similar to the plots of literary stories, lesson plots contain multiple questions that can be answered immediately or remain open for longer portions of the story. How each question opens and is addressed constitutes a *story arc*. Multiple story arcs can be open simultaneously. Within written curriculum materials, story arcs, indicated via questions and other curricular elements (e.g., teacher notes or expected responses), arise that may involve different kinds of thinking. Due to our focus on the integration of mathematical and social content, we are particularly interested in distinguishing whether story arcs involve students engaging with mathematical thinking, thinking about social phenomena, or both.

For the purposes of this study, *mathematical story arcs* are those that expect students to engage in mathematizing, which involves abstraction and pattern-seeking (Ernest, 2018; Gutiérrez, 2017; Su & Jackson, 2020), and using objects (e.g., numbers), or practices (e.g., proving) that have been developed over time through mathematizing. When engaging in mathematizing, those objects and practices are interpreted in terms of their meaning and relationships within mathematical systems. For example, a story arc based on a question about the distance between two buildings would include mathematizing the buildings' locations, as one calculates the distance between their coordinates, but does not require the consideration of the impact on humans who travel between the buildings. Common practices of mathematizing include counting, calculating, and measuring (Gutiérrez 2017, Ernest, 2018).

Likewise, we consider *social story arcs* to be those that require interpreting an object or practice within its social context. For example, a social story arc based on a question about the use of a building would include the consideration of how humans would use the building and what value it might hold for various people, but would not require mathematizing the building's coordinates on a map, even if they are noted superficially for communication purposes. Social values may be material, emotional, political, or spiritual (Gutiérrez 2017, Ernest, 2018).

Hybrid story arcs involve both mathematizing and interpreting a social context. For example, a story arc based on a question about how two proposed locations of a grocery store would impact local residents would be hybrid because answering the question requires both calculating distances between the proposed locations and other buildings (i.e., mathematizing), and comparing the impact of differing distances on potential shoppers (i.e., social thinking). These foci (mathematical or social) may occur simultaneously or in tandem. Although many conceptualizations of mathematical thinking define it as being detached from the material or human world (Ernest, 2018), we hold that it is possible to mathematize while recognizing social connections. Allowing for multiple types of knowing may lead to tensions (Gutiérrez, 2017) or explorations about what each can illuminate about the other.

Methods

To learn more about the nature of the content of SJMLs, we analyzed five lessons as stories. In this section, we briefly explain our processes of lesson selection and analysis.

Lesson selection

To analyze SJMLs that secondary teachers might use with their students,we identified lessons that teachers would have access to, including those that are published online and those published in print. We identified three main sources of SJMLs for high school mathematics topics that contained substantive teacher guidance (see Table 1). To create a set of lessons that would contain variety while being of manageable size for comparison, we selected one or two lessons from each source, aiming to have variety in mathematical topics and social justice foci.

Table 1: Lessons Analyzed

Curricular Source	Lesson	Social Justice Focus	Mathematical Topic
Reflecting the World: A guide to Incorporating Equity in Mathematics Teacher Education ("Reflecting", Felton-Koestler et al., 2017)	*Incarceration Rates*	Increasing incarceration rates in the USA	Modeling and making predictions from data
	Water Bottles for Detroit ("*Water Bottles*")	Access to clean water in Detroit, MI	3D nets, surface area, and volume
High School Mathematics Lessons to Explore, Understand, and Respond to Social Justice ("Responding"; Berry III et al., 2020)	*What's a Fair Living Wage?* ("*Fair Living Wage*")	Living wage	Systems of linear equations
	Bringing Healthy Food Choices to the Desert ("Food Desert")	Access to nutrition	Centers of triangles
Citizen Math ("Citizen", Citizen Math, accessed August 2021)	*Wage War*	Minimum wage	Systems of linear equations

For our analysis, we considered all available student and teacher resources, as well as any online materials referred to in the lessons, such as videos or infographics. In instances in which online materials had been updated since publication, we included the updated online materials.

SJM Plot Analysis

To examine patterns in how SJMLs unfold, we categorized story arcs that arose in the lessons according to our framework of mathematical and social expectations. We used teacher notes, lesson overviews, and student-facing curricular materials to determine how the lesson design expected content to unfold. For example, if the materials described students creating and presenting posters of information, we included this as part of the unfolding information that would enter that SJML story at that point of the lesson. This analysis was performed by researchers in pairs, who gathered periodically to find consensus.

First, to analyze the plot of a SJML, researchers identified the *acts* of the SJM story. The beginning of an act occurs when the focus of the SJM story changes. For example, if a lesson shifts from having students compare wages across the country to having students explain how wages are determined, then researchers would mark a new act.

Next, we identified all questions, both implicit and explicit, that potentially arise throughout each SJML. We included questions that were asked explicitly in the lesson materials, or were suggested implicitly (i.e., researchers anticipated that students would potentially consider the implicit questions in order to accomplish the goals of the SJML). For each question, researchers identified the story arcs by marking, for each question, the act in which it is initially proposed or formulated, how information advances what is known about the question in subsequent acts, and how the answers to questions were disclosed. We also noted whether there are potential moments that could prevent students from making straightforward progress toward an answer to a question. To do so, we borrowed three codes from the *mathematical story framework* (authors, year): *equivocation* (an instance in which students are allowed to make an incorrect assumption), *snare* (an instance in which there is explicit misinformation about a question), and *jamming* (an instance at which point something prevents students from making progress on a question).

We categorized the story arcs of each lesson based on whether they expected students to engage in thinking about mathematics, social contexts, or both. For example, the question "How would we describe the US imprisonment changes on the graph from 1925 to 1970 (stable / increasing / decreasing / fluctuating)?" (*Incarceration Rates*) would be classified as mathematical because it involves mathematizing and can be answered without considering the social context; the text indicates that it expects students only to identify that the graph is increasing. In contrast, the question "What are the benefits and limitations of Design 1 as a water bottle?" (*Water Bottles*) would be categorized as hybrid because students are expected to figure out that a given geometric design packs well for shipping to Detroit, but it is not the most efficient in holding water based on volume and surface area calculations. Finally, "What is minimum wage for tipped employees?" (*Fair Living Wage*) is an example of a social question as it expects students to consider people or aspects of the social world, but not to mathematize.

To compare focus on mathematics and social contexts across the lessons, we also evaluated how much each act of a lesson emphasized mathematics or social topics on a scale from 0-100%: 0% meaning a total emphasis on mathematics, 50% a perfect balance of mathematics and social topics, and 100% a total emphasis on social topics. To calculate these percentages, we assigned values for each question open in an act (0% for each mathematical question, 50% for each hybrid question, and 100% for each social question), found the sum, and divided by how many questions were open.

Findings

Within these lessons, students are expected to engage in both mathematical and social thinking, but the focus shifts between the two across a given lesson. Most of the lessons begin with a focus on social contexts, shift to mathematical phenomena, and then expect students to revisit the social context, perhaps answering questions raised earlier. Sometimes the transition is motivated because questions in one paradigm require inquiry in the other. To explain how these SJMLs integrate mathematical and social justice content, we first share our findings about the type and length of story arcs that compose each SJML. Next, we describe the variation in how the emphasis on different topics changes over the course of the lessons. Finally, we discuss how special narrative characteristics identified in three of the lessons could impact shifts in focus between social and mathematical ideas.

Story Arcs

We identified three distinct patterns in how the story arcs focused student inquiry. To illustrate these patterns, each row of the SJM plot diagrams in Figure 1 shows how a question is raised and addressed throughout a story (i.e., a story arc). The shaded portion of the row indicates in which act (represented by the columns) the corresponding story arc is raised and the extent of the lesson during which the question remains unanswered. The story arcs are colored based on their category (social, hybrid, or mathematical), and the letters in each cell represent a shift in what is known about the question during that act. In *Incarceration Rates* and *Water Bottles*, over two-thirds of the story arcs are mathematical. *Fair Living Wage* has a large concentration of hybrid story arcs, with mathematical and social story arcs interspersed periodically. Finally, in *Food Desert* and *Wage War*, the majority of story arcs are social or hybrid, while mathematical story arcs make up less than half of each lessons' arcs.

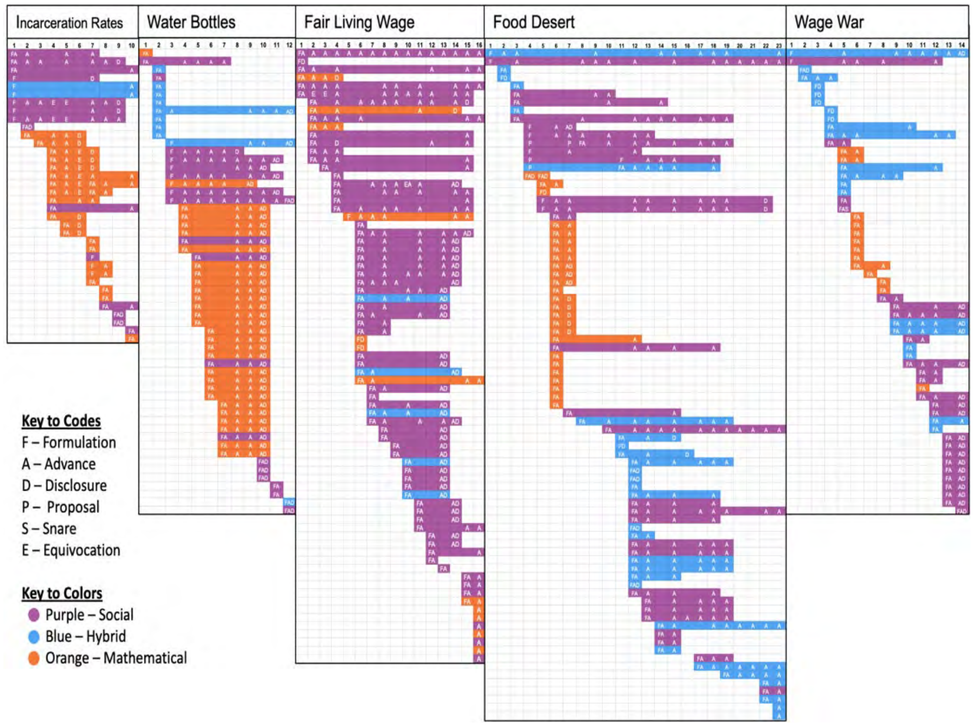

Figure 1: SJM Plots for the SJM lessons. Large version at [blinded].

In all of the lessons, students were invited to consider social phenomena for longer periods of time. All lessons contain overarching social or hybrid story arcs that stayed unanswered across the entire lesson, or all but one act. However, none of the lessons contain mathematical story arcs that spanned such a large portion of the lesson. Although some of the lessons do contain a large proportion of mathematical story arcs (i.e., *Incarceration Rates* and *Water Bottles*), the mathematical story arcs are often short and grouped together within only a few acts. On average, hybrid and social story arcs are longer and mathematical arcs are shorter (see Table 2). In two lessons, *Food Desert* and *Wage War*, mathematical story arcs are particularly short.

Table 2: Average Arc Lengths by Lesson and Type of Question

Lesson	Social	Hybrid	Mathematics	Overall
Incarceration Rates	10.0	5.7	3.1	4.2
Water Bottles	2.9	4.8	5.3	2.8
Fair Living Wage	4.2	7.0	6.4	6.4
Food Desert	4.8	9.5	1.8	4.6
Wage War	3.1	3.4	1.3	1.6

Story Acts

There are also distinct patterns of attention to mathematics vs social contexts that became evident as we compared the lessons (see Table 3). In all of the lessons, there is an early emphasis on social contexts. The emphasis on mathematics increases in the middle of the lessons, and then decreases as questions start to be resolved via the text. However, the degree of emphasis on mathematics and/or social context differs. Some lessons have a greater focus on mathematics (*Incarceration Rates* and *Water Bottles*), while others have a greater emphasis on social and hybrid phenomena throughout (*Fair Living Wage* and *Food Desert*). Another characteristic that distinguishes the lessons is that some shift abruptly between the two foci (note extreme values such as 0% and 100% in *Wage War*), while others are more balanced throughout (as can be seen by many acts with between 40-60% emphasis on social contexts).

Table 3: Focus Maps of the SJMLs (intensity of shading represents the relative degree of focus on mathematizing, where blue represents a focus on social contexts)

Lesson/Acts									0	1	2	3	4	5	6	7	8	9	0	1	2	3
Incarceration Rates	1%	2%	8%	2%	4%	%	7%	0%	0%	4%												
Water Bottles	5%	4%	6%	7%	2%	2%	5%	3%	7%	0%	7%	0%										
Fair Living Wage	8%	2%	1%	9%	5%	4%	0%	8%	0%	5%	2%	0%	3%	2%	7%	7%						
Food Desert	5%	00%	1%	8%	0%	0%	9%	0%	7%	7%	0%	1%	9%	0%	8%	5%	7%	7%	9%	0%	0%	3%	3%
Wage War	0%	00%	00%	2%	3%	1%	%	3%	1%	8%	5%	9%	5%	8%									

Special codes: Equivocations and Snares

Three lessons included equivocations and snares, which have the potential to motivate or curtail the pursuit of understanding of social issues within the lessons.

In *Incarceration Rates*, equivocations within six related mathematical story arcs enable a surprise with the potential to shift the focus of the lesson from mathematics to social contexts. Students are prompted to predict how prison populations will grow, using data from 1925 to 1970 (see Figure 2a). The data is fairly linear, which encourages students to assume that a linear equation would lead to an accurate prediction. Later, students are given additional data, up to 2006, which does not follow the linear trend (see Figure 2b). Instead, it increases at a much faster rate. Students' realization that the new values are much higher than their earlier predictions could provoke students to ask and pursue answers to questions about incarceration in the US that had not yet been raised in this lesson, such as "What caused US imprisonment rates to greatly increase in the 1970s?" The initial withholding of data may cause students to feel more impacted by the drastic difference in imprisonment rate, increasing their felt need to address it.

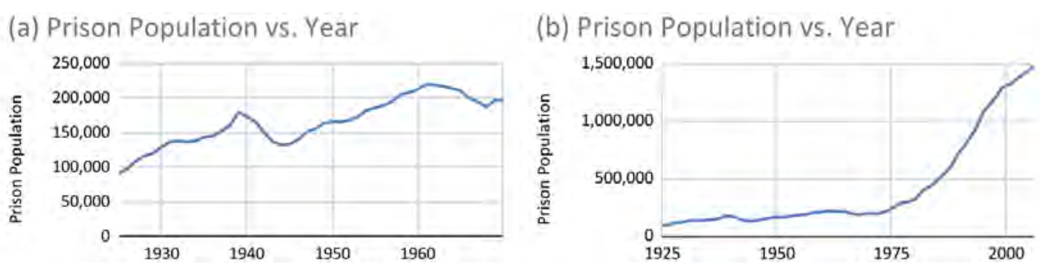

Figure 2: Incarceration rates for (a) years 1925-1970 and (b) years 1925-2006.

In *Fair Living Wage*, an equivocation in a social story arc gives students a reason to pursue mathematical questions. The text asks students to figure out what a suitable standard of living is. A video and infographic present a living wage for each of the 50 states, suggesting that the living wage is the same for every person in a state. However, students later learn that there are many factors that can impact the living wage of every individual (e.g., number of children). This complexity is revealed gradually, through hybrid story arcs. The initial equivocation that a living wage is a straightforward concept makes this complexity unexpected, which in turn can make the inquiry into related social issues (e.g., the racial pay gap in the US) more compelling.

In *Wage War*, a snare within a hybrid story arc demonstrates how mathematics can obscure a social context. The lesson models the relationship between supply (individuals who want a job) and demand (number of employees companies want to hire) of labor for a company with a system of linear equations. Students are prompted to calculate the intersection of the two equations, representing a supposedly ideal wage and number of workers. The lesson asks how changing the minimum wage could impact the labor market, suggesting that the company will hire fewer workers if it pays higher wages. No other factors are introduced for consideration. The simplistic linear function used to model a complex social phenomenon is a misrepresentation, constituting a snare. The snare does not engender further inquiry into the mathematical or social concerns of the lesson. That is, students are not expected to probe any related social or mathematical phenomena in order to identify the misrepresentation. Students who independently identify the model as overly simplistic may come away from the lesson with the impression that mathematics is not useful for interrogating a complex world.

Discussion

Since all lessons analyzed in this study were framed by extended social or hybrid story arcs, mathematical story arcs act as support for investigating social contexts in SJMLs, rather than being meaningfully integrated with social inquiry. Thus, mathematics is largely positioned as a tool worth using to solve social problems. This means that these lessons do not readily offer students the opportunity to engage in extended mathematical thinking, or develop complex mathematical ideas of their own through the exploration of social phenomena. While it is possible that the lessons may introduce new mathematical ideas when enacted in some classrooms, we found no evidence of that intent, and teacher-facing materials offered no support for doing so. We are concerned that the lack of extended mathematical inquiry in these lessons may perpetuate the belief that mathematics is for others to develop, and for students only to use. We wonder: Could SJMLs be designed to have extended mathematical questions, in addition to social ones, so that students can view mathematical inquiry as connecting to the world?

We also note that the design of lessons does not necessarily indicate how it will be enacted in a classroom, which has implications for teachers using these lessons. For example, we identified a trend of using narrative devices, such as withholding information, in order to enable a plot twist later in the lesson, such as that seen in *Incarceration Rates*. This design approach may serve to make these lessons more interesting and engaging for students. However, it also introduces the potential for lessons to fall flat during enactment. What if a lesson's success hinges on students being surprised by something that they already know? This points to the importance of teachers having knowledge of their students that goes beyond their mathematical abilities and classroom behaviors, to include students' prior experience with social justice topics.

Finally, we categorized story arcs based on whether they would include social interpretation, but we did not analyze how the arcs would engage students in thinking about social *justice*. Social justice involves critiquing the status quo or taking action to change the world, which is not necessarily happening just because students are considering questions about social contexts. Future work is needed to analyze how these lessons enable students to engage in the work of social justice and challenge the way things are.

This study presents the use of the Social Identity Wheel (SIW, Social Identity Wheel, 2021), to build community in a newly formed mathematics education research team. The SIW, originally built for use in classrooms, was used to allow each team member to share about themselves which led to the team learning about each other. The research focus of the team is to connect social and political issues to mathematics in elementary classrooms. Reflecting on identity and discussing social and political issues are essential components of this work. Hence, building community is part of fostering safe, productive environments in which to build these tasks. To better understand what building a community might look like, the project team used the Social Identity Wheel to build community within the team and get to know one another.

Keywords: Equity, Inclusion, and Diversity; Social Justice; Professional Development; Research Methods

Research suggests that understanding teacher identities in mathematics professional development (PD) can make PD more impactful. Teacher identities impact how they participate in PD, as well as what knowledge they both take up from the PD and how they implement PD ideas in their classrooms (Battey & Franke, 2008). Wager and Foote (2013) urge that mathematics and equity PD facilitators take teachers' lived experiences into account and view teachers as a resource. Moreover, implementing mathematical tasks that connect to social and political issues requires significant teacher reflection on their students' identities, their own identities, how these identities interact with the task context, and how these identities might interact with each other (Koestler et al., in press). Given this extant scholarship, it is important that professional development communities spend time reflecting on identities.

As part of a larger grant project, our team collaborates with a group of expert teachers in an ongoing PD setting to build mathematical tasks that connect to social and political issues. This work necessarily requires reflecting on identities and discussing social and political issues. To create a safe space for these potentially difficult conversations and to be able to better collaborate with each other and with the collaborating teachers, the project team considered ways that we could build community among ourselves. Particularly, our team wanted to create opportunities for each of us to share about our identities in an effort to get to know each other better. Thus, we decided to use the *Social Identity Wheel* as one way to do so.

The Social Identity Wheel (SIW, *Social Identity Wheel*, 2021), which was developed at the University of Michigan, is one tool that can be used to support sharing about identities. Jacobsen and Mustafa (2019) suggested a similar tool, a Social Identity Map, intended to support researchers in beginning to "think deeply about how their assumptions translate into discussions with participants, influence their understanding of participants' experiences and lives, and how this impacts the way they code, analyze, and interpret findings," (p. 11). The project team wanted to collectively get to know each other better as a community and explore the model of using the SIW with people who do not yet know each other well. We chose the SIW as a vehicle to present ourselves to each other to work towards forming a community.

Theoretical Background

The study of identity in mathematics education has taken many paths: student identity (e.g., Aguirre et al., 2013), mathematics teacher identity (e.g., Battey & Franke, 2008; Wager & Foote, 2013), and researchers' identities (e.g., Glesne, 2011). Bartell and Johnson (2013) argue that researchers should openly talk about identity and their own privileged research positions to avoid paternalism and consider the role of their privilege in their research. Similarly, Foote and Bartell (2011) propose that "life histories provide a particular opportunity to explore researcher positionality that might be used more widely as a support to understanding the relationship among the researcher, the researched, and the research problem," (p. 65). Given that it is important for researchers to share and reflect upon their own identities and how their identities shape and impact their research, then it is arguably just as important for teams of researchers to share and discuss their identities in the context of the research team.

Identity is dynamic, mutable, and socially constructed (Park, 2015; Vygotsky, 1979). Naturally, theories about identity are manifold and complex. Sfard & Prusak (2005) argue that identity does not exist as a tangible object; rather, it is discursive in nature. This means that identities are collectively created and exist in the narratives that are told about individuals and that individuals tell about themselves. These narratives become part of an individual's identity when they are "reifying, endorsable and significant" (Sfard & Prusak, 2005, p. 16). Tangible tools like Social Identity Maps or Social Identity Wheels become a means of eliciting and supporting a person's narration of their identities (Jacobson & Mustafa, 2019). Further, Social Identity Wheels could allow individuals on a research team to narrate their various identities and identify the resources that they draw upon when constructing their narrative. In turn, this storying can become a part of the ongoing discursive construction of identity, particularly within the context of the research team. We treated these narrative identities supported by the SIW tool as a vehicle by which we might get to know one another. In this paper, we examine the research question: *How, if at all, does the SIW tool support the project team in getting to know one another?*

Methods

Social Identity Wheel Presentations

The SIW (*Social Identity Wheel*, 2021) is an oval wheel, with 11 social identity categories listed around the outside: age, religious or spiritual affiliation, race, ethnicity, socio-economic status, gender, sex, sexual orientation, national origin, first language, physical/emtional/developmental (dis)ability. There are five prompts in the center of the oval to help users reflect on their identity, including "identities you think about most often" and “identities that have the greatest effect on how others perceive you.” Each team member created a representation of their own responses to each of the categories on the SIW, placed these in a shared online folder, and narrated their SIW to the group at later team meetings. Questions, comments, and connections from other group members were encouraged after the narrator was done. Time for sharing and asking questions was intentionally not limited and included up to two SIW per meeting. In this paper we treat the initial presentation and the discussion that followed as one unit, and we call this unit the presentation. The mean and median average presentation times were 30 minutes with a range of 17 minutes to 45 minutes. Team members consisted of 4 project PIs, 5 graduate students, and 1 project manager who is also a graduate student. The PIs are Andrew, Bailey, Sandy, and Anna; the graduate students are Augusto, Jeff, Judy, Ellison, and Silvia; and the project manager is Sharon (all names are pseudonyms). Data collected for this study included recordings and transcripts of the presentations of each team member’s SIW. Transcripts were broken into paragraphs by the constructs that they addressed (i.e., race, gender, etc.). Research team members then coded each presentation with the category of the SIW tool that was the focus of the paragraph. Multiple categories were coded if they were part of the same paragraph. Coding was done in MaxQDA. Visuals of each presentation were created based on the coding through MaxQDA.

Survey

After all SIW were presented, we surveyed all team members via Qualtrics to learn how presenting and listening to others presenting their SIW impacted the community formation. Questions included open and closed formats. Sample questions from the survey include:

- How, if at all, has this activity impacted your interactions with the group overall and/or specific group members?
- Were there things that you shared that you wouldn't have shared outside the group? If so, what were they, and why did you choose to share in this context?
- What, if any, were the benefits of having done this activity with our group?

Survey responses were coded using thematic analysis (Braun & Clarke, 2006) by a research team member to identify themes that appeared across multiple responses to each question and across multiple questions. For example, in response to Question B, participants wrote things like, “I am trying to become more open about who I am,” “I felt like I needed to share [about my anxiety] to be honest,” or “I felt like if I was going to convey an accurate representation of my identity… that [my mental health] was a very important piece that could not be left out.” Initial codes for these responses related to representing oneself honestly and authentically. Participants also wrote things like, “[The other group members] shared some vulnerable details, so it felt like it would be unfair NOT to also be vulnerable” in response to Question B, or “As a faculty member on the grant I did feel some responsibility to be a bit more open and illustrative of the kinds of things that could be shared and included,” in response to Question C. Initial codes for these responses related to desire for reciprocity in authentic sharing. Participants also referenced authenticity directly; one participant wrote, “After I shared, I felt like I was more able to authentically show up to the group in future meetings” in response to Question D. Together, responses like these and their initial codes constituted the theme of “authenticity and reciprocity,” which emerged across multiple responses to the same question and across responses to different questions. This example is illustrative of the way in which themes were developed. The final themes are shared in the results section.

Results

Social Identity Wheel Presentations

Though all team members used the SIW to begin their reflection and sharing, the topics discussed during presentations varied. Figure 1 shows the visualizations of the topics discussed for each team member; this provides an overview of some of the major topics that team members talked about. Duration varied across SIW presentations, but their visualizations were resized so that all visualizations are approximately the same size despite any time differences.

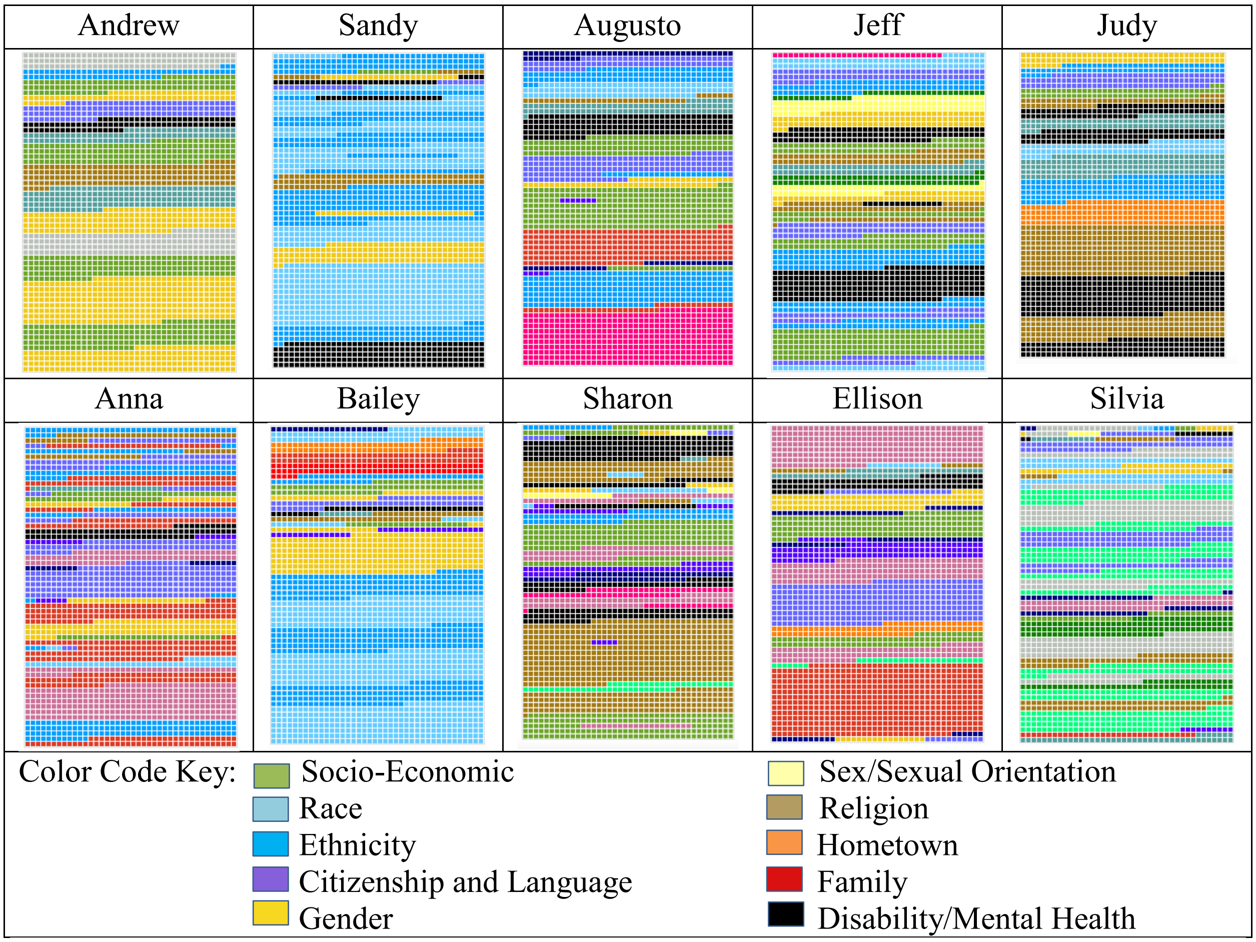

Figure 1: Visualization of topics discussed during team members' presentation of the SIW. *Note* The color code key includes only those codes that come directly from the SIW categories, or that came up across multiple presentations.

Of note is that for half of the research team the themes of disability/mental health (Sandy, Jeff, Judy, Anna, Sharon), ethnicity (Sandy, Augusto, Jeff, Anna, Bailey), and/or socio-economic status (Andrew, Augusto, Jeff, Ellison, Sharon) showed up in the presentations during the discussion portion. Sex and/or gender (Andrew, Sandy, Anna, Jeff, Bailey) was also discussed by 5 team members during the discussion portion of the presentation. Religion was discussed by 4 team members (Sandy, Jeff, Judy, Sharon) during the discussion portion of the presentation. These topics typically do not get discussed in large research group settings but are learned about in more intimate conversations. For most of the participants the presentation and discussion focused mainly on 2 to 4 constructs.

Survey Responses

The theme that appeared most in the survey responses was "Community Building," with 66 occurrences across the 10 participants and 8 open questions. Four of the codes within this theme appeared at least 8 times and across at least 7 team members, with "increased interpersonal knowledge" (IIK) mentioned by all 10 participants, "bonding, community/relationship building" (BCRB) and "authenticity and reciprocity" (AR) mentioned by 8 of the 10 participants, and "teamwork" (TW) mentioned by 7 of the 10 participants. See Table 1 for the code counts.

Table 1: Code Counts for Community Building Theme

Team Member	Code Occurrences				Total
	IIK	BCRP	AR	TW	
Andrew (PI)	1	2	1	1	5
Sandy (PI)	1	1	2	1	5
Augusto	2	0	0	0	2
Jeff	2	0	0	1	3
Judy	1	2	3	1	8
Anna (PI)	1	1	1	0	3
Bailey (PI)	3	3	1	2	9
Sharon	2	3	2	1	8
Ellison	1	3	2	2	8
Silvia	1	2	1	0	4
Number of Team Members with at Least One Occurrence	10	8	8	7	
Total Occurrences Across All Team Members	**15**	**17**	**13**	**9**	

Note **Codes are: increased interpersonal knowledge (IIK), bonding, community/relationship building (BCRB), authenticity and reciprocity (AR), and teamwork (TW).**

Increased Interpersonal Knowledge (IIK) Knowing more about someone does not necessarily mean that a bond or relationship is formed between individuals, so the code IIK is distinct from the BCRB code. However, some occurrences of IIK overlap with BCRB. For instance, Andrew said "I've enjoyed learning about others and I feel that it increases our intimacy and connection." The portion "I've enjoyed learning about others" on its own does not imply building an emotional bond but does emphasize learning about others, and so the response was coded with IIK. Because Andrew continued with "I feel that it increases our intimacy and connection," which indicates building relationship bonds, this response was then also coded with BCRB. Knowing about others and bonding with others *may* overlap, but they do not inherently overlap. Augusto and Jeff were the two group members who did not have any responses directly mentioning bonding with other group members, though they each had two instances of mentioning that they learned about others. Augusto shared that "I think for our group with such diversity, it was important to dive much deeper into our lives and backgrounds, and not just our names and professional credentials or programs and faces." Sharon felt that the activity supported "a deeper contextual understanding of a person's lived experiences." This knowledge of other team members was one benefit of using the SIW that Bailey identified: "I think one benefit is understanding people's backgrounds and identities, and knowing how they position themselves so that I don't have to assume."

Bonding, Community/Relationship Building (BCRB) Responses received the code BCRB when they referred to forming or building relationships, either with other team members or with the group as a whole. Several team members observed that the remote meetings made it hard to bond, and that the activity helped address this problem. Anna expresses it here: "I think it was a great bonding activity learning more about everyone. I feel like it sped up the process of having chats especially since we are on Zoom and I am not sure when and how we would get a chance to get to know one another better." Silvia joined the group for the first time to share her identity wheel, and felt "practically instantly at home with the group; I felt that all the ice had been broken after sharing, and that I was part of the group and less of an outsider." The activity allowed Silvia to quickly feel bonded to the group. It also created an opportunity for conversations that might not have happened otherwise. Sharon noted that she has "had a few one on one conversations with individuals that most likely would not have occurred had the identity wheel activity not taken place." Sandy echoed the connections others found, sharing that she "found resonance with people that I wasn't expecting to find, which was nice." This resonance and connection helped build community within the group. Judy shared that as a result of the activity, she felt "more empathy for the group members after hearing their own backgrounds and vulnerabilities and struggles." Ellison said that one of the benefits of the activity is the team's "ability to connect with and support others in the group making the group more cohesive." The BCRB code was present in all but two of the group members' responses, as seen in Table 1. However, those two team members' responses both showed instances of the code IIK.

Authenticity and Reciprocity (AR) A total of 13 responses were coded with AR, including the excerpts previously shared to describe how the theme was developed. Each response met at least one of these criteria: explicitly mentioned authenticity, indicated wanting to be open and authentic about themselves to the group, indicated sharing details to model authenticity or vulnerability *to* others, or sharing details because authentic sharing was modeled *by* others. Sandy explicitly mentioned authenticity in two of her responses, including this excerpt: "I also think it gave me some ideas of how people see/position themselves so I can integrate that into how I see them can work to have more authentic interactions with them." Sharon also explicitly mentioned authenticity, saying “I feel as though the senior leadership impart equitable practices, which were demonstrated by every person’s authentic participation.” Sharon shared that, though it was challenging, she gave herself “permission to speak and fully participate without regret.” Judy echoed this desire to represent herself authentically to the group with this response: “I wanted to share enough to feel like I was being honest and not hiding anything important.” For Bailey, their connection to other group members impacted their understanding of authentic sharing. Bailey wondered “what some people would think when I got to certain descriptions, especially those who know me well. Like, would [they] wonder why I was holding back?” Several people were encouraged by other SIW presentations to share more details about themselves, as seen in Ellison’s response: “I did return to my wheel after seeing others’ work and felt more comfortable adding to it at that point.” In response to a different question, Ellison also noted that “Because everyone was participating there is some comfort in the reciprocity.” The AR responses signal that team members were influenced by a desire to be honest and authentic, either for themselves or as a responsibility to foster reciprocal sharing with the group.

Teamwork (TW) Seven team members specifically referenced how the activity might impact the research work the team will do for the grant, as seen in the 9 instances of TW. Three of the PIs talked about the grant work generally. Andrew referenced specific goals of the grant, noting that the team’s experience with the SIW “will be helpful in thinking through our project work as we consider how to create lessons and ask teachers and ourselves to reflect on our identities relative to the topics in the lessons.” Sandy referenced the grant work more generally, sharing that we “now have a fuller understanding of each other and how who we are might shape how we approach the work of the grant.” Bailey referenced teamwork in response to two questions. One was more general: “I thought it was a good activity to do as a project team.” In another response, Bailey shared, “I only added in the pronouns in at the end because I thought that it was important to share since we would be working together for the next 3 years.” Three of the graduate students referenced teamwork interactions in their TW responses. Jeff shared that the SIW activity helped him “have a better sense of what should I be careful or attend to when I interact with other group members in general.” Ellison explicitly mentioned her graduate student role in the group related to teamwork: “I also feel more comfortable sharing my ideas, needs, and concerns since I feel like I have an identity beyond ‘graduate student’ in the group.” On a similar note, Judy shared “I feel emotionally safer in the group, so I feel like I can participate more and make mistakes and accept critiques easier.” Her response goes on to mention how the SIW activity might support navigating difficult conversations: “Before the activity, I felt like there were some ‘hot’ moments where maybe people misunderstood someone or felt challenged. It seems like we will be able to deal with those more directly as a group now.” Responses coded with TW talked about teamwork in reference to specific grant goals, working together as a team, and group interactions.

Conclusion

The activity with the SIWs supported the project team in getting to know one another and fostered bonding and building community. Every team member’s response was coded with at least two of the Community Building codes. Though not explicitly elicited with the survey questions, there were 9 instances in responses that referenced working together as a project team, as seen in the instances of teamwork. Every team member’s response showed at least two instances of either bonding, community/relationship building or increased interpersonal knowledge, which suggests the activity *did* support the team in getting to know each other at a deeper level.

The identity wheel allowed for the feel of more intimate discussions in the larger research group (over Zoom), as evidenced by discussions of disability/mental health, ethnicity, gender, and religion during the discussion portion of many presentations. Some team members described the activity as speeding up the getting to know you process. Anna shared "I feel like it sped up the process of having chats especially since we are on Zoom and I am not sure when and how we would get a chance to get to know one another better." This suggests that the SIW tool might accelerate community building in groups, particularly those that meet remotely and have fewer opportunities for casual, spontaneous conversations. It is also important to note that no one activity is sufficient for building community. Activities like this one can begin to facilitate community building, but community building requires sustained effort.

While this was implemented remotely, this tool was originally designed for in-person use. Research teams wanting to get to know one another and build community could possibly see similar results, but we do not claim that our experience is generalizable to other groups and settings. Rather, our goal is to contribute to ongoing work regarding researcher identity and positionality and how it can be explicitly shared. It is important to note that there may have been some status issues at play in our group. In fact, 4 of the responses mentioned power issues as a potential drawback or pressure that participants might experience, regardless of whether or not the respondent felt that pressure themselves. For example, all the graduate students have one of the PIs as their advisor. These power dynamics could have influenced the types of SIW sharing individuals engaged in, as well as the questions or comments they felt comfortable sharing. Group norms and feelings of safety will not be the same in every group. While our team emphasized several times that members need only share what they are comfortable sharing, some may have still felt pressure to share. Sharing identity stories requires vulnerability on the part of the sharer. Hence, careful emphasis needs to be put on establishing group norms. While many of our team describe that this experience *might* influence teamwork over the course of the project, we wonder what future studies might learn about how building community in research teams does or does not impact the work they do together.

EXPLORING WOMEN OF COLOR'S VARIED EXPRESSIONS OF MATH IDENTITY

Ciera Street
Colorado State University
ciera.street@colostate.edu

Jessica Ellis Hagman
Colorado State University
jess.ellis@colostate.edu

One area in the growing call to create more equitable and just mathematics classrooms is supporting and strengthening students' mathematical identities. Limited scholarship in this area considers an intersectional lens when exploring undergraduate mathematical identity (Leyva, 2021; McGee 2016). Informed by Data Feminism, this research uses a transformative, mixed methods approach to consider how women of color in introductory undergraduate mathematics group based on attributes of mathematical identity. We first analyzed quantitative data using cluster analysis followed by the discussion of qualitative data through free response survey questions and future follow-up interviews to better conceptualize the experiences of each cluster. Key ideas emerging from this work include the role of peers and friendship, instructor care, class structure, and mathematical affect in women of color's mathematical identities.

Keywords: Equity, Inclusion, and Diversity, Gender, Undergraduate Education, Calculus

A growing call from research and professional organizations within mathematics education aims to create more equitable and just mathematics classrooms for students with various identities (Mathematical Association of Mathematics Instructional Practices Guide, 2018; National Council of Teachers of Mathematics, 2014). This includes supporting and strengthening students' mathematical identities. Mathematical identity encapsulates students' relationship with mathematics and their perceptions of themselves as a doer of mathematics, including their beliefs about ability and participation, sense of belonging, and institutional and interpersonal supports (Voigt, 2020). Limited scholarship in this area considers an intersectional lens when exploring undergraduate mathematical identity (Leyva, 2016, 2021; McGee 2016). However, these studies suggest that gendered and racialized mathematical discourses uniquely influence expressions of mathematical identity for women of color. Mathematical discourses continue to communicate who belongs in the space by promoting values associated with dominant masculinities and whiteness, therefore often excluding women and students of color (Leyva, 2017; Adiredja & Andrews-Larson, 2017; Martin, 2006). Thus, this research engages critical frameworks at the intersections of gender and race to challenge those exclusionary norms and encourage counternarratives to white, masculine mathematical discourses. Using a transformative, sequential mixed methods design, we ask: How do women of color in introductory undergraduate mathematics group based on attributes of mathematical identity? With respect to which attributes do the groups differ? With respect to which attributes are the groups similar?

Theoretical Perspective

We utilize a Data Feminist lens to frame and support the design of this work. Coined by D'Ignazio and Klein (2020), Data Feminism encourages "a way of thinking about data, both their uses and their limits, that is informed by direct experience, by a commitment to action, and by intersectional feminist thought" (What Is Data Feminism?, para. 9). The authors argue how data have maintained inequitable power structures through promoting discrimination, policing, and surveillance. However, data similarly present an opportunity to challenge these dominant narratives and acknowledge the culture and community inseparable from the data collection and analysis. One area that exists at the intersection of these realms is higher education, and especially mathematics education due to the continued marginalization of women and students of color by maintaining white, patriarchal norms (Leyva, 2017). We chose to center women of color in this analysis to provide counternarratives to the white, patriarchal mathematical context without comparisons to the dominant group. Instead, we highlight the often submerged and undervalued variety of experiences of women of color related to mathematical identity.

Methods

We use a transformative, sequential mixed methods design in this work (Creswell et al., 2003; Mertens, 2012). We first analyzed quantitative data using cluster analysis (n=3296) followed by the discussion of qualitative data through free response survey questions and future follow-up interviews to better conceptualize the experiences of each cluster.

Quantitative Data Methods

The data for this study originate from the *S-PIPS-M* survey instrument administered by the Progress through Calculus (PtC) project. This survey collected information about undergraduate students' experiences in precalculus and calculus, including mathematical activities, interactions, and affect (Street et al., 2021). We considered the subset of the *S-PIPS-M* dataset that includes only women of color. We first classified women as any participant who selected at least woman from the following select-all response options related to gender: Man, Transgender, Woman, Not listed (please specify). We classified a person of color to include any participant who selected at least one of the following select-all response options related to race and/or ethnicity: Alaskan Native or Native American, Black or African American, Central Asian, Hispanic or Latinx, Middle Eastern or North African, Native Hawaiian or Pacific Islander, Southeast Asian, South Asian. Thus, women of color represent the intersection of these two participant classifications.

To narrow in on mathematical identity, we selected 22 survey questions that aligned with one or more of the components of mathematical identity, including students' perceptions of ability, participation in class, feelings of inclusion, and resources such as tutoring (Voigt, 2020). Previous research using this dataset (Voigt, 2020; Apkarian, 2019) suggests correlation between certain survey questions. Thus, we performed a factor analysis under a promax rotation with four factors as informed by the scree plot. We removed any loadings less than 0.2 and allowed factor items to load onto more than one factor. This resulted in four factors we label Class Experience, Inclusion/Positionality by Instructor, Mathematical Peer Interaction, and Self-Efficacy. These labels emerged from themes across the factor items and connections to the components of mathematical identity. We appended four new scores to each participant based on this factor analysis and then performed a cluster analysis over 4-dimensions, one for each factor. The graph of the total within-group sum of squares by cluster number implied an optimal four clusters.

Qualitative Data Methods

Informed by Data Feminism, we used participants' responses to four free-response survey questions about their classroom and mathematical experiences to help contextualize the clusters. This process involved filtering the responses by cluster and reading through each response looking for concepts related to attributes of mathematical identity such as peers, instructor, pedagogy, tutoring, and emotions. This was not intended as a full thematic analysis, rather as a means of helping illuminate common mathematical experiences within each cluster. The next phase of this work will deepen these results by collecting qualitative data from a sample of survey participants. We will conduct interviews with participants from each cluster and ask them to write a brief math autobiography. The interview protocol will capture questions around their relationship with undergraduate mathematics and their perceptions of themselves as doers of math, including questions related to the four key ideas presented in the discussion section.

Results

The results of the cluster analysis suggest four distinct groups related to women of color's mathematical identity. The table below outlines the mean scores for each factor of mathematical identity derived from the cluster analysis. Class experience, mathematics peer interaction, and inclusion have been normalized on a scale of 0 to 1 and self-efficacy on a scale of -0.5 to 0.5.

Table 1: Cluster Analysis Results

		Cluster				Overall Mean
		Cluster 1 (n=857)	Cluster 2 (n=842)	Cluster 3 (n=549)	Cluster 4 (n=1045)	
Mathematical Identity Factor	Self-Efficacy	0.04	-0.02	-0.14	0.04	-.004
	Mathematics Peer Interaction	0.76	0.15	0.52	0.43	0.46
	Inclusion	0.51	0.47	0.39	0.52	0.48
	Class Experience	0.78	0.35	0.34	0.61	0.54

The overall mean for Class Experience was 0.54. This factor measures students' perceptions of the frequency of class activities literature often relates with active, student-centered teaching. Clusters 1 and 4 have class experience scores above average, suggesting these students perceive their class to more frequently include active learning components. Clusters 2 and 3 have scores below average, suggesting these students perceive less frequency of these activities and more lecture. The overall mean for Inclusion was 0.48. A score of 0.5 in this factor implies students feel equally included by their instructor in class as their peers. Clusters 1, 2, and 4 have inclusion scores at about the mean, suggesting the women of color in these clusters feel equally included by their instructor in class as their peers. Cluster 3's below average inclusion score suggests the women of color in this cluster feel less included by their instructor in class as their peers. The overall mean for Mathematics Peer Interaction was 0.46. This factor measures the frequency of students' mathematical interactions with their peers both inside and outside the classroom. Cluster 1 had an above average mathematics peer interaction score, implying more frequent peer interactions. Clusters 3 and 4 present about average scores in this factor, suggesting a moderate amount of peer interaction. Cluster 2 has a far below average score in this factor, suggesting infrequent peer interaction. The overall mean for Self-Efficacy was -0.004 representing a practically null change in students' perceptions of their mathematical ability, interest, and confidence during the course. Clusters 1, 2, and 4 present self-efficacy scores essentially at the mean, suggesting little to no change in self-efficacy during the course. Cluster 3 has a below average score in this factor, suggesting a negative change in self-efficacy during the course.

Discussion and Key Ideas

To contextualize the quantitative results, this discussion presents key ideas that emerged when looking at students' free-response questions grouped by cluster appointment. The next phase of this research will use interviews and written reflections to investigate these key ideas and their potential role in supporting women of color's mathematical identity.

Key Idea 1: Peers and friendship

Students in Clusters 1, 3, and 4 frequently labeled peers and friends as notably helpful aspects of their course. In line with their class experience scores, Clusters 1 and 4 perceived more opportunities to engage in mathematics with their peers through group work and class discussions. Cluster 3 presented peer interaction almost solely with outside of class experiences such as study groups and tutoring. Notably more so than other clusters, these students used the term "friends" in their free responses. Coupled with the low class experience and inclusion scores in Cluster 3, these friendships may have acted as what Leath et al. (2022) describe as "communicative resistance" (p. 9) toward exclusion and frustration in class. Interviews will further explore the potential distinction between peer interactions and peer friendships related to these women of color's mathematical identity.

Key Idea 2: Instructor care

While the majority of the inclusion scores suggest equal feelings of inclusion from their instructor compared to their peers, how each cluster described this inclusion differed. Students in Cluster 1 described their instructor as patient, understanding, and encouraging. They also used more personally directed statements using "my" or "I", such as their "teacher's interest in *my* learning process." Other clusters usually addressed positive qualities about their instructor through teaching style and approachability or appeared fairly neutral toward their instructor. Students in Cluster 3, with their uniquely below average inclusion score, mainly pointed out negative qualities in teaching style or unapproachability in communication and office hours. Interviews will explore not only how general feelings of inclusion in classroom activities and opportunities to participate relate to women of color's mathematical identity, but also the role of students' observations of their instructor's care for them (Rainey et al, 2019; Bartell, 2011).

Key Idea 3: Class structure and implementation

Although the classroom experience score suggests different pedagogy types, additional data are necessary to describe these classrooms and how these activities and their implementation relate to women of color's mathematical identity. Generally for Clusters 1 and 4, students described consistent group work as a helpful class component, where the instructor provided explanation of a topic and then presented students with a task to complete in groups. Students in Cluster 2 described a mostly lecture-based course with some group work components, although some students mentioned discomfort working with peers in-class given the infrequent implementation of this activity (Yoon, 2011). Students in Cluster 3 appeared frustrated with in-class lectures and would have preferred more opportunities to work with others in class. Interviews will prompt participants for further details about their undergraduate mathematics courses and the classroom structures they found supportive of their mathematical identity.

Key Idea 4: What affects affect?

Surprisingly, only Cluster 3 showed a non-zero average change in affective components. While Clusters 1, 2, and 4 differed across various other factors, participants in these clusters on average maintained their same level of mathematical confidence, interest, and perception of ability. However, Cluster 3 resulted in negative average change in each of these components. Many students in Cluster 3 express how the negative experiences in their course contributed to confusion and frustration, which negatively affected how they viewed mathematics and their ability and confidence in the subject. Various studies show that supporting positive experiences in mathematics can improve students' perceptions of their mathematical ability (Hannula, 2006; Weber, 2008), but we appear to see the opposite effect here. While we see in this analysis either a negative or null change in self-efficacy, follow-up interviews will explore which components of undergraduate mathematics classrooms can promote feelings of confidence, interest, and competency for women of color.

gmhernandez@sdsu.edu

As identity becomes more discussed within education, it becomes crucial to understand identity in relation to power and social justice. In this paper, we discuss the identity frameworks of figured worlds and rightful presence to operationalize the critical consideration of identity within mathematics learning environments. We argue that by themselves, figured worlds and rightful presence have shortcomings that make it difficult to attend to power, and contextualize change, respectively. When considered in tandem, however, these two frameworks complement one another and build a stronger attention to identity that mobilizes student agency in the classroom. We call on educators and researchers to combine and utilize these frameworks to address the dissonance of identity that often occurs for marginalized students, thus building towards a greater harmony of identity and mathematics.

Keywords: Identity, Social Justice

Identity-- the notions and processes by which we recognize ourselves, and others recognize us, as a certain "kind of person" (Gee, 2000)--has become an increasingly discussed topic within education over the past several years. Within education, the development of identity has been articulated as the central purpose of education, where its outcome is, in fact, learning (Bracher, 2006; O'Donnell & Tobbell, 2007). Unfortunately, particularly in mathematics, many students are asked to give up parts of their identity in order to assimilate into the field. Thus, in order to ensure that students, especially those who are marginalized, are not leaving parts of themselves behind in order to study mathematics, it becomes critical to consider identity within mathematics education (Gutierrez, 2012).

As educators, we have the authority to position, or influence the ways that students are perceived, into a variety of identities, both academic and nonacademic (e.g., smart, lazy, collaborative, independent, etc.). The way that students are positioned to participate in mathematics learning environments affects how they learn math as well as how they perceive themselves as learners of mathematics (Turner et al., 2013). With this authority and understanding comes great responsibility. Students ought to be viewed as holistic beings with lives that extend beyond where they learn mathematics; thus, understanding identity is vital if we are to more fully understand and position our students in productive ways that help them succeed both in and outside these learning environments (Wilkes & Ball, 2020). Having a positive mathematical disposition impacts an individual's identity far outside of the walls of education. Positive dispositions towards mathematics–where one's identity is in harmony with the field as opposed to clashing with it– can lead to persistence, agency, and confidence, all of which are useful qualities for navigating everyday life (Bishop, 2012; Brown, 2004).

A focus on identity within mathematics education equips researchers with the analytic lens needed to comprehensively examine ethnicity, gender, culture, and power in mathematics (Brown, 2004; Martin et al., 2010). Identity research also helps us to understand the oppressive narratives, such as positioning students of color as "not being good at mathematics," that exists within mathematics classrooms (Reinholz, 2021). The dissonance that can arise from these dynamics can be leveraged to create harmony within mathematics by reauthoring narratives that allow us to more productively position students and help them succeed within mathematics (Gay, 2018; Gholson & Wilkes, 2017). In this paper, we will discuss two identity frameworks: figured worlds (Holland et al., 1998; Urrieta, 2007) and rightful presence (Calabrese Barton & Tan, 2019; Squire & Darling, 2013). We will discuss some of the main dimensions of these frameworks, and then synthesize the frameworks in tandem to highlight how these ideas, when applied together, can help educators and researchers bring identity as a tool into mathematics learning environments to build towards harmony between identity and mathematics, furthering the possibilities of learning for all students.

Background

While the field of mathematics has long been perceived as an objective field and thus a neutral space in which all students have equal access to succeed (Gutierrez, 2013), a large body of research exists that evidences the reality of mathematics functioning as a field which further marginalizes students (Dubbs, 2016; Gutierrez, 2017, 2019; Leyva et al., 2021; Reinholz, 2021; Solomon & Craft, 2015; Solomon et al., 2021). This body of research highlights dissonance (e.g., stereotype threat, mathematics anxiety, microaggressions, etc.) that exists for many students as they encounter mathematics through an identity-blind paradigm (Jett, 2019; Spencer et al., 2016).

Research shows that attending to the various aspects of students' identities can improve their learning opportunities and experiences (Gay, 2018; Bishop, 2012). In other words, attending to identity can serve as a way to create harmony and to mediate some of the challenges that otherwise exist within mathematics education. We present the identity frameworks of figured worlds and rightful presence to make sense of the vast concept of identity. Figured worlds is a commonly referenced identity framework (Hatt, 2007; Holland et al., 1998; Urrieta, 2007), and rightful presence is a more recent framework that contributes additional considerations to expand our understanding of identity and the possibilities that can be achieved by attending to it.

Figured Worlds

Figured worlds are "socially and culturally constructed realms of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (Holland et al., 1998, p. 52). Common roles in a mathematics classroom might include instructors, students, and teaching assistants. Certain types of actions are typically associated with each of these roles, such as lecturing, working with peers, and answering questions, respectively. Certain values are also promoted within this context, predicated by the norms that are established, such as solving for correct answers or collaboration. These characters, actions, and values inform how individuals can construct their identities in a given context. Thus, figured worlds function as a production of identity in mathematics education and serve as a framework for understanding the context in which certain identities can or cannot emerge (Voigt et al., 2021; Urrieta, 2007).

Figured worlds as a framework often provides a lens through which to identify the dominant narratives surrounding identity within various contexts (Hatt, 2007; Urrieta, 2007). However, values, such as smartness and success, can be associated with differing actions or roles in various figured worlds, creating inconsistent expectations students must negotiate (Hatt, 2007; Zuckerman & Lo, 2021). While there can be dissonance between various figured worlds, the concept of *third spaces* helps to conceptualize how these worlds can be mediated (Calabrese-Barton & Tan, 2019). According to Jackson and Seiler (2018), third spaces are spaces which blend multiple figured worlds. This enables individuals to incorporate resources from various figured worlds in which they participate into a new blended space which is itself a figured world. Participating in these third spaces also allows new resources to be created within them. An example of this might be students forming a study group outside of class. This space creates the opportunity to form different norms (e.g., sharing personal experiences, playful interaction, etc.) compared to those of the class. Students can pull from the figured world of their classroom, as well as personal figured worlds, to mediate a learning environment that better suits their learning needs. The emergence of third spaces allows us the opportunity to consider, and perhaps even disrupt dominant narratives that are shaped by these interpretations of characters, actions, and values.

Rightful Presence

Rightful presence is a social justice oriented identity framework, which implies that it is a framework that elicits action toward change. This framework was first applied to the concept of sanctuary cities serving refugees (Calabrese Barton & Tan, 2019; Squire & Darling, 2013). In these cities, refugees are often viewed as guests and the city as a host. This guest-host dynamic is thought to perpetuate inequity since the city functions as a host which extends rights to its guests-- the refugees. However, this notion of extended rights means that refugees are extended the opportunity to assimilate into the city and culture which they are now living in; it does not empower the refugees to change anything, rather it maintains the status quo, which is often rife with injustices. Rightful presence challenges this notion of extended rights (Calabrese Barton & Tan, 2019; Squire & Darling, 2013). The rightful presence framework seeks for people to reauthor their rights within a space, making all characters fully fledged members of their own accord rather than guests who must assimilate to the dominant notions that currently define the space. There are three tenets to the rightful presence framework: 1) allied political struggle is necessary to reauthor rights, 2) rightful presence is claimed when (in)justices are made visible, and 3) rightful presence is a shared burden between the guests and host.

We now outline what these three tenets might look like in a mathematical learning environment. In a mathematics classroom, reauthoring rights could take the form of challenging what valid participation or meaningful learning looks like. The first tenet of rightful presence highlights that if allies, like teachers, are not engaged in this political struggle, it is difficult for reauthored rights to gain legitimacy in the classroom (Calabrese Barton & Tan, 2019). For instance, if a teacher helps students challenge what are considered valid ways of knowing and doing mathematics (i.e., encouraging partial solutions, valuing and discussing mistakes, etc.), they are engaging in a politically-oriented act of reauthoring rights in mathematics. The second tenet underscores the need to highlight the cultural historical relevance of a context in order to understand its current dynamics, and how these injustices must be both visible and present in teaching and learning in the classroom. Teachers can make injustices visible in their classrooms by highlighting the voices of their students, creating opportunities to find intersections between students' authentic lives and the discipline of math. These greater insights can help instructors find ways to position students with greater agency (Calabrese Barton & Tan, 2019). Lastly, the third tenet states that rights are not reauthored with top down approaches from teachers to students, rather they must be mediated by both groups working together. While allied political struggle from a teacher is necessary, the teacher alone cannot reauthor their students' rights; together, action must be taken by both the students seeking to reauthor their rights and the teachers who have the power to extend rights, thus disrupting the traditional power dynamics in a mathematics classroom (Calabrese Barton & Tan, 2019).

We now discuss our reasons for bringing the two frameworks together, and what we believe can be accomplished through their synthesis

Purpose and Aim

In this paper, we advocate for research that collates the theoretical frameworks of figured worlds and rightful presence. In particular, we see a need for researchers and educators to consider these perspectives within mathematics learning environments. The racist and sexist narratives that women and people of color are forced to navigate in their pursuit of mathematics can inhibit them from viewing themselves as mathematicians (Leyva et al., 2021; Reinholz, 2021). Thus, we see a need to study identity from a critical lens that both recognizes the unjust reality that exists and leverages the discomfort created by this recognition in order to make mathematics classrooms more equitable.

Figured worlds is a commonly used framework in identity-based research (Holland et al. 1998; Hatt, 2007; Urrieta, 2007). While this framework does discuss notions of power and acknowledges the potential for artifacts to be repurposed for liberation (Holland et al., 1998; Urrieta, 2007), we believe that the insights that figured worlds provide cannot be successfully operationalized to disrupt the status quo without a more critical lens. We argue that while the framework of figured worlds allows us to study how classrooms function within the status quo and how students negotiate their identities within them, rightful presence gives us the tools to work toward disrupting the status quo locally. We believe that considering the figured worlds of mathematics learning environments while seeking rightful presence allows researchers to situate their research within the broader sociopolitical issues that affect traditionally marginalized students while providing tools to work toward healing local injustices.

Synthesis

In this section, we discuss the shortcomings of figured worlds and rightful presence and affordances that the two frameworks provide one another. In particular, figured worlds as a framework falls short of explicitly challenging power dynamics while rightful presence can be challenging to contextualize. By considering these shortcomings, we see opportunities for these frameworks to complement and support one another. Specifically, figured worlds help to identify change that can occur via rightful presence, and rightful presence provides a way to navigate the tensions that are merely identified within figured worlds.

Shortcomings

Figured worlds fall short as a framework in the way it models power and its impact within society. The roles and actors in any given figured world are likely to have rank and status associated with them, creating a hierarchy through which power and privilege play out (Holland et al., 1998). Power and privilege are not preexisting in figured worlds, but are constructed relationally and made visible through interactions (Esmonde & Langer-Osuna, 2013; Holland et al., 1998). While the figured worlds framework does account for power, it is often presented in an amoral, objective way, such as by stating who the actors are, what their roles are, and what significance is bestowed upon their acts. While the framework acknowledges that the constraints in a figured world (such as the actors, roles and actions permitted) can paradoxically be repurposed for change and thus disrupt power dynamics, it does not explicitly provide a way to analyze how such repurposing takes place (Holland et al., 1998). While figured worlds has helped many to conceptualize identity, these holes surrounding the concept of power make it challenging to use this framework to model a dynamic that challenges the status quo.

Because rightful presence seeks to disrupt oppressive power dynamics (Calabrese Barton & Tan, 2019; Squire & Darling, 2013), many may find the framework challenging to contextualize in their own learning environments, which could be interpreted as a shortcoming. Knowing *how* to engage in political struggles, to make invisible injustices visible, and sharing burdens of injustice with those who are marginalized is a different task from simply knowing the importance of these tenets. A framework is only as useful as it is applicable, and rightful presence might require some scaffolding for many in order for the action-oriented tenets to be approachable.

Affordances

While figured worlds and rightful presence both have shortcomings of their own, we see these two frameworks working together and complementing one another, allowing new ways for educators and researchers to consider identity within mathematics. We will first discuss how figured worlds questions and makes explicit the context in which rightful presence needs to occur, and then we will discuss how rightful presence navigates tensions created via third spaces within figured worlds. These affordances provide opportunities to create greater harmony amid the dissonance that often surrounds identity in the world of mathematics because these synthesized ideas attend to power dynamics and their potential oppression within figured worlds and provide actionable steps towards rightful presence.

Figured Worlds for Rightful Presence. While rightful presence in and of itself can seem like a major jump from reality for some, figured worlds provides a way to mediate some of these tensions by asking questions about the roles, actions, and values at play within a mathematics learning environment, which can help bring to light the local injustices that exist within them. When considering rightful presence, Yeh et al. (2021) challenges us to ask the questions “what is mathematics?”, “who can do mathematics?”, and “where is mathematics done?” (p.4). We now use these questions to help us consider the roles, actions, and values that might exist within a mathematical figured world, thus enacting the frameworks in tandem.

When we address the question of what mathematics is, we consider the actions that are expected for individuals to be perceived as successful in math. Is mathematics the process of memorizing procedures? Is it a representation of the universe that allows us to abstractly problem solve? These questions, and their subsequent answers for various mathematical figured worlds then give rise to roles that are allowed to exist, answering the questions who can do mathematics and where. What does it mean to be a mathematics student? Does this identity exist only in the classroom or does it extend outside of school? Are students’ funds of knowledge from outside of class valued in class discussion or are they dismissed and seen as irrelevant (Esmonde & Langer-Osuna, 2013; Langer-Osuna, 2015)?

These questions that naturally arise when considering mathematical figured worlds help us to recognize how and where we can start to enact rightful presence. As we critically consider the ways that mathematics is expected to be done in a given context, we can start to see the ways that certain types of students might be positioned as smart and successful or otherwise (Hatt, 2007; Leyva et al., 2021). As we consider these types of roles that we position students to fulfill within the classroom, we can see the values that are being assigned to math. These critical considerations allow us to bring to light some of the injustices that otherwise go unseen within mathematics, bringing to life the second tenet of rightful presence. Our understanding of the figured worlds that exist within mathematics is what allows us to understand what rights need to be reauthored so that students can be positioned for further success within and beyond the classroom.

Rightful Presence for Figured Worlds. Rightful presence and its orientation toward the illumination of political struggles can help educators be more intentional about creating opportunities for third spaces to arise in the classroom. Because each figured world has its own characters, roles, and values, the convergence of figured worlds in these third spaces can create tensions if characters, roles, or values do not align from one figured world to the next (Jackson & Seiler, 2018; Zuckerman & Lo, 2021). Rightful presence helps bring to light the tensions that can emerge in the process of creating these third spaces, and can also appropriate ways to navigate these tensions. By challenging the status quo of given figured worlds, rightful presence carves a pathway of political struggle, making injustices visible, and sharing the burden of reauthoring rights.

When various figured worlds are recognized within a classroom, then rightful presence as a social justice framework can be operationalized simultaneously as a means to productively leverage tensions that might arise with the emergence of third spaces, allowing for new resources to also emerge that students can utilize in the classroom. Rightful presence does this first by highlighting and giving permission for the political struggle that is a part of this process. While change is not a comfortable process, educators and researchers can take comfort in knowing that engaging in political struggles is to be expected on the journey towards liberation, where education fundamentally should act as a tool and process of empowerment and liberation (Calabrese-Barton & Tan, 2019; Gutierrez, 2013). Rightful presence helps to highlight *why* political struggle is necessary by demanding that injustices at play be brought to light. Where educators might recognize tensions within classrooms, rightful presence can bring these issues to the forefront of attention so that the group (both hosts and guests) can collaborate together to navigate and mediate these challenges. This process of open communication and collaboration is in and of itself the beginning of reauthoring rights, allowing the tensions that inevitably exist within learning environments to serve a purpose. When educators open up these spaces to include students in these ways, the burden of change can be shared by all involved, allowing for more resources to be utilized in navigating tensions by way of third spaces. Once these third spaces have been cultivated through enacting rightful presence, students have an ideal environment that affords the benefit and utility of their full identities, rather than just fractions of them, within mathematics.

Discussion

We see important implications that can stem from drawing upon the figured worlds and rightful presence frameworks together. The figured worlds framework allows educators to characterize how the status quo operates within their classroom. A mathematics classroom exists as a figured world but also serves as a third space where additional figured worlds with highly established hierarchies and power structures, such as race and gender, intersect. While students can draw upon more resources when figured worlds come together like this (Calabrese-Barton & Tan, 2019; Jackson & Seiler, 2018), in mathematics classrooms, the dominant narratives in the figured world of mathematics that regard innate ability, intelligence, race, and gender actively position women and people of color as not belonging in mathematics classes, and even as being incapable of mathematics altogether (Leyva et al., 2021; Reinholz, 2021). Thus, characterizing the extant roles, actions, values, and dominant narratives surrounding student identity in a mathematics classroom reveals to educators what currently exists in these educational spaces, bringing awareness to where change can occur. Rightful presence then provides a student-centered lens oriented toward creating this change.

For researchers, applying these theoretical perspectives concurrently provides a powerful lens through which to analyze how students renegotiate their identities and reauthor their rights within educational contexts. This perspective could be powerful in revealing how problematic narratives within mathematics manifest locally within classrooms and how educators can most effectively leverage the insights figured worlds grant them while studying how the tenets of rightful presence give space for students to renegotiate their beliefs and reconfigure their figured worlds within the classroom (Calabrese Barton & Tan, 2020). Thus, lessons and learning environments can be designed with an orientation toward revealing current injustices in the classroom through the active analysis of figured worlds while the tenets of rightful presence can orient the lesson and learning environment toward remedying these injustices. This creates an explicit focus toward leveraging student agency to use what exists within figured worlds to disrupt and ultimately rewrite the roles, actions, and values within students' figured worlds, creating new counter-narratives for what it means to study mathematics and to be a mathematician.

While we do not claim that this critical lens of identity can be operationalized to change mathematics as a whole, we believe they can greatly assist educators and researchers to better understand how students negotiate their identity and leverage their agency within mathematics learning environments. This can help educators and researchers to then enact these ideas, designing and implementing mathematics lessons and contexts that treat students as holistic beings, creating space for students to mobilize their agency, and working toward disrupting systemic issues within mathematics, one classroom at a time.

Conclusion

In this paper we have discussed the importance of identity in mathematics education and the affordances of synthesizing the frameworks of figured worlds and rightful presence as a means to create harmony among the dissonance in mathematics that surrounds mathematical identity. By viewing mathematics learning environments as figured worlds, researchers can identify how the status quo and power dynamics operate within it. Through explicitly identifying the roles, actions, values, and dominant narratives in the classroom, the possibility for change emerges. By contextualizing the dynamics of injustice, rightful presence equips us with the tools needed to navigate tensions within these environments. Thus, through the illumination of injustices, spaces like classrooms can be cultivated in a way that mobilizes student agency in order to disrupt and reauthor the roles, actions, and values within the pre-existing figured worlds. Through this reauthoring, counter-narratives can be created, blazing the trail for a new conception of what it means to study and do mathematics, as well as what it means to be a mathematician. Together, figured worlds and rightful presence can inform us of *what is* within mathematics and empower us to build towards *what could be.* We call on educators and researchers to consider and apply these frameworks, in tandem as outlined, in their future work so that we might work towards creating mathematics education as a space of liberation.

“I WATCHED AS HE PUT THINGS ON THE PAPER”: A FEMINIST VIEW OF MATHEMATICAL DISCOURSE

Allison S. Theobold
Cal Poly – San Luis Obispo
atheobol@calpoly.edu

Derek A. Williams
Montana State University
derek.williams2@montana.edu

In this study we present results of a discourse analysis of the interactions between two partners, Uma and Sean, through a feminist lens. During roughly five hours of small group work in a teaching experiment, how each partner used language to position each other’s thinking as mathematically significant and establish a collaborative environment varied dramatically. Specifically, Uma shouldered the burden of continuously working to maintain collaboration, oftentimes at the expense of having her thinking positioned as mathematically significant. On the other hand, Sean regularly offered little opportunity for Uma to engage openly with his thinking, which ultimately constrained Uma’s opportunities to learn.

Keywords: classroom discourse; gender; attitudes, affect, and beliefs; equity, inclusion, and diversity

Numerous organizations invested in transforming mathematics education from predominately teacher-center towards student-centered advocate strongly for collaborative group work (e.g., Conference Board of the Mathematical Sciences, 2016; National Council of Teachers of Mathematics, 2014). Group work has been identified as an element of ambitious teaching in college calculus (Sonnert, Sadler, Sadler, & Bressoud, 2014) and has been associated with undergraduate students’ positive attitudes towards learning mathematics (Sonnert et al., 2014). Research focusing on how mathematical ideas emerge as collective ways of reasoning during whole class and small group discussions has demonstrated the importance of interacting with peers’ thinking for students’ own learning (Rasmussen et al., 2020), and aligned mathematical development with the nature of collective mathematical argumentation during class discussions (e.g., Rasmussen, Wawro, & Zandieh, 2015). Additionally, language does much more than establish normative ways of reasoning about mathematics. In fact, discourse allows participants to enact and construct their identities (Gee, 2014; Langer-Osuna & Esmonde, 2017). Therefore, discourse occurring within small groups simultaneously offers students opportunities to learn mathematics and establish their identities. This study presents a discourse analysis of interactions between two students, Uma and Sean, to investigate how their use of language influences opportunities for learning.

Review of Literature

Mathematical Identity and Classroom Discourse

Over the last twenty years, mathematics education research has moved beyond “gap gazing,” (Gutierrez, 2008) at static pictures of inequity, and toward research on the role of identity in teaching and learning mathematics. A variety of perspectives on identity formation have arisen, each emphasizing how learning in classrooms goes beyond understanding new concepts. Students also learn who they are and what they can and cannot do “with respect to the norms, practices, and modes of interaction” (Bishop, 2012, p. 36). Students’ identities are “dynamically negotiated,” representing a synthesis of who they are and who they have learned to be through interactions with others (Bishop, 2012, p. 38). Researchers have found the study of how students enact their identity at the microlevel, through classroom discourse, to elucidate explanations for the variability in mathematical identities within the same classroom.

Building on the framework proposed by Gee (2014), alongside Sfard and Prusak (2005), mathematics education researchers have used classroom discourse as a window into the formation and enactment of students' identities. Every instance of discourse in a mathematics classroom affords students the opportunity to negotiate their identities and respective social positions (Davies & Harre, 2001; Gee, 2014; Sfard, 2001; Wetherell, 2001). Early research on discourse focused on differences in students' desires when participating in group collaborations, finding that girls preferred to work cooperatively in groups, whereas boys "disliked working in groups because they felt it slowed them down" (Boaler, 1997, p. 297).

Langer-Osuna (2011) and Bishop (2012) shifted these conversations to focus on how students used language to position each other. Bishop (2012) described discourse between two students, Bonnie and Teri, and showed how Teri enacted the identity of the mathematical expert—speaking with authority and controlling activity and the uptake of ideas. Whereas Bonnie's discursive actions provided a window into the identity she inhabited and, in fact, helped to author—"dependent, mathematically helpless, and, at times, unknowledgeable" (Bishop, 2012, p. 57). Meanwhile, Langer-Osuna (2011) analyzed discourse to map how two students, acting as leaders in the same group, "developed opposite trajectories of identity" (p. 222). Brianna, originally publicly positioned by her teacher as an example of strong leadership, saw these same qualities positioned as inappropriate by her group. Whereas, Kofi, also positioned as knowledgeable but who was initially unengaged in the group's activities, found himself positioned as an authority figure by his group. Thus, discourse enables participants to establish and enact mathematical identities and also works to position members with (or without) power and authority.

Power & Authority in the Mathematics Classroom

Research on student interactions during small group problem solving has further demonstrated how students' mathematical identities, power, and authority can influence students' opportunities to learn (Chohen, Lotan & Catanzarite, 1990; King, 1993). Group collaborations fall prey to issues of status – the distribution of power among peers. Langer-Osuna and colleagues have documented how power and authority is negotiated among groups of students and is directly connected with how responsibilities for shared work are distributed (Engle et al., 2014; Langer-Osuna, 2016). Students as young as fifth grade have been seen to compete for *intellectual* and *directive* authority, which are heavily influential in determining whose solution strategies are used, whose ideas are assumed to be mathematically correct, and how effort is distributed among partners (Langer-Osuna, 2016). Johnson (2002) states that fights over who gets to speak and whose words are recognized are indicative of power and status.

Historically, male students have been positioned with power in mathematics classrooms (Webb & Kenderski, 1985; Wilkinson, Lindow & Chiang, 1985). Forgasz and Leder (1996) observed two boys refusing to work with their female group members when collaborating on a project with a "female-stereotyped context." Instead, the boys "used sexist language and taunted the two girls" (p. 163), insulting them while the girls completed the project entirely on their own. Jill voiced her disdain for the boys' behavior yet voiced how she and Cara didn't have any recourse— "If we didn't do it, it wouldn't get done" (p. 165).

These chiding remarks by group members took on a different flavor with Brianna (Bishop, 2012), who took on an early leadership role in her group. Less than halfway through the project, however, "group members increasingly positioned Brianna as bossy, claiming that Brianna was overstepping her authority" (p. 212). Two boys, repeatedly interrupted Brianna and scolded her for "being bossy," positioning themselves as a unified front against Brianna's bossiness. While the boys assaulted Brianna's leadership with criticism, they actively positioned Kofi as the group's leader, asserting his ideas deserved attention and seeking out help from Kofi. The leader-related utterances from Kofi were taken up by the group over twice as often as Brianna's, and his utterances were ignored or rejected nearly 25% less often than Brianna's.

These studies offer two perspectives for how students' negotiated identities go beyond the social interactions in the day-to-day classroom. Rather, student's identities also depend on the broader context of a student's life experiences (Gee, 2014; Wenger, 1998) and society's expectations for who they are and how they behave. Society grants students who are members of certain social categories with the right to hold positions of power over others. For decades we have seen research comment on how women—expected to be polite, accommodating, and reassuring—are not afforded positions of power in mathematics classrooms. Discourse has allowed us to see how these subservient positions manifest in classrooms, where women and girls do not have access to the conversational floor, are not able to decide what is correct, and are not seen to contribute meritorious ideas.

Theoretical Framework: Feminist Theory

Boaler (1997) admonished mathematics education as a discipline to "stop blaming girls for the underachievement and non-participation caused by the educational system forced upon them" (p. 304). The root of this underachievement and non-participation, however, potentially lies outside the educational system. The goal in mathematics education is for every student to have access to the resources and opportunities to be successful (NCTM, 2000). However, if discourse is viewed as a resource, then Jill, Cara (Forgasz & Leder, 1996), and Brianna (Bishop, 2012) exhibited pervasive differences in their discursive opportunities.

The gendered macroaggressions Brianna (Bishop, 2012) faced caused her to disengage from her group's mathematical activity and disassociate herself from her ambitious mathematical identity (Bishop, 2012). Villain (1998) argues that experiences such as those seen by Jill and Cara (Forgasz & Leder, 1996)—having their contributions ignored—implicitly conveys the message that their ideas have lesser value. Researchers have discussed these inequitable discursive opportunities as issues of power and authority (Langer-Osuna, 2016), but this research has not named these actions for what they are—*oppression*. A feminist standpoint, however, demands a commitment to understanding and challenging systems of oppression (Crasnow, 2014; Harding, 2004; Intemann, 2010; Intemann, 2016; Wylie, 2003). Adopting a feminist standpoint requires "studying from the margins out," (Intemann, 2016, p. 269) to reveal how power structures shape and limit the scientific phenomena under investigation.

This research expands these political discussions to focus on how discursive patterns between two undergraduate students positioned one student's thinking as significant and restricted another student's opportunities to learn.

Methods

The purpose of this study is to investigate the learning opportunities afforded to two students, Uma and Sean, while they solved problems during a small-scaled teaching experiment (Cobb., 2002). In particular, we pay specific attention to how the students used language and actions to, (1) position each other's thinking as significant, and (2) establish a collaborative environment. Each of these "building tasks" (Gee, 2014) are accomplished through discourse and allow us to understand the learning opportunities afforded to Uma, Sean and their group as a collective.

Setting and Participants

Uma and Sean were among six students participating in a small-scaled teaching experiment covering concepts of logarithms. The experiment consisted of five sessions each lasting one hour. Uma and Sean elected to work with each other. The two did not know each other prior to the experiment. Uma, a traditionally aged white women, had recently changed her major to secondary mathematics education. Sean, a non-traditionally aged white man, had returned to school to major in secondary mathematics education after a military career.

Data Collection and Analysis

Data collected for this study include recordings from the teaching sessions and individual semi-structured recall interviews. Interviews took place after the teaching experiment.

To analyze the discourse between Uma and Sean, we first watched the recordings from the sessions and identified *meaningful interactions*, which we define as an exchange of one or many talk-turns around a common on-task topic, idea or subject. Meaningful interactions may contain intervals of silence as long as subsequent talk-turns continue with the same subject and no changes to conversants occur. We considered instances when the teacher-researcher joined or left the conversation to constitute new interactions. Then, we transcribed all meaningful interactions and coded each conversant's use of language with verbs (e.g., revoicing, clarifying, explaining). Then, we analyzed the groups of codes emerging in the meaningful interactions to characterize how students positioned each other's mathematical thinking as significant, and whether their use of language was open or closed to collaboration. For example, a student asking, "Before, you were thinking..., do you think that still applies?" is using language to revoice their partner's previous mathematical thinking, positioning it as significant, and is also inviting collaboration. We also noted whether Uma or Sean shared ideas or strategies in each interaction.

Participants were shown three clips during the recall interviews. The first clip depicted an interaction where the interviewee had expressed either a high- or low-point in their engagement (see Williams et al., 2020). The second clip depicted the interviewee sharing a mathematical idea, and the third clip depicted an interaction where Uma shared a potentially meaningful mathematical idea that was not pursued on Sean's authority. We judged Uma's contribution to be *potentially meaningful* because it could have led to a solution to the problems being solved based on our evaluation. The first two clips were unique to each student. The third clip was the same. We use interview transcripts as evidence to support our claims from the discourse analysis.

Results and Discussion

Uma and Sean participated in 67 meaningful interactions while working together during the teaching experiment. Uma shared her thinking or a solution strategy in 20 interactions, while Sean presented his thinking or strategy in 54 interactions. From these interactions, Sean positioned Uma's thinking as significant 6 times, compared to the 38 instances in which Uma positioned Sean's thinking as significant. The common clip presented to both students during their recall interviews emerged as an interaction marking a shift in Uma's behavior while working with Sean. In what follows, we describe the progression of Uma's use of language for accomplishing the building tasks before, during, and after clip 3, as compared to Sean's.

Prior to clip 3, Uma was much more forthcoming in sharing her own mathematical ideas or strategies for solving problems with Sean, even though she self-described having low confidence stemming from how long it had been since she studied logarithms. Uma would share her thoughts without solicitation from Sean, and would respond to Sean with questions, even when presenting an argument for her own thinking. These uses of language are exemplified in the following interaction, which took place half-way through the first teaching session when students were attempting to create a timeline that accurately positioned a set of events (note, we use dashes in the transcripts to indicate when a student is cutoff or stops speaking abruptly).

Sean: So, I kinda ran out of room here, but I just went 10 to the 10th, 10 to the 9th... [pointing to his paper and turning to Uma] and then will fit those within there.
Uma: Oh ok! And then we'll fit them. Yeah [both work independently] … [Looking at Sean's paper, thinking aloud] 10 to the 6th
Sean: Yep, 10 to the 5th, and then I'm going to start my line. Over here, I'm actually going to extend it on- [continuing to work on his paper]
Uma: [9 seconds, looking at Sean's paper] and then you're adding a little bit more?
Sean: Mmhmm [7 seconds] Well, and that's turning into a scale that I recognize [bobbing, smiling slightly, looking over his glasses at Uma].
Uma: Yeah, so then that's- it goes to 10 to the 4th and then that's going to be 10 to the 3rd, and then to the 2nd (?) [looking at Sean]
Sean: Yep. And then I just went on out to-
Uma: 10 to the 0, yeah to make it easier [4 seconds]. So then, "Now" falls in at the 0 mark, right? Right? Would that be where we have "Now?"---
Sean: That's "Now," yep [working on his own paper]
Uma: [5 seconds] and then 10 to the 2nd is 100, right?
Sean: Yeah, so you want to kinda like- [continuing to work on his paper]
Uma: So then you have- [working on her own paper]
Sean: So if you wanna like- [7 seconds] the difference from here is actually 900 years, right.
Uma: Yeah, but then with each one the years are going to be more [gesturing "expanding" with her hands]
Sean: Yep. Yep.
Uma: Yeah, that's what I was thinking. I was like- because 500 is going to be- this is 1000, so your 500 is kinda going to be like half-way, right?
Sean: Yeah [slowly and hesitant]
Uma: it should be like here, 500, and then this will be 1000

This interaction begins when Sean states how he is creating his timeline using "eras" based on powers of 10. Uma positions this approach as signification by agreeing with the approach, revoicing his thinking (e.g., "10 to the 0 to make it easier..."), asking clarifying questions, and implementing his approach on her own paper. Uma's use of clarifying questions and posing her argument about where 500 should be positioned on the timeline as a question work to establish an open collaboration between the two students. Alternatively, Sean does not position Uma's thinking about where to position 500 as significant (which he disagrees with in a later interaction), nor does he elect to have a conversation about her suggestion to achieve consensus. Instead, Sean's responses are frequently short acknowledgements ("Mmhmm") that are closed to further collaboration. In fact, during his interview, Sean explained, "I don't think we were working together, we agreed on things, but I don't think we were truly working in unison."

Sean's limited attention towards Uma's mathematical thinking and frequently closed use of language persisted throughout the teaching experiment. In some interactions, Sean would elicit Uma's thinking vaguely—e.g., "What are you thinking?"—while in others Sean would invite Uma to read the next prompt, locate events on the problem sheet, or "unvite" Uma as a way to work independently—e.g., “we’re going to do the math to see what it actually looks like, right?”. However, Sean’s use of language was not exclusively closed towards collaboration. Sean would initiate interactions by inviting Uma to share her thinking, or present his own thinking as an argument (i.e., Toulmin, 1963). Presenting an argument, over stating claims without evidence, is considered an open form of discourse because of the benefits to engaging with the reasoning of others (Rasmussen et al., 2020). In total, Sean’s use of language was open to collaboration in 27 interactions and closed in 37, where it is possible for both to occur in the same interaction. Language that functions to open interactions for collaboration versus that which closed interactions was one primary difference in the discourse between Uma and Sean. Uma never used language that closed collaborations, while Sean’s language was more closed than open.

The patterns of open and closed uses of language between the two students did not change much throughout the teaching experiment. However, Uma’s willingness to share her thinking or solution strategies changed dramatically after clip 3, which took place as the last interaction from session 2. Leading up to this interaction, Uma and Sean were discussing a prompt designed to have students compare two large values, represented as events on a timeline constructed with an exponential scale with base 2. Uma and Sean were discussing the prompt, “Consider events, A which would be positioned at 16.005 and B which would be at 18.013. Which event took place longer ago and by how much? Explain.”

Uma: [reading the prompt] Which event took place longer ago and by how much? So, did that just mean that the one point is going to be over here and the other point is going to be over here? Is that what that-

Sean: [looking back and forth between papers] Yep. Yep.

Uma: [quietly] So, B... and this is A. It says, which one of these took place longer ago. I mean, it would just be B, right?

Sean: It would be B, yep.

Uma: And that’s just because it’s farther back on the timeline.

Sean: [nodding, using his calculator] Yep. And then it’s asking by how much.

Uma: So, then you’d have- you would just subtract 18- [gets quite]

Sean: [11 seconds] So that would give us the, the- [using his calculator] I don’t know if there’s a simpler way of doing that... [4 seconds]. So about 199,000 years. Does that seem right?

Uma: I think- Does it- so I’m just trying to remember like with exponents, can you, if it had the same like number, you can- can you take- so, like if we were to subtract because what I had done- because if you had subtracted the one and then the other one, and if you were to put 2 to the power of that (?)

Sean: So by inspection that’s going to be-

Uma: be a little bit bigger, right?

Sean: be very, very small. Because that’s going to be almost 4. Right, because 2 squared. But I think you’re on to something. There’s probably a relationship there. Um- [working on his own paper]

Uma: [40 seconds, quietly thinking aloud, working on her own paper] 2 to the 18[.013] minus 2 to the...

At the end of this interaction, Uma can be heard implementing Sean’s subtraction approach for determining the amount of time between events A and B from the prompt, which takes place after she presents an argument for using a multiplicative approach that relies on properties of exponents. Implementing Sean’s strategy and foregoing her own positions Sean’s thinking as significant. Alternatively, Sean does not position Uma's thinking as significant in this interaction. In fact, there are two instances when Uma presents an argument (i.e., for event B taking place longer ago, and for how to compare the events using exponents), where Sean's responses are closed. Sean indicates agreement with Uma's first argument in a one-word response. Then, after Uma's second argument, Sean counterargues for why her response is different from his, and ends the interaction stating, "... but you're on to something..." while proceeding to work on his own paper. Sean's limited willingness to further consider Uma's approach while simultaneously comparing her solution to his own suggests he is positioning his own thinking as more significant than Uma's. Additionally, that Uma waited for 40 seconds, looking at Sean, before implementing his strategy may suggest she wished for more discussion.

Prior to and including the interaction from clip 3, Uma shared her thinking in 12 out of 27 meaningful interactions. Sean positioned Uma's thinking as significant in 4 of these instances. Following the interaction from clip 3, Uma only shared her thinking in 7 out of 40 interactions. Also, Uma adapts the way she positions Sean's thinking as significant in future interactions. Prior to clip 3, Uma would agree with, revoice, and implement Sean's thinking as a way of positioning his thinking as significant. Following clip 3, Uma also routinely invites Sean to collaborate with her by posing questions that also revoice his thinking. In other words, Uma found that Sean was a more willing collaborator when she initiated interactions with his thinking. For example, Uma would ask questions such as those in this interaction from the third session.

Uma: Well, it said that each segment is equal, right? So you're saying that this part [pointing to Sean's paper] is the same amount of space as this part, right?

Sean: I think from here there is about the same as there.

Uma: Yeah, okay, so now the question is, 'when you take the overlapped time, does this still preserve the same amount?'

Sean: As that 10 to 1? That is the question. I don't think that it is.

Uma: Mmhmm. Do you have any thoughts leaning you more towards why not?

Sean: [15 seconds] if we graphed them longer, we would end up with something like that. Um, we're saying then that is equal with that, or this is 10 times that, but I think-

Uma: that overlap takes away from it being able to be 10 times that, right?

Sean: Yeah, I just don't know how to- I guess here's what I would say. We know that if this were true, then shouldn't I be able to slide it a little bit further and a little bit further, and then I would have them on top of each other, and they are clearly not 10 to 1 then. You know what I mean? If I keep overlapping more and more, then they become the same time period. So, I don't--- any overlapping, I think is-

Uma: it conflicts, I guess. Yeah, that's a good way to-

Sean: does that make sense?

Uma: Yeah, that does make sense. What do you think about the overlapping? Do they still have a relationship similar to what you were looking at before, or how do you even compare their relationships with the overlapping?

Sean: Well, I think we are subtracting exponents here.

Uma: Mmhmm, and then you'd be comparing from there (?)

From Uma's interview, we know that she valued working with Sean because, "if I was struggling on something, we could talk it out, and I could like go somewhere with it." However, when reflecting on clip 3, Uma also explained, "in that moment, I felt like I actually knew what was going on... and it actually start[ed] to make sense to me." In this way, the interaction from clip 3 emerged as pivotal in how Uma positioned Sean's thinking as mathematically significant and maintained a collaborative working environment. Moreover, Uma appears to have made a conscious decision to sacrifice being viewed as smart by Sean in favor of maintaining collaboration, which proved productive when she positioned Sean's thinking as significant.

Unfortunately, Uma's approach worked. Sean did not appear to value Uma's mathematical contributions, and reflected on this in his interview, "I kind of felt like I wasn't getting much from her." Sean also did not place the same value on working collaboratively as Uma. It is possible that Sean's assessment of Uma's mathematical ability influenced his use of language to position her thinking as significant (or not) and to establish a collaborative environment. However, as demonstrated subtly in the previous example, Sean also began using strategies that involved properties of exponents ("Well, I think we are subtracting exponents here."). In fact, by the end of the last session, Sean posed an argument almost identical to the one Uma shared in the clip 3 interaction. Sean also reflected on this when discussing clip 3 in his interview, "... she's probably contributing more than I gave her credit for."

Conclusion

The discourse patterns emerging between Uma and Sean showcase how Uma took on the responsibility of establishing and maintaining a collaborative environment at the expense of having her own mathematical thinking positioned as significant. We believe Uma made this choice consciously, based on her reflection during the discussion of clip 3 in her interview and in the clear change in her use of language in all subsequent interactions. Uma took on significant cognitive load by deciding whether to share her thinking or create a collaborate environment by constantly posing invitations to Sean. We can imagine how tiresome it must have been for Uma to seek collaboration in this way. In fact, Gholson & Martin (2019) suggest these tedious micro-confirmations "might be experienced as pain" (p. 400). Moreover, seeking out these micro-confirmations, required Uma to "fundamentally distrust her own thinking and intuition" (p. 401), which could have contributed to her sense of co-dependence on Sean. In fact, in the interview, Uma stated, "I was looking to Sean to set an example of what his thoughts were and where he was going...I was watching as he put things on the paper."

Critically, Sean positioned Uma's thinking as significant in six of the 20 times Uma shared her thinking. This is not to say that Uma's ideas were inferior to Sean's, rather Uma's suggestion during clip 3 ultimately became the group's concluding "solution," nearly three hours after Uma's posed the argument to Sean. These constant negations of Uma's thinking as significant could be considered a type of microaggression (Sue et al., 2007).

To be clear, Sean was not outwardly harmful to Uma. In fact, their interactions may appear as "typical" or benign when viewed individually or through a non-critical lens. However, this is precisely our concern. The "typical" gendered interactions students such as Uma, Brianna (Bishop, 2012), Jill, and Cara (Forgasz & Leder, 1996) experience are oppressive and limit their opportunities to learn. Strategies for combatting such oppression consist of establishing classroom norms and cultures that value all mathematical thinking from each and every student such as rough draft thinking (Jansen, 2020) and holding all students responsible for actively engaging with their classmates' thinking and how that thinking contributes to problem solving (e.g., Rasmussen et al., 2020). Moving forward, our future research will investigate classroom and small group norms that elevate all students.

OPPORTUNITIES AND LIMITATIONS OF POETIC TRANSCRIPTION AS A CRITICAL QUALITATIVE METHODOLOGY FOR MATHEMATICS EDUCATION

Rachel Tremaine
Colorado State University
rachel.tremaine@colostate.edu

This work presents an exploration of poetic transcription as a promising critical methodology for use in mathematics education research. I make the case for mathematics education as a specific space in which such methodology could be valuable, and provide a use case for poetic transcription through the poetic analysis of three students' definitions of student success within mathematics. Following a reflection on some of the critiques and limitations of re-presenting data in this way, I conclude that poetic transcription offers mathematics education an imaginative and simultaneously grounded method of understanding, while still necessitating critical thought and methodological malleability.

Keywords: Research Methods, Ethnomathematics

As poetic transcription gains popularity and credibility in research spheres, it is prudent to investigate its efficacy in the context of mathematics education. Poetic transcription draws from the literary tradition of a *found poem*, in which excerpts from existing written media are juxtaposed to create poetry with distilled meaning. In poetic transcription, participants' words from interview or focus group transcripts are pulled in such a way as to honor and reflect the participant's meaning and narrative style (Glesne, 1997). Prendergrast (2009) emphasizes that these poetic transcriptions are built from the participants' words but filtered and "re-presented" through the lens of the researcher by referring to these poems as "participant-voiced poems." Via use of member-checking practices and researcher-participant co-construction of such poetry, poetic transcription can provide direction for research that is "genuinely inclusive and democratic" (Levinson, 2020, p. 195). Further, via the artistic embodiment of experiential knowledge, poetic transcription can present nuances of qualitative data in a way that the quoting and analysis of traditional prose may not, particularly when viewed through a lens of feminist theory (Faulkner, 2018) and critical qualitative research (Burford, 2018; Faulkner & Cloud, 2019; Keith Jr. & Endsley, 2020).

Poetic transcription is already utilized in meaningful ways in other educational spheres (see Mercer-Mapstone et al., 2019; Thunig & Jones, 2020; West & Bloomquist, 2015). Mathematics' well-chronicled existence as a racialized and gendered space which privileges White, masculine, Western ideology (Battey & Leyva, 2016; Gutiérrez, 2018; Leyva et al., 2021; Martin, 2006) makes for a particularly potent case in which critical methodology—that which not only uplifts but foundationally gives power to the voices present in its work—is necessary to explore (Skovsmose & Borba, 2004). As research in this field more closely seeks to align itself with critical perspectives, our own research methodologies should not be above the kind of critical questioning that we ask of mathematical content and practices. Poetic transcription offers opportunities to introduce a humanizing lens to research, center participant voices, and disrupt traditional hierarchies (Fernández-Giménez et al., 2019). If these are goals explicitly stated for our research foci in mathematics education, why would they not also be goals we bring into our methodological practices?

A Use Case for Poetic Transcription in Mathematics Education Research

As asserted by Prendergast (2009), poetic transcription is best utilized when the topic in question "lead[s] into into the affective experiential domain" (p. 546). O'Shea and Delahunty (2018) note that student-constructed definitions of student success are "embodied and emotional," and in this way they are ripe for exploration of and expression through poetic transcription. In the spring of 2021, I conducted semi-structured interviews of five first-year undergraduate women, all of whom identified as First-Generation, Pell-grant eligible, and/or women of color, with the intent of gaining insight into how these women define what it means to be "successful within mathematics."

Each transcript contained between ten and twenty minutes of spoken text, in which the women narrated a time in which they experienced success within mathematics and responded to the question "how would you define student success in undergraduate mathematics?" As in line with previous work on students' definitions of *student success* being nuanced and varied (see Weatherton & Schlusser, 2020, for a comprehensive overview), these women each carried and shared with me diverse experiences and definitions of this amorphous term. Quotes from several of these women students have been previously highlighted in advocacy for the necessity of explicit definitions of student success and acknowledgment of their nuanced and expansive nature with mathematics education (Tremaine, 2021). The purpose of the present work is to contemplate poetic transcription as a viable methodology in mathematics education; as such, I am not including the contextualization or discussion of these data and how they are situated in broader societal issues of how success within mathematics is conceptualized and valued, and by whom—that is outside the scope of this brief report.

My poetic transcription process was primarily informed by my readings of Glesne (1997) and Prendergast (2009). Both of these authors acknowledge that there exist a myriad of ways in which to engage with poetic transcription; I summarize here my methods, but explicitly note that because poetic transcription is inherently a creative process, the process which worked for me in the context of this affective domain of mathematics education research may not be appropriate for other explorations in which poetic transcription might be utilized.

The first phase of my process was an initial parsing of the data, in which meaningful phrases were highlighted and excerpted from the entire interview transcript. This parsing was done in careful conjunction with a revisitation of the audio recordings of the interviews, allowing for attention to vocal emphasis, and is reflective of Lahman et al.'s (2010) concept of "poking around poetically" and Glesne's (1997) concept of "sifting through the data". This selection was based upon my own recollections and perceptions of what the participant emphasized, and what phrases might best represent the meaning from longer narratives or passages. For example, Isabel expressed that she found mathematical success in being able to practically apply geometry skills to make buying fabric for her quilting efficient. While this anecdote was discussed at length, I found the phrase "I really enjoyed being able to know how much fabric to get" an effective and important phrase in her longer narrative, and thus it was selected in this parsing of the data. I also attended to phrasing which I found particularly poetic—sequences of words which gave myself as a listener pause for thought, or provoked imagery and emotion, and perhaps contained deeper meaning. Kenzie referred to her achievement of her definition of success as a "breath of fresh air"; this phrase's attribution to the acquisition of success provided vivid imagery and captured some of the "embodied and emotional" nature of student success definitions.

Once these phrases were distilled, the second phase entailed juxtaposing them in a variety of ways that were reflective of poetic structure. This proved to have many iterations, and resulted in two prominent methods of grouping meaningful phrases: grouping for structure, and grouping for theme. Thematically, certain phrases were grouped based on the topic or thread of thought they related to (i.e. a group of phrases which all related to success in math as pragmatic application). Structurally, phrases were grouped based on rhetorical parallelism (for example, grouping Kenzie's words of "that's where I want to be" and "that's what I was reaching for"). Phrases were often used multiple times in various groupings. These poetic juxtapositions then enabled the creative composition of poems, which were edited and re-edited in additional consultation with the full interview transcript to ensure fidelity to the individual's narrative. Poems and interview transcripts were then revisited several months after their initial composition, and edited in small ways as felt needed.

The final phase of this analysis consisted of a member-checking process, engaged in via email with each participant. Participants were provided a brief of the poetic transcription methodology of the project and were invited to edit and/or affirm their poem as they were written via an editable Google Document. Overall, five finished poems were produced for this work, and I showcase three of them below in *Table 1*.

Table 1. Three of the five poems resulting from poetic transcription, capturing undergraduate student definitions and experiences of student success within mathematics.

Isabel*	Kenzie	Taylor*
It's two different intelligences: being able to do well in school and being able to use what you've learned. Some people enjoy doing math for the sake of math; I really enjoyed being able to know how much fabric to get. Being able to practically apply your math skills- this is what math was meant to be used for.	They determined success: your grades matter a lot. That's what I'm aiming for. Having studied, internalizing the materials, I worked at my dues. Feeling proud after all that work- that's where I want to be, that's what I was reaching for: a breath of fresh air. Here I am.	Math can be really hard. Of course, grades are important. More important than that is understanding what you're learning. I met the requirement and passed it too.
*Poem affirmed by participant as reflective of their experiences and definitions.		

The resultant poems endeavor to present transcript data in a way that is unconstrained by any particular coding scheme or field-specific jargon, while still conveying the nuanced definitions of student success in mathematics held by each of these women. Faulkner (2019) notes that poetic transcription provides qualitative researchers with a "more approachable, powerful, emotionally poignant, and accurate form than prose research reports allow" through the incorporation of rhetorical style and dimensions of emotion that poetry can bring to qualitative work (p. xi). Certainly, the presentation of this data could benefit from an additional thematic or perhaps narrative analysis, as, I argue, would any data set benefit from additional lenses of applicable analysis. However, as Prendergast (2009) argues, the poems produced from poetic transcription are best when they are capable of standing alone. In poetic transcription, the poetry is both the analysis and the presentation of the analysis, rolled into a singular creative process.

Discussion of Limitations Inherent in Poetic Transcription

While poetic transcription affords mathematics education researchers an invigorating and holistic way through which to re-present data, it is important to also make explicit the limitations present in such a methodology as its use is contemplated in our field.

I choose here to acknowledge my positionality in the work I described above; I am a White woman who does not identify as First-Generation or Pell-grant eligible, and while I endeavored to maintain fidelity to participants' rhetoric and meanings, my filtering of participants' words through my own lens and poetic style is in itself a form of colonization of these stories and definitions. Glesne (1997) provides candid reflection on how she and her participant's differing native languages may have construed her ability to accurately reflect her participant's voice and experience in her resultant poetry. Similar to Glesne's concern of not capturing the nuance that would be present in her participant's untranslated responses, I recognize that I cannot fully understand the nuanced responses regarding the lived experiences of my participants. While poetic transcription can help "heal wounds of scientific categorization and technological dehumanization" (Glesne, 1997, p. 214), it also maintains opportunity for withholding and privileging certain lenses that are already dominant in research spaces through its inherent subjectivity. Burdick (2011) and Mercer-Mapstone et al. (2019) are two examples in which participants were explicitly involved in the creation of resultant poetry, thereby more effectively enabling the participant's own creative voice to shine within the work from its very genesis.

I also acknowledge the criticism put forth by Tuck and Wayne Yang's (2014) work, in which they note that, by advocating that poetic transcription join the ranks of established research methodologies in our field, I do nothing to disrupt the problematic exaltation of *research* as the dominant and most reputable form of knowing- *research*, of course, being a space which historically and contemporarily marginalizes important and necessary perspectives. Simultaneously, other scholars highlight that poetic transcription pushes back against the dominant culture of academia by "allowing [researchers] to communicate to cultures other than that of academics" (Vannini & Gladue, 2008, p. 146). Vannini and Gladue assert that, in conjunction with claims made by poetic inquiry powerhouse Laurel Richardson, most informants to research converse in non-academic voices that are better reflected by poetry than written academic prose. In approaching research presentation in a way that is more colloquial, embodied, and free from academic jargon and structure, we re-present research that remains accessible to the individuals who contributed to it. Faulkner (2018) also notes that poetic transcriptions' "evocative critique and resistance of the status quo" enables it to function extremely effectively within necessary critical discourse (p. 23).

In conclusion, I hope this work has provided the reader with food for thought regarding the use of poetic transcription within a mathematics education context. While by no means a methodology which is free from continued tensions regarding colonization and dehumanizing practices, it does endeavor to push back against such influence through a more embodied, accesible way of re-presenting data. Poetic transcription as a methodology remains in its infancy when compared to many other forms of qualitative inquiry, and as such has immense opportunity for development as scholars experience and refine it in ways that continue to grapple with the subjectivity of research. I present it here in this brief report with the hope that it (a) prompts others to engage in and research poetic transcription as a viable methodology for use within mathematics education and (b) allows for a continual reflection on how we, as researchers in this field, can be continually critical in our use of methodology and grow in what we conceptualize as valid and important ways of knowing and re-presenting the experiences of our participants.

TENSIONS OF KNOWLEDGE AND AUTHORITY: CHALLENGES OF TEACHING SJM

Trevor T. Warburton
Utah Valley University
trevor.warburton@uvu.edu

This study seeks to demonstrate how knowledge and authority are linked for preservice mathematic teachers and how this link may pose a challenge for teaching mathematics for social justice. A CDA of multiple preservice class discussions is presented.

Keywords: Social Justice, Equity, Inclusion & Diversity, Preservice Teacher Education

There is a great need for social justice mathematics (SJM) in U.S. schools. Students of color frequently feel disconnected in mathematics classrooms (Gutiérrez, 2012b). Despite the efforts of Frankenstein (1983), Gutstein (2006) and others, SJM has not gained wide acceptance (Gutstein, 2006). Bartell (2013) notes that mathematics teachers prepared to teach SJM often fail in the moment. De Freitas (2008) has suggested that mathematics teacher identities are tied to mathematics and Walshaw (2013) notes that teachers are caught by dominant discourses of mathematics. These represent mathematics as apolitical, acultural and neutral (Ernest, 1991; Walkerdine, 1988). These characteristics contrast sharply with the openly political aims of SJM. Further, these characteristics form the basis of White authority (Frye, 1992), thereby creating an overlap of authority between mathematics and Whiteness (Author, 2015). For mathematics teachers to address social justice requires that they come into conflict with this authority.

One means for teachers to connect to authority is by emphasizing mathematical competency. Since many teachers, White in particular, have limited knowledge of social justice issues they can feel a lack of authority in this area. Further, the mathematical competency of U.S. mathematics teachers is under fire (Wolfmeyer, 2012), potentially leading mathematics teachers to be defensive. This may link mathematical knowledge and authority, leaving little room for SJM. This study seeks to understand the relationship between knowledge and authority for secondary mathematics teachers. To this end I aim to answer the following questions:

1) How do we discursively link mathematical knowledge and teacher authority?
2) How can we disrupt this link to create space for social justice in mathematics education?

Theoretical Framing

Wagner and Herbel-Eisenmann (2014) found that authority issues were prevalent in mathematics classes. These issues may arise because of the perceived authority of mathematics (Amit & Fried, 2005). Skovsmose and Valero (2001) describe a kind of "omniscient authority" embedded in mathematical discourse. Authority relations are primarily between teachers, students, and mathematics. Authority is a key aspect of equity (Gutiérrez, 2012a). A potential problem arises when teachers use a knowledge-authority link to justify authoritative mathematics teaching. I focus primarily on this teacher-student authority relationship linked to knowledge. This link is important because the dominant mathematical discourses may dissuade teachers from questioning their authority and from creating equitable relationships. Amit and Fried (2005) note that when teachers are too authoritative it reduces student authority. One means of understanding authority is through the lens of agency (Sengupta-Irving, 2016). Authority can attempt to limit who (and how) can exercise agency. This may create a dynamic where students are mostly passive (Boaler & Greeno, 2000). While this passivity can be an exercise of agency (or resistance), it does not contribute to the mathematical development of the student or classmates.

Authority and Social Justice in Mathematics

Reforms in mathematics promote a redistribution of authority (Amit & Fried, 2005); this is not sufficient to equitable relationships. Because authority is in the discourses of classes (Skovsmose & Valero, 2001), it does not disappear with the adoption of more “student-centered” pedagogy. Gutiérrez (2009) notes that teachers cannot pretend to lack authority; instead teachers need to explicitly discuss authority (Gutiérrez, 2015), so that its use can be negotiated. In terms of equity, Gutiérrez (2012a) outlines four dimensions: access, achievement, identity and power. The power and identity dimensions intersect with authority in terms of which mathematical practices are valued, whose voices are heard, and in using mathematics to critique structures.

Discourse

Discourses can establish authority. I look at the discourses of mathematics, mathematics education, SJM and teacher and student roles. Discourses both enable and constrain (Fairclough, 2001). Appropriate discourses allow me to be recognized as a mathematics teacher through how I speak, interact, dress, and use mathematics materials. Discourses constrain by limiting what speech and behaviors are acceptable for a mathematics teacher. This enabling/constraining illustrate the operation of power in discourses. As a result the use of discourses is a negotiation of power. This negotiation occurs most directly between the teacher and students. These negotiations are implicit and dependent on a shared idea of teacher or student roles.

The discourses that carry the greatest power are dominant. A discourse becomes dominant by excluding other ways of thinking by establishing a static understanding of truth. Current dominant discourses about mathematics portray it as apolitical, neutral, acultural and objective (Ernest, 1991; Walkerdine, 1988). SJM argues, in part, that mathematics is political, cultural, and subjective. Since the dominant discourses of mathematics specifically disallow this perspective it may be difficult for teachers to understand the why and how of SJM. Walshaw (2013) notes that teachers and students are caught in these discourses. Thus, I expect to find that mathematics teachers generally will struggle to understand SJM, because of the of these dominant discourses.

Discourse and Whiteness. The pressure to conform to dominant discourses and their limits help maintain power structures. In the U.S. dominant discourses are discourses of Whiteness. Whiteness Theory helps uncover how discourses maintain white privilege. Whiteness Theory operates on the assumption that the lives of all people in the U.S., in particular, are racially structured (Frankenberg, 1993; Frye, 1992). Since mathematics achievement follows racial lines \ (Stinson, 2004), race is a significant factor in defining traditional measures of mathematical success. Further, Skovsmose and Valero (2001) explain that mathematics is used to sort students. Battey (2013) specifically applies Whiteness Theory to the material benefits of this sorting. Here I will analyze discursive connections between knowledge and teacher authority.

Methodology

Participants

Like my students, I am caught in the dominant discourses of mathematics education. As a young, white teacher I taught all of the mathematics classes for emergent multilingual students at a rural, public high school. I witnessed the roles of race and class in the lives of my students. There were clear divisions along race and class lines. As a teacher I felt pressure to support school policies; I also wanted to support my students who were not served by those policies.

Teacher Candidates. The teacher candidates included four White males (Pseudonyms: Jeff, Karl, Gavin, and myself), two White females (Stella and Lisa), one Latina (Esperanza), and one

Japanese-American female (Jane). They were working towards a Master's degree in mathematics with certification funded by Mathematics for America (MfA). During the Fall semester I supervised their student-teaching, attended monthly meetings, and a retreat. During the Spring semester I taught their action research class as I continued their supervision. Several of the preservice teachers expressed an interest in SJM and four attended a conference on SJM. I considered each of them to be capable and committed, who struggled with SJM.

Critical Discourse Analysis

Drawing from critical theory, critical discourse analysis (CDA) explains how language is linked to society (Chilton, 2011). Fairclough (2001) draws on Foucault to explore how consent is gained through dominant discourses. Fairclough uses discourse to explain the relationship between social norms and power. Here I will analyze discourses we used to explain the links between mathematics and authority. Critical discourse analysis draws on post-structural understandings of discourse and the circulation of power (Rogers et al., 2005). In particular, as speakers use discourses we construct objects and subject positions. But even these objects and subject positions are multiple and changing; they are negotiated and re-created. I have also framed these discourses within Whiteness Theory to analyze how they maintain white privilege and how we begin to re-work some of these discourses in order to understand SJM.

Data Collection

All data for this study were drawn from a teacher research (with a SJM focus) course for preservice teachers. Each class was recorded and transcribed, resulting in over 25 hours of recorded data. The teacher candidates' written work, as well as my reflection journal were additional sources. I chose sections in the data where there was evidence of, or potential for, SJM for further analysis. I performed line-by-line analysis of each of these transcripts using Gee's (2005) building tasks paying particular attention to authority. From these analyses I identified themes and re-analyzed for key ideas I missed, to fill in details, and to identify deviations.

Results

Linking Knowledge to Authority: A Traditional Frame of Knowledge and Authority

The transcript that follows illustrates the link between knowledge and authority, how that link is normalized, and is representative of other discussions. This discussion focused on the discourses that shape mathematics education. Prior to the transcript we discussed teacher and student roles. These discourses structure teacher-student relationships.

Jeff: It's inevitable I mean if I am more knowledgeable than my students you can't change that, that automatically gives me some more power that they don't have, you can't change it so that's not necessarily a bad thing. Sometimes there's this connotation that we want to remove all power differences.

Teacher: Right

Jeff: I think that that's erroneous.

Teacher: And I think to pretend that you don't have that authority is false and the students are going to recognize it right away and they're not going to respond to it.

Jeff: Well and if they don't respect the fact, if they don't think you have the knowledge you can't teach them in any way

Here Jeff draws on a discourse that links authority to knowledge. Within this discourse greater knowledge necessarily creates greater authority. In drawing on this discourse Jeff positions teachers as naturally having more authority than students since teachers have "more knowledge". Presumably he is talking specifically about mathematical knowledge. This knowledge differential is unchangeable ("inevitable", "you can't change it"). These statements naturalize the relative positions of teacher and student and the teacher's authority as authority over students, which is "automatic". Finally, he evaluates these positions as "not necessarily a bad thing". My comment does nothing to disrupt this link and, in fact, accepts it as natural. Jeff's final comment points to the necessity of this authority as necessary for teaching. Among the assumptions of this discourse is that authority is static (i.e., natural to a teacher), teacher authority and student authority are in an inverse relationship, and that the authority-knowledge link applies only to sanctioned knowledge—especially mathematics.

Lack of Knowledge as Justification

Alternatively, the following transcript shows how this link can be used as justification to not engage SJM. Prior to this, the teacher candidates had read an article by Gutstein (2012) on implementation of SJM. In response, we discussed various topics including the importance of addressing racism. During this discussion Esperanza drew on her experiences as an immigrant student of color to argue that teachers need to discuss these issues. In the transcript Jeff shifts the discussion by asking Esperanza more about her experiences.

Jeff: Because one of my fears is I don't see when I'm doing it wrong for them so but if I said look I want to have a discussion about immigrant reform . . . and I know that I'm not an immigrant so I'm not going to see all of the issues the way that you will and so if I do something you know prelude that says I'm going to probably screw some of this up but it's not because I'm trying to would that have made a difference for you

Esperanza: Letting me know yea and I think it would be great to not take on and shut because I know my U.S. history teacher he thought he knew everything he just knew the newspaper like you're not looking at the families that are being deported you're just bringing the issues the media brings out to the table and not other perspectives and so if you really want to do touchy subjects like that I feel like you have to make sure you know both sides of the coin you know what I mean like

Teacher: Yeah and I think like you said acknowledge the limits of your knowledge

Esperanza: Exactly let them know

Jeff: I don't know, at some point then I might just decide not to have it because the problem is that if there is something that the teacher brings to the class and if nothing else it's some sophistication in how debates can go and realizing that kids just like to argue and so what are they going to do they're going to bring the news to class and their parents views and if you aren't knowledgeable you can't manage that discussion very well right I mean if I personally am not knowledgeable about it it can get out of hand very quickly.

As Jeff directs his question to Esperanza he frames it around his own fear which is, "I don't see when I'm doing it wrong". In Esperanza's response she emphasizes that a teacher should "know both sides" of an issue. This would require a teacher to learn about issues before discussing them in class and positions the teacher as taking responsibility. It is at this point that the direction of Jeff's argument becomes clear. In response he says, "I might just decide not to have [the discussion]". Thus, he draws on a dominant discourse that uses ignorance as a reason not to engage rather than a responsibility to learn. He links this to the idea of "sophistication" that a teacher should bring to the class. This sophistication requires more knowledge than what the students have (who "just like to argue") in order to give the teacher the authority to control "how debates can go", since "if you aren't knowledgeable you can't manage that discussion". The concern is that the discussion "can get out of hand", which may undermine teacher authority. In this way, white ignorance (of racism) creates a fear of losing authority. This fear prevents a willingness to learn to have the difficult discussions that could benefit students. It is a fear of not being a “good” teacher, when a good teacher is understood as knowledgeable and in control. While Esperanza provided an opportunity for a different perspective, the dominant discourse of Whiteness, and a lack of white responsibility to understand racism was reasserted. Again these are the dominant discourses that are available to us.

Problematic Relationships in Social Justice Mathematics

In another moment of this same class Karl brought up a question of how to bring up difficult topics, such as HIV/AIDS, and have students engage appropriately. In our responses to this question we describe the concerns we have about teaching this kind of SJM lesson.

Teacher: So let’s talk about this so somebody there brought up the idea that if you're teaching this lesson on the west side [lower income, more students of color] that it could be possibly discouraging to students. How would you address that?

Gavin: Well just that life sucks and that's how it is.

Multiple: ((laughter))

Jeff: Isn't it all in the context of being able to create change if you can do that it doesn't have to be inherently negative being reminded of reality and if that’s all you're doing is saying yeah tell me something I don't know

Teacher: Isn't well ok I want to hear you out is there any benefit to doing that? . . . .

Jeff: Well maybe I mean to let them know that you're aware

Teacher: To remind them mhmmm why might that be beneficial?

Jeff: Because they may feel that you aren't and they can't approach you and talk . . .

From the beginning I position the teacher as the authority, bringing difficult topics to the class (“how would you address”). While this was Karl’s question, I do not challenge this assumption. This leads us to continue in a way that assumes the authority of the teacher. I ask the teacher candidates to recall a SJM lesson that Esperanza, Stella, Lisa, and Jane had written. Their lesson highlighted an unequal distribution of parks based on geography and population density.

After Gavin’s joke, Jeff mentions the importance of “being able to create change”. The passive construction here leaves it unclear who is creating change. However, if it is parallel to the structurally similar “being reminded of reality” where it is clear that the students are “being reminded,” the implied agent is the teacher. This passive role for the student maintains teacher authority, even if that teacher intends to “create change”. Picking up on Jeff’s point I ask if there is benefit to just pointing out inequity. Jeff mentions a benefit of overcoming some of the teacher’s authority to make them more approachable. This point suggests that students are careful in their relationships, positioning them as agents as they negotiate the school system.

This improved relationship could benefit students, as they will be more likely to have someone they can work with and who will listen to them. In this discussion there are implicit references to knowledge of inequality; this will become more explicit as the discussion continues. As Lisa responds (below) to my questions she seems to suggest that bringing up difficult, social justice topics is beneficial because it can increase teacher authority.

Teacher: And why would they care if you as their teacher are aware?

Jeff: Because you have authority that you're trying to hand out to them.

Teacher: K. other thoughts on that?

Lisa: Yeah. Because you're trying to teach them stuff if they think you have no idea what's going on and they don't get you at all they're not going to participate in your classroom

Jeff: So you can't create relationships you mean

Lisa: Yeah. So I think that's something that I never really thought of that much making them aware that you're aware of it

Teacher: Is there benefit in just making students aware of social issues like this . . . .?

Lisa: I think that you have to talk about the actual thing before you can start to talk about why that thing is occurring and I don't think that that is a given that all students know reasons that could potentially explain why things are unfair.

Lisa highlights the importance of what students think of their teacher. If their opinion of the teacher is low (in terms of knowledge) then “they’re not going to . . . participate in your classroom”. This is a very similar statement to one Jeff made in week 4, “if they [students] don't think you have the knowledge you can't teach them in any way.” Also “your classroom” suggests teacher ownership. Both Jeff and Lisa link teacher knowledge, with students’ willingness to listen. A lack of teacher knowledge may result in students exercising agency disagreeably.

If we discuss teaching mathematics in a traditional sense (as Jeff was) then the knowledge/authority link is restricted to mathematics. However, if we discuss SJM (as Lisa is) then that knowledge is expanded to include sociopolitical knowledge. This is a potentially disruptive view suggesting that being a mathematics teacher requires sociopolitical knowledge. However, increased knowledge is still linked to increased authority. There is no discussion of benefit to the students from this kind of teaching. It seems that our primary concern is how bringing up difficult topics in the classroom will affect the teacher. As I rephrase the question I maintain this focus on the teacher as agent who is “making students aware.” This may reflect my own whiteness where I was largely unaware and may also universalize this white perspective. Lisa also notes that we should not assume that “all students know”. We position ourselves as responsible for SJM and focus on the teacher as authority.

Balancing Teacher and Student Authority

In a later class, Karl shared an example of a SJM lesson in his class. A majority of his students were low-income students of color and bussed to the high school.

Karl: We calculated the area based on those grids that you put over the maps and then talked used that as a segue into you found the area it looks like you guys used a rectangle here this one you guys said was a half what's really going on so like that was kind of the math reason for doing it but the discussion was pretty good it started out kind of poorly . . . . they would say let’s just have it how it is now I don’t care what parks are like and that was about the first five minutes of the discussion was about how people don’t really care about parks

Here Karl explains the lesson that illustrates the ways local parks are distributed inequitably. His focus is on what the students did, positioning them as agents. Notice how he includes himself with his students (“we calculated”) and then the frequent use of “you” to refer to his students and their work. He positions students and their work as central, while he remains on the periphery. When the lesson “started out kind of poorly” he attributes this to his own inexperience. He emphasizes the students’ perspective and identifies with it by using first person (“let’s just”, “I don’t”). Their perspective went against what he was trying, but he valued their thinking. Students are portrayed as exercising agency in valid ways, even when they disagree with the teacher.

After listening to his students, Karl still thought the lesson was valuable and that his students would benefit. As a result, he persuaded them to give the lesson a chance.

Karl: And I had like a little bit of a discussion . . . . like this I know we’re talking about parks right now but take this a little more seriously for a little while this isn’t really about parks and I think you guys will figure out what’s going on here . . . . They brought up were things that I never thought about in terms of this park issue and one thing being cost or a couple things being cost of upkeep for a park I didn’t really think of that as a possible

> reason for maybe how they're distributed like maybe one park has more graffiti than another park and more cost is gone into upkeeping it. One student brought up the distinction between a community park and a city park and I didn't know the difference really and she was kind of thinking she was like schools are kind of supported and I don't know much about taxes and she was kind of asking me about taxes and I was like I don't know your idea could be right or it could be wrong. . . . which I thought was an interesting question that I didn't expect from a 17-year-old

In the beginning part of this section Karl portrays himself as using some of his authority to persuade. He did so through "discussion", recognized the students' perspective, and expressed confidence in their ability to see beyond the parks. The students brought up things, "that [he] never thought about". Karl clearly views this as a positive ("really good") even though it positions him as less knowledgeable in this area than some of his students. He believed that his students' ideas were valuable enough to share them with the rest of us. Karl also admitted his lack of knowledge on the subject to his students (frequent use of "I don't know" and variations). In previous discussions we had constructed teacher authority as closely connected to knowing more than students, this admission appears to work against that link. This admission was not related to mathematical knowledge. It is possible that Karl feels safe admitting a lack of knowledge about park funding, but not mathematics.

Discussion

Dominant discourses appear to link knowledge to authority. By doing so they either leave no space for SJM, an unwillingness to engage SJM, or inequitable relationships within SJM. Only occasionally were we able to break out of this link as Karl did.

No Space for SJM

In the discourses that left no space for SJM we struggled to even understand if or how SJM might be possible. This view seems to be consistent with Bartell's (2013) finding that teachers, after planning a SJM lesson, often focused on either the social justice or the mathematics. This discourse operates by restricting our ability to imagine alternative relationships between knowledge and authority and require a reimagining of what knowledge is valued in a school context (Gutiérrez, 2015). A potential alternative to this view of knowledge and authority would be one that recognized that both teachers and students have varying levels of knowledge in different areas. While the teacher may have more knowledge of school mathematics, students also have knowledge relevant to learning mathematics. However, the dominant discourses of school mathematics shape the roles of teacher and students to prioritize school mathematical knowledge. As a result, our relative lack of knowledge of social justice issues shut down discussions of SJM. Discussions that draw on dominant discourses feel "safe" (Yoon, 2012) by not disrupting the dominant view of mathematics with the racio-political views of SJM. Further, they can help participants maintain an image as "good" (white) teachers (Applebaum, 2008) by staying within knowledge domains that are comfortable.

White Ignorance

Discourses of white ignorance of social issues, especially of racism reflect a colorblind discourse that support racist structures in society (Bonilla-Silva, 2015). It is important for teachers, especially white teachers, to recognize the limits of their knowledge and experience. However, this recognition should be accompanied by a sense of responsibility, rather than a justification. This discourse restricts SJM by reducing the teacher's role to mathematics, since that is the area of knowledge expected for mathematics teachers and prioritized in teacher preparation. Alternatively teacher preparation might value multiple forms of knowledge, such as the classical, critical, and community knowledge suggested by Gutstein (2006). Importantly this discourse came about in response to Esperanza's explanations of how and why teachers must address sociopolitical issues. She was able to successfully draw from her experiences as an immigrant woman of color to access discourses that were temporarily disruptive. She may have done so because of an experience of "double consciousness" (Du Bois, 1903). As a woman of color in a white space she could see both the dominant discourse and alternatives.

Problematic Relationships

Importantly, even when we did successfully discuss SJM we often did so from within a dominant discourse linking knowledge and authority. The result, for us, was that we discursively constructed inequitable classroom relationships between teacher and students. These relationships emphasized teacher authority, the teacher as agent, and the beneficiary of SJM. There is little room left to construct an active role for students. Gutiérrez (2012a) in discussing identity and power explains that students should have opportunities to bring their full self, including knowledge and capabilities. Further, students need opportunities to participate in mathematics that is personally meaningful. This is more likely to happen when students have voice, which is part of Gutiérrez's equity dimension of power. In mathematics education we need to construct classroom dynamics that value and include student voices.

Shared Authority

Finally, Karl's description of his experience attempting to address a social inequity in his mathematics class shows potential for constructing more equitable classroom relationships. This occurred as students brought up ideas that Karl had less knowledge of. He was willing to listen to and learn from his students as they raised their voices and their ideas in the classroom. To further develop these relationships, students would also need opportunities to participate in similar ways with both mathematical and social issues and the teacher would need to demonstrate a similar willingness to listen to and learn from students.

Recommendations

Dominant discourses linking knowledge and authority imply that the simple solution to teachers' lack of knowledge of social issues, such as racism, is to gain knowledge in these areas. While increasing teacher knowledge is necessary, it is insufficient and may lead to inequitable relationships. In addition, teachers will need to create opportunities to learn from their students; white teachers in particular, will need to listen to their students of color. Teacher education programs largely focus on what Gutstein (2006) identifies as classical knowledge. This knowledge is developed both in mathematics content courses and pedagogy courses. Courses, such as multicultural education, may help to develop teacher candidates' critical knowledge, but a single course will not be enough. The embedding of critical themes throughout teacher education and beyond will likely be necessary. Community knowledge is challenging and is typically not included in teacher preparation. While community knowledge will vary and needs to be learned in conjunction with students and their communities, this process can be modeled as teacher educators also learn from and with their students.

Conclusion

Within mathematics education dominant discourses frame knowledge and authority in ways that challenge our ability and willingness to teach SJM. These challenges affect even those who desire to teach SJM. The challenges range from the more obvious where we struggle to conceptualize SJM or are forced to face our lack of critical knowledge to the more subtle concerning classroom relationships and the risk of diminishing student agency as we seek to take responsibility for a socially just mathematics classroom. The need for equitable mathematics is growing and it will require better and more thorough preparation. This preparation will likely need to include modeling and increased emphasis on critical and classical knowledge.

ICEBERG OF CULTURALLY RELEVANT MATHEMATICS AND SCIENCE PEDAGOGY: A PEDAGOGICAL AND ANALYTICAL TOOL FOR TEACHER EDUCATION

Craig Willey
Indiana University-Purdue University Indianapolis
cjwilley@iupui.edu

Paula A. Magee
Indiana University-Purdue University Indianapolis
pamagee@iupui.edu

There is a clear need for an operational framework that captures the difficulty of implementing culturally relevant pedagogy (CRP) and supports teachers to imagine new forms of pedagogy. In this report, we present the Iceberg of Culturally Relevant Mathematics and Science Pedagogy (CRMSP), a tool, grounded in the tenets of CRP, that delineates practices ranging from the most accessible and easy-to-implement, to the most subversive yet arguably the most significant in terms of their potential to re-characterize the acts of doing and being competent at mathematics and science. We provide examples of CRMSP that re-position marginalize learners in relation to mathematics and science. We discuss the levels in which this tool can serve to disrupt dominant, inequitable systems of instruction and preview ways it can support teachers' efforts to provide meaningful mathematics and science learning experiences for youth.

Keywords: Culturally Relevant Pedagogy, Preservice Teacher Education, Teacher Knowledge, Curriculum

Like other social institutions, schooling has served to disenfranchise and subjugate students of color and their families, and to reaffirm a white ideology that supports white students, teachers and families (Emdin, 2016; Leonardo, 2009; Picower, 2009). Scholars and practitioners have explored ways to confront the inherent racism that permeates schools and have developed critical frameworks such as culturally relevant culturally relevant pedagogy (CRP), culturally responsive teaching and culturally sustaining pedagogies (Paris & Alim, 2014; Ladson-Billings, 1995, 2014; Gay, 2002).

In this report, we describe our work with a teaching protocol that both supports the identification of CRP and the analysis of these practices within the context of culturally relevant science and mathematics classrooms. This approach to understanding *Culturally Relevant Mathematics and Science Pedagogy (CRMSP)* asks preservice teachers (PTs) to use readily identifiable practices and materials and then scrutinize them for how compatible or tenuous they are with CRP. For the final analysis of compatibility/tension, we use the idea of a continuum of criticality from the Iceberg of Culture (Hall & Hall, 1976; Weaver, 1986) to assist PTs in analyzing their own materials, dispositions and practices. To analyze, visualize, and develop responses to the challenges and limitations surrounding PTs' implementation of CRMSP, we use two theoretical frameworks: critical whiteness studies and the iceberg of CRMSP.

Theoretical Perspectives: Culture and Whiteness

Equitable teaching requires PTs be able to analyze their own teaching and to be able to speak clearly about where and how they are supporting all learners and recognizing inherently racist practices. Doing this with efficacy requires a deep understanding of whiteness and the many structurally racist practices that are often "invisible" to white educators (Leonardo, 2009). Supporting PTs to becoming culturally relevant practitioners demands that PTs be able to identify emergent, intermediate and advanced culturally relevant practices in STEM.

Inextricably connected to whiteness, we consider an understanding of culture and how that influences what teachers are willing to do pedagogically. If PTs have a shallow understanding of culture, it is going to be difficult for them to teach in culturally relevant ways. If PTs see culture as *only* stereotypical examples of food, holidays and celebrations, it is going to be challenging for them to see how they reinforce dominant oppressive practices. It also will be exceedingly difficult for PTs to fully understand, both theoretically and practically, the role of culture in equitable science and mathematics teaching and learning (Nasir, Hand & Taylor, 2008; Nasir & de Royston, 2013).

Research Design, Context, and Methods

This work is situated in urban teacher education programs explicitly focused on developing anti-racist, culturally relevant teachers. Major program goals are to develop critically conscious PTs who understand how whiteness permeates schools and classrooms. The PTs we reference in this report are both elementary and secondary students from alternative certification programs.

Using the frameworks above and our experiences with PTs we developed a series of activities for helping PTs better understand and enact CRMSP. Described below, the activities first ask teachers to identify concrete elements of their practice (curricular materials, instructional decisions and teacher dispositions). This is followed by mapping the teacher practices back to the tenets of culturally relevant pedagogy. Finally, we follow this with an alignment of the teacher practices on an "iceberg of CRMSP" to assess the criticality of the practices (see Figure 1 below).

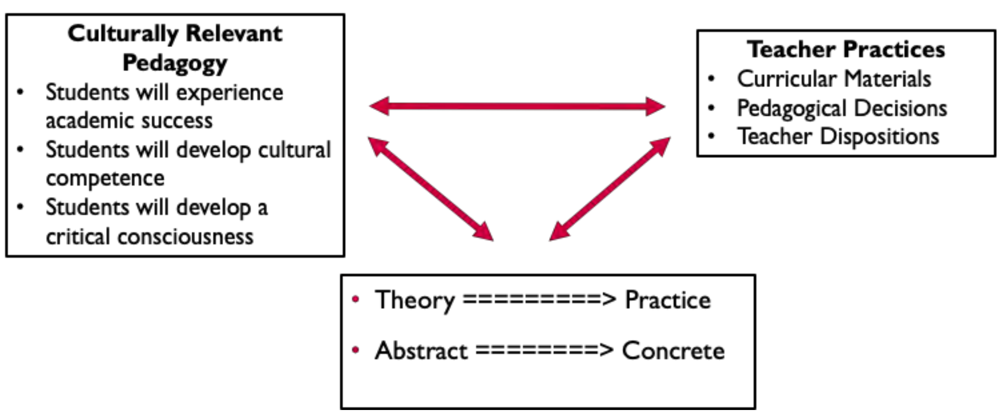

Figure 1: Supporting Teachers to Operationalize CRMSP

Data Sources

The data sources we draw upon include collaborative documents used in class (where PTs document CRMSP), lesson plans that PTs wrote, notes from debriefing sessions with PTs, and PTs' responses to reflection prompts used in class. The data was examined through the lens of culturally relevant pedagogy, specifically how each of the classroom events represents the tenets of CRP and what impact this event would likely have on dramatically shifting the experiences and success of children of color. In this analytical process, we relied heavily on our professional experiences as teachers and teacher educators, and our knowledge of the literature and judgement as to the degree to which PTs were moving beyond superficial notions of culture and critical pedagogy.

Results

As discussed above, PTs overwhelmingly support the *idea* of culturally relevant teaching, and they can, after study, articulate and operationally define the tenets. A disconnect comes when PTs are asked to analyze their own teaching through a CRP lens and identify how they are enacting or plan to enact CRP.

Components of Teaching in Culturally Relevant Ways

The three categories of teacher practice (curricular materials, instructional decisions and teacher dispositions) represent a bridge between the visualization of culturally relevant pedagogy and actual classroom interactions, and potentially offer PTs a way to access a critical analysis of their own science and mathematics teaching. The analysis is embedded within the course that the PTs take. For example, as a class assignment PTs read and analyzed Ladson-Billings' (1995) article, "But That's Just Good Teaching." PTs studied the concept of culture by working on their own understandings of culture and CRP. The analytical tool described here evolved out of this work with PTs and the provocations put forth by Ladson Billings (1995, 2014) and others (e.g., Gay, 2018; Paris, 2012).

In the first step of the analysis PTs are asked to list curricular materials, instructional decisions, and teacher dispositions for a lesson they are developing, have observed, or are going to teach. Some of the listings are easily evident, such as the use of a textbook (curriculum material) or the decision to move to small groups for problem solving (instructional decision). Others, such as how a PT responds to a student's question or "misbehavior" (teacher disposition) are more difficult to identify. We now recognize that the "difficulty" of identifying a practice is linked to the criticality of the practice and that the practices that PTs choose to "not see" are those that often reinforce a white, hegemonic classroom (one example from our practice and research is described below). Despite this recognition, the list offers PTs a series of things to analyze. Once a PT has listed a textbook as a curricular material, the conversation about the textbook begins and opportunities for discussion about what culturally relevant pedagogy looks like continues.

Curricular Materials. *Curricular materials* refer to any physical artifacts or resources that a teacher may use in class. These include, but are not limited to: trade books, textbooks, videos, speakers, handouts, worksheets, and manipulatives. PTs can quite easily identify the concrete curricular materials that they use. Once the PT has identified the curricular material we ask, "How does this choice connect to one of the tenets of CRMSP?" For example, a student teacher, Ned, chose to use an article from *The Atlantic* entitled, "The Myth of 'I'm Bad at Math'" (Kimball & Smith, 2013) after his middle school students took their first math exam. Ned was worried that the students did not see themselves as "good" at math and wanted to challenge the idea that some people are "just good" at math. In our class google doc, where we recorded our examples, Ned explained how the use of the article connected to the tenet of "academic success." Ned was considering how effort makes a much bigger difference in mathematical academic success than we tend to give it credit for, especially in middle and high school. Ned's example offers an opportunity to see how something as simple as a magazine article can be used as evidence of CRMSP. The example also reinforces the idea that the tenets *matter* and that PTs can think about them as a way to dig into what it means to be a culturally relevant teacher. The article also pushed the idea of "culture" since it is not specifically tied to the traits that PTs think of as culture (e.g., holidays, stereotypes, food, etc.). In this way it opened up a place for a conversation about how we can analyze our teaching using a CRMSP lens. It allowed us to talk about how society views "who can do math" as a cultural component. It also begins to set the stage for PTs to push themselves. In this example the connection to academic success is legitimate but it also generates the question, "What about cultural competence and critical consciousness?" Continuing to reinforce the idea that CRMSP *is* all three of the tenets is an important component of this work.

Instructional decisions. Instructional decisions refer to the ways in which teachers engage learners with curriculum. These include the structure of lessons, teacher moves in lesson delivery, managing participation patterns, orchestrating classroom discourse, collecting evidence of student learning, and overseeing interpersonal dynamics. Like curricular materials, instructional practices can be designed for white students (consciously or unconsciously) and guided by school or district-level initiatives, or they can be designed with equity and justice in mind. Our goal is to have PTs identify their own or other teachers' instructional decisions and then to connect them to the tenets of CRP.

Below we describe an observation with Sharon, a student teacher teaching a math lesson to 2nd graders. To prepare for the observation Sharon wrote a lesson plan which included a section specifically addressing culturally relevant pedagogy. She was asked to reflect on how her instructional decisions connected to CRMSP. She wrote:

> I am using a cognitively guided approach. Students will be leading the lesson with their thinking, and I will be able to better scaffold based on what I learn from the process. Rather than open with an algorithm, I want the students to tap into their number sense and sense-making skills to understand the thinking behind the function.

In this example Sharon identifies cognitively guided instruction (e.g., Carpenter et al., 2015) as the foundation for her math lesson. She is intentional about centering student thinking, which reveals her commitment to the value of her students' mathematical ideas, a component of CRP, and articulates how she will engage the students in the content. When asked to move from the concrete to the abstract, from the actual instructional decision to the tenets, Sharon writes the following as a rationale for the instructional decision:

> Soon, students will be introduced to two-digit subtraction with borrowing. Before this happens, I want them to get a better understanding of the math thinking behind the algorithms they will need to learn. I will use a Cognitively Guided approach to present them with a story problem and allow them to work in small groups to find a solution in a way that makes sense to them. The story problem is also based on their literacy text for this week. This way they have background knowledge that contextualizes the math problem and makes it easier for them to connect with. I will not be showing them the algorithm for solving an equation with borrowing. I will be walking around the room, checking in with groups, and asking them questions about their methodology and if their answer makes sense to them. I anticipate that many students will attempt to solve with addition or the improper use of an algorithm, so I will use some talk moves to try to guide them to question their own work and find another way. At the end, we will share what we did to find an answer. We may not arrive at the "correct" answer, but I will get several examples of student thinking that I can use to build upon as we move forward with math instruction.

In Sharon's rationale we can hear how she is building a theoretical base for her teaching. While not explicitly described in her lesson plan, in our debrief after the session we make sure to discuss how the instructional decisions made connect to both academic success and cultural competence. Like the in-class discussions with PTs the debriefs following teaching observations are critical spaces for productive talk about the connections between concrete teaching practices and the tenets of CRP and CRMSP. Often the PTs themselves are not even aware of how they are making these connections in practice. In this case since the use of cognitively guided instruction did not necessarily resonate with Sharon's idea of "culture" she did not recognize using it as evidence for CRMSP. During the debrief we highlight how Sharon's encouraging students to share their sense-making, being open to ideas that students share and facilitating student-to-student talking opportunities, are actual components of culturally relevant math teaching. We want to make sure that Sharon realizes that she is pushing back on the widely used math practices of teacher directed algorithmic memorization for problem solving and is instead demonstrating an actual practice that supports both academic success and cultural competence. Talking with Sharon also creates an opportunity for discussion about the critical consciousness tenet that is not addressed. During our debrief with Sharon, like discussions with Ned, we brainstorm how the lesson can be extended to interrogate something in the students' community or to investigate an injustice.

Teacher dispositions. Teacher dispositions refer to the beliefs about, and behaviors toward children, science, and/or mathematics that shape teachers' decision-making and interactions. With regard to our own science/math teacher education pedagogy (Willey & Magee, 2019), we believe that PTs are more likely to develop an awareness of their, often unconscious, biases if they are consistently asked to reflect on how and why they operate as they do. In discussions with PTs we often ask: How do you/teachers respond when students offer answers that do not match your/their expectations? How did you/teachers respond when students are disengaged or resistant to instruction? How do you/teachers perceive how math and science should be taught in schools and how are these ideas discussed with students? What behaviors do you/teachers display when motivating students to engage in challenging curricula?

Teacher dispositions can be framed as how educators respond to students at various moments. Teacher dispositions, like curricular materials and instructional decisions, are often rooted in long-established, oppressive and racist practices that PTs replay with little scrutiny or awareness. Intentionally including teacher dispositions has the potential to push PTs to look beyond curricular materials used to see CRMSP. Dispositions reveal how underlying beliefs about science and mathematics intersect with views of students, and how these beliefs are externalized in messaging about the importance of science and mathematics and students' success with the content. It is the identification of these dispositions and further analysis of them that offers PTs a way to scrutinize and grow their own teaching practice.

To illustrate teacher dispositions in practice we share Trevor's story. Trevor is a secondary alternative certification student studying to be a science teacher. After learning about CRP and CRMSP he used the categories of curricular materials, pedagogical decisions and teacher dispositions to mine his practice for evidence of CRMSP. He shared the following vignette in a written assignment that was shared with his classmates:

> After being out of the classroom for over a month (and being out of their medication for a longer time) the student was disengaged from what we were doing in class. This student has ADHD and with it has difficulty focusing during a note taking session. During this time, I gave the student the notes but filled in, so they can work ahead or go back in case they missed something and sat them in the back of the room on some comfortable furniture. Since doing this, they have taken all of their notes, actively participated during class time, and has not distracted other students during this time.

Trevor described his actions as supporting the student's academic success through the use of a pedagogical decision - using prepared notes in class and offering a comfortable physical space for the student to work. However, in class discussion with Trevor, it was clear that his teacher dispositions were *also* important here and warranted analysis and discussion. By sharing the prepared notes and finding ways to include the student honorably, and without humiliation, Trevor demonstrated his ability to be supportive and to do whatever needed to be done to re-engage the student. Importantly he did this without bribes, threats or negative talk to the student.

Trevor's story presents an opportunity to talk about the often unanalyzed dispositions that are so difficult for PTs to name. Bringing out and interrogating the dispositions was a key goal for the classroom discussion which occurred during a student teaching seminar. After Trevor shared his story in seminar the following question was posed, "How can the frame of whiteness and cultural norms help us analyze Trevor's vignette?" Given that the story doesn't center race or culture explicitly, the PTs were asked to consider the importance of whiteness and cultural norms in this story. Helping PTs see that race influences and informs all that we do as teachers, especially the often "invisible" dispositions, is a critical component of the preparation program goals. Supporting PTs to see where and how they are negatively impacted by whiteness as well, as then they are resistant to its trappings are difficult skills to develop and take time. We will often ask, "What does this have to do with Whiteness at all?" The PTs know that Trevor is a white male and the student in the vignette is Black.

Iceberg of Culturally Relevant Mathematics and Science Pedagogy

The Iceberg of Culturally Relevant Mathematics and Science Pedagogy (see Figure 2 below) is used to illuminate the complexities of internalizing and enacting CRMSP in school settings, where there is little space readily afforded teachers to innovate and create STEM learning experiences grounded in cultural knowledge and experiences. Moreover, the Iceberg of CRMSP expands the rigid and problematic boundaries of how science and math teaching and learning have historically been characterized.

Like the Iceberg of Culture, the top of the Iceberg of CRMSP includes visible teaching practices that are of low emotional load. These curricular materials, instructional decisions, and teacher dispositions are the most accessible for teachers to employ and the least likely to create friction in school settings, where teachers are often closely surveilled. For example, common practices at the top of the iceberg include, celebrating holidays, using students' names and hobbies in word problems, and using texts and trade books that include diverse characters or historical figures. The use of these types of strategies is not bad, and these are, in fact, the ones that our PTs often use. What we find worrisome, and what we use the iceberg metaphor for, is to help our PTs see that these practices sit at the top of the iceberg in an area of low emotional load. They are generally not controversial, and, while not insignificant, they do not really push into a critical space where the status quo is challenged and reshaped. Pedagogically speaking, they are an acceptable place to start but not where we want our PTs to stay.

The teacher practices in the middle of the iceberg are more emotionally challenging and observed less often in science and math classrooms than those at the top. They represent a level of cultural engagement and awareness more emblematic of CRMSP. These practices draw on more fundamental aspects of students' cultural lives, including invisible cultural practices.

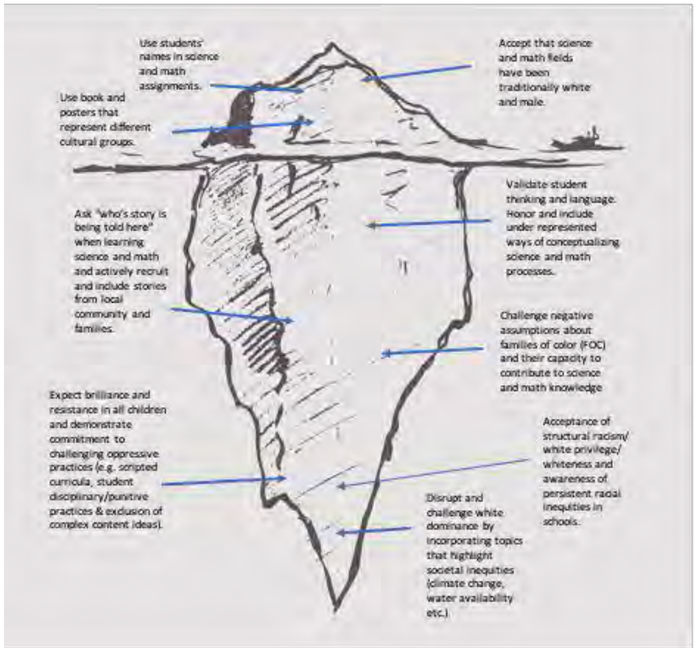

Figure 2: Iceberg of Culturally Relevant Mathematics and Science Pedagogy

Finally, the teacher practices closest to the base of the iceberg are the least likely to be observed in science and math classrooms and are arguably the most tenuous to enact. These moves indicate a strong political and racial consciousness, and a profound understanding of CRP. These practices demonstrate a commitment to all tenets of CRP and to a version of science and math education concerned with the critical science and math identities of the students. For example, one example that we highlight in Figure 2 is "Expect brilliance and resistance in all students and demonstrate commitment to challenging oppressive practices (e.g., scripted curricula, student disciplinary/punitive practices, exclusion of complex content ideas)." In practice this looks like teachers pushing back against skill-based and white-washed curricula and demanding that *all* their students become engaged in learning.

Discussion and Conclusions

Mathematics and science educators have been exploring CRP for at least two decades (e.g., Barton, 2003; Johnson, 2011; Willey & Magee, 2019; Vazquez Dominguez, Allexsaht-Snider, & Buxton, 2018), but it is clear that much work remains to be done. Resistance to change is not surprising given the pervasiveness of structural racism, including how mathematics and science teacher organizations have long appealed to white sensibilities (e.g., Martin, 2015). Preparing new teachers is particularly challenging since most PTs bring to their preparation program unchallenged experiences that support westernized perceptions of math and science, white supremacy, anti-blackness and a superficial understanding of (cultural) difference. As teacher educators immersed in equity work for over 10 years, it is hard to accept the limited progress that PTs make in a year or two of a preparation program. Our response to this dilemma has been to commit to the framework of CRMSP, trusting in the idea that as PTs explore the tenets and CRP holistically, they have the greatest chance of developing long-lasting commitments to racial justice and equitable teaching for all their students. We see that time invested in operationalizing the tenets, interrogating their own cultural identities, and exploring what CRMSP looks like *in practice*, has the potential to support PTs in their long-term development as critical practitioners.

The two-pronged approach that we outline here is grounded in our acceptance that PTs need support as well as opportunities to understand CRMSP. We do not see these activities as a simple protocol, but rather as a way for PTs to understand and internalize the dimensions of CRP, develop a stronger sense of their impact, and to serve as a roadmap for how to live them in real life. We recognize the inherent danger in "breaking down" a framework into manageable pieces as a way to teach it. This is indeed how complex ideas become shallow and superficial (Ladson-Billings, 2014). With this in mind we are mindful of constantly returning to the idea that CRP and CRSMP are not complete without all of the tenets. Working with PTs to see how the concrete and abstract come together - and the theoretical and practical - is the goal of this work.

Supporting PTs to reflect on and analyze their own teaching through the lens of CRP is a critical piece of developing critically conscious teachers. We are hopeful that the approach we describe here can guide research investigating mathematics and science teachers' learning about and implementation of critical pedagogy, and be used within teacher preparation programs and professional development settings to support humanizing, culturally relevant mathematics and science teaching.

There has been growing interest in the development of theoretical knowledge on the design of learning environments supporting nondominant communities (Bell et al., 2017). We explore the ways students are under surveillance (Lugo, 2007) in the mathematics classroom. Particularly, how student responses to being under surveillance inform the development of equitable mathematical learning environments. We identify mathematics as a social practice (D'Ambrosio & D'Ambrosio, 2013), defined by its accompanying context (e.g., school, every day, workplace; Moschkovich, 2002a). School mathematical discourse represents a language of power (Delpit, 1988). Free use of the word 'mathematics 'outside of the classroom represents an important step toward recognizing non-school mathematics as mathematics and challenging the intellectual hierarchy permitting school mathematics dominance over all other mathematics. In our research all practices of mathematics are referred to as *mathematics*, excluding the mathematics typically found in US classrooms, which we refer to as *school mathematics*.

The white construction of school mathematics (D'Ambrosio, 1985; Joseph, 2010) carries with it a history of cultural erasure (Dowling, 1991; Gutiérrez et al., 2017) and predominantly English-only enactment in US classrooms (Gutierrez, 2002; Moschkovich, 2002b). Students are constantly building upon their linguistic and mathematical repertoires of practice (Garcia-Sanchez & Orellana, 2019), and the mathematics classroom is one of many arenas in which their knowledge resists disregard and fights to assert and maintain its value. There is violence when dominant mathematics and languaging practices encroach upon student borders of their own mathematics and language, shifting and reshaping these borders (Anzaldua, 1987). Surveillance in the mathematics classroom is influencing how students speak and what they say. Students are learning, through responses to seen and unseen work, how to adhere to dominant mathematics classroom cultural norms. In order to begin healing from this violence, for students to trust in themselves and their instructors mathematically, we must understand how that violence manifests in the classroom. Work (Star & Strauss, 1999) students do in the mathematics classroom, both traditionally seen and unseen, is one such manifestation.

We discuss how students are responding to their surveillance and what work should be considered in the development of classroom mathematical experiences. In this poster, we analyze how elementary Latiné students discussed the surveillance of their language in the context of the mathematics classroom, how they expressed the role of mathematics in their world, and how they incorporated school mathematical discourse into their communications of mathematics.

TEACHERS' USE OF "ROUGH DRAFT MATH" AS A CURE FOR TEACHING DURING THE PANDEMIC

Crystal Collier
University of Delaware
crystalc@udel.edu

Amanda Jansen
University of Delaware
jansen@udel.edu

Keywords: Equity, Inclusion, and Diversity; Instructional Activities and Practices

Rough Draft Math (Jansen, 2020) is a teaching practice in which mathematics teachers strive to welcome and integrate students' in-progress thinking as a valuable part of their learning process, inspired by the concept of "exploratory talk" (Barnes, 2008). When enacting this practice, teachers foster a mathematics learning environment where students feel safe to share their unfinished ideas knowing that they will have the opportunity to revise and refine those ideas as they continue to learn. This practice also has the potential to position students as mathematical authorities in the classroom and foster students' sense of ownership of their learning.

Due to the global pandemic, the landscape of education has changed. K–12 math teachers are being asked to create highly flexible and engaging learning environments in which all students are intellectually challenged. Applying a strengths-based lens to students' thinking has potential to challenge the deficit narrative of "learning loss" that has been prevalent during this pandemic (Chen & Krieger, 2022). As an example of changes in teaching, Roman et al. (2021) found that secondary mathematics teachers increasingly attended to supporting students' affective and social engagement over time in their instruction as the COVID-19 pandemic unfolded.

In the spirit of ambitious mathematics teaching (Lampert et al., 2013), "rough draft math" can support teachers to engage students with mathematical content, specifically by encouraging students to explain their own in-progress thinking and to elaborate on that of their peers. It also provides a way for teachers to create a more equitable classroom by publicly valuing all students' thinking at any stage, as well as validating the notion that learning is as an ongoing process. The guiding question for this research was: *How do K-12 mathematics teachers enact Rough Draft Math in their classrooms within the context of the COVID-19 pandemic?*

Data were gathered, by interview, from 32 teachers who participated in book studies about *Rough Draft Math* (Jansen, 2020) from five states around the U.S.A. During the interviews, teachers were asked to explain how they enacted rough draft math in their classrooms and to share what motivated their use of it. The teachers were also asked to share a digital artifact to illustrate their enactments and to reflect on the perceived benefits and challenges associated with their enactments of "rough draft math." Data analysis allowed for the emergence of themes from teachers' responses (Corbin & Strauss, 1990).

In this poster, we will share unanticipated findings – teachers' voices about how "rough draft math" helped them navigate difficulties of teaching during the pandemic. Teachers expressed that they worked to extend grace to their students as they encountered instability and frustrations. Teachers reported that their responses to changes in the world included becoming more open to welcoming students' draft thinking and embracing continuous revision of ideas; they reported "really needing this" [rough draft math] so that they could meet students as they were, to gradually support students to develop their ideas through revising, and to increase empathy in the classroom. "Rough draft math" helped teachers move away from a deficit perspective toward learners so they could support all students to learn together from one another.

LEVERAGING A CASE TO DISRUPT THE OVER-IDENTIFICATION OF BLACK MALES IN MATHEMATICS SPECIAL EDUCATION

Monica Gonzalez
East Carolina University
gonzalezmo18@ecu.edu

Alesia Mickle Moldavan
Georgia Southern University
amoldavan@georgiasouthern.edu

Annie George-Puskar
Fordham University
ageorgepuskar@fordham.edu

Keywords: Preservice Teacher Education; Special Education; Equity, Inclusion, and Diversity

Historically, there has been an over-identification of Black students in special education in early childhood, even more specifically Black males (Cruz & Rodl, 2018). Black males are 1.4 times more likely to be referred to special education than students of other racial backgrounds (Gordon, 2017). Teachers' biases about academic success and the behaviors deemed appropriate and respectful in a classroom can influence instructional decision-making and students' mathematics learning (Moldavan et al., in press). This study reports on a multi-site, interdisciplinary research collaboration where preservice teachers (PTs) from programs of mathematics, special education, and early childhood education participated in case-based instruction (Decker & Pazey, 2017; Gorksi & Pothini, 2018) to explore racial biases during a kindergarten mathematics task. The following research question guided this study: How do PTs recognize and respond to race within a case designed to elicit discussion about racial bias in mathematics special education?

Racial noticing (Shah & Coles, 2020) was used as a lens to attend to the various ways PTs perceive, make sense of, and react to moments where race and racism occur during a mathematics task. We used this framework to guide the case design, which explored a kindergarten student named Tay who exhibited typical 5-year-old behaviors while engaging in a counting collections task. In the case, a White teacher was frustrated with Tay's seemingly disruptive behavior, which overshadowed his counting strategies and knowledge. When faced with the disruptive behavior, the teacher removed Tay from the task, attributing his actions to a learning disability. Following the case, the PTs were asked prompts to engage in discussion related to the teacher's instructional decisions and biases as well as Tay's behavior and mathematical understanding of counting. We analyzed the PTs' responses by first using a priori coding to look for instances of race within the responses (Saldaña, 2016). Once those instances were identified, we then used in vivo and descriptive coding to further analyze how those PTs attended to, interpreted, and responded to race-related phenomena occurring within the case. The codes were cross-checked for inter-rater reliability to corroborate the findings (Grbich, 2013).

Out of the 60 PTs in the study, only 9 PTs (15%) mentioned Tay's race in their responses. Interestingly, the 9 PTs only mentioned Tay's race in one of the seven discussion prompts. That prompt was: How do you think Ms. Caldwell's implicit bias impacted her instruction with Tay? A few PTs (n=4) explicitly stated that Ms. Caldwell had a bias toward Tay due to his skin color, and the others mentioned Tay's race without making a connection to Ms. Caldwell's race (n=3) or an observed racial phenomenon (n=2). In addition, 80% (n=48) of the PTs indicated that Tay's behavior was age appropriate. The other PTs considered Tay's behavior to be "delayed" or "disruptive" from his peers, justifiable for removal from the task. Implications from this study indicate that PTs need explicit opportunities and prompts to recognize racial biases, including how such biases can impact instruction and students' mathematics learning. Cases can be used in teacher education to disrupt the over-identification of Black males in special education to ensure appropriate supports are made to empower rather than dismiss Black males in early childhood.

RECOMMENDATIONS FROM LATINX, INDIGENOUS, LGBTQ+, AND/OR WOMEN STEM-MAJOR STUDENTS TOWARD ONE REHUMANIZING DIMENSION

Kelly MacArthur
Montana State University
kellymacarthur@montana.edu

Keywords: Calculus; Undergraduate Education; Equity, Inclusion and Diversity; Rehumanizing

Many scholars have advocated for more sociopolitically oriented research in mathematics education (e.g. Adiredja & Andrews-Larson, 2017; Aguirre et al., 2017; Gutiérrez, 2013) to address inequities. In that vein, Gutiérrez (2018) created an eight-dimension framework highlighting ways to rehumanize mathematics with a distinct call to center the voices of students from historically marginalized groups. Further, the gatekeeping function of undergraduate calculus courses for STEM majors has been well documented (e.g. Gasiewski et al., 2012), especially for marginalized students (e.g. Leyva et al., 2021). This study considers one particular dimension of the Gutiérrez framework (2018), namely Theirstories/Culture, and investigates how educators can move toward rehumanizing goals for STEM-major students. This dimension aligns with teacher moves that acknowledge and center differing ways for people to do mathematics.

In this mixed methods study, I address two research questions: (1) Is there a difference in how students from dominant vs. focal groups view a hypothetical scenario relating to the Theirstories/Cultures rehumanizing dimension?; and (2) What can instructors do to implement this scenario in ways that positively support students from historically marginalized groups?

To answer these questions, I analyzed survey data from 153 STEM-major Calculus 2 students at two PWIs. From this data, two groups were considered, namely the dominant group (73 white, cis-male, heterosexual students) and the focal group (80 students who identified as being in one or more of the marginalized groups listed above). From the survey responses, 20 students were interviewed, such that all interviewees self-identified as one or more of the following: Native American, Latino/a, Hispanic, Mexican, mixed race, LGBTQ+, or female. In particular, this report focuses on the results of one scenario from the survey regarding the Theirstories/Cultures rehumanizing dimension (Gutiérrez, 2018), which in part states: *Imagine that every week in your calculus course, the instructor spends a few minutes in class to discuss a current-day Indigenous, Black, Latinx, female or LGBTQ+ mathematician and showcase a bit of their work.* Students were asked the following three Likert questions regarding this scenario, with a 7-point scale ranging from Strongly Disagree to Strongly Agree for each question. A. I would likely feel valued and an increased sense of belonging. B. I would likely feel a sense of connection between mathematics and my life. C. I would likely feel supported in my learning.

Using statistical techniques to analyze the Likert questions for this scenario, it was found that the distribution of responses to each question were significantly different with a higher proportion of students from the focal group reporting positive rankings. Focal group interviewees further discussed how this scenario would boost their connections with peers and the instructor as well as their confidence by providing role models of mathematicians who looked like them. They also voiced concern that this scenario could be dehumanizing if the instructor did not implement it thoughtfully and judiciously. Interviewees recommended instructors incorporate this practice in ways that don't interrupt their covering the necessary mathematics curriculum and that take an appropriate amount of class time while also providing links to read about the mathematicians outside of class time.

BLACK TEACHERS' TRAJECTORIES: STORIES OF EARLY LEARNING, NAVIGATING INEQUITIES, AND TEACHING ELEMENTARY MATHEMATICS

Kayla Myers
Georgia State University
kmyers@gsu.edu

Susan Swars Auslander
Georgia State University
sauslander@gsu.edu

Sterline Caldwell
Georgia State University
scaldwell16@student.gsu.edu

Shani Walker-Jackson
Gwinnett County Public Schools
shani.walker@gcpsk12.org

When I was in kindergarten, which was a long time ago, I was very, very quiet, and because I was so quiet, my teacher felt that I just didn't know the content. So, towards the end of the year, she recommended to my mom that I repeat kindergarten. My mom asked her, of course, "why?" She said, "well, she doesn't know how to read. She doesn't know her numbers." And so, my mom said, "okay well can I come observe tomorrow? Can I come sit in the class?" And so my mom came and every question that the teacher asked, she asked me, and I would answer. So I knew all the content, but just because I didn't raise my hand or present the information, I was labeled as not knowing it. And at the time, as a kindergartener, you don't really think about it [equity or inequity]. But I think my mom, just being a person of color, recognized that this is the only Black child in the class, and she thinks she doesn't know anything, because she's a Black child and because she's so quiet. And the teacher said I didn't know my colors because I colored the sun purple or something. My mom said, "why'd you color the sun purple?" I said, "because all the kids were fighting over the yellow [crayons] and it wasn't that important to me." So just being passive and quiet, I just kind of got labeled in kindergarten as not knowing. And they did move me on to first grade and the first-grade teacher told my mom, like, I definitely should not have been kept back. I was bright. I just kept to myself. And I just didn't want to fight over the crayons.

This presentation highlights a compelling story of dissonance and harmony—Black teachers' early histories as learners of mathematics, and how those early experiences have shaped their identity as learners and teachers of mathematics. There is an aligned dissonance in these stories, one of inequity and barriers, that has harmonized as they find themselves together striving to teach for equity and social justice, to build their students' positive mathematical identities, and to be leaders in their schools.

Teacher identities are deeply connected to early learning, communities, and professional experiences (Aguirre, Mayfield-Ingram, & Martin, 2013). During both individual and focus group interviews with 27 elementary mathematics teachers, we asked about those early learning experiences, the support and community they had as young learners, and how those have shaped them into the teachers they are today. In our analysis of that interview data about histories with mathematics learning, we kept returning to provocative stories about navigating inequities and redirecting obstacles in order to better serve the students in their classrooms. For this poster, and as we prepare for publication, 5 Black elementary mathematics teachers share stories of feeling inequities as young learners of mathematics. These stories spoke to us as mathematics teacher educators, as qualitative researchers, and as social justice advocates. These inequities, though they vary in scope, had a profound impact on the professional trajectory for these 5 Black elementary mathematics teachers, as well as their journey towards teacher leadership. Our poster presentation will highlight these teachers' stories, provoking an important conversation about the significance of racial injustice on mathematics learners and identity.

SYSTEMIC BARRIERS TO COLLABORATIVELY DESIGNING FOR HIGH QUALITY MATHEMATICS INSTRUCTION

Olanrewaju T. Oriowo
UNC Charlotte
ooriowo@uncc.edu

Christine K. Fisher
UNC Greensboro
cakierna@uncg.edu

P. Holt Wilson
UNC Greensboro
phwilson@uncg.edu

Keywords: Instructional vision; systemic change; equity, sustainability.

Philosophers and critical thinkers have advocated for all students to be given access to high quality education irrespective of ethnicity or social status (e.g., Adler, 1982; Dewey, 1900; Freire, 1970; Ladson-Billings & Tate, 1995). The state of mathematics in the US K-12 education system has not experienced successful mathematical reform that projects a unified vision of high-quality mathematics instruction (VHQMI) (Munter, 2014). The purpose of this poster is to explore some systemic barriers that thwart the best intentions of mathematics educators, administrators, and policy makers at all levels of the US K-12 education system, in developing and designing around a common vision of high-quality mathematics instruction. We articulate three context theories which Edelson (2002) defines as theories that highlight "challenges and opportunities presented by a class of design contexts" (p. 113); these include certain types of education structures, inequitable distributions of funding, and sociopolitical influences.

Education systems in the US are decentralized and hierarchical, exacerbating systemic barriers; curriculum control is an example of such a barrier. When schools and districts with differing fiscal resources make mathematics curriculum decisions but are subject to the same state level accountability measures, inconsistent visions are inevitable (DeBoer, 2012). Inequitable funding across subsystems inhibits the development of shared VHQMI; because funding relies on local revenue, access to curricular resources, high quality teaching, and professional development vary, perceptibly, in districts within a state system. Underfunded districts and schools become scapegoats when they are penalized for failure to meet unfunded mandates and for their inability to provide necessary resources to support instruction (Robinson, 2015). The sociopolitical nature of education is an additional barrier to the growth of a shared VHQMI. Instructional decisions are made by policy makers and stakeholders vying for positions of power without regard to the best interests of students, teachers, and educational leaders (DeBoer, 2012). For example, the adoption of Common Core State Standards for Mathematics (CCSSM) became, according to Larson (2012), a tug-of-war between attention to standards and the need for discussions that impact student learning of mathematics.

We believe that system-wide collaboration and co-designing of implementation resources improves equitable access to material and social resources. Research Practice Partnerships can offer a solution by bringing together policy makers, researchers, and educators (Henrick et al., 2017) to co-design and share resources. Such an initiative will stabilize resources for instruction and learning for transient students and teachers; all schools can have access to the expertise that will be distributed across subsystems.

MATH AS A GATEKEEPER: NARRATIVE IDENTITY OF ONE COMMUNITY COLLEGE STUDENT IN NON-CREDIT BEARING REMEDIAL MATH

Ranza Veltri Torres
University of Wisconsin-Madison
rveltri@wisc.edu

Keywords: Equity, Inclusion, and Diversity; Systemic Change; Undergraduate Education

Racially minoritized students are disproportionately tracked into non-credit-bearing remedial (NCBR) math classes upon entering college and are often trapped in a cycle of take-fail-repeat. While math is positioned as more important than ever before for a diverse pool of learners, inequitable access to quality math-learning experiences prevails. This poster features a case study of one participant, Marty, a furniture maker and community college (CC) graduate who identifies as Latina, whose story may help us see how certain math requirements and learning experiences may serve as a dehumanizing force in some students' lives and function to shape their mathematical identities. I address the following research questions:

RQ1: How do CC students who have taken NCBR math identify as math learners and doers?
RQ2: What mathematical activities or what kinds of discourses do students articulate for themselves that evidence the kinds of mathematics identities they associate/identify with?

My theories and methods privilege narrative in order to center the voices of mathematics learners and their interpretations of their experiences, rather than analysis about their experiences. I use narrative theory as defined by Langer-Osuna and Esmonde (2017): "[m]athematical identities develop as people make sense of their experiences with mathematics and develop stories of success and failure and belonging or distance." I combine this with the frame of mathematics identity (as defined by Larnell, 2016), who defines math identity as "...a set of personal narrativizations about mathematics-learning or mathematics-teaching experiences that reify, endorse, and signify their subjects as a certain kind of mathematics user or doer."
Two 90-minute interviews are analyzed using Martin's Central Themes of Math Identity (2000), and findings align with four of the six themes:

a) the instrumental value of mathematics, (Marty says she doesn't need math to make furniture, when she engages in mathematical problem-solving techniques in her furniture making.)
d) strategies to learn or participate in formal and informal mathematics contexts, (when Marty sees her strategies as mathless, and in her mind is avoiding formal math)
e) constraints or barriers on participation within mathematics-learning contexts (she describes how math hasn't posed a barrier for her, because she other ways of figuring things out)
f) one's own capacity to perform in mathematics-learning contexts. (Marty refers to herself as "dumb" and unable to engage in formal math)

In relation to RQ1, Marty refers to herself as "dumb" (her words) and unable to engage in formal math. However, Marty often engages in mathematical activity without realizing she is doing so. Marty sees her furniture building as mathless. In relation to RQ2, Marty articulates a discourse of math avoidance, despite the fact that she unknowingly uses math every day in her work. Implications press for deeper thought about how CCs can implement supportive and appropriate math pathways that are best suited to students' academic and career goals.

SUPPORTS AND CONSTRAINTS FOR LGBT+ STUDENTS SEEKING COLLEGE DEGREES IN STEM

Kellie J. Pop
University of Nevada, Reno
kpop@nevada.unr.edu

Lynda R. Wiest
University of Nevada, Reno
wiest@unr.edu

Keywords: LGBTQIA+; Equity, Inclusion, and Diversity; Higher Education

The purpose of this study was to investigate possible supports and constraints students pursuing STEM degrees experienced during their transition from high school to college. Only recently have scholars begun to recognize the heteronormativity of STEM and the disconnect that can thus occur between the STEM disciplines and students who identify as LGBT+ (e.g., Cech & Waidzunas, 2011; Rubel, 2016). Cultural norms can result in invisibility for LGBT+ students and ultimately academic and social isolation (Bright, 2016; Cech & Waidzunas, 2011; Dzurick, 2018). Gottfried, Estrada, and Sublett (2015) note, "We surprisingly know very little about STEM education as it relates to the fuller spectrum of sexual diversity" (p. 66). Creating a "gender-complex" education requires greater understanding of LGBT+ students' experiences, and this must extend to STEM (Rands, 2013). This research provides insight into this area, which has received little attention to date (Cooper & Brownell, 2016).

Methods

Recruitment of LGBT+ college students took place through social media posts and notifications through LGBT+ college student organizations and community organizations in one region of a Western state. Four students pursuing college STEM degrees participated in one-on-one interviews of 20-40 minutes each with the first author: one lesbian, one gay man, one bisexual man, and one male-to-female transgender student.

Interviews focused on what supports and constraints participants perceived they had in high school and college in relation to pursuing a STEM degree and career. The interview transcripts were analyzed into thematic categories by identifying main ideas in the data, a process that was not linear (Cresswell, 2014; Gay et al., 2012). The hand-coded categories were constructed independently and then jointly by the two authors during multiple readings of the data and adjusted as needed until they were perceived to represent the data accurately. The categories were reviewed for their individual meaning and importance and for larger themes in relation to the research question.

Results & Implications

In terms of encouragement for pursuing STEM, no consistency appeared across the four participants. The following influences were reported once each: self, teacher, family, friends, and nature of the field. In naming deterrents, participants were equally likely to state incongruence of an LGBT+ identity with STEM and the challenge of the subject matter. (Participants often named more than one influence in each of those categories.) Suggestions participants offered for educators for supporting LGBT+ students in STEM were highly varied and included rigor, encouragement, emotional/psychological support (e.g., let them know they are not alone and signal a safe environment), and preparation for possible mistreatment/opposition from others.

Chapter 5:

Geometry and Measurement

TANGRAM PUZZLES' PRIMING OF SQUARES FOR MATHEMATICS EDUCATORS

Laura Bofferding
Purdue University
lbofferd@purdue.edu

Although solving tangram puzzles is a popular activity for helping students move along the 2D shape composition learning trajectory, there is little evidence of what makes one tangram puzzle with no internal lines more difficult than another. In this study, 46 educators saw either a square in a traditional or non-traditional orientation and then were asked to identify (within 4 seconds) where the square puzzle piece would go in a series of 75 tangram puzzles. Results indicate that adults were more likely to identify the location of the square if it had more sides outlined, but the orientation of the square or number of places it would fit in the puzzle were not associated with their success. These results call for similar studies with children and suggest that educators need to be careful to look beyond their own impressions when choosing suitable puzzles for students.

Keywords: Geometry and Spatial Reasoning; Cognition

As children move through the 2D shape composition learning trajectory, they learn to combine shapes, using turns and flips, and explore what new shapes they can create (Clements & Sarama, 2009, 2014). To encourage students' movement through the levels of the learning trajectory, teachers can use shape puzzles that increase in complexity, moving from shape puzzles—such as tangram puzzles—with each piece separate and outlined, through pieces being connected but still outlined, to puzzles where there are no internal lines (i.e., silhouette puzzles) and pieces need to be turned (Clements & Sarama, 2009, 2014). However, there are a variety of silhouette tangram puzzles, which have varying numbers of sides, piece orientations, and number of solutions that might increase or decrease puzzles' levels of difficulty (Bofferding & Foster, 2021). When choosing a puzzle to support or a challenge a student, educators might consider *their own impressions* of whether particular pieces are easy to place. This study explores whether silhouette tangram puzzles encourage correct or incorrect placement of the square piece based on educators' initial impressions and highlights which factors play a role in their choices.

Framework

Given the 2D shape composition learning trajectory (Clements & Sarama, 2009, 2014) and an analysis of tangram puzzles (Bofferding & Foster, 2021), there are several factors that could contribute to whether the placement of a shape piece is easy or difficult to identify in a silhouette tangram puzzle. One of the initial factors that distinguishes difficulty between puzzles for preschool children is whether each shape piece stands alone or is combined with another piece (Clements & Sarama, 2009, 2014). Therefore, the extent to which each side of the shape pieces are exposed, or part of the puzzle outline, could make it easier to identify. Likewise, silhouette tangram puzzles with more sides would likely have more sides of the individual shapes exposed (Baran et al., 2007) and make it easier to identify where the pieces go (van den Heuvel-Panhuizen & Buys, 2008). Certain puzzles also can be solved in multiple ways (Bofferding & Foster, 2021), which could play a role in how easy placing a particular piece is in the puzzle. Another important factor is the orientation of the pieces. Baran et al. (2007) found that adults had difficulty placing the square piece in tangram puzzles if the square needed to be placed with a corner upward (i.e., a nonstandard orientation for how it is often seen), a difficulty shared by children (Clements & Sarama, 2009, 2014). The adults also placed larger pieces in the puzzle first (Baran et al., 2007), making the case of the square all the more interesting, especially as the square and two small triangles can make up the large triangle.

Given the relative difficulty of the square piece and relative lack of research on tangram puzzle difficulty, we chose to further investigate how adults identify squares in puzzles. The research questions included the following: (1) To what extent are educators' judgements on where the square should go associated with the silhouette tangram puzzles' number of sides, the squares' number of sides outlined in the puzzle, the squares' orientation in the puzzle, number of locations the square could go in the puzzle, and the orientation in which they were shown the square? (2) What characterizes educators' choices on where the square should go?

Method

Participants included 46 educators (e.g., elementary teachers, high school teachers, math coaches, professors) and graduate students in education. Participants accessed a link to a Qualtrics survey through a message posted to mathematics education professional groups on Facebook and the National Council of Teachers of Mathematics message board. The first part of the survey asked participants to indicate their occupation and demographics. Eight participants indicated male pronouns, thirty-six indicated female pronouns, and two did not answer. Further, 41 participants identified as White, one identified as Black or African American, one identified as Hispanic, Latino, or Spanish Origin, one did not disclose, and two people did not answer.

Participants were randomly assigned to one of four versions of the survey, which consisted of ten sections. For sections 1-4 and 6-9 participants were shown a square presented in a standard or nonstandard orientation and asked to indicate where the square would go in a series of silhouette tangram puzzles. Instructions indicated that the square might have to be turned to fit into the puzzle. Participants had four seconds to click on the part of the puzzle where the square would go; therefore, they did not actually have to fit a square in the puzzle. There were ten silhouette puzzles in each section, and if participants saw the square in standard orientation for sections 1-4, they saw the square in nonstandard orientation for sections 6-9 and vice versa. Two more versions of the survey were created by reversing the order of all of the puzzles (except session 10 was always last). In section 5, participants had to identify where a parallelogram would go in 10 tangram puzzles, and in section 10, participants were shown an arrangement of puzzle pieces and had to pick the silhouette tangram puzzle that had the same arrangement (out of four choices). Then, they described how they determined where the square and parallelogram should go in the puzzles (see Figure 1 for an outline of the four versions of the survey).

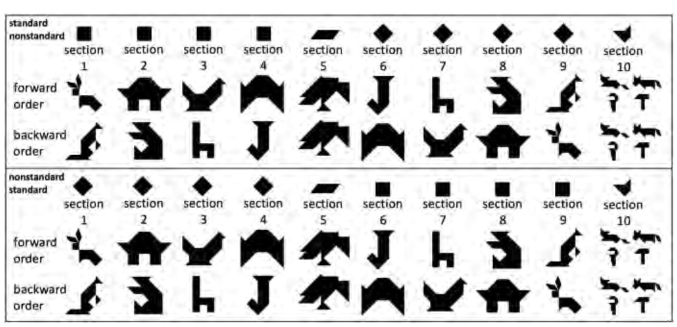

Figure 1: Four Orders of the Test Items (10 Items Per Section)

Of the 80 puzzles where participants identified where the square would go, the square could sometimes fit in multiple places. Five of these puzzles had different numbers of sides of the square visible depending on which of the multiple places it could fit, so they were excluded from further analysis, leaving 75 puzzles in the analysis.

Analysis

To answer the first research question, I grouped participants' responses for each puzzle into two groups: those who saw the shape in a standard orientation and those who saw the shape in a nonstandard orientation. Then, I ran a correlational analysis on the percent of participants successfully identifying where the square would go and the silhouette tangram puzzles' number of sides, the squares' number of sides outlined in the puzzle, the squares' orientation in the puzzle, and number of locations the square could go in the puzzle. Further, I classified participants' descriptions on how they decided where the square should go. To address the second research question, for puzzles where participants' overall success rate was lower than chance (e.g., 1/7=14% if the square can go in one place), I identified common locations where they thought the square should go in relation to their descriptions.

Results

Puzzle Features and Participants' Responses

Based on the correlational analysis for participants who saw the square in a standard orientation, there was a positive and highly significant association between them correctly identifying the location of the square and the number of outlines of the square visible in the silhouette tangram puzzle: r=.550, p<.001, [.366-.689]. They had higher performance when more of the sides were visible. Related to the square outlines, there was also a highly significant correlation for identifying the standard square and the number of sides on the silhouette tangram puzzle: r=.308, p=.007, [.085-.499]. Puzzles with more sides tended to have more sides of the square showing, making the location of the square easier to find. The number of locations that the square could go and the orientation of the square in the puzzle were not associated with participants identifying the correct spot when shown the square in a standard orientation. Participants who saw the square in a nonstandard orientation had similar results. Their performance was highly and significantly correlated with the number of outlines of the square visible in the silhouette tangram puzzle (r=.551, p<.001, [.368-.690]) and significantly correlated with number of sides of the puzzle (r=.275, p=.017, [.049-.471]). Again, number of locations and orientation of the square in the puzzle were not associated with them correctly identifying where the square would go.

Overall, 33 of the participants provided one or more explanations for how they decided where the square should go. The most popular strategy (from 17 participants) was to look for right angles, also described as 90-degree corners. A few elaborated that they started looking for four right corners, then looked for two, and then one. Another anticipated strategy (from 14 participants) was to look for an isolated or obvious square. One person elaborated, "First, I looked for a square shape. Then I looked for somewhere a diamond might fit." Her statement suggests that she intentionally looked for the square in more than one orientation regardless of how it was shown during the survey. Five participants indicated that they paid attention to the sides of the square, looking for parts of the puzzle with the same length sides or part of the square "jutting" out. Seven others tried to make sense of the amount of space the square would take up. One unanticipated type of response came from five educators; these people eliminated spots based on where other shapes would go: "I tried eliminating corners that could be constructed with the large triangle or the parallelogram." Three others considered "if other shapes would hook on to a square to create the figure." Further, three people mentioned symmetry in the puzzles as playing a role. For instance, one person wrote, "Some of them had so much symmetry – with the square being one of a kind…I usually put it in the center."

Incorrect Placements

Out of the 75 puzzles used in the analysis, participants did no better than chance at identifying where the square would go on 16 of the puzzles (in seven of these puzzles the square would work in two or four spots). Two of the puzzles had squares with zero sides outlined, eight puzzles had one side of the square outlined, five puzzles had two sides outlined, and one puzzle had three sides outlined. Although 42% of participants identified that the square piece would go on the inside of the square puzzle; there were four possible inside positions for the square, so they did no better than chance. Their most likely incorrect spot to select was the bottom right corner (35%; see Figure 2a). The shark puzzle was interesting because the square was supposed to go in the head, a common place in several animal puzzles, but only 19% of participants identified it. There was also no strong consensus on where participants thought it should go, with 16% choosing the small triangle poking out on top, 16% selecting the large triangle space below it, and 19% selecting a spot outside of the puzzle (see Figure 2b). Finally, even though the square had three sides outlined in the chair puzzle, only 9% of participants identified it. the chair appeared to have several spots where it might go; however, 45% of participants thought the square should go on the right where a large triangle should go (see Figure 2c).

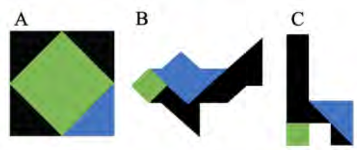

Figure 2: Where the Squares Go (Green) and Popular Locations Participants Chose (Blue)

Discussion

Based on these results, those of Baran et al., (2007), and learning progressions (Clements & Sarama, 2009, 2014), there is additional consensus that how distinguishable a shape is plays a role in how easy it is to place in a silhouette, tangram puzzle. Puzzles where more sides of the square were visible were easier for educators to identify, except in circumstances such as the chair, where there were additional distractor areas that looked like squares. Educators relied on properties of squares (i.e., right angles) to identify places to place the square, as in the square puzzle, and also looked for spots where sides were equal, as in the fin of the shark; this suggests that a strong focus on shape properties might also help children solve these puzzles when the properties align with the shape's locations. Contrary to results suggested by Baran et al. (2007), the participants in this study did not have any difficulty choosing squares based on their orientation. One reason Baran et al. (2007) may have noticed difficulty with this is that they required participants to rotate shapes using a computer app, which is more difficult than selecting a spot where it should go (regardless of its current orientation). Rotating shapes is an area that does cause difficulty for children (Clements & Sarama, 2009, 2014), so if adults, as in this study, do not struggle with rotating shapes, they may not consider this factor when choosing silhouette tangram puzzles for children, especially since there is no classification of puzzles' difficulty based on shape rotation. Likewise, we need more information on whether the rotation and outline of specific shapes (e.g., square versus triangle) are more difficult because multiple shapes could be rotated or outlined in the same puzzle. Investigating these factors in relation to students' success in solving the puzzles will help us better understand the relative difficulty of the puzzles and what factors to attend to when choosing puzzles to support and challenge students.
